

—PRESENTED TO— S.2.A

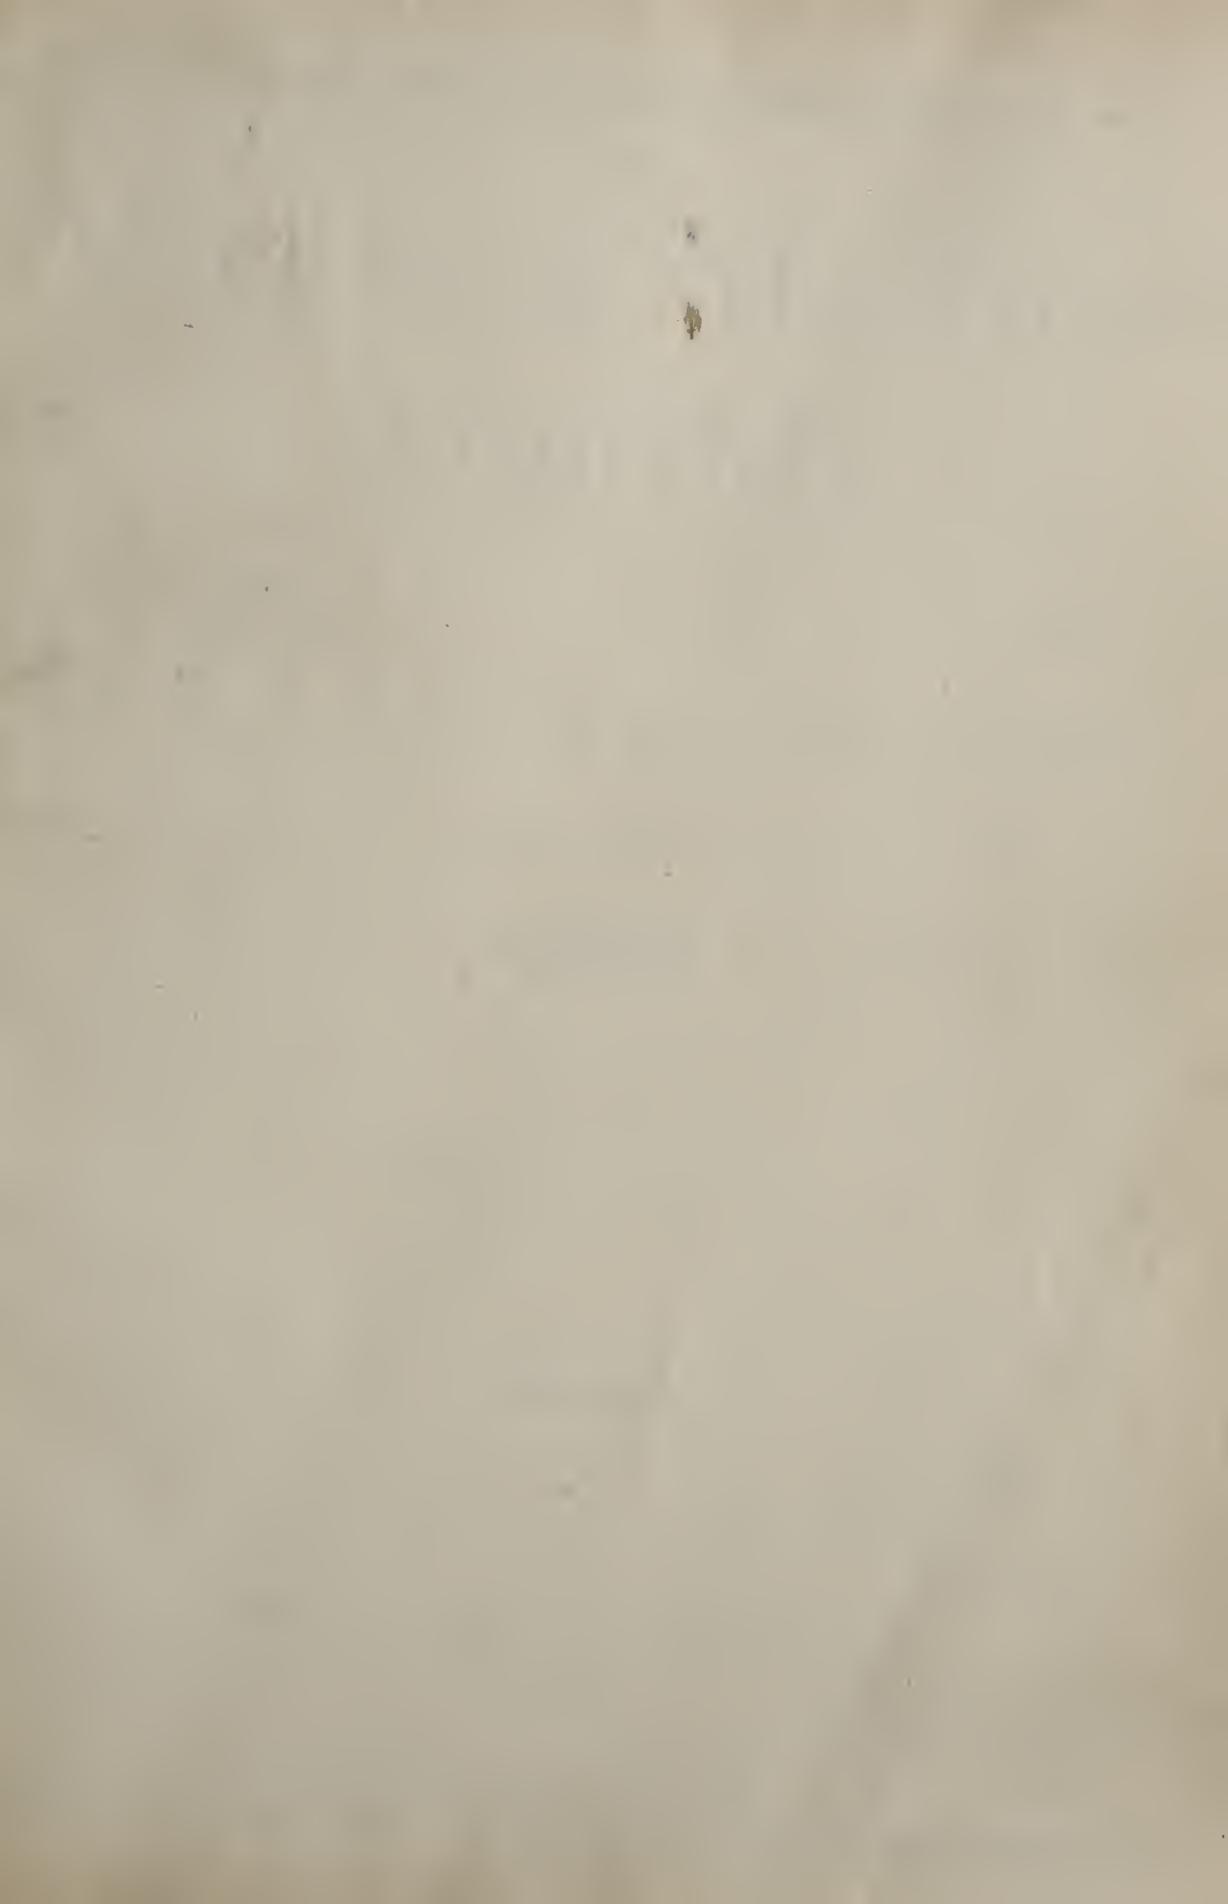

The seal of the New York Academy of Medicine is circular, featuring a profile of a man's head facing right. The Latin inscription around the border reads "DEOS ACCEDUNT HOMINIBUS DANDO SA" at the top and "UNA FIDES ALTARE COMMUNE" at the bottom. In the center, the letters "N.Y.A.M." are visible.

INDEX OF SUBJECTS

<i>Clostridium tetani, identification of (Bacillus Tetani)</i> -----	250	Elbow, case of fracture of, from throwing ball -----	618	<i>Goitre, exophthalmic, symptomatology and diagnosis of, 703; Report of a case of acute — — treated successfully by use of X-ray, 37; Medical treatment of —, 705; Surgical treatment of —</i>	705
<i>Coagulation time of the blood, significance of a prolonged</i> -----	475	Electrocardiographic and X-ray studies, case of complete heterotaxia with -----	198	<i>Goitres, treatment of certain types of</i> -----	351
<i>Colitis, chronic ulcerative, and its treatment</i> -----	304	Electricity and the electron reasoning as a chemical reaction, resulting in an atom complex thought; man the physicochemical complex -----	810	Gonococcus and other diplo cocci in chronic urethral infections, diagnostic consideration of the -----	775
<b>Colleges</b>		Embolism, report of a case of metabolic -----	594	<i>Gonorrheal arthritis</i> -----	695
Medical College of Virginia -----	211	<i>Empyema, 404; The closed method of treating — vs. rib resection; summary or cases</i> -----	840	<i>Granuloma inguinale</i> -----	401
University of Virginia -----	212	<i>Endocarditis in children, subacute bacterial</i> -----	769	Graves' syndrome and the involuntary nervous system -----	131
Colles' fracture, case of -----	555	Endocrine, nervous and mental manifestations in menopause-----	317	Gull's disease -----	60
Conjunctivitis, phlyctenular kerato -----	117	<i>Esophagus, etiology of benign stricture of</i> -----	265	<i>Handicaps to public health administration</i> -----	754
Conservation of life -----	262	<i>Ethmoiditis, 196; —; diagnosis and treatment</i> -----	193	Hay fever and asthma and allied conditions, some results of protein sensitization in, 379; Allegry in — — —; resume for general practitioner, 221; <i>Studies in — —; dates of pollination of anemophilous plants in D. C. and vicinity, observed in 1922</i> -----	41
Contused abdomen, the -----	411	<i>Ethylene-oxygen anesthesia; report of 116 anesthetics</i> -----	822	Head injuries: hemorrhage and economic prognosis -----	601
<i>Coue's method and its fallacies, a brief analysis of</i> -----	511	<i>Exophthalmic goitre treated successfully by use of X-ray, report of a case of acute, 37; Symptomatology and diagnosis of — —</i>	703	Health, public, administration, handicaps to, 754; <i>Two short — — courses at University of Va., 752; The family physician in the — — program, 520; Duties and advantages of the "whole-time" county — officer</i> -----	466
<i>Cranial injuries; hemorrhage and economic prognosis</i> -----	601	<i>Extra-uterine pregnancy, some points in diagnosis of</i> -----	747	<i>Heart disease in early life, 644; Incidence of — — in the negro race, 784; Pathology and diagnosis of chronic — —, 174; — block, 597; The — in old age, 135; The — in thyroid disease, 137; Treatment and prognosis of chronic — lesions</i> -----	172
Cyst, ovarian, with report of unusual case -----	767	<i>Eye pathology of dental origin, 48; The relationship of the — to general diseases, 110; — inflammations caused or influenced by dental sepsis; report of cases, 547; "Cattle truck" symptom of</i> -----	333	Hemorrhage, Sehrt aorta clamp for control of postpartum-----	162
Deaths (see <i>Obituary Record</i> ).		Facial paralysis complicating case of acute mastoiditis -----	615	<i>Hemorrhoids under regional anesthesia</i> -----	805
Depression in acute brain injuries, scope and limitations of subtemporal -----	742	<i>Factors often overlooked in the treatment of disease</i> -----	6	Hernia, sciatic; report of case of — of Meckel's diverticulum through greater sciatic foramen.	853
<i>Delivery at term, an unusual accident during; report of case</i>	457	<i>Fever</i> -----	384	<i>Heterotaxia, a case of complete, with electrocardiographic and X-ray studies</i> -----	198
Dental origin, eye pathology of, 48; — <i>reclamation through medical revolution, 182; Eye inflammations caused or influenced by — sepsis</i> -----	547	<i>Focal infections, 779; — — from the specialist's viewpoint, 553; Relation of — — in production of ocular disease</i> -----	603	<i>Hospital in a Chinese city, planning a</i> -----	114
<i>Dentistry and the practice of medicine, correlation of</i> -----	186	<i>Fracture work, some essentials in, 328; Case of Colles' —, 555; Report of case of — of elbow from throwing ball</i> -----	618	Hygienic measure in treatment of acute infectious diseases, neglected -----	632
Diabetes, insulin in, 129; — —, 209; — — — juvenile, 417; <i>Insulin treatment of —, 461; Insulin in — mellitus, 524; Etiology and prevention of —, 672; Treatment of — with diet and insulin</i> -----	678	Freezing, effect of, on toxin-antitoxin mixture -----	855	Hypertension, certain phases of arterial -----	163
Diabetic diet in general practice, system for use of insulin with the -----	683	<i>Gall bladder disease, some practical points in the diagnosis and treatment of, 692; Opinions on various questions in — — surgery, based on 1,000 operations, 688; Early recognition of — —, 15; Discases of — — and bile ducts, 722; Remarks on transduodenal drainage of the — tract, 1; — stones, 793; The surgical management of — —</i> -----	831	<i>Hyperthyroidism, roentgen ray treatment of</i> -----	709
<i>Diagnosis by the general practitioner, 58; A problem in —</i> -----	839	Gasserian ganglion, division of posterior sensory root of, for trifacial neuralgia -----	236	<i>Hysterectomy and ovariectomy for benign tumors and suppurative disease in 600 women</i> -----	156
Diagnostic aid, the blood culture as a -----	701	<i>Gateway of digestion, the</i> -----	812	Idiocy, mongolian, or thymus deficiency -----	60

# CALCREOSE

## Creosote in Pulmonary Tuberculosis

Powell, Latham, Ransome and other clinicians who have given the treatment of pulmonary tuberculosis special attention are of the opinion that creosote not only produces a beneficial effect on the digestive organs, and, so, on general nutrition, but also is of undoubted value in lessening the cough and the amount of expectoration.

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime.

CALCREOSE has the pharmacologic action of creosote but does not have the untoward effects on the digestive tract that creosote has. Patients do not object to taking CALCREOSE.

Write for the "Calcreose Detail Man."

Francis H. Smith: 1829-1906  
Founder of The F. H. Smith Company

Fifty years ago the late Francis H. Smith, who was then employed in the House of Representatives and also a member of the commission appointed by President Grant to settle the Sioux Indian disputes, decided to go into business for himself.

Born and raised on a farm in Connecticut, he knew that the foundation of all wealth was land. He knew, furthermore, that the presence of the National Government in Washington, D. C., was a **guarantee of constantly increasing real estate values.** He knew that money would be needed to finance the Capital's expansion.

**Started in 1873**

So it was, in 1873, that Francis H. Smith opened an office and engaged in the real estate mortgage loan and investment business.

In 1873 there were no apartment houses in Washington and only thirty-three small hotels. Today there are approximately a thousand handsome apartment structures and some one hundred and twenty-five hotels, which rank with the best to be found in any city in the world.

**Developing Washington**

The F. H. Smith Company has played its part in this work of development. Buildings like these necessarily had to be financed in order to be built. Such financing in the

majority of cases has been in the form of mortgage loans.

It is these loans—loans on apartments, hotels, office buildings, etc.—that are offered by us to the investing public in the form of First Mortgage Bonds. The security back of them is Washington real estate—improved, income-producing property.

**Safe for 50 Years**

Our First Mortgage Investments have behind them a record of **no loss to any investor in fifty years.** Funds may be invested for as short a period as two years or as long as fifteen years, in denominations of \$100, \$500 and \$1,000.

**The interest return of 6½% is made all the more attractive by definite tax free features.**

Our Investment Savings Plan puts these investments within the reach of every-one who can save even as little as \$10 a month.

Let us send you a free copy of our Golden Anniversary booklet. It contains the illustrated story of F. H. Smith's remarkable career and of one of the most interesting periods in the Nation's Capital.

### REMARKS ON TRANSDUODENAL DRAINAGE OF THE GALL TRACT.\*

By WALTER B. MARTIN, M. D., Norfolk, Va.

It is my purpose to review my experience in drainage of the gall-bladder by the so-called Lyons' method, and by certain case reports to illustrate the conditions under which non-surgical drainage is indicated, and the benefits that may result.

As is well known, the procedure is based on the assumption that the introduction of a concentrated solution of magnesium sulphate directly into the duodenum through a duodenal tube will result in the relaxation of the sphincter of Oddi with practically simultaneous contraction of the gall-bladder and the free outpouring of bile. Meltzer in 1917 originally noted the action of magnesium sulphate when applied directly to the duodenal mucosa and suggested that its relaxing effect might be utilized clinically in draining the biliary passages. Lyons in a series of papers has outlined a practical method of procedure for non-surgical gall-bladder drainage and has presented weighty evidence as to its value in the diagnosis and treatment of certain biliary conditions.

The method of application is briefly as follows. The patient presents himself in the fasting state. A sterile duodenal tube is passed directly into the stomach and any residual stomach contents is aspirated off. The stomach is then washed thoroughly with an alkaline antiseptic solution; the tube is withdrawn until the tip is just within the cardia: the patient placed on the right side with the hip slightly elevated and allowed to slowly swallow the tube until the desired point is reached. In the great majority of cases no difficulty

is encountered in introducing the tube into the duodenum. In ninety per cent. of my cases this has been accomplished in ten minutes.

After the tube has been satisfactorily adjusted, 30 to 50 c.c. of warm 25-30% solution of magnesium sulphate is introduced through the tube and in about two minutes gentle suction is exerted with a syringe. Usually a small amount of the magnesium sulphate is recovered, followed by a flow of golden yellow bile. Characteristically the three types of bile as described by Lyons can be obtained; viz.: a few c.c. of yellow or brownish colored bile, coming presumably from the common duct, followed by a larger quantity of darker, more viscid and concentrated bile believed by Lyons and others to be the contents of the gall-bladder, and finally, a persistent though much less voluminous flow of thin, light straw colored fluid which is considered to be the freshly secreted bile directly from the liver. This sequence of events can actually be observed by anyone who carefully carries out the procedure. Agreement, however, as to the significance of these changes is lacking.

The recent work of Auster and Crolin would seem to indicate that the gall-bladder has no ejaculatory mechanism and that while circular muscle fibres are contained in the gall-bladder wall, they are not of sufficient strength to bring about expulsion of bile. They found, however, that definite relaxation of Oddi's sphincter and the surrounding duodenal muscles occurs after lavage of the duodenal mucosa with magnesium sulphate. Rous and McMasters have presented evidence of the function of the gall-bladder in concentrating bile, and it is a matter of common observation at the operating table that the gall-bladder bile differs in color and consistency quite strikingly from freshly secreted bile.

If by means of the duodenal tube one obtains a specimen of bile that corresponds in volume to what one might expect to obtain

\*Read by title at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

from the gall-bladder, that in color, concentration, viscosity, and chemical composition resembles specimens of bile taken at operation directly from the gall-bladder, one is justified in strongly suspecting that this material is gall-bladder bile. This opinion is reinforced by the position of the "B bile" in the sequence. It seems to me a matter of some indifference from the practical standpoint whether the gall-bladder extrudes the bile or whether it is siphoned off. The ability to obtain it is the important point. Work done on lower animals, especially under anaesthetic with the abdominal cavity open, can not well be translated in terms of human physiology: After all, the permanent place that the Lyons' method will occupy in diagnosis and treatment will be based on clinical results; viz.: the number of correct diagnoses made and the relief given to suffering individuals.

In this connection the published clinical records of Cutler and Newton are of interest. While they conclude that the test is not a dependable diagnostic aid, their case records show a coincidence of drainage and operative findings in about 87%. I am not aware of any other procedure that will diagnose as large a percentage of pathological gall-bladders.

Again I wish to emphasize that the question of whether the gall-bladder empties itself through an effort of its own musculature or by some other mechanism is of scientific interest, but has no real bearing on the argument. The question is, can gall-bladder bile be accurately and consistently obtained by means of the duodenal tube? My own experience leads me to believe that this can be done and case records will be presented to show that a flow of bile can be initiated, symptoms relieved, and that a high percentage of drainage and operative findings agree.

What, then, is the field of usefulness of this procedure?

*First*, diagnosis.

*Second*, prognosis as to relief by surgical intervention.

*Third*, treatment.

- a. Simple catarrhal jaundice.
- b. Unsuitable surgical risk.
- c. Mild and early cases of gall-bladder infection.
- d. Typhoid carriers.

The diagnosis of gall-bladder disease is not

always a simple matter. Given digestive disturbance, right upper quadrant pain and tenderness, pain referred to back and shoulder, with or without jaundice, the diagnosis need not be in question, but classical symptoms may be absent or confused by other complicating factors. Association of chronic appendicitis with gall-bladder disease is not uncommon, and the appendiceal symptoms may overshadow the picture. Infection can exist in the gall-bladder practically without symptoms directly referable to that organ. It is in such cases that direct drainage and examination of gall-bladder contents is of especial value. The following cases will illustrate this point.

Mrs. J. M., age 37, seen August 23, 1921, complaining of pain in the left side. General health had been good, nothing noteworthy in past history except an abdominal section at age of seventeen, at which time the appendix and one ovary were removed. In January, 1920, the patient had influenza followed by pneumonia. Since that time she had had severe pain in the left axilla extending into the back. This pain had been almost constant and at times was very severe.

Physical examination revealed a moderately obese woman near middle age. The skin, teeth and mucous membranes were normal. The lungs were normal except for a few fine marginal rales at the left base. The patient complained of pain on deep breathing. There was marked tenderness along the course of the left seventh and eighth intercostal nerves. The heart was normal; pulse 80, regular in force and rhythm; blood pressure 110/70. Liver and spleen not felt, and there was no abdominal tenderness. The extremities and reflexes were normal. X-ray of chest showed no abnormality. Wassermann was negative. Urine was negative except for a faint trace of albumin. Red count and haemoglobin were normal; white count 6,100; 48% polys. 46% small mononuclears. It seemed evident that this patient was suffering with an intercostal neuritis and careful search was made for a focus of infection. The teeth, tonsils, sinuses, kidneys and genitalia were ruled out. As a final measure the gall-bladder was drained and several ounces of thick, turbid, infected bile was obtained. This was followed by complete relief of symptoms. The patient remained free from pain for three weeks. Symptoms returned at the end of that time and she

was again drained with the same result. She was then advised to have the gall-bladder removed, which she refused to do for several months. During this time she came back at intervals for drainage and each time secured relief. The patient finally consented to operation and Dr. C. C. Smith removed a chronically infected, thickened gall-bladder. The patient has now been entirely well for a period of about ten months.

Mrs. G. B. L., age 28, seen March 28, 1922, complaining of stomach trouble. The patient had never been very strong, and had had chronic sinus trouble for several years, tonsils removed in September, 1921. She had double pneumonia following measles three years ago. Following this patient's pulse remained elevated and she had an afternoon temperature for several weeks. She was sent to Catawba at this time but diagnosis of tuberculosis was not definitely confirmed. An abscess at the root of one of her teeth was found and her temperature returned to normal after the removal of this tooth. She had had mild digestive disturbance with tendency to diarrhoea for several years, much more marked during the past six months. During this time she complained of pain in the right upper quadrant of the abdomen, eructation of gas and cardiac palpitation. She had had some nausea and three or four vomiting attacks during the past six months. Recently she had had a burning pain in the abdomen, coming on two or three hours after meals and partly relieved by food. She had been very nervous for several years.

On physical examination the skin was dry, no jaundice, acne papules over the shoulders. Eyes were somewhat prominent, convergence poor, distinct lagging of the lids, moderate fine tremor of the hands, thyroid definitely enlarged. The heart and lungs were normal; pulse rate 104, blood pressure 125/80. There was slight tenderness on deep palpation over the gall-bladder. The uterus was retroverted and the cervix lacerated. Reflexes were normal. The blood picture was normal; no eosinophils were seen in counting two hundred cells. The urine was negative except for trace of albumin. Stomach contents showed a free hydrochloric of 18 and total acidity of 28, no blood, microscopical findings normal. Basal metabolism was plus 40.

Fifty c.c. of very thick, turbid bile were

obtained with the duodenal tube. This material contained many flecks of changed blood and microscopically showed large numbers of free *Giardia intestinalis*. On culture a pure growth of streptococcus was obtained. Cholecystectomy was advised and Dr. R. L. Payne removed a chronically infected gall-bladder. Unfortunately the contents of the gall-bladder were not examined for *Giardia* so cannot say definitely that they were harbored in that organ. Following the operation the patient improved but continued to show cysts in the stools. Later she was given salvarsan intravenously and intraduodenally with apparent eradication of the flagellate. She is now completely relieved of her digestive symptoms and her thyroid condition has also markedly improved.

These two cases have been given in detail. In six other cases that have come to operation, the diagnosis was absolutely confirmed in four. In the fifth case the only pathology was a band of adhesions making an hour-glass constriction about the middle of the gall-bladder. The patient obtained partial but not complete relief by the operation. In the sixth case a diagnosis of chronic gall-bladder and chronic appendicitis was made. The surgeon who operated on this case considered the gall-bladder normal and did not remove it but did remove a chronic appendix. The patient was not relieved by the operation.

The fact that a patient has a diseased gall-bladder is not specific indication that the symptoms complained of are referable to that organ or that they will be relieved by surgical removal. If by non-surgical drainage we can demonstrate definite relief of symptoms, operation can be undertaken with much more assurance of beneficial results. In this connection I wish to again refer to the case of Mrs. J. M. given in detail above. This patient had a severe intercostal neuritis coming on immediately after an attack of pneumonia. Even if a diagnosis of gall-bladder disease had been self-evident in this case, I could not have assured the patient that operation would effect a cure unless I had observed such marked relief after draining her gall-bladder by the Lyons' method. I felt in this case I could positively promise the patient a definite cure if her gall-bladder was removed, and this has been borne out by the subsequent course of events.

One other case is also to the point. This patient is a woman sixty years old who complained of severe pain in her back and in both legs. On getting up in the morning she was very stiff and any movement was extremely painful. Clinical evidence pointed to gall-bladder disease. She had previously been gone over and other foci of infection eliminated, and I advised her to have her gall-bladder removed. She wanted definite assurance that the operation would relieve her. Medical drainage was instituted to test this point. The patient has been completely relieved of the symptoms complained of over a period of several weeks. I now feel that operation in this case gives very definite promise of real benefit to the patient.

Medical drainage of the gall-bladder should supplement but not supplant surgery in the treatment of gall-bladder disease. Given a clear cut case of gall-bladder infection, I would always advise operation if there was not some specific contra-indication.

Lyons reports sixteen cases of catarrhal jaundice, nine of which were treated by the usual expectant method and seven by means of the duodenal tube. The average duration of the first group was thirty-five days, of the second group seventeen days. In other words, the average duration of the disease was shortened fifty per cent. by means of drainage. I have had three cases of what was apparently simple catarrhal jaundice that I have treated by this method. In one case I was entirely unsuccessful in obtaining bile. I felt at the time that I did not get into the duodenum, although this was not checked by fluoroscopic examination. The other two cases responded promptly to treatment.

Mrs. C., a patient of Dr. Roche, gave a history of jaundice that had lasted about two weeks. The stools were apparently acholic, jaundice was very deep, and the patient was suffering from the usual symptoms associated with this condition. Following introduction of the tube and stimulation with magnesium sulphate, a considerable flow of bile was obtained on first examination. Treatment was repeated on several successive days, stools became highly colored, patient's clinical condition improved, she was discharged from the hospital and promptly cleared up her jaundice.

Mr. J. G. H., referred by Dr. Hancock,

with a history of jaundice of two months' duration. The patient had a slight fever at the time of onset of his jaundice, but since that time had been afebrile. He had had no pain but had lost about ten pounds in weight and was suffering with mild digestive disturbance; stools were clay colored. The patient did not appear to be very sick, and his principal objection to the jaundice was that it interfered with his business as a salesman. A small amount of bile was obtained at the first treatment, which was repeated three times. Following the second drainage a very free flow of bile was obtained, stools became dark brown in color, and the jaundice began to rapidly clear up.

I am aware of the fact that any conclusions drawn from the clearing up of catarrhal jaundice are very uncertain because of the fact that these cases run a course that varies greatly in length, and in any given case the clearing may have simply been coincident with the institution of a certain line of treatment and not the result of that treatment. Lyons reduced the average duration of his cases over fifty per cent. by means of the tube, and it is certainly suggestive that in both of these cases noted the jaundice which had been intense and which showed no evidence of clearing, promptly began to clear on institution of drainage.

There are cases that come under observation that need surgical intervention but, on account of the condition of the patient or some associated disease outside of the gall-bladder, operation is inadvisable. These cases can often be relieved and restored to health by means of medical drainage. About ten months ago I saw such a case with Dr. Ashburn. This patient was a man fifty-nine years old who had been deeply jaundiced for a period of three months. When first seen he presented a picture very similar to that seen in advanced carcinoma of the head of the pancreas. The jaundice was maximum. He had lost forty-seven pounds in weight, was having chills and a daily rise of temperature to about 103. History of the case showed that at the time of onset, fever had preceded the jaundice by about two weeks. Five years before he had had a similar attack lasting about one month. The physical examination was essentially negative except the evidence of marked inanition and extreme degree of jaundice. No mass

could be palpated in the abdomen, the liver was slightly enlarged, blood Wassermann was negative, leucocyte count 15,000, urine showed casts and a moderate amount of albumin, and X-ray of the gastro-intestinal tract was negative.

The patient was sent to the hospital and was drained by means of the duodenal tube every other day for two weeks. The first time the tube was introduced into the duodenum, no bile was obtained. On the second occasion, however, a free flow of bile was secured and on every occasion thereafter. Following the second drainage the stools became highly colored, temperature dropped to normal and remained so, leucocyte count returned to normal, and the patient's appetite and general condition began to improve. At the end of two weeks he was discharged from the hospital, having gained five pounds in weight, and feeling much stronger and better in every way. The patient was given a Jutte tube with instructions to drain himself twice a week for four weeks and weekly thereafter for another month. On the outside he rapidly cleared up his remaining jaundice and steadily gained in weight and strength. At the end of two months he had returned to approximately his former weight, and since that time has been actively engaged in his usual business. This man when first seen was extremely ill, he had lost forty-seven pounds in weight and his general condition was very poor. Surgical intervention was out of the question, and I believe that without drainage the patient would have died.

Mrs. E. A. M., age 59, seen January 21, 1922, complaining of shortness of breath and stomach trouble. Her family history and past history were not significant except that patient had had several attacks of upper abdominal pain of no great severity. In the spring of 1921 the patient had a severe cold and cough, and following this ran a low grade temperature for about six months. Since then she had suffered from shortness of breath, fatigue on exertion, and digestive disturbance characterized by gaseous eructation and sourness. Bowels had been loose, with four or five movements each day.

Physical examination showed the skin dry with increased pigmentation, no jaundice. The eyes, ears and nose were normal, the teeth absent, mucous membranes normal. The lungs

were clear except for a few scattered rales at both bases. The transverse diameter of the heart was 16 cm., the point of maximum impulse 11 cm. to the left of the midsternal line in the fifth interspace. The heart sounds were muffled and of poor quality, no murmur detected. Pulse rate 96, regular in force and rhythm. Blood pressure 170/95. There was slight tenderness on palpation in the region of the gall-bladder, abdomen otherwise negative. There was a slight oedema about the ankles. Reflexes were normal. Red blood count 4,150,000; haemoglobin 86%; white blood count 12,000; polys 54.5%, small mononuclears 35.5%; Wassermann negative. Stomach contents, 44 free hydrochloric, total 68, negative for blood, microscopic normal. Stools negative for blood and ova. Urine negative. Drainage of the gall-bladder returned about 100 c.c. of thick, slightly turbid bile containing considerable sediment. Microscopical examination of the sediment showed many pus cells.

In this case we have a patient with a very serious myocardial involvement combined with a fairly active gall-bladder infection. It seemed probable that her cardiac condition was being aggravated by her infection and that to obtain relief, treatment must be directed to her source of infection. She would have been a very poor operative risk and, as she had apparently been benefited by the first drainage, treatment was repeated a number of times over a period of several weeks. This was followed by a fall in the leucocyte count, although it did not return entirely to normal, and quite marked improvement in the patient's condition. Not only were the digestive symptoms ameliorated, but the cardiac condition was greatly helped.

I do not believe that we are yet in a position to make any positive statement as to the permanent results of drainage in treatment of early and mild cases of gall-bladder infection. Certainly there are many cases whose symptoms are not severe and who will not consent to operation. It does not seem unreasonable, in light of the favorable outcome of some severe cases, to believe that many early cases can be cured. If drainage is instituted, foci of infection eliminated, and the general condition of the patient built up, I believe that it is not unlikely that many of these infections can be permanently cured. Demonstra-

tion of this will have to await our future records. I have numerous case records that show relief over a period of many months. With few exceptions these are patients on which surgery has been advised and who have refused operation.

There is one other group of patients that deserves brief mention. That is the typhoid carrier. As is well known, the bacillus typhosus is often harbored in the gall-bladder, and after a case of typhoid fever it may be extremely difficult to rid the stools of the organism. These individuals constitute a constant menace to the community in which they live. Smithies mentions two cases in which he obtained the typhoid bacillus from the bile recovered by means of the duodenal tube. I have had experience with only one case, a patient at the Marine Hospital of this city. This patient had been kept in the hospital for months with constantly positive findings in the stools. Drainage was instituted. We did not recover the bacillus in culture from the bile, but the stools promptly became negative. Three successive cultures were made on the stools with negative results in each case. It is suggested that this method of treatment may be of value in clearing up persistently positive stools.

The cases reported above are not quoted from memory but are abstracts of case records made at the time. They are given in some detail to illustrate the clinical value of the Meltzer-Lyons' procedure. The usefulness of the method as a diagnostic weapon and as a means of determining the probable benefit from surgery has been illustrated. Definite and marked improvement in certain cases treated by this method has been shown. Its possible value in the treatment of mild and early cases and of typhoid carriers has been suggested.

*Flatiron Building.*

### FACTORS OFTEN OVERLOOKED IN THE TREATMENT OF DISEASE.\*

By TOM A. WILLIAMS, M. B., C. M., Washington, D. C.  
ALL IMPORTANCE OF PROCESS AS COMPARED WITH PRODUCT.

The mere giving of a name to a disorder of a human being is not helpful unless it is accompanied by an understanding of the manner

in which that disorder arises. It is not even enough to know the cause of the disorder unless one knows the process by which the human organ reacts to that cause of disease. For instance, the treatment of a patient is not helped by the mere knowledge that a minute rod like vegetable is the cause of tuberculosis of the lung, unless it is accompanied by the knowledge of the processes which occur in that lung and why they do so. An understanding of this may form the foundation for methods by which we may be able to combat the inconvenience or dangers to life of the disease process, even when we cannot outright and forthwith destroy or neutralize the cause itself.

Diagnosis then must mean not a mere labeling but the comprehension of a process and a name which does not imply this kind of knowledge is more harmful than helpful, for it gives the illusion of knowledge without valid basis. It may produce complacency in the breast of the physician and give satisfaction to the patient's friends, but it is of no value to the patient himself. It is this kind of medical procedure which has given rise to the satires of Moliere, and the diatribes of Bernard Shaw. These strictures are well taken, and it is not by cavilling at them that our profession will help its status, but by taking thought so that these kinds of strictures may cease to find justification.

The factors apt to be overlooked in the treatment of disease mostly depend upon the physician's incomplete conception of the process in the patient's body or mind with which he is dealing, and the incompleteness is very often due to the blinding of the physician's thought by conventional names. This is often the fault of teachers in medical schools, more especially in those men without elasticity of mind whose categories are hard and fast men whose knowledge has been obtained not from nature but from books, which they cannot use wisely, because they have never studied nature enough to know that hard and fast lines are the exception, that academized categories are merely conveniences and that in nature there are infinite gradations and few abrupt differences.

Not only that, but it is not enough to understand the end product in disease processes. That is what we aim to prevent by our therapeutics. It is not helpful to the patient that we are able to detect the mere fact of a con-

\*Read by title at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

solidated lung, alteration of the heart sounds or rhythm, an exaggerated reflex, hemianopsia, lymphocytosis of the spinal fluid, a diminution of iron or an increase of nitrogen in the blood, albumen or sugar in the urine, a false sense of perception, an exaggerated emotivity or a wrong way of thinking. These are only signs of disease or the result thereof. What interests the therapist is the process which produces these, whether it is a reaction to a microorganism, whether it is a disturbance of metabolism or an endocrine imbalance, or whether it is a disharmony in the integration of the neurones within the body, or whether it deals with adaptations to the surroundings. In all alike the process must be understood. It is not even enough to know the causative agent. For instance, the awfulness of a combatant's life in the recent war does not tell us why a psychoneurosis developed in many men. The knowledge is derived only from the study of the processes occurring in his mind and body. It was only when that understanding was gained by the medical officers that such men could be treated in such a way that they recovered the power of adaptation to the conditions of war.

Again, there is little therapeutic help in the knowledge that once upon-a-time the reaction to a streptococcus injured the mitral valve so as to lead to an incompetence of the patient's heart. Only by the knowledge of the processes concerned in the physiology of the circulation are we able to so order the patient's life that compensation may return.

Our conception of many of the processes occurring in disease is purely inferential and cannot be demonstrated to persons without an extensive knowledge of physiology. Besides, concerning some processes we are still in the dark. In these cases we have to resort to empirical methods and to confess incompetence. However, the number of these has diminished very rapidly as the attention of clinical investigators has become more concentrated upon the study of processes and less absorbed by interest in end results in the post-mortem room and even in primary causes in the bacteriological laboratory.

#### ATAXIAS DIFFER IN MECHANISM.

For example, the clinical result ataxia is a stage in the progress of a posterior radiculitis which can be readily discerned post-mortem. However, the process which interferes with the

integrity of the roots differs with the cause which has produced it and must be treated in a quite different manner. If the bacillus of Koch is concerned, immobilization of the spine, rest, sunlight, air and generous feeding must be employed. These measures will usually facilitate resolution of the inflammatory exudates, whereupon the roots will again functionate and the ataxia will cease.

On the contrary, when the roots have been affected by the *treponema pallidum*, immobilization will not cut short the pathological processes concerned. But treponemicides will; and, if the process has not gone too far, the cessation of root infiltration will permit root functions to return and the ataxia will cease or improve.

A Government official, age 41, was sent because of a severe ataxia which had lasted less than a month. The man could scarcely cross the room without falling, so great was the stagger. He complained also, of numbness of left foot, abdomen and back, and tiredness on walking, no severe pains, but a dull ache in the back now and then, slight difficulty of micturition also. The patient admitted a chancre five and half years before with sequelae, followed by three years' treatment by mercury pills, without loss of weight.

The present illness had begun with a stiff soreness on front of the right thigh, three weeks before, followed one week later by numbness in the rectum, and soon after this ataxia.

Examination showed lost patellar and achilles reflexes, diminution of the plantar, especially on the left and of the bulbocavernosus. The left pupil was irregular and larger than the right and contracted feebly to light. There was no Romberg, though the patient swayed on walking. Heel to knee test was performed steadily, diadokokinesis was slowed and there was some tongue tremor. No impairment of attitude sense was detected, but deep pain sense was impaired especially on the left, and that to vibration especially on the left. Light touch sense was diminished in the inner border of the feet, especially the right. Wassermann test was positive. The patient was treated by intravenous injection of mercuric chloride, and by salvarsan. One week after treatment the walk was steadier, deep pain sense had returned, vibration sense had improved. One month later the ataxia was only slight and there was no impairment

of sensibility, the blood Wassermann was negative, the right pupil reacted better than before. Two months later the left pupil reacted, the numbness of the abdomen had much diminished, the Wassermann reaction was doubtful, as was the case still one month later. Still later, girdle and leg pains developed but soon ceased. A year after beginning, treatment, the Wassermann was negative and the patient, who had been at work all along, walked almost normally, and seemed well except for a drawing now and then in the abdomen and some pain in the arms. Unfortunately the patient ceased attending and repeated efforts failed to trace him. The case is reported to illustrate how rapidly an ataxia may be made to disappear with proper diagnosis and treatment.

A young man who had contracted syphilis only 16½ months before I saw him had been treated once by salvarsan (intramuscular) and by 13¼ grains of protiodide of mercury by the mouth, for a year. In spite of this, headaches ensued fourteen months after exposure. About the same time he showed a marked coarse tremor of the hands, of intentional type; tremor of the tongue and unsteady gait occurred also. Micturition became slow and halting, and erections became ineffectual; poor appetite and constipation; vomiting occasionally occurred; the temperature at times rose to 100. His temper had been irritable.

His physician thought that the tremor might be mercurial, and ceased to give the drug. The headaches and micturitional symptoms improved slightly; but the tremor did not; so a month later, I was asked to advise whether to resume specific treatment or not.

My EXAMINATION showed that the reflexes of the patella were absent with a slight response of the left by reinforcement. Achilles reflexes were active. The radials were doubtful on account of tremor of the arms. The maxillary was faint; plantar flexion was faint. The abdominal and cremaster reflexes were present, but that of the bulbo-cavernosus was absent. Pin prick, touch, cold, vibrations and pressure pain, were felt everywhere except that in the thigh muscles and the right neck and arm deep pain could hardly be elicited.

Motility was not enfeebled; but station was slightly unsteady. He could not stand steady on the right leg and there was a Romberg sign of the left leg. The gait was inco-ordinate and spastic, especially on turning. Heel

and knee test with eyes closed, performed with great tremor. Diakocokinesis much impaired. Finger to finger test showed much coarse tremor. There was coarse tremor of tongue, jaw, face and neck, but not of the trunk. No nystagmus. Passive raising of the leg in recumbency produced an oscillation of 6 to the minute. There was a tremulous speech due to a coarse tremor of tongue; but the lips did not tremble during speech. The laryngeal tone was steady.

The skin was covered with branny scales. The veins of the left fundus oculi were larger and more tortuous than normal.

SUMMARY. A distinctly rubrospinal tremor, loss of the patellar and bulbo-cavernosus reflexes, and loss of pressure pain sense in part of the body, along with the history and micturitional symptoms, indicate lues of the central nervous system, even without Wassermann test or lymphocyte count. The character of the tremor entirely excludes mercury in its causation, for the mercurial tremor is of the toxic type and much finer than the coarse oscillations characteristic of the lesion of the cerebellorubrospinal system, the characters of which are now classical and need not be particularized. The lesions I supposed to be present were (1) an arteritis proliferans of the vessels supplying the rubrospinal system in the midbrain: this was the cause of the tremor; (2) a widespread leptomeningeal specific radiculitis, causing the loss of reflexes and of pressure pain sense.

The TREATMENT recommended was salvarsan, followed by mercury.

The PROGNOSIS given was an arrest of the syphilitic process with a probable diminution of the tremor, possibly sufficient to permit the work of an artist to be resumed.

RESULT: The first dose of salvarsan produced a tremendous diminution of the manual unsteadiness, and the patient began to paint, somewhat tremulously but effectively, in ten days. A second dose, a month later caused a further improvement, so that the tremor is now (two months) hardly perceptible; all the deep reflexes have returned, although that of the right patella is hard to elicit; the deep pain sense is everywhere present, although less easily elicited than normal over the areas impaired. His nutrition is greatly improved; and he has no pain nor any of the spasticity nor inco-ordination formerly present.

#### ATAXIA FROM POLYNEURITIS.

Again post-mortem examination of an ataxic may reveal intact spinal roots. Then the process at work may be a deterioration of the peripheral nerves themselves, the state known as polyneuritis.

In this case neither rest nor a treponemicide will be efficacious. Only after the regrowth of the deteriorated neurofibrils will the ataxia cease. This can only be effected when the pathogen no longer acts upon the nerves. This must be sought, and, as the case may be, arsenic must be eliminated, alcohol must be abstained from, diphtheritic toxin must be neutralized, or immunity must be established against whatever infection may be at work.

Thus, a woman of 53, wife of a well-known Government official, referred by her physician because her convalescence from diphtheria was complicated by Vincent's angina which she had contracted two months before. There ensued weakness of voice, numbness of feet and thigh and more recently a progressive weakness of the limbs. She was very nervous and was taking osteopathic treatment.

EXAMINATION revealed absence of the triceps, radial, and biceps reflexes as well as a reduction of the patellar, achilles and plantar, while there persisted the deltoid, masseter and abdominal reflexes.

There were subjective tinglings in the extremities and tenderness, both to prick and pressure was increased; the vibration sense was diminished in the leg, arm and trunk; the nerve trunks were tender. The spacing sense was diminished in the left hand, where she could not distinguish two points nine millimeters apart. The localization of touch was almost lost in the toes and ankle, and scarcely perceptible in the hands. The walk was unsteady, the hands unskilful, and the motor power much diminished, yet there was no perceptible atrophy. Both optic disks were slightly pale. There was a slight tachycardia. She was seen several times, during which the symptoms rapidly regressed after the administration of antitoxin which was recommended, so that she was able to go to her new home about six weeks later.

The DIAGNOSIS, of which there was no question, was post-diphtheritic polyneuritis, and the recovery was gratifyingly rapid.

#### ATAXIA FROM PERNICIOUS ANAEMIA.

It may be still another agency which is pro-

voking the ataxia, and neither the peripheral nerves nor the spinal roots may be at fault. The long tracts in the posterior columns of the spinal cord itself may deteriorate and necessarily ataxia ensues. Pernicious anaemias commonly are accompanied by such medullary deteriorations, and of this ataxia is often a conspicuous sign. This will not be benefited by treponemicides, immobilization, nor by dealing with any known infection. The process could conceivably be arrested if we knew and could deal with the noxa of pernicious anaemia. Concerning this, however, we are still in the dark. But even if we could arrest the process, we could not restore to integrity spinal tracts which had been destroyed, for within the central nervous system regeneration of destroyed fibres does not happen.

#### ATAXIA FROM NEOPLASM.

Ataxia, however, may arise from still other causes; for instance, the pressure of a neoplasm in the long spinal tracts. None of the afore-mentioned measures of treatment are then to be thought of, but extirpation of the growth must be attempted through surgery or its necrosis by means of radiotherapy may be the preferable method as the case may be.

These five entirely different processes which may produce ataxia are merely mentioned to bring into relief how pernicious it would be to treat this symptom as such; and yet there are very many persons who submit themselves to unjudicious manipulations when they are led to believe that symptoms they suffer are concerned with the spine.

#### SPINAL MANIPULATORS.

Fortunately, perhaps, most medical men recognize the need of special training in the differentiation of manifestations of nervous disease of this kind and hence they invoke the collaboration of neurologists, but there are a great many medical men who do not realize the importance of doing so quickly. In consequence, many patients invoke the services of spinal manipulators much to their detriment; for these practitioners are quite incapable of a differential diagnosis, which in many cases requires the highest training and judgment. Hence, they treat them nearly all on the basis of a local functional disturbance of the neurovascular mechanism, lose valuable time, and sometimes injure the patient. Their continuance in practice is due to the fact that in many

cases of arthralgia, myalgia and neuralgia, manipulation activates the local circulation. This removes discomfort, and, besides this, reflex excitations play a part also; and there are other factors as well, such as suggestion, which need not be particularized here.

#### FAULTY POSTURE.

Pains in the back or limbs, however, may be purely the product of faulty posture; and it is very unsound to treat them empirically by so-called anti-rheumatic drugs. The rectification of the faulty posture may lead to removal of the pains as in the following case:

A stenographer became progressively weaker and less able to perform her work, which rendered her more and more irritable, and she began to sleep badly mainly because of a gnawing pain in the shoulder and lower neck. Her physician detected no physical signs and treated her by the tonics unfortunately too usual. Examination discovered that the whole syndrome was really secondary to the pain in the neck and that this was due to a faulty stooping posture at the keyboard. A few exercises, with attention to posture at work, removed the pain, and the asthenia ceased for a period of eight years.

#### DISTINCTION BETWEEN ATAXIA AND TREMOR.

A man of 46, was referred by Dr. W. P. Carr, on account of a shaking of the left arm since four years, and the right hand since November. There are times when he can control the shaking, especially when alone. When under stress, the eyelids twitch also; and when eating, quivering of the abdomen occurs, and he has a sensation of twisting intestines when he lies down. He is worst in the morning. Upon exertion, a severe pain occurs in the right chest and arm since September; it is somewhat relieved by standing.

The previous history is insignificant except where it concerns a pain in the back and "sciatica" after lifting a weight, eighteen years ago. This ceased about three years ago. He is better when starving. The patient gave out an odour I have frequently noted in Parkinson's disease. The teeth had been well attended to.

EXAMINATION showed hyperactive reflexes. Clonus of the left wrist when held in semi-extension, clonus of the left thumb when held in semi-adduction: tremor-clonus of fingers at times when held in semi-extension; pronation clonus at times when the flexi-extensor clonus

diminishes. The left pectorals are rigid, the neck stiffened, the shoulder muscles are semi-rigid; the left arm and wrist show characteristic cogwheel resistance, but there is none elsewhere. A monotonous and deliberate speech he says is the result of his success in curing a stammering which lasted for years. The expression of the face is rather blank. Blood pressure was 136 and 88.

The scanning speech, twittering of the eyes and tremor, gave rise to a suspicion of multiple sclerosis on the part of some who saw him. This opinion could be rejected at once; for the tremor was not intentional, almost ceasing during movement, the eye movements were not nystagmoid, and the speech was not characteristic at all.

The intensity of the tremulousness, its variability, the extraordinary contortion of the eyes and face, the intensity of the effort required to speak when he first entered the room, gave the impression that one might be dealing with a neurotic; but this interpretation was negatived by the blank expression, the regular clonus, and, above all, by the cogwheel resistance of the left arm and wrist, and the board-like hardness of the pectoral and cervical muscles.

The DIAGNOSIS of paralysis agitans was further confirmed by the complete disappearance of the tremor and rigidity when 1/100 of a grain of hyoscine was injected hypodermically.

The patient continues to take hyoscine and is considerably relieved.

#### DISTINCTION BETWEEN ATAXIA AND WRITER'S CRAMP.

A single woman, aged twenty-nine years, was referred April 10, 1910, by an orthopedic surgeon, after the failure of orthopedics and massage to improve an incapacity to write, apparently due to a painful stiffness and cramp of the shoulder and wrist of two years' duration. Several months in the country had also failed to remedy the cramp, although she had gained ten pounds in weight and become much stronger.

When in the act of writing, the wrist stiffened, the forefinger and thumb tightened up on the pen, the hand trembled, and she complained of severe pain in the wrist and between the first and second metacarpal bones.

Psychologically, she was overconscientious and inclined to melancholy. She was employed as bookkeeper in a railroad office and

upon returning to work, after treatment, she had great difficulty in finishing the day. She felt that this position must be kept, as she could no longer, by singing, earn the money she needed to support herself, as she had formerly done. Against the increasing difficulty of writing her daily quota, she struggled hard; but anxiety only added to the physical burden, and she finally succumbed after trying various methods of holding her pen in the effort to write. This process occupied about six months, and ended in a tremor so violent that she had to be fed. She attributed her incapacity to a broken muscle in the shoulder, and hoped that a month's rest would enable her to return to work. This belief was largely the fruit of medical opinion, showing the need for psychopathological skill in a variety of conditions common in medical practice.

After a month's treatment she greatly improved, but was very pessimistic, and thought she had a tapeworm because of her ravenous appetite.

After the first eight weeks I did not see her so often, and she unfortunately relapsed on account of frequent discussions of her state by well-meaning friends; so that toward the end of July she was firmly impressed with the idea that there was a deformity in the hand and shoulders. This was disproved with some difficulty, as her attitude was distinctly contrary. But after this, she fell back upon the notion that she needed something to make her food assimilate. A re-discussion of her digestive difficulties showed her that they were caused by her emotions.

In spite of all reasoning to the contrary, she declared that she could feel her hand contract sometimes, even when not writing. I decided, therefore, that she had not a real grasp of the principles I had been trying to inculcate. One is apt to fail to carry the patient along in understanding unless the temptation to go rapidly without sounding the patient all the way is not succumbed to. Accordingly, I recapitulated them systematically, with great care, and wrote out a summary for her to take home and study. After her next visit, I kept this, and asked her to write to me an account of the mechanism of her condition as she understood it. From this account it can be seen that she had not even yet transcended the physical explanation, as she referred her condition to disease of the brain cells, fail-

ing entirely to appreciate that her disability was psychological; that is, a disharmony of acts arising in ideas. It was as though on a typewriter neither broken nor worn, one wrote the wrong letters. It would not be possible to overcome the normal acts derived from diseased brain cells by any amount of studied indifference or exercise of self-will, which would serve in a psychological situation.

The patient's own explanation of the mechanism of her affection showed that she had by no means an adequate conception of her own condition; she believed that the brain cells were diseased. As it was necessary for her recovery that she should have a clear understanding, I again tried to place before her that which it was necessary for her to comprehend and to eradicate from her mind her erroneous ideas about herself as follows:

First it is an error to say that your "brain cells have become diseased." There is no disease of your cells, there is a disorder only of the harmony of motion among them in writing, etc. This originated in the extraordinary efforts to accomplish much during a time of fatigue and mental distress. It was the difficulty of doing this which caused the unusual attitude of the hand, which arose from conscious effort to perform what was beyond your staying power. The tightening of the muscles was "mental." The habit of wrong writing was thus engendered and it is this which now persists as an automatism. That is to say, when you are not paying attention, the hand of itself is guided by the mind unconsciously into these perverted positions.

But even when attending, there is an inclination to fall into the very position you desire to avoid. This is partly due to its habitualness and partly to the natural tendency of many persons to perform the very act they most wish to avoid; a familiar example is of the cyclist to collide with the obstruction he sees in the road. By practice, this tendency is soon overcome. So understand that the abnormal acts are not the result of disease of the cells; but are merely bad habits to be overcome in the same way as those of the learning of the piano or of any act needing mechanical dexterity.

It was only after this that rapid improvement occurred and the writing, though a little large, became normal. Perfect ease, however, was not attained, although she did a good

deal of clerical work intermittently, and was ready to take a position demanding it continuously, knowing that if the right hand failed the left hand with which she had learned to write could take its place.

As a result she was one year after, in better physical condition than she had been in for years, and was able to walk long distances and to do hard housework without fatigue; whereas formerly she was tired out by walking a few squares or by any hard work. But that the restoration of her physical health was not the cause of her partial recovery from writing cramp is proved by the relapse of the latter, in spite of continued improvement of her physique. This relapse was due to circumstances which compelled the cessation of the re-educative training. The patient, however, has remained for ten years in important clerical positions.

#### WRITER'S CRAMP DUE TO APPREHENSION.

A man, referred by Dr. Williams, of Boston, had been unable for one month to write his name clearly on account of a tremor. We know tremor is a symptom of toxemia or of nervous disease; but this man could draw without trembling, which he could not do if his neurones were diseased or intoxicated, so we concluded that his tremor was psychogenetic. On investigation we found that the first time he trembled was when he returned to work after a surgical operation before he was fit. The bank did not recognize his signature, and apprehension of this caused him to tremble thereafter when attempting to write. Re-education led to his cure in a month after one visit.

The role of mental prepossession inhibiting the due co-ordination of muscular movements was explained to him and illustrated by means of the strokes in lawn tennis, more especially that known as the drive. It was shown that fear of making an improper stroke is very likely to lead to lack of freedom and cramping of the muscles, which are the very positions to be avoided. Still greater anxiety will create an uncertain, wobbling stroke, the in-co-ordination of which is comparable to his writing.

The relation of these facts to the episode of the refused check was discussed with him at length. When he had clearly realized the psychological mechanism of his condition, he was directed to entirely cease writing with

purpose, and to begin exercise with free-arm movements with chalk on a blackboard, not paying attention to the forms he drew, but concentrating upon the attainment of freedom in action. When this was insured, he might pass to a slate, and later to pencil and paper, and gradually reduce the size of the writing. But over two years later, he sent me a specimen and informed me that he had almost entirely recovered after one month of the exercise prescribed. (*N. Y. Med. Jour.*, March, 1911).

#### SO-CALLED NEURASTHENIA AND DEPRESSIONS REQUIRE DIFFERENTIATION.

The oversight of innumerable important factors in the treatment of disease has been conducted to by the concept of neurasthenia as an individual disease to be dealt with by a routine method. It is true that the routine used, the Weir Mitchell treatment, fitted a large number of persons diagnosed under the caption of neurasthenia. But the routine failed to benefit thousands in whom a more careful study of the body processes did lead to measures which benefited them. Besides, the "cure" was highly detrimental to many. In some cases isolation should never have been imposed; in others the forced feeding was a mistake; to others the expense was a handicap to the conservation of their energies.

#### TONICS.

But if now-a-days an indiscriminate "rest cure" is condemned in this way, how can strong enough censure be inflicted upon the common practice of prescribing "tonics" to persons who are supposed to be run down, without even a proper search for the process responsible for the symptoms? If lassitude is complained of, strychnine is given irrespective of the cause, although the patient may be infected, or ill-nourished or over-nourished, or depleted by anxiety or insomnia, or over-exertion or disturbance of the internal secretions. Although perhaps no permanent harm may be done except in cases of cardiac enfeeblement, yet time is lost, money wasted, and we as a profession are failing in our function.

To patients described as DEPRESSED the same remarks apply, but here the danger is greater, for the term depression is used in several senses quite different in kind. It has been applied to patients who are merely asthenic as well as to persons who show themselves in-

tellectually below par. The term had better be restricted to cases of sadness, despondency, affective distress, or be given up altogether. To give strychnine or other tonics to such patients is to overlook entirely the essential features of the condition, for strychnine is merely an activator of the cells of the spinal cord. Affective depression may arise from hepatic inadequacy, infection, endocrin imbalance, or from psychic causes purely. It is the cause that must be dealt with then.

#### DIS-ADAPTATIONS MUST BE DISTINGUISHED.

In the psychogenetic cases, equally unscientific measures are often attempted, as, for instance, crude distractions by amusement or change of scene. The proper therapeutics is the penetration into the psychic process which has eventuated in pejorative thinking. This is the preliminary step towards a reordering of the mental attitude of the patient into a truer appreciation of the circumstances which have hitherto distorted his thinking into sadness.

Treatment may demand a readjustment of his whole life which will make him both happier and more efficient as in the following case:

A woman of 26, was referred by a physician who had unsuccessfully treated her several months. She was very reticent in disclosing her complete story with much difficulty and trepidation. She was eating her heart out in routine work in which she was neither using her college education, nor satisfying her craving for contact with other human beings. Nor did her leisure afford her the kind of companionship she longed for. She did not know how to reach away from the safe monotony of a sheltered life into the adventurous variety of the constructive idealism which she worshipped. She was immensely handicapped by a lack of ease of manner and charm, which she envied in others; she was ashamed of her awkwardness.

This situation might only too readily have been attributed to the humiliation she felt at the intense and facile stimulability of her physical sexuality, and a prolonged analytic search might have proved too strong a temptation to those psychopathologists who can think only conventionally.

But as insistent as were the physical discomforts of the patient, I considered that the psycho-social problem was even more important and that to solve this a change of environ-

ment was imperative. It should not need to be said that explanations as to the significance of reproductive physiology were given and that these were of great comfort to the patient. Although they scarcely affected the phenomena themselves, they altered many of the psychological consequences. The patient was assisted to take steps to prepare for an occupation which would favor human contact in constructive work, in which she is now a year and a half later happily engaged without supervision.

#### MORTIFICATION.

Many of the situations which have been invoked in support of the sexual origin of the psychoneuroses are in reality issues depending upon mortifications. But the inhibitions of personality produced by mortifying experiences or the dream of them occur even perhaps more frequently regarding social intromissions of kinds other than sexual. The conventions of fashion are a particularly frequent source of these. In young people the ethics of sport furnish occasions. Relationships in business are another source where motivation by fear of mortification plays a strong part. This is particularly true with hierarchical organized services such as the Army. It is most true of all perhaps in that form of activity among women under the misappellation of society which has become an occupation to which great devotion is paid.

This is no novelty, it having been expressed over two hundred years ago by John Locke, in a principle which he called the association of ideas, but which had already been observed by Aristotle and considerably developed by Thomas Hobbes when he says, "Not every thought to every thought succeeds indifferently, but as water on a plane table is drawn which way any one part is guided by the finger." He gives the famous example:

"What could seem more impertinent in the discourse of our present civil war than to ask what is the value of a Roman penny? Yet thought of the war introduced the thought of King Charles to his enemies; that brought the thought of the delivering up of Christ; that the thought of thirty pence. Thence easily followed that malicious question."

#### OTHER INSTANCES WHERE SEX PLAYED A PART.

Better adjustment and greatly improved physical health occurred when a truer perspective was acquired by a patient through the

learning of the great importance of her feeling of resentment, more especially during the inception of her disadaptation in childhood, and after constructive activities were fomented.

*Impotence from diffidence grounded in misinformation.* In the case of a man sent by a genito-urinary specialist because of an impotence in view of which he was afraid to marry, an undue emphasis upon the physical sexual had caused him to lose perspective, and rendered him almost hypochondriac, as is so often the case. When a new setting of his mind was given him by a dispassionate presentation of the whole sexual relation, his difficulties were enormously mitigated in only a few days. For the efficient factor in his disability proved to be diffidence, which is not sexual at all.

Craving for security and for fulfilment in another patient, the over emphasis upon the sexual factor, almost paralyzed the efforts of some of those who had been dealing with her in fear of what is termed by some "the transference." As a matter of fact an affection which seemed inordinate, and wore a carnal mask, was in reality a craving for protection, safety and trust.

#### INSOMNIA AND HYPNOTICS.

Grave and often permanent harm does come from the practice of prescribing for a symptom without understanding the process which is responsible for it. When insomnia is complained of, the immediate giving of a hypnotic is all too frequent. Now insomnia is always an expression of disease of mind or body. Sleep being an imperative function, anything which interferes with it must be regarded as quite serious. The morbid process which disturbs sleep is in no way combated by a hypnotic. Hence, the physician's first duty to an insomniac is not to club him into unconsciousness with a narcotic but to ascertain what is disturbing the cerebrum. Even when this cannot be exactly found it is usually possible to differentiate between such causes as infection, intoxication, nerve irritation and psychic pre-occupation. Even when the former causes cannot be immediately removed, calm if not sleep can be more safely induced by hydrotherapy than by narcotics. It is very rare that proper attention to ingestion and excretion along with the removal of minor irritants to the skin, mucous membranes and special senses will not

induce sleep when the exciting cause is not psychological.

In the latter case, which is perhaps more frequent than is commonly supposed, the appropriate psychotherapy should be almost invariably successful. A most instructive case of this kind was published in the *Virginia Medical Monthly* in 1913.

#### A CASE ILLUSTRATING THE MECHANISM OF TIC AND INSOMNIA BY SUGGESTION.

A child seen with Dr. Perrie, of McKendree, Md., had a series of tics of smacking the lips, bending down, touching the floor resulting from her desire to avoid hurting others with her breath, which she believed was noxious, and to avoid hurting the floor with her heels.

Therefore, she applied the "healing kiss" to the air which she expired, and the "healing touch" to the floor. After these had been removed in a sanitarium, she was thought to be too nervous for school, especially as she could not sleep for hours after her mother attempted to teach her. In reality this child was not "nervous" at all.

She was neither apprehensive, nor fidgety, nor irritable, nor of a difficult temperament. She had stayed awake by suggestion, because her parents had let her see that they were afraid of it. The matter was explained to the parents, and the child has attended school and remained perfectly well. (See *Am. J. Med Sci.*, Oct., 1912.)

#### CONCLUSION.

Thus these few examples have shown how important for therapeutics is the understanding by the physician of the process which causes the disease of the patient. This is equally true whether the causation is physical or psychological. Thus, faulty co-ordination due to the process of infiltration of spinal roots is rectified by arsenicals and mercurials only when the reaction to treponemata is in activity. Faulty co-ordination due to infiltration in reaction to the bacillus of Koch is removed only when the immunizing of the locality is augmented. Faulty co-ordination due to a process of nerve degeneration ceases only when the nerve elements are permitted to regrow through removal of the responsible toxin. Faulty co-ordination due to a necrotic process in the spinal cord is without present remedy when due to pernicious anaemia. When due merely to the pressure of a new growth, the

process may be arrested by removal of that growth if destruction of the responsible tracts has not occurred.

The inco-ordination of tremulousness when due to a process of ingravescent abiotrophy or slow destruction of the tonus-regulating mechanism in the brain stem or basal ganglia may only be palliated. But when the process which induces tremor is a dynamic response to a situation, known as emotion, it can be completely abolished by proper dealing with the psychological processes of the patient, whereby his conception of the situation is changed.

A depressed patient may be pricked into responsiveness for a time, but he is only truly helped by the removal of the cause of depression, which may come with the understanding of the process which produces it, whether infection, intoxication, endocrin deficiency or a mental attitude.

An insomniac may be clubbed into unconsciousness by a narcotic, which in no wise alleviates the process or eliminates the cause thereof which is responsible for insomnia. This may be a metabolic disturbance, a lesion of structure, or the kind of dynamic process we call psychological. By proper discrimination among these we usually are able to modify the processes disturbing proper function, and when that is done insomnia spontaneously ceases.

These principles are not only true of the few examples above cited, but apply to the whole sphere of medicine. Indeed they are an induction from the whole field of human experience and are known to every thinking individual. However, there need be no apology for their explicit statement; for alas! they are too often forgotten in a short-sighted attention to details, a human weakness from which the medical profession has acquired no special exemption.

1746 K Street.

### THE EARLY RECOGNITION OF GALL BLADDER DISEASE.\*

By E. L. KENDIG, M. D., Victoria, Va.

One year ago my subject before this Society was the early recognition of Acute Appendicitis. On account of its frequency and dangers, appendicitis has long occupied the first and most important place in abdominal dis-

eases. Today this place is being rivaled by diseases of the gall-bladder. The recognition of gall-bladder disease is important alike to the general practitioner, the internist and the surgeon. Because of the uncertainties of diagnosis before exploration, this region has been called the romantic area of the abdomen. In choosing the early recognition of gall-bladder disease for discussion at this time, I fully realize that it is much easier to discuss its early diagnosis than it is to make it.

The gall-bladder acts as a reservoir for bile. Whether such a reservoir is necessary or not, there seems to be some doubt. McMasters relates that gall-bladders are normally found in some animals and not in others. He gives a long list of those having gall-bladders and those of somewhat similar species not having this organ. As an example, a mouse has a gall-bladder and a rat has none. Woods Hutchinson says that one giraffe may have a gall-bladder and another may not. Man normally has a gall-bladder and, after cholecystectomy, he has none. All seem to get on quite well, with or without. Although there is a doubt as to the real necessity for the gall-bladder, it has the function of storing up bile, and regulating its flow into the intestines. It is only after the gall-bladder has become diseased that it causes trouble. Gall-bladder disease usually has its origin in an infection, although gall-stone formation in some instances is attributed to a faulty cholesterol metabolism. This infection is caused by a similar infection in another part of the body, and reaches the gall-bladder either through the blood stream, through the bile from the liver above, or through the common and cystic ducts from the intestines below. Rosenow demonstrated that the most usual course is through the blood stream. Observations of different investigators vary slightly as to the types of bacterial infection found in the different series of gall-bladder cases reported, but all agree that the streptococci are the chief offenders. Brown reports that in a series of cases examined, showing bacterial infection, more than half were caused by streptococci. It must be remembered, however, that cases of long standing with definite pathological changes may become sterile and fail to show the presence of the causative microorganism.

In order to weigh properly the manifestations of gall-bladder disease, consideration

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

should be given to the stage and virulency of the infection and the pathological changes, which have taken place in the gall-bladder region. The infection gives rise to a cholecystitis. As a result of the infection, the bile becomes thicker and more viscid and may contain bacteria, pus, blood, epithelium and cholesterin crystals. Later, gall-stones may develop. The mucous membrane of the gall-bladder becomes redder, granular and often ulcerated. The gall-bladder wall grows thicker and sometimes fibrous. These changes in the gall-bladder wall may cause a contraction of the organ, and render palpation of the gall-bladder impossible. The regional lymphatic glands, situated along the course of the cystic and common ducts, may become enlarged. The peritoneal surface of the gall-bladder may, as a result of the infection, become adherent to the pyloric end of the stomach, the duodenum, or the hepatic flexure of the colon. The grade of the infection is usually mild with recurring exacerbations. A virulent infection or empyema of the gall-bladder may develop. The cholecystitis may become complicated with gall-stones or a stone may become lodged in the cystic or common duct with partial or complete obstruction. According to Graham, 87% of all cases of cholecystitis are accompanied by inflammatory changes in the parenchyma of the liver, which may vary from an infiltration of small round cells to a necrosis with fatty infiltration. Wilensby stresses the point that a gall-bladder infection may cause a swelling of the head of the pancreas, due to a hemorrhagic pancreatitis. McEachern claims that the pancreas was involved in 36% of a series of cases of cholecystitis, reported by him. In the recognition of gall-bladder disease, dependence is mainly placed on the history, physical examination, laboratory reports and the use of the X-ray.

**HISTORY.** The colonization of bacteria is made easier by stasis of the bile. For this reason, gall-bladder disease is usually found in middle life, more often in women than in men, more often in those who lead a sedentary life than in the active, more often in the fat than in the thin, and more often in those who over-indulge in rich foods than in those who do not. Smithies in a report of 1000 cases showed a relationship between gall-bladder infections and the following diseases: Typhoid fever 20.6%, measles 18%, chronic tonsillitis 14.6%,

scarlet fever 14.5%, pneumonia 11.5%, infected teeth 9.3%, chronic rheumatism 9.2%, malaria 8.7%, whooping cough 7.5%, la grippe 6.6%, mumps 6.2%, diphtheria 4.7%, chickenpox 4.7% chronic sore throat 4.6%, and chronic bronchitis 2%.

The history of the condition itself is the most important study in making a diagnosis. The different types of gall-bladder diseases can usually be classified under one of the classes advocated by Cheney. I believe that class one should include the early stage of the disease and class four the later stage. For this reason I have reversed the order of his classification.

*Class I.* The patient exhibits symptoms of chronic stomach trouble with no history pointing to the gall-bladder for long periods of time. Frequently these cases go unrecognized until biliary colic develops or an exploratory operation is performed. Recent methods of duodenal drainage and examination of the fasting stomach render an early diagnosis in these cases more possible.

*Class II.* The patient exhibits symptoms of a chronic stomach trouble with subacute gall-bladder attacks. Here are found the digestive disturbances coupled with a periodic fullness or soreness on the right side. These attacks are known by the laity as bilious spells and are ordinarily relieved for the time by calomel and salts.

*Class III.* The patient gives a history of recurring attacks of mild biliary colic with more or less constant indigestion between. In these cases the stomach disturbance will overshadow the mild attacks of biliary colic, and the patient will overlook telling about the colic unless questioned on this point.

*Class IV.* The patient gives a history of recurring attacks of biliary colic with good health between. Here the typical biliary colic is easy to recognize. However, the pain may radiate or the other symptoms may vary. A diagnosis in these atypical cases can usually be made without difficulty if the main features of biliary colic are borne in mind, such as the sudden onset, the severity of the suffering, the site of the pain, and the unexpected repetition of an attack after an interval of good health.

These constitute a majority of gall-bladder pictures, but there may be certain complications. Should the attack become rapidly more

severe, with rapid pulse, chills and fever, there is probably a more virulent infection or empyema of the gall-bladder. If complicated with the periodic colic, the case should develop chills, fever and paroxysmal sweats, resembling malaria, a stone is probably lodged in the common duct. A tumor of the gall-bladder indicates an inflammatory obstruction of the cystic duct, a stone in the cystic duct or a cancer of the gall-bladder.

**PHYSICAL EXAMINATION.** The value of physical examination is not as great as would be expected. In a large number of cases of chronic cholecystitis, the gall-bladder is shrunken and palpation of the organ is out of the question. The Murphy sign, or tenderness on pressure over the tip of the ninth costal cartilage on deep inspiration in a sitting posture, is a good sign but not conclusive. A general tenderness over the gall-bladder area is suggestive, but a diagnosis cannot be made from this without good corroborative evidence. Just after an acute exacerbation, a rigidity and increased resistance may be detected over the gall-bladder region by a comparison with the opposite side. A tumor in this region, due either to obstruction or cancer, may be readily palpated.

**LABORATORY METHODS.** An examination of the stomach contents will help rule out intragastric disorders. The presence of bile in the fasting stomach is strongly suggestive of gall-bladder disease. Achylia gastrica is more often associated with gall-bladder disease than any other extragastric disorder. Sailer found that 22% of all cases of achylia gastrica examined by him in a series of cases were due to gall-bladder disease. The Lyon method of non-surgical drainage of the gall-bladder has promise as a means of diagnosis. Examine the A, B and C bile for red blood cells, pus cells, epithelium, microorganisms and cholesterol crystals. Their presence strongly suggests gall-bladder disease. There is some doubt as to the bile coming from the gall-bladder, yet the method as a whole, in the opinion of some men who have used it a great deal, is valuable in diagnosis and has some merit in the treatment of catarrhal jaundice and mild cases of cholecystitis. Auster and Crohn report in September of this year the result of experimentation on dogs in an effort to test the Meltzer-Lyon theory of "contrary innervation." They injected a stain into the dog gall-blad-

der and applied the magnesium sulphate solution to the duodenal mucosa and papilla of Vater. Although a stimulation of flow of bile into the duodenum was caused, no evidence of the stained bile from the gall-bladder was seen. In our laboratory at Victoria, we had the same result with a little different technique, this work having been done in June and July before the appearance of the Auster and Crohn notes. We were doing some intestinal surgery on dogs whose owners gave them away rather than pay the license tax. On a series of twelve dogs, we decided to test the effect of magnesium sulphate in the duodenum first, before using the dog for anything else. We injected the magnesium sulphate into the duodenum with a large hypodermic syringe and a methylene blue stain at same time into the gall-bladder. The flow of bile was observed, but there appeared no evidence of the stained bile from the gall-bladder in any case. We simply report this as corroborative of the work of Auster and Crohn.

The examination of the feces will rule out intestinal parasites. The discovery of gall-stones in the feces is positive, but a search to determine their presence for diagnosis is too uncertain.

An examination of the urine is useful to ascertain mild jaundice and help eliminate kidney disease.

A leucocytosis is present in gall-bladder disease according to the nature and virulency of the infection.

Syphilis of the liver may closely simulate gall-bladder disease and for that reason a Wassermann should be done on every doubtful case.

**THE X-RAY.** The use of the X-ray is valuable, but this is not conclusive. The findings should be taken into consideration with the other methods of examination. X-ray may in some cases show stones, or changes in the bladder wall, but more often it does not. The X-ray may show the effects of a pericholecystitis, such as flattening of the duodenal cap, reversed duodenal peristalsis, displacement of the stomach to the right, or a high fixed position of the hepatic flexure of the colon. These latter findings may, however, be produced by a localized peritonitis due to disease of the pylorus, duodenum or colon, and it is necessary to establish negative findings in these

organs before ascribing the symptoms to gall-bladder disease.

The differential diagnosis between cancer and gall-bladder infection is difficult in the early stages. Ochsner says, until a firm tumor is detected in the gall-bladder region, there may be nothing to make a diagnosis of cancer in this region certain. Cheney declares that the inference usually suggests the diagnosis, but exploratory operation is required to prove it. Sooner or later cancer will obstruct the common duct and produce jaundice. Here Lyons' method of non-surgical drainage may be used to determine the presence of catarrhal condition of the gall ducts or a cholecystitis.

Certain diseases of the liver may simulate gall-bladder disease, but they will usually present some distinguishing feature such as a large and tender liver in cirrhosis, a poor heart action in chronic passive congestion, and a positive Wassermann in syphilis. Diseases of the right kidney can usually be eliminated by urinalysis, ureteral catheterization, character of the pain and the use of the X-ray. A differential diagnosis between a chronic appendicitis and gall-bladder disease is sometimes difficult. This is especially so with a chronic post-cecal appendix where the pain is reflected towards the right hypochondrium. It is also difficult when the two conditions are associated. Ochsner says that 35% of all cases of cholecystitis are associated with disease of the appendix. A careful physical examination, a good history, and full laboratory report will be very necessary in making diagnosis.

Diseases of the stomach can usually be eliminated by gastric analysis and the X-ray. McKeand recently reported a case where a chronic cholecystitis with stones presented a typical picture of duodenal ulcer. Both pneumonia and angina pectoris should by history and physical examination be eliminated before making a diagnosis.

The gastric crises of tabes are suggested by disturbed reflexes and definitely recognized by an increased white cell count and positive Wassermann of the spinal fluid.

Herpes zoster and intercostal neuralgia will show tender points along the intercostal nerves.

Lead colic can be determined by the lead line, anemia with basophilic degeneration of the red blood cells, tremor, palsy, impaired sight and a history of contact with lead.

The diagnosis of some cases of gall-bladder disease is easy, but those of easy diagnosis are usually the ones of much severity or long standing. I think it can be safely said that the diagnosis of gall-bladder disease in its early stages is difficult in every case.

A complete history, a careful physical examination, a full laboratory report, a thorough X-ray study, and a careful consideration of those diseases likely to confuse, are essential to a diagnosis in early gall-bladder disease, but even then it is not always sufficient to tell the condition of the gall tract.

Early cases of gall-bladder disease are the ones with gastric symptoms and few or no symptoms pointing to the gall-bladder itself. It is in these cases that Lyons' method of duodenal drainage, proper diet, adequate exercise, symptomatic treatment and vaccine therapy are advantageous. When the disease has caused a formation of stones, a thickened gall-bladder wall, adhesions in the gall-bladder region, or a moderately severe or virulent infection, surgery is the only treatment, but here again it is important to make an early diagnosis in order that the better condition of the patient will minimize the operative risk and the operation itself will prevent many of the secondary changes, which gradually develop during the progress of the disease in the gall-bladder region, liver and pancreas.

I shall in conclusion report four cases. In order to be brief I shall mention only the important positive findings.

CASE I. Mr. M., age 28, white, male, railway fireman, was admitted to hospital March 23, 1921. On admission he had the right lobar pneumonia of four days' standing. Pneumonia ran an ordinary course with a definite crisis five days after admission, the temperature and pulse dropping to normal. Two days after the crisis, he developed pain in the right epigastrium, with temperature of 99.6°, and pulse 82 and slight nausea. This subsided in two days, and few days later he was discharged from hospital, returning to his work. During the following year he had three attacks similar to the one following the pneumonia, each one worse than the preceding, and complained most of the time from stomach trouble. A little more than a year, April 11, 1922, after his previous discharge, he was again admitted to the hospital with a temperature of 103°, pulse rate 100, severe pain over right epigas-

trium, palpable tumor over the gall-bladder, moderate jaundice and a leucocyte count of 14,000. The gall-bladder was removed. It contained about 1000 c.c. of dark viscid fluid, which was made up of bile, degenerated blood cells, pus cells, and epithelium with a streptococcal infection. The wall of the gall-bladder was thickened, and the mucous lining was reddened. The patient made an uneventful recovery and was discharged on May 6th, following.

I report this case because it is unusual for a staff in a hospital to have under observation the primary development of a case of cholecystitis and for the same staff in same hospital to later ascertain the pathology of the case in operation.

CASE II. H. S., age 44, colored, servant, married, female, weight 150 pounds, was admitted to hospital March 12, 1922. Had two miscarriages and four children. Healthy all life until six years before. Past six years has suffered most of the time with stomach trouble. Had periodic colics during this time with severe pain over the stomach. At first these attacks of pain would leave a soreness over the gall-bladder region. For the last two or three years the soreness was sometimes left over the gall-bladder region and sometimes over the appendix. Lately she said she had had more nausea with the beginning of the attack, and sometimes she felt she had a fever after the pain subsided. In two of the attacks she had had some jaundice. Upon admission she had just had an attack. The temperature was 99.6° and leucocyte count 10,300. She had tenderness over gall-bladder and appendix. Duodenal drainage was negative for microorganisms, although bile was dark. Operation disclosed a sub-acute appendix and a thickened gall-bladder wall, containing thick bile, and an enlargement of regional glands along the cystic and common ducts. Patient now doing servant's work.

I report this case because it is a case of associated appendicitis and gall-bladder infection with definite symptoms indicating each disease.

CASE III. Mr. J., white, male, age 37, married, family history negative, admitted to the hospital 20th of this month. Had measles, chickenpox, scarlet fever, pneumonia and influenza. Bad teeth. Present symptoms began one year ago after an attack of influenza, and

developed sufficiently acute to cause trouble four months ago. Had periodic attacks of dull aching pain over gall-bladder and pylorus, radiating to right shoulder. Pain has no relation to the taking of food. Had what he called bilious spells every week or so. Marked tenderness over gall-bladder region, especially after these attacks. Examination of stomach contents normal. Duodenal drainage showed B bile dark in color, but otherwise negative. The X-ray showed a distinct outline of the gall-bladder and a flattening of the duodenal cap. Diagnosis was cholecystitis. Operation revealed a large gall-bladder, filled with dark viscid bile, in which were pus cells, epithelium and streptococci. The wall of gall-bladder was thickened and attached to the duodenum by a band of adhesion as wide as the fundus of the gall-bladder and as deep as diameter of the duodenum. The special feature of this case was the definite picture of the gall-bladder and the distinct flattening of the duodenal cap, as shown by the X-ray.

CASE IV. Mrs. A., female, married, age 45, housekeeper, weight 160 pounds, was admitted to the hospital February 16th last. She had had one miscarriage and was mother of nine children. All labors normal except one about five years before, which was difficult. She did not know cause of trouble at this labor, but was in bed about six weeks following it. History of malaria and measles. Had bad teeth. Had history of periodic attacks of pain over the gall bladder region since the trouble with her delivery. This pain would last about twenty-four hours at a time, and was mitigated by rest in bed. Had stomach trouble in between the attacks of pain. On several occasions she had some jaundice. Stomach contents showed diminished gastric secretions. Apparent fullness over gall-bladder region, but no palpable mass. Tenderness over this region on pressure. Diagnosis of cholecystitis with gall-stones was made. Operation revealed a soft tumor about four inches in diameter, lying just anterior to the fundus of the gall-bladder and attached to the peritoneal covering of the quadrate and right lobes of the liver above and the upturned end of the omentum below. The tumor was removed and the omentum was allowed to go back to its place. The gall tract was found negative. Microscopical examination showed tumor to be a lipoma. The results were good. I report this case because it pres-

ented, in our judgment, before operation a gall-bladder picture and operation showed a lipoma.

## DISCUSSION.

DR. JULIAN RAWLS, Norfolk: I would just like to state that at the Peter Bent Brigham Hospital, in Boston, last week, I heard their pathologist state that they had obtained typical A, B and C bile from cholecystectomized patients.

## VASCULAR OCCLUSION OF THE MESPENTERIC VESSELS.\*

By J. W. TANKERSLEY, M. D., F. A. C. S., Greensboro, N. C.

I bring this obscure and infrequent condition to your attention with the hope that those occasional deaths we have always had may be made still more infrequent. The problem of the surgeon in this day of perfected technique is to lower our death rate, and I believe it is in these obscure cases we now have to look for results.

My first experience with this condition was in 1914 and since then I have seen two others. All were lost and I believe with an early recognition of this condition, one, and possibly two of them, might have been saved. All three of my cases occurred following operations, but this does not mean the cases are confined to those following operations, many of them occur independently. The question of early recognition is important whether occurring post-operatively or independently. Since the first case reported by Tiedman in 1843, and Beckman in 1858, slightly over 400 cases have been collected by various authors. There is no doubt that many cases go unobserved, they are not so infrequent. Watson, at the Boston City Hospital, had his attention drawn to this subject and in the next year found eight cases. In 1,600 autopsies at the Johns Hopkins Hospital, four cases of thrombosis were found which had given no symptoms.

I have used the term "vascular occlusion" advisedly, because I am making no effort to distinguish between arterial embolism and thrombosis, neither am I going to try to differentiate between arterial and venous occlusion. While this may interest the pathologist, I believe clinically the course to be practically the same, certainly the ultimate results are the same in most cases unless we recognize the condition and give adequate treatment. It is true several cases of occlusion have been diagnosed and they recovered without operation, but these cases were the exception and likely of a slowly developing thrombosis in which collateral circulation developed, and I do not doubt that recognition of the condition with adequate treatment aided materially in the recovery. Trotter mentions in his report that in only about four per cent. of the cases was a diagnosis made.

\*Read by title at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

The pathogenesis of the condition is not well understood and several theories have been advanced with much experimenting, but from the very nature of the pathology one may readily see how hard it would be to simulate the actual conditions experimentally. It is true that occlusion practically always occurs in some part of the superior mesenteric, but I cannot see that its origin being higher up on the aorta or the angle of its origin being less acute can influence this condition. Most likely the distribution to the most active part of the intestines plays a more important role. It no more explains the cause than it does in thrombosis of the femoral in appendicitis, typhoid, etc. While an embolus will give a sudden closure should it lodge in a small vessel, it is logical to assume that it will be one of the small vessels near the distribution and that collateral circulation to a certain extent at least will delay actual necrosis and cause the symptoms to supervene so gradually that it is impractical to differentiate from a thrombosis, provided it causes any symptoms whatever. Then, too, a thrombus may not close the lumen completely and will not give positive symptoms until complete interference with the circulation is effected, or it may cause a spasm of the intestines with functional obstruction. It has been shown experimentally that you may have sufficient blood passing through a part to maintain life to that area but that it will not functionate. This may account for the symptoms simulating obstruction without finding obstruction at operation. Also, occasionally in experiments thrombosis has produced no pathology in the intestines, as shown by the post-mortem room. However, it will cause a sudden spasmodic contraction of the intestines, interference with function, and, if the ischaemia is continued, death of the part. This contraction may prevent the collateral circulation from adjusting itself as we know by experiments when blood is cut off from an area the vessels dilate and the blood flows faster in the surrounding area, nature's effort at repair. This prevention of the collateral circulation may give rise to the violent spasms, practically the same as in embolus. From these reasonings, you may readily see the futility of trying to differentiate between embolus and thrombus, venous and arterial, clinically. This might explain too why theoretically the collateral circulation should prove

sufficient but practically does not. How often a thrombus or embolus may cause trouble we are unable to say. Frequently too the area of infarction may be multiple, as appeared in one of our cases. Undoubtedly, we must have had a collateral circulation established after the thrombus formed but multiple emboli broke away from this thrombus causing separate infarcts.

Welch and Mall have shown by constricting mesenteric and anastomosing vessels to the point where  $1/5$  of the normal is reached infarction takes place. This brings us again to the pressure exerted by the spasmodic contraction of the intestines, which would decrease the blood in that area, also the aid to lowered blood pressure obtained in decompensation from valvular lesions, myocarditis, arteriosclerosis. In one of our cases there was marked arteriosclerosis. I know I have ligated mesenteric vessels in accident cases far beyond what I considered the ordinary conception of safety to the intestines, only to have them make an uneventful recovery. If this interference is not too close to the gut, recovery is more apt to occur. Neiderstein's experiments show as much as 3 to 5 c.m. of gut, may be, separated from its mesenteric attachment and collateral circulation will be ample, but beyond 5 c.m. gangrene will supervene. (In 3 c.m. superficial necrosis occurs and with 5 c.m. necrosis and hemorrhage into the other coats.)

In the symptoms of this condition there is nothing pathognomonic. We find from cases observed that it occurs most frequently in men and about the middle decade of life. Cardiac disease, arteriosclerosis and recent operations are predisposing factors. Of course acute injury is always a factor to be considered. Pain is very severe and colicky-like, usually generalized in the abdomen, though it may become local later. If peritonitis sets in, it may again become general or local. In my cases nausea and vomiting did not set in till late. When vomiting does occur, it is first bile and the contents of the stomach, and later may become fecal. Obstipation is the rule and, when bowels are moved by means of an enema, frequently small amounts of blood may be found in the stools. This is not indicative but suggestive, always bearing in mind that blood may be found associated with obstruction, intussusception, tumors, etc. Tenderness of the

abdomen and muscle rigidity are always present and frequently may be localized over the involved area or mid-abdomen. Distention gradually develops and occasionally a small mass may be felt in the abdomen. The temperature is no guide, it usually falls at first and then gradually rises as peritonitis develops. This is true also of the leukocyte count, as the peritonitis commences, the white count rises. Shock is considerable in these cases and, from my experience, seems to be greatest with the initial onset of the pathology.

These are general symptoms only and represent the average case and diagnosis will have to be arrived at mainly by exclusion. As in other abdominal conditions you may find these symptoms aggravated or indefinite, especially may this be true where collateral circulation has been effected.

The first case in 1914, male 34 years old, of rather heavy build, was operated on for acute appendicitis. Did not have any trouble for about five days and then suddenly complained of severe pain in the mid-abdomen. Bowels were easily opened and we did not anticipate further trouble; however, that night he became worse and fever began to rise, abdomen slightly distended. On opening incision, lower ileum was found to be gangrenous from thrombosis in mesentery. Condition precluded extensive operation and he was drained freely with the hope of doing something radical should he improve. Condition gradually grew worse and he died that afternoon.

The second case was somewhat similar but more rapid in onset and more quickly terminated. A colored man 47 years old was operated on for suppurative appendicitis, peritonitis general, freely drained. Six days afterwards while temperature had been normal and apparently well on the road to recovery he developed acute pain in the right iliac region, abdomen rapidly began to swell, and he went into profound shock. Temperature in this case fell and pulse became very rapid and weak, breathing fast and shallow and he soon passed out. Did not go in for further examination of his intestines but from the original wound intestines were seen to be almost black at upper part of the wound. Their color had previously been good and from the general symptoms and onset we were sure an embolus had developed. We were assisted in this diag-

nosis by the fact that while he gave his age as 47 it appeared nearer 67 and there was extensive arteriosclerosis. Possibly this extended from the abdominal aorta.

The third case was a young lady of 21, operated on July 28, 1921, by Dr. Henry Boyles, for subacute appendicitis, clean case. Had been suffering with her appendix for one year. She was apparently making a good recovery from her appendectomy till August 6th, nine days after her operation, when she started vomiting and became somewhat restless. No rise in temperature and pulse only slightly quickened. Next morning had a small bowel movement from enema, developed hiccough, temperature now began to rise and she complained of severe pain in abdomen, general but somewhat to lower abdomen, abdomen distended somewhat and much muscle rigidity. Bowels moved again that afternoon and had a fairly good night. No report of blood in the stools. Next morning vomiting fecal in character and it was at this time I saw the case. Advised immediate operation and found one large infarct from thrombus in mesenteric vessel, several smaller infarcts in walls of intestines (ileum) on distal side, entire area covered about 20 c.m. This was resected and end-to-end anastomosis done. Patient was very much shocked when we operated and died about twelve hours later. This was the case I believe started from a thrombosis and emboli developed causing the multiple infarcts.

#### TREATMENT

The question of palliative or imperative treatment requires the most careful consideration. The mortality rate seems to be almost as high in one as in the other but I believe with early diagnosis of the condition we will offer our best chance to the patient by surgical interference. I believe where the symptoms come on gradually there is a chance of possible recovery by complete rest to the intestines, supportive measures, saline, glucose and opiates, and hot applications to the abdomen. On the continent, where they seem to have given this subject more attention than here, the Germans advocate diuretin. Just how this does good I do not know and have had no experience with it. Jaschke, of Berlin, says it is important to give digitalis before operation, especially if there is doubt of the heart action. In his experience, getting patients up

early has reduced thrombosis one-half and emboli one-third.

Should an infarct occur, I believe there is only one treatment, excision of that area. This operation was first performed by Elliott in 1895 and reported in the *Annals of Surgery*. Since then many have been successfully operated. Should the onset and symptoms be mild, I would advocate watchful waiting but should the symptoms be very acute or rapid in onset, I think your best hope would be quick interference. Even then the extent of the involvement would indicate the possible chances of recovery. Exploratory laparotomy under local anesthesia will certainly do little harm and might be the deciding factor in what appears otherwise a hopeless case. Having decided upon operation, the sooner it is undertaken, the better the patient's chances.

#### SUMMARY

1. That the pathology is most often a thrombosis in some part of the superior mesenteric vessels and that the mucosa of the intestines suffers first and most. This gives the blood in the stools.

2. Occasionally an embolus or thrombus may cause no apparent symptoms; or, if symptoms do occur, they may clear up, due to the establishment of collateral circulation. This is accounted for possibly by the slowness in closure of the vessel. The permanency of the collateral circulation is to be doubted as cases have been reported where it broke down subsequently and caused infarction with death.

3. Intestinal obstruction may occur without infarction, as the blood supply to the parts may be sufficient for nourishment but not for function.

4. Should infarction occur, as shown by degree and progress of the symptoms, operation, with excision of the infarcted segment, offers the only solution.

### MESENTERIC THROMBOSIS WITH REPORT OF TWO CASES.\*

By STUART McGUIRE, M. D., Richmond, Va.

Individual surgeons do not often see cases of mesenteric thrombosis, hence the occurrence of two cases in my practice has led me to write this paper. Virchow in 1847 first described occlusion of the mesenteric vessels as a pathologic entity; Litten in 1875 published

a paper describing the clinical manifestations of the disease; Jackson, Porter and Quimby in 1904 analyzed the histories of 214 reported cases, of which forty-seven had been operated on with four recoveries or a mortality of ninety-two per cent.; Trotter in 1913 collected and tabulated 366 cases, of which only thirteen or four per cent. had been correctly diagnosed before operation or autopsy.

The number of recorded cases of mesenteric thrombosis has largely increased and the death rate greatly diminished since Trotter's investigation of the subject in 1913, but the disease still presents problems in diagnosis and treatment sufficiently important to make it well worthy of thought and study. The superior mesenteric artery supplies all the small intestines and the upper portion of the large bowel. It is what is termed an end or terminal vessel and, if it becomes occluded, collateral circulation is very rarely established. The same factors which lead to embolism and thrombosis in general may occasion embolism and thrombosis of this artery. In some cases no adequate cause can be discovered, while in other cases the condition may be attributed to injury, to an infection, or to diseases such as arteriosclerosis or endocarditis. The usual effect of obstruction to a superior mesenteric vessel is a hemorrhagic infarct of the small intestine corresponding to the distribution of the branches involved. The intestinal wall becomes thickened, edematous, and of a dark red color. There is usually a sharp line of demarcation between the healthy and diseased bowel, although this is not always the case. The lumen of the bowel is distended with dark, tarry blood, and the peritoneal cavity usually contains a considerable amount of bloody fluid. In some cases the gangrene is limited to a few inches of intestines. In other instances many feet are involved.

In rapidly forming thrombus involving a considerable part of the intestinal tract the invasion is sudden and the course rapid. On the other hand, if the thrombosis is of slow formation and the segment of intestine is small, the invasion may be more gradual and the course may be prolonged. In acute cases, the symptoms are ushered in with absolute abruptness at a time when the patient is apparently in good health. The pain is at first colicky in character, but later becomes continuous. It is often so agonizing that it pro-

\*Read at fifty-third annual meeting of Medical Society of Virginia held in Norfolk, October 31—November 3, 1922.

duces collapse or shock as evidenced by subnormal temperature, rapid irregular pulse, cold clammy skin and blueness of the extremities. Usually there is nausea and vomiting. There may be either diarrhoea or constipation. If the former, the movements are watery and frequently blood stained. If the latter, obstruction is complete, neither flatus or feces being passed. At first the abdomen is soft and flaccid and palpation gives no pain or discomfort. If the patient lives sufficiently long, however, the abdomen becomes distended, rigid and tender, and the temperature rises to 104° or 105°F.

The diagnosis of mesenteric thrombosis is extremely difficult. There is no symptom-complex of the disease, and it is rarely recognized before operation or post mortem. Fortunately, the condition is so acute and urgent than an exploratory operation is plainly indicated. When the peritoneum is opened, there is usually the escape of a considerable quantity of dark colored or bloody fluid which makes it evident that the disease is not appendicitis, cholecystitis or a gastro-jejunal perforation. The distended black coils of gangrenous bowel are most commonly found in the pelvis or lower abdomen.

The operation of choice is, of course, the resection of the diseased bowel, followed by the restoration of the continuity of the intestinal canal by an anastomosis of the divided ends. If the general condition of the patient renders this impracticable, then the gangrenous portion of the bowel should be excised and the two cut ends drawn out of the abdomen and fastened to the edges of the wound, with the hope that a secondary anastomosis may be done later. In doing the resection, great care should be taken to divide the intestines well outside the infected area in tissue with good blood supply. It is remarkable what a large proportion of the length of the patient's intestines may be removed without death or subsequent impairment of health. Flint collected from literature fifty-eight cases in which for various causes more than four feet of small bowel had been removed. Of these cases forty-nine survived operation. The greatest length resected was in a case of strangulated hernia reported by Brenner in which over twelve feet were removed. This patient died two and half years later of inanition. Zenas concludes from the results of ex-

periments on animals that it is possible for a man to live even though as much as one-third of his intestinal tract has been sacrificed. In the two cases reported in this paper seven feet four inches of small bowel were removed in the first case and four feet six inches in the second, and up to this time no digestive or metabolic disturbance has been noted in either patient.

CASE I. Mrs. T. W. E., age 27, patient of Dr. Edward McGuire and Dr. B. H. Gray of Richmond, was admitted to St. Luke's Hospital, February 15, 1918. The patient had been operated on about two years before for chronic appendicitis and retroversion of the uterus. She was now four months pregnant and had suffered considerably with nausea and vomiting.

The following was the history of her present illness. After a comfortable night's sleep, she took a bath, ate her breakfast, went to the toilet and had a satisfactory stool. At 9:30 a. m. she was suddenly seized with agonizing pain in the abdomen for which repeated doses of morphia were given with comparatively little relief.

She had nausea and vomiting and showed evidence of shock. Her temperature by rectum was normal, but her pulse ranged between 140 and 150. Her abdomen was not tender, rigid or distended, on the contrary its walls were soft and relaxed and the enlarged uterus could readily be palpated.

The uterus was apparently considerably larger than the period of pregnancy would account for, and Dr. Gray stated it was almost double the size it had been when he examined the patient a week or ten days previously. The leucocyte count was 20,000 and hemaglobin was sixty per cent.

Forty-eight hours after the onset of the attack she was brought to the hospital. She continued to suffer intense pain and to have a very bad pulse, but she had developed no fever or local evidence of peritoneal infection.

No definite diagnosis could be made, although intrauterine bleeding or rupture of the uterus were considered the most likely possibilities. It was realized that some catastrophe had occurred in her abdomen, and as she was rapidly growing worse, it was decided to do an exploratory operation. Under gas oxygen anesthesia her abdomen was opened by a midline incision. As soon as the peri-

toneum was opened, there was the escape of a quantity of bloody fluid. When the abdominal contents were exposed, a mass of gangrenous small bowel was found surrounding the fundus of the uterus. There were no adhesions, but the black coils of intestines made a Medusa-like cap which invested the uterus so closely and symmetrically as to give it the apparent increase in size noted before the operation. The gangrenous bowel was delivered through the wound and a rapid excision done with end-to-end anastomosis. The pelvis was drained with rubber tissue and the wound closed. The specimen of bowel removed measured seven feet four inches. The patient was given no treatment to combat shock while on the table, but every effort was made to complete the operation with the least possible delay. She was returned to bed apparently none the worse for the ordeal, and her general symptoms shortly began to improve. She made an uneventful recovery, and eventually was delivered of a living child. The patient is now in good health and apparently suffers no symptoms from the curtailment of the length of her intestinal tract.

CASE II. Miss S. W. age 46. patient of Dr. M. O. Burke and Dr. Garnett Nelson of Richmond, was admitted to St. Luke's Hospital, March 27, 1922.

The patient had been operated on some years before and a supra-vaginal hysterectomy done. She had for some time apparently been in perfect health. On the morning of the day of her present illness she went to her place of business and was suddenly seized with violent abdominal pain while at work at her desk. She was carried back to her apartment and physicians summoned. She was given two hypodermics of morphia with atropia, and later a soap suds enema was administered which resulted in a large stool accompanied by the discharge of considerable gas.

When I saw her in consultation several hours later she was still suffering severe paroxysmal pain in the abdomen, although her pupils showed the effect of the large doses of morphia she had been given. She had constant nausea and occasional vomiting. Her temperature was 96° F., pulse 120, and she showed evidences of marked shock.

Her abdomen was not distended, there was no tenderness or rigidity on palpation, and no

mass or tumor could be made out. There was no visible peristalsis and no movement of gas could be heard with the stethoscope. The leucocyte count was 18,000 and hemoglobin was seventy per cent. The patient's agony was the most extreme I have ever witnessed and she begged for relief or death.

The possibility of volvulus, acute pancreatitis, or a gangrenous Meckel's diverticulum was considered, but no diagnosis more definite than an "acute abdomen" was made.

As the indications for an immediate operation were plain, she was transported to the hospital. Under ether anesthesia her abdomen was opened six hours after the onset of her illness. As soon as the peritoneal cavity was incised there was the escape of a quantity of bloody serum and coils of gangrenous small intestines presented themselves in the wound. After being delivered through the incision, the bowel was found to be distended and filled with dark fluid. The mesentery was thick, edematous and no pulsation could be felt in the mesenteric vessels. The line of demarcation between the healthy and diseased bowel was sharp and well defined.

The mesentery was ligated and divided, the bowel resected and an end-to-end anastomosis with suture done. The abdomen was closed without drainage. The specimen removed measured four feet, six inches.

The patient made a rapid and uneventful recovery. She states that before the operation she suffered from chronic constipation. Now she has a natural action each day and does not have to take laxatives.

#### DISCUSSION.

DR. J. SHELTON HORSLEY, Richmond: The condition described by Dr. Stuart McGuire is a very interesting one. In general practice great attention should be accorded it. There is much difficulty in making a correct diagnosis. The onset of sudden pain without distention, and usually without much abdominal rigidity, and the passage of blood, are always significant.

A very important point in operating for this condition is to take out a sufficient amount of bowel. It is much better to risk too much bowel than too little in cases of this kind. If the bowel looks healthy, but does not bleed readily on incision, the resection should be carried back to a point where it bleeds readily. I lost a case once because of this error.

DR. J. BOLLING JONES, Petersburg: I remember a case on which I operated, upon which a diagnosis of ruptured appendix had been made. All of the symptoms were in the right side and pointed to ap-

pendicitis. The onset of the illness was very sudden and, when I saw the man after the onset of the illness, I gave a diagnosis of ruptured appendix.

To operate I gave a saline transfusion. Upon taking out the appendix, the blood just spurted out. I never saw so much blood in my life. After looking into the mesentery I found nothing wrong. I closed the incision, and went back to the original operation.

The man's condition improved visibly while on the table, and he made an uneventful recovery.

DR. C. C. COLEMAN, Richmond: I have been very much interested in the causes of pain associated with certain vascular lesions. Terrific abdominal pain characterized the clinical history of both Dr. McGuire's cases, and this appears to be the outstanding symptom of mesenteric thrombosis. It is interesting to speculate upon the cause of this pain when the mesenteric vessels are occluded by blood clot. If the mesenteric artery is ligated, it is hardly probable that the pain would be extremely severe, or that shock would be a pronounced symptom. Certainly ligation of the femoral artery, even under local anesthesia, causes very little pain, whereas occlusion of the popliteal or femoral by an embolus causes intense pain. The mechanism of pain conduction in these cases is not clear.

It has been thought by some that the sympathetic fibres which accompany the vessels are pain conductors, or that some of the peripheral nerve fibres have been split off high up, and become fused with the sympathetic, and that these fibres are unmyelinated and convey painful stimuli in certain vascular conditions. When a vessel is ligated, the sympathetic fibres in the vessel wall are intercepted along with the blood stream, whereas, in thrombosis it may be that these fibres are stimulated, thus causing the pain which clinically characterizes the latter condition.

As a practical application of this theory, it is sometimes advisable to excise the sympathetic fibres from the large blood vessel walls in certain painful amputation stumps. It is well known that in some of these cases, unless an adherent neuroma is present, re-amputation does no good, whereas stripping the vessel of its sympathetic fibres is considered by Le Riche and others a procedure of the greatest value for relief of pain.

This discussion naturally has no bearing upon the important feature of Dr. McGuire's paper, which is that an abdominal emergency, generally fatal, was recognized and relieved by prompt operation.

DR. STUART MCGUIRE, Richmond, (closing): As I brought out in my paper, I did not make a correct diagnosis before operation in either of the two cases reported. If I see a third case, however, I am reasonably sure I will recognize its true nature.

In mesenteric thrombosis everything depends on an early diagnosis and prompt operation. I believe the disease is much more frequent than is generally supposed, and many cases die without a correct diagnosis being made. At present 92% of these patients die, but the mortality should not be greater than in other acute abdominal conditions.

I trust that every time we have a patient with agonizing abdominal pain, attended by symptoms of shock, we will bear in mind the possibility of mesenteric thrombosis in determining whether or not an immediate operation is indicated.

## THE DIAGNOSIS OF INTESTINAL PARASITIC INFECTION.\*

By T. DEWEY DAVIS, M. D., Richmond, Va.

Assistant in Nervous and Mental Diseases, Medical College of Virginia.

The importance of intestinal parasitic infection in the rural districts of the South has been frequently emphasized, and the general practitioner, as a rule, is on the alert for these cases, but many of them get through his hands either because he is not prepared to make the stool examination or the examination can not be sufficiently thorough. Some obscure cases are referred to specialists for diagnosis, and in this examination the presence of parasites is more frequently recognized. This statement is supported by the fact that in 248 stool studies made by the author, twenty-seven, or eleven and two-tenths per cent, were positive for parasites of various kinds. Practically all of these cases were referred for some neurological condition.

The complaints of these patients were many and varied, but about eighty-five per cent. of them had symptoms relative to the gastrointestinal tract. Most frequently there was constipation and gas with vague discomfort in the abdomen consisting of fleeting and indefinitely localized pains. The cases of pin worm infection all had pruritus ani, and two of them had a persistent vaginal discharge. This symptom in female children should always be investigated by careful stool study or examination of scrapings from the anal region. In about half of the cases there was an increased appetite, or the desire for certain foods was noted. There was a very slight anemia in a few of these cases, but in most of the patients the hemoglobin was well within the normal limits. The stunted stature and backward mentality usually considered in connection with intestinal parasites were not marked features in these cases, probably because the number of parasites present was relatively few. The majority complained of general weakness and fatigability.

One fact that should be considered is the home environment of the patient. Practically all of the positive cases came from small towns or rural districts where sanitary disposition of human excreta is not generally practiced. It is of importance to inquire if

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

the patient has ever had "ground itch" or "dew sores," for these are always suggestive of hookworm infection. It is also well to ask if any worms or segments have been passed.

The routine differential blood count is of especial value in determining the advisability of stool examination, for in the author's series about eighty per cent. showed an eosinophile count of three or more per one hundred white cells. This increase was particularly marked in two cases of strongyloides intestinalis infection. In one it was fifteen, and in the other twenty-one per cent.

The special neurological complaints were depression, vague nervous symptoms, hysteria, epileptiform convulsions and choreiform movements. One case is of such interest that it is worthy of mention in detail. This was a boy five years of age who came into the Sanatorium with a severe multiple neuritis which later developed into a suggestive subacute poliomyelitis. A stool examination was not made until a week after admission. At this time it was found to contain numerous round worms and a few hookworm ova. By the concentration method given below it was estimated that there were fifteen thousand ova per cubic centimeter of stool. One enormous round worm was expelled after a treatment with oil of chenopodium. The child could not remain in the hospital longer, but after discharge began to improve rapidly and in three months was absolutely well. It seems entirely possible that the nervous symptoms were toxic in origin, the source of this toxin being the parasite, since shortly after its expulsion the child began to improve. With a true poliomyelitis and the amount of paralysis present, it hardly appears possible that recovery should have been so rapid with no resultant weakness or atrophy. Norbury,<sup>1</sup> in a recent article, states that hookworm disease may at times be confused with poliomyelitis.

Osler<sup>2</sup> and other authors state that intestinal parasites may give rise to various and sundry nervous symptoms such as epilepsy, hysteria, chorea and mental disturbances. The question of how these are produced is still a debated one. Various investigators have found that toxic substances can be derived from the ascaris lumbricoides which will produce an intoxicating effect on the nervous system shown by hallucinations, delirium and other disturbances, and also blood destruction. This may

possibly be due to an anaphylactic reaction, but the symptoms were more on the order of a toxemia. With these toxic substances in the worm it is hardly necessary to turn to mechanical and impaired nutritional effects as an explanation of all the symptoms produced. The injury produced by the hookworm in attaching itself to the intestinal mucosa is of some consequence, especially when there are several hundred of the worms present, and the local infection about these points which must certainly take place from the swarms of bacteria constantly present may play a part in producing the symptoms. This is undoubtedly a causative factor of some of the abdominal pains. The intense anal pruritus produced by the pin worm may easily irritate an unstable individual and throw him off his normal nervous balance.

The method of examination used by the author is a combination of the centrifuge and salting out procedures. In addition one or two slides are studied made from an emulsion of the feces in water. These plain slides are of value chiefly in the search for larvae of the strongyloides intestinalis since their ova are rarely found in the stools. Several different procedures were tried out on the same positive stools, and the method outlined below gave the highest concentration of ova.

A piece of stool of approximately a cubic centimeter in size is emulsified with about thirty mils of water and this is poured into centrifuge tubes. These are run at a moderate rate of speed just long enough to throw the larger particles of feces to the bottom. The proper length of time may only be determined by experience with the centrifuge machine in use. The water is then decanted off and discarded. The tubes are filled with a saturated solution of sodium chloride and centrifuged a somewhat longer time than the above. The surface liquid is carefully removed by means of a capillary pipette. It is worthy of note here that one should place the tip of the pipette close around the side of the tube since the outer portion of the meniscus is the highest and the ova necessarily collect in this circle. The contents of the pipette are then discharged into a clean centrifuge tube, the tube is shaken after filling with water, and centrifuged for about the same length of time as in the first instance. The water is then decanted, the sediment is thoroughly shaken

up and transferred to a slide. Examination is made with the low power objective using the higher magnification for identification in the doubtful cases. If the procedure has been properly carried out the ova will stand out clearly with little fecal matter to cloud the field of vision. This method is of special value in examining stools containing any of the petroleum oils where the oil droplets are very annoying. These droplets are entirely separated by this procedure. The whole process takes very few minutes and saves considerable time over the straight slide method, especially should the stool be negative.

The author has never seen the fact mentioned in the literature, but the diagnosis of pin worm infection may be made in the routine urine examination of females. The worms invade the vagina and deposit their ova about the vulva from which they are washed by passage of the urine. Recently two such cases were seen where the ova were present and easily identified.

**SUMMARY:** The general practitioner, particularly in rural districts, should be constantly on the alert for intestinal parasitic infection.

The history, environment, eosinophilia, and clinical symptoms of the patient are of help in suspecting the presence of parasites.

Parasitic infection may account in part, or in whole, for the symptoms of certain neurological conditions.

Many of the symptoms are undoubtedly a result of toxins excreted by the parasites.

The method of stool examination outlined above was found to be the most reliable to detect the presence of the ova.

Urine examination is of value in making the diagnosis of some of the cases of pin worm infection of females.

#### DISCUSSION.

DR. W. A. PLECKER, Richmond: This question of intestinal parasites has in recent years been almost forgotten as a subject of much importance, particularly that of hookworm. Ten or twelve years ago the people of the Southern States were pretty well informed as to the importance of this by means of the Rockefeller fund of one million dollars, which was used for education along this line in these states.

Since the intense educational work that was done at that time in many sections of the South, we probably do not see so many cases of hookworm as we saw formerly,—children that were undersize, bloated and anaemic, and those who could not make any progress in their studies when at school. Those cases have been pretty well cured, I think, but there are still a great many cases of mild hookworm infection which should receive attention, and it seems to me to be the duty of the family physician in the rural sections of the State, where he is responsible for the well being of all members of the family under his care, to see that examinations are made and children cured. I have seen acute symptoms entirely cleared up upon the removal of three or four hookworms. Just that small number will produce a condition which will be very marked. It is surprising what they will do.

I personally made examination of children in the schools of four counties, 10 to 12 years ago; one county showed 65% infection and one school 100%. These children were treated and instructions given as to sanitary conditions, and several years afterward another member of the Board of Health examined the school children in this county and found 11% infected where I found 65%.

That, of course, is the best evidence I ever had of the real effect of the work that was done at that time. But it has not all been done, and I would like to impress upon you who practice in the rural sections of Virginia, the importance of keeping this question in mind and watching out for these infections. I do not know of anything that will give better results, in the easiest manner possible, than the cure of cases of hookworm infection.

### STRICTURE OF THE URETER.\*

By AUSTIN I. DODSON, M. D., Richmond, Va.

Urologist to St. Elizabeth's Hospital, and Instructor in Genito-Urinary Surgery, Medical College of Virginia.

Strictures of the ureter resulting from tuberculosis of the kidney and the occlusion of the ureter in malignant processes are overshadowed by the pathology causing them, while congenital strictures usually result in a fatal issue before their presence is known. Acquired strictures of traumatic and pyogenic origin are now known to be a definite clinical entity and, if not relieved, may be the cause of irreparable damage to the kidneys.

The pathology of ureteral stricture is inconstant, varying with the degree of stricture, the length of time it has existed, and whether or not there is infection. In the earliest stage there are no demonstrable changes except obstruction to the passage of a catheter. Dilatation of the ureter and pelvis is not present if the patient is seen early. In two of our patients pyelograms were entirely negative. Later there is dilatation of the ureter and pelvis. In one case an ounce of urine could be

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

withdrawn. Four months after dilating the stricture the pelvis contained only ten c.c. of urine.

Stasis encourages infection and stone formation so that it is not infrequent in long standing cases to find a rather marked pyelitis and occasionally a stone. Quite recently we have observed a case in which a small stone had lodged in a stricture completely occluding the lumen of the ureter and destroying the function of the kidney.

Every surgeon can recall patients who have had abdominal operations for chronic appendicitis, malposition of the pelvic organs or exploratory operations where no definite pathology was found, and who later returned stating that their symptoms were just as bad as before operation. There are others for whom, because of the vagueness of the symptoms and the absence of physical signs, operation was refused. Many of the former group of patients are often operated upon a second time for adhesions, which are usually found, as after most abdominal operations, but the adhesions are innocent of causing any discomfort to the patient. Others may be passed up as neurasthenics and rest and "change of scenery" prescribed.

If such patients are more closely questioned, many of them will give a history of night voiding and day frequency of urination which should put the examiner on the right track. In ureteral stricture this symptom occurs either periodically or constantly in a large percentage of cases. The symptoms of ureteral stricture are largely due to increased tension in the pelvis of the kidney and, like the symptoms of most renal lesions, are often indefinite and confusing. They are insidious in onset and usually worse during a menstrual period or after exertion. All of the cases in our group have complained of pain in the lumbar region and lower part of the abdomen. There is usually tenderness over the abdomen and in advanced cases costovertebral tenderness. I have found pus in the urine in about fifty per cent. of cases, dependent on whether or not there is an accompanying infection. The urinalysis is not significant. The diagnosis is dependent on a thorough cystoscopic and X-ray examination of the urological tract, which should be carried out in all cases having abdominal pain or distress which does not point

definitely to some organ as the site of disease.

The cystoscopic appearance of the bladder is in no way helpful. It is frequently entirely normal and, when there is hyperemia and edema around the trigone and ureteral orifices, it is the result of an accompanying pyelitis. In the opinion of most writers the wax bulb or acorn-tipped bougie is necessary for the detection of strictures. In the cases coming under our observation this has not been necessary. The obstruction has been found by a number six catheter, and always in the lower three inches of the ureter. In some cases, after injecting mineral oil and inserting a stilet, the catheter will slip by the obstruction; in others, a small catheter has to be used. The smallest stricture met with in our group admitted with difficulty a number three bougie. When an obstruction is met with, stone, ureteral kinks and pressure on the ureter from tumors must be ruled out before a diagnosis of stricture can be made. The wax-tipped catheter and an X-ray picture will rule out stone. Ureteral kinks can usually be demonstrated by a pyelo-ureterogram made with the catheter withdrawn to within a few centimeters of the ureteral orifice. Tumors large enough to cause pressure on the ureter can be palpated. With these factors eliminated, any obstruction met with in the same location at two examinations may safely be considered a stricture.

The chief causes of ureteral stricture are pyogenic infection, traumatism, and tuberculosis of the kidney. In renal tuberculosis the kidney itself demands our attention, and the condition of the ureter is of no importance. Strictures from pyogenic infection may be the result of infections adjacent to and involving the ureteral wall, or may be due to a descending infection from the kidney pelvis or to a localized ureteritis caused by distant foci of infection. Attention was first called to focal infection as a cause of ureteral stricture by Hunner. Geisinger (*Annals of Surgery*, December, 1917), cited cases in which focal infection seemed to bear a definite relationship to ureteral inflammation. More recently Bumpus and Meisser of the Mayo Clinic have succeeded in producing lesions in the kidney, bladder and ureters of animals by injecting intravenously cultures of organisms recovered from teeth and tonsils of patients suffering

with infection of the urological tract (Bumpus and Meisser, *Jour. A. M. A.*, 1921, Vol. LXXVII, pp. 1475-1479). Traumatic strictures are caused by the passage of stones from the kidney, and by traumatism of the ureter during operative procedures, especially operations on the pelvic organs.

The treatment consists in dilating the stricture with bougies and catheters. I have found the Garceau catheter quite satisfactory. The manipulations should be very gentle and may be repeated in from five to ten days, according to the reaction produced. Often the gentlest possible manipulation will bring on an attack of intense pain accompanied by nausea and vomiting, requiring large doses of opiates for relief. Fortunately, these attacks are less severe following each succeeding dilation. Usually four or five treatments are sufficient to produce a symptomatic cure, but it is well to have the patient return for examination at intervals of two or three months for at least a year. If there is an accompanying pyelitis, it can be treated at the same time by pelvic lavage. We have found a solution of silver nitrate to be very satisfactory.

We have had eight cases of ureteral stricture under observation. Three had had previous abdominal operations without benefit. Two of these were operated upon for chronic appendicitis, and one for retroversion of the uterus. One patient had his right kidney operated upon and drained for pyonephrosis ten years before we saw him. In two cases symptoms came on shortly after a difficult delivery followed by pelvic infection while two others had had repeated attacks of tonsillitis.

Six of these patients have been free from discomfort since treatment. One refused treatment because of a severe attack of kidney colic brought on by examination, and one has recently returned with a recurrence after complete relief for twelve months.

#### DISCUSSION.

DR. J. F. GEISINGER, Richmond: I have for some years been interested in the condition admirably described by Dr. Dodson in his paper.

In some quarters, it is fashionable to deny that there is such a thing as a stricture of the ureter of the type under consideration. This is due largely to the tendency to accept and imitate the attitude of some of the great lights of genito-urinary surgery, who have long ago lost personal contact with the minor procedures of urology, from which come the data necessary for a recognition of this condition. As a result, many cases which appear to be entitled to more consideration, are passed unnoticed.

On the other hand, there is in a different quarter

a tendency to go to the opposite extreme, and one occasionally hears of immense series of cases reported in blocks of five hundred at a time. It is not difficult to imagine that enthusiasm has here been allowed to get somewhat out of bounds.

I prefer the medium ground. At the Stuart Circle Hospital, in Richmond, we were among the first to give serious attention to this condition and some years ago published our conclusions as explicitly as was possible at that time. Increasing experience has served only to confirm those conclusions. I am, therefore, in spite of any opinions to the contrary from whatever source, convinced that there is such a thing as a stricture of the ureter of the so-called Hunner type, that it is of fairly common occurrence, that it is productive of definite and sometimes disabling symptoms, and that it is amenable to control and often to cure by appropriate measures. I admit that the diagnosis must be made with caution and requires some experience and judgment; and furthermore that the prognosis must be guarded. This, however, obtains of many conditions. In the main, therefore, it may be said that with the indispensable aid of the cystoscope, the diagnosis of ureteral stricture can be accomplished with reasonable accuracy and that its treatment, usually by the same instrumental means, offers relief to the patient that, when it occurs, is always gratifying and often striking. It is assumed, of course, that the data assembled is always sufficient to justify the diagnosis. The urinalysis may be entirely negative. The pyelogram, in the early stages of this low grade obstruction, may be practically normal. The pain, which generally constitutes the chief complaint, may express itself in unusual locations. In spite of these drawbacks, however, the experienced urologist will usually be able to detect the condition and not infrequently to proceed therefrom to its correction.

DR. ———: I want to ask Dr. Dodson if this condition occurs more frequently in the female. The literature on the subject gives one that impression.

DR. DODSON, in closing: In answer to Dr. ———'s question, I believe strictures of the ureter do occur more frequently in women. The fact that they are more frequently subjected to pervic operations and are more prone to pelvic infections furnishes a reason for this. Strictures do occur in the male ureter and should be looked for.

### UROLOGICAL DIAGNOSIS FROM THE STANDPOINT OF THE GENERAL PRACTITIONER.\*

By LAWRENCE T. PRICE, M. D., Richmond, Va.

A good many patients have come to me for urological examination in whom it has seemed probable that a tentative or complete diagnosis could have been made by the family doctor, with proper use of the methods and information at his command. The object of this paper is to emphasize the value of some of these simple methods, and also to call attention to the fact that a careful history combined with local examination may bring out many facts which would ordinarily be overlooked.

That it is to the interest of the general prac-

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

itioner to obtain as much information as possible toward the diagnosis of these cases will be readily admitted. If his diagnosis is positive, it may be possible for him to institute his own treatment and thus save his patient the time and expense of a journey to a specialist. If his diagnosis is tentative, he may direct his case more intelligently and the more information he can give his patient as to the nature of the trouble the greater is apt to be the respect accorded to his knowledge.

Many of the points brought out are not new and some of them have been included in the course at medical schools. The seeming unfamiliarity on the part of many members of the general profession with certain essential urological facts has been deemed sufficient justification for discussing the subject in some detail.

It should be remembered that a discharge from the meatus of the urethra is not always gonorrhoea, that every case of frequent and painful urination is not due to cystitis, and that a hematuria may originate elsewhere than in the kidney. Subjective and objective symptoms apparently of serious import may be due to some simple condition which can be easily relieved.

On the first examination of a patient presenting urological symptoms, it is of primary importance to have a careful and detailed history, as it is only in this way that a clear conception of the case may be obtained. Information should be elicited as to the following details: (1) time and circumstances of first symptoms, (2) predisposing causes, (3) history of traumatism, (4) previous attacks of similar nature, (5) treatment already instituted. The patient's own idea as to the nature of his trouble should be noted, but the physician should draw conclusions only after painstaking interrogation followed by careful physical examination. For instance, a patient may present himself for treatment for a case of gonorrhoea and his own observation of his malady may seem to corroborate the diagnosis; the presence of a balano-postitis or a chancre or chancroid of the meatus or urethra may be the cause of the purulent discharge. If the first condition be present, the pus, together with inability to retract the prepuce, and the history of omission of bathing for several days will establish the diagnosis without the aid of a microscope. If a chancre be

present, the diagnosis may be established by the time of incubation together with the presence of a localized area of induration. The period of incubation in chancroid is the same as in gonorrhoea, but the character of the discharge is different, and palpation will reveal an infiltration which does not occur in chancre. It may be noted, however, that it has been my experience to observe the appearance of a chancre of the meatus during the treatment of a gonorrhoea. This observation was fortunate for the patient, in that treatment for the specific condition was begun at an unusually early period of the disease.

A patient with an apparent gonorrhoea may have instead, an aseptic urethritis or a non-specific urethritis. Here the history of exposure to infection, excessive use of alcohol or sexual over-indulgence is very helpful in establishing the diagnosis. It should be mentioned that the use of the microscope is more definitely conclusive in differentiating these latter conditions than the history alone, as it will demonstrate the presence of gonococci in the discharge, the presence of microorganisms other than gonococci, or the absence of bacteria.

The prostatic urethra, the verumontanum and the neck of the bladder contain highly developed sensory nerve terminals in their mucous membrane and are very vascular. These localities, therefore, are extremely sensitive and may present symptoms due to causes more or less remote. For example, a pyogenic infection in the kidney pelvis will produce a secondary bladder infection with symptoms at the bladder neck; there being no subjective evidence to indicate the location of the primary lesion. The bladder acts as a reservoir, giving an opportunity to the organisms to attack the tissues.

In the urological examination of male patients I use the Thompson three glass test, as a routine measure. For this simple test the conical urine sedimentation glass is desirable and may be obtained at any drug store. Ordinary drinking glasses or white glass bottles may be used, however. The patient voids the entire bladder contents into the three glasses, making the amounts as nearly equal as possible. Glass number one represents the first urine, glass number two the middle urine, and glass number three the last.

In an acute gonorrhoea, the urethra is washed

clean by the first urine, therefore, the first glass will be cloudy and the second and third clear. In chronic anterior-posterior gonorrhoea and prostatic infections, the first glass will be cloudy, the second clear, and the third cloudy. This is because the pus from the urethra appears in the first urine, while at the end of urination the perineal muscles contract, causing expulsion of the infected contents of the prostate and vesicles with resulting cloudiness of the third glass. In the presence of a vesical calculus causing bladder infection, the first and second glasses will be relatively clear and the third cloudy or bloody, owing to the fact that by sedimentation the blood or pus has accumulated in the lowest part of the bladder. In kidney infections the infectious products have become thoroughly mixed with the urine so that all three glasses will appear cloudy.

Three cases will be cited to illustrate the value of the above test.

CASE 1. Patient sent for examination on account of the presence of hematuria. The doctor who referred the case wrote a letter indicating his belief that a pathological condition of the kidney was present. The three glass test showed almost pure blood in the first glass, second and third clear. Urethroscopic examination revealed a very vascular papilloma in the pendulous urethra, which was removed by cauterization. The hematuria immediately came to an end.

CASE 2. Patient referred for a protracted and obstinate case of gonorrhoea with continued meatal discharge. All three glasses very cloudy. Enormous amount of pus and many bacteria found under microscope. Cystoscopic examination with ureteral catheterization revealed marked unilateral pyelitis.

CASE 3. A patient came under my observation with the following history: Five years before he had had a swelling in one epididymis with apparent abscess formation. A diagnosis of tuberculosis of the epididymis and testicle was made by a surgeon whom he consulted, and a radical operation was done for removal of the offending organs. Three years later a similar condition developed on the opposite side and the remaining testicle and epididymis were removed by a second surgeon. At the time I saw him, all three glasses of the voided urine were cloudy, which caused the opinion that kidney pathology was present. Cysto-

scopic examination revealed a well developed tuberculous infection of one kidney and of the bladder. If this simple test had been done at the onset and the obvious deduction made, a complete urological examination would have revealed the primary condition and the double castration would possibly have been avoided. At least, he might probably have been saved the second operation.

Urine which is cloudy in appearance does not necessarily contain pus. Alkaline urine may be heavy in phosphates, especially after the ingestion of albuminous food, e. g., eggs or milk. A few drops of acetic acid will cause such urine to become perfectly clear. Phosphatic urine sometimes causes frequency of urination and burning, which may simulate a more serious condition. The internal administration of sodium acid phosphate will acidify the urine, it will become clear and the symptoms will come to an end.

As is well known, the old method of diagnosis of stone in the bladder was the attempt to elicit a grating sensation upon passage of a sound. This procedure seems to have been forgotten or neglected, as many cases referred for diagnosis turn out to be due to vesical calculus. A sound, passed with the bladder partly full of urine or water, should detect a stone unless it be encysted. This is not a difficult procedure in the hands of the general practitioner and the method possesses value. Of course, the size and number of stones can be determined only by cystoscopic or X-ray examination. Correct diagnosis of acute pain in the right side of the abdomen may be a most difficult problem, especially in the female. However, the ability to use a microscope and to make a blood count will enable one to form a fairly clear idea as to the possibility of a right renal or ureteral calculus being the cause of the symptoms. The absence of leucocytosis plus the characteristic urinary findings will be overwhelmingly in favor of the presence of a calculus, and the history and symptoms will, of course, be of value proportionate to the completeness of the clinical picture. A hypodermic of morphine administered at home may thus be the only immediate treatment necessary and the consideration of removal to a hospital for a possible emergency surgical operation will be eliminated. If the doctor himself is not equipped to do the microscopical work, he may in the present day often find

a nearby physician or technician who can help him out.

Digital rectal examination will often establish a diagnosis of hypertrophied, adenomatous or malignant prostate. Acute prostatitis or vesiculitis may likewise be discovered by this method. The hypertrophied or adenomatous prostate is invariably symmetrical and its contour is smooth: it is not hard to the finger and not tender, but is distinctly dense. Acute prostatitis presents somewhat similar palpatory findings but is softer and extremely tender on pressure. A malignant prostate may be normal in size or enlarged, and can be felt to be very hard and irregularly nodular. It is not usually symmetrical owing to unequal distribution of the involvement. There is no pain on pressure, as a rule. In vesiculitis, a soft nodular, fluctuating mass, very painful on pressure, may be made out adjacent to either of the upper corners of the prostate. The latter may be normal or acutely inflamed. Massaged secretions from acute prostatitis or vesiculitis examined microscopically or culturally will show the character of the infection present and thus treatment will be indicated. Prostatitis and vesiculitis occur in the young and middle aged adult; hypertrophy and malignancy are seen in patients past middle age.

It is obvious that the points brought out in this paper have in no way been intended to cover the whole subject of urological diagnosis. Many cases will require cystoscopic or X-ray examination, or both, with special urinary and bacterial studies, to work them out satisfactorily. I would reiterate that my idea has been to be of assistance to the general practitioner by taking up some points believed to be of real value to him. It is hoped that this object has been to some extent fulfilled.

### ROENTGEN RAY AS AN ADJUVANT IN TREATMENT IN ADVANCED CASES OF CARCINOMA OF THE STOMACH.\*

By CHARLES R. ROBINS, M. D., Richmond, Va.

Professor of Gynecology, Medical College of Virginia; Surgeon, Stuart Circle Hospital.

This paper is based on observations and experiences with one case. It is, therefore, sub-

ject to the criticisms of such a paper. On the other hand this case has been selected because I had the opportunity to thoroughly study it and verify my conclusions so that the deductions are based on fact and, in addition, the case is one of a type, and experiences of a similar nature in other conditions, lead me to believe that this case is in a way representative.

Carcinoma of the stomach presents many problems, the greatest of which in my experience is that these cases come too late for radical treatment by operation. Cancer of the stomach is seen not infrequently, but it is certainly uncommon to find cases that are seen early enough to warrant an operation for radical cure. What we usually see is an emaciated patient, vomiting, and with a fixed palpable mass in the abdomen and with no prospect at all for operative cure. Efforts have been made to temporarily alleviate this condition by the operation of gastroenterostomy, done in the hope that the food will pass through the artificial opening and in this way give them temporary relief by relieving the vomiting. My experiences with this operation have been rather discouraging and I have found that, although the operation was successful in securing the mechanical result of an artificial opening, often the nausea would continue and certainly the benefit to the patient would apparently last but a very short while. The nausea in these cases is not altogether due to the obstruction but is to a great extent due to the bloody exudate thrown out in the stomach from the cancerous growth, and the vomiting of this is likely to continue independent of the relief of the obstruction. The real relief to the patient has been so frequently negative or of such short duration that I had been rather discouraged and inclined to forego operation entirely unless the case presented hope for radical cure. I have, however, had rather gratifying experiences with the treatment of malignant growths by Roentgen Ray, resulting in a prolonged relief of symptoms although the cases were not finally cured. This has been practically true where Roentgen Ray treatment was accompanied by indicated operative treatment, and often I believe we can secure the best results by this combined treatment. The case which I wish to report today is as follows:

CASE No. 25-377. Mr. L. B. W., 59, white, male, married. He came to me for treatment on May 30, 1920. He stated that his trouble

\*Read by title at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31-November 3, 1922.

had commenced about 15 months before. The symptoms were those associated with ulcer of the duodenum, hunger pain, food relief, and indigestion. He had been treated by various doctors and at first had been relieved of his symptoms and had gotten so that he could eat nearly anything he wanted. In the preceding fall, however, he commenced to complain again and was told that he had pylorospasm but was finally diagnosed as carcinoma of the stomach and operation suggested. At the time that I saw him he was suffering from pain in the abdomen, which had its maximum intensity in the epigastrium. The pain was not constant, was of a cutting character and was produced by anything he ate. At that time he was eating rice and other soft food and up to that time had had no vomiting. On examination of the abdomen a mass was not felt, patient was pale and anaemic looking, hemaglobin 45%, occult blood in stools. The x-ray showed a constant defect in the stomach. It was thought that the case was possibly one in which a radical operation could be done and the patient was operated on June 1st, 1920. Exploration showed a hard indurated tumor involving the stomach just proximal to the pylorus, and about the size of a small fist. The abdominal wall was thick and mass had not been felt at examination. It was freely movable but seemed to involve the lumen of the stomach sufficiently to almost completely occlude it. Some metastasis was found in the omentum draining from the carcinoma and one of the nodules was taken for microscopic examination. The pylorus was loosened and on lifting it up there was found a chain of glands extending upward as far as could be reached. As under these circumstances a radical operation could not promise any cure, a posterior gastro-enterotomy was done for temporary relief. The patient stood the operation very well although he was in a very much depleted condition. After the operation there was considerable distress and vomiting. It was determined in this case to supplement the operation by x-ray treatment of the growth and, as soon as the patient could be moved, the treatment by x-ray was commenced and was administered by Dr. Fred M. Hodges. It was thought that the case was one in which a good effect was problematical, but from the first treatment with the x-ray his condition began to improve and in a short time he got so that he could eat

any sort of food he desired except pickle and his general condition improved remarkably. This improvement continued over a period of fifteen months, at the end of which time he died of the carcinoma in the liver.

The experience in this case was so remarkable and so different from that of similar cases in which the x-ray was not used, that I am convinced that we have in this combination treatment of operation for relief of obstruction together with treatment of the growth by the Roentgen Ray, a method which holds out great possibilities. It is possible that some of these cases may be cured entirely, but if not, the prolonged relief secured is certainly well worth the inconvenience and distress of the operation.

The use of the Roentgen Ray in this and similar cases is undoubtedly accomplishing a great deal. It has the advantage of being easily applied and with the technique used at the present time there is comparatively little danger of burns to the skin. It is possible to concentrate the ray on the growth without injury to the intervening tissues. In this way the efficiency of Roentgen Ray treatment is materially increased and a large field for its application is opened up.

*Stuart Circle Hospital.*

## PROGRESS OF MALARIA CONTROL IN VIRGINIA.\*

By L. L. WILLIAMS, Jr., M. D.,  
P. A. Surgeon, U. S. Public Health Service,

and  
CLINTON A. KANE, M. D.,  
Director, Malaria Control, Virginia State Board of Health.

Malaria is a mosquito borne disease, the control of which most effectively depends upon preventing the easy access of mosquito to man during those times when the malaria mosquito, the Anopheles, feeds. Another good method of control is the attack upon the parasite through quinine campaigns. A combination of these two methods may be used to advantage.

Obviously, the most effective control is through the suppression of the Anopheles mosquito which is the only vector of malaria. This was first done in our hemisphere in 1901 in Havana where drainage of ponds and cleaning and oiling of streams was instituted in connection with the combined yellow fever and malaria campaign which removed or rendered

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

unfit for use the propagation areas of these water breeding insects.

Three years later the same type of work was commenced in the sanitation of the Canal Zone and carried through to the well-known result. It was not until 1915 that Virginia commenced control of malaria. Since then control work has advanced with its ups and downs, with its experiments and testing of new methods, until the present year in which we see work well started and on a firm foundation.

Since the start, practically all methods of malaria control have at one time or another been tested in this State with varying degrees of success. Table one shows the various methods adopted in the 1922 program as outlined by Dr. H. R. Carter, the measures of control being used as particularly suited to each community. When the first work was commenced seven years ago in a small town<sup>1</sup> in

#### DIAGRAM SHOWING METHODS AND MEANS OF PREVENTING MALARIA.

- I. *Getting Rid of Anopheles.*
  1. Destruction of shelters.

tidewater Virginia, some drainage of mosquito breeding areas was undertaken which was good though incomplete. The greatest dependence was placed upon screening. This town undertook to see that all homes were properly screened. This is an excellent method provided it is done by the greater number of homes and provided the screens are kept in good repair. This takes advantage of a well known characteristic of the *Anopheles* mosquito. This mosquito flies and bites only at night. Of all the *Anopheles* (in Virginia we have three species) the *Anopheles quadrimaculatus* probably carries most of our malaria. This species prefers to bite in-doors, in a room without light. These conditions are found almost exclusively in bedrooms at

night; hence adequately<sup>2</sup> screened houses are an almost complete protection against malaria.

The history of this town is interesting in that they commenced with a small amount of drainage and much house screening; allowed screening to become less and less effective through lack of repair, but, have increased the drainage operations until this year when it has been decided to complete the drainage of all mosquito breeding areas in or about the town.

The year following the commencement of work, four new towns undertook anti-malaria campaigns. The parallel history of two of these places pointed a lesson. One town controlled malaria very effectively through the complete screening of all homes, the reduction of human carriers by a quinine campaign, and a small amount of drainage work. The work has not been kept up and this place has been renewing its malaria ever since. The other town controlled malaria through drainage of mosquito breeding ponds and cleaning and oiling of all streams. This work has been regularly maintained every year through annual appropriation including the appointment of a municipal officer to take charge of the work. For a municipality anti-mosquito drainage is the method most productive of permanent results. The year 1917 started out well with three new places, commencing some drainage but extension of the work was disrupted at the commencement of this country's participation in the world war. Practically all work ceased except those places where camps or other war work went on on a large scale. Twelve such places were drained for the control of mosquitoes and the work of maintenance continued through the next year at all places. With the cessation of the war only one town of the twelve war-projects maintained the excellent work completed.

The next year surveys were commenced of numerous tidewater communities and supervision of the maintenance of three towns which were all of the twenty projects to continue work during the reaction which followed the war. 1920 saw a slight increase of two new projects and three continuing, 1921 with one new project and four continuing.

Prior to the season of 1922 the State Health Department organized a Bureau of Malaria

<sup>2</sup>Adequate screening means the screening of all doors, windows, chimneys, and other openings, with screen not larger than 16 meshes to the inch.

<sup>1</sup>Wakefield.

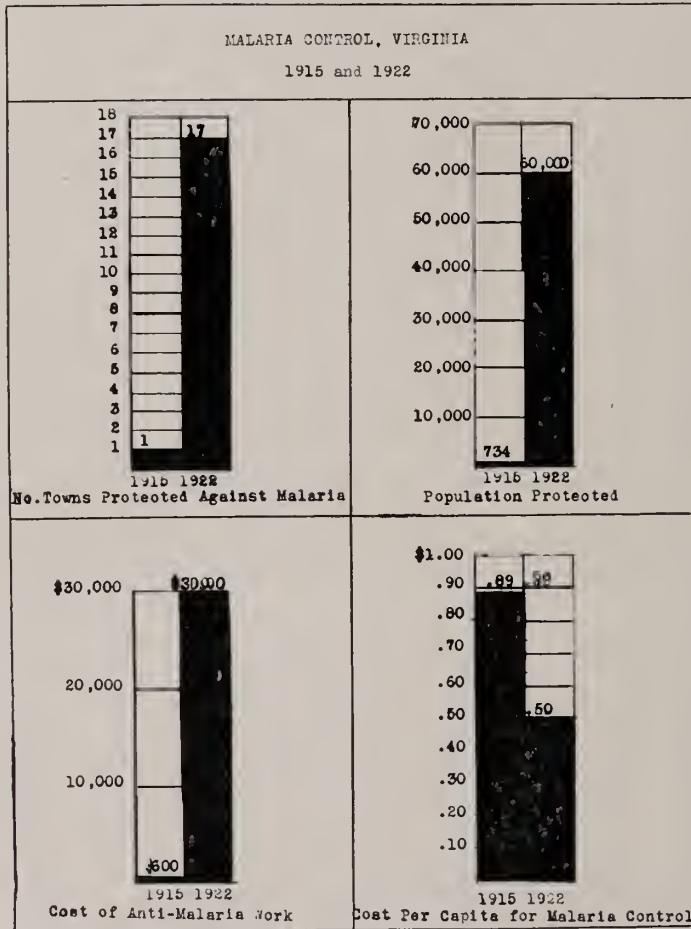

Control and, in co-operation with the International Health Board and the Public Health Service, placed three men in the field for the sole purpose of malaria control. As a result of this, plus the excellent education accomplished by the former workers, the work was maintained at those four places which had previously continued control and thirteen new towns commenced malaria-control through anti-mosquito drainage.

That this type of work is effective is unquestionable. A quotation from Dr. Bagby of West Point will illustrate the result, "Of 158 patients seen in 1909, ninety-six had well defined cases of malaria with chills, fever, sweats, etc. \* \* \* \* During the five summer months of 1922 I did not have in town a single typical

probably maintain the same for all time. Five have done partial drainage and are in a position to complete and maintain the work during subsequent seasons.

It will be noted that work heretofore has looked towards malaria control in towns. It is necessary to extend this work to the rural sections and place malaria control on a county-wide basis. It is readily seen that this cannot be economically done through drainage alone. We believe that drainage immediately adjacent to farm houses, that the extension of agricultural drainage will play a part, but that the main dependence for many years to come will be secured through the adequate screening of the country homes.

Experience has shown that screening cam-

case of malaria. \* \* \* \* My competitor \* \* \* \* says he has not had a case of malaria this summer." Anti-malaria work was done in this town in 1920 and it is one of the towns which has maintained the work ever since.

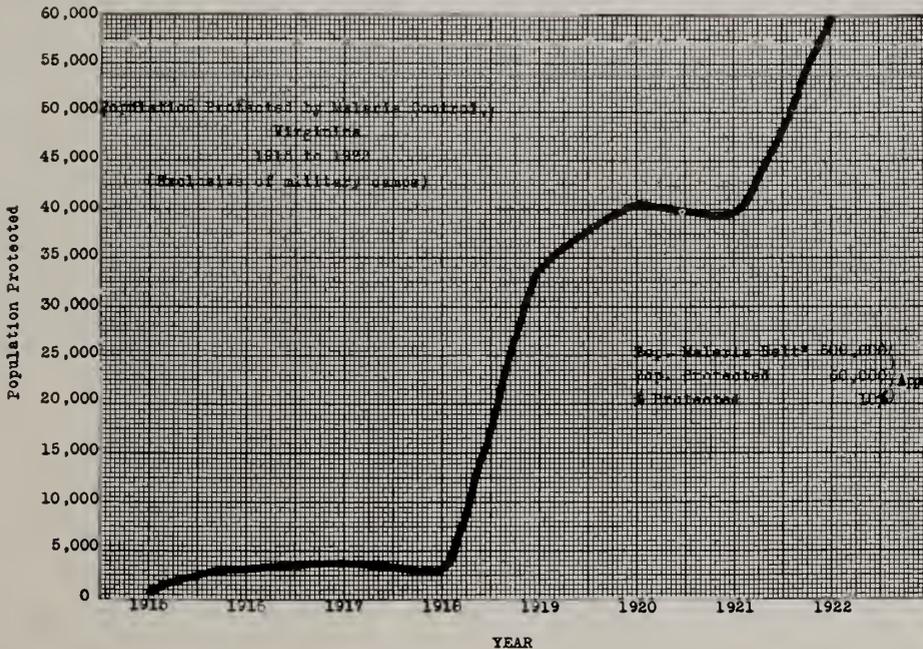

Of the thirteen new projects, eight have completed necessary drainage work and will

paigms are productive of a good immediate result, but maintenance is not secured. There is one exception, Greensville County, where in the most malarious section a screening campaign was not only successful but has been maintained to date. In this county a sanitary officer, supported largely by the county,

has been on active duty for three years. He carried on the campaign and has secured adequate maintenance ever since.

If the counties in the malaria sections of Virginia had active health organizations, then rural malaria control would be added to their activities. Two such counties support Health Departments which have undertaken to add rural malaria control to their other activities. As there are no other such, then the first step in rural malaria control is the building of an active organization in these counties. We are glad to report that a good start has been made, in that one county has just organized a health department, the main consideration being the control of malaria on a county-wide basis.

1922	Smithfield Suffolk Lawrenceville Oceana	Wakefield West Point Emporia Newport News

In conclusion, I present this chart showing the population protected against malaria in Virginia from one town in 1915 of 734 people to seventeen towns in 1922 of 60,000 people.

The work has steadily progressed in almost exact ratio to the advancement of popular education. To further aid this propaganda, a course of school instruction in malaria control has been in force during the past season in 300 schools and will be extended into 300 more this coming year.

**REPORT OF A CASE OF ACUTE EX-OPTHALMIC GOITRE TREATED SUCCESSFULLY BY USE OF X-RAY.\***

By M. D'ARCY MAGEE, M. D., Washington, D. C.

The successful use of X-ray as in the case of hyperthyroidism, especially of the acute ad-

\*Read before Society of Northern Virginia, District of Columbia and Maryland, November 22, 1922.

weeks. fracture healed but frequent attacks of tachycardia, von Graefe's sign, and usual clinical evidence of toxic thyroid became more pronounced. She was put to bed, digitalized, and under careful supervision failed to show any subsidence of symptoms. Dr. Lindsay, at Garfield Hospital, made a metabolic reading April 31, 1922, and patient's weight at that time was 105 lbs., temperature 98, pulse 100, respiration 24, and basal metabolic rate, plus 42 per cent. She showed marked tremor, bulging of eyes, with insomnia. She was then referred to Dr. C. Augustus Simpson for X-ray therapy and operation deferred on account of marked thyro-toxicosis. Seven X-ray treatments were given at intervals of three weeks. Interspersed with these were observations and metabolic tests to determine the effect of the rays on toxicity and the progressive decline of the metabolic rate.

Clinical symptoms present were tachycardia, tremor, sweating, headaches with loss of weight, and digestive disturbances. There was a noticeable decline in the nervousness and pulse rate following first few treatments which is shown on the chart herewith. The gland itself was of the soft parenchymatous variety, both lobes uniformly enlarged with no redness or evidences of cystic or colloidal degeneration. At present it is scarcely visible.

This fact is borne out by the pathology of the proven effect of X-ray on the thyroid gland. If any doubt exists in the minds of the internist or surgeon, I should like to refer them to an article appearing in the December, 1919 number of the X-ray journal, by Waters, of Johns Hopkins University, who in collaboration with Dr. Goetch gives a series of five dogs whose right glands were exposed to the action of X-ray and then removed and compared to the left untreated glands which he used as controls.

The alveola epithelium of the treated gland was atrophied and thinned out to a mere line resembling an inactive gland such as is frequently seen in symptomless colloid goitre; in other words, from the pathology there was in evidence a very marked reduction if not very nearly complete absence of secretory function in the cells of the thyroid gland as a direct result of the X-ray exposure.

Recent reports of Massachusetts General Hospital disprove the old idea that X-ray

therapy renders a subsequent operative interference more difficult.

The marked decline of the pulse with the metabolic curve and increase of the weight in this case will be observed. At present the patient's metabolism is 6 plus and her pulse 72, and return of weight lost before treatment.

I do not wish to detract from the brilliant results obtained in surgery, but realize that in such cases as the one I report where rest and treatment do not ameliorate symptoms, we should consider X-ray therapy, since it entails less risk, does not inconvenience the patient, or hospitalize the sufferer.

This case only confirms the results of other successful achievements attributed to the X-ray, and I feel it should encourage its use in just such cases where operative procedure is hazardous.

1623 Connecticut Avenue.

### REPORT ON A CASE OF SECONDARY CARCINOMA OF THE LUNG WITH PULMONARY TUBERCULOSIS.

By J. TERRELL SCOTT, A. M., M. D., Colorado Springs, Col.  
Associate Physician, Cragmor Sanatorium.

NAME: J. F. R.—American farmer, age 50 years, entered August 10, 1922.

COMPLAINT: Weakness, loss of weight, cough, expectoration and hemoptysis.

FAMILY HISTORY: Negative; no tuberculosis or malignancy.

PAST HISTORY: Has had the usual diseases of childhood but no serious illnesses or operations. He denies venereal disease and has always been in good health until several months ago. A year ago, in the fall of a truck from a bridge, he was thrown against the seat and injured his back.

PRESENT ILLNESS: Began last spring with cough, expectoration and loss of appetite. He consulted his physician in May, was told that he had some trouble in his lungs, although sputum was negative, and was advised to come to Colorado. His cough and expectoration is slight, appetite good and at entrance he feels fine. His sputum has been blood streaked with clots at times since June. Highest temperature has been 101. Normal weight is 150 pounds, but he has declined from 163 to 123 pounds.

PHYSICAL EXAMINATION: On inspection, the patient appears fairly well nourished,

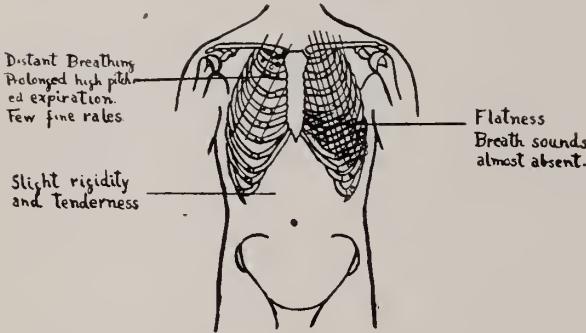

slightly anemic, and accustomed to hard manual labor.

On *percussion* on the right, there is dullness over the front, and to the 5th dorsal spine behind; on the left, dullness over both front and back.

*Auscultation* reveals markedly prolonged high pitched expiration on the right to the 3rd rib and 4th dorsal spine with distant breathing, a few rhonchi over the front, no rales. On the left, breath sounds almost absent over the base behind; no rales.

A few weeks later a second examination showed a few fine and medium coarse rales in the 2nd interspace on the right and in the base behind on the left.

Heart normal. Trachea drawn to the right. Thyroid isthmus palpable. Marked myoidema

of the biceps—more on the left. Pupils equal and react normally. Other reflexes normal. Abdomen negative except for slight tenderness and rigidity in the right upper quadrant.

CLINICAL LABORATORY FINDINGS: Temperature range: 98.5 to 100. Pulse 80 to 100.

Blood pressure: systolic 107, diastolic 77. Urine negative. Sputum negative for tubercle bacilli repeatedly. A guinea pig was injected with sputum but autopsy showed no

tuberculosis. The X-ray showed a dense triangular shadow on the left extending from 6th rib to diaphragm with the apex outward, and numerous small calcified nodules and extensive mottling throughout the right lung and upper left.

August 21st, the patient first complained of pain in stomach.

September 6th, he had severe vomiting and cramps but had gained 6 pounds.

September 11th, blood Wassermann negative. Hemoglobin 85% (Talvquist). Total whites 21,600, lymphocytes 24%, polymorphonuclears 73%, eosinophiles 1%. Gastric analysis showed the presence of large amounts of blood and bile. Total acidity 20 degrees, free hydrochloric acid 8 degrees. The patient complained of pain upon passage of the Einhorn tube, and stated that he had passed some dark blood by bowel the previous day and had felt dizzy at times. No diagnosis yet made; malignancy strongly suggested. Patient put on a modified Sippy diet.

September 21st, patient expectorated a semi-solid gelatinous mass, stating that it was the second occurrence. Upon section and microscopic examination by Dr. Ellis of Colorado Springs, it was pronounced a bronchial cast containing mucus, blood clots and carcinoma-tous cells.

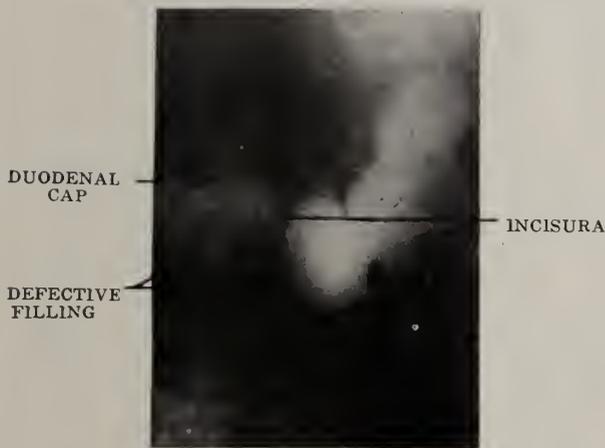

September 25th, the patient was given a

barium meal, X-ray and fluoroscoped by Dr. W. F. Drea. The plates showed imperfect filling of the duodenal cap and pyloric end of the stomach.

DIAGNOSIS: Carcinoma of the stomach metastasizing in the lung; pulmonary tuberculosis.

**AUTOPSY:** The patient was sent home and intensive X-ray treatment suggested, which was tried without benefit. He died November 13th. At his request, an autopsy was performed by Dr. J. L. Travis of Germantown, Ohio. The entire lower half of the left lung was carcinomatous and firmly adherent to the diaphragm. A carcinomatous mass the size of a golf ball was found in the pylorus, ad-

herent to the head of the pancreas and to two inches of the transverse colon. The pylorus was patent. A tuberculous non-caseating mass about three inches in diameter was found in the upper half of the left lung.

**DISCUSSION:** This case had many of the classical symptoms of pulmonary tuberculosis and of course this was first considered. The X-ray shadows in the right and upper left chests are characteristic and the absence of tubercle bacilli does not rule out tuberculosis. Secondary anemia, leucocytosis and subacidity are all compatible with such a diagnosis. Were it not for the unique shadow in the left base and the late gastro-intestinal symptoms, we would be justified in making such a diagnosis alone. Gastric ulcer will produce hemorrhage and blood in the stools but is usually accompanied by hyperacidity and the absence of high leucocytosis. In favor of malignancy of the digestive tract we have: (1) the age and sex of the patient, (2) moderate subacidity, (3) blood in gastric contents and feces, (4) marked loss in weight, (5) moderate anemia, (6) symptoms referred to stomach, (7) suspicious X-ray shadow.

This case is interesting:

1. Because of the *delayed appearance of symptoms* referable to the gastro-intestinal

tract, probably partly due to the patent pylorus.

2. Because of *metastasis* to the lung causing pulmonary symptoms before any other.

3. Because of the expectoration of bronchial *casts of carcinomatous cells*.

### STUDIES IN HAY FEVER.

#### Dates of Pollination of Anemophilous Plants in the District of Columbia and Vicinity, Observed in 1922.\*

By HARRY S. BERNTON, A. B., M. D., Washington, D. C.

Associate-Professor of Hygiene and Preventive Medicine, The School of Medicine, Georgetown University.

In order to determine the degree of importance of various plants in the causation of hay-fever in the District of Columbia, it has been deemed essential to secure pollen from as many species as possible. It is a well established fact that entomophilous plants, such as the rose, daisy, goldenrod, goldenglow, sunflower and dandelion, play no part in hay-fever, despite the popular belief. These plants are insect-pollinated. The amount of pollen floating in the air is exceedingly scant. Hay-fever symptoms, however, may be produced by them in sensitive individuals upon direct inhalation. Attention has, therefore, been given only to the anemophilous plants, i. e., those which depend upon the wind for distribution of their pollen.

The seasonal occurrence of hay-fever symptoms is obviously dependent upon the flowering period of the offending plant. It is consequently a matter of great interest to know what plants have come into bloom, coincident with the onset of the disease. In the fall type of hay-fever, this information does not assume the importance it does in the spring and summer types. There is a succession of dates between April and the middle of August which mark the advent of the initial symptoms. Knowledge of flowering dates inevitably assists in the selection of appropriate pollens for cutaneous testing. As a rule, this important data is not available for a given community, and standard text books of Botany are restricted of necessity to general rather than to specific information in regard to flowering dates.

It is our purpose, therefore, to record herein the dates of pollination of various wind-pollinated

\*From the Clinic of Applied Immunology, Woman's Welfare Association.

nated plants, 66 in number, which have been observed in the course of field work during the current year. This list does not include all the anemophilous plants in the District of Columbia. Completion of this work will demand additional effort.

The value of the following tables is only relative because of the many factors which influence the flowering of plants. Thus, trees, lining the city streets, are likely to pollinate earlier than similar trees in the suburban districts, because of the heat retained in the asphalt pavements. Even a difference of seven days in pollination has been noted in a cluster of black walnut trees on one lot.

TABLE I.

ALPHABETICAL LIST OF ANEMOPHILOUS PLANTS WITH DATES OF POLLINATION.

It is a pleasure to record my indebtedness to the several members of the United States Department of Agriculture—Miss P. T. Newbold.

Drs. W. W. Stockberger and C. E. Chambliss, and Mr. H. A. Allard—whose co-operation has made this investigation possible. I desire especially to thank Mr. Homer C. Skeels who has so generously given of his time and rich experience to me in the field.

The expense involved in these studies has been defrayed by a grant from Mrs. Charles W. Wetmore, President of the Woman's Welfare Association. In expressing my thanks to Mrs. Wetmore, I feel that I am voicing the gratitude of the many beneficiaries of the institution which owes its usefulness to her unflinching interest.

### THE CLINICAL SIGNIFICANCE OF REDUCTIONS IN THE WHITE CELLS OF THE HUMAN BLOOD.\*

By WYNDHAM B. BLANTON, M. D., Richmond Va.

Variations from the normal in the human blood picture have, naturally, great significance in the study of disease. In the past much has been made of changes in the red cells as well as of leucocytosis. On the other hand, little attention has been paid to reductions in the white corpuscles, leukopenia, or hypoleucocytosis as some prefer to call it. This lack of interest has been voiced in assertions such as Todd's<sup>1</sup> "that leukopenia is not important." Catton<sup>2</sup> exemplifies the other extreme, tabulating seventy odd causes. This paper is directed to a discussion of the background, mechanism and clinical significance of leukopenia.

The bone marrow represents the scene of manufacture of the white cells in adult life. In the embryo, the liver, lymph nodes, and spleen are active blood forming centers. In early life the whole of the marrow cavity of all bones is devoted to this function. After puberty, fat occupies most of the shaft of the long bones so that blood formation, exclusive of the mononuclear series, is confined to flat bones and to the head of the long bones.

The architecture of the bone marrow is better understood than formerly. Drinker<sup>3</sup> claims to have demonstrated closed sinuses in the marrow. He lays particular stress upon an inflexible bony case which permits of the proper functioning of a delicate reticulum binding the various islands of the blood form-

ing cells, as well as upon the closed nature of the wide sinuses with their sluggish blood stream into which the mature blood cells are pushed in response to the stimulus of growth in a non-expanding bony case.

The output of the bone marrow undoubtedly varies in response to inhibitory and acceleratory influences. What the stimulus of growth is, is as yet undetermined. Whether it is mechanical or nervous in origin is undemonstrated. Its specificity, however, is certain. The polycythemia of lowered barometric pressure (mountain residence) is accompanied by a fall of the leucocyte count. The response of the blood picture to intestinal parasites, the failure of response in such diseases as syphilis and the lymphocytosis of whooping-cough and mumps bespeaks a similar specificity of stimulus. Chemotactic influences undoubtedly determine the migration of cells in the human body. Catton<sup>2</sup> states that certain bacteria, or their extractives, copper, mercury, and the extracts of dead leucocytes have a positive chemotaxis for the polymorphonuclears but not for the mononuclears. In the peritoneum the live bacillus of anthrax, or bacilli coli are unattacked by polymorphonuclears; these organisms injected dead are quickly ingested. Organisms and different species of organisms elaborate different toxins, which undoubtedly have varying effects upon the body tissue, particularly the bone marrow.

In the normal human count there are 6 to 10,000 white blood cells per cubic millimeter. Sixty-five to seventy per cent. of these should belong to the granular series. There is, therefore, a moderate fluctuation in health of the leucocytes of the human blood. Posture, altitude, emotion, all influence this side of the blood picture. A count lower than 6,000 leucocytes is usually considered leukopenia.

The function of the polymorphonuclear leucocyte is elaborate. Briefly, these cells offer a line of defense against bacteria by ingesting them, or by elaborating antibacterial substances formed either as a secretion or as a result of going to pieces after injury. They are concerned with the transportation of food material. They convey protein, glycogen, fat and proteolytic ferments. In terms of the function of the leucocyte, therefore, leukopenia may handicap the body in more than one way.

\*Read before the Richmond Academy of Medicine and Surgery, September 12, 1922.

#### THE MECHANISM OF LEUKOPENIA.

Adami<sup>4</sup> points out that reductions in the leucocytes of the peripheral blood stream may result from one of two causes. There may occur an actual destruction of the white corpuscles in the tissues, blood stream or bone marrow. This he calls leucolysis. On the other hand, a similar blood picture may result from "local accumulation." In this event a migration of leucocytes from the peripheral blood to the internal organs accounts for the blood picture. That such migrations do occur has been proven both experimentally and clinically. Opie<sup>5</sup> demonstrated in peritonitis massive accumulations of eosinophiles in the omentum and mesentery.

Löwett<sup>6</sup> pointed out in 1892 that the products of protein decomposition, bacteria or their autolysates may cause leukopenia followed by leucocytosis. Pepper and Miller<sup>7</sup> unsuccessfully attempted to demonstrate in rabbits that there was an increase in the nitrogen fraction in the urine synchronous with leukopenia. Löwett's<sup>6</sup> original contention was that cell destruction was responsible for cell loss. Goldscheider and Jacobs<sup>8</sup> in 1892 explained leukopenia on the basis of the withdrawal of leucocytes from the peripheral blood. Silverman<sup>9</sup> in 1904 maintained that the swelling of the endothelial cells by producing obstruction in capillaries accounted for the accumulation of leucocytes in the internal organs. Bruce and Ewing pointed out this accumulation. Wells<sup>10</sup> in an elaborate series of experiments on rabbits showed that, by injecting dead typhoid bacilli intravenously, marked leukopenia occurred as early as ten minutes after injection. On killing his animals during such leukopenias he was able to demonstrate the accumulation of both bacteria and leucocytes in the liver, spleen and lungs. He considered this evidence of a positive chemotaxis, bacteria being entangled in these localities to await the mobilization of leucocytes.

Leucolysis appears to be well established. Adami<sup>4</sup> quotes Albertoni who showed the destructive power of pancreatin upon leucocytes. Likewise, he states that bile salts and bacterial poisons are destructive to the white cells. The leucolytic effect of benzol is well-known in the diphasic leukopenia of animals and the marked changes in the blood picture of human leukemia. The result is a marrow which is practi-

cally nothing but yellowish fat. Krumbhaar<sup>11</sup> reports similar findings in certain types of gas poisoning. Catton<sup>2</sup> quotes Emerson and others to show that exogenous intoxications such as mercury, arsenic, lead, alcohol, morphine, ether, ergot, tannic acid, atropine, picrotoxin, sulphonol, curare, quinine, diastase and trypsin cause reductions in the white corpuscles. The emanations of radium and the X-ray likewise affect harmfully the leucocyte.

The failure of leucocytosis without an actual reduction of the number of leucocytes, in the face of all the evidence of a severe infection, has to be considered also in this connection; for example, a normal blood count in the presence of a demonstrated typhoid infection. In such a case I do not believe that either leucolysis or local accumulation accounts entirely for the finding. It is customary to state that the toxin of the typhoid bacillus has a specificity for the bone marrow, paralyzing its output. MacCallum<sup>12</sup> states that a mild stimulus to the bone marrow produces proliferation, whereas a violent poison, such as a severe infection, may produce leukopenia from an overwhelming of the marrow. It appears to me that the most logical explanation in such cases lies elsewhere, despite the pathology of the bone marrow in typhoid fever. In the first place the mortality from the typhoid infection is not distinctly different from the mortality of a pneumococcus infection. Now, if the body's resistance to both infections equally depended upon the numerical strength of the so-called standing army of the leucocytes, typhoid fever ought to be a far more fatal disease than pneumonia. There are undoubtedly means of defense at the disposal of the body other than the white cell. The method of defense lies in such substances as precipitins, agglutinins, lysins, etc. Now, in such a disease as typhoid fever in which the blood stream is not crowded with leucocytes, may it not be that the normal method of defense depends upon such other substances as we have enumerated? Good evidence against the fact that such an infection as typhoid fever produces a leukopenia by paralyzing the bone marrow lies in the well-known fact that when perforation occurs and secondary invaders, or organisms whose infection is commonly characterized by leucocytosis, gain entrance to the body, leukopenia gives way to leucocytosis.

Finally, a fourth mechanism may be operative in causing leukopenia. Physical encroachment upon the blood forming tissue of the bone marrow by tumor formations, such as the metastases of hypernephromata, or the crowding in of mononuclears as in kalaazar may be the cause. From these facts, therefore, it seems allowable to enumerate four processes through which leukopenia develops:

1. Leucolysis.
2. Local accumulation.
3. Specific failure of stimulation of bone marrow.
4. Physical encroachment on the bone marrow.

#### CLASSIFICATION OF LEUKOPENIA.

Reductions of the white cells of the blood may occur under the following conditions: 1. Leukopenia in diseases which it normally characterizes. 2. Leukopenia in diseases which should give leucocytosis, usually a grave occurrence. 3. Leukopenia occurring during leucocytosis with the other signs of disease unabating,—this always portends an unfavorable outcome. 4. Leukopenia suddenly giving place to leucocytosis, as for example when secondary invaders complicate typhoid fever.

#### DISEASES CHARACTERIZED BY LEUKOPENIA.

*Typhoid fever*, best known of the leukopenic diseases, has a very definite blood picture. A relative lymphocytosis with absence of eosinophiles occurs during the second or third week. A steady drop in the polymorphonuclear neutrophiles, characterizes especially the third and fourth week. So important is the drop in eosinophiles that Stitt<sup>13</sup> maintains that an increase in them negatives a diagnosis of typhoid fever, and Sahli<sup>14</sup> quotes Nageli saying that a few of these cells cast suspicion on such a diagnosis.

*Influenza*: In a series of 1,600 white cell counts made by me<sup>15</sup> in 1918, seventy per cent. showed less than 8,000 leucocytes per cu. mm. during the prepneumonic stage. In the pneumonic stage, the counts were even lower, twice as many ranging under 6,000. This failure of leucocytosis in influenza in the presence of the secondary invaders of pneumonia is sharply opposed to what occurs under similar circumstances in typhoid fever. Leucolysis, or bone marrow paralysis, is therefore probably operative in influenza.

*Tuberculosis*: Acute invasions by the tuber-

cle bacillus, especially in miliary tuberculosis, are often characterized by leukopenia. Williamson<sup>16</sup> recently emphasized this, citing a case with positive Widal, the symptoms of typhoid fever, and a blood count of 6,000 leucocytes. On account of the rapid pulse and respiration, a diagnosis of miliary tuberculosis was made. This was confirmed by autopsy. In chronic pulmonary tuberculosis, interest has centered about the lymphocyte and prognosis has been made in terms of these cells. It is important to recall that the relative increase of the lymphocytes is almost a regular occurrence in leukopenia.

*Malaria*: Leukopenia in this disease is accompanied by a relative increase of large mononuclears and a remarkable accumulation of pigment in the white cells. Thompson<sup>17</sup> states that leukopenia is characteristic of the severer infections and is proportionate to the number of plasmodii. Wells<sup>10</sup> considered the enlargement of the spleen the result of polymorphonuclear accumulation at this site in response to a positive chemotaxis. A typical count shows about 5,000 white cells per cu. mm.

*Measles*: Following a transient leucocytosis during the incubation period, a well marked leukopenia is the usual blood picture. The diminution of the lymphocytes is the chief cause of the low count. Counts from 2,500 to 8,000 leucocytes are common.

*German Measles*: This mild infection is likewise accompanied by a low leucocyte count.

*Kala Azar*: A striking reduction in white cells occurs in this tropical disease and is interesting chiefly because of the mechanism of its production. There is no toxemia as Lavarin<sup>18</sup> showed, but the parasites invade the endothelial cells all over the body. Especially is this true in the bone marrow. The diffuent marrow is largely composed of such parasite-laden mononuclears. Leucocyte production, therefore, is seriously compromised. Leukopenia in this disease appears to be dependent upon the failure of the bone marrow whose endothelial elements have suffered an overwhelming blow.

*Malta Fever*: Another tropical disease with a moderate reduction of white corpuscles.

*Dengue*: A disease characterized by marked leukopenia and relative increase of the mononuclear cells. The average leucocyte count in

this disease is about 3,500. Counts of 1,000 are not rare.

*Trypanosomiasis*: Slight leukopenia occurs in this infection with increase of the large mononuclears.

*Severe Pyogenic Infections*: An extraordinary case was recently observed in a man of about sixty years, suffering from an unexplained temperature of 101 with a slightly red and sore throat and prostration of a marked degree. There were no definite focalizing symptoms or signs. The blood count showed 1,340 white cells with an entire absence of polymorphonuclears. Ten days later, redness and swelling, followed by fluctuation was noted in the side of his neck. Pus laden with hemolytic staphylococci was evacuated. The subsequent course was one of multiple abscesses and eventual recovery. With the appearance of the physical signs of local inflammation the blood picture changed to normal. This might be cited as an illustration of an extreme leucolysis due to specificity of a bacterial poison for white cells in the blood stream and in the bone marrow. The absence of the local signs of inflammation may have been due to a complete breakdown in the polymorphonuclear supply. Therefore, since the essential element of pus formation was lacking no pus was formed during the early stage of the infection.

Another explanation has to be considered. Zinsser<sup>19</sup> demonstrated leukopenia following the injection of dead typhoid germs into rabbits, and Miller showed the same thing in men following typhoid vaccination. It has also been pointed out by Wells<sup>10</sup> that the injection of bacteria into animals is often followed by a rapid filtering out of these organisms into the liver and other internal organs. Leukopenias, therefore, under such circumstances may represent temporary withdrawal of circulating white cells for central mobilization where circulating bacteria are also arrested and await destruction by leucocytes. It may, therefore, be possible that in this instance an initial bacteremia carried the conflict to the internal organs with the withdrawal of peripheral leucocytes. A corollary of this is to be observed in certain infections with or without bacteremia accompanied by sudden and striking changes in the blood picture characteristic of leukopenia. The probable explanation of such an occurrence again lies in the fact that

there has been a new or a fresh shower of bacteria into the blood stream and the conflict again is central and not peripheral.

#### AFEBRILE LEUKOPENIA.

*Pernicious Anemia*: A disease of abnormal blood destruction as evidenced by urobilin in the feces and urobilinogen in the urine. Likewise, there is an abnormal blood formation with a red overworked marrow trying to make good the loss. In such a heated erythroblastic effort to produce cells there is little room or time for the making of leucocytes; hence leukopenia. The index of progress often lies in the fluctuation of the white corpuscles.

*Aleukemic Leukemia*: Is also known as leukopenic leukemia.

A typical count in the disease:

Hgb.	47	Myelocytes	6.5
Rbc.	3,030,000	Myeloblasts	3.5
Wbc.	5,900	Monocytes	45.
P.	42		

*Banti's Disease*: A typical count in this disease:

Hgb.	55	P.	55
Rbc.	3,300,000	S. L.	38
Wbc.	4,000	L.	10

*Chlorosis*: The leukopenia of this disease does not occur early. It is accompanied by the usual picture of a low index in the presence of a good erythrocyte representation. It is probably an index of marrow inactivity.

*Aplastic Anemia*: A leukopenia occurs with low reds and platelets. Bone marrow cells in the peripheral blood are very rare. In this disease there is blood destruction in the bone marrow without evidence of regeneration.

*Myelophthisic Anemia*: In this condition tumors in the bone marrow leave as little room for leucocytes as they do for red blood cell formation. Myelomata, sarcomata and the metastases of hypernephromata all have this effect.

*Simple Chronic Anemia*: No evidence of blood destruction is to be observed. Leukopenia here is accompanied by a low color index, reduced red cells, and usually a discoverable cause such as defective diet.

*Hemophilia*: Leukopenia in this disease, of course, occurs only in the male sex.

#### AFEBRILE LEUKOPENIA OF UNDETERMINED ORIGIN.

An analysis of 1,025 recent routine blood examinations made on office patients revealed in eighteen cases unaccountably low white cell

counts. In most instances, the leucocytic reduction was striking. The highest count was 5,200 and the lowest was 2,700. In about half there was a definite accompanying anemia. The differential count was not remarkable. There were no bone marrow cells noted in the peripheral blood. In nine cases subsequent counts showed continuance of the leukopenia. In one instance, there was a count of 4,800 white, which two years later was 3,500. This patient's sister was subsequently examined and

This is probably, therefore, a chronic idiopathic leukopenia. It may represent an inherited bone marrow deficiency. An instance was noted of similar findings in brother and sister. The same factors may be operative here as have been brought forward to explain simple chronic anemia. It may lie in a food deficiency, though probably not iron as in the case of anemia. Or there may be some hidden intoxication with a specificity for this element of the bone marrow. The whole appearance

showed a leukopenia of 3,900. The comitant findings in these cases were usually low blood pressure, slight anemia, marked nervousness with the chief complaint of ennui and lassitude.

of the patients strongly suggests such an intoxication.

It is interesting to speculate upon the reaction of such individuals to infections ordinarily characterized by leucocytosis. Doubt-

less, many of them meet such infections with the usual blood picture. Others probably cannot and the suspicion of miliary tuberculosis, typhoid fever or influenza makes diagnosis difficult. Catton,<sup>2</sup> in a series of articles in 1916-1917, develops this phase of the subject in relation to orchitis, bronchitis and neuralgia. He showed that those diseases in which orchitis, bronchitis and neuralgia were complications were likewise characterized by leukopenia. It was his opinion that a pre-existing leukopenia foreshadows this condition, or that an existing leukopenia shows that a tendency to these diseases exists. He cites a case with abnormally low leucocytes in the blood which had successively seven infectious diseases, six of which were diseases which are characterized by leukopenia. He further suggests that a leukopenia "may be most significant as an indicator of tendency toward disease."

#### LEUKOPENIA IN DIAGNOSIS.

In the presence of temperature, a reduction in the leucocyte count suggests enteric fever, influenza, miliary tuberculosis, malaria, measles, or an overwhelming acute infection. In differentiating the common febrile leukopenias, in the absence of more definite physical signs and laboratory data, the season of the year, pulse, temperature, respiration or eosinophile count may be the deciding factor. Among the uncommon causes of febrile leukopenia in this climate are dengue, trypanosomiasis and other tropical diseases. Concerning them we need speak no further.

Almost as common are the leukopenias unaccompanied by pyrexia. It is well in such cases to inquire into the drug history of the patient. Quinine<sup>20</sup> produces striking leukopenia. Arsenic<sup>20</sup> may also result in leukoblastic destruction of the bone marrow as was the case in the Manchester epidemic of 3,000 cases. Benzol likewise is a familiar cause of white blood cell destruction. Catton<sup>2</sup> enumerates many other drugs, such as morphine, atropine, alcohol, curare, sulphonol, lead and mercury. If these latter drugs do produce leukopenia they are far less important than the others first enumerated.

The leukopenia of the various blood dyscrasias must be recalled and classified according to their respective blood picture findings. Recent vaccination must be considered. Malnu-

trition, exhaustion, hay fever and disturbances of the glands of internal secretion must be borne in mind, and the familiar symptom-complex of each sought for. Finally, having encountered none of the etiological factors enumerated above, we must put many cases of leukopenia, in our own experience eighteen in 1925, into a cryptogenic category until we gather enough information for a more satisfactory classification.

#### SUMMARY.

The leucocyte and its relation to the bone marrow has been discussed, the mechanism and classification of leukopenia pointed out, the diseases in which it occurs enumerated, and its diagnostic significance emphasized.

#### EYE PATHOLOGY OF DENTAL ORIGIN.\*

By W. W. GILL, M. D., Richmond, Va.

Associate in Ophthalmology, Medical College of Virginia.

While offering nothing new in presenting these remarks, the writer has chosen this subject on account of the frequency with which inflammatory conditions of the eye have been accompanied by oral infection especially about

\*Read at the meeting of the Virginia Society of Otolaryngology and Ophthalmology in Norfolk, November 1, 1922.

the teeth. And it is the writer's desire to impress you with the relative importance of such infections as a possible cause of diseases of the eye which you see every day, perhaps eight times more frequent than the tonsils as a causative factor.—and the tonsil has no mean reputation as a trouble starter. The above proportion is the writer's experience.

Inflammatory conditions of the uveal tract have long been considered secondary. And of iritis, de Schweinitz states that it is always secondary, while on the other hand most authorities consider infected and sloughing ulcers as of local origin. And well can the writer remember these cases: the local care, the bacteriological examinations, the hot applications, the cautery, the frequent irrigations, instillation of atropine, antiseptics, and what not. They lingered for weeks and months, some finally getting well in spite of treatments; others going on to blindness or panophthalmitis.

The writer is not decriing the old methods as aids, but of vital importance is the establishment of the primary cause, the pneumococcus, the streptococcus, the staphylococcus. Perhaps they are present, one or all, and it is well to know which, but where did they come from? What was their origin?

In the cases which will be cited, the practical results obtained, from assuming abscesses at the roots of teeth to be the primary cause or focus, have been infinitely better than those in which medication or surgery was directed to the eye alone.

CASE 1. Mrs. C. G. W. Ulcer with hypopyon. Called to see this lady Sunday afternoon, January 26th, 1921. A sheet of newspaper had scratched the eye three days previously and the pain grew steadily worse in spite of physician's attention. A dense infiltration of cornea just below center was noted, the eye was extremely red, and hypopyon present, though small. The teeth were found to be in bad condition, and immediate removal of infected ones suggested. Patient at first demurred, but was told that it was only on this condition that the case would be accepted. Copy of report was as follows.

*X-ray findings:* The following teeth are non-vital and have infection of the alveolar process about them: lower right lateral and left central, lower left cuspid and first bicu-

pid, upper left cuspid and first bicuspid, and upper right cuspid.

Extraction was begun immediately on receipt of report, and after each a reaction was noticed. Reaction was indicated by temporary increase in size of hypopyon and local eye congestion. Culture from apex of teeth showed staphylococcus and streptococcus. A guinea pig injected died in forty-eight hours with intestines inflamed and pus in the abdominal cavity ( $\frac{1}{2}$  cc. suspended culture used). After the first extraction reaction was very severe, and hypopyon larger. But in this case there was not enough exudate in the anterior chamber to justify opening. The cornea was slit through the dense infiltrated area. After the second extraction recovery was rapid and uneventful, vision at discharge being 20/20.

CASE 2. Miss S. L. age 26. First seen May 15th, 1920.

Left eye, retinal detachment, tension and irritable.

Right eye, patches of choroiditis.

Wassermann, negative; very anaemic, history of hookworm infection and examination of stool showed hookworm still present. Tonsils diseased, also evidence of trouble around roots of teeth.

*Treatment:* Left eye enucleated. One week later tonsils were removed.

Right choroidal patches did not involve macula. Vision, with correction, 20/20. Went home for hookworm treatment by her physician in North Carolina.

August 6th, 1920, the patient returned on account of sudden and marked diminution of vision; had to be led about, could count fingers at a few feet. Examination showed fresh exudation into the vitreous. Hookworm negative. She was put to bed, eliminative treatment instituted, and conjunctival injections given. Responded well and returned home.

On April 1st, 1921, patient returned to hospital with a relapse. At this time vision was reduced to 20/100. On re-examination I found that although work on teeth had been advised, it had not been attended to, so she was referred for X-ray examination of teeth.

*X-ray findings:* There are slight indications of pyorrhea present in the mouth, more extensive in the molar regions. Upper right first bicuspid non-vital, small area of periapical infection. Lower right second molar devitalized, slight periapical infection of anterior root.

Lower left first molar devitalized, slight periapical infection involving both roots. Lower left second molar devitalized, but free from X-ray pathology at present time. Such extractions as were necessary were done.

She left the hospital on April 27th: vision 20/50, nearly all exudate absorbed, and has had no recurrence to this day. Was last seen on December 11th, 1921. Vision 20/20. In this case I believe the causative condition was hookworm and infected teeth.

CASE 3. R. L. B. Age 40. Housewife. December 1920. Recurring superficial ulcers of cornea, single at times, at others multiple; sometimes one eye, at others both. Very painful and resistant to ordinary methods of treatment. Gone over by internist; negative history except trace of albumen and occasional pus cells in urine. Was dieted and tested for protein reaction with negative results. These ulcers would appear very suddenly.

After treating this case through several relapses for a period of many months, an X-ray of the teeth was advised, although they appeared perfect. The result was that two were so badly infected that they had to be extracted, another was treated. A severe reaction was noticed in the eyes after the extraction of each tooth. Extraction took place six months after the first appearance of the ulcers, which was in June, 1921. Since then there have been only two recurrences, and these have been very mild, lasting only a few days. This case was last seen September, 1922.

CASE 4. T. J. F. Male. Age 48. Occupation, farmer. Admitted to the hospital December 3rd, 1920.

Hypopyon in right eye, filling more than half of anterior chamber. Three weeks previously had gotten foreign body in eye which was removed at home by local doctor. In a few days the eye was painful, and sight gradually left. At time of admittance vision was limited to light perception. Large hypopyon filling half of anterior chamber.

*Treatment.* Cornea incised with keratome, and hypopyon evacuated. Very little reaction. In twenty-four hours pus formed again, and was again let out. As teeth showed evidence of pronounced infection, he was sent to a dentist who reported as follows:

*X-ray findings.* Very few teeth in the mouth and those present are in bad condition. The following teeth, most of which were pieces of

roots, had periapical involvement: upper right lateral incisor, upper left cuspid, lower left central incisor, lower right and left lateral incisors and right cuspid, lower left first bicuspid and first molar. The periapical infection around most of these roots involved a small amount of the process, but the upper left cuspid had a large rarefied area.

Considerable reaction in eye followed extraction, but this soon cleared and improvement thereafter was rapid. The usual local treatment was resorted to in addition to the above. When he left the hospital on December 20th, his vision was 20/200. A letter received some months later stated that vision was good in infected eye.

**SUMMARY:** In this case the exciting cause was injury; the underlying cause, focal infection. I attribute the remarkable result in this case to early surgical intervention in mouth.

CASE 5. Mrs. C. E. M. Chester, Va., 65 years of age. March 1919. Complaining of floaters in right eye, and blurring of vision.

Examination showed vision right, with correcting lens 20/20. Left eye, with correction 20/40.

Ophthalmoscopic examination showed opacities in vitreous and beginning lenticular opacities of radiating variety. Teeth were bad and all such as remained were extracted. Tonsils diseased and were removed. General health improved. No opacities noted and process of lenticular change checked. This was in August 1921, also vision in left eye was 20/30.

CASE 6. J. G. S. 50 years of age. Male. Married. First seen in August 1913. Right eye detached retina and inflammatory symptoms. Left eye showed signs of sympathetic irritation. Immediate removal advised and assented to. Left eye cleared up, but indiscretions in diet brought about much discomfort in left eye. Urine, negative. Wassermann, negative.

June 1914. Pain worse in left eye and vision reduced to 15/30. Small patch of exudative choroiditis seen. This responded to eliminative treatment, associated with usual local treatment. He was warned again about diet and habits.

Returned in August of same year with ciliary infection, discomfort and pain. At this time he stated that there was undue sensitiveness about one of his teeth, which he noticed while

chewing some taffy candy. The tooth was extracted and abscess found at root. That was in August 1914. No X-ray was taken. From that time to December 8th, 1921, eye was impervious to indiscretions of any sort although patient is a high liver.

December 8th, 1921, seven years later, patient stated that he thought his glasses needed changing as his eye had been uncomfortable of late. I suggested as he had only one eye, an X-ray of his teeth.

*X-ray report:* Upper right first bicuspid has periapical granuloma. Upper left second bicuspid has periapical infection. Upper left cuspid is deeply impacted. Lower right second bicuspid has periapical infection. There is considerable pyorrhea about the other teeth in the mouth. In this case, I am positive that dental pathology caused the loss of right eye and very nearly cost loss of left.

Many cases of sties, iritis episcleritis, and other manifestations of infection in or about the eyes might be cited, but if these remarks will impress you with the necessity of an oral examination in connection with eye pathology, then the object of this paper will have been accomplished. Somehow, the writer has found of late every few cases of tuberculosis of the eye since conversion to the theory of focal infections, and he is constrained to believe that many such cases, in fact a majority, were erroneously diagnosed back about 1907 or shortly after Calmette and others gave us easy methods of diagnosing tuberculosis.

As a prophylactic measure, before any eye operation (or other for that matter) eliminate focal infections. All of you have wondered why dirty operators seem to get as good results as clean ones. It is because they were operating on clean subjects. Of course, the combination of clean operation and clean subjects is the most desirable.

Recently the writer has been having the teeth and tonsils examined, also other possible foci eliminated before operating for foreign bodies in the vitreous, cataract, glaucoma, etc.

#### Chiropractic Bill Killed in South Carolina.

After a long and stormy debate, the bill to create a state board of chiropractic examiners in South Carolina was finally killed in the House of Representatives. The final vote was 65 to 46 against the bill. This action of the House was considered a hard blow to chiropractic in that State.

### BRAIN ABSCESS OF TEMPORO-SPHENOIDAL LOBE COMPLICATING ACUTE MASTOIDITIS: OPERATION: RECOVERY.\*

By ELBYRNE G. GILL, M. D., Roanoke, Va.

**PATIENT**—L. L. B., female, age forty-one, came under my observation April 22, 1922, complaining of deafness in left ear. This symptom was preceded by a "cold."

**PAST HISTORY**—No previous history of ear trouble. Has had the diseases of childhood. Was in a tubercular sanitarium for treatment eight months, five years ago. Has had no further trouble.

**SPECIAL EXAMINATION**—*Nose*—negative. *Throat*—tonsils small, submerged and diseased. *Ears*—A. D. normal; A. S. Membrani tympani thickened and slightly congested. *Sinuses*—Maxillary and frontal all clear to transillumination. Functional examination:

	Whisper	Weber	Schwaback	Rinne
Right Ear	25 Ft.	—	—	+
Left Ear	3 Ft.	+	+	—

	Lower Tone	Galton Whistle	
Right Ear	C-32	.2	Fistula
Left Ear	C-128	.2	Negative

**DIAGNOSIS** at this time: Tubo-tympanic congestion following acute rhinitis.

Four days later, April 26th, I was called to see the patient and on examination a bulging left ear drum was revealed. The patient was suffering most excruciating pain. The ear drum was incised under local anesthesia, pus escaped under pressure. Examination of smear revealed pneumococcus infection. Patient was treated for acute middle ear suppuration and did not have further trouble until April 30th, (four days later), when she began having severe pains in left ear. At this time there was slight tenderness, on pressure, over the mastoid antrum and tip. The aural discharge was thick and profuse.

As I was leaving the city at this time for a few days, my colleague, Dr. G. M. Maxwell, kindly consented to look after the patient. The patient's condition grew progressively worse and on Wednesday morning, May 3rd, Dr. Maxwell sent her to the hospital for X-ray examination, preparatory to doing a mastoidectomy. The X-ray report is as follows:

\*Read at the sixteenth annual meeting of the Southern Medical Association in Chattanooga, Tenn., in November 1922.

"X-ray examination of left ear shows a definite increased density and cloudiness of the mastoid. The cells do not appear to be completely broken down, but there is a definite involvement, and this case should be carefully watched clinically, with an idea of early operative procedure."

After receiving this report and noting the severity of the clinical symptoms, operation was advised. Patient refused and left the hospital the same day of admission, May 3rd. I returned to the city May 6th and visited the patient at home, and found the condition as follows: Pulse and temperature normal, profuse ropy discharge from ear, no pain, tenderness only on pressure over mastoid tip emaciation noticeable, pupils equal in size and react to light, no spontaneous nystagmus, eye grounds negative, apparent cloudiness of sensorium. Patient was urged to return to the hospital for another X-ray examination but refused. Family was advised to notify me if any unfavorable symptom developed. The following morning, May 7th, 5 a. m., I received a telephone call stating that the patient was unconscious and having convulsions. On reaching the home I found the patient unconscious. Rotary nystagmus to the right was noticed. The patient was hurried to the hospital, spinal puncture performed immediately. Fifteen cc. of fluid withdrawn. First fluid was blood tinged. Last only faintly cloudy. Cloudiness due to blood. Blood count: 3,480,000 red blood cells, a hemoglobin 60 per cent, white blood cells 22,600, 90 per cent. neutrophils, and 10 per cent mononuclears. Urine negative.

Sudden development of this unfavorable symptom prevented a satisfactory neurological and Barany examination; consequently we were not able to localize any definite lesion. Temperature on admission, 100 degrees F, pulse 100, respiration 18.

With a history of suppurating middle ear and mastoiditis for the past ten days, followed by sudden development of unconsciousness and a negative spinal fluid and urine, we made a tentative diagnosis of an abscess of the temporosphenoidal lobe.

The family was advised accordingly and after much persuasion we were permitted to operate.

Patient prepared as usual for mastoid operation. (Ether anesthesia). Profound coma

when sent to operating room. Simple mastoidectomy was performed. Small amount of

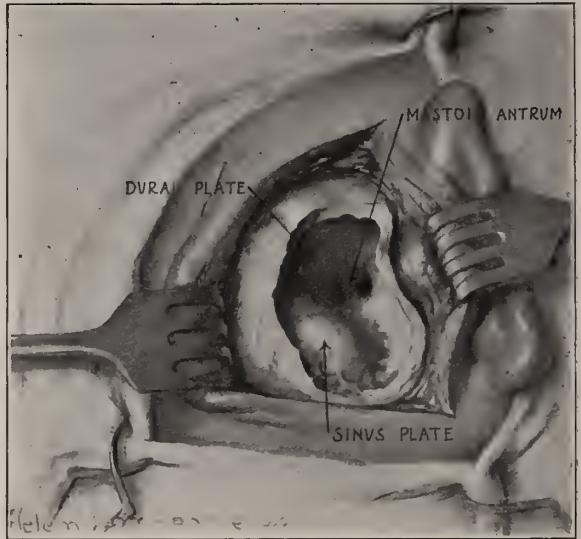

Fig. 1.

pus escaped when the mastoid cortex was removed. No pus in antrum, tip or over the lateral sinus. The lateral sinus was uncovered from the knee to the sigmoid. Color normal. No evidence of necrosis of bone covering sinus. Cerebellar dura normal in appearance. Nothing found so far to account for the symptoms present. The dura in the middle cranial fossa

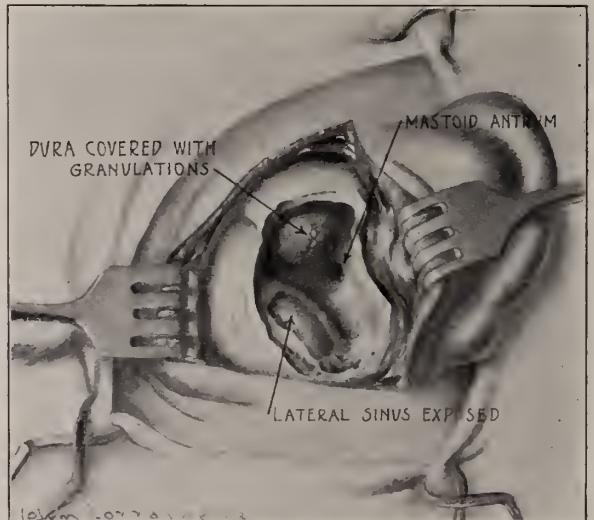

Fig. II.

was uncovered to the extent of a twenty-five cent piece. The dural plate was intact. No evidence of necrosis. (The dura was red, congested and covered with granulations,

bulging very slight, if any). No pulsation. It was not adherent to the bony wall.

All instruments used in operation were removed from table, gloves changed, mastoid cavity swabbed with iodine, full strength. The dura was incised in the middle fossa. Knife inserted into brain to the depth of two inches. No pus escaped. I then opened the incision by spreading apart a pair of forceps; when this was done, about two ounces of unorganized pus escaped under pressure. The pus had no odor and there was apparently no abscess wall. Culture showed pneumococcus infection.

A small rubber cigarette drain was then inserted into the brain cavity and held in place by packing placed around it in the mastoid cavity. Mastoid wound left open. Dressing applied and patient sent back to room in good condition. Temperature 100.4. Pulse 120. Respiration 24. Time of operation one hour and thirty minutes.

Four hours following operation patient regained consciousness and subsequent history was one of gradual improvement. First two weeks following operation patient had marked word aphasia and weakness of muscles of right arm persisted for nearly three months.

Fig. III.

When drainage tube should be removed was a question of paramount importance. At the end of the first week the discharge from the tube was every slight and of a serous nature and in view of these findings together with

the improvement of the general condition prompted me to remove the tube. On the following day patient complained of severe headache and there was a beginning cloudiness of the sensorium. Dural incision was again opened with forceps and dark blood-tinged pus was evacuated. A small male catheter was inserted into the cavity and allowed to remain until May 25th, nearly three weeks following the operation. The tube was not changed but twice during this period and then on account of the dressing slipping.

The anemia which was present at the time of admission continued to become more marked, as shown by the following blood pictures.

May 8.	Red blood cells -----	3,480,000
	Hemoglobin -----	60%
	White blood cells -----	22,600
	Polynuclears -----	90%
	Mononuclears -----	10%
May 22.	Red blood cells -----	3,080,000
	Hemoglobin -----	45%
	White blood cells -----	10,000
	Polynuclears -----	80%
	Mononuclears -----	20%
May 24.	Red blood cells -----	3,420,000
	Hemoglobin -----	50%
	White blood cells -----	9,400
	Polynuclears -----	76%
	Mononuclears -----	24%
May 26.	Red blood cells -----	3,600,000
	Hemoglobin -----	55%
	White blood cells -----	8,800
	Polynuclears -----	77%
	Mononuclears -----	23%
May 30.	Red blood cells -----	3,480,000
	Hemoglobin -----	55%
	White blood cells -----	7,800
	Polynuclears -----	76%
	Mononuclears -----	24%
June 2.	Red blood cells -----	2,800,000
	Hemoglobin -----	50%
	White blood cells -----	5,400
	Polynuclears -----	65%
	Mononuclears -----	35%
June 8.	Red blood cells -----	2,440,000
	Hemoglobin -----	50%
	White blood cells -----	6,000
	Polynuclears -----	68%
	Mononuclears -----	32%

At this time blood transfusion was decided upon as the most effective means to combat the progressive anemia. A suitable donor was selected and a transfusion of 250 cc. of blood was given, June 10th. A very severe reaction accompanied the transfusion. Blood count June 15th as follows:

Red Blood cells -----	4,360,000
Hemoglobin -----	65%
White blood cells -----	7,800
Polynuclears -----	70%
Mononuclears -----	29%
Eosinophiles -----	1%

Patient's general condition very much improved, mastoid wound practically healed and she was discharged from hospital June 18, 1922.

This case is of unusual interest in that we had the rapid development of an abscess to quite a large extent without any focalizing symptoms for the patient. As late as 10 p. m., May 6th, was feeling quite well and talking with neighbors and members of the family. Seven hours later she suddenly became unconscious and begun having recurrent convulsions. We attribute our success in this case to the following factors: **FIRST**, that the abscess was evacuated without undue trauma to the cerebral tissue. **SECOND**, that the drainage tube was allowed to remain in situ continuously and not removed daily as this manipulation would tend to break down nature's barriers, thus having a tendency to spread the infection. The time to remove the drainage tube depends upon the individual case. It may vary from one week to three months, depending upon the character and amount of discharge. If it no longer contains pus and is of a serous nature, the tube may be removed. **THIRD**, that the patient was kept in bed, on back, for four weeks following operation.

612 MacBain Building.

## Proceedings of Societies

### Constitution and By-Laws of the Woman's Auxiliary to the Medical Society of Virginia.

As Tentatively Submitted for Adoption at the Meeting in October, 1923.

OFFICERS ELECTED IN NORFOLK, OCTOBER, 1922.

*President*—Mrs. R. Lloyd Williams, 801 Stockley Gardens, Norfolk, Va.

*First Vice-President*—Mrs. J. Allison Hodges, 107 E. Franklin St., Richmond, Va.

*Second Vice-President*—Mrs. S. S. Gale, Roanoke, Va.

*Third Vice-President*—Mrs. Southgate Leigh, Norfolk, Va.

*Fourth Vice-President*—Mrs. W. E. Anderson, Farmville, Va.

*Recording Secretary*—Mrs. Burnley Lankford, Norfolk, Va.

*Treasurer*—Mrs. Starke Sutton, Norfolk, Va.

#### CONSTITUTION

##### ARTICLE I—Name

The name of this Association shall be the Woman's Auxiliary to the Medical Society of Virginia.

##### ARTICLE II—Object

The object of this Auxiliary shall be to aid and encourage the medical profession in its efforts to educate the public in matters of sanitation and health; to assist in entertainment at State, district

and country society meetings; to promote acquaintanceship among doctors' families, that local unity and harmony may be increased.

##### ARTICLE III—Membership

The membership of the Woman's Auxiliary of the Medical Society of Virginia shall be composed of the County Women's Auxiliaries to the County Medical Societies. The wives and daughters of all doctors shall be eligible for membership.

##### ARTICLE IV—Officers

The officers of this Auxiliary shall be a President, four Vice-Presidents, a Recording Secretary, a Corresponding Secretary and a Treasurer.

##### ARTICLE V—Executive Board

These officers, together with one representative from each of the ten Councilor's Districts of the State Medical Association, shall constitute an Executive Board to conduct the business of this Auxiliary.

##### ARTICLE VI—Elections

(a) These officers and the ten district representatives constituting the Executive Board shall be elected by ballot at the general meeting for a term of two years.

(b) A nominating committee shall be appointed by the Executive Board to present a list of officers and representatives for election; this committee to be composed of five members, not more than three of whom may be members of the Executive Board.

##### ARTICLE VII—Meetings

The meetings of the Woman's Auxiliary shall be held at the same time and place as the Medical Society of Virginia.

##### ARTICLE VIII—Delegates

Each County Auxiliary shall be entitled to one delegate for each twenty-five members or less, and for each additional twenty-five members, one additional delegate, these accredited delegates with the members of the Executive Board to form the voting body.

##### ARTICLE IX—Dues

Each County Auxiliary shall pay dues to the State Auxiliary at the rate of ten cents per capita, at least one month prior to the annual meeting. Each County Auxiliary shall decide the amount of their local dues.

##### ARTICLE X—Amendments

This constitution may be amended at any regular meeting of the State Auxiliary, provided written notice has been sent each County Auxiliary not less than one month prior to said meeting.

#### BY-LAWS

1. **DUTIES OF OFFICERS.** The duties of the President, Vice-Presidents, Recording and Corresponding Secretaries and Treasurer shall be those which usually devolve upon such officers.

2. **COMMITTEES.** The President and Executive Board shall have power to create such committees as become necessary to promote the work of the Auxiliary.

3. **MEETING.** All meetings of the Auxiliary and the Executive Board shall be conducted according to the regular order of business and Robert's parliamentary laws.

4. **QUORUM.** Seven members of the Executive Board shall constitute a quorum.

5. **AMENDMENTS.** These by-laws may be amended at any meeting of the Executive Board or at the annual meeting of the Auxiliary by a two-thirds vote of the members present, not less than fifteen, provided such amendments must not conflict with the spirit of the constitution.

### The Dinwiddie County Medical Society,

At a recent meeting, unanimously elected

Dr. George H. Reese, Petersburg, president; Dr. E. W. Young, Petersburg, vice-president; and re-elected Dr. W. C. Powell, Petersburg, secretary-treasurer, for the ensuing year.

Dr. Fletcher J. Wright, Petersburg, was chosen as delegate to the annual meeting of the Medical Society of Virginia in Roanoke.

#### **The Southside Virginia Medical Association**

Met in Petersburg, March the 13th, Dr. W. C. Harman, first vice-president, of Dolphin, presiding. A large number of excellent papers were read and discussed. Between the afternoon and evening sessions, the members were entertained by the Petersburg Faculty at a course dinner at Petersburg Hotel.

The next meeting will be held in Lawrenceville on the second Tuesday in June.

R. L. RAIFORD, *Sec'y.*

### **Bonds for Roads.**

As all doctors as well as other citizens of Virginia are interested in voting for the quickest and surest way of securing good roads for our State, we are publishing a note which was received at this office as it may have weight in making our readers get solidly behind the movement for good roads when the question comes to the vote.

WARRENTON, VA.

March 24, 1923.

TO THE EDITOR:

Let us have bonds for roads. Why? Because the bond-issuing states are the only ones which now have and enjoy good roads. That is convincing argument that bonds "do the trick." Women, especially, should vote solidly for bonds as they need good roads for recreation and as a health measure for themselves and their children.

Doctors! vote for bonds for good roads, the plan adopted by other states which have secured good roads.

STEPHEN HARNSBERGER, M. D.

### **Bismuth in the Treatment of Syphilis.**

Clemens Simon and J. Bralez (*Bull. Med.* 1922, 36:523) reviews the recent literature regarding the treatment of experimental and human syphilis with various salts of bismuth,

the most important of which is sodium and potassium tartro-bismuthate. The first Congress of Dermatology and Syphilis which just took place at Paris devoted a whole session to reports of investigations with these drugs. The authors report their own experience in the treatment of 113 cases of syphilis with insoluble bismuth salts. They employed four different preparations of sodium and potassium tartrobismuthate. The route of the administration was intramuscular, the drug being given in oily suspension. The dosage was 20 cg. each injection being given twice a week, a course of treatment consisting of from 6 to 12 injections.

The authors find that the reactions from the use of this drug are in general those described by previous investigators. The most important reaction is stomatitis which occurred in about 12 per cent of all cases treated. In a somewhat higher proportion of cases, however, there appears also a bluish line on the borders of the teeth and large bluish spots on the internal surface of the cheeks, this pigmentation being similar to that observed in chronic lead poisoning. In practically all instances the stomatitis was mild and cleared up promptly on the cessation of bismuth treatment. An additional 12 per cent of patients developed reactions of other types during the course of treatment, these reactions being for the most part, cramps, malaise, nausea, headache, and a single reaction simulating nitroid crisis after arsphenamine. In general, reactions of all types are mild and did not interfere to any great extent with the treatment.

So far as the therapeutic results are concerned, treponema disappeared within 2 to 14 days from chancres and from the mucous lesions of secondary syphilis. Chancres were healed in the average of 14 days after a total of 4 injections, whereas the lesions of secondary syphilis healed in an average of 22 days after 6 injections. A number of cases of latent Wassermann positive syphilis were treated, but the authors conclude that too little time has elapsed to permit any evaluation of the serologic results. Their impression is that bismuth acts less rapidly than arsphenamine on the Wassermann reaction. They treated 3 cases of cerebro-syphilis and 7 of tabes dorsalis. In several of these there was notable improvement of clinical symptoms, but no change occurred in the cerebrospinal findings. They conclude that the salts

of bismuth may prove to be of great value in the treatment of syphilis, particularly in those cases unfortunately too common, which are intolerant of arsphenamine and mercury. (Progress of Medical Science, *American Journal of the Medical Sciences*, November, 1922.)

## The Truth About Medicine

During February, the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Non-official Remedies:

Eli Lilly and Co.,

Schick Test and Schick Test Control. Eli Lilly & Co.

Diphtheria Toxin-Antitoxin. Eli Lilly & Co.

H. K. Mulford Co.,

Pneumococcus Antibody Solution, Types I, II and III Combined. Mulford.

Parke, Davis & Co.,

Diphtheria Toxin and Control for the Schick Test. P. D. & Co.

Neo-Silvol.

Mercurosol

Tincture No. 111 Digitalis. P. D. & Co.

### NEW AND NON-OFFICIAL REMEDIES.

**Bacillus Acidophilus Milk—Lederle.**—Whole milk cultured with *Bacillus acidophilus*. It contains not less than fifty million of viable organisms. (*B. acidophilus*) per Cc. During recent years reports have been published which indicate that the growth in the intestinal canal of the normally present *Bacillus acidophilus* may be increased so as to make it the predominating organism, by the administration of milk inoculated with *B. acidophilus*, by the administration of viable cultures of *B. acidophilus* in conjunction with lactose (sugar of milk), or by administration of lactose alone. The therapeutic value of cultures of *B. acidophilus* is still in the experimental stage. For a discussion of the actions and uses of lactic acid ferment preparations, see New and Non-official Remedies, 1922, p. 156. **Bacillus acidophilus milk—Lederle** must be kept on ice and should be used within one week of the expiration date which appears on each package. Lederle Antitoxin Laboratories, New York. (Jour. A. M. A., February 3, 1922, p. 323).

**Theocin Sodium Acetate.**—A brand of theophylline sodio-acetate—N. N. R. (See New and Non-official Remedies, 1922, p. 357). Winthrop Chemical Co., New York. (Jour. A. M. A., February 10, 1923, p. 401).

**Diphtheria Toxin and Control for Schick Test—P. D. & Co.** Diphtheria Immunity Test (New and Non-official Remedies, 1922, p. 320), marketed in packages containing one vial of 0.1 Cc. of undiluted, standardized diphtheria toxin, one vial of 5 Cc. of sterile physiologic solution of sodium chloride, one vial of 5 Cc. of diluted control of Schick test and one sterile syringe point. Each package contains material sufficient for fifty doses. Parke, Davis & Co., Detroit, Mich. (Jour. A. M. A., February 17, 1923, p. 475).

**Diphtheria Toxin—Antitoxin Mixture—Lilly.**—A diphtheria toxin-antitoxin mixture (see New and Non-official Remedies, 1922, p. 282), each Cc. constituting a single human dose and containing 3 L+ doses prepared in accordance with the requirements of the U. S. Public Health Service. Marketed in

packages of three vials sufficient for one treatment. Eli Lilly & Co., Indianapolis, Ind.

**Schick Test—Lilly.** A diphtheria immunity test. (See New and Non-official Remedies, 1922, p. 320). Marketed in packages containing one vial of diphtheria toxin sufficient for ten tests and a vial of sterile physiological solution of sodium chloride and in packages of ten vials containing toxin sufficient for one hundred tests accompanied by ten vials of sterile physiological solution of sodium chloride. As a control, the Schick test control, representing diphtheria toxin of the same lot treated to destroy the specific exotoxins is supplied. Eli Lilly & Co., Indianapolis, Ind. (Jour. A. M. A., February 25, 1922, p. 553).

### PROPAGANDA FOR REFORM.

**More Misbranded Nostrums.**—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act:

**Healing Springs Water** (Virginia Hot Springs Co.), a moderately mineralized water, containing bicarbonates of calcium and magnesium, and magnesium sulphate (Epsom salt); **Brick's Sarsaparilla** (Palestine Drug Co.), containing small amounts of sodium salicylate, potassium iodid, plant drug extractives, including sarsaparilla and a laxative drug, sugar, alcohol and water; **Yerk's Wine Extract of Cod Liver Oil** (Yerk's Chemical Co.), consisting essentially of compounds of sodium, potassium, calcium, iron, quinine, strychnin and phosphorus, extracts of plant drugs, possible traces of cod-liver oil, malt extract, sugar, alcohol and benzaldehyde as a flavoring; **Anemia Tablets** (Carlos M. Rivoll), containing 95 per cent. of milk sugar and small quantities of cinchona alkaloids, charcoal, sulphur, gum and compounds of arsenic, phosphorus, iron and sodium. (Jour. A. M. A., February 3, 1923, p. 343).

**A Patented Consumption Cure.**—The U. S. Patent Office has issued patents for many preparations to be used in medicine for which there has not been the slightest scientific justification. The most recent and most flagrant lack of intelligent patent law administration is to be found in a patent issued to Sergluson and exploited by the Savrite Medical Manufacturing Co., Los Angeles, Calif., for an alleged cure for tuberculosis.

This is the patented cure: Pure olive oil 1 gallon, squill root 3 pounds, bitter almonds 1¼ pounds, nettle (the plant except the root) 1½ pounds, red poppy flower petals 1 pound. These various ingredients are to be mixed, put in a closed container, gradually warmed and left standing for about 72 hours, when the mixture is squeezed, mixed and filtered. The filtrate comprises the "cure." (Jour. A. M. A., February 10, 1923, p. 420).

**Brown's New Consumption Remedy.**—The Post-office Department has issued a fraud order against B. H. Brown, M. D., of Jacksonville and St. Augustine, Fla., and Brown's Magnolia Remedy Co. For some time Dr. Brown, a negro, has been advertising Dr. Brown's New Consumption Remedy, especially to members of his own race, who are afflicted with tuberculosis. In 1917 the federal authorities prosecuted Brown under the Food and Drugs Act, holding that the claims for the preparation were false and fraudulent. Though convicted, he continued making his claims in newspaper advertisements, and in circulars that answered these advertisements. While the Department of Agriculture is helpless to prevent this form of fraud under the provisions of the Food and Drugs Act, the Post Office authorities are able to reach this form of fraud. The Department filed charges against Brown and after hearing the defense issued a fraud order against Magnolia Remedy

Co. and E. H. Brown. (Jour. A. M. A., February 17, 1923, p. 495).

Allen's Goiter Treatment.—At Sheffield, Iowa, the Allen Remedy Co. conducts a mail order business in "Dr. C. J. Allen's Goiter Treatment." The A. M. A. Chemical Laboratory analyzed the Allen nostrum and found it to consist essentially of ferrous iodide and hydrogen iodide (hydriodic acid), in a colored and flavored syrup. The serious side of the Allen Goiter Remedy Co. business is the indiscriminate sale of the nostrum to those who may be, and are likely to be suffering from exophthalmic goiter. It is well known that the use of iodine is likely to aggravate this disease and hence it is not surprising that physicians are beginning to report serious results from the use of the Allen preparation. (Jour. A. M. A., February 24, 1923, p. 572).

## Book Announcements

**Clinical Medicine.** I. Tuesday Clinics at Johns Hopkins Hospital. By LEWELLYS F. BARKER, M. D., LL.D., Professor of Medicine, Emeritus; Visiting Physician to Johns Hopkins Hospital, Baltimore. Illustrated. Philadelphia and London. W. B. Saunders Company. 1922. Cloth. Price \$7.00

This volume of modest size consists of thirty-one of Dr. Barker's clinical lectures. The cases presented are such as are often met in general practice but not always correctly diagnosed. In the opening chapter in which he discusses *his* method of arriving at a diagnosis, Dr. Barker decries that not very ancient practice of jumping at a diagnosis based on a single symptom, generally that most complained of by the patient, such as "headache," "cough," "lumbago," etc.

He emphasizes that the first step in arriving at a correct diagnosis is the *feeling of a diagnostic difficulty*. It is safe to say that some doctors *rarely* experience this "feeling" and the chiropractors *never*.

Representative of the highest ideals in modern clinical teaching this book is worth not only a careful reading but study. H.

**The Riddle of the Rhine.** By VICTOR LEFEBURE, Officer of the Order of the British Empire (Mil.), Chevalier de la Legion d'Honneur, Officer of the Crown of Italy, Fellow of the Chemical Society, etc. With a Preface by MARSHAL FOCH, and an introduction by FIELD-MARSHAL SIR HENRY WILSON, BART., Chief of the Imperial General Staff, New York. E. P. Dutton and Company, 681 Fifth Avenue. 8vo. Cloth. 282 pages.

This book deals with chemical warfare and the scientific and economic conditions that underlie it. The author was on the firing line with the British from the time the Germans threw over the first poison gas, and his work is considered authoritative by Marshal Foch, Field-Marshal Wilson and other leaders of

the allies in the field, as well as by Lord Moulton and other chemical authorities. It is an account of the critical struggle for power and for the decisive war initiative.

**Textbook of Anatomy and Physiology.** For Training Schools and Other Educational Institutions. By ELIZABETH R. BUNDY, M. D., Formerly Adjunct Professor of Anatomy, Woman's Medical College of Pennsylvania. Fifth Edition Revised and Enlarged by MARTHA TRACY, M. D., Dr. P. H., Professor of Nutritional Hygiene, Woman's Medical College of Pennsylvania, and GRACE WATSON, R. N., Educational Directress, Philadelphia General Hospital Training School for Nurses. Philadelphia. P. Blakiston's Son & Co., 1012 Walnut Street. Cloth. 1923. 442 pages, including a Glossary and 266 illustrations, 46 of which are printed in colors. Price, \$2.50.

The fact that this is the fifth edition of this book and that it has been revised and enlarged attests its popularity.

All revisions have been made with a view to giving the reader the benefit of the latest results in research and experimental work.

### To Establish Mental Hygiene Clinic.

The Board of Mental Hygiene of Maryland plan the establishment of a mental hygiene clinic in Baltimore, where physicians from the state institutions will be in attendance and will endeavor to come into contact with patients with mental disorders in the incipient stage. This should mean a reduction in the number of admissions to the state hospitals for insane. This clinic will be conducted in connection with the medical work of the University of Maryland.

### Contract Placed for Virginia Baptist Hospital.

Trustees of the Virginia Baptist Hospital, to be located at Lynchburg, placed the contract for construction of the central plant of the institution, the middle of February. Work will be started as soon as practicable and will be completed, according to specifications, in eight months. It is understood that the cost of this building is to be about \$200,000.

### Veterans' Hospital Near Battle Creek.

One of the veterans' hospitals for which Congress made appropriation is to be built west of Battle Creek, Mich., where Camp Custer sprang into a great cantonment. This hospital will have thirty buildings, which will spread over 500 acres of land, and will be for former service men suffering from nervous and mental disturbances. It is stated that the buildings will cost a million and a half dollars.

## Editorial

### Diagnosis by the General Practitioner.

Far-sighted and candid minds in medicine are confessing openly, at least within medical circles, that the modern practice of the medical art has fallen in some evil ways. These evil ways have come as a result of the specialism of medicine. These evil ways of practice have come along with great benefits, however: the benefits have been untold in advancing the knowledge of medicine and in adding to the skill and perfection of the art. But, in connection and as a result of these benefits, have come evils which now must be squarely faced: not only must we recognize these deterrents to practice, but we must take steps to eliminate them while retaining all the good possible.

There are always in every stage of professional progress and in every advance of scientific knowledge a proper and healthful reaction from the extreme position. This is seen, on the one hand, in the widespread movement in medical practice to specialize; to divide and sub-divide into specialists, until the sick or diseased body must be subjected to the inquiry and study of groups composed of more or less multiple specialists. From such a condition, on the other hand, conservative medical men are dissenting. From such an extreme and useless complexity of practice, the public, itself, may soon assert a vigorous protest.

But the demands of modern medicine must be met. The reaction from the large number

of specialists must be met by a movement for the wider and greater improvement in the work of the general practitioner. The general practitioner must avail himself of newer opportunities for a "look-in" on the simpler methods of investigation used by the specialists. The general practitioner must be equipped with a broader knowledge of the more elementary facts and methods of specialism. If changes can be brought about whereby the family doctor may be shown and taught a wider knowledge of the more essential things of the special fields of medicine and the specialists themselves be re-taught from time to time, the more fundamentals of general medicine, the conditions which appear to deter the progress of medicine today will be largely corrected and the public usefulness of the profession will be greatly enhanced.

With just one phase of this very large subject the title of this editorial has to deal. Every practitioner, for instance, should possess and use a head mirror. A large number of the patients who pass before the bar of judgment of the general practitioner never receive the benefits which would come to them from a careful reflection of light in the mouth and throat from a head mirror. The mouth, nose and throat, after all is said, are very vulnerable. There enter and here are harbored the foci of much disease, oftentimes in its very incipiency, sometimes in its late manifestation.

Diagnosis is the most important procedure in medicine. Amid the multiplicity of laboratory and instrumental methods of examination, one may overlook the most essential methods of examination. No one possessing a true appreciation of the advantages of accurate scientific methods of investigation of disease would utter a word derogatory to this great field of modern medicine but would, on the contrary, proclaim highest appreciation of these advances of modern medicine. But the general practitioner or family physician can only hope to make use of these more or less technical methods in a limited number of or in obscure cases. In the large number of cases coming under his observation, the use of the simpler methods of investigation, such as the use of the head mirror or even the "flash-light" may disclose often some important point in the diagnosis or etiologic phases of cases. Some recent writer has said that eighty per cent. of the usual routine cases coming

under observation of the general practitioner may be diagnosed without resort to the more extensive laboratory and special investigation.

The resourceful and thoughtful practitioner may simplify the problem of diagnosis by the use of a carefully taken personal history of the case, plying careful inquiry into the previous events and into the circumstances of the illness under judgment; by the diligent and precise use of the special senses, observing, inspecting, hearing, smelling, feeling the presenting signs and symptoms; by the use of the thermometer, the watch, the head mirror, the tongue depressor, the stethoscope, he may bring out the leading points in the case. A careful and accurate physical examination, with the patient prepared to submit to a methodical examination unobstructed by clothing, is an important point in the back-to-common-sense-method of medical diagnosis. Inspection, palpation, percussion and auscultation of the diseased body will bring to light much and telling information, if methodically and carefully conducted.

Let every practitioner make of his daily routine of practice a clinic for himself. Let him quicken his powers of perception by the careful study of the clinic passing through his hands daily. This he can do by the earnest effort in perfecting himself in a systematic and methodical examination of the head, the neck, the thorax, the abdomen, the genitalia, the extremities, the examination of the systems or the organs, et cetera; any method that covers the body may be adopted; and such observations as are made should be recorded. The written record of one's findings serves a double end: (1) as a record; (2) as educational and instructive in its making to the practitioner.

Special examinations are demanded in a part of one's cases. Those cases which do not yield to the usual careful investigation of average examinations may need further study in the pathological laboratory of the blood, urine, the sputum, secretions, excretions. These may need careful study by special men and methods. The careful examination of urine, blood, sputum, feces, stomach contents, may be easily conducted by the general practitioner after a little study. The more difficult examinations in the hands of specialists must be used in obscure cases. The X-ray, the blood culture, bacteria studies, serology, blood chemistry and the multitude of highly specialized inves-

tigations of the specialists have a place in cases not diagnosed by the easier methods.

As pointed out by Billings\*, cases of chronic nephritis, heart diseases, diseases of the lungs, diseases of the stomach, anemia, appendicitis, cholecystitis and acute diseases, in the usual and ordinary types, the general practitioner may rather readily diagnose without resort to the ultra-scientific methods of modern medicine.

International Clinics, for March, 1923, has the following comment to make on the question of "The Rational Attitude Towards the X-rays in Diagnosing Digestive Diseases":

"The recent death of Roentgen should not make us oblivious to the fact that his epoch-making discovery has been distinctly a two-edged sword in the digestive field. Dr. Thomas R. Brown, of Baltimore, believes that in the case of a great many physicians, the X-rays have consciously or unconsciously persuaded them to be much less thorough in their careful analysis of the case and in their clinical studies, and this, we feel, is very deplorable, because from X-ray studies alone diagnosis should not, and in many cases cannot, be made. It is to Dr. Brown peculiarly distressing to see a diagnosis founded on very careful clinical study of the case overthrown by a few words from a radiologist, who often is untrained clinically and only too frequently has not had a broad experience in reading X-ray plates. While it is obviously easy to fluoroscope a patient and to take X-ray plates, nothing is more difficult than to explain the pictures on the screen, or to interpret the abnormalities of form or position as manifested in the plates. 'I would rather,' said recently a celebrated Italian internist, 'have no X-ray examination in a case than X-ray plates interpreted by anyone other than a master in this field.' To regard the X-ray as the court of last resort in diagnosis is fundamentally wrong except in gross conditions which can, in the majority of cases, be diagnosed just as definitely by other means. Except in such cases the X-ray diagnosis can rarely be definite—should only suggest various possibilities the probability of which must be dependent upon other features of the case, as determined by careful history taking, a thorough clinical examination, and the use of various special tests. The X-ray is but one of many means of reaching a diagnosis, none of

\*J. A. M. A., February 24, 1923.

which except in occasional instances is capable of furnishing the diagnosis *per se*, but each of which should be used in proper proportion in reaching a probable or, in rare instances, an absolute diagnosis. To show the difficulty even in the hands of experts, Dr. Brown suggests the advisability of having the same case studied under exactly the same conditions by various radiologists. In certain cases all will agree on the diagnosis. These, as a rule, are the easy cases, diagnosable by other means; but in a considerable proportion of cases very different diagnoses will be furnished by different men, all honest, all experienced, all capable in this field. The pictures are definite, the images on the screen are definite, but the interpretation always is a question of subjectivity, and must differ unless the picture is perfectly obvious."

#### **Mongolian Idiocy or Thymus Deficiency.**

If cretinism is a disease of fetal or infantile life, brought about by the deficiency of the thyroid or its absence, resulting in failure of the body and mind to evolve into normal physical and mental proportions, may we not think of the possibility of a decreased or absent thymus gland in early life, producing such a condition in the physical and mental side of infants and the young as we know of as mongoloids?

The physiognomy of the mongolian is rather typical. The head is often flattened. The hair is straight, thin, fine and there is tendency to baldness at the parts in the hair. The skin is pale and dry. The nails are fragile. The nose is snubbed, small and flat; the ear lobes crimped and distorted. The mouth is usually open; the lips thin. Mouth breathing expression is common. The body is dwarfed. The chest is small, the abdomen prominent and balloned. The long bones are thin. The hands are stubby and the feet are small and the mentality is retarded. Signs of feeble-mindedness appear early. There is mental apathy; the good natured, quiet, satisfied mental attributes may be quite indicative of the mongoloid. As they grow older, they accentuate the faculty of possessing "a secret joy," by displaying an active, happy, bright, smiling, aggressive, familiar amiableness. There is, often, no restraint by timidity or bashfulness; on the contrary, the mongoloid makes acquaintances with the aggressiveness of the politician seeking office.

It is thought that mongoloids appear in parents of advanced age, when the mother parent is approaching the end of gestation, and in the case of twin birth.

#### **Myxedema or Gull's Disease.**

This is a constitutional disease seen in the adult, which results from a decrease or absence of the thyroid secretion (thyroxin). It is characterized by decreased metabolic rate, by marked changes in the skin, by impaired mental development associated with a typical facial expression.

The causes are not altogether known. Atrophy of the thyroid appears to be the cause, although it is not known what are the etiologic factors always at the bottom of such atrophy. Thyroiditis at some time is accepted as the most common causative factor. Plummer's suggestion is that the thyroiditis may be set up by an infection entering through "the hyperplastic lymphoid tissue of the nasopharynx." Heredity has been also considered as a cause of the atrophic thyroid. The pathological changes are characterized by a small gland, showing microscopically a "marked increase in fibroid connective tissue with a decrease in the vesicles;" possibly round cell infiltration is found in walls of the vesicles.

Myxedema is more frequent in women than men, at a ratio of five to one.

The disease is characterized by rather slow but definite changes throughout the body, and the onset is gradual and, at first, quite subtle: (1) lassitude; (2) lack of energy; (3) general slowing down; (4) increase of weight; (5) decrease of appetite; (6) non-pitting edema; (7) skin thickened and scaly, particularly, hands, arms and legs; (8) nails striated and brittle; (9) decrease in perspiration or absence of it; (10) dryness of hair, fine and thin; (11) eye lashes and eye brows thin out; (12) facial features broaden, lips thicken, nose flattens; (13) subcutaneous tissue of the entire body becomes infiltrated with non-pitting edema; (14) speech slows and thickens; (15) vision and hearing, sense of smell and mental alertness decrease in acuity; (16) forgetfulness, imperfect cerebration; (17) calm, placidity; indifference; drowsiness falls like a pall over the mental self.

Diagnosis of these cases should be made early. No doubt, early cases of myxedema are escaping diagnosis. The obesity of the

female as she passes into her climacteric cycle may obscure the presence of the myxedematous patient. Fat in the female who has passed the menstrual period should be studied for hypothyroidism and early symptoms of the marked alteration in physical features and functions of the body.

The basal metabolism rate should be studied; thyroxin influence on the metabolic rate is a useful method of determining the diagnosis, along with careful history and physical examination.

### The General Assembly of 1924 and Good Roads!

The decks are cleared at last and the ship of state may now be manned for a battle royal in the cause of good roads. This is the hour for the doctors of Virginia to go into politics. No friend of the physicians of the State would want to urge doctors to go into politics in the ordinary acceptance of that term. Nothing could happen to do greater harm to the profession than to have a large number of the physicians of Virginia go into politics for selfish ends or for political honors. On the other hand, in this big patriotic call that is given to doctors to become interested personally in the next General Assembly of Virginia, one can have no other reason than that it is a call to duty: not for selfish ends, but for the advancement of the welfare and interests of the people of Virginia.

It is needless to go into details. Every one knows that the next election of the members of the Senate and House of Delegates is the most important in the present generation from the standpoint of material and cultural development and progress.

The doctors of the State are urged to enter actively into the campaign of election of candidates. If possible, let doctors "run" themselves. The sacrifice will be great but the reward will be adequate, if a new and progressive step is taken in Virginia for the purpose of pulling Virginia out of the mud.

It is not too early to begin to think and work on this matter. The following groups of counties compose the Senate districts: (1) Washington, Smith and city of Bristol; (2) Scott, Lee and Wise; (3) Buchanan, Dickenson, Russell and Tazewell; (4) Roanoke County, Montgomery and the cities of Roanoke and Radford; (5) Giles, Bland, Pulaski and Wythe; (6) Carroll, Grayson and Pat-

rick; (7) Craig, Botetourt, Alleghany, Bath and city of Clifton Forge; (8) Rockingham; (9) Augusta, Highland and city of Staunton; (10) Shenandoah, Frederick and city of Winchester; (11) Fauquier and Loudoun; (12) Clarke, Page and Warren; (13) Spotsylvania, Stafford, Louisa and city of Fredericksburg; (14) Arlington, Prince William, Fairfax, and city of Alexandria; (15) Culpeper, Madison, Rappahannock and Orange; (16) Goochland, Powhatan and Chesterfield; (17) Albemarle, Greene, and city of Charlottesville; (18) Appomattox, Buckingham, Fluvanna and Charlotte; (19) Amherst and Nelson; (20) Campbell and city of Lynchburg; (21) Halifax; (22) Bedford, Rockbridge, and city of Buena Vista; (23) Pittsylvania, Henry and city of Danville; (24) Pittsylvania and city of Danville; (25) Mecklenburg and Brunswick; (26) Franklin and Floyd; (27) Greensville, Sussex, Surry and Prince George; (28) Nottoway, Amelia, Lunenburg, Price Edward and Cumberland; (29) Dinwiddie and city of Petersburg; (30) Isle of Wight, Southampton and Nanseamand; (31) Norfolk city; (32) Caroline, Hanover, King William; (33) Norfolk County and city of Portsmouth; (34) King George, Richmond, Westmoreland, Lancaster, Northumberland; (35) Henrico, New Kent, Charles City, James City, and city of Williamsburg; (36) Elizabeth City, York, Warwick and city of Newport News; (38) Richmond City; (39) King and Queen, Middlesex, Essex, Gloucester, Mathews.

What an array of historic names! What do they not stand for in English and Colonial American history!

What of the future, doctors of Virginia?

## News Notes

### Our Semi-Centennial Volume

Begins with this issue and it may not be amiss to say something of our journal. With one exception, *The New Orleans Medical and Surgical Journal*—the VIRGINIA MEDICAL MONTHLY is the oldest medical journal published in the Southern states. It was established in 1874 by the late Dr. Landon B. Edwards, has been published continuously since and, until its complete adoption, was known as the non-official organ of the Medical Society of Virginia. For twenty-two years it appeared as a monthly, for twenty-

two years (lacking three months) as a semi-monthly after which it resumed monthly publication. During the meeting of the American Medical Association in Richmond, in 1881, a daily edition of the journal was published that the Association news might promptly reach those interested.

Upon the death of the founder of the journal, its management and editorship was assumed in December, 1910 by the Associate Editor, Dr. Charles M. Edwards, who associated with him a staff of editors. Beginning January, 1918, the journal was changed back to a monthly publication. It remained under this management through October, 1919, at which time it was purchased by the Medical Society of Virginia as their official organ. Since then it has been under the charge of the Publication Committee of the Medical Society of Virginia, with Dr. Alexander G. Brown, Jr., as editor.

In accordance with the needs of the times, this journal has always aimed to maintain a high standard and it is our purpose now to make and keep it at least the equal of any State medical journal. To this end, we want your co-operation in every way. One of these is to patronize our advertisers. A large part of the revenue for running the journal has to be obtained from its advertising pages. All of our advertisements are acceptable to the Council on Pharmacy and Chemistry of the American Medical Association, the highest standard set.

Won't you look over our advertising pages regularly and write to and patronize our advertisers that they may know you are interested? Tell them where you saw their advertisement. This will help us all. If we personally appreciate interest manifested in us and our work, why should not our advertisers?

#### **The Southwestern Virginia Medical Society**

Will hold its next meeting in Christiansburg, May 17th and 18th. Dr. R. H. Woolling, Pulaski, presiding. Dr. E. G. Gill, Roanoke, is secretary of the Society, and Dr. A. M. Showalter, Cambria, is chairman of the local committee of arrangements for this meeting. The preliminary program shows a number of interesting papers on a variety of subjects. There will be a symposium on "Cancer," which will be discussed as follows: Etiology and Pathology, by Dr. K. D. Graves, Roanoke. Symptomatology and Diagnosis, by Dr. W. H.

Ribble, Wytheville; Surgical Complications, by Dr. T. Allen Kirk, Roanoke; Treatment (X-ray), by Dr. B. E. Rhudy, Abingdon. The discussion on these papers is to be opened by Dr. J. Coleman Motley, of Abingdon.

A subscription banquet is to be held on the evening of the 17th of May at the Courthouse.

#### **The Walter Reed Medical Society**

Will hold its next meeting at the National Soldiers' Home, Hampton, Va., Wednesday and Thursday, May 2nd and 3rd. This meeting promises to outstrip all former meetings in interest and it is expected to be the largest from the standpoint of attendance in the history of the organization. Among the visitors who will read papers are Drs. B. B. Vincent Lyon, Philadelphia; Walter E. Dandy, Baltimore; W. B. MacNider, Chapel Hill, N. C.; H. A. Royster, Raleigh, N. C.; W. L. Peple and Murat Willis, Richmond; J. E. Diehl and L. T. Royster, Norfolk. In addition to these, interesting papers will be presented also by members. Interesting clinics will be conducted by Dr. C. P. Jones, of Newport News, and Dr. J. J. Cullinan, of the staff of the Soldiers' Home.

Further information may be obtained from the secretary, Dr. L. E. Stubbs, Newport News. The president is Dr. Rea Parker, Smithfield, Va.

#### **The San Francisco Meeting.**

For the convenience of those who expect to attend the meeting of the American Medical Association in San Francisco, June 25 to 29, it is announced that, effective May 15 and daily thereafter until September 30, western railroads will place on sale round trip tickets to San Francisco, with a return limit of October 31. These tickets will permit stopovers at any point on the going or return trip. Many social, sight-seeing trips and tours are being arranged by the California committee to suit the convenience of visiting Fellows and their friends.

From a scientific standpoint, in addition to the excellent papers which will be presented in the many sections on June 25 and 26 a series of nearly one hundred diagnostic clinics will be held and, on July 2 and 3, post-convention diagnostic clinics will be held in many places in the State.

All scientific meetings, exhibits, the House of Delegates, and, in fact, all important ac-

tivities, will be held in one building, the Civic Auditorium, which is close to the commercial and hotel section of the city.

Requests for service of any kind should be addressed to Dr. W. E. Musgrave, Chairman California Committee, Convention Headquarters, 806-809 Balboa Building, San Francisco, Cal.

### **The Woman's Auxiliary to the Medical Society of Virginia.**

Is anxious to get actively to work and the Constitution and By-Laws of the Auxiliary, as tentatively submitted for adoption at the Roanoke meeting, appear under the Proceedings of Societies in this issue. As the wives and daughters of all members of the Society are eligible to membership in the Auxiliary, it is hoped they will familiarize themselves with the work of this Association and take an active interest in its proceedings. Mrs. J. Allison Hodges, Richmond, was organization chairman and was appointed a delegate from Virginia to the Woman's Auxiliary of the A. M. A. meeting in San Francisco in June.

At the Norfolk meeting, Mrs. R. Lloyd Williams, Norfolk, was elected president; and Mrs. J. Allison Hodges, Richmond, Mrs. S. S. Gale, Roanoke, Mrs. Southgate Leigh, Norfolk, and Mrs. Wm. E. Anderson, Farmville, vice-presidents; Mrs. Burnley Lankford, Norfolk, recording secretary, and Mrs. Starke Sutton, Norfolk, treasurer.

Roanoke doctors and their wives are planning for a large and interesting meeting. Begin making your plans now to be there.

### **Doctor's of Virginia—We Invite You.**

The West Virginia Medical Association will hold its annual meeting in Beckley, West Virginia, June 12, 13, 14. The Raleigh County Medical Society is busy making elaborate preparations for the entertainment of our visitors. Beckley is a splendid mountain city of 8,000 population, altitude of 2,500 feet, delightful climate, and a wonderful place to spend your vacation. The various civic, business and professional organizations of Beckley are co-operating to the limit with the medical profession in putting over the *biggest* and *best* medical meeting ever held in West Virginia. The program is going to be an unusually good one. Visitors from many states have already made their hotel reservations. We promise to comfortably care for all who attend the meet-

ing. We will rejoice in your coming, and we shall hope for your days with us to be brim full of pleasure.

Doctors of Virginia—we extend you a most cordial and fraternal invitation to attend this meeting. Come—bring your wives, daughters, sons or sweethearts. Elaborate preparations have been made for the comfort and pleasure of the ladies. Arrangements are being made for a pullman-party from Richmond to Beckley. The pullmans may be utilized for living quarters, if so desired, while in Beckley. Definite announcement relative to this matter will be made in the May issue of the VIRGINIA MEDICAL MONTHLY. In the meantime, commence making your plans to be with us, because we are expecting you, and we promise you the best-three-days-time you have ever had.

RALEIGH COUNTY (W. VA.) MEDICAL SOCIETY.

### **The W. Va. Medical Association**

Is to meet in Beckley from June the 12th to 14th inclusive. The invitation given above from the local medical society speaks for itself. It is so cordial that we hope many of our Virginia doctors will be able to make their plans to attend. West Virginia doctors are well known to the doctors of this State; a number of them also attended Virginia medical schools. Why not take this opportunity to renew old acquaintances and make new friends?

### **Married.**

Dr. Thomas Neill Barnett and Miss Mary Gladys Reamy, both of Richmond, March the 28th.

Dr. William Neill, Jr., and Miss Alice Lawrence Buckler, both of Baltimore, April 7.

### **Dr. S. E. Weymouth,**

Callao, Va., has resigned the presidency of the Callao State Bank.

### **U. S. Veterans' Hospital at Tuskegee.**

The new U. S. Veterans' Bureau Hospital, for colored veterans, is shortly to be opened at Tuskegee, Ala. It is being erected on ground donated for the purpose by Tuskegee Normal and Industrial Institute. Its capacity is about 600 beds. It has been built for colored patients only, and is the best hospital of its kind in the world. It will be the policy to select colored eligibles for appointment when reached for certification in accordance with the civil service rules. Persons who are quali-

fied and who desire to enter the Government service at this hospital should immediately request full information and the appropriate application blank, addressing the U. S. Civil Service Commission, Washington, D. C., for positions as graduate nurses for chief, assistant chief, head and staff positions; reconstruction aides in occupational therapy and physiotherapy; reconstruction assistants in same; and dietitians, chief and staff positions.

Persons wishing to apply for the following positions should send for full information and application blanks, addressing The Secretary, Fifth U. S. Civil Service District, Atlanta, Ga.: physicians, general medicine, surgery and specialists; dentists; laboratorians in roentgenology, bacteriology and dentistry; and pharmacists.

#### **The Inauguration of an Undergraduate Prize.**

At the sixteenth regular meeting of The Richmond Pathological Society held Thursday, January 18, 1923, it was moved, seconded and carried that the Richmond Pathological Society appropriate \$25.00 for a prize to be offered for the best original research work produced by undergraduate students of the Medical College of Virginia during each current year, the idea being to encourage initiative among the students. The award is to be made under conditions prescribed by a committee consisting of the President of The Richmond Pathological Society, Chairman; Dr. Cook, Professor of Pathology; Dr. Noback, Professor of Anatomy, and the Secretary:

*First*, the prize will be awarded at commencement time.

*Second*, the applicant must be a bona fide undergraduate student of the Medical College of Virginia.

*Third*, the paper must be based on original observations and must be presented to the Secretary of the Richmond Pathological Society at least one month prior to commencement.

*Fourth*, the Richmond Pathological Society reserves the right to withdraw the prize for any particular year if no paper is presented which they consider worthy.

#### **Dr. John Terrell Scott,**

Of Cragmor Sanitarium, Colorado Springs, Col., and his wife have been on a visit to rela-

tives in Lynchburg. Dr. Scott is a grandson of the late Dr. John Terrell, of Campbell County, Va.

#### **Dr. R. E. Booker**

Has returned to his home in Lottsburg, Va., after a visit of several weeks in Florida.

#### **Dr. Robert P. Kelly,**

Lynchburg, Va., leaves the latter part of April for Chicago, where he has received an appointment as a regular house surgeon at Chicago Lying-In Hospital, effective May 8th to November 8th. This is the institution of which Dr. Joseph B. De Lee is the head, and Dr. Kelly is one of the few Southern doctors who has received an appointment there. On returning to Lynchburg about the middle of November, Dr. Kelly will limit his work to obstetrics as he has been doing for sometime.

#### **The South Piedmont Medical Society**

Will hold its regular meeting in Danville, April 17, under the presidency of Dr. George B. Barrow, of Clarksville. Dr. George A. Stover, South Boston, is president. The subject for general discussion is "Pneumonia." This will be discussed under the following subdivisions: Etiology and Symptoms, by Dr. J. A. Owen, Turbeville; Pathology and Diagnosis, by Dr. R. M. Taliaferro, Lynchburg; Treatment and Prognosis, by Dr. J. J. Neal, Danville; Surgical Phases, by Dr. H. Stuart MacLean, Richmond.

The meeting promises other good papers. The annual election of officers will be held at this time.

#### **Fairfax County Health Work Continues.**

The Fairfax County supervisors, at a recent meeting, decided to continue the health work in that county, and Dr. W. P. Caton, of Fairfax, was retained as local health officer.

#### **Dr. Allen W. Freeman,**

Formerly of this city, but now of the school of public health administration of Johns Hopkins University, was the principal speaker at the annual reunion and dinner of the Hopkins alumni in Richmond, March 16.

#### **Hospital Staff, Salvation Army Home.**

Dr. Robert C. Bryan has been appointed head of the staff of physicians who will be in charge of the Salvation Army Home and Hospital, in Highland Park, Richmond. Other physicians on the staff are Drs. Thomas W.

Murrell, Benjamin H. Gray, Paul Redd, and Clifton M. Miller.

**Dr. and Mrs. Loren E. Cockell,**

Reedville, Va., were recent visitors in Fredericksburg, having gone there to see their son who was taking Pasteur treatment after being bitten by a mad dog.

**Dr. James K. Hall,**

Richmond, has been appointed by Governor Trinkle as a member of the Board of Directors of Central State Hospital, Petersburg. The appointment is for a period of six years, beginning March 1, 1923.

**Dr. W. W. Keen,**

Emeritus professor of surgery at Jefferson Hospital, Philadelphia, who was invited to deliver the John McTyre Flowers Foundation lectures at Trinity College, Durham, N. C., this month, was unable, on account of sickness, to be on hand.

**Dr. Dean B. Cole**

Has returned to his home in Richmond after a short visit to New York and other northern cities.

**Dr. Newton Still III.**

As we go to press, we are advised that the condition of Dr. McGuire Newton, of this city, is slightly better, though he is still critically ill. Dr. Newton has been ill since November with inflammatory rheumatism, with heart complications.

**Martin County (N. C.) Health Board.**

Drs. V. A. Ward, Robersonville, and James E. Smithwick, Jamesville, have been appointed members of the Board of Health of Martin County, N. C.

Dr. William E. Warren, Williamston, N. C., was re-elected County Physician and Quarantine Officer.

**The Medical Society of Virginia, Maryland and District of Columbia**

Will hold its semi-annual meeting at Sandy Spring, Md., on May the 16th. Dr. William L. Lewis, Kensington, Md., is president, Dr. Wm. T. Davis, Washington, recording secretary, and Dr. Joseph D. Rogers, Washington, D. C., corresponding secretary.

**The National Board of Medical Examiners**

Makes the following announcement as to examinations for June and September: Part

I, June 25, 26, and 27, and Part II, June 28 and 29, 1923; also, Part I, September 24, 25, and 26, and Part II, September 27 and 28, 1923.

All applications for these examinations must be made on or before May 15th. Further information may be obtained from the Secretary, Dr. J. S. Rodman, 1310 Medical Arts Building, Philadelphia, Pa.

**Dr. J. R. Adams,**

Blackstone, Va., who was confined to his home for sometime by an attack of influenza, is able to be out again.

**Dr. S. W. Maphis**

Has returned to his home in Warrenton, Va., after a visit to Atlantic City, N. J.

**Dr. William E. Brown,**

Superintendent of Blue Ridge Sanatorium, Charlottesville, Va., and his wife recently visited Mrs. Brown's former home in Buckingham County, Va.

**Dr. W. W. Chaffin,**

Pulaski, Va., was a visitor in Richmond last month, having come here for treatment.

**The Southern Public Health Laboratory Association**

Had a most successful meeting in Richmond, March 23 and 24, from a scientific standpoint. A number of prominent speakers were heard and subjects of interest discussed. On the evening of the 23rd, Mr. Aubrey Straus, secretary, entertained the members and visitors at his home. Birmingham was selected for the next place of meeting and the following officers were elected: Chairman, T. F. Sellers, of the Georgia State Laboratory at Atlanta; vice-chairman, Aubrey H. Straus, of the Virginia State Laboratory, Richmond, and secretary-treasurer, Dr. Lynn C. Havens, of Montgomery, Ala.

**Loudoun County Health Unit.**

The Loudoun County (Va.) Health Unit has started active work, with Dr. P. M. Chichester, recently of Richmond, as director, W. G. Cline assistant director, and Miss Annie Gulley, nurse. Their services will be the same as those rendered by health units in other counties.

**Dr. L. N. K. Bell,**

Formerly of Waynesboro, Va., was a recent

visitor in Richmond, and gave a talk to the students at the Medical College of Virginia, under the auspices of the Y. M. C. A. Dr. Bell was a member of the class of '16, Medical College of Virginia, and in the October after graduating, went to China as a medical missionary from the Southern Presbyterian Church. He is now connected with the general hospital at Tsing Kiang Pu, China, and expects to return to China in August.

#### **Major Henry C. Michie, M. C.,**

Of the class of '07, University of Virginia, Medical School, has received the "French Medaille d'Honneur des Epidemies (argent)," according to a notice recently issued.

#### **Dr. J. B. Woodson,**

Lowesville, Va., it is announced, will offer himself this year for re-election as a member of the State Senate from his district.

#### **Chiropractors Fined.**

Two chiropractors in Norfolk, Va., were recently fined \$25 and costs on the charge of conducting a business in that city without proper city license.

#### **The American Proctologic Society**

Has issued the preliminary program for its twenty-fourth annual meeting to be held in Los Angeles, Cal., June 22 and 23, 1923, under the presidency of Dr. E. H. Terrell, of Richmond, Va. Dr. Ralph W. Jackson, Fall River, Mass., is secretary. Meetings will be held at Hotel Alexandria and the clinics at Los Angeles County Hospital.

#### **Dr. Henry E. Davis,**

Of this city, qualified April 2, before the City Clerk, as medical inspector to be attached to the Health Bureau of Richmond. He fills the vacancy caused by the resignation of Dr. P. M. Chichester.

#### **"Sleeping Sickness."**

According to reports made to the Division of Communicable Diseases of the New York State Department of Health, 308 cases of encephalitis lethargica developed in New York State during February of this year, which is more than in any other month in the last two years.

The U. S. Public Health Service states that it has no sufficiently reliable statistics in regard to the prevalence of "sleeping sickness," or encephalitis lethargica, to warrant a state-

ment as to the prevalence of the disease throughout the United States, as it is reportable in comparatively few states.

#### **Dr. William Flegenheimer,**

Of Guinea, Va., had a narrow escape from death recently, when his auto was stalled on the railroad tracks at a crossing near his home. Realizing his danger, Dr. Flegenheimer jumped just in time to save his life and was unhurt, but his roadster was entirely demolished.

#### **Surgeons Return Home.**

The last of March, the members of the American College of Surgeons, nearly two hundred in number, who had been touring South America, left Montevideo, Uruguay, for New York City. During their stay in South America, they visited a number of the principal hospitals and spent much time in sight-seeing.

#### **Dr. Charles E. Conrad,**

Harrisonburg, Va., has recovered from an attack of influenza.

#### **Dr. A. C. Byers,**

Harrisonburg, Va., was in Roanoke, Va., on business, the latter part of March.

#### **Public Health Work of the A. R. C.**

As some differences of opinion existed among members of the American Red Cross and members of the medical profession as to the peacetime health program of the American Red Cross, a Health Advisory Committee was appointed in October, 1922, to fully consider the subject. This committee was composed of Dr. William H. Welch, Baltimore, President of the Maryland State Board of Health; Dr. Hermann M. Biggs, New York City, Health Commissioner of the State of New York; Dr. Thomas S. Cullen, Baltimore, of Johns Hopkins University; Dr. Hugh S. Cumming, Surgeon General of the U. S. Public Health Service; Dr. Livingston Farrand, Ithaca, N. Y., President of Cornell University; Dr. Franklin H. Martin, Chicago, director of the American College of Surgeons; Dr. Fred B. Lund, Boston, Chief Surgeon at the Boston City Hospital; Dr. George M. Piersol, Philadelphia, editor of *American Journal of Medical Sciences*; Dr. John H. J. Upham, Columbus, O., member of the House of Delegates of the A. M. A.; and Prof. C. E. A. Winslow, New Haven, of Yale University Medical School.

After giving the subject most earnest and exhaustive consideration, the committee unanimously adopted a report which provides for the Red Cross a definite constructive program which every member and every chapter may follow with confidence. For the success of this program, a Director of Health Service is to be appointed, as soon as a suitable person can be selected, and the recommendations of the committee put into effect. It is stated that the national Red Cross should include in its permanent membership from 10 to 20 per cent. of the population of the country.

#### **The American Laryngological Association**

Will hold its forty-fifth annual congress at Hotel Ambassador, Atlantic City, N. J., May 16-18, under the presidency of Dr. Emil Mayer, of New York City. Dr. George M. Coates, of Philadelphia, is secretary.

#### **Normal School to Give Degree Course in Physical Education.**

The Fredericksburg, Va., State Normal School for Women has been designated by the Virginia Normal School Board to offer a four year B. S. degree course in Physical Education. This will commence next session. A new concrete open air theatre has been constructed and a standard athletic field is to be constructed during this summer, to be used for outdoor athletic activities. The faculty will be increased to take care of this new degree course.

#### **Dr. Frank W. Lewis,**

Of Morattico, Va., recently underwent an operation at Johns Hopkins and is reported improved.

#### **Communicable Diseases and Travel.**

Uniform provisions governing the travel of persons suffering from contagious diseases are now in force over a large part of the United States, according to a bulletin just issued by the U. S. Public Health Service. Twenty states (Alabama, Florida, Georgia, Illinois, Kansas, Kentucky, Louisiana, Maine, Maryland, Michigan, Minnesota, Mississippi, New Hampshire, North Dakota, South Carolina, Tennessee, Virginia, West Virginia, Washington, and Wisconsin) have already adopted the Standard Railway Sanitary Code approved by the conference of the State and provincial health authorities of North America and later by the U. S. Public Health Service in con-

ference with the health officers of the United States. The essential part of the code has also been incorporated in the United States interstate quarantine regulations which apply to travel from one state to another.

The code looks to either the prevention of travel by infected persons or to the taking of measures to render such travel harmless; to the adoption of such general provisions as may render unlikely the transfer of infection to travellers by towels, drinking cups, and other objects of general use; and to the control of food and water on trains so as to protect them from contamination by the secretions of infected persons.

#### **Delegates to Good Roads Convention.**

Among the names of delegates appointed by Governor Trinkle to the U. S. Good Roads Association to meet shortly in Greenville, S. C., are noted the following: Drs. S. B. Moore, Portsmouth; C. F. Eason, Hickory; Sidney L. Scott, Fredericksburg; S. S. Guerrant, Callaway; R. W. Holley, Appalachia; J. M. Dougherty, Nickelsville; R. E. Booker, Lottsburg.

#### **The American Gynecological Society**

Is to hold its annual meeting at Hot Springs, Va., May 21, 22, and 23, under the presidency of Dr. John A. Sampson, of Albany, N. Y. Dr. A. H. Curtis, of Chicago, is secretary.

#### **Dr. Dean Lewis,**

Of Chicago, a man of national reputation and a true scientist, was the guest of the Richmond Surgical Society, on April the 6th, and read a paper on "Some Problems in Peripheral Nerve Surgery."

#### **Norton to Have Laboratory.**

The first branch of the State laboratory has just been established at Norton, Va., the Wise County board of supervisors having made the appropriation required for this purpose, together with funds already available. This new laboratory will serve the entire section of the State known as the Clinch Valley coal district. Norton was selected as the most easily accessible point of this section. Dr. W. R. Culbertson, Coeburn, Wise County Health Officer, and Dr. C. B. Bowyer, chairman of the medical committee which considered the establishment of the laboratory, deserve much credit for their work in health matters in Wise County.

**Dr. J. A. Hart,**

Recently of Norfolk, Va., is now connected with the U. S. Public Health Service and stationed at Hampton Roads Quarantine Station, Fort Monroe, Va.

**Dr. George G. Howery,**

Recently of East Radford, Va., has moved to Christiansburg, Va.

**Dr. C. W. Thomas,**

Floyd, Va., has been appointed a member of the Floyd County Board of Health, to succeed Dr. M. L. Dalton who resigned as he expected to locate elsewhere.

**Dr. and Mrs. R. H. Wright,**

Richmond, have returned home after a visit to Bermuda.

**Dr. A. A. Cannaday,**

Who has been in Miami, Florida, for two months, has returned to his home in Roanoke, Va., and resumed his practice.

**Dr. Perkins Glover,**

Arvonias, Va., was a recent visitor in Richmond.

**Dr. William P. Gilmer in Korea.**

As we announced in a recent issue, Dr. William P. Gilmer, recently connected with the Chesapeake and Ohio Hospital, at Clifton Forge, Va., has entered medical missionary work in Korea. Word has been received of his safe arrival at Mokpo, Korea, where he will work under the auspices of the Southern Presbyterian Board of Missions.

**Changes at St. Elizabeth's Hospital.**

Dr. Warren T. Vaughan has resigned as attending physician to St. Elizabeth's Hospital. He will soon assume editorship of the *Journal of Laboratory and Clinical Medicine*, and this, with the increase in his private practice, consumes his time.

Dr. William H. Higgins will be head of the Medical Department of St. Elizabeth's Hospital beginning April 1, 1923. Dr. Higgins is well known in Richmond and throughout Virginia and the South.

**Civil Service Examinations.**

The U. S. Civil Service Commission announces open competitive examinations for: Junior pathological technician, receipt of applications to close April 24 to fill a vacancy in the Army Medical Museum, Washington,

D. C.; Junior biochemist, examinations to be held throughout the country on April 25, to fill vacancies in the Public Health Service; Inspector, antinarcotic act agent, and agent, antinarcotic act, receipt of applications to close May 15, these examinations to fill vacancies under the Internal Revenue Service of the Treasury Department.

Full information and application blanks for the three examinations listed above may be obtained from the U. S. Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. Civil Service examiners at the postoffice or customhouse in any city.

**Dr. Richard W. Vaughan,**

Recently of Richmond, has moved to Statesville, N. C., where he will continue the practice of his profession.

**Standardization of Biological Stains.**

The need for American made dyes for staining specimens in the laboratory diagnosis and investigation of disease became apparent when the war broke out and America was unable to obtain these stains from foreign source. For this reason the Society of American Bacteriologists began an investigation of American made dyes that were being sold as biological stains. The results of this investigation were encouraging enough to secure the assistance of the National Research Council through whose agency a co-operative investigation was planned among the members of several national societies. The work has now been organized under a special commission. At a recent meeting of the executive committee of this commission, it was shown that already the stains available in America are practically in all cases as good and sometimes better than the best of the pre-war stains. An important fact brought out at this meeting was that, while pre-war stains were standardized only in an empirical way by buying large batches without knowing the exact composition of the dye, they must now be standardized on the basis of pure chemicals.

The commission will shortly issue certification of definite batches of stain that have been found satisfactory. These stains will have a special label bearing the name of the commission. Certifications on labels not bearing the name of the Commission are made by the manufacturer or dealer and have not the approval of this commission. The Chemical

Foundation is supporting the work of this commission financially.

#### **Dr. C. S. Dodd.**

Petersburg, Va., has been named on the board of directors of the City Savings and Land Corporation, a new bank organized in that city.

#### **Health Legislation in Sixty-seventh Congress.**

During the four sessions of the sixty-seventh Congress, over 21,000 bills and resolutions were introduced in both branches. Of these only about 350 bills and resolutions were of direct interest to sanitarians. Of the 931 laws placed on the statute books during this Congress, only 31 have a direct bearing on public health.

#### **The Association of Surgeons of the Southern Railway**

Will hold its twenty-seventh annual meeting in Charleston, S. C., May 22 to 24, under the presidency of Dr. W. M. Cunningham, Corona, Ala.

#### **The Virginia State Dental Association**

Will hold its annual meeting jointly with the North Carolina Dental Society, at Pinehurst, N. C., April 30, May 1, 2, and 3, with headquarters at Carolina Hotel. Dr. W. M. Sturgis, Warrenton, is president, and Dr. Harry Bear, Richmond, secretary, of the Virginia Association.

#### **Dr. George M. Cooper,**

Raleigh, N. C., has been appointed assistant secretary of the State Board of Health of North Carolina.

#### **Dr. Hubert Work,**

After serving as postmaster general under the Harding administration, has become Secretary of the Interior and has taken his place as a member of the President's cabinet.

#### **Dr. Fletcher H. Harris,**

Henderson, N. C., has been appointed health officer of Vance County, North Carolina, succeeding Dr. B. A. Olds, resigned.

#### **New York City Health Commissioner.**

Dr. Frank J. Monaghan has been appointed health commissioner of the City of New York, to succeed Dr. Royal S. Copeland, who is now in the U. S. Senate. Dr. Monaghan has been the deputy commissioner.

#### **Dr. Everett F. Long,**

Raleigh, N. C., has been appointed director of county health work of North Carolina, to succeed Dr. Knox E. Miller, of the U. S. Public Health Service, who has been assigned to duty in Louisiana.

#### **Dr. Robert A. Ashworth,**

Moundsville, W. Va., has been elected secretary of the Marshall County (W. Va.) Medical Society.

#### **New Hospital on Site of old One.**

The old building on North Twelfth Street, this city, formerly used by the Retreat for the Sick, is being torn down to make space for the third of the buildings in the group to be used by the Medical College of Virginia. Plans for the building have not yet been worked out but it is understood that this building is to replace the present one used as Memorial Hospital, and that the new building will be connected by underground passage ways with the Dooley and St. Philip's Hospitals. This building will complete the hospital division of the Medical College of Virginia.

#### **Dr. J. H. Crouch.**

Recently of Smithfield, R. D., Va., has been appointed full time health officer of James City County, Virginia, with headquarters at Williamsburg.

#### **Physician Wanted.**

To rent or buy on reasonable terms, good country home of seven rooms and bath, near Lynchburg, Va. Twelve acres excellent land, garage, barn, fruit. Good farming section. Convenient school and churches. Owing to urgent community need, will give physician first four months rent free. Address "H. E. Steptoe, Lynchburg, Va." (Adv.)

#### **Wanted.**

A physician to locate in a very promising community. Address P. O. Box 141, Millboro, Va. (Adv.)

#### **Wanted:**

By a senior medical student, of class A school, a position from June 1 to September 15, as an assistant or relief undergraduate physician. State terms. Apply P. O. Box 371, Richmond, Va. (Adv.)

## Obituary

### Dr. Eugene Myron Herbert,

Of Roanoke, Va., died recently from influenza. He was born in Norfolk, Va., fifty-four years ago, and studied medicine at the Atlanta College of Physicians and Surgeons, from which he graduated in 1902. He then returned to Virginia and joined the Medical Society of Virginia the same year.

### Dr. Andrew Browne Evans, Jr.,

Of Church View, Va., died March 18, after a short illness. He was a native of Middlesex County, Va., and was 49 years of age. He was a graduate of the Southern Medical College, Atlanta, in 1892. Shortly afterwards he located at Church View and had since practiced in that section. He is survived by his widow, a son and a daughter. Dr. Evans was at one time a member of the Medical Society of Virginia.

### Resolutions of respect on the death of Dr. W. W. Rangeley.

The Montgomery County Medical Society, at a meeting on March 6, passed the following resolutions:

WHEREAS, God in his infinite wisdom has seen fit to remove from our midst our esteemed friend and co-worker, Dr. W. W. Rangeley, and

WHEREAS, He has been for a number of years a member of our County Medical Society, always true and faithful to his duties, and

WHEREAS, We recognize his ability, not only as a physician, but as a member of society in this community, to the extent that it will be a great loss, not only to the Medical Society, but to the community at large; Therefore be it

*Resolved by the Montgomery County Medical Society:*

*First,* That we, his colleagues, honor his memory because of the high and distinguished characteristics which signalized his life, both as a man and as a physician.

*Second,* That we revere his memory and accord him a position of prominence in the roll of distinguished physicians who have served the county and the state.

*Third,* That we express our sympathy to his bereaved family, and request that the secretary transmit these resolutions to them, and also spread these resolutions on the minutes, and publish them in the local press.

MONTGOMERY COUNTY MEDICAL SOCIETY.

By A. M. SHOWALTER, *Secy.-Treas.*

### Dr. George Frank Lydston,

Of Chicago, died in Los Angeles, Cal., March 14, his death being due to pneumonia. Dr. Lydston was a native of California and was 65 years of age. He graduated from Bellevue Hospital Medical College, New York, in 1879, but, after service in several New York hospitals, located in Chicago, where he had

since made his home. He was professor of genito-urinary surgery and venereal diseases in the College of Physicians and Surgeons, Chicago, for many years. Dr. Lydston was also well known as a writer of ability and had made contributions to both medical and general literature.

### Dr. Cyrus Lee Stevens,

Athens, Pa., an ex-president and for many years secretary of the Medical Society of the State of Pennsylvania, died February 19, after a long illness. He was prominently identified with the medical interests of his State as also of the American Medical Association, in which he was a member of the House of Delegates for six years. Dr. Stevens was for some time editor of the *Pennsylvania Medical Journal*.

### Dr. Walker Gill Wylie

Died at his home in New York City, March 13, at the age of 75 years. He was a native of Chester, S. C., and, upon leaving the University of South Carolina, he served throughout the Civil War. Following his graduation in medicine from Bellevue Hospital Medical College, New York, in 1871, he went abroad to study the Nightingale system and, upon his return, established the first training school for nurses at Bellevue Hospital. He was for many years professor of gynecology at New York Polyclinic Medical School, having recently been made professor emeritus.

### Dr. Lewis Coleman Morris,

Of Birmingham, Ala., and a prominent surgeon of that place, died suddenly while at dinner, March 23. He was born in Hanover County, Va., and owned the old home place there, which he visited every year. Dr. Morris was fifty-one years of age and graduated in medicine from the University of Virginia in 1892. He served there for one year as demonstrator in anatomy, after which he moved to Birmingham. His wife and three children survive him.

### Dr. William Winston Snead,

Of Harlan, Ky., died in Louisville, March 17, from pneumonia following an operation. He was 44 years of age and a native of King William County, Virginia. Dr. Snead studied medicine at the University of Virginia, graduating in 1906. Shortly thereafter, he moved to Kentucky where he practiced medicine and was much interested in the civic and business affairs of his community. The interment was made in Richmond, Va.

## Spring pollens bring Allergy's manifestations

**S**QUIBB ALLERGENS offer a safe and effective means of diagnosing those idiosyncracies responsible for many of the common and obscure diseases of the skin and upper air passages. The value of the Allergens in the anti-anaphylactic treatment of such sensitization through desensitization is now thoroughly established.

With Spring come many of the flowers and garden products known to produce such sensitization. Every physician will find abundant need for these valuable diagnostic agents during the coming Spring months.

The Squibb Allergens are highly concentrated proteins from food, pollens, and other common materials with which man is daily brought into contact, especially purified for diagnostic purposes.

The Group Allergens, or combinations of those proteins producing similar clinical manifestations, represent a distinct advance in diagnostic technic. They simplify the diagnosis by reducing the number of tests required to a minimum.

*Write for complete descriptive literature and lists of Squibb Allergens and Group Allergens now available.*

# CALCREOSE

## Creosote in Pulmonary Tuberculosis

Powell, Latham, Ransome and other clinicians who have given the treatment of pulmonary tuberculosis special attention are of the opinion that creosote not only produces a beneficial effect on the digestive organs, and, so, on general nutrition, but also is of undoubted value in lessening the cough and the amount of expectoration.

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime.

CALCREOSE has the pharmacologic action of creosote but does not have the untoward effects on the digestive tract that creosote has. Patients do not object to taking CALCREOSE.

Write for the "Calcreose Detail Man."

**Francis H. Smith : 1829-1906**  
**Founder of The F. H. Smith Company**

Fifty years ago the late Francis H. Smith, who was then employed in the House of Representatives and also a member of the commission appointed by President Grant to settle the Sioux Indian disputes, decided to go into business for himself.

Born and raised on a farm in Connecticut, he knew that the foundation of all wealth was land. He knew, furthermore, that the presence of the National Government in Washington, D. C., was a **guarantee of constantly increasing real estate values.** He knew that money would be needed to finance the Capital's expansion.

#### Started in 1873

So it was, in 1873, that Francis H. Smith opened an office and engaged in the real estate mortgage loan and investment business.

In 1873 there were no apartment houses in Washington and only thirty-three small hotels. Today there are approximately a thousand handsome apartment structures and some one hundred and twenty-five hotels, which rank with the best to be found in any city in the world.

#### Developing Washington

The F. H. Smith Company has played its part in this work of development. Buildings like these necessarily had to be financed in order to be built. Such financing in the

majority of cases has been in the form of mortgage loans.

It is these loans—loans on apartments, hotels, office buildings, etc.—that are offered by us to the investing public in the form of First Mortgage Bonds. The security back of them is Washington real estate—improved, income-producing property.

#### Safe for 50 Years

Our First Mortgage Investments have behind them a record of **no loss to any investor in fifty years.** Funds may be invested for as short a period as two years or as long as fifteen years, in denominations of \$100, \$500 and \$1,000.

**The interest return of 6½% is made all the more attractive by definite tax free features.**

Our Investment Savings Plan puts these investments within the reach of every-one who can save even as little as \$10 a month.

Let us send you a free copy of our Golden Anniversary booklet. It contains the illustrated story of F. H. Smith's remarkable career and of one of the most interesting periods in the Nation's Capital.

The F. H. Smith Company,  
 Washington, D. C.

Without any obligation on my part, you may send me your Golden Anniversary booklet, together with information about first mortgage investments in the Nation's Capital.

### SOME REACTIONS IN THE TREATMENT OF SYPHILIS AND THEIR PROBABLE SIGNIFICANCES.\*

By S. G. GILL, A. B., M. D., Norfolk, Va.

The tendency in the recent treatment of syphilis is to render the drugs easier of administration; to cause less reaction to the patient, and at the same time to promote sufficient treponemicidal activity on the spirochaetae pallidae.

Our experience in the treatment of many luetic cases has convinced us that the more arsphenamin has been adulterated or changed to try to meet these requirements, the less potent has become the drug in its therapeutic effects, both clinically and serologically.

Thus, in a large number of cases of secondary and tertiary syphilis treated with as many as eight injections of the various compounds of arsphenamin and fifteen injections of mercury, the Wassermann has become unaffected or to a greater degree positive, while similar conditions treated at the same time with arsphenamin, there has been a more marked clearing up of lesions and symptoms and an appreciable percentage of persistent negative Wassermann tests. We came upon this conclusion on experimentation of cases that were serologically and clinically as similar as possible with due regard to previous treatments, if any, and length of the disease.

Neo-arsphenamin has been condemned by public assent and relegated to a secondary place in the rank of arsenicals.<sup>1</sup> However, on account of its comparatively low toxicity and freedom from severe reactions, we have found it useful in certain cases.

In the treatment of debilitated syphilitics—especially those persons suffering with con-

comitant tuberculosis, of which we have many, or valvular diseases, or even when they are weakened by the ravages of syphilis itself—we have found it profitable to carry them through a course of neo-arsphenamin and mercury until they have regained enough strength to react properly to arsphenamin.

Silver salvarsan is passing through a hectic period of diversified opinion as to its efficacy. To date it is impossible to arrive at a definite conclusion as to its efficiency.

Arsphenamin and its substitutes, for subcutaneous injection, have already been studied experimentally.<sup>2</sup>

Mercury in many forms has been used in the treatment of syphilis, as rubs, intramuscularly, inhalations, internally and intravenously. Of late the intravenous methods of administration seem to have met with success by several prominent syphilographers and bacteriologists.

Thus it is interesting to note that arsphenamin and its compounds, as well as mercury in its different forms, are running the gamut of new compositions and of varied methods of administration.

Having already rendered arsphenamin easier of administration by using a few simple additions to the salvarsan gravity apparatus,<sup>3</sup> we tried to experiment with the two other main issues in successful treatment, viz.—“to cause less reaction to the patient and at the same time to promote sufficient treponemicidal activity on the spirochaetae pallidae.”

In order to try to eliminate some of the reactions, we tabulated them in a series of over one thousand administrations of arsphenamin and neo-arsphenamin in various dosages. In our series we found that we had better clinical and serological results in those that showed reactions to the drugs, but in some cases we were able to eliminate or ameliorate the unnecessary reactions.

#### GENERAL CLASSIFICATION OF REACTIONS.

The reactions are classified as to male and female and the following types:

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

1. Nitritoid, or those that showed vasodilatation, or immediate reactions.

2. Vomiting.
3. Chills and fever.
4. Diarrhea.
5. Slight malaise.
6. Severe.
7. No reaction.

The arsphenamin was administered by gravity and modification of gravity, and the neo-arsphenamin was diluted to make 10 c.c. of solution.

After thoroughly testing out both methods of administration of arsphenamin, we found no appreciable difference in the reactions. A slightly concentrated solution was used because we had only one available table, and many patients to treat. In debilitated patients, as stated before, we first used neo-arsphenamin, but later on, when the patient's condition became stronger, used either drug. Some cases were given one drug through a whole course, and some the other respectively.

In 473 injections of arsphenamin given to men, 358 had no reaction, and 115 or 24% had reactions of some description. In 226 injections of arsphenamin given to women, 145 had no reaction and 81 or 35% had reactions.

In 170 injections of neo-arsphenamin given to men, 136 showed no reaction, and 34 or 2% showed reactions. In 223 injections of neo-arsphenamin given to women, 143 gave no reactions and 80 or 35% had reactions.

It is interesting to note that we had more reactions in women and that they showed the same percentage of reactions to arsphenamin and neo-arsphenamin.

*Nitritoid Reactions.*—Nitritoid reactions occurred more often in women and in some cases were unaffected by dosage or method of administration. Of the sixteen such reactions in women, we found definite lack of ovarian secretion, either caused by previous operations or diseases of these organs. By the internal administration of ovarian substance, beginning five days before subsequent administration, we were able to eliminate this reaction in about 90% of these cases. As examples of this we will relate two cases: On March 14, 1922, two women had severe nitritoid reactions from .6 gms. neo-arsphenamin. Both these subjects had had their ovaries removed some years previous. Ovarian substance was prescribed for both of them and with the following tabulated results. March 21, 1922, neither had any

reaction from .6 gms. neo-arsphenamin. March 28, neither had reaction from .4 gms. arsphenamin. April 3, neither had any reaction from .6 gms. neo-arsphenamin. On April 11, 1922, no reaction from .4 gms. arsphenamin, and so on until May 9, 1922, when one of them had a severe nitritoid reaction from .6 gms. neo-arsphenamin. This woman had discontinued taking her ovarian substance a few days previous.

Although the nitritoid reaction has never proved a serious one and usually can be readily controlled by the hypodermic administration of adrenalin, it is very distressing to the patient and also delays the physician when he has a large number of patients to treat in a short time. We have lately made it a rule to particularly get a history from every woman applying for treatment in regard to her previous operations and her menstrual condition.

There is one more case in this series that is probably interesting. Mrs. T., whose husband had recently died of neurosyphilis, had a 4+ Wassermann test May 16, 1922. This was about her usual time to menstruate. She received nine injections, .6 gms. neo-arsphenamin and nine injections mercury between this date and August 1, 1922, during which time she had had no menses. She had no reaction until the last injection August 1, 1922, at which time she had a marked nitritoid reaction, and one day afterwards her menstrual flow commenced. We assumed that the internal secretion of her ovaries was sufficient up to the time of her ninth injection. It may appear to some that we have laid too much stress on organotherapy in combating nitritoid reactions in these women, yet it has proven more satisfactory than the previous hypodermic administration of adrenalin.

Nitritoid reactions in men, in our series, were not as severe as those in women. Of the eleven cases we had, all were easily controlled by the hypodermic injection of adrenalin.

*Vomiting.*—In our series vomiting was the most consistent form of reaction with the exception of slight malaise. Some cases reacted at once, and others a few hours after the injection. Thirty out of 473 injections of arsphenamin in men, or 6%, had this reaction. Forty of the 226 women injected with arsphenamin, or 17%, vomited. Fifteen out of 170 men injected with neo-arsphenamin, or 8%, and 20 out of 223 women injected with neo-

arsphenamin, or 8%, vomited. A large number of these cases were from the City Jail and, although given proper instructions as to diet, several of them paid no attention to directions at all. A certain percentage of these cases ate fruit several hours or just before the administration of the drug. We found that the ingestion of acid fruits and the condition of having overloaded stomachs probably caused the majority of these reactions; however, there were some patients who had this reaction notwithstanding the fact that they apparently carried out our instructions as to diet.

*Chills and Fever, Diarrhea and Malaise.*—Chills and fever, diarrhea and malaise were reactions that we did not consider of much importance. The liberation of toxins from the destruction of the spirochetes would necessarily cause a reaction and in proportion to the amount of secondary eruption or localized infection.

The percentage of cases having malaise were as follows:—

- 42, or 8%, in arsphenamin to men.
- 25, or 11%, in arsphenamin to women.
- 11, or 6%, in neo-arsphenamin to men.
- 41, or 18%, in neo-arsphenamin to women.

*Severe Reactions.*—Of the five severe reactions we were able to tabulate, the outstanding significance is that the Wassermann test became negative; and of the four with whom we have kept in touch, none has as yet showed a reversion to a positive test. It is true that we have only had these cases under observation for from five to nine months after their severe reactions. All these cases are in good clinical condition; however, we realize that a further study is necessary.

We have had the idea and the conviction for some time that the ideal treatment for syphilis would be to give as large doses of arsphenamin as the patients can tolerate. A reaction is more to be desired than condemned, provided the incidental, useless causes can be eliminated. These causes would embrace a large variety of functional and organic conditions that could be treated in order to enable a larger dose of arsphenamin to be administered.

Insufficient treatment of syphilis is worse at times than no treatment at all. "Ehrlich's explanation of neurorecurrence is based on the theory of a sterilization which just falls short of being complete."<sup>4</sup>

It has been our experience in the treatment

of syphilis with arsphenamin that we will get reactions quite frequently if a large dose is given. We have found, however, that the results justify maximum doses, provided one has the facilities for after treatment and for proper care of the patient. We, therefore, recommend maximum doses of arsphenamin for syphilitic patients when it can be tolerated, but strongly advise individual treatment to meet the existing conditions of the patient.

No doubt there are many ways to eliminate unnecessary severe reactions. When these avoidable reactions have been excluded and the patient is given the largest doses conforming to safety, we believe the results will be better than using any standard universal dosage.

We realize that we cannot come to any definite conclusion as to therapeutic efficiency based on as few as five cases, yet it is a significant fact that these were the only severe reactions we were able to tabulate. None of these cases, at any time during their treatments, showed any marked nitritoid reaction except those having Jarisch-Herxheimer reactions, and the severe reactions came on within one to five days after the administration of arsphenamin. Two of these cases had definite hepatic symptoms, one had exfoliative dermatitis, and two can probably be classified as having quite severe Jarisch-Herxheimer reactions.

We will report in brief one case of each form of these reactions.

*CASE I. Exfoliative Dermatitis.*—R. W., White, male, age 21, single man. Seen by us October, 1921. He had had the diseases of childhood, including articular rheumatism.

*Examination.*—Patient had had for two months a chancre on lower lip and an enlarged gland just beneath right lower jaw. He had mitral regurgitation, moderate amount of albumen in his urine and a kyphosis due to his rheumatic attack. Wassermann test 4+.

*Treatment.*—He received weekly injections, .4 gms. arsphenamin and one gr. soluble mercury, with only slight reactions until the fourth injection of arsphenamin, November 30, 1921. Four days after this injection, patient noticed an itching sensation all over body and legs. Next day he had an urticarial like rash over body and legs. Treatment discontinued.

Five days later I was called to see patient, and at this time he had large vesicular erup-

tion over body, face, scalp, feet and penis. His eyes were completely closed from the swelling of the surrounding tissues and his breath very foul.

His condition became critical; he could not move in bed on account of weakness; there was a continuous dripping discharge from the breaking of the vesicles; at times he suffered from anuria and constipation.

Later on his skin became very scaly all over his body and extremities and, each time olive oil was applied and warm sponge baths given, a large amount of desquamated skin came off and pinkish new skin would show underneath.

On January 8, 1922, patient had regained his strength and there were large spotted brownish discolorations all over his body. Wassermann negative.

April 14, 1922, Wassermann negative.

August 21, 1922, Wassermann negative.

September 15, 1922, Blood Wassermann and spinal fluid Wassermann negative.

*Comment.*—The patient's weakened condition and the possibility that there was a slight Herxheimer reaction before the last injection given to the patient, may have been the cause of his severe reaction.

*Liver Reactions with Jaundice.*—"Milian states that in 2,125 injections of arsphenamin, he has observed jaundice and liver symptoms 17 times. He found that jaundice usually does not appear until about two months after treatment, and that it usually developed in those who had received insufficient treatment."<sup>5</sup>

CASE II.—Mrs. S., age 49, white. Had diseases of childhood, malaria and dyspepsia. Husband died of rheumatism and syphilis ten years previous. On admission she had had rheumatism and occipital headache six years. Wassermann 4+.

Patient took seven injections arsphenamin and six injections mercury with no reaction. Three days after the eighth injection of arsphenamin, she had an urticarial like eruption over body and at the same time her face and feet swelled up very much and became purplish colored. These symptoms lasted about two weeks. Her urine was negative for albumen, but filled with bile. Her liver was very much enlarged.

As soon as eruption left, her eyes and skin were markedly jaundiced. Two weeks later patient complained of pain in her back. At this time no jaundice but slight palpitation of the heart.

Patient recovered in about two months after her severe reaction and felt well. She has had a continuous negative Wassermann test for six months.

This woman had her menopause just about the time of her severe reaction. She menstruated regularly one year before taking treatment, twice the month she had severe reaction, and has not menstruated since.

*Jarisch-Herxheimer Reaction.*—"This reaction consists in the exaggeration of the pathologic and hence the clinical processes, following the administration of antisyphilitic medication. Clinically, it is noted that the lesions become of a brighter color, and that some swelling usually takes place."<sup>6</sup>

CASE III.—Miss M., in 1919, started taking treatment for syphilis. At that time her Wassermann test was 2+. After her first course of treatment, her Wassermann was 4+. This woman, after having taken treatment for over a year, and after having had a continuous 4+ Wassermann test, was given two courses of treatment, consisting of 8 injections of neoarsphenamin and 15 injections of soluble mercury each, after which her Wassermann was 4+. During the third course of treatment given her by us, which consisted of administration of arsphenamin and mercury, she developed a rash over her body, and both knees became swollen and red. She had a negative Wassermann test a few weeks later. Unfortunately, we have been unable to see this woman again to get any more tests on her, but we understand she is still living in this city.

#### SIGNIFICANCE OF CONDITIONS ASSOCIATED WITH SYPHILIS.

It is well to bear in mind that though a patient may have well defined clinical and serological syphilis, yet the very condition for which he seeks relief is some concomitant unassociated lesion. There is a tendency of late years, since the Wassermann test has become so popular, to relegate a case for syphilitic treatment, as soon as this test is found to be positive, not always taking into consideration that this may be only one of the diseases with which the patient is afflicted.

One case that proves this significance came to us recently. A negro had been treated locally for an ulceration on his penis which, when seen by us, looked as if a penile amputation would be necessary in order to save

other structures. He had typical skin lesions of syphilis, and the bony septum of the nose was partially destroyed.

Three injections of arsphenamin cleared away the lesions on his skin, but the ulceration on his penis continued to spread, two other similar ulcerations appearing on the inner side of left testicle, and inner side of left leg respectively.

We tried intravenous injections of tartar emetic for granuloma inguinale, and the patient's genital lesions improved after the first dose, showing continuous betterment until cured. The patient is now under syphilitic treatment.

This case is cited to illustrate the clinical significance in the treatment of syphilis associated with some other disease, and it is always well to bear in mind that, although a patient may have syphilis, he may have other contemporaneous diseases as well, along with other symptoms due to these diseases.

CONCLUSIONS.

1. In our series of cases, arsphenamin and neo-arsphenamin are both useful in the treatment of syphilis, but the former is more potent and should be used whenever practicable.

2. A great many useless, unnecessary reactions from the administration of the drugs can be eliminated, thereby increasing its usefulness. No attempt has been made to incorporate in this paper every method that we have tried out to avoid these reactions.

3. There are very often many diseases and conditions associated with syphilis that we must not expect to respond to luetic treatment.

4. That, although in our series the severe reactions were followed by negative tests and eventually clinical improvement, we hope some day to be able to increase the tolerance of the drug to the desirous therapeutic effects without these distressing phenomena.

LUMBAR PUNCTURE IN THE ROUTINE TREATMENT OF SYPHILIS.\*

By WARREN T. VAUGHAN, M. D., Richmond, Va.

Many cases of syphilis are treated routinely with intravenous arsphenamine, mercury and iodides, with no investigation whatsoever of the reaction of the spinal fluid. In the majority of instances the duration of treatment is controlled by the intensity of the blood Wassermann reaction, no attention being paid to the possible persistence of a positive spinal fluid after the blood has become negative. In a large proportion of late neurologic syphilides with positive spinal fluids, the blood Wassermann is negative. I wish to present a few cases in which these facts are well established and to suggest remedial measures.

Mr. M., when first seen, complained of "an unbalanced feeling." The patient was a mid-

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

de-aged man with an alcoholic history and a story of having had gonorrhoea several times and a chancre twenty-five years previously. He was married, had four children, none of whom apparently showed signs of congenital lues. His wife had had no miscarriages. He had received only local treatment for his chancre, and had been told that secondary lesions did not develop. Two years before the first examination he had developed some unsteadiness in walking, with slight impairment of vision and urinary incontinency. He then received two intravenous doses of salvarsan and potassium iodide. Within six months the blood Wassermann had become negative, and treatment had been discontinued, but the symptoms progressed. Examination at the first visit showed typical Argyll-Robertson pupils, absent knee-jerks and Achilles jerks, a positive Romberg, and impaired co-ordination in the lower extremities. The liver was enlarged. Systolic blood pressure was 160. Lumbar puncture was performed, and the spinal fluid showed 20 cells per cubic mm., and a positive globulin reaction. The blood Wassermann was negative. The spinal fluid Wassermann was four-plus, with .5 cc. of fluid.

Here is a case with insufficient intravenous treatment, in which no attention was paid to the central nervous system until after irreparable damage had occurred, when the spinal fluid was found to be still strongly positive.

Mr. W., when first seen complained of inability to walk well. Fourteen years previously he had developed a genital chancre which was followed in due time by a secondary rash. He took mercury inunctions and medicine internally for a period of two years. Four or five years later he complained of feeling "light-headed," and later noticed that he could not walk straight. Two or three years after this he began experiencing sharp shooting pains in his hands and his feet, with occasional twitching of the muscles of the extremities. During the two years previous to the first visit he had had rather indefinite abdominal pains, intermittent in character, never severe, and not connected with his meals. On physical examination the pupils were found to be Argyll-Robertson in type, and the tendon reflexes were all absent. There was marked ataxia of the upper and lower extremities, and the patient was scarcely able to stand without support. The blood pressure was slightly elevated, the systolic being 170. A diagnosis was made of

tabes dorsalis and hypertension. The blood Wassermann reaction was negative, while the spinal fluid Wassermann was four-plus with .2 cc. of fluid. The cell count was 76, all lymphocytes, and the globulin was increased, four-plus.

Mr. L., aged 49, first complained of dizziness, weakness in the legs, and inability to walk straight. From the examination, a diagnosis was made of syphilis of the central nervous system, chronic nephritis, and hypertension. He was treated over a period of several months. Throughout the period of treatment the blood Wassermann was constantly negative. The original spinal fluid Wassermann was positive, and the cell count, 16. Under treatment the cell count fell to 2 per cubic mm., and the spinal fluid Wassermann improved so that it eventually became two-plus and, to obtain this reaction, 2 cc. of spinal fluid were necessary. There was considerable subjective improvement.

Mr. O., aged 62, when first seen, complained of pains in the legs and arms of twenty years' duration, and so severe as to require the use of morphine. He had had a gonorrhoeal infection when young, and a chancre with satellite bubo but no secondary manifestations, twenty-five years previously. He had had various therapeutic measures applied for his symptoms, among which had been the extraction of all of his teeth. He had received one course of mercury. His nervous symptoms had started with headache, but later the pains had passed into the extremities and disappeared from the head. The attacks consisted of typical crises coming on three or four times a year at first, but steadily increasing in frequency, and relieved only by the use of morphine. He complained of pains in the legs, griping pains in the abdomen, marked constipation, and formication and ataxia at night. Again the pupils were Argyll-Robertson in character, unequal and irregular. The tendon reflexes were absent, there was a positive Romberg, some roughening over both tibiae, and a tendency to a positive Babinski in the right foot. In this foot there was a loss of pain sense, with preservation of tactile, muscle and temperature senses. The patient also had a typical tabetic bladder. A diagnosis was made of tabes dorsalis, secondary anemia, chronic cystitis and chronic morphinism. The blood Wassermann was negative. The spinal fluid Wassermann was four-

plms with 2 cc. The cell count was 0, and the globulin test negative.

The following cases differ from those just described, in that the blood Wassermann was negative, in spite of the fact that the patients had never received antiluetic treatment.

Miss F., aged 29, first complained of nervousness and of weakness of the left leg. Venereal disease was denied both by name and symptom. Eight months previous to the first examination her left leg below the knee began to feel weak, and she had experienced some difficulty in walking, particularly in climbing. The symptoms gradually progressed, and there had developed a sensation of numbness in the same extremity. At the same time the right upper eyelid had begun to droop and to swell. She had also noticed that the right pupil was larger than the left. She consulted a physician, who put some drops in the right eye, and the pupil became temporarily smaller. She complained of some blurring of the vision, and occasional diplopia. Physical examination showed a perforated nasal septum, unequal pupils which did not react to light but did react well to accommodation, absent knee jerks and ankle jerks, and a marked swaying in Romberg's position, with considerable difficulty in turning about quickly. A diagnosis was made of tabes dorsalis. The patient had never had antiluetic treatment. The blood Wassermann was negative. The spinal fluid Wassermann was four-plus with 1 c.c.; cell count 14, all mononuclears. Spinal fluid globulin was one-plus.

Mr. G., aged 42, first complained of pains in his chest. His family history and past history were both negative. Six months before admission he had had a double hernia operation. Four months before admission he had first experienced a poorly described pain in the skin over the chest. This persisted constantly, but was never very severe. On examination he was slightly irrational. The pupils were sluggish, irregular and unequal. The tendon reflexes were all exaggerated except the Achilles reflexes, which were present but obtained with some difficulty. A diagnosis was made of dementia paralytica. The patient denied both gonorrhoea and syphilis, and had, so far as he knew, never received anti-syphilitic treatment. The blood Wassermann was negative, but the spinal fluid reaction was four-plus. The spinal fluid cell count was 20, all lymphocytes, and the globulin was two-plus.

Summarizing the cases so far described, we may emphasize that a negative blood Wassermann does not rule out syphilis of the central nervous system, neither in those cases which have undergone routine antisyphilitic treatment nor in some cases in which there has been no previous treatment whatsoever. Where symptoms or signs point to a possible central nervous involvement, a diagnostic lumbar puncture should be performed, even though the blood reaction be negative and even though there is a negative past history both for infection and for treatment.

The converse is likewise true, as we shall see in the following cases. Individuals with positive blood Wassermanns, having no central nervous symptoms or signs, may yet have positive spinal fluid Wassermanns. In these cases particularly, the fact should be recognized early, and the condition of the spinal fluid should be followed as a guide, together with the condition of the blood Wassermann and the clinical findings.

Mrs. K., aged 31, was admitted with a traumatic ulcer on the right leg. The ulcer had persisted for a year, nearly healing, only to break down again. She had no nervous symptoms and no neurologic symptoms. The pupils reacted both to light and distance, although the reaction to light was poorly sustained, there being a moderate hippus. The patient was somewhat euphoric, although not pathologically so, and there was no memory defect and no defect of judgment. The blood Wassermann was four-plus. The spinal fluid was four-plus with .2 cc., cell count 18 per cubic mm., all mononuclears, and the globulin two-plus.

Mr. B., aged 60, entered complaining of pains in the abdomen and back. He knew that ten years previously he had contracted syphilis, and had developed the usual secondary lesions. Treatment had consisted of mercury pills by mouth three times a day over a period of three years. After this for several years he had taken the same pills for three or four months each spring. He had remained well until three months before the first visit, when he had developed attacks of epigastric pain, coming on immediately after breakfast, and relieved by the taking of food. They also occurred at night after he had retired. The blood Wassermann had been positive five years previously, and was again positive when the patient was first examined. Detailed neuro-

logic examination was entirely negative. The patient felt that his memory had become impaired during recent years. The spinal fluid Wassermann was four-plus with .3 cc., cell count 30 per cubic mm., 97% mononuclears and 3% polynuclears, and the globulin reaction was three-plus. A diagnosis was made of syphilis, syphilis of the central nervous system and dementia paralytica.

Mr. G., aged 65, has had recurrent attacks of rheumatism since the age of 35, with some indefinite pains in the stomach usually worst during wet weather. Fourteen or fifteen years previously he had had a nervous breakdown of indefinite description, but in which he had been extremely ill. There had been a slow convalescence therefrom. On admission, he was suffering from palpitation and dyspnea on exertion. The only neurologic symptom consisted of numbness and "pins and needles" sensation in the right hand. There were no objective neurologic findings whatsoever. The blood Wassermann was four-plus, and the spinal fluid reaction four-plus with .3 cc.; globulin two-plus. Cell count was not made because of the presence of blood in the spinal fluid.

Mr. B., aged 51, complained of frequent micturition, with a throbbing in his head at night. Eleven months previous to admission he had contracted a chancre, which was followed by secondary manifestations, and was treated by two intravenous injections of salvarsan five weeks apart. This had relieved all of his symptoms except the sensation in his head and the frequent micturition. Physical examination was essentially negative except for right middle ear deafness and rather hyperactive reflexes. The deafness was found to be due to a large accumulation of wax in the ear. Bone conduction was normal. The blood Wassermann was four-plus, spinal fluid Wassermann was four-plus with .4 cc., cell count 11, globulin one-plus.

These patients showed positive spinal fluid findings in spite of absent or minimal signs of cerebrospinal involvement. Conversely, again, it occasionally happens that undoubted syphilitic nervous lesions may occur in the presence of a negative spinal fluid. The spinal fluid reaction is determined chiefly by the extent of involvement of the meninges. With purely cortical or cerebral vascular invasion in the absence of meningeal irritation the spinal fluid may be expected to be negative.

The following case, with signs pointing to cerebral vascular damage, showed a positive blood Wassermann and a negative spinal fluid Wassermann, but positive cytologic findings in the fluid.

Mr. D., aged 31, complained of numbness of the left side, of four years' duration. At the onset he had evidently had a cerebral vascular lesion, which had started with numbness of the left foot, quickly spreading over the entire left side, followed by unconsciousness and then delirium, from which he slowly recovered. Three years later he had a second similar attack. On physical examination the tendon reflexes of the left side were all exaggerated, and cutaneous sensation over the entire left side was diminished. There was a positive Romberg, and marked ataxia over the left arm and leg. The surface temperature of the left hand seemed somewhat lower than that of the right. There was no muscular impairment. The findings were otherwise negative. This patient showed a four-plus blood Wassermann, and negative spinal fluid Wassermann with 2 cc. on two examinations. The spinal fluid cell count was 40, all mononuclears, and the globulin two-plus.

Examination of the spinal fluid for Wassermann reaction alone is not sufficient. Both the cell count and globulin may be increased, with a negative Wassermann. As Fordyce, Wile and Stokes have all pointed out, in early syphilitic lesions, particularly the early secondary stage, the cell count is customarily increased before the spinal fluid Wassermann becomes positive. Thus, Mr. M., with a chancre of the lip and an early secondary eruption, a four-plus reaction of the blood and a negative reaction of the spinal fluid, showed an increased globulin content and a cell count of 35. There were no neurologic signs or symptoms. Here is a case in which treatment will not be completed until after we have convinced ourselves that the spinal fluid findings as well as the blood findings are negative. It is this type that, untreated, is prone to develop the late neurologic accidents.

Of course, as far as the patient is concerned, it would be of no advantage to study the spinal fluid if the treatment were not to be guided by the findings. Thus, there are those who claim that intraspinal therapy is unnecessary; that the results from intravenous treatment alone are entirely satisfactory. But, if this were true, the only method of

proving it would be by examination of the spinal fluid for evidence of complete cure. A second group of syphilographers contends that in cerebrospinal involvement intravenous therapy should be supplemented by spinal fluid drainage—while yet another group holds that for proper treatment salvarsanized serum should be given intraspinally in conjunction with intravenous treatment. Dereum is among the leading proponents of spinal drainage, while Fordyce, who has had an extraordinary experience in the treatment of cerebrospinal syphilis, is firmly convinced of the superiority of intraspinal therapy.

Time does not permit a summary of the evidence for and against the three methods of treatment, but the weight of evidence indicates that intraspinal administration of salvarsanized serum has a distinct field and should be employed in all cases in which intravenous treatment has not satisfactorily cleared up the central condition. For satisfactory results intraspinal treatment must be begun early. Tabes and taboparesis when usually recognized are past cure and usually past improvement. The future hope of therapeutic advancement in this field consists in early recognition of neural involvement and intensive treatment before the appearance of localizing signs or symptoms. The routine which I have followed consists in the giving of an initial course of intravenous therapy, followed by re-examination of the spinal fluid. If improvement is noted the method of treatment is not changed. If no improvement in the spinal fluid findings has occurred intravenous treatment is reinforced by intraspinal therapy, using the Swift-Ellis technique. In cases of early secondary syphilis it is safer to give three or four intravenous treatments before performing the initial lumbar puncture, so as to lessen the hazard of meningeal invasion subsequent to the puncture itself.

#### CONCLUSIONS.

A negative blood Wassermann does not rule out central nervous system syphilis, even in those cases who have had no anti-luetic treatment. In case of doubt, a diagnostic lumbar puncture will give valuable information. The intrathecal pressure should be roughly estimated, cell count and globulin content should be recorded, and Wassermann reaction should be determined. Recently we have also been employing the colloidal gold reaction as a con-

trol for the Wassermann. It is important to use amounts of fluid up to 2 cc., in the Wassermann test, so that a weak positive will not be overlooked.

No case of syphilis can be said to be successfully protected against late neurosyphilis until the spinal fluid has been studied and found to be normal.

Early treatment of neurosyphilitic lesions, before the development of localizing signs, offers the only promise, at present, of satisfactory therapy. Spinal fluid examination affords the only means of recognizing this early involvement.

Every syphilitic should have at least one lumbar puncture performed, early in the course of his disease.

### A PLEA FOR A MORE COMPREHENSIVE VIEW OF THE CORRELATIONS IN THE STUDY OF MEDICINE.\*

By J. H. HIDDEN, M. D., Pungoteague, Va.

The subject is so broad and many-sided, so mingled and intermingled with every department of medical science, that it may be designated as almost as broad as the study of medicine itself. The physician of only average ability, with a very limited degree of culture, merely grasps a bird's-eye view of the subject, while the accomplished, matured physician, with his analytical powers well trained in medical thought, with his intellect stimulated with the rich accumulations of knowledge, stands, at times, appalled, as he sees far beyond his ability to advance. He soon realizes that it is not a mere theoretical view of an almost unlimited degree of learning for which we are struggling; but a practical, intimate knowledge of the various departments of the science that can be skilfully and effectually used for the relief of human sufferings and for the cure of disease. This decision is not only individually, but is generally correct, provided such a decision is not reached by the physician until he has accumulated sufficient general knowledge to act as a safe and scientific balance in his chosen field of work, otherwise, this view becomes questionable, oftentimes embarrassing and, in some cases, even dangerous to the welfare of the public.

The correlations of medicine may be divided into several headings: (1) "Those having re-

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

reciprocal or mutual relations; (2) Those manifesting a relation of parallelism; (3) Those showing interdependence of structure, organs, functions or natural forces." In this paper, however, I shall not follow any definite order, for my object is not to give any logical, symmetrical discussion of the subject, but only to throw out some suggestions for the stimulation of further thought. The classification itself is purely artificial and is by no means well-defined; for the correlations of medical study are so numerous and, as I have before intimated, so intimately associated in this great fabric of medical science, that they may be often seen and studied under almost any classification you may suggest.

Within the last decade an increased interest in the reciprocal or mutual relationship of the vital structures, organs and functions of the human body has been awakened by the brilliant work of Dr. George Crile. This is especially true in the field of the endocrine system. And though his materialistic view of these correlative forces, expressed in his so-called "Mechanistic activation of the kinetic drive," has introduced more complex problems than he has ever solved, his work still stands out as a remarkable stimulation to modern medical thought. In addition to Dr. Crile's work, with the great volumes of literature that have appeared in our standard medical journals within the last two or three years, where is the physician, who does any thinking for himself, who has not been deeply impressed with the potent properties of the ductless glands? And where is the physician who does not feel the need of a more intimate knowledge of these organs, not only in their relation toward each other, but also in their relation to the complex cardio-vascular system, the phenomena of the nervous system, and indeed, the entire nutritional processes of our whole anatomical structure?

Yes, this awakening has come, and it is a daily observation in medical circles that a deficiency of study, and consequently, a lack of practical insight along these lines is often responsible for some of our most humiliating failures in the diagnosis and treatment of a certain class of our patients. For instance, we read and hear volumes of discussions of the hyper- and the hypo-thyroidism, and theoretically we are fairly well informed upon what we have read; but for all practical purposes oftentimes the reader has really taken in only

two pictures of these disorders, namely, exophthalmic goitre and myxedema. All the intermediate disorders of thyroid toxicity or deficiency are only hazy, complex problems for some of the specialists or group practitioners. While this state of professional deficiency exists among so many of our general practitioners, many of these poor sufferers pass from one physician to another without finding relief and, in their desperation, often seek aid from the osteopath or some other quack. More often, however, they are sent to some hospital surgeon in whose hands they finally undergo an exploratory laparotomy.

Now, this is no imaginary picture. It has been a common occurrence all over the country. I have at present three cases in my own practice—each giving this history—all undergoing exploratory laparotomies to no appreciable advantage. They were all finally diagnosed as sufferers of thyroid deficiency. I may also add, they were all rapidly restored to health by treatment with thyroid extract.

As these cases represent striking illustrations of the lack of practical clinical insight into the intermediate state of thyroid deficiency, let us examine their history a little more closely. One of these cases had been repeatedly diagnosed as hysteria, one as neurasthenia, and the last as a sort of neurotic phenomenon, better suited for the diagnosis of the Almighty Himself. A review of the history and symptoms of these cases calls for no justification of these repeated diagnostic and therapeutic failures. They were all cases of obesity with more or less abdominal and tympanic distention, with, at times, simple pelvic congestions with disturbed menstrual disorders of the menorrhagic type. They were all patients with weak hearts, slow and irregular pulse and low blood pressure. Moreover, these patients were subject to varied and multi-form attacks of neuralgia, digestive disturbances, neurotic irritations and evidences of lowered metabolism. They also gave a more or less swollen appearance in their faces, and finally, suggestions of arrested mental development. It certainly seems here that an intimate knowledge of the correlations of medical science ought to have aroused a strong suspicion of thyroid deficiency in these poor sufferers, and yet they suffered for years before the dominant, etiological factor in their pitiful conditions was discovered. It may be asked: who was responsible for all this suffering?

Again, a closer and a more comprehensive study of the correlative relations of the structures, organs and functions of the human body is becoming more essential each day to meet the requirements in the social changes of modern life. Indeed, under our political, social, economic and domestic conditions, we find a frequent perversion of almost all the secretory structures of our entire organism. And, at times, many of these structures or organs may be involved in any given case. As a result of these conditions, the number and variety of neurotic disturbances occurring annually in almost any well populated community are simply appalling, requiring the most discriminating sagacity in ferreting out their respective etiology and in making correct classifications. Moreover, this work must be often done by clinical observations alone.

Indeed, in many cases the laboratory gives little or no assistance, and often what is given is only of a negative character. Under such circumstances the physician who has developed keen clinical insight is the one who is in demand. On the other hand, the less observant physician who depends almost entirely upon laboratory assistance from the technician to form his conclusions in any given case is so often a pronounced failure. Please understand I am not depreciating laboratory work. We all recognize that in many cases this is indispensable, but it is too often used as a sort of substitute for professional alertness in clinical observations. And as this alertness in our clinical vision is allowed to become more or less dormant in our daily service, we are sure to deteriorate in this important line of our work. In other words, we are simply gaining in one direction and losing in another. Real progress demands a gain in both directions. If either department of medicine must be neglected by the practicing physician, let it not be the clinical; for deficiency here, in the long run, means failure.

With this brief digression from my last thought, dealing annually with the appalling number of neurotic patients, I do not hesitate to say that the great majority of our failures to give relief in such cases is due almost entirely to a deficiency, not in theoretical knowledge of medical literature, but in alertness or practical insight in our clinical observations. How often do we find the physician face to face with one of these neurotics say, for example, a mild case of manic de-

pressive psychosis, with a cycle of symptoms—periods of mental stimulation and depression, accompanied with other neurotic disturbances, polyglandular involvement, a low blood pressure and deficient metabolism! He is dreaming over volumes of medical lore, and is completely at sea. The neurotic disturbance is allowed to progress, and the patient is called a neurasthenic when a practical insight into the clinical conditions—a familiarity with the correlations of the organs and functions of the nervous and glandular systems would solve his problem and save his poor patient from the most distressing state of mental deterioration.

Again, leaving the field of nervous disorders and coming to the specialist, how often is the oculist, after using his impressive examinations and local treatments, not only embarrassed, but perplexed and even helpless in some given case, say, for example, a case of chronic choroiditis, because he cannot find the dominant factor in its etiology among the correlations of some constitutional disorder! Just here I may say that two very interesting cases of choroiditis with exactly this history came under my observation several years ago, and that they were both finally cured by a general practitioner simply by giving careful attention to the underlying factors of some constitutional disturbance.

Now, while the whole medical field of activities abounds with such illustrations, why should I make a plea for more careful and comprehensive study along this line? My answer is because this line of work appears less attractive, more laborious and more tedious than many other lines to the coming generation of physicians. Indeed, to make an able, skilful, clinical diagnostician, requires not only time and patience to acquire a broad scope of medical knowledge, but also the time and experience to assimilate it. Moreover, in this restless age when there is a fascination in exchanging the old, tried methods for almost anything that is new and glittering, when there is a growing tendency among many to avoid intellectual drudgery and to hurry through with their work, to shift responsibility upon others, and to seek an easy seat in the band wagon of the great parade of medical progress, it is well to bear in mind that the so-called commonplace observations of the trained clinician are still indispensable. In closing, I will also add that in the face of all our recent, wonderful scientific discoveries, the

profession at large still needs, above all other things of similar import, a more intimate and comprehensive knowledge of the correlative relations of the structures, functions and, in case of disease, pathological processes of the human body.

#### DISCUSSION.

DR. M. W. CRAFTON, Lee Hall: I would like to ask Dr. Hiden what symptoms preceded the laparotomy which was performed in three cases of hypothyroidism. I have seen hypothyroidism with flaccid muscles, low blood pressure and various symptoms, but I have failed to ever see one have symptoms which would lead me to think of having a laparotomy done, and, judging from his paper, I suspect these were cases already having been done by some other surgeon. If so, possibly he could not state, but if he had taken these cases from a history of the laparotomy, I wonder if they were not done for some other cause than hypothyroidism.

DR. J. H. HIDEN, Pungoteague: I can answer in two of these cases. I do not know about the third case, because it had been operated on before I saw it; it was turned over to me after the operation, and I don't know positively what the symptoms were previous to operation. But I feel sure that the case was suffering with hypothyroidism at the time I saw it, and I was the ninth physician that saw the case professionally. Of course, I do not know what the surgeon had in mind when he performed the laparotomy.

The other two cases referred to were seen by me before they went to the hospital, and they gave the symptoms of thyroid deficiency, as I have described in my paper. In one of these cases the operating surgeon gave me as his reason for operating that the patient had been sent to him by her physician, and that she insisted upon an operation. I suppose he thought that medical efforts were practically exhausted without relief, and that, as the patient desired an operation, he was justified in making an exploratory incision.

The second case had been treated unsuccessfully for a long time and was finally sent to the hospital. The surgeon in charge of the case, unable to make a positive diagnosis, did an exploratory laparotomy, pronounced it a case of neurasthenia, and sent her home. He was a good surgeon, too, but I can't say that he did any wonderful work on that occasion.

### PRENATAL CARE AND TREATMENT.\*

By ROBERT P. KELLY, M. D., Lynchburg, Va.

This is a subject on which much has been written, but its importance justifies any emphasis it may be given. There has been much discussion of the causes of maternal and infant mortality in obstetrics, and many methods of obtaining better results and of improving present records have been suggested by various authorities. As an obstetrician, it has fallen to my lot, of course, to deliver many women who have previously been delivered by other physicians. From discussions with these

patients and from observation, I have reached the conclusion that the most neglected stage of pregnancy or labor is the ante-natal period, and it is my opinion that herein lies the chief opportunity of reducing maternal and infant mortality.

To the accomplishment of this end three things are essential:

(1). We must educate the *physician* to a proper realization of the importance of pre-natal care.

(2). We must educate the *pregnant woman* to see medical advice early.

(3). We must find some way by which we can reach the newly married women of the country with literature which will make them realize the importance of seeking this ante-natal care in the early months of pregnancy.

As to the first of these points, I feel sure that practically all physicians are capable of doing what is required in ante-natal treatment. For them all that is necessary is a keen realization of the importance of their work, of the serious consequences arising from its neglect, and of the excellent results obtainable through its proper execution.

On account of our failure to apply properly our knowledge in this field, I believe we are responsible for a large percentage of the infant and maternal mortality and morbidity, half of which, as well as half of the gynecological operations, may be traced to complications or causes which could have been relieved or prevented by proper prenatal care and treatment combined with skillful attention during labor and delivery. Assuming that this is true, is it not time that we were doing something to correct the fault and to prevent this loss of so many young mothers and babies? It is sad to see anyone die, but what else can so deeply stir our sympathy as the death of a mother in her effort to produce a living child?

Let us make a few inquiries into our methods of treating these cases. How many of us are doing our complete duty; how many of us would be satisfied to have our own wives receive the same prenatal treatment as we are giving to the wives of other men; how many of us pay any especial attention to this stage of a confinement case; how many are satisfied with a single examination of the urine, or even fail altogether to examine it; how many take the blood pressure regularly, if at all; how many take any notice of diet, exercise,

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

environment, family history and personal history, not to mention numerous other points of equal importance; how many ever listen for the fetal heart before or during delivery; how many make a diagnosis of position and presentation before or after labor begins; how many make a complete physical examination of the patient, as to pelvic measurements and the like? All these details and others are essentials of proper prenatal care and treatment. Unless we do these things, or most of them, whether we are specializing in the city or doing general work in the country, we are not doing our duty to our patients, and we are, at best, little better than many midwives. There is not a general practitioner among us who is not capable of giving his patients all necessary prenatal care, and if he is not willing to do so, he should not assume the dual responsibility of a confinement case. By properly carrying out this treatment, he will not only fulfill the better his duties as a physician and save himself much embarrassment, but he will thereby save the lives of many mothers and babies, and have the satisfaction of knowing he has been true to his patients and to his profession.

If I may indulge in a personal reference, I should like to cite a bit of my experience in this field. Throughout my fifteen years of practice I have been deeply interested in obstetrics and have always watched these cases very carefully. As a result, I have never had in my own practice a case of convulsions, the only such cases coming to me being those referred, or seen in consultation. Of course, I have had cases of toxemia, but—doubtless by good fortune—I have always been able to do one of two things: To get the mother through pregnancy by appropriate treatment, or, failing in this, to deliver her prematurely without convulsions, probably thereby saving her life.

If one should ask me what I consider the most important stage of pregnancy or labor, my reply would be the prenatal period; and for my patients, as a rule, if I should advise them to take only one of the three—prenatal care, attention during labor and delivery, or thorough post-partum care—I would select prenatal care. Of course, I do not mean to minimize the importance of a proper delivery nor of first-class post-partum care, but I do believe that more can be done, in the majority

of cases, toward saving the lives of mothers and babies, by efficient ante-natal care and treatment than by any other means. In fact, there will be less need for interference during labor and delivery, and the post-partum period will present fewer complications, if we give to these patients the prenatal treatment they should have.

I wish to outline briefly what I consider some of the most important points in this treatment:

(1). A careful general physical examination, including heart, teeth and tonsils.

(2). A careful special examination, including measurements of the pelvis, diagnosis of position and presentation, condition of soft parts, position of uterus, etc.

(3). Past history, including family history, miscarriages and their cause, gonorrhoea, syphilis, nephritis, childhood diseases, past labors, if any, etc.

(4). Wasserman test, *at least* in suspicious cases.

(5). Regular urine examinations. At first every three weeks, then every two weeks, or oftener the last month.

(6). Blood pressure readings regularly, as in the case of the urine.

(7). Diet when necessary. To this point we are inclined to pay too little attention.

(8). General health rules, exercise, fresh air, sleep, no worry, condition of bowels, home conditions, etc.

(9). Give patient a list of instructions. Tell her to notify her physician when any of the following symptoms appear: Severe headache, edema, visual disturbances, vomiting in excess, retention of urine, bleeding, however slight, unusual pains in the abdomen, or any symptoms she cannot readily explain.

(10). Limit sexual intercourse, total abstinence the last month, possibly also the first few months.

(11). Pay particular attention to breasts, deformed nipples, etc.

(12). Do not allow patient to go long beyond term. Make careful examinations to determine this. Many babies die from this cause.

(13). Advocate the establishment of prenatal clinics, where the poor may go for examination and advice. We have such a clinic in Lynchburg, and I have the honor of conducting it. The greatest difficulty we encounter, in a large percentage of cases, is to

induce these patients to consult us early in pregnancy. If they do not come to us until near the end of pregnancy, of course we cannot give them the treatment they need. This lack of self-interest on their part is apparently due largely to ignorance and partly to embarrassment, both of which could be overcome, if we had some way to reach them and make them understand the importance of seeking medical aid early in pregnancy.

The question presents itself, therefore, as to how we are to reach these patients in a proper ethical way with literature which will teach them to realize the importance of seeking early this prenatal care. After careful deliberation, I have deduced a plan which I should like to present to this Society for consideration. I hope it may win your approval and co-operation to such an extent that definite steps may be taken at this meeting or in the near future toward perfecting it and putting it into operation.

I would suggest the enactment of a law requiring that the name and address of every newly married couple in Virginia be forwarded promptly to the State Health Department by the official issuing the marriage license, and that properly prepared literature on the subject of pregnancy and prenatal treatment be forwarded by the Health Department to each couple within sixty days after marriage. I think it would be well also to include in such literature information on sex relations, the injurious effect of interference with normal sexual intercourse, its bearings on sterility, and many other things of more or less importance, of which, as a rule, nine-tenths of the newly married couples are completely ignorant until too late. Special attention should be called to the importance of consulting a physician as soon as pregnancy is fairly certain or even suspected. If such a plan as this could be developed in Virginia and throughout the country, it would not be long before we would have a well informed public. Our cases would come in earlier and, as a result, many lives would be saved.

As a brief summary of my opinions on this subject, I would say:

(1). We are not doing our duty to our patients, to our country or to ourselves, if we fail to give the expectant mothers every possible attention during pregnancy.

(2). There is scarcely a physician in the

state who is not capable of making these simple investigations, which are so important, as there is no other way of learning the condition of the pregnant woman.

(3). By giving the proper prenatal care and treatment, we can reduce, practically to zero, the deaths from convulsion, which now claim many.

(4). Through our medical journals, textbooks and colleges, we can bring physicians to a realization of the importance of this work, and through the State Department of Health we can educate expectant mothers.

(5). When possible, a specialist should be called in consultation on every complicated prenatal condition and on every difficult or complicated labor case.

*705 Church Street.*

#### DISCUSSION.

DR. W. A. PLECKER, Richmond: This is an extremely interesting and instructive paper. This is a subject that has engaged my attention since I have been State Registrar. I took up that work as an old obstetrician, and one of the things that has grieved us most in our office is the large number of absolutely preventable deaths from childbirth that come in to us. If we take these statistics and study them, we can see the evidence of neglect all the way through.

We have been trying to work out a method in the office to overcome this, as far as it is in our power. In order to do this, we have had the legislature place under the supervision of the State Registrar all the midwives of the State, and we have tried to give them some instruction as to prenatal care, as far as it is possible to teach these ignorant creatures. We have forbidden these midwives to make vaginal examinations under any circumstances. If we can succeed in enforcing that regulation, we can save, each year, fifty to seventy-five deaths of mothers from septicaemia.

We have been trying to carry out a little educational work. We have a little booklet which we call "The New Family," which we send out to newly married women, which touches a little on this subject. We are treading on new ground and a delicate subject, and we are wondering how far we can go with this method. That has been so gratefully received by hundreds of the most intelligent women to whom we sent it, and so many inquired for further prenatal literature, that we have something more comprehensive just from the press. This purports to deal with the nutrition of the new family; we call it "Feeding the New Family," and it emphasizes particularly prenatal feeding of the mother, in the interest both of mother and child.

As to giving some of the advice mentioned in this paper, I would be rather afraid to risk it, because there is a little danger of offending some of these people when they have not asked for information. As to just what sort of prenatal talk we are trying to get over; of course, what we try to impress on these women is the fact that they must stay away from the midwives, and they must go to the best doctor they can, and then we urge upon them to place themselves under the care of a physician as soon as they discover that they are pregnant. We

suggest that regular examinations of urine be made, but we don't tell her her blood pressure should be taken and that those other things should be done, because she might have a doctor who does not do these things.

DR. KELLY, closing: I fear that Dr. Plecker misunderstood my idea. I did not mean to convey the idea that the patient was to be given all the information contained in this paper. The thing I wish to emphasize is the importance of having the pregnant woman educated to the necessity of going to a physician early in pregnancy. I did not mean to include in these instructions to be sent these women anything that would tend to treat or induce these cases to treat themselves at home; far from it, but only such information as would persuade them to seek medical attention early.

## CANCER, THE TRIBULUS TERRESTRIS OF DISEASES.\*

By STEPHEN HARNSBERGER, M. D., Warrenton, Virginia.

A NUCLEUS OF TRUTH. The West and Southwest grow a weed known as Tribulus Terrestris, or puncture vine, possibly a creptogamous plant, which, devoid of flowers, reproduces by minute one-celled spores. But this is of less importance than the truths we wish to impress by mentioning this accursed immigrant from Southern Europe. In its relation to the automobilist it is the very accurate counterpart of cancer to man. This vine or weed, if you prefer, lacks attraction, is innocent looking, and presents no appearance of danger, but when it is irritated by the impact of the wheels of the automobile driven against it, it punctures at once and forever destroys the life of the tire.

DELUSIVE SECURITY. So it is with the innocent looking skin blemishes which most people let pass as of no further concern than that they exist. Notably the little hard scale about the face, lips, ears, eyelids or bordering the mucocutaneous surfaces or elsewhere; also the little painless knots, lumps, moles, warts, nevi, and the irregular nodules or any other blemishes perceptibly raised above the skin, especially that common incrustation called keratosis senilis. While ulcerative changes in these skin defects multiply rapidly after middle age, *malignancy does appear at much younger ages*. Do not let your eyes wake to weep.

MINDFUL AND FAITHFUL. In recent years I have removed warts and other defects from quite young children, one not over thirty months, advisedly, to prevent their fingering them. Plus the benefits of ablation, parents

are relieved of the associated anxiety and I feel I have filled a just obligation.

I cannot estimate the large number of adults who have rid themselves of like skin faults through my advice; and without exception they were made happier because their minds were put at rest.

CONSIDER THE END. If these local trophic imperfections are removed early, the person is absolutely barred against future danger from that source. If left to later life, especially until the lymph nodes are invaded, the limit of sure exemption has passed, the human tribulus terrestris puncture is as certain as death is *inevitable*.

"They would none of my counsel . . . therefore shall they eat of the fruit of their own way."  
—Prov. 1:30.

IN ANY CASE, A CASE OF CONSCIENCE. The majority of people are ignorant of the mischievous meaning of these skin faults, as well as of the comprehensive means of providing for health in general; and all are more or less careless and inclined to drift along the unwitting way that induces malignance and the lesser ailments. They should be made to know and to realize that they hold a sacred personal part in making and keeping health.

"Through dreary wastes we wandering go, and weep each others woe."

DARE TO BE WISE. Surely it is a good thing to live and a natural thing to die. Then why should people put off doing that which prolongs the thing they desire and hastens the thing they want deferred,—it is a paradox that bars solution. But that's not our business as physicians, we are here for an ulterior and more merciful purpose, to lessen suffering and save lives. Hence, this is an appeal to interest, an argument to the judgment, that is, an argument deriving its force from the situation of the person intended, founded on his ignorance of facts.

Pertinent advice, "It is well to profit by the madness of others."

NOT MERELY FOR OURSELVES. While this paper discloses an appeal to physicians to "get busy," it is designed to urge the people to take an intelligent view of the matter as it exists and to join us in our anxious effort to safe-guard them against that terrible, yet preventable tribulus terrestris burden of suffering and death. *It is for them and their children*. Shall it be tears of joy or wails of grief? *It is just as they make it*.

\*Read by title at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31-November 3, 1922.

**THE STRONGER REASON.** The late world struggle for the freedom of the nations was unavoidable but the havoc assembling by the steady increase of cancer can and should be met and met promptly. To the United States Public Health Service is due the major part in skyrocketing the preventent and persistent preventive knowledge that today is swiping the world of the waste of diseases. Its sustained intelligent aim and endeavor should have the force of the willing and grateful cooperation of the people whose welfare it has at heart. Don't be a moppet or a musang-coffee rat.

**TEAM WORK COUNTS.** Physicians are the duly authorized actors in the play of naturalizing prophylactic practices to the common good; all welfare workers are co-equal and essential factors in the canvass to establish habitual usage and insure lasting maximum results. Keep step with us! Fix in mind this statistical fact. In New York City last year the increase of the death rate from cancer was greater than from tuberculosis. Looking at it in this convincing way, how will it be with your children and grandchildren when they reach your age? If we fail in our duty now their suffering and deaths will be upon our heads.

**NOT TO BE FORGOTTEN.** It is a one-sided question but it is all on the side of conation; in other words of desire and will or volition. Get the idea? Save your children.

Read what Shakespeare tells you:

"This our life, exempt from public haunt,  
Finds tongues in trees, books in running brooks,  
Sermons in stones, and good in everything"—  
except DELAY.

## OBSTETRICS A NEGLECTED SCIENCE AND ART.\*

By GEORGE THOMAS MYERS, M. D., Norfolk, Va.

I shall preface my remarks with a brief apology in stating that I read a paper by this title before the Norfolk Medical Society, November 24, 1913, but as we have had quite a number of innovations in obstetrics within the past ten years, and all innovations are not progress, I am of the opinion the title is apropos at this time.

Obstetrics is a scientific art and mechanical skill that should be given to woman during pregnancy, at the confinement, and through the puerperium. The scientific art can be learned

only from a correct understanding of the obstetrical pelvis, the female organs of reproduction and the female generative organs, the physiology and pathology of normal and abnormal diseases in the female. If normal conditions are understood, abnormal ones will be recognized and appreciated in pregnancy, at the confinement and through the post-partum period. The mechanical skill can only be learned at the bedside and then only by painstaking attention to every detail in eliciting the presentation, position, location of the foetal heart sounds, a correct appreciation of the diameters of the pelvis, and every other method in vogue that is used to make a correct diagnosis of the particular case; and close attention during the delivery. This can be accomplished in only one way, and that is by competent instruction from one who has had special training and practical experience in this science. To succeed in any science one has to master the elements; the foundation well laid, attainment of knowledge will surely follow. The obstetrical teaching in the past in our medical schools has been neglected; the article of Dr. J. W. Williams of Johns Hopkins University that was published in the *Journal A. M. A.*, in 1912 in reference to the qualifications of professors of obstetrics in our medical schools was astounding. I think this paper has proved beneficial and encouraged better teaching of obstetrics in our medical schools during the past decade. A few years ago men graduated from our universities and medical schools and were licensed by our state examining boards, allowed to practice obstetrics upon an innocent community, who had actually never seen a case of labor, much less assisting in one. The condition is bad at this time, and there is a large field for better clinical teaching of obstetrics; the science of obstetrics has been looked upon as a minor subject, and the child-bearing woman in general has reaped the benefits thereof.

The profession of today underestimates the importance of the subject, and countless infants are sacrificed or made cripples and mentally defective for life, the mother shares the fate of invalidism for life, purely from ignorance on the part of the attendant at this eventful time. This is speaking conscientiously and frankly; it is high time that the profession were awakening to this important branch of medicine.

Obstetrics of all the branches of medicine should be specialized. The obstetrician should

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

be a man well versed in gynaecology, pediatrics, therapeutics, physiology, pathology, and, above all, he should be sound in his judgment, conscientious in his work, and capable. He should be able to perform any abdominal operation, thereby being in a position to cope with any complication that may arise in this particular line of work; capable of performing cesarean section, abdominal section for ruptured uterus and ruptured ectopic pregnancy. These complications do occur and, in the event of such, the obstetrician should be master of the situation, thereby giving to his patient that skill and attention she should receive and demand from him. The general surgeon is not as conversant with the various obstetrical operations as the obstetrician should be. A skilled surgeon is not necessarily a competent obstetrician, due to the fact that obstetrical operations are far different from other surgical conditions; that is to state, such as the application of forceps, performing version, podalic or cephalic, manual dilatation of the cervix, and in exercising the proper judgment and skill in dealing with a case of placenta praevia; face presentations, occiput posterior, transverse presentations, and many other complications that the obstetrician has to meet with in this branch of medicine; requiring the utmost skill and judgment from a ripened experience in this particular surgical obstetrical technique. I have seen thoroughly competent surgeons who did not know how to apply forceps correctly, namely; making a pelvic application in all forceps operations, or performing version without doing considerable damage to the mother and the child. Therefore, the various obstetrical operations and complications should be dealt with by the obstetrician and not by the general surgeon.

The application of forceps is a dangerous procedure in the hands of the inexperienced. The correct application of forceps requires a good deal of skill, and in many instances is a more serious operation than an appendectomy. Every graduate of medicine, if the occasion arises in his obstetrical work to apply forceps, will attempt to do so without even having had practical experience, although he will send his appendicitis cases to the surgeon. This is due to the fact that the importance and danger of obstetrical operations has not been taught the general practitioner, and the laity have not been educated to expect any more skill from one physician than another in the science of obstetrics. If the case terminates either in

the death of the child or its mother (and in many cases both are sacrificed), the practitioner is exonerated from any blame, as it was the will of Providence and not his ignorance.

The vast majority of gynaecological cases that are met with are due to mismanagement or avoidable accidents of the pregnant and parturient state. This large class of invalids who owe their condition to careless, incompetent and unclean obstetrics can be reduced, if not practically prevented: the remedy is to be found not in the preaching, but in the practice of skilful, clean and conservative obstetrics. The old adage is apropos here: "An ounce of prevention is worth a pound of cure." De Lee in his text-book asks the question: "Is labor in the woman of today a normal function?" I feel confident he answers the question satisfactorily to us all, namely: "I say it should be, but is not."

With all the attendant zeal of modern obstetrical asepsis and antisepsis within the past twenty-five years, the deaths from child-birth in the United States are appalling, twenty to twenty-three thousand women dying annually. The percentage of still-births is entirely too high. We have had campaigns inaugurated to fight against tuberculosis, cancer, malaria, typhoid-fever, pellagra, hookworm disease and many other ills that the human frame is heir to, but I have yet to hear of one inaugurated for the betterment of obstetrical practice. The science and art of obstetrics has dragged along for centuries, and it has not reached the elevated place it deserves in medicine. The day is not far distant when the profession, as well as the laity, will awaken to the importance of the subject and demand better obstetrical skill and attention. Of all the branches of medicine obstetrical work is the most arduous, nerve racking, and the least remunerative from a financial point of view. But as to the accomplishment of actual results of scientific work, and the relief of pain, it outshines the other branches of medicine. No where is the conscientious physician put more to the test than in a complicated labor, if he has the interest of his patient and her offspring at heart; and I say frankly that in no other branch of our noble calling can as much harm, suffering and actual sorrow be brought to those most vitally concerned, than in the hours of promised motherhood.

Pelvimetry by the general practitioner is tabooed as being fallacious, but it is of the

utmost importance to have correct measurements of the pelvis in all primigravida, and in every case that gives a history of preceding difficult labors. If pelvimetry is practiced, the various contractions of the pelvis, exostosis, tumors and ectopic pregnancy are discovered. This enables the obstetrician to treat the case scientifically, not waiting until the patient has advanced in labor, with much suffering, before the true condition is elicited, when possibly it is too late to give the patient the benefits of the induction of premature labor or cesarean section. It can readily be seen and appreciated that pelvimetry is of the utmost importance and benefit. Pelvimetry in relation to the foetal head has not been perfected, although it is of some importance. When pelvimetry is adopted as a routine by the profession, craniotomy will only be occasionally performed, as this operation is unscientific and barbaric and should be relegated to the past as history of obstetrics. When we have awakened to the importance of details of pre-natal care in our patients, this operation will only be performed on the dead child.

It would be preposterous to apply forceps in a delayed labor due to a narrow conjugate. The obstetrical forceps is one of the greatest inventions in the obstetrician's armamentarium, and the one mostly abused. The name of Chamberlen should have gone down to posterity as one of the greatest benefactors to womankind; if the greed of filthy lucre had not been predominant in his makeup, his name in obstetrics would have been immortalized as is that of our illustrious father of gynaecology, J. Marion Sims, is by the speculum. The indications and contra-indications for the interference of labor by forceps I will not discuss, but it is well to bear in mind their usage is to extract a living foetus from the pelvis without injury to itself or the maternal soft parts. My own rule to to apply forceps in the second stage of labor if there is no advance in the head after two hours of full dilatation, the pains becoming less frequent and lacking in expulsive power. As a routine, the application of floating forceps should be condemned, and internal podalic version or cesarean section elected as the operation indicated. As to the interruption of labor before the completion of the first stage, I am of the opinion there can be no fixed rule; the individual case and experience of the obstetrician will be the deciding factors as to what method to pursue. The

innovation by Potter in performing internal podalic version in every normal labor that is progressing satisfactorily, is unscientific, and will never become a routine procedure. With this panacea for the amelioration of pain and shortening of the second stage of labor, Potter performed one cesarean section out of every eleven cases admitted to his clinic last year. I have seen his work and I am still of the opinion that where version is indicated, forceps are contra-indicated, and *vice-versa*. Bear in mind one important operative technique in all forceps operations; the uterus should be fully dilated, membranes ruptured, bladder and rectum empty, the vulva shaved, the blades applied in relation to the position of the foetal head, the patient on a table, and under complete anaesthesia. In some cases it is preferable to deliver with the blades in position; in other cases to remove the blades when you can control the head at the vaginal outlet.

Placenta previa should be dealt with early as delay is dangerous. The treatment will depend upon the period of gestation and the stage of labor. If dilatation is sufficient to admit the performance of internal podalic version in the lateral and marginal varieties, this is the operation of election; if there is not sufficient dilatation, rupture of the membranes, sterile gauze tampons, Champetier de Ribes, or Voorhees bags may be used. In the central variety with hospital facilities, cesarean section, either the classical or Krönig's operation, is the obstetrical course to pursue. Accouchement forcé as a treatment of placenta previa should be condemned.

In speaking briefly relative to the treatment of eclampsia, and severe toxemias, the exact etiological factors are still in debate, with one exception: that they are the result of an impregnated uterus. In consideration of this fact, I feel that the best obstetrical course to pursue in these complications is an early emptying of the uterus. The method adopted will depend upon the stage of gestation, stage of labor, and whether the case is a primipara or multipara. In a primipara, with an elongated rigid cervix, cesarean section is the operation of election. Stroganoff's method has not proved satisfactory to me.

Puerperal sepsis is a preventable disease and is too frequently encountered in this enlightened age of asepsis and antiseptics. If we do not forget the clarion note of Oliver Wendell Holmes, the magnificent work and ap-

peals of Semmelweiss, and if in all obstetrical manipulations, cleanliness is our rule and guide, this disease will rarely be encountered.

Another innovation we have had is twilight sleep. The original technique as promulgated by Krönig at Freiburg has justly died a natural death; it was "weighed in the balance, and found wanting."

The innovation of bagging all cases that are presumably overdue is not sound obstetrical judgment, as there are numerous factors to be taken into consideration before arriving at such a conclusion.

The use of pituitrin during the first and second stages of labor is an innovation that is dangerous: the physiological action of the drug will ultimately result in serious complications to the advocates of this method. During the past decade experimental research has thrown much light on the physiological and pathological problems to be met with after the use of pituitrin, leaving out of consideration any speculative hypothesis. I have endeavored, in the time allotted to each paper before this section, to give you the salient points in this science and art. In conclusion, always bear in mind that the very outcast of the streets should receive the best attention, judgment, and skill from the obstetrician, in the hours of promised motherhood, remembering this motto: "*Non nobis solum.*"

624 Armistead Bridge Road.

#### DISCUSSION.

DR. M. P. RUCKER, Richmond: Dr. Myers has given us a good deal to think about. His opinion that our medical schools and colleges do not educate the student thoroughly in obstetrics is correct. In Richmond, in 1920, there was one maternal death in every eighty-eight cases. Of course, this is exaggerated, because some are abortions, but it is sufficient to show that there is a tremendous mortality.

When you stop to think, you can very readily see the reason for this condition. The medical student is taught obstetrics on the banks of Shockoe Creek, instead of in an up-to-date hospital, and therefore he gets a poor idea of the technique with which he goes out of school.

It is a well known fact that you very seldom do better than the ideals with which you start out. You usually drop a little below those ideals. If you carry from school a below-standard technique, you are not very likely to rise above it.

We have to do one of two things. We have to educate the people that an M. D. degree does not mean a master obstetrician, or we have to provide means for our schools to give their students all the facilities of studying obstetrics that a modern hospital has. I do not see anything else to do. You have got to have a post-graduate course in obstetrics, or else improved facilities for teaching obstetrics properly in the regular course.

DR. J. BOLLING JONES, Petersburg: I greatly enjoyed Dr. Myer's paper. To my mind this is one of the biggest subjects that we have to think about

today. Obstetrics pertains not so much to the mortality, but to the morbidity. I am sorry to say that the average doctor thinks everything is all right if the baby is born, without giving any regard to the poor woman's condition.

I think that no obstetrician can be absolutely competent unless he has a thorough knowledge of gynecology. I believe that if all medical students were thoroughly educated in obstetrics, and the patients could be taught to see the subject in the true sense, the question of the midwife would be settled. There is just one other point that I want to speak of, and that is that too many surgeons cut in any old place without any regard to the pelvimetry.

DR. G. B. BYRD, Norfolk: I want to emphasize one or two of the points that Dr. Myers made. The first is the examination of the woman during the pregnancy and before the labor. I think that these examinations should be made as early in the pregnancy as possible. As to the method of pelvimetry to be used, use all at hand.

After the baby is delivered and the placenta delivered, I carefully examine the patient for any involvements. A great many men tell me that they have done a great deal of obstetrics and have never had any lacerations. A great many of mine have to have sutures. Examination should always be made just as thoroughly after delivery as before. When the patient is shocked and you are unable to do anything at the time, you should have the patient report back to you at some later time for a thorough examination. In treating a patient I do not believe that you have given all of the service you could if you do not ask her to report back to you for examination after the baby is born and after she is up. I am sure that if the men who boast that they have never had any lacerations had had the patient report back after about eight or ten weeks, they would find some little involvement.

DR. A. W. GRAVES, Lacey Spring: Obstetrics should be a very easy matter when you have the facilities of a hospital with all modern technique, but when you get back in the rural section, where the patients call you in at the very last minute, what are you going to do? It is too late, without secondary operation, to do anything. The only thing I see to do is to educate the expectant mother and the anxious father. Most of the complications are due to too much neglect afterwards by the mother. Where you have a case in a rural district, most likely someone has advised her not to go for examination and incur unnecessary expense. After the trouble it is too late to accomplish much. The fetal mortality in our section is very small where you have seen the mother beforehand and several times afterwards. After they get up they do not want to see you, as they think you want to get the extra fees. They do not realize the importance of coming for a urinalysis. Some people will take the good advice of other people and come to consult an obstetrician, but on the other hand, others will not call on you until their confinement. I feel what should be done is for all physicians to notify the health authorities of the expectant mothers in their districts or localities and have them sent letters or literature which would be of benefit to all newly married couples or expectant mothers.

In regard to the after treatment, one important point is the treatment of umbilical hernia, "tongue tie." Some cases can be cured, if you get them early enough; if they are neglected six or seven years, they of course come under surgical procedure: e. g., umbilical hernia.

If a physician knows of any women in his community who are going to be confined, whether cases of his or not, that physician should notify the health

authorities, and at all times co-operate in that capacity and treat all correspondence as confidential. Be ready or willing to aid in the one great purpose which we are in honor bound to fulfill and to assist new born babies to health, which should be under modern conditions.

Again I find so many mothers who have been "badly treated" by some one at first delivery. Why should some of our profession be so negligent at the most important moment of a woman's life, for health and liberty should be pre-eminent and we should not accept such a case if we are going to neglect the most important part of treatment—lacerations. Patients should be properly prepared, and I find the lateral position in bed the most successful for the post-operable conditions, enabling discharges to drain over non-lacerated tissues, thereby causing certainly a better union of lacerated tissues, if you have any.

DR. GEORGE T. MYERS, Norfolk, (closing): This is a serious subject. Dr. Rucker is entirely right, in that students should be given special training in obstetrics, not only in Richmond, but everywhere. The men who attend Cornell and other big universities are required to attend so many labors before they are allowed to practice. As Dr. Rucker says, the science of obstetrics has been sadly neglected by the profession as a whole.

In reference to pelvimetry, of which Dr. Jones spoke: pelvimetry is not accomplished until you use both internal and external pelvimetry. Dr. Byrd, in reference to lacerations: The patients should always be urged to return after six or eight weeks after delivery so that you can look for lacerations and misplacements. Dr. Graves, in reference to country practice: It has been my experience, in going to the country, to find a lack of co-operation among the doctors. The country practitioners cannot get help from each other. Obstetrics can be done as well in the country as in the city, and hospital facilities are not absolutely necessary. If you have competent assistance, there is almost no danger in performing the various obstetrical operations, namely: forceps and version and, if absolutely necessary, the cesarean operation can be performed in the country districts.

### LATENT MAXILLARY SINUSITIS.\*

By J. WARREN WHITE, A. B., M. D., Norfolk, Va.

The anatomy of the maxillary sinus will be described briefly so as to show how easily an infection may be latent for years and produce no local symptoms.

The maxillary sinus is a pyramidal shaped cavity hollowed out of the superior maxillary bone. The floor may be on a level with the floor of the nasal cavity or it may be at a considerably lower level. The floor of the cavity is by no means smooth and regular, and quite frequently it is divided by bony septa into pockets. Frequently, roots of the bicuspid and molar teeth project into the cavity. The walls of the cavity vary considerably in thickness. The mucous membrane is continuous with that lining the nasal cavity and does not differ materially from it. The maxillary sinus com-

municates with the nasal cavity by a small opening in the middle meatus. Thus we can easily see the difficulty in drainage of an infected maxillary sinus and how easily an infection may become encapsulated in the cavity.

As to the percentage of maxillitis, from dental and nasal infections, there is a wide difference of opinion. It is, however, invariably secondary to either infections of the nasal cavity or infections around the roots of the bicuspid or molar teeth.

The mucous membrane of the cavity usually becomes very much thickened and polypoid-like. Frequently, well formed polypi are found projecting from the mucous membrane. With a thickened mucous membrane, pus can easily become encapsulated on account of the difficulty in drainage through the normal opening in the middle meatus. Chronic infections of the maxillary sinus are far more prevalent than the rhinologist and others have realized. Coffin, of New York, was among the first in this country to do any original work along this line and brought to the attention of the medical profession the frequency of sinusitis among children and the eye affections associated with it. At one time it was considered more a factor in dental than nasal diseases and then the surgery of this important sinus was turned over to the dentist. The drainage of the sinus through the alveolus was the operation for years, until its utter ineffectiveness was demonstrated and more rational methods were instituted.

Have we done our full duty in adenoid and tonsil cases until we have made a thorough nasal examination for the presence of infected sinuses? The reduction of mortality today is not in the treatment of diseases but in prevention. Thus, a searching investigation should be made for any other undermining factors in each case before removing the tonsils and adenoids. The presence of pus in the maxillary sinus with no tendency to recover spontaneously or by non-operative treatment is an indication for operative interference. In recent years the profession have come to realize the great number of systemic diseases resulting from latent infection. Several cases of tic douloureux have been reported as cured by clearing up a low grade maxillary sinusitis by operative treatment, with satisfactory drainage. The sinus disease, in this case, is more of a chronic infection of the mucous membrane than of a collection of free pus. The connection between maxillary disease and trifacial

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31-November 3, 1922.

neuralgia is certainly worthy of investigation. The question has arisen, is there any such thing as latent infection? The infection may be latent as to giving no local symptoms at its original source, but is there not going on a continual absorption into the general system from the original point of infection? We all realize the insidiousness of focal infections and the irreparable damage resulting therefrom before the patient even realizes the gravity of his condition. Preventive medicine is the medicine of the future and I am taking up latent maxillary sinusitis as one of the sources of focal infection that is frequently overlooked. As to the determination of the presence of pus in the maxillary sinus, it is very easy at times, but in some cases it is quite difficult. On nasal examination, if we find pus in the middle meatus, it is wiped away and the patient is told to place his head on his knees with the affected side down. This places the ostium in a dependent position and, if any pus appears in the middle meatus, we can feel reasonably sure it comes from the maxillary sinus. Transillumination is of great diagnostic value in some cases. Roentgenography has, however, supplanted all other methods of diagnosis as it is most convincing. A very slight infection will be shown by the X-rays on account of the obstructive character of pus and diseased mucosa. Exploratory puncture is frequently resorted to when all other methods of diagnosis are negative. A painstaking history is very important in these obscure cases in assisting us in a diagnosis.

I will report several interesting cases that have come under my observation. *First*.—Mrs. A., age 35, was referred to me by her dentist, with the following history. After the extraction of several teeth, he found the right maxillary sinus was infected. Drainage through the alveolus continued for several weeks prior to my seeing the patient. The personal history in this case showed that she had had severe headaches for two years, and had sought treatment at various times in an effort to be relieved of these headaches. The source of her trouble, however, was accidentally discovered by her dentist. A Caldwell-Luc operation was done. The opening in the alveolus persisted for several months but eventually closed.

*Second*.—Miss C., age 38, came to me complaining of a cough and feared tuberculosis of the larynx. Physical and X-ray examination of her chest were negative. I found nothing

on examination except a left bicuspid tooth that looked suspicious to me. She was referred to her dentist for further examination. The report came back that the X-ray picture showed an abscess at the root of the tooth and the root of the tooth extended into the maxillary sinus. The X-ray of the sinuses showed the left maxillary sinus infected. An intranasal opening was made and 15 cc. of pus was aspirated.

*Third*.—Mrs. G., age 55, came to me with a history of pain in the left side of her face and headaches for ten years. This dated from the time she had a severe spell of typhoid fever. Her eyes gave her a great deal of trouble and looking at a bright light would give her severe headaches. The X-ray plate showed a cloudiness of the left antrum. An intranasal opening was made and 10 cc. of pus was removed. The culture gave a pure growth of staphylococcus aureus. I will only report these cases in an effort to show their obscurity at times and also the importance of being on the lookout for this condition.

In closing, I wish to emphasize the following points which are most convincing. *First*, infections of the maxillary sinuses may be the etiological factor in arthritis and many other diseases; *second*, this infection may produce almost no local symptoms for many years; *third*, this infection works insidiously and irreparable damage may result therefrom; *fourth*, a search for foci of infection is incomplete until a thorough investigation of the sinuses has been made. The finding of other foci should be no excuse for not investigating the sinuses.

526 Monroe Building.

#### DISCUSSION.

DR. B. R. KENNON, Norfolk: I wish to thank Dr. White for reminding us again of something very important in the question of focal infection.

I am speaking of the other sinuses as well as the maxillary. There is no doubt that there are a great many infections of all the nasal sinuses that go along without any active symptoms to make a diagnosis for us, and it requires a more careful examination than has formerly been given these cases to give them the proper care. I have been in eye and throat work for twenty-three or twenty-four years and, when I first started, years ago, this sinus work was hardly begun. Patients would come to me and complain of having headaches and want their eyes examined. I would examine them thoroughly and, not finding anything the matter, would pass it up. I would let them go out of my office without examining the nose at all. We are not doing the best we know how by our patients if we let them go out of the office without examining the nose. If the case is then still obscure, we should take an X-ray. The X-ray will show where the trouble lies.

The X-ray is the best thing we have in these cases, because so often a transillumination does not show any trouble when the X-ray will do so.

When the X-ray is positive, you look in the nose and find pus, but you can have a diseased membrane where there is no pus.

The most important remark in Dr. White's paper was the examination of children for sinusitis, when they come complaining of respiratory trouble. Those children should be well examined. You have no idea of the number of children that have acute sinus infection. They are very, very important. I think that there has been entirely too much carelessness in the treatment of children.

If Dr. White can just impress on the members of the profession the importance of careful examination of children's noses, he will have done a great deal of good.

DR. A. A. BURKE, Norfolk: I think Dr. White's paper is very timely. It is a plea for thoroughness. In the past we have been prone to overlook these cases. If you have not made mistakes, it is because you have not found anything to make mistakes with. Unless we give a thorough and complete examination, we have failed in our duty. All cases should be gone into thoroughly—not only one case, but all cases. We should examine thoroughly not only the maxillary, but all of the sinuses.

I remember when we had the scare in New York about trachoma. They thought that there had been an enormous increase, but it had not increased, it was only because they were paying more attention to the examination.

Regarding the X-ray and the transillumination, of course the X-ray will give us forms of information that we cannot get through transillumination, but in my hands the transillumination has been of far more value than the X-ray. I believe it to be probably twenty-five per cent more accurate than the X-ray.

DR. H. L. MYERS, Norfolk: If we find the sinuses involved we know that we must do something. There are cases in which you look into the nose and cannot find anything amiss; even if you have looked well you are liable to say that there are no signs of infection. But that is not far enough. We know that we have something that is producing infection. Every single means of which we know should be used. Transillumination, inspection, radiographs, etc., should be used not only once but often.

Another important thing is getting the patient at the right time. Sometimes between my office and the office of the X-ray man the patient will blow his nose and all evidences of disease will be removed. If we do not have an X-ray several times, we are overlooking part of our duty.

What Dr. White has said of the maxillary is true of all the sinuses. A great number of the headaches that we cannot account for, can easily be accounted for if we look into the nose more often.

DR. J. W. WHITE, Norfolk (closing): The head-mirror I think should be used more frequently. A nasal examination should always be made before removing adenoids and tonsils. In reply to Dr. Kennon as to why I confined my paper to latent infections of the maxillary sinus and did not refer to the other sinuses: The anatomy of the maxillary sinus, as I briefly described in my paper, shows how easily an infection may be latent for years and produce no local symptoms.

## ART AS APPLIED TO ANATOMY.\*

By JOHN WILKINS BRODNAX, M. D., Richmond, Va.  
Associate Professor of Anatomy, Medical College of Virginia.

In considering the application of Art to Anatomy, it is my purpose to confine this paper to two aspects of the subject only; first, to the debt that anatomy owes to art, and, second, the benefit to be derived by artistic methods of observation in the study of anatomy.

To appreciate the debt that anatomy owes to art it is pertinent to give, in brief, the development of artistic illustration in its application to anatomical teaching, and the evidences of anatomical investigation by artists in the period when this science was in its infancy.

Anatomical knowledge of a certain character is as old as art itself, but this primitive knowledge was debased by imperfect observation and blind reverence for the many misleading traditions of the times. Even in these early days art was utilized, and anatomical illustration was employed wherever a semblance of anatomy was taught. Greece, India, and even China, in the remotest periods of their history, resorted to drawings, showing more or less imperfectly the relative positions of the heart, lungs and other large organs, for the purpose of demonstration. These crude efforts, however, need only to be mentioned, for it is not to the flimsy imitation of visceral anatomy that one must look for examples of art, but rather to these masterly drawings of a later date, that display in the highest degree two of the qualities upon which scientific progress depends, accurate observation, and a true record of the thing observed.

The history of art and that of anatomy are by no means contemporary. When art had reached a high stage of perfection, and the sculptor was producing those wonderful masterpieces, known to us as the antique, which are today the admiration of the world for their beauty of contour and faithfulness to nature, medicine was vague and obscure, and in the hands of charlatans, while anatomy, the basis of all medical science, was, for even a mind like that of Hippocrates, a collection of crude and imperfectly noted facts modified by the time-honored fictions of the day. During this dark era of medical knowledge, it was the artist alone who found light to study the anatomy of man. More than a century before the

\*Read at the meeting of the Richmond Academy of Medicine and Surgery, May 8, 1923.

school of Alexandria had, under the Greek anatomists Herophilus and Erasistratus, inaugurated for the first time, the study of human anatomy by dissection of dead subjects, and it is said, even of living men, Phideas, the great sculptor of the age of Pericles (450 B. C.), and a contemporary of Hippocrates himself, had acquired such perfect knowledge of surface anatomy that his works appear to us now as the very acme of truth and beauty in the representation of the human form. His noble figures of the Theseus and of the Ilyssus of the Parthenon, the most familiar of his works, might be submitted to the scrutiny of the critical eye of the most finished anatomist or artist of this day, and I would venture to say that neither could discover an error in science or point out a line or contour which could be changed without detracting from the beauty and symmetry of the whole.

At the time these works of art were produced, the dissection of the human body had not yet been attempted; the respect in which the dead body was held was such that the physicians themselves, who should have been able to justify their motives for this study, had never as yet dissected a human body. Hippocrates had dissected animals, and had arrived at certain conclusions by the analogy that exists between the organs of lower animals and those of man. Galen himself dissected monkeys only, seeking to confine his examination to animals whose anatomical construction might be considered as most closely resembling that of man. Galen never possessed a human skeleton, for in a passage in his anatomical works he states the pleasure in studying at last some human bones that had been deposited in a marshy place by a river which had overflowed its banks. When we reflect that Phideas had not the advantages of the study of anatomy by the practice of dissection as did Michel Angelo, but acquired his knowledge of the subject solely through the constant observation of athletes in action during games and military exercises his achievements appear all the more wonderful.

The establishment of the school of Alexandria, less than a century after the death of Phideas, should have done much to advance the knowledge of anatomy, as it is known that under Erasistratus and Herophilus the dissection of the dead body was practiced openly, but there was strangely little harvest from such a broad and fertile field, and the cultivation of

original observation in human anatomy rapidly declined, until in the second century of our era, when Galen, strongly imbued with the spirit of research, by his investigations, was able to give to the world a series of writings which placed anatomy among the sciences, and furnished the profession of medicine with descriptions, so far as they went, not materially different from those contained in the text books of the present day.

Following the fall of the Roman Empire, we come to that darkest of all periods—the middle ages—when art was at its lowest ebb, when learning represented chiefly by Moslems and Arabs and a bigoted clergy was opposed alike to scientific investigation and artistic culture. During all this time anatomy remained at a standstill and little advancement was made in any of the departments of medicine. It was not until the thirteenth century that Frederick II., Emperor of Germany, and King of the Two Sicilies, revived the study of anatomy by dissection, by passing a law prohibiting the practice of medicine without the practitioners having first studied the anatomy of the human body. In spite of two papal excommunications hurled against him, dissections were from that time on regularly pursued in Italy. The first outcome of the new departure was the publication in 1316 of the first treatise on human anatomy, that of Mundini de Luze of Bologna, containing descriptions made from studies of the dead body.

Dissection was introduced into France at Montpellier in 1376, and it is to a French surgeon and artist, Henry de Mondeville who lived at the beginning of the fourteenth century, that credit belongs for having first made use in Europe of anatomical drawings as a means of instruction. The first really important application of art to medicine, however, belongs to a period no earlier than the fifteenth century, at which time artists rivalled physicians in the ardor with which they pursued their anatomical studies, and it may be said that all the painters and sculptors of that period gave the most careful attention to dissection, or at least studied demonstrations made upon the dead body, for all have left amongst their drawings anatomical studies that give evidence of that fact.

To this period belongs one of the most versatile geniuses in history, Leonardo da Vinci, painter, sculptor, scientist, poet, and musician. It was he who, first amongst the artists,

deemed it profitable to cultivate the friendship of representatives of the medical science. It is known that he became intimately associated with the physician, Marcantonio della Torre, of Ferrara and Padua, and that he made for him many drawings to illustrate an anatomical treatise, but the untimely death of Marcantonio in 1506 severed a connection which under more fortunate circumstances might have raised the anatomist to the eminence afterwards occupied by Vesalius. As it was, the great work remained unfinished, all that had been written was lost, and along with it disappeared the drawings of da Vinci. Only a few of the numerous anatomical studies made by this great artist still exist, but the skill

The Nike of Paionios (Circa 420 B. C.).

and anatomical exactness displayed in these bear witness of the care and attention he gave to the study of anatomy. Leonardo himself was the author of a "Treatise on Painting," in which he devotes numerous chapters to the description of the muscles of the body, the joints, and, in his words, the "Cords and small tendons which meet together when the muscles contract to produce action," etc. In this book, he makes allusion at different times to a "Treatise on Anatomy," which he intended to publish, and for which he had gathered together numerous notes.

The period of Leonardo and of the succeeding generation was a glorious one in the history of art, for while the great Tuscan was still in his prime, there appeared upon the

horizon another many sided genius in the person of Michel Angelo Buonarroti, at once painter, sculptor, architect, engineer, and poet. The latter had just reached the zenith of his fame, when Leonardo, full of years and honors, died in the arms of the monarch whose graceful tribute to his genius did more to perpetuate the memory of King Francis I. than any other act of his long and stormy reign.

Michel Angelo, like his predecessor, was not long in seeing the advantages to be derived by associating art with anatomy. He attached himself to Realdo Colombo, one of the foremost anatomists of his day and for twelve years, first in Florence, then in Rome, he devoted himself to the study of anatomy. The results are apparent, possibly too plainly, in all his works. His statues of David, the Captives, and many others, give striking evidence of his profound knowledge of anatomy. Among the large number of drawings which Michel Angelo left to posterity are many beautiful illustrations of dissections made by his own hand.

Another of the great artist-anatomists of this period was Raffaello Santi, better known as Raphael, again painter, sculptor, and architect, who won triumphs as lasting as those which fell to the lot of his illustrious contemporary and rival. Raphael's knowledge of anatomy was not perhaps as deep as either that of Leonardo or Michel Angelo, but it must be remembered that fewer years were allotted for the consummation of his goal, for the grim-reaper claimed him before he had ended the fourth decade of his brilliant career. It is nevertheless shown by his anatomical sketches that he not only appreciated the importance of the science, but that he was well informed on those portions of it which are of most concern to the artist. Among his drawings deserving of special mention as particularly remarkable for its fidelity to nature, is a study of the skeleton intended to give him an exact indication of the direction of the limbs and the position of the joints of the swooning virgin in his picture of the entombment.

To this list may be added the names of Rosso de Rossi and Benvenuto Cellini, both of whom studied anatomy by the practice of dissection, and made many realistic anatomical drawings, some of which are still preserved. Rosso de Rossi holds the distinction of having been the first artist to attempt to prepare a

volume on anatomy for the use of painters; unfortunately, however, he did not live to complete his work. The one plate, showing the bones and muscles, given to the world as an earnest of his good intentions, is, however, so rich in strength and accuracy that it has been mistaken for the work of Michel Angelo himself. Benvenuto Cellini became associated with the eminent Florentine physician Vidus Vidius, whose book on anatomy was not published until long after his death, but it is believed that Cellini greatly assisted him in its preparation.

Up to this time the art of the fifteenth and the first half of the sixteenth centuries bore little relation to medicine, if we leave out of consideration the drawings of Leonardo da Vinci. While great artists left accurate record of all that their dissecting-room experiences had revealed, two of the most distinguished physicians of the age, Magnus Hundt, of Leipzig, and Lorenz Phryesen, of Colmar, for some unaccountable reason, had recourse to the crude

faith to the pedantic utterances of his august teacher.

The second period, that of artistic illustration of anatomical works by wood engravings, began in the first half of the sixteenth century with the appearance of a commentary upon the anatomical work of Modino by Berengario da Carpa (1521). This work was followed in the next year by a compendium by the latter author, in which he corrected many errors of Modino, and added much new material. Both of these books were embellished with woodcuts, a few of which, chiefly myological, displayed much artistic beauty and were fairly accurate, while others were of a traditional character and in keeping with the descriptions of Galen. Berengario himself was artistically gifted and maintained relations with artists and friends of art. It is possible that he received some artistic aid from Benvenuto Cellini, with whom he was on intimate terms, and who was at that time in his early manhood. About twenty years later Johann Eichman, a professor at Marburg, issued an original composition upon the dissection of the human body, with illustrations made by himself, and engraved upon wood by his own hand.

Both Berengario and Eichman accomplished much towards the advancement of anatomical science, and opened the way for a higher school that was destined to consign that of Mondino and his contemporaries to the category of the imperfect sciences. Berengario had half caught the vision of a genuine treatise upon the anatomy of man, based upon facts obtained by actual dissection, but the consummation of such a work was reserved for a far greater mind—that of the immortal Belgian anatomist, Andreas Vesalius.

Vesalius was born in Brussels in 1513. At the age of twenty-four he went to Italy where he pursued the study of anatomy, with unremitting zeal up to the time of his death, which occurred October 15, 1564. In 1847, his native city of Brussels erected a magnificent bronze statue to his memory.

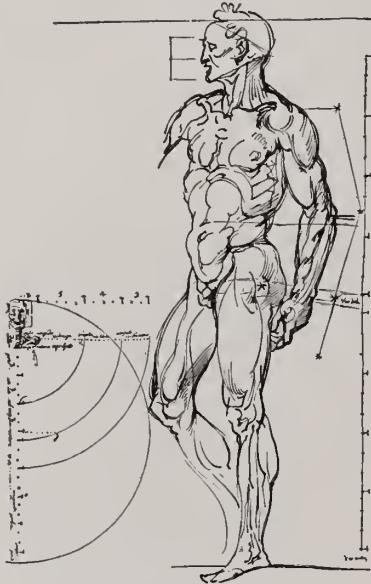

The student of medicine of the present day, who recognizes the name of Vesalius only in association with a small and insignificant foramen in the base of the skull, can hardly realize that it is to his great genius we owe the entire scheme of human anatomy, as a study involving accuracy of observation and description. Yet this is true, for to turn from the pages of his predecessors to the works of Vesalius, is to step from the bewildering glim-

Drawing of muscles by Leonardo da Vinci.

drawings in the anatomy of Galen to illustrate their own treatises. In Phryesen's work, entitled "Spiegel der Artzney," published in 1518, he gives us only a wretched caricature of the skeleton, a view of the thoracic and abdominal viscera, evidently drawn from the anatomy of the dog, one or two confused sketches of the brain, and a carefully executed picture of himself seated in majestic dignity, while cringing bareheaded before him is an humble disciple, listening with undoubting

mer of supposition and tradition into the light of fact and order. It is to be especially noted that, from the first, the great teacher availed himself of the assistance of the artist, and directed his interpretations of the subject at every step. It is possible that he himself learned much in teaching his associates, and it is certain that the value of his own labors was

Sketch of anatomical figure by Michel Angelo Buonarroti.

greatly enhanced by the skilled pencil which wrote his story in characters that all men could understand.

As the designers of the Vesalian illustrations many famous artists have been named, among them Tiziano Vecelli, Christoforo Coriolani, Titian, and his illustrious pupil, Jan Kalkar. It is probable that all of these contributed to his works. To the divine Titian has been ascribed the superb figures which illustrate his great work, "De Humani Corporis Fabrica," which raised Vesalius to an eminence that no other anatomist had reached before, and fastened to his name the title of Father of Modern Anatomy.

His "Magnum Opus," the illustrations of which are accredited to Jan Kalkar, was published in Basle in 1543. To men of science it was a revelation as an example of unprecedented anatomical research, and to the disciples of art the volume has always been precious on account of the harmonious union of strength and truthfulness in the designs, and beauty and symmetry of the forms. The bones and muscles are reproduced most skill-

fully and with greater anatomical exactness than had ever been attained before; the viscera, vessels, and nerves were less successfully portrayed, but it is true that the anatomy of these parts was, at that time, not so well understood. The main features, however, were faithfully described and portrayed, and the work as a whole was a miracle of wide and original research. It is difficult to say whether it was the text or the illustrations that exerted the greater influence over the contemporaries and followers of the author, but for a century afterwards the anatomists of Europe did little more than to compose variations upon the united achievements of Vesalius and Kalkar.

Vesalius was not without rivalry in the field of anatomical research. In 1545, two years after the appearance of the "De Humani Corporis Fabrica," a French physician named Charles Estienne published a book descrip-

Jan Kalkar's drawing of the skeleton for "De Corporis Humani Fabrica" by Andreas Vesalius.

tive of the dissection of the various parts of the human body, in which he used woodcuts of a most curious character. The author, whose work was commenced long before the appearance of that of Vesalius, was a practical anatomist and, although an original worker, he was far inferior to Vesalius, and made use of art in a much less intelligent way. In Vesalius the illustration though of the highest merit, was always subordinate to the subject of the text, while in Estienne's cuts the

anatomy often appeared to be little more than a medium for the fanciful ideas of the artist. Some of the drawings were, indeed, very striking as artistic compositions, but the figures were often placed in queer and repulsive positions, while the introduction of many non-essentials rendered the anatomical parts small and indistinguishable; as for example, a plate showing the entire form of a man in the foreground of a pastoral landscape, his calvaria hanging from a limb of a tree above his head, while his denuded brain turned towards the observer represents all the anatomy to be seen in the whole picture; and another, a full length nude figure of a woman seated in a chamber of classical design, has no other purpose than to display the contour of the external genitals. Nevertheless, except in the case of the muscles, which were miserably portrayed, the anatomy of Estienne's plates was for the most part fairly true to nature.

Another competitor of Vesalius, and a far more serious one, was the Italian physician, Bartolomeo Eustachio. He, more than any other anatomist of his time, enriched his science by accurate investigation. His published work on the anatomy of the kidney was an admirably thorough piece of original research. He also engaged in pathological research and is said to have been the first anatomist to introduce postmortem examinations in Roman hospitals.

Eustachius himself made most of the drawings to illustrate his anatomical writings, others were made by his relative and assistant Pier Matteo Pini of Urbino. Only eight of his drawings appeared during his lifetime, in connection with his "Opuscula Anatomica," published in 1564. Thirty-nine other engravings made by him remained unused until a hundred and forty years after his death, when the papal physician, Giovanni Lancisi, found them with the heirs of Pini and published them with his own commentaries in 1714. Despite their long slumber, the pictures were so little behind the age when they were introduced to the world that edition after edition was called for, the demand ceasing only at the beginning of the nineteenth century. The drawings were indeed in some respects even richer and more trustworthy in detail than those of Vesalius; and, although both drawing and engraving were feeble and inartistic, the scientific value of the plates more than counterbalanced their aesthetic imperfections.

The third period, extending from the middle of the sixteenth to the early part of the nineteenth century, may be called that of artistic engraving on copper. The process was not a new one, but had been practiced long before this time, at least as early as 1461, but no extensive use of it had been made in medical illustration before the seventeenth century, and the few examples that had appeared in medical books were of small artistic importance as compared with the contemporary work of the wood engraver.

The first important medical work embellished with copper-plate engravings was the "Historia de la Composicion del Cuerpo Humano" (1556,) by Juan Valverde de Hamusco, a Spaniard, who had studied anatomy under Colombo and Eustachius. The illustrations in this book were mostly copied from those of Vesalius, but the engraving on copper was skilfully done. One plate, however, not taken from Vesalius, is interesting as a curious instance of the tendency shown by the old anatomical artists to make the most

Anatomical figure by Juan di Hamusco.

of the subject from their point of view. It represents the figure of a man who, having just succeeded in divesting himself of his skin, stands in a pose of dignified self-approval, grasping the knife dripping with blood in one hand, while with the other he holds up to view his detached integuments, from the midst of which the flabby features of his face stare in feeble disapproval at the spectator.

The use of wood engraving in the embellishment of anatomical works did not end with the advent of copper-plate etching or afterwards, but it ceased to hold the important place it had hitherto occupied as a means of artistic expression. Many writings of great value, however, such as the contribution of Constantio Varoli to the anatomy of the brain ("De Nervis Opticus." etc., 1573), the "Historia plerarumque partium Humani Corporis" (1585) of Solomon Alberti, and the artistic treatise "Varia Commensuracion para la Escultura y Arquitectura" (1585) of Juan de Arphe were illustrated by woodcuts; but the power that stamped the cuts in Vesalius had disappeared.

In the seventeenth century copper plate engravings, which had been used for anatomical illustrations in the preceding century by Eustachius, held undisputed sway. The anatomical works of Giulio Casserio (1627), and those of his successor in the chair of Padua, Adrian van de Spieghel (Spigelius) were copiously and artistically illustrated by this process. Another valuable set of drawings was made a little later by the famous artist, Pietro Berretini of Cortona, for the anatomist Johannes Maria Castellanus, and skilfully transferred to copper, but, unfortunately, these plates, like those of Eustachius, remained hidden, and it was not until a century later, in 1747, that they were discovered and published: a lapse that was the more to be deplored since they gave to the anatomy of the nervous system an artistic manner of representation and accuracy of detail not equalled by any of his predecessors.

In the drawings of Berrentini, as in most cases where artists have interested themselves in the work of the anatomist, the grimness of the motive disappears under the artistic touch which injects life, and even humor into the composition.

The great landmark of progress in the still somewhat barren field of medical science, the immortal "Exercitatio Anatomica de Motu Cordis et Sanguinis" by the celebrated English physician, William Harvey, was published in 1628, but the book owed nothing to the quality of the copper plates which illustrated it, nor did English art make a creditable showing in any of the anatomical publications of the seventeenth century. The plates of Samuel Collin's "System of Anatomy," published in 1685, though executed by one Faithorne, con-

sidered the ablest engraver of his time, displayed little excellence, while those of a contemporary treatise upon the muscular system by John Browne, a surgeon of London, have even less claims to artistic merit.

Anatomical figure by Peter Paul Rubens.

The dissected figures in the latter case, drawn with pretentious badness, are placed in the most curiously affected and self-conscious attitudes, as though proud of the exhibition of their anatomical details. The pictures, however, were interesting from the fact that the names of the structures were, for the first time, engraved on the parts, a practice afterwards followed by Gray and Holden, and which has continued its popularity to the present time.

The palm of artistic pre-eminence in the medical books of the seventeenth century belongs to Holland. The publication in 1665 of the "Anatomia Humani Corporis" of Godfried Bidloo, a professor of anatomy at the Hague and Leyden, did not contribute much to science, but the author had the sagacity to associate with himself in the work the eminent artist, Gerard de Lairese of Amsterdam, and was thus enabled to produce a book which to the present day has remained greatly prized, if little read, for the accuracy and strength of the drawings. Some of the plates, however, are too naturalistic both for art and for science, but in two of the osteological designs, which are particularly noteworthy as works of art, the temptation to pictorial dis-

play is too strong for the artistic mind to resist; in one of these, a figure standing within the entrance of a sepulchre holds up an hour glass as if to remind us that our condition is separated from his only by the moments of passage of a few falling grains of sand; and in the other, the animated skeleton is seen descending into the grave, not without a certain grace and dignity, to escape from a world where the grim simplicity of the uncovered bones could find neither condolence nor repose.

Before leaving the seventeenth century, it may be stated that the two greatest artists of that period, Rembrandt and Rubens, have left their impress in connection with medical science; Rembrandt in his celebrated picture of the physician Van Tulp demonstrating the structures of the arm to some of his compatriots (painted 1632), as well as two other works less known, and Rubens by several bold and characteristic studies of the surface anatomy of the body.

In the next century (the eighteenth), anatomy was elevated by the publication of some splendid anatomical atlases, printed in the most expensive style and embellished with exquisitely engraved plates. Practically, there was but one method of reproduction during this period—that of etching on copper—for the wood block had fallen from the high rank it formerly occupied, and produced no more pictures like those engraved for Guido Guidi and Vesalius.

The list of important works is too large even to name, but as examples for beauty of illustration may be mentioned the "Osteographia, or Anatomy of the Bones" by William Cheselden (1733); the "Tabulae Selecti et Musculorum Corporis Humani" of Bernhard Siegfried Albinus of Leyden (1747) and the "Anatomia Uteri Humani Gravidi," by William Hunter (1774). Cheselden, a man of artistic taste, spared neither trouble nor expense to secure the most artistic reproductions of his specimens, but he was above all a man of science, and he was equally as zealous that they be accurately presented. The result was, as would be expected, a magnificent volume of great artistic excellence as well as fidelity to nature. The "Osteographia" was a distinct contribution to the anatomical science, and an ornament to the medical literature of the day.

The Atlas of Albinus was even a more scientific work than that of Cheselden. Myology had been well and broadly treated in the illus-

trations of many preceding works, but the detail of form and attachments of each individual muscle were represented in this book for the first time, and the task was performed with so much thoroughness that little has remained to be added. The drawings of the various figures displayed great skill and accuracy and, although the artist lacked ability to reproduce the tectorial character of the structures, he so ably preserved the essential truths that the great atlas fully merits the high rank it held during three generations as a standard of reference both for artist and anatomist. It was not until the middle of the nineteenth century that its place was taken by other works more suitable to the requirements and pocket of the student. An illustrated volume by the same author confined to osteology, "Tabulae Ossium Humanorum" (1784), is especially to be remembered as being the first attempt to show the exact area of muscular and ligamentous attachments upon the bones.

William Hunter's treatise on the Gravid Uterus ranks with Cheselden's "Osteographia" as an ornament to the library, for the best art available at the time had been used on a subject that would appear to be little capable of aesthetic treatment. The foremost artists of the day were employed upon the plates, and one of the number, the famous Sir Robert Strange, is said by Hunter himself to have given "his advice and assistance in every part of the work with a steady and disinterested friendship."

The fourth or modern period of anatomical illustration may be dated from the close of the second decade of the nineteenth century. Art has become more and more essential to medical science as an aid both to record and expression. The diagram, the more highly finished drawing, and the model serve as a new language that speaks with strength and clearness where written or spoken words would convey their meaning slowly and imperfectly. The new period has been characterised by the multiplication of methods of pictorial reproduction. Engraving on copper, which stood at the forefront during the last period, gave way to cheaper and more readily adaptable processes. Of the new processes, lithography, invented in 1796, was destined to hold an important place in medical illustration, as was also photography and photographic processes of engraving which came in use later on.

The first medical essay of moment in lithography appears to have been the engraved plates of the "Arteries," published by Friedrich Tiedemann, in 1822, but the result here was by no means striking. It was not long afterwards, however, in 1831, that Jacob, the father of the modern French school of anatomical drawing, unveiled the possibilities of engraving on stone in the great anatomical work of Bourguery. This magnificent achievement of Jacob's gave a wide impetus to anatomical illustration by the new process, and many works of high scientific value and artistic excellence, illustrated in this manner, made their appearance in rapid succession. The most important of these, from an artistic point of view, was Hirschfeldt's "Anatomie du Systeme Nerveux" (1853). The illustrations for this work were made by the French artist Jean Leveille, the favorite pupil of Jacob. This gifted man was an accomplished anatomist as well as artist and thus combined in his person a profound knowledge of the subject with an ability to depict it in the most skilful and accurate manner. In the designs for this book, Leveille reached the highest point of artistic excellence and placed France beyond rivalry in anatomical illustration. Another book illustrated by lithographic plates, deserving of mention, is the "Anatome Artistic du Corps Humain" by Dr. Paul Richer of Berlin. This is the best treatise on Artistic Anatomy that has ever been written, and is unique in the fact that this talented physician not only wrote the text but also made the drawings to illustrate it.

Since the advent of lithography, the process has been carried to such a high degree of development, that by this method we are now enabled to utilize colors in reproduction in so perfect a manner as to give to the structures an appearance closely resembling their natural state. Multicolor lithography, as it is called, has been most successfully employed in medical illustration. The first and, up to this time, the only anatomical work to be printed by the color process has been the beautiful Atlas of Johannes Sabotta of Wurzburg. The superior quality of the drawings and the life-like effect given them by the colors renders this book a valuable contribution to the anatomical science.

Photographic processes too have made rapid strides of advancement. The half-tone method,

based on photography, gives most excellent results, and is now even more extensively employed for book illustration than is lithography. The advantage of the half-tone, aside from its cheapness, is the unerring exactness with which drawings are reproduced. This process is well exemplified in Spalteholz's magnificent Atlas, and the monumental work of the American anatomist, Dr. George A. Piersol of the University of Pennsylvania. It is needless to add that, in all reproductive work, the merit of the illustration depends not so much upon the manner of its reproduction as upon the deft hand of the artist who fashioned it.

In conclusion, the service that art has rendered to anatomy is sufficiently apparent, even in the few pictures I am able to show you tonight. We all know the great advantages to be derived from book illustration as a means of fixing and clarifying our knowledge, and how often an accurate picture appears to us like an oasis in the midst of a desert of unintelligible text. It is true that pictorial anatomy, like every other good thing, may be misused. It is a poor substitute for direct personal study and examination of the structures themselves, although for many parts of the body it is a necessary one for the ordinary student, but it is always an efficient preface and an invaluable sequence for such parts, for it shows us better than any written description what to look for, and it recalls to us what we have seen.

The service that a love of art may confer upon us personally and individually is a matter of a different kind. The study of art is a mental culture of the highest order; it gives a training to the eye and hand of inestimable value to the surgeon and the anatomist, and there is no diversion that can reflect more rays of sunshine across the dull shadow of the daily routine of our professional life. The medical profession has numbered among its ranks many distinguished patrons of art, and not a few men who have displayed a power of artistic attainment that would have made them great artists, had not their destiny guided them to eminence in the medical sciences instead. In this class belong the famous anatomists, Bell, Maclise, Holden, and Godlee of England, and Keen, McClellan, and Spitzka of our own country. Though better known as anatomists,

they were artists as well and, by their achievements, added lustre to both professions.

Of the possession of a skilful knowledge and facility of drawing to a teacher of anatomy, little need be said, for it is obvious that one who can demonstrate an idea clearly and succinctly by a few strokes upon the blackboard will, other things being equal, best claim and hold the attention of his students and let them leave with the most lasting mental impression of the subject of his lecture.

### THE RELATION OF BIOLOGY TO SURGERY.\*

By J. SHELTON HORSLEY, M. D., Richmond, Va.

The privilege of addressing the members of the Atlanta Academy of Medicine, of the Fulton County Medical Society, on such an auspicious occasion as the opening of their new home, is an honor that I greatly appreciate. There is a spiritual inspiration about the dedication of a monument, the unveiling of a statue, or the opening of a home that is hard to estimate. It seems to mark a distinct era in the lives of the individuals or of the society for which such an event occurs. It offers an opportunity for resolutions of doing better work, for broader vision, for greater brotherhood among the members of the medical profession that are directly concerned in such an event, and for an elevation of ideals that will not be satisfied with anything but the very best in scientific medicine and surgery. It is a great privilege to be a participant in such an event.

I have chosen for the subject of my address "The Relation of Biology to Surgery," because I feel that the future of both medicine and surgery is very intimately involved in the proper appreciation of biologic principles. Biology covers, to be sure, a wide field and is often rather vaguely defined. I am using it as the science that has to do with living tissue in its various manifestations. This necessarily embraces physiology, because physiology is a study of normal function, as well as pathology, which broadly includes the study of abnormal function and of diseased tissue. In the living body, all the reactions of tissues to disease or trauma are biologic processes.

In the science of medicine, as in religion, certain great prophets stand out who mark the

way and whose teachings and vision are too frequently neglected until succeeding generations. The work of such a man as John Hunter is classic on account of the marvelous accuracy of observation and the logical deductions from the observed facts. The epoch-making works of Pasteur and of Lister are now fully appreciated. In this goodly company there is a man whose reputation is less widely known, and yet, though his chief work is contained in the lectures given at the Royal College of Surgeons in England in 1860, there is an amount of accurate observation and philosophical deduction that should be the admiration of every physician and surgeon. I refer to the lectures of John Hilton, which were published under the title of "Rest and Pain." Pre-eminently, he emphasized the causation of pain as a protective phenomenon and the beneficial influence of physiologic rest. He may be considered a pioneer in thus calling attention to the great value of the observation of biologic principles in the comprehension and the treatment of disease.

We of the medical profession are sometimes too often inclined to confuse the relation of cause and effect in treating disease. This applies not only to pharmaceutical remedies but to surgical measures. Accurate observations such as Hilton's frequently clear the atmosphere and show a sharp outline of the true condition. Particularly in surgery, we must never forget that the patient is a highly organized mass of living tissue, every cell of which is capable of a certain definite reaction to trauma or disease. Surgical operations that look well on a cadaver may be utterly unsuccessful on a living human being. A beautiful operation that results in the death of the patient is not satisfactory surgery. The mechanical portion of the technic is important, but it should not entirely dominate. The ideal is to be thoroughly imbued with the principles of the biologic sciences, thoughtfully to apply these principles, and at the same time to be mechanically skilful.

The science of anatomy is essential to the mechanics of surgery. He would be a poor locomotive mechanic who did not understand the construction of his engine; and in operations on the neck, for instance, a surgeon who is ignorant of anatomy would be like the proverbial bull in a china shop. A knowledge of anatomy is essential to good surgery, but

\*An address delivered December 7, 1922, by invitation, at the opening of the new home of the Atlanta Academy of Medicine of the Fulton County Medical Society.

in the ever shifting problems of tissue repair and metabolism, physiology is just as necessary. The principles underlying an operation are correct only if they conform to the laws of physiology and of repair of the tissue or organ that is affected. If we could get away from blindly following what some one says merely because he says it, and do things because of reasons that have sound biologic foundations, we should undoubtedly do work more satisfactory to our patients and to ourselves.

The ideal in surgery should be first of all a thorough and complete removal of the pathology, and a close second to this should be restoration of the physiologic function. These ideals cannot be intelligently even approximated without a consideration of the biologic principles not only that accompany the disease, but that are an essential part of the process of repair after an operation or of the readjustment of the tissues because of changed anatomical relations brought about by operation.

#### DRAINAGE.

Probably we can best illustrate the intimate relation which biologic processes have to the mechanical procedures in surgery by considering surgical drainage. An appendicular abscess is opened and drained by the insertion of a tube *down* to the abscess. The pus is drained uphill. There is no effort to secure dependent drainage by gravity, and yet the vast majority of these abscesses heal satisfactorily with this treatment. An abscess of the same kind of infection in the muscular tissues or in the pleural cavity would probably not heal unless drainage was made at the most dependent portion. Why, then, does this abscess heal readily when drained from its roof, whereas the same type of pus elsewhere requires gravity drainage?

It is common knowledge that gauze drainage is often beneficial. A cigarette drain carried to the bottom of an abdominal wound with local peritoneal infection limits the inflammation and promotes cure, but if we were to examine this drain within twenty-four hours after being placed, we would find the meshes and fibers of the gauze plugged with coagulated lymph, so instead of acting as a drain it really becomes a plug—yet it is a common experience that this is a very beneficial procedure, and often the gauze drainage is better than a tube. Surely such contradictory conditions

cannot be reconciled by any law of mechanics.

Let us consider the biologic processes that may explain the beneficial effects of surgical drainage.

First of all, we must recognize that the body has certain definite biologic defenses against trauma and disease. These defenses are usually not perfect, and sometimes are quite feeble, but with very few exceptions they exist. The defenses against the injurious effects of foreign substances in the epithelial lined cavities where such substances are prone to lodge are highly specialized. Thus, the stomach emits, by vomiting, food that is spoiled and many irritating drugs. Excessive salivation which accompanies nausea tends to dilute the offensive material and to protect the mucosa of the mouth and the esophagus. Irritating material in the nose produces a profuse secretion which may wash away the irritating substance, and sometimes there is sneezing which is a violent propulsive force. In the eye a cinder causes spasm of the eyelid and a flow of tears to wash away the cinder. An irritating body in the larynx, bladder or rectum immediately calls for spasm. In the endothelial lined cavities, however, and in solid tissue, the chief, if not the only, method of extruding an irritating foreign substance is by a flow of lymph. This is such a common occurrence that we are inclined to overlook it. If a boy sticks a splinter in his toe, it may not annoy him for one or two days. Then there is some swelling about the splinter, and the tissues around it "fester." For some days there is a discharge of pus, which becomes thinner, and then on inspection a small black speck can often be seen. If he is a normal country boy, his mother usually picks out the splinter with the point of a needle, and the discharge ceases by the next day.

This homely illustration demonstrates the foundation principles of surgical drainage. An irritating substance in solid tissue or in a serious cavity causes the lymphatics in the neighborhood of the irritation to pour out abundantly lymph or serum around this foreign body. If bacteria are present, pus is formed and this augments the flow of lymph because it adds an additional irritation. The splinter, for instance, which was firmly fixed in the tissues at first is somewhat loosened, and the constant flow of lymph around it tends to wash the splinter toward the surface along its track of entrance. After its removal there

is no longer a stimulus for the flow of lymph, and the wound quickly closes.

These phenomena are well known in surgical experience. The beneficial results of surgical drainage, then, come partly from relief of pressure in a suppurating cavity, which thus lessens the absorption of the toxic products, and partly from the stimulus to the neighboring lymphatics to pour out the lymph or serum into the drainage tract. This explains why an uphill drainage will be satisfactory in the abdomen, but not in the pleural cavity or in the solid tissues of the thigh, for the peritoneum is a huge lymphatic sac, and its lymph supply is so abundant that the irritation from the foreign substance of a drain, plus the local infection, will direct an ample lymph stream along the drain and so wash out from the peritoneal cavity the bacteria and their toxic products that would otherwise be absorbed. In solid tissues or in the pleural cavity where the lymphatic supply is much less than in the peritoneal cavity, there is not enough of the serum or lymph available to clean the abscess cavity, so that toxic products cannot be satisfactorily eliminated solely by the outpouring of lymph. Consequently, gravity must be invoked.

Gauze is more irritating than rubber. The application of dry gauze to a wound is quickly followed by an exudate of lymph. Nature pours into the meshes of the gauze an abundant quantity of lymph in an effort to extrude the gauze, which is irritating. For this reason we will cover a fresh wound with gauze when pus must be evacuated over the wound, and we are accustomed to see very little contamination of the raw surface if it is thus protected. The gauze reverses the normal lymph flow, and the lymph supply is poured out into the gauze instead of absorbing the toxic products of the bacteria. For this reason a cigarette drain is often of more value in limiting infection and directing the lymph current toward it than would be a tube. The combination of a tube and a cigarette drain in large cavities is frequently most effective.

#### HYPEREMIA.

The principles that govern repair and nutrition are the underlying essentials of most surgical procedures. Nutrition comes largely or entirely through the blood stream, and depends upon the caliber and the character of the vessels which deliver the blood, the capil-

laries which distribute it, and the veins which return it—as well as upon the quality and quantity of the blood itself.

Walter B. Cannon, of Harvard, has shown the very striking influence emotions may have upon the quality of blood and upon its distribution. He has found that under great emotional or physical strain an excessive amount of sugar is often found in the blood and this produces a temporary glycosuria. The secretion from the adrenal glands apparently continues the impulses that are initiated by the sympathetic system and puts the body on a war footing. This lessens the peristalsis of the intestines, increases the action of the sphincters, dilates the bronchioles, increases the caliber of the arterioles to the muscles while constricting the arterioles of the body surfaces, and dilates the pupil. All of this mobilizes the energies of the body, and temporarily interferes with the absorption of nutrition from the gastro-intestinal tract. Such a process may amount to little if it is temporary, but no one can doubt that the condition of the war footing produced by the emotions, added to the necessary strain of the surgical operation, to some extent increases the risk. This, then, shows the necessity for the conservation of the patient's energies by measures that tend to prevent a useless exhibition of the patient's emotion of fear or anxiety.

The problem of local hyperemia has not infrequently been a puzzling one. Occasionally therapeutic measures have been adopted along the same principle that Hertzler says some surgeons utilize in the abdomen, namely, when an organ is tied up by adhesions, the adhesions must always be released, and when it is free, adhesions must be created. Too often there has been a tendency arbitrarily to decrease hyperemia when it is present, or to promote it when absent, without regard to what will be accomplished by such procedures. The old method of treating subacute or chronic inflammation of the joints or tendons was to paint the skin over the affected part with iodine. This was done on the theory that the application of iodine would draw blood *from* the injured region, and so by relieving congestion would benefit the inflamed tissues. It has been well known that such applications are often beneficial, but we are now aware that the benefit is attained not by drawing blood *from* the tissue, but by bringing more blood *to*

the injured tissue, and so increasing the metabolism and nutrition that a more rapid repair can take place. How often we see a chronic indolent wound that heals after a vigorous application of nitrate of silver, which cuts down the superficial granulations. The action of the silver, of course, destroys useless and poorly built granulations, but probably its chief beneficial result is the creation of an increased hyperemia, which will permit the construction of proper granulations that will go through the normal cycle and result in scar tissue and healing.

Some chemicals promote a hyperemia more readily than others, but may also produce too much local destruction. The silver preparations are remedies that seem to cause a maximum amount of hyperemia and a minimum of destruction of tissue. Frequently, too, such applications are followed by relief from pain in painful ulcers, where nothing else is effective. In such instances there is doubtless an ischemic pain in which the nerve fibrils do not receive a sufficient amount of blood for their needs, and consequently register pain until the hyperemia relieves their distress.

The influence of hyperemia in tuberculous diseases has long been known. This has been utilized to the benefit of the patient by the method of Bier. The pathologic process in the formation of the tubercle causes a hyalinization of the minute blood vessels, so that in the tubercle is a giant cell, with surrounding tubercle bacilli and epithelioid cells, to which there is practically no blood supply. If we can flood the tubercle with rich blood, the tuberculous process is overcome and nutrition is sufficient for the formation of normal granulation tissue and healing by scar formation. Blood is a great enemy of the tubercle bacillus, which in most tissues can only live because of the pathologic processes tending to decrease or shut off the blood supply to the tubercle.

It is doubtless within the memory of many surgeons and physicians when tuberculous ascitic peritonitis was treated in many weird and fanciful ways. One surgeon would make a long opening, evacuating the fluid and manipulating the intestines. Another, after incision, would dust the peritoneal cavity with some particular preparation. Still others insisted upon letting the sunlight in. Many used drainage of various kinds. A large percentage of cases of ascitic tuberculous peritonitis recovered after these operations, and each sur-

geon was thoroughly convinced that his own method was the peculiarly correct one. It was some time before it was discovered that the evacuation of the fluid and the manipulations produced a hyperemia, and it was the hyperemia that cured.

But excessive or constant hyperemia may not be an unmixed blessing. Just as over-nutrition has a deleterious action on the whole body, so over-nutrition of local tissue by excessive hyperemia may have a harmful effect. It must be constantly borne in mind that nature in what we consider normal moods does not deal in excesses, but in a happy mean, and this frequently is within narrow limits. Too much food produces disease just as would too little or improper food. For every set of flexor muscles there is a controlling set of extensor muscles. Regulation of the heat mechanism is wonderfully delicate, and provides for a practically constant body temperature in mammals. Excessive acute active hyperemia may defeat its own purpose by causing stasis and clotting, and so filling the vessels with clots as to decrease nutrition at a point where it is most needed. Chronic hyperemia may produce excessive scar tissue. Hyperemia may render the nerve terminals supersensitive, so that they are supersensitized to pain. This is one of the reasons why hyperemia around the point of inflammation produces marked tenderness and pain. This, too, in turn is often a protective mechanism, which tends to keep the part at rest and to protect against trauma.

Recent researches by Krogh, Hooker, Danzer and others have thrown much light upon the physiology of hyperemia. (Evidence of Functional Activity on the Part of the Capillaries and Venules, by D. R. Hooker, *Physiological Review*, Vol. 1, No. 1, pp. 112-141). It has formerly been considered that hyperemia was dependent upon the arterioles: that the action of the muscular coat in these small blood vessels largely controlled the supply of blood to the tissues. As the histology of the capillaries shows only a layer of endothelium without any muscle, it was assumed that the capillaries possess no power of contraction. It has been proved, however, that this is not true, and that the capillaries have a wide range of contraction or dilatation, even though they do not possess a muscular layer. This seems to be due to the alteration in the size of the endothelial cells composing the capillaries, and is effected by chemicals or by nervous stimuli.

Broadly speaking, dilatation of the capillaries and venules seems to be caused by chemical stimuli, and contraction by nervous impulses. Histamine produces strong contraction of smooth muscle in the arterioles, but causes an intense dilatation of the capillaries and of the venules. The venules have a connective tissue layer in addition to their endothelium, but no muscular coat. The toxic products of wound shock have been shown by Cannon and others to have an action on the capillaries similar to the action of histamine, which appears to be a poison to the endothelial cells of the capillaries and venules, causing them to shrink. Thaysen has ascribed the remarkable variation in the number of red cells in a case of polycythemia to changes in the tone of the capillaries and precapillaries of the skin.

#### SURGERY OF THE BLOOD VESSELS.

The surgical treatment of slow or threatened gangrene has been much discussed. Carrel and Guthrie, in 1906, after two experiments, concluded that the blood circulation in the leg of a dog could be completely reversed within six hours. They severed the femoral artery and vein just below Poupart's ligament and united by suture the cardiac end of the artery to the distal end of the vein, and the distal end of the artery to the cardiac end of the vein. After a few hours, when red blood was seen returning, they assumed that the circulation was reversed. I think it can now be stated, however, that it is impossible to reverse the circulation in this manner. In a series of experiments which have been reported, we have shown that when the severed femoral artery and vein of animals are sutured together in a reversed direction there is no real reversal of the circulation, and the arterial blood never goes more than a short distance below the knee and is then quickly switched back to the iliac veins through the dilated collateral vessels. Instead of the heart action mechanically breaking down all the valves in the vein, it biologically strengthens most of them. Evidently what happened in Carrel's experiments was that dissection paralyzed the vasoconstrictor nerves, and the dilated capillaries permitted red arterial blood to flow through unchanged. When the sciatic and crural nerves are divided in a dog, red blood appears in the femoral vein because of the extreme dilatation of the capillaries. Clinically, this is often seen to follow an application of the elastic tourniquet which, if

left on for even a short time and removed, produces an intense flushing of the limb until the temporarily paralyzed vasoconstrictors have resumed their function. Many useless operations have been done attempting so-called reversal of the circulation in threatened gangrene. The only good accomplished was damping back the venous blood and forcing the small amount of arterial blood that reached the tissues to stay longer than it normally would and so deliver to the tissues more nutrition than would be possible when the arterial blood was quickly drained off by unobstructed veins. This can be very simply effected by ligating the femoral vein.

Surgery of the blood vessels shows the application of biologic principles. In young individuals the main arterial trunks can usually be ligated with the preservation of the nutrition of the limb. This, however, is not invariably true, for ligation of the popliteal artery or of the lower portion of the brachial artery may be followed by nutritional disturbances, or even by gangrene. In a few instances the wounds of blood vessels can be sutured, and even a section of a vein may be transplanted between the ends of an artery where it is necessary to remove the injured segment. This work, however, requires some special training, and frequently when the operation is indicated the conditions are such, as in military surgery, that make efforts at immediate arterial suture unwise. Later on, if an arterio-venous aneurysm forms and the coats of the vessels become infiltrated with scar tissue and thickened, arterial suturing with the delicate needles and silk as used in the experimental laboratory is impossible of application. If there is any reasonable doubt of the collateral circulation around an aneurysm, tests which have been described by Matas should be employed before the artery is tied. The circulation, however, can be improved by pressure over the main trunk for a limited time each day, or by the application of the aluminum band which has been devised by Halsted and by Matas, and which can be so adjusted that the lumen of the vessel is not entirely occluded. After this band is left on for several days or longer, the collateral circulation may be developed to an extent that complete occlusion of the main arterial trunk will be safe. Such a procedure in ligation of the common carotid artery in middle-aged or elderly patients is exceedingly important,

especially if the operation be done under local anesthesia when the ordinary tests of function of the brain can be made during and immediately after the operation.

In the preparation for the transference of a pedicle flap, the principle of development of the blood supply by gradual increase and dilatation of the vessels from one portion of the flap is exceedingly valuable. A long, narrow flap for the face can be outlined from the forehead or from the neck and shoulder or chest, and completely undermined only near its pedicle. The flap is gradually dissected free under local anesthesia, doing the work in stages at intervals of a few days. In this way the blood supply is transferred slowly to the pedicle, and the flap can be turned into position without fear of necrosis. This is probably better than dissecting the flap free except at the pedicle and replacing it in its bed, because a too violent and sudden change is made in the blood supply, which may result in a partial necrosis—whereas when this dissection is done in stages the blood vessels are gradually trained to take on the additional burden. Five days after the flap has been transferred into position, a soft-bladed clamp or a rubber band is placed on the pedicle for fifteen minutes to half an hour. This procedure is repeated each day for a week or ten days, when the flap can be severed with the assurance that no portion of it will be lost because of faulty blood supply.

Connective tissue is a very hardy tissue. It will stand more insults and more trauma than highly differentiated tissue such as muscle or glands, and at the same time it can live on less nutrition. Consequently, the question of the amount of scar tissue after plastic operations sometimes depends upon the local nutrition, though many other things may determine scar tissue, such as infection, and the personal idiosyncrasies of the patient. Infection acts largely by destroying the more highly differentiated tissue. If, then, it is essential to avoid as much scar tissue as possible, the nutrition of the flap should be particularly considered, for if the blood supply is cut down to a minimum, scar tissue will dominate—and not only that, but infection is more likely to ensue when nutrition is at a low ebb. For the immediate vitality of the flap, for the future cosmetic appearance, and to avoid scar tissue contraction, the development of a satisfactory

blood supply, by considering these biologic principles, is quite necessary.

#### SURGERY OF THE GASTRO-INTESTINAL TRACT.

Surgery of the stomach frequently suffers from the lack of application of physiologic principles. There is no one operation satisfactory in all different types of ulcers of the stomach or duodenum. Much depends upon the location and the extent of the ulcer. Gastro-enterostomy has a distinct field, but only when the pyloric portion of the stomach or of the duodenum is so extensively infiltrated by inflammatory products or so affected by the extent of the ulcer or by the resulting cicatricial contraction that it would be impossible to restore this greatly damaged tissue to normal. There is an analogy between gastro-enterostomy and amputation of an extremity. When the tissues of an arm or leg have been so thoroughly damaged as to make it impossible to restore function, then amputation may be considered. So, when the pyloric outlet of the stomach or of the upper portion of the duodenum has been irreparably destroyed, a short-circuiting operation has a very proper field. Gastro-enterostomy is not a drainage operation, because the stomach is a hollow muscular organ and drainage is best accomplished by making an opening as nearly as possible in the axis of the peristaltic waves. We do not drain the urinary bladder from the most dependent portion, and we perform an enterostomy in the distended loop of bowel that is nearest the incision, and not the loop that is most dependent in the pelvis, because we know that normal peristalsis will keep the bowel empty when the opening is made. The dumping of the acid gastric juice into the jejunum, which is accustomed to alkaline contents, is certainly an unphysiologic procedure, yet amputation is also an unphysiologic procedure. Gastro-enterostomy is most beneficial when the pyloric outlet has been permanently closed, for the alkalinity of the duodenal contents remains high, and cannot be lowered by the passage of gastric juice through the pylorus. Consequently, this alkalinity can protect the jejunum in the region of the gastro-enterostomy stoma from the action of the acid of the gastric juice. However, when there is a small ulcer which can be excised, or when there is occasion to give rest and relaxation to the pyloric end of the stomach because of the excision of a gastric ulcer near the cardiac end, a pyloroplasty is indicated. By the division of the pyloric

sphincter and its adjunct gastric muscles the spasm which frequently accompanies an ulcer in this region is overcome and the stomach can empty its contents with a minimum amount of effort because of the diminished resistance at the pylorus. Here we take advantage of the general principle of physiologic rest in lessening the obstruction which would call for strong contractions in the stomach wall. In this manner the normal physiologic function of the stomach is restored.

The same principle has been utilized since the early days of surgery, in operations on the rectum, when the sphincter ani is temporarily paralyzed by division or divulsion in order to promote healing of an ulcer within its grasp or higher up in the rectum. Such a procedure not only gives rest, but provides an easy exit for the fecal contents, so there is not the same necessity for strong contractions of the colon and sigmoid which would be necessary to overcome a spastic sphincter.

It seems rather definitely settled that there is a sensory nerve supply to the stomach and intestines. It is a meagre supply, however, and the sensory nerves terminate in the muscular coats of the stomach and intestines and do not reach the mucosa. They are stimulated largely by certain types of pressure. Around the region of an ulcer they become particularly sensitive, just as the sensory nerves would be sensitive around any inflammation on the surface of the body. It is doubtless for this reason that the strong peristaltic waves produce discomfort in the region of an ulcer in the stomach or duodenum; not only are the peristaltic waves stronger than normal, but the nerves themselves are more sensitive.

In surgery of the intestine, the work of Cannon and Murphy in their studies of peristalsis after resection of the bowel has called attention to the fact that in lateral anastomosis the food must be pushed through the opening by the peristalsis in the upper end. The incision in the intestinal segments involved in the lateral anastomosis destroys the action of the circular muscles. If a pouch is left at either end, there is a potential source of trouble. In some instances, however, when the bowel is small and the mesentery fat as in stout patients, a lateral anastomosis is essential, as an end-to-end cannot always be safely done under these conditions. It is necessary to close the triangular space formed by the mesentery, as it widens to encircle the bowel,

and to clamp and tie every raw surface in the mesentery before the bowel is opened. In this way infection is avoided. The bowel should also be cut from the mesenteric border outward. Whenever an end-to-end operation can be done safely, there is undoubtedly a more nearly perfect restoration to the physiologic function than when a lateral anastomosis is performed.

Murat Willis has recently advocated the so-called ideal cholecystotomy. In cases in which there are a few stones in the gall-bladder, but the gall-bladder appears otherwise normal, without adhesions or thickening, drainage of the gall-bladder, as he has pointed out, seems unnecessary, and is followed by adhesions that are frequently crippling. He opens the gall-bladder, removes the stones, and sutures the gall-bladder. In a certain limited number of cases this is an excellent procedure. It not only removes the pathology, but it does no unnecessary mutilation, and restores the gall-bladder to its physiologic normal. This, of course, is only one of the operations that may be necessary upon the gall-bladder, but it shows that here, as elsewhere in surgery, we must always remember the ideal of first removing the pathology, and then so far as possible restoring the physiology.

#### NEUROLOGIC AND BONE SURGERY.

There are many problems in neurologic surgery which require some knowledge of physiologic principles in order to be settled satisfactorily. Spiller and Frazier have demonstrated that section of the posterior sensory root of the gasserian ganglion produces what is called "physiologic extirpation" of the gasserian ganglion. It has been known for years that a nerve which is injured on the central side of its ganglionic cells does not regenerate; yet when the operation of division of the posterior sensory root for tic douloureux was suggested, it was received with some skepticism. This operation is safer than surgical extirpation of the gasserian ganglion, and is followed by less trophic disturbance. The plugging of foramina in the skull from which neuralgic sensory nerves have been removed in order to prevent regrowth of the nerves has sometimes been done with metal screws. Because an iron screw can stop a hole in a piece of wood is not necessarily a reason why it should be employed in living tissue. On the other hand, some substance that does

not cause reaction in bone is preferable. What happens after an iron screw is applied? Nature in an effort to extrude the irritating foreign substance removes lime salts in its neighborhood, the bone softens, the screw becomes loose, and the nerve can grow around it.

The fashion for plating fractures fortunately is on the decline. Hundreds and probably thousands of fractures have been plated with heavy metal plates for no reason except that it appeals to the mechanical sense and because some eminent surgeons advocated this operation. In many cases it is followed by attempted extrusion of the plate, and the plate has to be removed. To the casual observer it seems strange that permanent union does not always occur when a nice cabinet joint is made between the ends of a fractured bone, which are held securely in position by steel plates and screws. The same process goes on here as when an effort is made to plug a foramen in the bone with iron. The iron is an irritating foreign substance and, in order to extrude it, nature causes an absorption of the lime salts. As a result, a screw which may at first be firmly fixed in the bone soon becomes loose. But more important is the fact that osteoporosis is induced in this effort at extrusion, and callous formation is thereby prevented or retarded. A poorly fixed fracture without the use of metal is more likely to give eventual good results than the neatest union with heavy plates and screws.

#### BASAL CELL CANCER.

The biologic processes that concern immunity are directly linked with the treatment of many diseases. The study of cancer, which has fascinated laboratory workers as well as clinicians, has shown that there is a tendency to resistance of most cancerous processes, and that the various types of cancer frequently develop in different ways. The basal cell cancer of the skin—or the rodent ulcer, as it used to be called—shows a very definite and constant peculiarity in that it does not metastasize, but extends only by continuity or contiguity of tissue. This is impressive when we recall that a basal cell cancer may occupy the same region of the face as the spinous cell often occupies, and consequently has access to the same lymphatics. The cells are usually smaller than the spinous cells, and should gain access to the lymphatics just as easily as the spinous cells do. It seems most probable that

the basal cells are taken up by the lymphatics, but do not find favorable soil, and consequently perish; while the cells of the more malignant grades of spinous cell cancer can grow in the lymph glands and channels.

It may be assumed, then, that there is something in tissues at a distance from the basal cell cancer that causes an insuperable resistance to the cells of this neoplasm. This is not true of the spinous cell cancer, particularly of the more malignant grades, which may flourish wherever they are deposited by the lymph channels.

A crude illustration may show this biologic difference: If there was a field containing dry broom-sedge, and a fire was started in the middle of it, not only would the fire burn from this point, but if there was carried a burning brand to any other part of the field, it would also burn there. This may be likened to the spinous cell type of cancer, in which there is very little resistance to destruction by fire, even at a point distant from the original fire. If, however, the field of broom-sedge was damp, and a fire was started in the middle with a sufficient amount of inflammable material to dry the broom-sedge in its immediate vicinity, the fire would extend as far as the heat had dried the broom-sedge. If a burning brand should be carried into other portions of the wet field, it would not start a fire, because the dampness would render the broom-sedge unflammable, unless the fire was sufficiently large to dry the broom-sedge first. This might be compared to the basal cell type of cancer.

It appears to be perfectly useless to treat an extensive basal cell cancer by operation with a knife. The tissue in the immediate neighborhood of the cancer has had its natural resistance broken down, doubtless by some product of metabolism formed during the growth of the cancer. The cancerous cells are simply implanted on the new raw surface, whose resistance against these cells has been destroyed, and they grow rapidly. In practically all cases that have become extensive, the roentgen ray or radium has been tried and has failed, so but little can be expected from this source.

The principles that appear to underlie the surgical treatment of extensive basal cell cancers demand, first of all, that the surface of the cancer be destroyed and sealed by cautery so that transplantation of cancer cells will be avoided; secondly, that the excision be done as far as possible with the electric cautery and

the raw surface be further cauterized after the excision has been completed, and, thirdly, that the raw surface be covered as soon as possible by tissue from a distance, where the normal resistance to cells from a basal cell cancer has not been destroyed.

I have had four cases of extensive basal cell cancer which seem to illustrate this principle. In each of these the cancer was removed, and a flap from a distant part was transplanted as soon as possible. In three of these there was a complete cure. In the fourth case the basal cell cancer recurred and the patient eventually died. This, however, was the strongest proof of this theory, because the cancer had invaded the antrum, and the flap was so transplanted that the skin surface was opposite a portion of the raw surface from which the cancer was removed. Too much of an effort was made to produce a cosmetic result. The carcinoma recurred at no point where the raw surface of the graft was in contact with the raw surface left by the removal of the cancer, although there was extensive recurrence where the skin surface of the flap was apposed to the raw surface of the ulcer for in such areas there could be no inhibitory effect of the raw transplanted tissue.

It seems logical to conclude, therefore, that in extensive basal cell cancers, in addition to cauterization and excision with a cautery, an important principle is to apply as soon as possible, to the raw surface from which the cancer was excised, the raw surface of a pedunculated flap transplanted from a distance. It was formerly thought that plastic operations for defects caused by the extirpation of cancer should not be done until it had been determined, after the lapse of months or of years, that there would probably be no recurrence. The idea seems to have prevailed that it would be useless to transplant a flap when cancer might recur beneath it. With basal cell cancer, however, this practice appears to be erroneous, and a flap from a distance should be applied as soon as possible after the excision of the cancer, for the flap seems to add an additional obstacle to the growth of the cancer by interposing its own natural resistance to the cancer cells.

#### TRANSPLANTATION OF ORGANS.

Skin grafting and transplantation of organs or tissues are dependent on biologic laws. Surgeons who have had great experience in this type of work, such as Lexer and Davis, believe that skin grafts from others than the

patient are practically never permanent. They either melt away at once or, if they appear to "take," are later absorbed and replaced by connective tissue. It has been suggested that tests, as for transfusion of blood, would be of benefit in selecting a donor for skin grafting; but so far this has not been put to any extensive practice. The transplantation of highly developed organs, such as a kidney, from one animal to another, even if of the same species, is always a failure. The kidney may function for a while, but the fine biologic differences in the body fluids of the donor and the recipient cause degeneration, and the kidney eventually becomes a mass of connective tissue. This has been acknowledged by Carrel, Guthrie and others who were at one time enthusiastic about the success of such a procedure. The reconstruction of channels, as the bile ducts, from tissues that have no immunity to the irritating discharges with which they must come in contact is also unwise. Operations in which strips of fascia, pieces of vein, and other tissue unaccustomed to the action of bile are used, ultimately result in failure, no matter how skilfully the mechanical part of the operation is done. There must be some natural biologic resistance to irritating discharges by the tissues in normal contact with these discharges.

These are merely a few instances of what every surgeon sees in his work, and they illustrate the profound influence that the application of biologic principles has on surgical practice. Real progress in surgery lies not so much in cultivating the art of surgery and in striving after mechanical dexterity, which is important, but can be acquired in a few years, as in the study of biologic principles that concern function, nutrition, metabolism, and repair of tissues, and in the thoughtful application of these principles to every operation and to every method of surgical treatment.

It seems to be the duty of every disciple of medicine and surgery not only to apply biologic principles in his daily work, but to record instances in which new applications can be made. A study of nature nowhere offers a greater field than in the practice of medicine and surgery. Biologic processes are constantly before us, and their proper interpretation and application to our problems is not only a duty, but a great privilege. A discoverer of a new truth, be he ever so humble, is a great benefactor of science.

*St. Elizabeth's Hospital.*

## THE RELATIONSHIP OF THE EYE TO GENERAL DISEASES.\*

By G. B. DUDLEY, JR., M. D., Martinsville, Va.

Before beginning the relationship of the eye to general diseases, let us briefly consider the innervation of the eye, as on this anatomical arrangement depends to a large extent much ocular pathology produced by intracranial diseases and injuries.

The two optic tracts originate in the primary optic ganglia, viz., the anterior corpora quadrigemina, the external geniculate bodies, and the pulvinar of the optic thalamus, (these as you know are portions of the midbrain, and the midbrain lies in the opening of the tentorium cerebelli, and connects the pons with the hemispheres), wind around the crura cerebri, and the optic tracts terminate in the optic chiasm, which lies in the optic groove of the sphenoid bone, in the front of the infundibulum and above the pituitary body. There the optic tracts semidecussate and form the optic nerves, which continue through the optic foramina of the lesser wings of the sphenoid bone. The optic nerve has three divisions: first, the intracranial portion between the optic foramen and the chiasm; second, the orbital portion extending from the eyeball to the optic foramen; and third, the intraocular portion, which is the head of the optic nerve. The nerve pierces the sclera and choroid a little to the inner side of the posterior portion of the eyeball, and the sheaths of the nerve become continuous with outer layers of the sclera.

By this decussation of the optic nerve fibres at the optic chiasm, it is easy to understand how in various intracranial lesions, tumors, injuries, etc., we get our various hemianopsias, by which term we mean a blindness of one-half of the field of vision. For instance, if we have a lesion of the right optic tract posterior to the chiasm, we have a blindness of the right halves of both retinae and as a result the left halves of the fields of vision of both eyes will be lost. This is known as homonymous or lateral hemianopsia, and in this particular case the condition is called left homonymous hemianopsia. Therefore, a lesion on the cranial side of the chiasm and on the same side as the blind halves of the retinae will produce an homonymous hemianopsia.

Bitemporal hemianopsia indicates a lesion through the chiasm, that is, the nasal halves of the retinae are destroyed. Should a lesion attack each side of the chiasm we would have a binasal hemianopsia. Bitemporal and binasal hemianopsia are known as crossed hemianopsia in contrast to homonymous. Complete blindness in the eye is produced when the lesion is anterior to the chiasm.

The third cranial (oculomotor) nerve supplies all the extrinsic eye muscles, except the external rectus which is supplied by the sixth (abducens) and the superior oblique, which is supplied by the fourth (trochlear). These nerves all originate from the floor of the fourth ventricle.

The contracting fibres of the iris (sphincter pupillae), are supplied by the third nerve, the dilating fibres (dilator pupillae) are supplied by the sympathetic. Hence, a contraction of the pupil is either caused by a stimulation of the third nerve or by a paralysis of the sympathetic, and a dilatation follows paralysis of the third nerve or stimulation of the sympathetic.

We shall now discuss the individual diseases of the brain. In *cerebral hemorrhage* we frequently find homonymous hemianopsia, mydriasis due to paralysis of the third nerve supplying the sphincter pupillae, neuritis or choked disc, with or without retinal changes, and sometimes later an optic atrophy.

An *embolus* or *thrombus* produces the same symptoms in general as a hemorrhage and often is hard to distinguish from the latter. In a *thrombosis* of the *cavernous sinus*, edema of the lids, exophthalmus, dilated pupils, blindness, loss of sensation of the eye, etc., may result. The marked stasis of the retinal veins will distinguish this condition from meningitis, which may cause some venous congestion and a neuritis.

*Tumors* and *abscesses of the brain* present practically the same ocular symptoms, that is, choked disc, paralysis of various ocular muscles, mydriasis, etc. Ocular changes are invariably present in tumors and other diseases of the *pituitary* body, of which we hear so much today in the various discussions of endocrinology. Bilateral hemianopsia is frequently seen in tumors of this gland, also other ocular paralyzes and symptoms of optic nerve pressure.

In *meningitis* we may have optic neuritis in

\*Read before The Danville Academy of Medicine, November 14, 1922.

every stage from a simple congestion to a choked disc or atrophy, as well as various muscular paralyses.

In *encephalitis lethargica*, which we may classify as a brain condition, and of which we saw something during and succeeding the last war, the chief ocular symptoms are diplopia, ptosis, impaired accommodation, nystagmus, sluggish pupils, optic neuritis and choked disc.

In *paralysis agitans* (*Parkinson's disease*), we frequently see incomplete unit or bi-lateral ptosis, crossed diplopia for near and rarely gray atrophy of the optic nerve or nystagmus. Not long since, a patient (an old gentleman who lived in Schoolfield), with paralysis agitans, came under my observation, with a gray atrophy of the optic nerve.

Eye symptoms are highly important in *dementia paralytica* (*paresis*). There is usually a simple gray atrophy of the optic nerve with narrowing of the vision field, eventually terminating in blindness. This is usually a late symptom of paresis, but it may occur at an early period or even precede the mental disturbance. Ocular paralyses of central origin are very frequent, including the Argyll-Robertson pupil phenomenon. Pupils may be contracted, dilated or unequal.

The eye is often affected in *multiple* or *disseminated sclerosis*. From the general picture of the disease, and the ocular examination, I have seen oculists unhesitatingly make a correct diagnosis of the disease. With the characteristic intention tremor, scanning speech and limb paralyses, a nystagmus and primary optic atrophy leave little else to be desired in making a diagnosis of this condition.

*Diseases of the spinal cord* give rise to eye symptoms only when the region of the cilio-spinal centre is affected, directly or indirectly. Other eye symptoms occur when the disease of the cord extends to the cranial cavity or in case of complications.

*Tabes Dorsalis* furnishes ocular symptoms too well known for any lengthy discussion. The ocular symptoms are frequently the first noticed. Primary optic atrophy, with disturbances of vision and muscle paralyses, are the chief symptoms. The vast majority of optic nerve atrophies may be traced to syphilis, probably 70% to 90%. Nystagmus is rare. Ptosis not so rare.

In injuries of the spine, as "Railway Spine," we some times get various eye symptoms.

Under functional *psycho-neuroses* we may discuss *hysteria*, *neurasthenia*, and *epilepsy*. Unilateral diminution of vision, frequently with complete blindness, is the most usual ocular symptom of hysteria. The vision field may be contracted and the color fields reversed (i. e., green the largest, red next, and blue the smallest). Photophobia, blepharospasm, diplopia, ptosis and various anaesthesias and paraesthesias may exist. With the ophthalmoscope nothing is seen, and malingering must be excluded in making a diagnosis. The *neurasthenic* may have almost any kind of ocular complaint or pain. But we should not be too severe on this class of patients, for very frequently there is some refractive error at the root of the whole trouble, and with the proper glasses worn, the symptoms disappear.

A visual aura frequently marks the beginning of an *epileptic seizure*. During the attack the pupils are generally dilated, and there is often a spasm of the extrinsic eye muscles, with a rolling of the eyes. Frequently, epileptic-like attacks may be reduced by properly fitted glasses where refractive errors exist.

The most usual ocular symptom which we observe in *trifacial neuralgia* is the neuro-paralytic keratitis. This is a form of progressive infectious corneal ulcer which is somewhat peculiar. Many think that this is proof that special trophic fibres exist in the first branch of the trifacial nerve. In practically every case, certainly that I have seen, where the gasserian ganglion or its sensory root is extirpated, these corneal ulcers develop. Personally, I think that lack of the normal sensation in the cornea to protect it from foreign bodies and dust has as much or more to do with the formation of these ulcers as the destruction of the so-called trophic nerve fibres.

The ocular symptoms of *facial paralysis* are well known to all, viz., inability to close eye of affected side, drooping of lower lid and lachrymation.

*Albuminuria* is the term now generally employed in discussing kidney (Bright's) diseases, and as the retina is the part of the eye most affected by renal involvement, albuminuric retinitis is the pathological condition we describe. *Chronic interstitial nephritis* is the type most commonly responsible in retinitis albuminuria. Next in frequency is the *chronic*

*parenchymatous type.* Subjectively, there is a diminution or loss of vision without pain, as a rule. Objectively, albuminuric retinitis is characterized by the presence of white or yellowish spots in the retina, hemorrhages, edema and blurring of the outline of the disc. These changes occupy particularly the region surrounding the disc. The white spots may coalesce, forming large irregular patches. The so-called typical picture includes the stellate figure at the macula, which consists of radiating white lines and spots, with the fovea centralis for the center. This figure, however, is often missing and must not be considered essential for a diagnosis. The ability to recognize the minute changes that occur early in the course of the renal disturbance is of far more value than distinguishing the retinal lesions themselves, as the cases are usually far advanced when true retinal changes have occurred. Here we have changes in the vascular tunics similar to those occurring in arteriosclerosis, which we will discuss in a few moments. The external puffiness of the eyelids is too well distinguished to require other than mentioning. The *albuminuria of pregnancy, uremia, eclampsia, and scarlet fever* present the same picture as above described.

In *diseases of the Blood and Circulatory system* we shall first discuss *Arteriosclerosis*. Among the early evidences of arteriosclerosis in the retina are great tortuosity of the small arterial twigs, irregularity in the calibre of the vessels, narrowing of the arteries, loss of transparency of the vessel walls, hyperemia of the nerve head and flattening or indentation of the veins where crossed by arteries. Among the later changes are included hemorrhages into the retina, occlusion of the central retinal artery, thrombosis of the central retinal vein or its branches, and perivasculitis, which manifests itself as white lines bordering the vessels. Hemorrhages into the retina due to arteriosclerosis are of prognostic significance; they are followed by cerebral apoplexy in more than 50% of the cases. Thrombosis of the central retinal vein or its branches has a like prognosis.

*Valvular heart disease and fatty heart* are often accompanied by hemorrhages into the retina, less frequently into the vitreous. *Aortic insufficiency* may cause pulsation of the central artery of the retina. *Endocarditis* may cause embolism of central artery of

retina. The edema caused by cardiac disease may involve the eyelids.

*Aneurysm of the Aorta* frequently affects the eyes, viz., mydriasis, exophthalmos and enlarged palpebral aperture due to the irritation of cervical sympathetic, or miosis and endophthalmos due to paralysis of sympathetic. This may also cause thrombosis or embolism of the central retinal artery or one of its branches.

In *Simple Anemia* and *Chlorosis* we usually find pale conjunctivae and pearly white sclerae. The fundus and disc may be pale as well as the retinal vessels. Occasionally, retinal hemorrhages are found. *Pernicious Anemia* often causes retinal hemorrhages, and the fundus is very pale. *Hemophilia* predisposes to profuse hemorrhage after injury to the eye.

In *Leukemia*, retinal hemorrhages are common, the vessels are greatly dilated and tortuous, the fundus is pale red with a yellowish tinge, and there are white and yellow spots of exudation.

*Purpura* is frequently accompanied by hemorrhage beneath the conjunctiva, in the retina, skin of the lids and occasionally into the orbit.

*Severe hemorrhage* may be accompanied by amblyopia, either temporary and accompanied by little or no ophthalmoscopic change, or permanent and followed by optic nerve atrophy. Such sudden and severe anemia may cause retinal hemorrhages.

Under the acute infectious diseases we shall first consider the diseases of childhood. Some variety of conjunctivitis usually accompanies *Scarlet Fever, Measles, Diphtheria, Whooping-Cough* and *Mumps*. During *Scarlet Fever* an albuminuric retinitis or an uremic amaurosis may suddenly develop. Optic neuritis, orbital cellulitis, choroiditis, and corneal ulcers are very rare complications of scarlet fever. Rarely in *Measles* does the conjunctiva take on a blennorrhoeal or diphtheritic aspect and then the cornea is in danger of ulcer formation. Muscular paralysis in the latter part of the disease, or often weeks later, is the most usual complication of *diphtheria*. Paralysis of the intrinsic muscles is by far the most common, but extrinsic muscle paralyzes are not unusual. In *Mumps*, edema of the lids may occur; optic neuritis, iritis and ocular paralyzes have occasionally occurred. In *Whooping-Cough*,

conjunctivitis and epiphora are common in the prodromal stage. In the convulsive stage, extensive hemorrhages, due to violent coughing, may develop.

Before vaccination was introduced, much blindness was produced by *Smallpox*. The lids and conjunctivae are often the site of pustules, and keratitis and corneal ulcers frequently develop; the ulcers frequently perforate, producing as sequelae, opacities, adherent leukoma, and even destruction of the globe.

In *Typhoid* and *Typhus Fevers* rarely there may be catarrhal conjunctivitis, ulcers of the cornea, and retinal hemorrhages. Paresis of accommodation and of the extraocular muscles may develop during convalescence.

In *Tuberculosis* we may have conjunctivitis, blepharitis, phlyctenular conjunctivitis, keratitis, interstitial keratitis, and, at times, involvement of the iris, choroid and sclera.

*Gonorrheal ophthalmia* and *ophthalmia neonatorum* are too well known ocular infections caused by "The Neisser Brothers" to require other than mention. Corneal ulcers, with or without perforation, may result, leading to incarceration of the iris, staphyloma, panophthalmitis, etc.

*Syphilis* frequently causes ocular diseases. Rarely the primary sore may occur on the lids or conjunctiva. About 35% of iritis is due to syphilis, being an early symptom of the secondary stage. Later in this stage choroiditis, chorioretinitis, optic neuritis and vitreous opacity may develop. In the tertiary stage, gumma may develop, also optic neuritis, optic atrophy and sometimes interstitial keratitis. Congenital syphilis is largely responsible for interstitial keratitis and some congenital ocular defects. As *tabes dorsalis* and paresis are of luetic origin, the ocular pathology discussed under them, of course, may be said to be manifestations of syphilis.

*Malaria* may produce a keratitis, optic neuritis, retrobulbar neuritis, hemorrhages into the retina and vitreous, amblyopia and paresis of accommodation.

*Erysipelas* may cause great swelling and edema of the eyelids; following this there may be an abscess of the eyelids or an orbital cellulitis. Sometimes thrombosis of the retinal veins, optic neuritis, or atrophy of the optic nerve may follow. Several years ago, I saw a case complicated by an orbital cellulitis and

abscess, which in turn was complicated by a meningitis, and death resulted.

During the past few years *Influenza* has been much in the limelight. It is practically always accompanied by a congestion of the conjunctiva or by an acute catarrhal conjunctivitis. Frequently there is severe pain in and back of the eye balls. Rarely there may be corneal ulcers, paresis of extrinsic ocular muscles, retrobulbar neuritis, neuroretinitis, optic nerve atrophy and orbital cellulitis. The extreme depression following the disease probably accounts for many of the ocular complaints credited to the disease itself.

The edema of the eyelids, which often appears at the very beginning, frequently aids in diagnosing a case of *Trichinosis*. In only severe cases does the trichina spiralis emigrate into the external eye muscles.

*Cataract* and retinal hemorrhages are the most usual ocular complications of *Diabetes*. Less often we may find retinitis, optic neuritis, retrobulbar neuritis, iritis, ocular paralyses, and broken down vitreous conditions.

*Rheumatism* may be ascribed as the cause of some cases of iritis and iridocyclitis.

*Rickets* often causes congenital (Zonular) cataracts, interstitial keratitis and phlyctenular kerato-conjunctivitis.

*Scurvy* most frequently causes an exophthalmos due to hemorrhage into the orbit. This occurs in about 10% of cases. Subconjunctival and retinal hemorrhages occur at times.

The various ocular symptoms and signs of *Exophthalmic Goitre* (*Graves' or Basedow's Disease*) are probably well known to all. Varying degrees of exophthalmos are usually present. Von Graefe's sign (lagging of upper lid when looking down), Dalrymple's sign (abnormal widening of palpebral aperture), Stellwag's sign (diminution in power of normal involuntary winking), Moebius' sign (imperfect power of convergence), Gifford's sign (difficulty in everting upper lid), are all due to and produced by the exophthalmos. The cornea may suffer when the exophthalmos is extreme, and epiphora is common.

Space and time forbid me to discuss the effects of many drugs and poisons on the eye. *Quinine* in large doses, or occasionally with moderate doses in susceptible individuals, may produce more or less complete blindness, often noticed suddenly, contracted visual fields, dilated pupils, and marked pallor of the disc,

with extreme contraction of the retinal vessels.

Since the so-called prohibition went into effect *methyl-alcohol amblyopia or amaurosis*, resulting from the drinking of cheap whiskeys, "moonshine," "hootch," "monkey-rum," "corn," cordials, essences, and other alcoholic beverages, is quite frequently seen and read in the daily papers. Wood alcohol is a protoplasmic poison, possessing a selective affinity for the delicate nerve tissues of the eye. Sudden blindness with vomiting and abdominal pain should arouse suspicion of methyl poisoning; especially if diplopia or ptosis are associated. The ophthalmoscopic appearances are hyperaemia of disc with blurring of edges and later atrophy of the optic nerve with small retinal vessels.

Diseases of the *Accessory Sinuses (maxillary, ethmoid, sphenoid and frontal)* are frequently responsible for many ocular symptoms and diseases, among which are orbital cellulitis, exophthalmos, paralysis of ocular muscles, asthenopia, reduction in acuteness of vision, changes in fields of vision, optic neuritis, retrobulbar neuritis, atrophy of optic nerve, corneal ulcers, keratitis and iritis.

The "innocent" *facial tonsils* frequently produce ocular troubles, especially conjunctivitis, keratitis and iritis.

*Bad teeth* are frequently responsible for much ocular pathology, especially keratitis, corneal ulcers and iritis. The subject of accessory sinus diseases, tonsils and teeth as factors in eye pathology would require a paper alone and our time only permits mentioning them.

In this paper, I have by no means covered the relationship of the eye to all general diseases, but I have tried to select the most usual ones met with in the practice of general medicine.

## PLANNING A HOSPITAL IN A CHINESE CITY.\*

By CLAUDE M. LEE, M. D., St. Andrew's Hospital, Wusih, China.

There are many here today who remember the difficulties encountered in founding and carrying on the University Hospital. Picture to yourselves these difficulties, plus those which are added to such an enterprise by its being undertaken in a distant land, the work to be

done through the medium of a strange tongue. Stand by my operating table with me and hear me say: "*Tau. Yeu ngo-ts kuh kyien. Pih zeh kuh makkwen kyien. Bing li-hyang kuh sien, ih au.*" Which means: "Knife. Toothed forceps. Straight clamps. Plain catgut, No. 1." Think of the agony of wanting these things and forgetting their names in Chinese. And think of the time it took before these orders came out as easily in Chinese as in English.

Having got you into what is, I hope, a sympathetic frame of mind, I am now going to tell you where St. Andrew's Hospital is. It is in Wusih. Wusih is a cocoon raising centre, with large manufacturing interests, situated on the Shanghai-Nanking Railway about half way between these well known cities.

The country around Wusih is an alluvial plain, intersected by very numerous canals. The canals are so close together that on the narrow foot paths between the fields, bridges occur several to the mile. These canals are the roads of this part of China and all are tributaries of the Grand Canal of China, one of the world's most famous waterways. This abundant water supply is vital to the farmers. Rice fields lie between the mulberry groves and these two divide the countryside with the last resting places of the mortal remains of those Chinese who have passed on. The striking features of the landscape, then, are the flat rice fields, green and damp looking; the stunted mulberry trees which are cut back each summer to get the leaves for feeding the silk worms; the canals which are at once the roads, the water works, and the sewers of the populace; and the nodular grave-mounds, which must never be disturbed.

The city of Wusih stands surrounded by a ring of factory chimneys. There are silk mills, cotton mills, flour mills and oil mills, the latter the most deadly of all to the hands of the laborers. The machinery in all these mills is of foreign make, the laborers are men, women, and children. There are no child labor laws in China and in the silk mills conditions are fearful. The hours are from five a. m. to seven p. m., with half an hour out for eating, or a fourteen hour day. The laborers, most of whom are children, work in rooms full of small vats of warm water in which the cocoons are flung to soften the fibre so that

\*Read at the meeting of the Piedmont, (Va.) Medical Society at University, Va., November 25, 1922.

they may be reeled. The children must reach up to put the cocoons into the vats. A man with a split bamboo whip walks up and down between the rows of children to keep them at work. He does not hesitate to use his whip.

If you lump the census figures of Roanoke, Lynchburg, and Charlottesville, you have approximately the population of Wusih. The trading population, or those whose business makes this city their "base," amounts to probably 500,000 people.

The climate is about like that of North Carolina along the coast, damp and hot in summer and damp and cold in winter. Probably twice as much rain falls in our neighborhood as falls annually in Albemarle County. This damp hot climate makes central China an ideal home for tuberculosis, malaria, and hookworm. Venereal diseases are very much on the increase. If the pallid spirochete originated in China—and many scholars think it did so—the people showed a great immunity to their home strain. But after part of the family had taken a tour of the world, lasting for centuries, and returned to China by the seaports, luetic infections took on a new virulence.

The valley of the Yang-Tze River is probably the greatest hot-bed of tuberculosis in the world. There are thousands of deaths each year from pulmonary tuberculosis, and the other forms are very abundant.

The rice fields, stagnant pools, myriads of receptacles for night soil, which is one of the most prized commodities of the land, in fact all fishless water, give harbor to myriads of mosquitoes. Malaria carriers infect the mosquitoes, who in turn help the good parasite on its way. The common type of malaria is quartan, but there are epidemics of tertian and estivo-autumnal fevers which are veritable scourges.

Hookworm infests the intestines of eighty per cent. of the farmers. The primary infection through the skin, a cough with possibly some hemoptysis, a period of indigestion, and in about two weeks anaemia and loss of strength, make a clinical picture very familiar to the people of Wusih. They call the disease "The Mulberry Leaf Anaemia" from the fact that it chiefly comes on them in the summer, when heat and moisture have made hookworm larvae very comfortable under the shade of the mulberry groves. Men, women, and children repair to the fields for leaves and, as the

ground under the trees is kept aromatic with freshly applied night soil, they all get ankylostomiasis. Massive infections are seen and, owing to the branches of the trees being dragged on the damp ground and then hoisted to the bare back, the characteristic skin lesion is seen there too. We have seen such severe infections that the dyspnoea was bad enough to threaten life.

Epidemics of cholera, diphtheria, meningitis, and malignant malaria are occasionally encountered. In one epidemic of cholera we treated over six hundred cases in a little over a month. More than 2,500 cases of diphtheria have been treated in the out-patient department of St. Andrew's Hospital. An epidemic of cerebrospinal meningitis ran to about 120 cases before it stopped itself. We estimate that there were nearly a thousand deaths from malignant malaria year before last in the district around Wusih. About forty per cent. of all the inhabitants of China have trachoma.

Surgery in China does not differ very much from surgery in any other new territory. There are numbers of neglected cases, which are more common, possibly, than in this country where modern surgery has been available for years. At St. Andrew's we try anything that comes along and are amazed at how many specialties we can invade with fairly good results.

But we must get along to the actual starting point of this hospital. The out-patient department was opened in March, 1908. The first year's work saw us take care of 27,500 visits from patients, out-calls, etc. There was a small operating room in the building we had put up for this out-patient work and I well remember the first operation in it. We were engaged in taking off a small epithelioma from an old gentleman's eyelid when he suddenly went bad from the anaesthetic. I doubt if any of you can appreciate the horror of that moment. Like the man in the medical school who was asked what he would do in a certain emergency, I certainly did want to send for a doctor; but there was not one in town at the moment. However, the old man came around and all was well.

Our first in-patients were kept on boats on the canal in front of the dispensary. One or two cataracts were successfully done, the patients being obliged to disembark for dressings and inspection of the eyes. Boats are not a

good way to house surgical cases, however. They really leave much to be desired as hospitals when they are only twelve or fourteen feet long and have a whole family aboard, as well as the sick one.

There was one woman cared for who had lost her scalp. She was standing on the deck of her boat using bad language at a fellow boatman, when an anchor swung at a big boat's bow caught her on the forehead with one of its flukes. The scalp peeled back much like the skin of a very ripe peach does when a thumb is judiciously pressed upon it. Her scalp, completely torn off, was sutured into place and the boat moored in front of St. Andrew's dispensary. She got along pretty well until the third day when she suddenly tried to jump overboard. It was found that a three month's fetus had been lost and the woman went plumb crazy. Puerperal insanity can not be treated very well on a small boat.

Then five beds were put in a Chinese house centuries old and we felt that we had arrived. We had a hospital on land. In spite of considerable pride in this achievement, we kept going until we got a larger house also of Chinese construction, into which we put twenty beds. Our next step forward gave us a very nice building of foreign construction, of a capacity of fifty-five beds. In the last year we built an operating room which compares in convenience and sanitary conditions very favorably with the average in this country. We have a series of rooms consisting of anaesthetic, scrub room, sterilizing room, and operating room, all with steam heat and with running hot and cold water laid on. Across a corridor in this building are the offices and X-ray department. All the wards, the offices, the furnace room, and the various departments and residences are connected by telephone. We have our own private exchange. For out-calls two motor boats are kept in commission. Where there are no roads a motor boat is the equivalent of an automobile. The water supply is owned by the hospital and consists of an artesian well and pumping plant. The well supplies us with 8,000 gallons in twenty-four hours, though at present we are using only a fourth of that amount. The water is pumped to a tower and distributed to the different buildings by gravity.

There are five residences in connection with

the hospital for the staff, besides buildings for the servants, laundry, and stores. The staff consists of two foreign doctors and four Chinese doctors, two foreign trained nurses and fifteen Chinese graduate and pupil nurses, a chaplain and a foreign social service worker, as well as numerous attendants. The outpatient department maintains a branch dispensary about two miles away in a populous mill district which is a new and growing part of the town. Daily clinics are held in the outpatient department. There is one free day each week which is much appreciated, for there were nearly 10,000 visits to this clinic last year.

The mere recital of physical equipment does not give any idea of the intense human interest in a venture of this kind. Cut off from professional association in large measure, and without the possibility of consultation, there is a great strain to be borne always—first, a strain from responsibility, and second, a strain on the conscience, to keep a man from letting down on asepsis, and on good careful work.

There are adventures from time to time which enliven things. Let me pause to classify some of them and give examples of each kind. There are social, physical, and professional adventures. In a social way things in China are very different from things over here. Have you ever heard of the ancient eggs of Chinese feasts? A young man went out to Wusih from Charlottesville. He was invited to a feast, given by some Chinese gentlemen. Buried eggs which had been recovered as the result of excavations were served. These eggs are buried in lime and when exhumed the meat has a distinctly cyanotic color. Chinese officials of the old regime used to let their nails grow long to show they never had done any manual labor. One old gentleman at this feast had a long black claw on his little finger which had on its under surface a specimen of everything he had ever eaten since childhood. He sliced a bit of egg with this nail. He speared the slice with that same horrid nail and offered it to the pale young American. That young hero, this is not a personal narrative, though I know it to be true, took the egg and ate it all. It stayed down. This young man never got the medal his conduct deserved.

For obvious reasons one does not give personal narratives of physical adventure. But I knew a man in China who had all his clothes

taken away from him by rapacious bandits when he was miles from home and blown upon by an icy night wind in mid-winter.

It is something of a professional adventure to have a patient for whom you are harmlessly changing a surgical dressing expire, when you are a long way from your friends and surrounded by his friends. Yet, I know a man to whom this happened. He was dressing a carbuncle, which was doing beautifully, but the patient suddenly died. The Greeks had a pleasant custom under certain circumstances of chaining a living man to a corpse. Just exactly this procedure was proposed, the great doors of the Chinese house were shut and clamor arose and horrible pandemonium. The doctor escaped, but he was thoroughly frightened. It is an interesting thing to work in a Chinese city.

In closing, I am going to ask a question. What is to be the fate of a foreign hospital in a Chinese city? We hope that St. Andrew's Hospital will ultimately become the City Hospital of Wusih—under Chinese management entirely and under Christian management, if possible. With the return of numerous students of medicine from abroad, with the graduation of still more numerous students from real medical schools in China, it seems to me that ten or twenty years will see mission hospitals largely turned over to the Chinese and the work taken out of foreign hands.

### PHLYCTENULAR KERATO-CONJUNCTIVITIS.

By SIDNEY TRATTNER, M. D., Richmond, Va.

This paper is a review of the literature on phlyctenular kerato-conjunctivitis, with regard to etiology only. It might seem that this is a timeworn subject, but it is surprising to see how little has been written on this condition in the past few years. What is still more surprising is that in spite of excellent authority and emphatic statements in favor of one theory of causation or another, the etiology is still a matter of dispute. Men whose opinion is to be respected, are ranged for and against every factor indicated, and it was this that suggested that a review of these opinions might show where the greatest weight of authority rested.

To indicate what conflicting views there are

as to the origin of this condition, the following list will be of interest. At various times these causes have been assigned to phlyctenule: Exposure to wind, dust, bad living conditions, anemia, poor health, intestinal derangements, pediculosis, errors of refraction, auto-intoxication, eczema, various bacteria, scrofula, the exudative diathesis, tonsil and adenoid conditions, nasal conditions, herpes, anaphylaxis, and a derangement of carbohydrate metabolism.

Of these, tuberculosis, the exudative diathesis, eczema, scrofula and faulty digestion and metabolism have received the most attention. Probably the earliest observations were those which noted the frequent occurrence of phlyctenule with the condition known as scrofula. The name conjunctivitis externa scrofulosa was given it as long ago as 1813, by Beer. Later investigators agreed with this, although Mackenzie in 1833, while regarding the scrofulous condition as being the chief predisposing factor, thought that remote causes operated in the production of the disease.

Since then opinions have been conflicting, and the long list of causes ascribed to phlyctenule is evidence of how obscure the basis of this condition is. However, these divergent views may be roughly classified into two groups for the purposes of this paper: the first, those which ascribe the cause to tuberculosis, and the second, those which ascribe it to other factors.

Considering first the non-tuberculous theories that have been discussed in the literature since 1910, we meet with the following:

Colombo in 1911, did some work with the object of proving that phlyctenule was the result of gastro-intestinal disturbance. His method was to determine the amount of indicanuria in his cases, and he found that in one series forty-two out of forty-three had indican. A later series showed somewhat the same findings. However, it was afterwards shown by von Hippel and others that in phlyctenular disease indicanuria was no more frequent than in other eye conditions, or for that matter in conditions elsewhere in the body. More recent experiments in metabolism have shown that the degree of indicanuria is no gauge of intestinal toxemia. However, other observers have noted that gastro-intestinal disturbances are by no means a constant factor in cases of phlyctenular ophthalmia. In ninety-two cases

\*Read at the November meeting of the Richmond Society of Ophthalmology and Oto-Laryngology.

studied, W. S. Gibson found only nineteen in which there was any evidence of derangement of the gastro-intestinal tract.

Will Walter (*J. A. M. A.* Sept. 1913) wrote that the theory of bacterial infection was not proven; that the malnutrition and auto-intoxication theory was important and fundamental; but that neither of these factors was the specific cause. He stated that the endogenous infection theory considered latent tuberculosis as the most probable cause, and concluded by saying that the part played by a possible anaphylaxis was to be considered.

Another adherent to the auto-intoxication theory was H. D. Bruns, who in 1912 stated that he believed the condition to be a neuropathic one, depending on auto-intoxication and gastro-intestinal disturbances.

In a later discussion Bruns said that he favored a neuropathic origin following some shock, disturbance of metabolism or gastro-intestinal disturbance. He likened the lesions to herpes and stated that they occurred in the nerve-ends. He quoted I. Dyer, a pathologist, to the same effect.

Samuel Theobald (*A. M. A.* Aug. 1914) stated that the evidence in support of a tuberculosis or pseudo-tuberculosis origin was far from convincing. The almost constant association of facial eczema with the ocular inflammation showed that it was an ocular eczema.

Hunter H. Turner, discussing the question in 1917, said that faulty carbohydrate metabolism could not explain the variations in phlyctenulosis. He thought the condition due to a chronic low-grade ethmoiditis with obstruction to drainage.

M. Goldenburg, in the Section on Ophthalmology 1917, read a paper in which his conclusions were as follows:

1. Ophthalmia ezeematosa, or phlyctenular disease, is not a true pathologic entity, but a symptomatic manifestation of a systematic disturbance.

2. Tuberculosis, syphilis and sepsis can be excluded with certainty as causal factors.

3. Phlyctenular disease is in all probability one of the expressions of a vagus system irritability produced by some toxic agent resulting from carbohydrate chemism.

4. Correction of the chemism by a carbohydrate-free diet and control of the vagus hypertonia through the topical and internal

use of atropine yield the best and quickest possible therapeutic results.

These conclusions were arrived at as the result of the study of five hundred cases covering a period of seven years.

Duane, in his translation of Fuchs, writes, "In any event it seems clear that the relationship of this disease to tuberculosis is at most an indirect one. The results of treatment point to some other contributory or perhaps essential cause (disturbance of metabolism due to gastro-intestinal toxemia, pharyngeal and tonsillar infection, etc.)" Further on he writes, "Sweets, especially candy, cakes, pies and pastry of all kinds should be forbidden, and only very plain but substantial food allowed. It would seem that regulation of the diet alone may do a great deal toward effecting a cure in these cases."

A number of writers on the subject are neither for or against tuberculosis, but include it as one of a variety of causes.

Lafon divided the cases into three classes etiologically:

1. Tuberculous.
2. Following the exanthemata.
3. Gastro-intestinal and naso-pharyngeal.

Schuetz and Videky classified according to therapeutic results and found two groups:

1. Tuberculous, and cured by tuberculin.
2. Exudative, and cured by a diet free from sugar and eggs, and with little meat.

Oskar Everbush in his text-book on Diseases of the Eye in Childhood says: "Particularly are children of the scrofulo-lymphatic habitus attacked by conjunctivitis phlyctenulosa.

"Catarrhal conjunctivitis, the acute exanthemata, skin eruptions such as eczema, intertrigo, prurigo, urticaria, various forms of blepharitis, ezeematous eruptions of the skin of the face, pediculosis capitis, and general uncleanness are etiologically of significance. In phlyctena in non-tuberculous children 'Lymphatism,' 'Oxyopathy,' or the 'Exudative Diathesis' following a diet with excess of fat producing foods or an intestinal auto-intoxication, are the bases, following which the tissues of the conjunctiva and cornea of these children are strongly susceptible to infection through their great sensitivity to bacterial proteins, particularly when resistance has been lessened as the result of a previous tuberculous infection."

Roemer in his Greifswald lectures published in 1913, says: "Although a certain connection exists, scrofulosis is not necessarily the only cause of kerato-conjunctivitis eczematosa. All scrofulous children do not suffer from this disease, and, on the other hand, we meet with cases in which positive signs of scrofulosis cannot be demonstrated, even though it cannot be excluded. . . . All that we can say as yet is, that in the majority of cases the scrofulous diathesis predisposes to this disease." Discussing the theory of endogenous infection he says, "In the first place no micro-organism yet known to us can be found within the fresh efflorescences on microscopical examination (Axenfeld, Wagenmann, Hertel, L. Mueller and others). Cultures likewise fail to detect ordinary bacteria in these nodes. Dead tubercle bacilli are not to be found in them. In the second place Leber and others have demonstrated that the inoculation of fresh efflorescences into the anterior chamber of rabbits excites no inflammation. In the third place the giant cells occasionally found in the efflorescences are not evidence of a tubercular origin especially as these cells are not of Langerhans' type. The evidence which has been brought forward does not convince me that kerato-conjunctivitis eczematosa is caused by an endogenous infection.

"I maintain on the contrary that an ectogenous origin must be granted before the disease can be understood. . . . The entire clinical picture of kerato-conjunctivitis eczematosa becomes comprehensible at once when we assume that a specific agent as yet unknown, but perhaps widespread, excites the discrete diseases on the surface of the eye, especially in persons with a scrofulous diathesis."

Fuchs in Duane's Sixth Edition states that phlyctenular disease has its origin in the scrofulous diathesis. Discussing the nature of the efflorescence he says that two things have to be kept in mind: "1. The efflorescences when quite recent are sterile, containing neither the ordinary pyogenic germs nor tubercle bacilli. Inoculation from them into a test animal does not lead to tuberculosis. Hence it cannot be assumed that, like other inflammations of the conjunctiva, they are referable to ectogenous infection, and as little are they to be regarded in the light of true tuberculous nodules.

"2. In a great number of patients with conjunctivitis eczematosa there are changes which

are certainly tuberculous. . . . But even in those patients who otherwise show no clinically demonstrable evidence of scrofula or tuberculosis the examination with tuberculin . . . proves with rare exceptions the presence of latent tuberculosis. . . . We should not be far out in explaining them (the efflorescences) as being due to the action of toxic substances, in the same way, as for example, nodules develop in tuberculous individuals after the rubbing of a tuberculin ointment into the skin (Moro)."

It will be noted that the only point upon which Fuchs and Roemer agree is the culpability of the scrofulous diathesis.

Everbush speaks of von Hoffman as having "first mentioned the connection between phlyctenular kerato-conjunctivitis, persistent eczema and inflammation of the lids, on the one hand, and, on the other, disease of the lacrimal passages, tonsillar disease and concretions, as well as the usefulness of treating the nose and throat in scrofulous children."

When we turn to the tuberculous theory we find a rather long, weighty list of names in support of it. In this connection it might be well to mention that there is no lack of opinion to the effect that scrofulosis always means tuberculosis, and that some who support the scrofulous theory might properly be regarded as supporting the tuberculous. The relation of scrofula and tuberculosis is still in dispute, so that this factor must remain unsettled. Many writers on the subject seem to believe that scrofula is a condition or habitus which predisposes to tuberculosis. A. Czerny, in 1913, in an attempt to straighten out the contradictory observation in this condition, named the predisposing habitus the "exudative diathesis" and taught that it was only when these cases became infected with tuberculosis that the term scrofula was applicable.

R. Hilbert (Sensburg, 1902) found in 100 cases of phlyctena, scrofulous glands in seventy-three, scrofulous eruption in twenty-two, and rachitis in five. He accordingly decided that the association with scrofula was not a coincident.

Leber contended that the phlyctenule was the result of substances from dead tubercle bacilli set free from caseous foci elsewhere in the body. He presented some experimental support. Later he injected dead tubercle bacilli into rabbits with the intention of pro-

ducing phlyctenules in that way, but had no success in this attempt.

O. Bruns, a pupil of Leber, repeated Leber's experiments with like results. He also tried to produce phlyctena by injecting tubercle bacilli into rabbits, but the result was a true ocular tuberculosis and not phlyctenular disease (*Archiv. f. Ophthalm.* 1904).

De Wecker was of the opinion that the condition was due to the toxin of the tubercle bacillus and thought that the phlyctenules were analogous to tuberculides of the skin.

Turien, writing in 1911, stated that "1. The tuberculous nature of conjunctivitis eozematosa is established and this opinion is supported by the results obtained in cases subjected to tuberculin both diagnostically and therapeutically, and by the majority of other essential findings. 2. The cutaneous diagnostic test of von Pirquet is a dependable method for recognizing tuberculosis, particularly in children. 3. Tuberculin as a therapeutic agent in the treatment of conjunctivitis eozematosa is an agent of distinct and special value."

The von Pirquet test and reactions following the use of tuberculin diagnostically and therapeutically figure largely in the attempts to establish the tuberculous etiology. Apparently few writers who oppose the tuberculous theory seem able to explain away these reactions. The only definite statement of that nature which I have seen is one by Geo. S. Derby, in the *J. A. M. A.* Sept., 1912, and that is a negative one. He said, "I have had considerable experience with tuberculin in the treatment of phlyctenulosis, and I feel doubtful whether any of these cases have been much benefited by it." However, elsewhere he says that though the tuberculosis theory was not proven, evidence showed that the incidence of phlyctenule has a relation to the incidence of tuberculosis.

Regarding the value of the von Pirquet test, statistics are interesting in this connection. In twelve series of cases by eleven investigators, the total number of cases of phlyctenulosis was 903. (Ayrenx, Bednarski, Belenky-Raskins, Bruns, Bywater, Davis and Vaugan, Derby, Pyfer, Rosenhauch, Tivnen, and Weekers.) Of these 769 gave positive tuberculin reactions, which is eighty-five per cent. The claim was then put forward that the percentage of positive reactions would probably be as

high in any group of individuals examined. Figures seem to deny this. In three series\* investigated by three different men, totaling 1,806 children under six years of age, the percentage of positive von Pirquet reactions was eighteen and eight-tenths per cent. These children were taken at random. Whereas in three series of cases of phlyctena investigated by three different men (Belenky-Raskin, Weekers, Gibson), in a total of 118 children under six years of age, ninety per cent. gave positive reactions. This strongly suggests that there is some connection between phlyctena and a positive tuberculin reaction.

Belenky-Raskin (*Zeitschr. f. Augenheilk.* vol. 29, part 6) subjected 100 cases to the von Pirquet test and to the Moro test; ninety-two per cent. gave a positive von Pirquet and eighty-five per cent. a positive Moro reaction. He was convinced of the tuberculous nature of this disease.

The experimental production of phlyctenules has been reported by a number of men. In 1910 Rosenhauch (*Archiv. f. Ophthalm.*) introduced staphylococcus pyogenes aureus into the eyes of tuberculous rabbits and phlyctenular disease resulted. Introducing the staphylococci into the eyes of healthy animals did not produce this result. He also took healthy rabbits and injected them with tuberculin. Into the eyes of one series he introduced staphylococcus pyogenes aureus, and into the eyes of another series, toxin from the same organism. Phlyctena resulted in seventy per cent. of both series. He concluded that phlyctenular disease was the result of the combined action of the toxins of tubercle bacilli and some other organism.

Weekers produced phlyctenules by the instillation of old tuberculin into the conjunctival sac of tuberculous rabbits. He believed the condition due to the toxin of the tubercle bacillus, and did not consider other organisms played any part, as he achieved his results by the use of tuberculin only.

J. Rubert (*Klin. Monatsbl. f. Augenheilk.* Sept., 1912), in addition to the experiments of Rosenhauch and Weekers, tried various modifications of them. His results were somewhat contrary, and he came to the conclusion that phlyctenulosis is the result of metabolic action and that auto-intoxication and the exuda-

\*Von Pirquet, Hamburger and Monti, and Veeder and Johnston.

tive diathesis cannot alone be blamed but must be accompanied by tuberculosis.

W. S. Gibson (*Amer. J. Dis. Child.*, Feb., 1918) produced phlyctenules eight times in tuberculous rabbits; six times following the injection of tuberculin into the conjunctival sac, and twice in the absence of any local irritation. He states that numerous attempts to produce the disease in non-tuberculous animals were unsuccessful.

In 1912, Davis and Vaugan reported forty cases in which tuberculin was used diagnostically and therapeutically. They decided that the results indicated the value of tuberculin.

S. Stephenson (*Lancet*, July, 1914) writes that from the similarity of findings of many observers the association between phlyctena and tubercle was proven on biologic and clinical grounds and could not be doubted.

Igersheimer was in favor of the tuberculous origin, but could not get away from the fact that some cases have no suspicion of tuberculosis at all.

F. H. Verhoeff thinks the disease is always due to tuberculosis clinically and by tuberculin tests. He believes the phlyctenule is an anaphylactic reaction and that the reason that some cases do not react to tuberculin is that they are at the time in a refractory state. A later test might prove positive in these instances.

A. C. Norman (*Hospital*, London, 1915) remarked that "Under tuberculin treatment the process of ulceration was arrested very much more quickly than by ordinary methods alone, and the resulting area of corneal opacity was correspondingly diminished. Another advantage is a remarkable freedom from relapse, but to insure this we find it necessary to give the full course of fourteen injections in all cases."

J. H. Elliot (*Trans. Nat. Assoc. for the Study and Prevent. of Tuberculosis*, 1916) says that "it has been our experience that every child that has phlyctena has given a tubercular reaction."

R. Tivnen, as the result of the study of fifty cases treated with tuberculin, 1917, believes the disease due to tuberculosis.

L. J. Goldbach (Sect. on Ophthal. 1917) sums up a report on the study of thirty-nine cases by saying "I am not claiming this manifestation as a certainty of tuberculosis, but that in a majority of cases, if we use all methods of

diagnosis we will find some evidence of symptoms that go with tuberculosis."

W. S. Gibson (*Am. J. Dis. Child.*, Feb., 1918), in the summary of a comprehensive article, says "Clinical observation on ninety-two cases of phlyctenular conjunctivitis revealed the presence of tuberculosis in ninety cases, as shown by a positive von Pirquet test. In the two giving a negative reaction the diagnosis was doubtful. No other condition, either local or general, could be found with sufficient frequency even to suggest any direct influence in producing the disease."

In a discussion following papers on phlyctenular disease before the Section on Ophthalmology, in 1917, H. W. Woodruff spoke against the tendency of trying to make one factor responsible for the production of this condition. He thought it was the result of a combination.

In summing up the evidence presented in the literature reviewed here, we find: In favor of:

Auto-Intoxication .....	2 men
Carb o-Hydrate metabolism disturbance .....	1 man
Eczema .....	1 man
Ethmoiditis .....	1 man
Ectogenons Infection .....	1 man
Scrofula .....	4 men
Tuberculosis .....	15 men
Tuberculosis, with reservations .....	4 men
Undecided .....	1 man
Variety of causes (any of a) ..	7 men

In addition to this two men enumerated above, while favoring some specific cause, believe that the condition may be an anaphylactic reaction. Many that give a multiple etiology include tuberculosis in their list.

Regarding the question from the standpoint of sheer numbers, it would seem to be settled beyond doubt in favor of tuberculosis. From the standpoint of authority and weight of argument, it is not as obviously decided in favor of tuberculosis as it might seem. This is a decision that cannot be presented in mathematical terms but must be left for the reason and judgment of the reader. The impression gained in reviewing the literature was that the tubercle bacillus was the most probable etiological factor discussed.

114 North Fifth Street.

## AFTER CARE OF OBSTETRIC PATIENTS.\*

By C. J. ANDREWS, M. D., F. A. C. S., Norfolk, Virginia.

A consideration of the after care of obstetrical patients leads us to consider at least the principal pathological conditions which may follow labor. Examination at the time of discharge will be expected to show the degree of injury to the perineum, cervix, uterine supports—evidence of subinvolution, infection of cervix, uterus, or adnexa, and mal-position, as well as general condition of patient.

The frequency of these conditions will depend to a large extent upon the degree of success with which the pregnancy, labor and puerperium have been conducted, but so far we know of no way of preventing these in all cases, and until we do this, we know that a certain number will have some of these conditions. Therefore, it seems difficult to avoid the conclusion that all cases should be examined before discharge, in order that the abnormal condition may be discovered, and suitable advice given.

My records of 200 discharge examinations, made from six weeks to three months after labor, showed that in 21 cases the perineum was in an unsatisfactory condition. About sixteen of this group were multiparae, with previous injuries: one a primipara, who had a rapid, easy labor, with only a mucous membrane tear. Two others had induced labor, and forceps for threatened eclampsia.

Recently, I have used the Potter method of ironing the perineum with considerable satisfaction, and only occasionally used the episiotomy. In the first 150 cases, episiotomy was used rather often in primiparae with good results. Practically all were delivered under deep anesthesia.

Primary repair of the perineum has been usually very satisfactory, but occasionally the stitches will break down. In a few such cases I have done a secondary repair after about ten days, while the patient was still in the hospital. The results have been good, except in one case the perineum was closed somewhat too effectually. In those cases which require operation later, they are advised of this fact, usually after the nursing period is completed.

The unhealed, infected cervix laceration is of great importance to the patient's future

health. It is the beginning of endocervicitis, which forms a focus of infection which may destroy the woman's health. Examination of the cervix, particularly, has a secondary function—that of testing the relative merits of various methods of delivery.

My observation has led me to believe that forceps delivery, with the head still in the cervix, has given the greatest number of injuries. Properly performed version gives less. Forcible delivery by any method when the cervix is not fully dilated is usually very difficult, and the cervix is exposed to considerable trauma, and often badly torn.

My records show that 17 in 200, or 8½%, private patients had evidence of cervical infection at time of discharge. Some of these more superficial erosions are improved by silver nitrate or iodine, or other local applications. If the cervical glands are infected this will do no good. An electric cautery, such as is used for nose and throat treatment is most effectual. This method was described by Dickenson in the *American Journal of Obstetrics and Gynecology* during the past year. The small point is carried into the crypt, actually destroying it. If the eroded surface is broad, the blade makes one or two cuts in each lip of the cervix. The cautery is not heated to a very high degree, and has somewhat the effect of the Percy cold iron treatment. The slough separates in one or two weeks, and the surface heals with considerable rapidity.

My experience with this has been largely with old cases. One cystic cervix, which had followed labor nine years before, healed satisfactorily with this treatment. Some of these cases will require surgical treatment later. Where there was a well established endocervicitis, the Sterndorf operation has been very satisfactory, although the Schroeder, or some modification of it, has been used in a number of cases with satisfaction.

Retrodisplacement of the uterus seems to be very frequent. Many observers agree that it exists in about 22% of all women examined. E. Schroeder, 1900, reported 28.7 retroversions in 411 gynecological cases. Only a few have investigated the frequency of uterine displacement after labor. Winter found that they occurred in 12% of 300 women from two to ten months after labor. Lynch, 1922, reports 41.1 in 505 clinic cases; and in 19.6 of 186 private

\*Read before the Norfolk County Medical Society November 27th, 1922.

cases examined from six to eight months after labor.

My own records show 27 retrodisplacements in 200 private cases, or 13.5%. In my own cases I do not know how many were present before pregnancy but I think only about four were of the type which is usually congenital. It was to double this to provide a margin, and say that 4% of all cases existed before labor, it would still leave 18% as due to labor. I hope that our hospital records may soon be available to give us additional information on these subjects.

If we admit the approximate accuracy of this, and also that the retrodisplacement is a considerable factor in pelvic diseases, we still have to agree that the discharge examination for the purpose of discovering these conditions, and applying suitable relief, is a necessity. Fortunately, the relief of retroversion after labor seems to be comparatively easy. With the exception of the cases which have had some inflammatory condition, simple office treatment will leave the percentage about the same as in the nulliparous, and some of these will be benefited by suitable operation.

Face position, knee chest position observation of patient as to progress of involution before allowing out of bed, have all been used to prevent retrodisplacement. The kangaroo walk as recommended by Polak has not yet been tried.

Pelvic inflammation of any kind favors retrodisplacement. Laceration of perineum does not appear to affect it. Stretching of the round ligaments during pregnancy, together with injury of the cardinal ligaments during delivery, promotes retrodisplacement. When the uterus is found to be retrodisplaced after labor, it is replaced manually by the aid of a tenaculum on the cervix. Gentle traction is made until the fundus is released, then the tenaculum is held by an assistant and, with two fingers in the vagina behind the cervix, the fundus is lifted forward. At this moment the assistant carries the cervix forward and downward, while the left hand on the abdomen catches the fundus and brings it forward. In some cases the uterus is left without any further treatment. If it remains in position, nothing further is needed, but if the retrodisplacement has recurred when the patient returns a week later, a pessary is used. This is changed once in thirty days. Usually

after about two months, in uncomplicated cases, the fundus remains in normal position. If adhesions are present the pessary will be of no use.

Twenty-two of my 27 cases of retrodisplacement after labor were in position when last examined. These patients can often tell when the uterus is out of position. The pessary gives information as to the relation of the symptoms which the woman may have due to retrodisplacement. If the symptoms are relieved, it is very good evidence that they are due to the displacement. If the retrodisplacement persists, and there is later evidence that it is interfering with health, some operation for retrodisplacement is done. I have used a considerable number, but have had most satisfactory results from a modification of the internal Alexander, which brings the round ligament to the under surface of the fascia near the internal ring.

The Johnston-Willis modification of the Coffey operation is extremely satisfactory, but the use of non-absorbable suture in the abdomen is not entirely satisfactory, and therefore we are not using that at present.

Does retrodisplacement of the uterus give symptoms? E. Schroeder in 1900, examined 411 women. Seventy-three per cent, or 303, had no pelvic symptoms, yet 26%, or 79, of these had retroversion. There were 108 women who complained of lower abdominal symptoms. Thirty-six per cent, or 39 cases, had retrodisplacement. He concludes that 25% of women who complain of no symptoms referable to the pelvic organs have retrodisplacement.

A recent study, 1922, by Lynch, showed that in a series of 505 cases of retrodisplacement, 32% complained of bearing down sensations, pressure in the pelvis, and backache; while only 10% of 725 normal cases complained of these symptoms. In other words, he found pelvic symptoms three times as frequent with retrodisplaced uteri as in normal cases. Apparently, the observations as to symptoms from retrodisplacement have been largely centered on local symptoms. Probably the effect on the patient's general condition is often as important. Although it is admitted that 22% is approximately a correct estimate for the incidence of retrodisplacement in cases examined, this does not mean that 22% of all women have retrodisplacement of the uterus.

When one considers that a woman is not likely to have a pelvic examination unless she has some pelvic symptoms, it seems reasonable to conclude that 22% who have symptoms referable to the pelvis have retroverted uterus. This would certainly seem to show that retrodisplacement was a factor of considerable importance in pelvic diseases.

Potential prolapse, cystocele, and rectocele cases are kept under observation until the nursing period has passed, when suitable treatment may be instituted. It seems particularly important that patients be told very plainly of the prospects if these conditions are not treated. The problem of the prolapsed uterus would be largely solved if this course could be always pursued.

512 *Taylor Building.*

### THE DIAGNOSIS OF TUBERCULOSIS IN CHILDHOOD.\*

By FRANK B. STAFFORD, M. D., Blue Ridge Sanatorium, Charlottesville, Va.

In recent years the diagnosis of pulmonary tuberculosis in adults has been placed on a fairly satisfactory basis. Dr. Lawrason Brown<sup>1</sup> has by formulating his five diagnostic postulates, given a valuable contribution to this work and placed it at the disposal of the entire profession. Briefly, they are as follows:

- (1). Definite physical findings above the second rib in front and the third vertebral spine behind.
- (2). Blood spitting.
- (3). Pleurisy with effusion.
- (4). Parenchymatous X-ray lesions in an apex.
- (5). And most important, the presence of tubercle bacilli in the sputum.

When we come to consider the diagnosis of tuberculosis in childhood there is quite a different situation confronting us. Little has been said or written that is really helpful. All have been satisfied to pass up the situation as most difficult without seeking to learn something of its various aspects. There is today a growing demand for a more thorough analysis and diagnosis of childhood cases, and any information or discussion of the problem must be helpful. It is quite obvious that the diagnosis must be made early and the proper treatment instituted at once if the prognosis is to be good. This has long since been proven true

in adult tuberculosis. Surely, it would apply more to the growing child that has the disease.

There is not a single diseased condition that requires more careful study of all the available data on the part of the clinician than childhood tuberculosis. Short cuts, clues, easy signs and clear markings of the disease are conspicuous by their absence. Time must be given; the case must be studied from every available angle; the data must be carefully correlated and digested before a final verdict can be rendered. Symptoms will invariably be more pronounced than physical signs. Other factors which will greatly aid in the diagnosis and must be considered are X-ray findings and the cutaneous tuberculin test.

Before taking up each of these separately it might be well to devote a little time to the discussion of what constitutes a normal chest in childhood. A committee<sup>2</sup> appointed by the National Tuberculosis Association to study the normal chests of five hundred children between the ages of 6 and 10 years reported their findings to the Association at the last meeting in Washington. The committee studied the chests from both, the standpoint of the physical signs and X-ray findings, and reported many variations in each that were still well within the limits of normal. They found the percussion note elicited over the normal chest to be fuller, more tympanitic and higher pitched; while the breath sounds varied from puerile, where the expiration was prolonged and higher pitched, to the normal type heard in adults. The X-ray findings were at such variance that it was decided to divide the chest into three zones from within outward, and deal with the shadows cast according to their location in the zones.

Tuberculous infection, considered now to be almost universal, is quite different from open, active, clinical disease. The infection may remain well under control and never give trouble if the child is kept strong and healthy, while on the other hand some exciting factor is apt to break down the resistance and sickness is the result with definite signs and symptoms. It is this form producing definite signs and symptoms and ranging from a tracheo-bronchial lymph adenitis to a localization in the hilar regions, occurring in children between the ages of six and twelve or fourteen years, in which we are most interested.

\*Read at the meeting of the Piedmont Medical Society in Charlottesville, November 25, 1922.

**HISTORY:** The history is perhaps the most important piece of evidence at our command and is often the chief reliance in determining the real nature of the trouble. This, however, is not always easily obtainable; the child will have very little knowledge of past events and we must rely on the parents for this information. To consider the onset of the disease gradual and usually pursuing a chronic course in childhood, we can better understand why much time should be given to collecting all the positive facts connected with a complete history. Living conditions in the home should be investigated. A history of repeated contact, or prolonged exposure to the disease, whether in the home or outside of it, is of great importance. For one of the parents to be suffering from the disease, or a grandmother or aunt living in the home to have an old chronic fibroid lesion, it would make one search more carefully. It is also important to know that the milk supply in the home comes from a tuberculin tested herd. The child may get infected from this source. The German Commission<sup>3</sup> appointed to investigate the danger to human health from drinking milk from infected cows reported one-fourth of the children examined to be tuberculous. The English Commission serving the same function reported one-half of the children having tuberculosis of the digestive tract to be due to bovine type. These reports seem to be rather high, probably due to the fact that the European cattle have a higher percentage of infection than the American. This is sufficient to say that bovine tuberculosis is now a reality and not a fancy. It should be remembered, however, that even though you are not able to get a history of exposure to tuberculosis, child is not tuberculous. On the other hand, either human or bovine, is no proof that the if such information can be obtained with definite clinical evidence, corroborated by X-ray findings, the diagnosis is well established.

**SYMPTOMS:** Certain local symptoms, such as cough, expectoration, hemoptysis and pleurisy, are important when they exist; but, where the lesion is well localized in the glands in the hila regions, all are apt to be absent unless it is a slight cough. Constitutional manifestations, such as afternoon rise in temperature, increased pulse rate, poor appetite, languor, loss of strength, fatigue, or lack of endurance, and failure to gain weight, should be carefully

noted. A stationary weight in a child is equivalent to the loss of weight in an adult. Any child who fails to gain weight over a period of from three to six months is suspicious and should make one think of pulmonary disease. Of all the symptoms that a tuberculous child may have, failure to gain weight, irregular and "finicky" appetite, and fatigue on exertion, are probably the most important. On returning from school in the afternoon the child prefers to lie around, has no energy, and is tired all the time. There is a distinct lack of "pep" which is so manifest in growing, healthy children. Susceptibility to colds is another important factor and when present should be carefully noted.

**PHYSICAL SIGNS:** The examination of the chest in this type of the disease is usually not worth much. The situation of the lesion makes it difficult to detect any abnormal condition. If the examiner has a full appreciation of the wide range the normal may present, less erring is apt to take place. Also, the younger the child, the more exaggerated are the normal findings. D'Espines's sign once thought to be indicative of enlarged glands in the hilum region is now known to be of little value. Dullness in the para-sternal and para-vertebral regions is to be relied on only when supported by the X-ray. A hilum dimple is of some diagnostic value when it exists. The breath sounds may be harsher, higher pitched, and have the expiration more prolonged than the normal puerile breathing heard in the hila regions. Palpable glands in the cervical and submaxillary regions are of no special significance unless superficially located, matted together, and they have a tendency to necrosis. Infected tonsils and carious teeth can cause enlarged glands in these regions. The chest should be examined for rales heard during inspiration following expiration and cough; but this, like hemoptysis and tubercle bacilli in the sputum, will not occur unless the disease has spread beyond the hilum into the parenchyma of the lung, or a caseous nodule has ruptured into a bronchus.

**X-RAY:** No examination of the child's chest is complete until stereoscopic X-ray plates have been taken and carefully interpreted by one experienced in this line of work. "Visionary interpretations"<sup>4</sup> of the plates spoken of by Osler may occur if the internist attempts to read them. Especially is this true if on the

physical examination evidences of hilum involvement have been found and he is over-anxious to confirm it by the X-ray. Skill and good technique are necessary in making the picture, since it is hard to keep children quiet and have them hold their breath during the exposure. This adjunct like the physical has been found to show many variations from the normal. After-effects of certain diseases, such as deep colds, grippe, bronchitis, infected tonsils, measles and whooping cough, may cause increased hila shadows and thickening of the bronchial trunks not unlike a tracheo-bronchial tuberculosis. The expert in this particular field usually has certain differential points that guide him and prevent misinterpretations.

**TUBERCULIN TEST:** In regard to this point the same applies as to others entering into the diagnosis. There is a wide difference of opinion. Some have even gone so far as to say the diagnosis of tuberculosis in any form is incomplete unless supported by a positive tuberculin reaction. This is indeed, putting it too strong and we may expect much damage to the patient by its careless use. Especially is this true if administered subcutaneously. The cutaneous test of von Pirquet is the one most frequently used in children. This method is simple, harmless and easily applied. When positive, it only indicates the presence of a tuberculous infection and not necessarily a diseased condition. Too much importance must not be placed on a positive cutaneous test where there is no indication of sickness. On the other hand, if a child has a suggestive history with definite symptoms and signs, and the von Pirquet test is positive, the burden of proof is in favor of active, clinical disease. Certain conditions will alter this reaction. In advanced tuberculosis where the resistance is broken down and in some of the acute infectious diseases like measles the test may be negative. Of the 63 children admitted to Blue Ridge Sanatorium in the last few months, 55 have given a positive von Pirquet test. In most of these cases there was clinical evidence of disease and a positive diagnosis made. Of the eight that were negative, two were in the terminal stages of the disease with tubercle bacilli in the sputum, running temperature, and died soon after discharge. In the remaining six who were repeatedly negative there was no evidence of the disease and we were unable to make a diagnosis.

In the diagnosis of childhood tuberculosis, many other conditions not discussed here must be taken into consideration. Intestinal parasites, bad teeth, infected tonsils and adenoids, and the various physical defects may upset a bodily balance and be stepping stones to active disease. Again, these conditions may cause the disease to be masked in its incipency and the proper diagnosis postponed until it is too late to effect a *cure*. Many children are today dying of pneumonia and chronic dysenteries who have tuberculosis as their background.

#### SUMMARY.

1. To diagnose tuberculosis in childhood is to strike at the very root of the disease; to give the patient a chance to take the treatment early; and ultimately offer a better chance for recovery.

2. There is a much higher incidence of active tuberculosis in childhood than is generally thought.

3. In considering the normal chest of a child, many variations have been found from both the standpoint of physical signs and X-ray findings that are to be considered normal.

4. The diagnosis of hilus tuberculosis requires much time and a thorough analysis of four points:

- (a). Complete history, including symptoms.
- (b). Physical examination.
- (c). Stereoscopic X-ray plates.
- (d). Cutaneous tuberculin test.

All of these points are important but the outstanding factors are complete history with symptoms and X-ray.

#### A REAL MAN

The test of a man is the fight he makes,

The grit that he daily shows;

The way he stands on his feet and takes

Fate's numerous bumps and blows.

A coward can smile when there's naught to fear,

When nothing his progress bars,

But it takes a man to stand up and cheer

While some other fellow stars.

## NEWER METHODS OF DETERMINING CONDITION OF NUTRITION IN CHILDREN.

By SAMUEL NEWMAN, M. D., (Member Medical Commission, American Joint Distribution Committee).\*

The problems of nutrition during the war and post war periods in Europe have been most vital to the very existence of the people and still are of great concern to those interested in the rearing of a young healthy generation in Europe. The question of practical and objective methods of determining the condition of nutrition among the millions of children became of paramount importance, since not all children in Europe could be considered in the scheme of supplementary feeding and other child welfare programs initiated by European and American relief agencies.

The question of malnutrition, and methods for its determination, have an entirely different aspect in private practice from that in social medicine. In private practice, or where the examination of only a small number of children is concerned, it is a mistake to consider malnutrition as a clinical entity and seek for a formula or mathematical index to express it. The physician must endeavor to go deeply into the history of the case and to bring into light the underlying cause of the poor state of nutrition of the individual which may be due to various causes, such as cardiac disease, metabolic disturbances, hyperthyroidism, faulty habits, etc. It is hardly probable that in America actual lack of food should be responsible for malnutrition.

However, the situation is entirely different when we are dealing with large groups of children, especially in Europe, which come under consideration from the nutritional viewpoint. Here malnutrition must be considered as a clinical condition *per se* and, when the necessity arises to select certain groups of children for certain feeding benefits, the need for objective methods whereby to determine the state of nutrition becomes evident—methods which will yield the same results in the hands of different examiners. The usual ratings, such as "good," "bad," "very bad," will suffer very much from the personal element of the examiners, and will not always admit those who, in the opinion of critical parents or com-

munities, are entitled to the feeding benefits, and will not be at all applicable to the examination of large groups of children.

Personally I was faced many a time with responsibility for selecting certain groups of children for various benefits, such as supplementary feeding, summer colonies, tuberculosis sanatoria, etc., from among war orphans, street and school children in Poland. The different standards of physical development used in the States as a measure of nutrition could not be applied in Poland for the reason that their use even in America is open to serious objections. All these standards state the degree of nutrition in terms of *weight* in relation to *height*. The fundamental objection to these standards are the following:

a. The height-weight index, or relation, varies with different races.

b. The relation of body weight—a quantity of three dimensions—to body length—a linear measure, is mathematically wrong and can by no means express a true inner relation between them, unless a formula is found whereby weight and length are reduced either to linear or cubic measures.

c. Anthropometric studies have shown that the body weight curve is a truer index to growth than body length. The standing height includes both trunk and lower extremities, but these do not grow as a functional unit. The trunk and the lower extremities both grow in accordance with an index of their own, therefore the comparison of standing heights is false for they represent merely the sum of different functional units—the trunk and the extremities—each growing in accordance with a law peculiar to itself.

In view of the above, a simple weight-and-length table could not be used in a country where the standing height of the children was subjected to even greater variations due to all sorts of disturbances of growth.

However, the war necessity proved also to be the mother of invention in the field of Nutrition Indexes. Space will not permit me to enumerate them all, neither is it necessary, as many have not yet stood the tests of time and critical application. I shall mention here two nutrition indexes and a brief clinical method to determine the state of nutrition in a child.

*The Rohrer Index.* The Child Welfare program of the Quaker Relief Mission to Germany depended upon the selection of children as its

\*Dr. Newman is a member of the Medical Society of Virginia and was connected with the Health Department of Danville, Va., prior to becoming a member of the Commission. He is now attending the Children's Clinic, University of Vienna.

beneficiaries on the index devised by Rohrer, in Germany. This gives an expression of body volume, i. e. weight, thus: "Body weight X 100: length cubed." (Hundred times the weight of the body divided by the length of the body after it has been raised to the third power.)

This index, extensively used in Berlin in the examination of thousands of children, has been subjected to great criticism in Germany. In the examination of eighteen thousand children in Munich in accordance with the Rohrer Index it was noticed that many children looked far better than their grade obtained through the use of the index. Also the experience of school physicians in Germany spoke against the correctness of the values obtained for length in certain age groups, by means of the Rohrer Index. Personally I have had no experience with the Rohrer Index.

*The Pelidisi Index.* Professor Pirquet of Vienna made the observation that the sitting height of an individual, that is the distance from the top of skull to the sitting level, is equal to the cube root of ten times his body weight. This relationship is expressed by the following formula:

$$Si = \sqrt[3]{10 \text{ weight}} \quad \text{or,} \quad Si^3 = 10 \text{ weight}$$

By dividing the cube root of ten times the body weight we get the figure *one*, or

$$\sqrt[3]{\frac{10 \text{ weight}}{\text{sitting height}}} \quad \text{Equals 1.}$$

For convenience, we make this one 100 in order not to have to deal with decimals.

Now this relationship of *sitting height* to body weight—not standing height—has proved to be applicable to examinations of hundreds of thousands of children in Austria. The feeding program of the American Relief Administration in Austria was based upon the selection of children by means of the Pelidisi Index. A normal individual should have a pelidisi of 100. Above 100 means overfeeding and below 94.5 means malnutrition. In the practical application of this Index of Nutrition all children with a pelidisi of 93 were at once admitted to the feeding stations.

This relationship of *sitting height* raised to the 3rd power being equal to 10 times the body weight, has been verified by Pirquet in the examination of fetuses, new-born, infants, chil-

dren and adults. This relation holds good for every period of life and only slight variations are to be taken cognizance of; namely, fat and well nourished infants reach an index of 100, while muscular adults show an index of 105. In school children a pelidisi from 95 to 100 is normal, below 95 is under nourished.

In selecting large groups of children and in classifying them in accordance with the varying degrees of undernourishment, the Pelidisi Index of Pirquet is the best and quickest method we have and can be carried out even by laymen. The determination is made very easily by means of the ordinary technical sliding rule or by means of the simple Pirquet Pelidisi table. I have had considerable experience with this method and it checks up fairly well with closer clinical examinations. The word "pelidisi" is not an accidentally coined word, but simply expresses the true relationship of the sitting height to body weight which Pirquet discovered. Thus—Pondus (weight), decies (ten times), linear (extracting root), diviso (divided through), sidentis (sitting height) expresses the relation.

A concise clinical method of determining the degree of undernourishment which can also be reduced to a schematic formula is the Sacratama method, also devised by Professor Pirquet. Pirquet states that in the picture of nutrition four (4) main components enter; namely, (*sanguis*) blood, (*crassitudo*) fat, (*turgor*) water content of subcutaneous tissue, and (*muscularis*) degree of muscular development. These four qualities are abbreviated thus.

- S=blood
- Cr=fat
- T=turgor
- M=muscle.

Any of these four components or qualities may be increased or decreased. The degree of increase or decrease is expressed by the vowels *i, e, a, o, u*, in the order of the lesser depth of the vowel sound. Thus—

- i=very great: excessive; super-abundant.
- e=increased; more; much; abundant.
- a=normal.
- o=decreased, less.
- u=very little; almost absent.

The physician proceeds with the examination as follows: The child strips to his waist and the color of the skin is noticed as to its blood content. If normal the physician writes

*Sa*. Now a fold of flesh is raised below the clavicle and the fat content is noticed. If increased *Cre* is written down. Now a fold of skin is lifted up on the forearm. In case of the diminished turgor a fold is formed which stands up for a little while. In marasmic children we all noticed how the skin lies over the body in folds because of the lack of water in the subcutaneous tissues. If the skin fits well over the contour of the extremity the turgor is normal, hence *Ta* is written down. Lastly the degree of muscular development is noticed in the arms. The muscles may be weak and flabby, hence *Mo* is written down. We thus obtain the key word *Sacretamo*, which means a child with a normal blood content, very fat, normal turgor and weak muscular development. Similarly a child may obtain the formula *socrotomo*, which means pale and lean, with flabby muscles and diminished turgor.

The classification of a group of children in accordance with varying degrees of under-nourishment takes places after the sacratama method thus: A normal child has a rating of sacratama, that means he has not a single bad mark. Such a child belongs in the zero class. A child with one bad vowel, in the *one* class, etc.

No bad vowel.....	in 0 class
One bad vowel.....	in 1 class
Two bad vowels.....	in 2 class
Three bad vowels.....	in 3 class

After a little experience this method of examination gives the physician a great deal of clinical insight and teaches him that the various bad or good vowels he obtains in the examinations are not accidental but stand in definite relation to clinical conditions which the child has undergone. For instance, very diminished turgor will indicate an acute condition, for in chronic conditions, even though the blood content and the muscular development may be poor, yet the turgor accommodates itself to the underlying tissue and no fold of skin can be readily raised—that will mean that the turgor for this particular condition is normal whereas in relation to true health it is very much diminished.

In the Children's Clinic of the University of Vienna, pelidisi and sacratama determinations of all patients are a matter of routine and in a compact way give a real insight into the clinical history of the child.

## Reports of Cases

### INSULIN IN DIABETES.

#### A Preliminary note on Personal Experience in the Use of Insulin

By ALEXANDER G. BROWN, Jr., M. D., Richmond, Va.

Insulin (Lilly) is an aqueous solution of the active principle obtained from the Islets of Langerhans in the pancreas. This extract has been used in the treatment of human diabetes during the past year in several clinics in this country and Canada. It has been made under license from the University of Toronto which controls the product. Those who were privileged to participate in the investigation during this early stage of its development were requested to refrain from publication until a considerable amount of clinical data had been accumulated and the Toronto group had gotten ready the publications of their observations. The preliminary papers of the Toronto group have been published for several months and their final conclusions are soon to appear in print. And so, now, others who have had opportunity to use and observe Insulin (Lilly) during this general experimental investigation have been notified of not only their release from further necessity for secrecy regarding results observed, but, on the contrary are urged to submit the results of their clinical and experimental observations to the profession.

The chapter of events and course of experimental development which entered into the evaluation of this product is a story of definite scientific interest and will have a place in the annals of medicine for all time. But we shall not tarry on this phase of its interest.

The unit is the standard of measurement of insulin. The unit of insulin originally adapted was the amount required to lower the normal blood sugar of a one kilogram rabbit to 0.45 per cent., at which convulsions generally occur. This was taken as the standard of dosage; but its standardization has been very difficult of uniformity. It is expected that in the near future considerable improvement may be expected in this. Of course, the effect on human diabetes must vary with individuals as there is variability in the power to burn carbohydrate. A unit of insulin, when injected into a human diabetic, enables the

patient, it is believed, to utilize or store from 1 to 4 grams more of carbohydrate than he could before administration. The number of units required to maintain a nearly normal blood-sugar, a sugar free urine, with a limited carbohydrate intake, is the amount needed for the patient under treatment.

Our experience with Insulin began on November 15, 1922. From that time up to the present time, April 28, 1923, we have been using it daily. We believe the claim made for it by its discoverers and the reactions it produces in the animal experimentation are justified by our observations.

In our clinical observations of it in the Stuart Circle Hospital, its effect upon the blood sugar of the patients was definite and uniform. Our first patient was brought in the Hospital in a semi-comatose condition, with a blood sugar of 426 milligrams per 100 cubic centimeters of blood; with a urine showing marked reactions of a diacetic acid, and a urine heavily loaded with sugar. The first day insulin was given in dosage of 8 units every hour for 12 hours. The second day the insulin was continued every hour for 12 hours. The urine was examined every hour without noting any change in the sugar reaction or in the diacetic acid.

On November the 17th, 10 units were given every hour for 12 hours. The patient's clinical appearance began to show marked improvement, but laboratory findings of urine showed no marked change. On November 18th, the fourth day of his treatment with insulin, 10 units were given the patient subcutaneously every hour until the fourth dose, when the urine reports from the laboratory began to show improvement. The sugar was disappearing; the diacetic acid reaction was becoming faint; and the blood-sugar had fallen to 168 milligrams per 100 c.c. of blood.

On November 28th, thirteen days after entering the hospital, this patient was being given subcutaneously only 10 units of insulin three times daily; he was receiving in his diet 30 grams of carbohydrate, 86 grams of protein, and 184 grams of fat; he was sugar-free in the urine; he was free of diacetic acid; and his blood sugar was 153 milligrams per 100 c.c. of blood. The patient had subsequent history of interest which will be reported in full later.

Another case was admitted to Stuart Circle Hospital January 4, 1923, in a state of pro-

found diabetic coma. The coma began about eleven hours before she was brought to the hospital. A catheterized specimen of urine showed an estimated 5 per cent. of sugar; the blood sugar was 580 milligrams per 100 c.c. of blood.

Insulin (10 units) was given subcutaneously at 7 A. M., 8:30 A. M., 9 A. M., 9:30 A. M. Twenty units were given at 10:30 A. M., 11:30 A. M., 12:30 P. M., 1:30 P. M., 2:30 P. M., 3:30 P. M., 4:30 P. M., 5:30 P. M.

January 5th, patient was unimproved; coma was deep; 10 units of insulin was given every hour for 12 hours. Blood-sugar examinations showed 320 milligrams per 100 c.c. of blood.

January 6th, patient was unimproved; coma was profound. Insulin, 10 units every hour, was continued. Blood-sugar was found to be 302 milligrams per 100 c.c. of blood. The patient was fed through a stomach tube liberal amounts of fruit juices and was given glucose intravenously. The patient died in coma. The marked drop of blood sugar from 580 to 302 milligrams of blood-sugar was significant.

The daily use of insulin in our hands has disclosed the following results:—

A. Favorable influence in diabetes in reducing hyperglycemia.

B. Favorable effect on ketonuria.

C. Favorable effect on urinary sugar.

D. Favorable influence on the increase of carbohydrate metabolism.

E. Favorable effect upon the mental symptoms of diabetes—giving a decided improvement in morale.

F. Favorable influence on the physical strength of diabetics.

G. Favorable effect on the distressing symptoms of diabetics, as thirst, inordinate appetite, polyuria, etc.

H. Favorable effect on all skin lesions, boils, scalp ulcers, hang-nails, cuts, hair, eruptions, accidental infections of diabetes.

Insulin does not supplant the diet-treatment of diabetes. While insulin does increase the power of the diabetic to burn carbohydrate, the dietary management of the patient is quite as necessary as heretofore. One of the problems before the internist in the use of insulin in diabetes is the adjustment of the dosage of insulin to diet; much the same method is followed in arranging the diet. The carbohydrate tolerance is determined, the ketogenic and anti-ketogenic balance is struck, the nitrogen balance is maintained. Insulin will make

each of the problems easier. Insulin is an agent that enables the crippled pancreas to receive help from the outside. There are untold possibilities in insulin for the control of hyperglycemia.

The treatment of coma is wonderfully advanced by the discovery of insulin. It undoubtedly is a direct and specific product which may be utilized with confidence in acidosis and coma. Not only is experimental proof given in the work of the Toronto group but, in the cases that have come under our immediate observation, insulin has shown undoubted favorable influence in acidosis and coma.

Precautionary measures in the use of insulin are necessary. It is undoubtedly a potent agent that is fraught with no inconsiderable risk. No one should attempt to use insulin unless the dosage and the effect is carefully checked by competent laboratory examinations of the urine and the blood chemistry. The too sudden lowering of blood sugar may make the diabetic the victim of convulsions and death may result. The medical profession and the public must be on their guard against such serious accidents as may result from the ill-advised and unskilful use of insulin. Already the wide publicity given this product in the lay press makes for serious dangers which must be averted by the careful and watchful use of the great discovery.

The Lilly Research Laboratories deserve our grateful appreciation for the large amount of insulin with which they supplied us free of charge in our clinical study of its use in diabetes.

*Stuart Circle Hospital.*

## Analyses, Selections, Etc.

### Graves' Syndrome and the Involuntary Nervous System.

Under the general caption, "Studies of Graves' Syndrome and the Involuntary Nervous System," Kessel, Lieb and Hyman<sup>1</sup> report in a series of nine articles a study designed "to promulgate a definite policy for the management of individuals suffering from Graves' Syndrome." Among the more striking conclusions reached by the authors are, that the complete picture of Graves' Syndrome may exist without elevation of basal metabolism, the normal metabolism establishing a differential

diagnosis from Graves' Syndrome; and that there is a marked tendency in patients with exophthalmic goiter to recover spontaneously.

Paper I<sup>1</sup> deals with thyroid enlargement in individuals without sympathomimetic manifestations. The authors have adopted the term of Barger and Dale, "Sympathomimetic," to denote manifestations that are tantamount to electrical stimulation of the thoracolumbar division of the involuntary nervous system, or to stimulation of the same system by adrenalin. In other words, *anatomically*, the term has reference to the same part of the nervous system as the "Sympathicotonia" of Eppinger and Hess.

Patients with "Graves' Syndrome," but with no significant elevation of basal metabolism, they regard as subjects of "autonomic imbalance," and the clinical study of these patients is presented in paper II<sup>2</sup>.

The clinical study of 50 consecutive cases of exophthalmic goiter, (Graves' Syndrome with elevated basal metabolism) is reported in paper III<sup>3</sup>.

A study of the physiology and pharmacology of the involuntary nervous system, with an "attempt to find an index for the activity of the involuntary nervous system" is described in paper IV<sup>4</sup>.

Papers V, VI and VII<sup>4</sup> deal with the application of this index to the role of alleged etiologic and therapeutic influences, as well as to factors which maintain the tonicity of the involuntary nervous system.

Paper VIII<sup>5</sup> is a general summary of the clinical and laboratory work on the involuntary nervous system.

Paper IX<sup>6</sup> is a discussion of pathogenesis and an evaluation of popular therapeutic procedures.

The general conclusions reached in the nine articles are as follows:<sup>3</sup>

1. Thyroid hyperplasia and thyroid adenoma may exist for years without at any time causing sympathomimetic symptoms or alteration in metabolism.
2. Disturbances of the involuntary nervous system clinically occur frequently (autonomic imbalance).
3. Such disturbances are usually not attended by metabolic elevation.
4. While these clinical manifestations of disturbances of the involuntary nervous system (autonomic imbalance) are often associ-

ated with thyroid hyperplasia, there is no reason to believe that the thyroid enlargement is causative and many reasons for thinking that it is secondary and symptomatic.

5. In exophthalmic goiter the dominant derangement is in the realm of the involuntary nervous system. This may not be primary, but the primary cause, whatever it be, must at least operate through the mediation of the involuntary nervous system.

6. The primary cause of exophthalmic goiter must be sympathomimetic.

7. There is a close relationship between exophthalmic goiter and autonomic imbalance. The latter usually presages the former, and is probably a stage in its development.

8. Evidence is presented to show that thyroxin is not sympathomimetic either directly or indirectly through synergism with epinephrin, even if it be granted that epinephrin controls the involuntary nervous system either in the tonic state or in emergency.

There is a marked tendency in patients with exophthalmic goiter to recover spontaneously. This factor must be carefully considered in evaluating "specific" therapeutic procedures.

### Spinal Drainage Following Intravenous Arsphenamine.

From the N. Y. Urological Institute. Author's conclusions relative to the treatment of syphilis of the nervous system are:

1. No single method of treatment is applicable to all cases.
2. The intravenous administration of arsphenamine is the method of choice.
3. Spinal drainage after intravenous administration of arsphenamine is not a hazardous procedure.
4. Drainage will benefit some cases which have arrived at a position of inertia under intravenous administration alone.
5. As satisfactory clinical and serological results may be obtained by intravenous arsphenamine and drainage as are produced by intraspinal method and without the severe root-

pains frequently set up by the latter method. (C. Burns Craig, Journal of Nervous and Mental Disease, August, 1922).

### Sulpharsphenamine: Its Manufacture and its Chemical and Chemotherapeutic Properties.

The data presented show that sulpharsphenamine is an arsphenamine derivative very closely related in chemical structure to neoarsphenamine. This slight change in chemical constitution, however, imparts to the drug certain definite advantages over neoarsphenamine, as (1) ease of manufacture, (2) great stability of the drug in dry form and in watery solutions, (3) constancy of toxic and parasiticidal action of different lots, and (4) suitability for hypodermic administration. Every one of these advantages is of far-reaching importance, when consideration is given to the fact that enormous numbers of doses of arsphenamine are used in the control of syphilis.

As far as the experimental evidence is concerned the above mentioned advantages of sulpharsphenamine are firmly established. However, it is strongly emphasized that before this drug can be introduced for general use, it will be necessary to give it an exhaustive trial as to its curative power in human syphilis. (Carl Voegtlin, J. M. Johnson, Helen Dyer, *Public Health Reports*, November 10, 1922.)

### Treatment of Neurosyphilis.

Every case of neurosyphilis, diagnostically established by combined clinical and serological tests, demands assiduous treatment of the general syphilitic infection by every means at our disposal. Antisyphilitic remedies, including mercury, iodides, arsenobenzol, etc., are to be administered by the most efficient route, whether by the mouth, by inunction or fumigation, by intramuscular injection, or by intravenous injection into the blood stream. In no case should our remedies be directed exclusively to the nervous system.

In gummatous and meningo-vascular neurosyphilis the foregoing anti-syphilitic treatment is usually all that is necessary.

Some cases of parenchymatous respond, but the majority are resistant to general antisyphilitic treatment, even when carefully and thoroughly carried out. Such cases are those which should be selected for supplementary

subarachnoid treatment, whether intrathecal or intracisternal.

Intraspinal treatment by salvarsanized serum prepared from the patient's own blood or by human or horse serum mercurialized in vitro, is specially suitable for cases of tabes and of cerebrospinal syphilis, provided cerebrospinal fluid shows evidence of active meningeal reaction. It is also suitable for meningo-vascular spinal syphilis when resistant to ordinary treatment.

The direct intraspinal administration of arsenobenzol into the cerebrospinal fluid is liable to produce acute softening of the spinal cord and should be discarded.

Cases of general paralysis of optic tabes, of tabo paralysis, and of tabes with negative reactions in the cerebrospinal fluid, are not likely to benefit by intraspinal treatment.

Cases of meningo-vascular cerebral syphilis benefit much by intracisternal administration of salvarsanized serum.

General paralysis, if recognized in the early stage, is definitely benefited by intracisternal treatment. This method is superior in efficacy to intraventricular operation and entails much less risk to the patient.

Pyrexial treatment of early general paralysis—for example by tuberculin, nuclein, etc., may induce temporary remissions in the disease. So also can simple drainage of the cerebrospinal fluid, combined with general antisyphilitic treatment.

Advanced cases of general paralysis, with extensive destruction of cortical nerve elements, are hopeless for curative treatment by any method whatever. (James Purves-Stewart, *British Medical Journal*, October 7, 1922.)

### Treatment of Neurosyphilis with Spécial Reference to the Changes in the Cerebrospinal Fluid.

Two hundred cases were treated as regards the question of serological improvement; the results obtained in the treatment of fully established cases of neurosyphilis show a constant and progressive fall in the cell count until this reaches normal limits, almost constant modification of the colloidal gold reactions in the direction of a negative result, and in occasional cases, a change in the Wassermann reaction from positive to negative.

Improvement as regards gait, bladder control, lightning pains, and general health has

been repeatedly observed, though the lapse of time is not yet sufficient to warrant the conclusion that the disease has been arrested. The whole hope of the successful treatment of tabes and other forms of neurosyphilis lies in early diagnosis.

The routine treatment adopted has been a preliminary course of mercury and iodide for an average of two weeks, followed by a series of from 20 to 40 injections of 0.45 to 0.6 gram novarsenobenzol given at 7 day intervals. After every fourth injection two weeks rest was given. In addition mercurial inunction according to the Aachen methods was carried out and intramuscular injections of intramine in 5 c. cm. doses were given at monthly intervals. No intrathecal therapy has been attempted and silver salvarsan has not been employed. (Douglas K. Adams, *British Medical Journal*, October 7, 1922.)

## The Truth About Medicine

During March, the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Non-official Remedies:

Abbott Laboratories

Sulpharsphenamine-Abbott.

Borchardt Malt Extract Co.

Borchardt's Cod Liver Oil and Iron Iodide.

E. R. Squibb & Sons

Sulpharsphenamine-Squibb

Nonproprietary Article

Sulpharsphenamine.

### NEW AND NON-OFFICIAL REMEDIES.

**Mercurosal.**—Disodiumhydroxymercurisalicicyloxyacetate. Mercurosal contains from 43.0 to 43.8 per cent. of mercury in organic combination. It is claimed that mercurosal is relatively free from irritant action, that it is eliminated without untoward effects on the kidney, and that the toxicity is relatively lower than mercuric chloride or mercuric salicylate. Mercurosal is intended for the mercurial treatment of syphilis. It is administered either intramuscularly or intravenously. Mercurosal is marketed in two forms: Mercurosal Intravenous, tubes containing mercurosal 0.1 Gm., and Mercurosal Intramuscular, tubes containing mercurosal 0.05 Gm. Parke, Davis and Co., Detroit, Mich. (*Jour. A. M. A.*, March 24, 1923, page 844).

**Pneumococcus Antibody Solution, Types I, II and III combined.**—An aqueous solution of the specific pneumococcus anti-bodies, Types I, II and III in equal proportions, approximately free from the proteins of horse serum. There is some evidence that this antibody solution is of value in the treatment of lobar pneumonia.

**Pneumococcus Antibody Solution, Types I, II and III Combined.**—N. N. R., marketed in packages of one 50 Cc. double-ended vials with a complete intravenous outfit, and in packages of one 50 Cc. double-ended vials. H. K. Mulford Co., Philadelphia. (*Jour. A. M. A.*, March 24, 1923, page 844).

**Sulpharsphenamine.**—The salt, disodiumdiomin-

odihydroxyarsenobenzenedimethylenesulphonate, adjusted by the addition of inorganic salt to an arsenic content of from 18 to 20 per cent. The arsenic content of 3 parts of sulpharsphenamine is approximately equal to two parts of arsphenamine. The actions and uses of sulpharsphenamine are the same as those of nearsphenamine, over which it is claimed to have the advantage of greater stability of solution in the presence of air and of permitting subcutaneous injection. For subcutaneous or intramuscular use the drug is dissolved in sterile, freshly distilled water in the proportion of about 0.1 Gm. to 0.3 Gc.; for intravenous use a greater dilution is desirable. (Jour. A. M. A., March 31, 1923, page 919.)

Sulpharsphenamine-Abbott.—A brand of sulpharsphenamine—N. N. R. It is marketed in ampules containing respectively, 0.2 Gm., 0.3 Gm., 0.4 Gm., and 0.6 Gm. The Abbott Laboratories, Chicago. (Jour. A. M. A., March 31, 1923, page 919.)

#### PROPAGANDA FOR REFORM.

Peralga, a new German Synthetic.—For the past few years American Physicians have been relatively free from the propaganda of the foreign synthetic drugs—real or alleged. Recently, however, there have been signs of revival of this type of product. One of the products being endowed with the halo of creative chemistry is Peralga (Schering and Glatz), known in Europe as Veramon. The product is claimed to have been originated in the pharmacologic laboratory of Professor Starkenstein, University of Prague (who has lent his name to a number of statements valuable to the proprietary interests). Peralga is claimed to be a definite chemical compound, made by heating a mixture of barbital and amidopyrin, and it is claimed that this compound is absorbed without being split up into its component radicles. The A. M. A. Chemical Laboratory investigated Peralga. The examination developed that Peralga is not a definite chemical compound as claimed, but essentially a mixture of barbital and amidopyrin, containing an impurity produced in the fusion of the mixture. To determine if Peralga will produce any effects different from a mechanical mixture of barbital and amidopyrin in the same proportion, a specimen of Peralga and a mixture of barbital and amidopyrin in the same proportions as in Peralga were sent to the Pharmacologic Laboratory of Cornell University Medical College for comparative tests. The summary of the laboratory report was: "We can see no difference in the behaviour of cats towards similar doses of the two preparations; the mechanical mixture made in the A. M. A. Chemical Laboratory and the preparation of Schering and Glatz—and they show very little difference between similar doses of barbital and those contained in Peralga. \* \* \*

"Of course there is no chance of making observations on cats that would show analgesic actions in headache. But since the observable effects on cats are so nearly identical, it is only fair to presume that the 'synthetic' and the mixture are practically alike in action." (Jour. A. M. A., March 31, 1923, page 942).

Prescribing Codein.—Codein is a derivative of opium and hence prescriptions for it come within the purview of the Harrison Narcotic Act, no matter what the individual physician may believe in respect to its habit forming properties. (Jour. A. M. A., March 31, 1923, page 945).

Biologic Reactions of Arsphenamin.—The complexity of the physical and chemical properties of arsphenamin probably accounts for the complexity of its biologic reactions resulting from the passage through the body. Among the most disturbing of these reactions are the nitritoid or anaphylactoid symptoms

occurring after intravenous injection. The earlier studies of the anaphylactoid reactions from arsphenamin cleared up certain features, but left the underlying causes untouched. The investigations of Jean Oliver and his collaborators lead to the conception that arsphenamine can exist in the colloidal state temporarily at least, and that the temporariness of this state is essential to anaphylactoid reactions. The investigators find that arsphenamin has a fairly constant agglutinating titer for blood corpuscles. The presence of electrolyte is essential for agglutination. The work suggests that agglutination by arsphenamin occurs during the transition stage from its colloidal into the crystalloidal state in the circulation, and that stabilization in the colloidal state prevents the agglutination. From their work they conclude that there are two phases to the reactions from arsphenamin: (1) the early or physical phase, which is concerned with the physical properties of the agent and results in the corpuscular agglutination with multiple embolism, the outcome being fatal sometimes, and (2) the later or chemical phase that results in parenchymatous degeneration of viscera (kidney and liver), this being due to the action of the arsenic ions in the usual way. (Jour. A. M. A., March 31, 1923, page 920).

## Book Announcements

**Essentials of Surgery.** A Textbook of Surgery for Students and Graduate Nurses and for Those Interested in the Care of the Sick. By ARCHIBALD LEETE McDONALD, M. D., of Johns Hopkins University; formerly in charge of Department of Anatomy, University of North Dakota, etc. Second Edition Revised. Philadelphia and London. J. B. Lippincott Company. One of series of Lippincott's Nursing Manuals. Cloth. 1923. 8vo. 293 pages including a Glossary and 49 illustrations. Price, \$2.50.

**Physics and Chemistry for Nurses.** By A. R. BLISS, JR., A. M. Phm. D., M. D. Lecturer on Chemistry and Materia Medica, Grady Hospital Training School for Nurses, Atlanta; etc., and A. H. OLIVE, A. M., Ph. Ch., Phm. D., Lecturer on Chemistry, Hillman Hospital Training School for Nurses, Birmingham, etc., with collaborators. Third Edition Thoroughly Revised and Rewritten and conforming to requirements of the standard curriculum (1922) of the National League of Nursing Education. Philadelphia and London. J. B. Lippincott Company. One of series of Lippincott's Nursing Manuals. Cloth. 1923. 8vo. 190 pages including a Glossary and 70 illustrations. Price, \$2.50.

**The Form and Functions of the Central Nervous System.** An introduction to the Study of Nervous Diseases. By FREDERICK TILNEY, M. D., Ph. D., Professor of Neurology, Columbia University; Attending Neurologist, Presbyterian Hospital, and New York Neurological Institute, etc., and HENRY ALSOP RILEY, A. M., M. D., Associate in Neurology, Columbia University, etc. Foreword by GEORGE S. HUNTINGTON, Sc.D., M. D., Professor of Anatomy, Columbia University. Second Edition. 591 figures containing 763 illustrations of which 56 are colored. New York. Paul B. Hoeber. 1923. 8vo. 1019 pages. Cloth. Price \$12.00.

## Editorial

### The Heart In Old Age.

He was seventy-three. He never had had an acute sickness. He was Cornish. He had worked in youth for years as a miner. For the last ten years he has been retired from active business and has lived with his son on a farm. He has taken care of fifty hens, one cow, a small garden, and in winter cut fire wood and performed a few duties about the place. He has had a good appetite; he has grown stout.

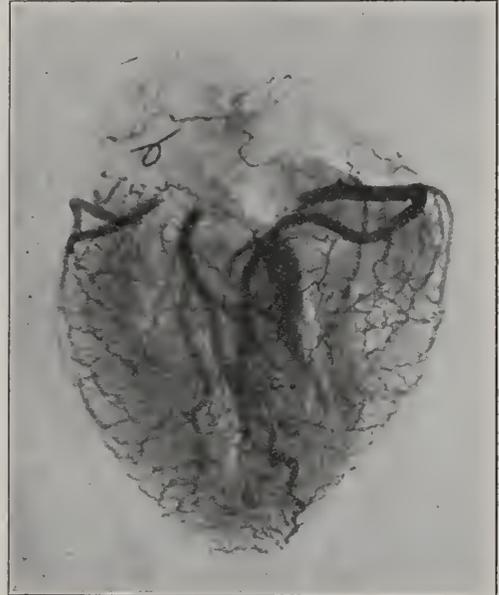

Within the past three months his breathing has become more frequent on exertion; within the last three weeks he has had shortness of breath; his legs have swelled; his heart now beats fast; his pulse has become rapid and irregular.

The heart of old age is grossly neglected. For seventy-three years, in this case, it has been beating one hundred and fifty thousand times daily; or, for seventy years, this man's heart has made three billion, eight hundred and thirty-two million and five hundred thousand contractions, without showing to him, at least, any signs of failure in compensation, or failure to do its work. And here within the last few months, after contracting and maintaining a balanced circulation through the elaborate vascular channels of the body, it has begun to show gross and serious evidence that it will no longer, for any considerable period of time, continue to perform its ceaseless task.

This old man's heart is going on a strike.

This old man's heart is losing its conductivity, rhythmicity, contractility and irritability. After three billion odd beats, it is beginning to fail.

As age advances, there is a right side hypertrophy in the heart and the distribution of the blood supply undergoes considerable alteration with the evidence of increase in tortuosity. The blood supply of the average heart of the first decade, in its main branches, pursues a straight and even course.

\*Roentgenogram of the blood supply in the average heart of the first decade.

In the seventh decade you observe the increased relative anemia of the right side, the marked tortuosity of the vessels, the rich and abundant septal anastomoses, and the well-developed fat-vessel network.

One of the most common causes of heart failure in the old is disturbance in the coronary circulation that brings about poor heart nutrition. Of course, this may occur in a sudden manner by an embolus or thrombus. But the most common way in which this occurs is sclerosis in the coronary vessels or in the aorta. The nutritional changes in the heart muscle will follow upon circulatory sclerosis. Likewise, it will be found that myocardial degeneration will occur in the muscular deficiency due to muscular fatigue or from general constitutional diseases where there has been over years a retention of body poisons.

Myocardial weakness of old age may show

itself as a result of high blood pressure resistance or from over-work or severe physical labor. The outstanding symptom in these cases is the evidence of cardiac deficiency. The deficiency may be ushered in by some symptom-complex like an attack of angina pectoris, an Adams-Stokes' syndrome, and an arrhythmia, or a pulmonary edema. The symptom may be mere faintness or dizziness. Or there may be the serious sign of breathlessness or a sense of oppression. Pain may be the dominant symptom, sometimes associated with work af-

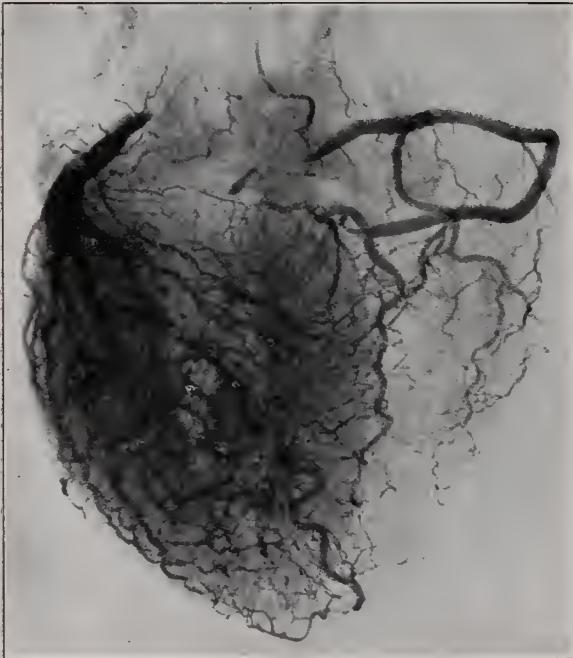

be intermitting. But irregularity in systolic contraction is the most common manifestation of its impending failure. The arrhythmia may be extrasystoles or auricular fibrillation. The heart is enlarged and cardiac dullness is increased. As you place your stethoscope over the heart, you note the distant feeble heart sounds; the first sound may be sharp and short and the second pulmonic or aortic may be accentuated, but repeated examination may disclose the gradual loss of this accentuation. A systolic murmur along the base is usually heard. The murmur may be soft or blowing or may be harsh and have musical quality, depending upon the vegetative growth about the endocardiac openings. Murmur may be increased by exercise, or discovered at one time and not heard at another. Venous pulse and tricuspid regurgitation and pulmonary edema may be added signs of impending heart failure.

What can be done for these old hearts?

- I. Carefully study the whole body.
- II. Carefully study the habits.
- III. Put the patient to bed.
- IV. Make a blood chemistry examination, blood sugar, blood urea, non-protein, nitrogen.
- V. Look for focal infections and eliminate them.
- VI. Regulate the diet and reduce the intake of food at night.
- VII. Consider digitalis, caffein, strychnine.
- VIII. Cut out salt and meat.
- IX. Admonish against over-exertion.

### Angina Pectoris.

The question of anastomosis of the coronary arteries seems to have been very much interlinked with the question of the production of angina pectoris. But now, it is generally conceded that anastomosis\* exists between the right and left coronary arteries, in their capillary as well as their precapillary distribution; that anastomosis exists between the branches of each coronary artery; that anastomosis exists between coronary arteries and vessels from adjacent and attached organs; that anastomosis in the heart is universal and abundant. The coronaries do anastomose and angina pectoris is not due to the closure of one artery and failure of collateral circulation to be established. It is rather due to combined

\*Roentgenogram of the blood supply in the average heart of the seventh decade.

ter meals. Eructation may relieve the pain. Erroneously, this important cardiac symptom is overlooked by both the doctor and the patient. Precordial fullness, a lump in the chest, difficulty of breathing in a man in the sixth or seventh decade, are serious signs. Dyspnea or anginal pain in the sixth or seventh decade means that the myocardial structure of the body is becoming ominously defective. Observation of the apex beat shows it is displaced, may be beyond the nipple line, and the impact and impulse are diffuse and feeble. There is also pulsation in the vessels of the neck to a marked degree. The heart may be beating regularly but too slowly; it may be beating rapidly and irregularly or irregularly; it may

\*Roentgenograms taken from "The Blood Supply to the Heart," by Louis Gross, M. D., C. M., Paul B. Hoeber, New York, publisher.

\*\*"The Blood Supply to the Heart," by Louis Gross, M. D., C. M., Paul B. Hoeber, New York, publisher.

disease of the coronary arteries in which inadequate cardiac circulation may be maintained. It may be due, however, to diseases not in the coronary, but in the aorta, by partial or complete occlusion, of the lumen of the coronaries at the origin; such as, aortitis or valvulitis of the aortic valve.

Of course, the coronaries may participate in a general arteriosclerosis of the systemic vessels and the same ischemia of the myocardium may be produced, resulting in the anginal syndrome.

An embolus or thrombus also may block one coronary and the age of the patient may be such that the anastomoses are incapable of affording an adequate arterial inflow of blood and thus may ensue the same clinical picture.

Again, on the principle of the intermittent claudication which occurs in the abdominal arteries, the coronaries may become, from some cause, suddenly in arterial spasm and the blood supply of the contracting myocardium may become consequently restricted to the point of producing muscle pain or angina.

Anginal attacks come in the fifth or six decade from fast walking, walking against the wind, some form of over-exertion, from sudden emotion, as fear or anger, from over-eating, a distended stomach. The condition is characterized by an intense pressure in the upper chest; the vise-like pain is sometimes agonizing, possibly only a substernal ache or radiation of pain down the left arm is felt, mental distress and sense of impending death. The attack may terminate by sudden death, by an attack of syncope, by feeling of exhaustion and evidence of heart dilatation. The patient may, however, recover in a short time.

The patient who once has an attack of true angina pectoris should receive a painstaking examination of the entire body and the problem of prolonging the life by preventing return attacks should be fairly faced.

### The Heart in Thyroid Disease.

The hyperfunctioning thyroid adenoma and exophthalmic goiter produces and discharges into the systemic circulation an excessive amount of thyroxin, the physiologic and normal active principle of the thyroid gland, and, after an indefinite period of time, this product, probably perverted somewhat, in the case of exophthalmic goiter, produces two fundamental reactions on the heart. This effect upon the heart should be clearly appre-

ciated because cardiac activity and function may play an important part in the clinical cause of hyperthyroidism.

The first effect is brought about by the excess of thyroxin in the tissues of the body. This makes for an elevation of the basal metabolic rate. This produces increased cardiac work, increased cardiac rate, increased contraction amplitude. The greater volume outflow of blood for each beat, which results, leads to hypertrophic changes in the heart muscle and eventually dilatation of the organ.

The second effect of thyroxin is on the heart muscle cells. The muscle structure, under the influence of excessive thyroxin, undergoes a degenerative myocarditis. Muscle fatigue results. Heart contractions may become irregular, following increased rate. The hypertrophy and dilatation of the heart may lead to its failure. The irregularities of the heart culminate in auricular fibrillation often times. In the Mayo Clinic,\* auricular fibrillation was found in seven per cent of patients suffering with exophthalmic goiter and in nine per cent of cases of hyperthyroidism.

Auricular fibrillation may be present at times only, or it may be persistently present in these cases. Of course, its presence considerably accentuates the gravity of the prognosis; approximately, it is estimated, doubling cardiac mortality. Auricular fibrillation in the goiter heart may be taken to mean definite myocardial degeneration from overdoses and over time saturation of thyroxin. Of course, its persistence is a strong contraindication to operative procedure for the relief of goiter. Likewise, auricular flutter, with or without partial heart block, is a graver indication of muscular degeneration from thyroxin of hyperthyroidism and perversion of the secretion of exophthalmic goiter. Such cases are, strictly speaking, medical cases; while operation is indicated, no doubt, to curtail the hyperactivity of the diseased thyroid, the stage of the clinical evaluation that is characterized by auricular fibrillation (persistent) and auricular flutter is one to be managed by the internists, so far as cardiac irregularities go. It is in this goiter heart activity that massive digitalis administration is indicated by the internist. Digitalis saturation is needed. Digitalis to the point of vomiting and even to partial heart block may enable the internist to establish in the thyroxin poisoned myocardium

\*"The Heart in Thyroid Disease," by Fred A. Willinus, Mayo Clinic, Rochester. *Annals of Clinical Medicine*, Jan., 1923.

some form of normal conduction, contractility, irritability and rhythmicity.

In our experience with digitalis in thyroxin cases, no one plan for its administration can be at once laid down. With the idea of bringing the myocardium under the effect of digitalis by mass attack, the administration for a period of seventy-two hours may be made by giving 2 c.c. (30 minims) every eight hours. Even larger doses may be required. Care should be exercised, however, remembering that the "couple beats," "nausea," "slowing pulse," or "heart block" are all signs of digitalization. The radial pulse must not be trusted. The stethoscope over the apex, the finger on the radial pulse, and the eye on the right supraclavicular space may give you the evidence of digitalis-control with fair accuracy.

---

## News Notes

---

### Dates Selected for State Meeting.

The Executive Council of the Medical Society of Virginia, at a session held April 27, selected October 16, 17, 18 and 19 as the dates for the Roanoke meeting of the State Society. It is hoped that all members of the Society will work for the success of this meeting and that as many as possible will attend. Roanoke doctors have been actively at work on their plans for sometime.

### Nutrition Institute.

During the two weeks beginning April 9th, Dr. William R. P. Emerson, pediatricist, Boston, Mass., and his assistant, Miss Mabel Skilton, conducted an institute in Richmond on the nutritional problems of childhood. The institute, which was a decided success, was conducted under the auspices of the Virginia Co-operative Child Welfare Committee, an organization composed of representatives from forty-six State and City organizations. Dr. C. C. Hudson, health officer of Richmond, served as chairman of this committee. Approximately one hundred and twenty public health workers from various parts of the State took advantage of this opportunity to learn more about this very important phase of public health work, and took the full two week's course. In addition to those taking the full course of instruction, some sixty others took most of the course during the second week.

The nutrition class was addressed by Prof. Harris Hart, State Superintendent of Public Instruction, Dr. Roy K. Flannagan, Assistant State Health Commissioner, Dr. L. T. Royster, of Norfolk, Dr. Beverley R. Tucker, of Richmond, Miss Agnes D. Randolph, Director of the Bureau of Tuberculosis Education of the State Health Department, and Mr. Irving R. Spear, of the Virginia Tuberculosis Association.

This was the thirtieth institute conducted by Dr. Emerson during the past three years, and his course of instruction here, as elsewhere, was exceedingly valuable to public health workers, especially those interested in school inspection. From investigations, Dr. Emerson's belief is that the problem of malnutrition of children is one with which the poor are not so much concerned as the rich, some of the prime causes of malnutrition being irregular habits of sleep, food, exercise and rest.

During Dr. Emerson's stay in Richmond five nutrition classes were organized in the Richmond public schools, and one class among the children of the Methodist Orphanage. The five classes organized in the public schools are being continued under the supervision of Dr. N. Thos. Ennett, Director of Medical Inspection of Schools. The class organized at the Methodist Orphanage is under the supervision of Dr. M. E. Nuckols, who has charge of the Orphanage medical work. Dr. James B. Stone, of Richmond, will be in charge of two classes which are being organized for mothers. It is expected that additional nutrition classes will be organized in the near future.

### The Virginia-West Virginia Section, American College of Surgeons

Held a two day's session in Norfolk, Va., April 23 and 24, Dr. Lomax Gwathmey, Norfolk, presiding over the Virginia division, and Dr. J. Ross Hunter, Huntington, over the West Virginia Section. Dr. Julian L. Rawls, Norfolk, was secretary for the Virginia section, and Dr. Thos. W. Moore, Huntington, of the West Virginia section. Between thirty and forty physicians outside of Norfolk County registered attendance. Excellent clinics were held at the various hospitals during the morning hours of both days. As the American College of Surgeons has made hospital standardization one of its principal works, much time was given to the discussion of this sub-

ject and much valuable information was elicited.

The new officers elected for the Virginia Section are: Dr. J. Shelton Horseley, Richmond, chairman; Dr. A. Murat Willis, Richmond, secretary; Dr. Stephen H. Watts, University, counselor. The place of the next meeting is to be decided later.

### **The Virginia Society of Oto-Laryngology and Ophthalmology**

Held its annual meeting in Richmond, April 18, with an attendance of about seventy-five specialists. Eight new members were received at this meeting. Dr. Elbyrne G. Gill, of Roanoke, presided and delivered his address as president. A symposium on "Refraction" was handled by Drs. Emory Hill, Richmond, H. S. Hedges, Charlottesville, and Hunter McGuire, Winchester. Several other members also presented papers and Drs. Walter Lambert, New York, Lewis Fisher and H. M. Langdon, both of the latter of Philadelphia, read papers by invitation. Dr. Wells Eagleton, Newark, N. J., was prevented by illness from taking part in the program. Luncheon was tendered the visitors and out-of-town members at Commonwealth Club, by the Richmond Society of Oto-Laryngology and Ophthalmology.

It was decided to hold the next meeting in Lynchburg in the Spring of 1924. Dr. Joseph A. White, Richmond, was elected president; Dr. James Morrison, Lynchburg, vice-president, and Dr. E. U. Wallerstein, Richmond, was re-elected secretary-treasurer.

### **The South Piedmont Medical Society**

Met in Danville, Va., April 17, and had an excellent meeting. A number of interesting papers were read, including a symposium on Pneumonia. South Boston was selected as the next place of meeting and the following officers elected: President, Dr. P. W. Miles, Danville; vice-presidents, Drs. James Morrison, Lynchburg, S. T. A. Kent, Ingram, W. E. Jennings, Danville, and C. W. Tucker, Drakes Branch. Dr. George A. Stover, South Boston, was re-elected secretary-treasurer.

### **The San Francisco Meeting.**

Official call has been issued for the seventy-fourth annual session of the American Medical Association in San Francisco, Cal., June 25-29, inclusive. The House of Delegates will

convene on Monday, June 25th; the Scientific Assembly will open with the general meeting on the 26th, at 8 P. M.; the various sections of the scientific meeting will meet Wednesday, the 27th, at 9 A. M. and 2 P. M., and subsequently according to their respective programs.

Many attractive side trips have been arranged. Those who wish to enjoy a short water trip may have an 18 hour ocean trip between Los Angeles and San Francisco, either going or returning.

The Salt Lake (Utah) County Medical Society has issued invitation for members to stop over in Salt Lake City, before or after the meeting, and, if you communicate with Dr. Floyd F. Hatch, secretary, Deseret Bank Building, Salt Lake City, Utah, as far in advance as possible, giving number in party and length of stopover, arrangements will be made to show visitors something of the beauties of that section. Other local medical organizations will also entertain visitors, especially those who are on special trains.

A special train will leave Chicago, over the Burlington Railroad at 11 p. m., June 20. This will make stops at a number of places and reach San Francisco at 5:30 p. m., June 25. Particulars as to this train and any other information may be obtained from Dr. W. E. Musgrave, chairman, Local Committee of Arrangements, 808 Balboa Bldg., San Francisco, Cal.

Another special to this meeting will be that known as the "Southern Medical Association's Special Train," which will leave St. Louis, at 9 a. m., Tuesday, June 19th, and, after stopping at several places, will reach San Francisco at 5:45, June 24th. For fares, Pullman rates, schedule or other information, write "Southern Medical Association, Empire Building, Birmingham, Ala."

### **The Southampton County (Va.) Medical Society**

Met at the home of Dr. R. L. Raiford, in Sedley, May 3. This meeting was largely attended and was most successful from a scientific point of view. At 2 p. m., there was a clinic at which time normal and subnormal children were examined. This was followed by a paper on "Nutritional Disorders of Childhood," by Dr. Franklin D. Wilson, of Norfolk. Later there was a reception at which there were five minute talks on "The Aims of

our County Society," by the president, Dr. E. F. Reese, Courtland; on "The Co-operation of the Medical Profession: With the Church," by Rev. Nathan Pickett, Sedley; "With the Public School System," by R. M. Newton, Superintendent of Public Schools of the County; "With the Board of Public Welfare," by Miss Mary Babb, Superintendent of the Board of Public Welfare; and "With the General Public," by Paul Scarborough, Editor of the *Tidewater News*. It is thought that much good will result from this meeting.

#### **Dr. Dunn Resigns Professorship.**

Dr. John Dunn, Richmond, has tendered his resignation as professor of otology, rhinology and laryngology at the Medical College of Virginia, effective at the end of this session, and was by unanimous vote chosen professor emeritus of this branch. Dr. Dunn was connected with the faculty of the former University College of Medicine from its organization in 1893 and has been a member of the faculty of the Medical College of Virginia since the consolidation of these two medical schools in 1913.

It is announced that Dr. Joseph A. White, now professor of ophthalmology, will have charge of the combined chairs of ophthalmology, otology, rhinology and laryngology, next session.

#### **Dr. Dean B. Cole,**

Richmond, has been called to Chilhowie, Va., on account of the illness of his father.

#### **Celebration of Pasteur's Centenary.**

A number of physicians from the United States are planning a tour of France between July 11 and August 18. Because this is the time of the celebration of Louis Pasteur's centenary, this visit is being sponsored by the French government and participants will have free access to many highly interesting social functions not ordinarily open to visitors. It is possible to leave New York as late as July 4 to join this party. The trip is to include visits to many places of unusual interest.

If interested, write for full details, addressing L. J. Garcey, General Agent, Railways of France, 281 Fifth Avenue, New York City.

#### **West Virginia Medical Association.**

Don't forget the dates of the West Virginia Medical Association are June 12, 13 and 14,

and the place Beckley. A most cordial invitation has been extended all members of the Medical Society of Virginia as well as other medical associations to attend. It is likely that several pullman parties may be made up from Virginia. If you expect to attend, communicate with Dr. Charles S. Smith, Beckley, W. Va., secretary of the Raleigh County Medical Society for details as to the meeting.

#### **Box for State Health Department Supplies Furnished Physicians.**

In order to facilitate the collection of reports of contagious diseases and other vital statistics by county health officers so that they may more quickly apply preventive measures, the State Health Department has sent to each physician, in counties having organized health departments, attractive boxes containing report cards and forms, mailing cases for collecting and sending specimens to the State Laboratory, and a copy of the revised rules and regulations. Inside the lid of each of these boxes is a synopsis of public health laws and a list of supplies furnished by the State Board of Health. Having these health department supplies all in one place should prove a convenience to the doctors and a great aid in promoting prompt reports. These boxes, while prepared primarily for physicians in counties where there are whole time health officers, are available, on request, to other physicians, as long as the present limited supply lasts.

#### **Malaria Control.**

Pursuant to a change of plan in malaria control work, the counties of Accomac, James City, Princess Anne and Henrico have accepted the financial aid of the State Board of Health in co-operation with the International Health Board in establishing whole time county health units. These units began operation on May 1, each with a personnel consisting of a medical health officer and public health nurse. Two of these counties have a sanitary officer. These units will feature malaria control.

Dr. B. B. Bagby, recently of West Point, Va., will have charge of the work in Henrico County, with headquarters in Richmond; Dr. John O. Gaston, of Rochester, Mich., will be in charge of work in Accomac County, with headquarters at Accomac; Dr. J. L. Sanford, of Clifton Forge, will look after the work in Princess Anne County, with headquarters at

Oceana; and Dr. J. H. Crouch, of Smithfield, Va., will look after the work in James City County, with headquarters at Williamsburg. All entered upon their duties May 1.

#### **Dr. Malcolm Hart Harris,**

Of Pendletons, Va., located in West Point, Va., the first of May, and will take up the practice of Dr. B. B. Bagby, who has entered the malaria control work in Virginia. Dr. Harris is a graduate of the class of '22, Medical College of Virginia, and has for the past ten months been an assistant physician at Southwestern State Hospital, at Marion, Va.

#### **Dr. Hunter McGuire**

Returned to his home in Richmond, the latter part of April, after a pleasure visit to Philadelphia.

#### **Dr. and Mrs. J. J. Kindred,**

Of New York, recently visited their son, who is a student at Randolph Macon College, Ashland, Va. Dr. Kindred is a native of Southampton County, this State, and has many friends in Virginia.

#### **Dr. M. L. Dalton,**

Recently of Floyd, Va., has located at Hinton, W. Va., where he will continue the practice of his profession.

#### **Dr. William M. Sheppe,**

Who has been instructor in pathology and bacteriology at the University of Virginia, is now at Ohio Valley Hospital, Wheeling, W. Va.

#### **Doctors With Richmond Rotarians.**

Dr. Charles R. Robins has been elected a member of the board of directors and Dr. Greer Baughman has been appointed a member of the Program and Entertainment Committee of the Richmond Rotary Club.

#### **The Woman's Auxiliary to the Richmond Academy of Medicine and Surgery**

Was organized at a meeting held at the home of Mrs. J. Allison Hodges, in this city, on May 2nd. Sixteen ladies were present and they were enthusiastic in their endorsement of the Auxiliary. Officers elected are: County chairman, Mrs. Ramon Garcin; City chairman, Mrs. Francis W. Upshur; vice-presidents, Mrs. C. E. Llewellyn, Mrs. J. Blair Fitts and Mrs. Thos. Wheeldon; secretary-treasurer, Mrs.

Arthur S. Brinkley. Committees were appointed to assist in the various phases of work to be undertaken by the Auxiliary.

#### **The American Association of Pathologists and Bacteriologists,**

At its annual meeting held recently in Boston, elected Dr. Theobald Smith, Princeton, N. J., president, and Dr. Howard T. Karsner, Cleveland, secretary. At this meeting the custody of the cane was conferred upon Dr. William H. Welch, of Baltimore. Dr. Harold C. Ernst, of Boston, the first recipient of the cane, before his death in 1922, conceived the idea of conferring the custody of the cane for lifetime in recognition of the services of those who represent the best in the traditions of medicine. Dr. Welch is the second recipient of this honor.

#### **D. Charles E. Conrad**

Has returned to his home in Harrisonburg, after a visit to Atlantic City, where he spent some time recuperating from a recent illness.

#### **Dr. B. P. Seward,**

Of the class of '22, Medical College of Virginia, who has been an interne in Stuart Circle Hospital, Richmond, since July 1, 1922, will be associated in practice with Dr. W. W. Seward, at Surry, Va., beginning next July.

#### **Dr. R. W. Garnett**

Has been re-elected city health officer of Danville, Va., for a period of two years.

#### **Miss Rose Z. Van Vort,**

Superintendent of Stuart Circle Hospital, was recently elected president of the Richmond Nurses' Clubs.

#### **Dr. W. Harman Evans,**

Lynchburg, Va., was badly bitten by a German police dog, last month, when he went to make a professional call several miles out of the city. The dog attacked Dr. Evans, knocked him down three times and severely hurt his left arm and right leg, before Dr. Evans was able to catch and hold him until he could get help.

#### **Dr. W. P. Hoy,**

A member of the board of directors of the Rotary Club of Petersburg, Va., has been elected manager of the Rotary baseball club of that city.

**Dr. E. C. Harper,**

Who has been connected with the medical staff at Catawba Sanatorium, Va., is now located at Fries, Va.

**Dr. H. D. Ribble**

Has returned to his home, Sandy Mound Farm, just outside of Blacksburg, Va., after being out of the State since last November.

**Dr. Willim H. Higgins**

Became head of the Medical Department of St. Elizabeth's Hospital, Richmond, April 1, 1923. He gives a few hours in the afternoon to this work. While Dr. Higgins is attending physician to St. Elizabeth's Hospital, he will, of course, continue his private practice as heretofore, with offices in the Professional Building.

**New Hospital Wing at University.**

Contract has been let for the immediate erection of the \$115,000 wing at the University of Virginia Hospital and it is planned to have it ready when the University opens in September. This wing will be immediately south of the present hospital buildings and will conform to the Steele wing on the north. This new building is made possible at this time by a gift from Paul Goodloe McIntire. This new wing is to house the obstetrical and orthopedic departments of the hospital and will provide sixty-three beds in addition to two nurseries, one for white and one for colored children. The moving of these departments from the main hospital building will give more room there for general cases.

**Dr. R. E. Booker**

Has returned to his home at Lottsburg, Va., after a vacation of several weeks spent in Florida.

**Dr. A. I. Dodson**

Has opened offices in Professional Building, this city, for the practice of urology, and will have office hours from 5 to 7 P. M. and by appointment. He will, however, continue his association, as before, with St. Elizabeth's Hospital and Dr. J. Shelton Horsey.

**Public Health Institutes.**

Such general interest was manifested in the venereal disease institutes conducted by the U. S. Public Health Service, that the Service now contemplates the establishment of in-

stitutes for supplementary training in the field of preventive medicine. It is proposed to establish one or more such institutes, of six to eight weeks' duration, at important medical centers or at Washington, the subjects to be decided upon later. An institute of the character proposed would aim to stimulate up-to-date intensive training for all persons engaged in various kinds of public health work; it would provide up-to-date instruction which would enable practicing physicians to deal effectively with the more important causes of mortality and disability; and it would bring together practicing physicians and health officers and so establish a more co-operative relationship in the work of disease prevention.

**Married.**

Dr. Charles Young Bidgood, Baltimore, Md., and Miss Mary Taylor Carrington, Danville, Va., April 21. Dr. Bidgood is an alumnus of the University of Virginia, being a member of the class of '20.

Lt. William Harvey Whitmore, M. C., U. S. N., and Miss Harriet Weiss Angeny, Philadelphia, April 5. Dr. Whitmore was formerly of Lynchburg, Va., and a member of the class of '16, University of Virginia, Medical School.

**The American College of Physicians,**

Meeting in Philadelphia, April 6 and 7, elected Dr. Harlow Brooks, New York, president, and Dr. Frank Smithies, Chicago, secretary.

**The Tennessee State Medical Association,**

In annual session in Nashville, in April, elected Dr. Hampton L. Fancher, Chattanooga, president, and Dr. Jos. F. H. Gallagher, Nashville, secretary. The next meeting is to be held in Knoxville.

**New Professor at Jefferson Medical College.**

Announcement is made of the election of Dr. Withrow Morse, professor of physiological chemistry in the West Virginia University School of Medicine to the position of professor of physiological chemistry and toxicology in Jefferson Medical College. Dr. Morse is recognized as a man of ability and Jefferson College is fortunate to have secured his services.

**American Society for the Scientific Study of the Medical Aspects and Treatment of Cancer.**

It has been proposed by a number of phy-

sicians to form an association for the above purpose and Dr. L. Duncan Bulkley, 5 East 53rd Street, New York City, has been requested to issue a call to those especially interested in cancer to get together and form such an association. It has been decided to hold this organization meeting in San Francisco, doing the meeting of the American Medical Association, June 25-29. At this time, the plans, scope, details, and name of the association could be worked out and the organization effected.

Even if you cannot attend the organization meeting, please advise Dr. Bulkley, at the above address, if you are in sympathy with the work and would accept membership in the Society when it exists.

**Dr. and Mrs. Edwin B. Claybrook,**

Cumberland, Md., recently visited relatives in Richmond.

**Surgeon General Hugh S. Cumming,**

Of the U. S. Public Health Service, by invitation addressed the Woman's Club of Richmond, Va., on April the 30th. His talk related to the part the Federal government should play in the direction of health work in the various states. He paid high tribute to Virginia's chief health executive, Dr. Ennion G. Williams, and to Dr. E. C. Levy, director of public welfare of Richmond, and their co-workers.

**Dr. A. D. Tyree**

Has moved from Fireco, W. Va., to Clifton Forge, Va.

**Dr. Newton G. Wilson,**

After practicing for sometime at Fieldale, Va., has located at Hendersonville, N. C.

**Statistical Data Concerning Personnel of Medical Corps of Army.**

In a recent issue of *The Army Medical Bulletin* appeared an article on the above subject which was of more than passing interest. In this it is noted that the average age of Colonels of the Medical Corps of the Army is 53.3 years; of Lieutenant Colonels, 47.7 years; of Majors, 40.1 years; and of Captains and Lieutenants 36.6 years.

The University of Pennsylvania has the honor of having furnished more medical officers in the Army than any other medical school: Jefferson Medical College holds second place, with the University of Maryland and

the University of Virginia in the third and fourth places, respectively. The University of Virginia has 45 medical officers now in the Army, and the Medical College of Virginia 15.

As to the state of nativity, Virginia holds third place, with a total of 62 native Virginians in the medical service of the Army. Pennsylvania and New York hold the first and second places with 111 and 99 representatives, respectively.

**Dr. and Mrs. B. M. Rosebro**

And several friends, of Richmond, motored to Sweet Briar College, where their daughter is a student, to attend May Day exercises.

**The Medical Society of the State of North Carolina**

Held its annual meeting in Asheville, in April, with a very large attendance. Dr. J. V. McGógan, Fayetteville, was elected president for the ensuing year, and Dr. L. B. McBrayer, Sanatorium, was re-elected secretary-treasurer.

**Dr. Frederick W. Rankin,**

Formerly of Mooresville, N. C., but recently of the Mayo Clinic, has been appointed professor of surgery in the University of Louisville, Medical School.

**Dr. and Mrs. S. E. Weymouth,**

Callao, Va., left the middle of April for an extended visit to Baltimore and points farther north.

**Improvements at Pine Camp, Richmond.**

With an appropriation of \$125,000 from the city and a gift of \$15,000, extensive improvements are being made at Pine Camp, Richmond's municipal tuberculosis sanitarium. The new buildings and changes in the old sanitarium are about complete and the result is that in the late summer, Richmond will have possibly the best municipal tuberculosis sanitarium in the United States. When completed, there will be accommodations for ninety-two patients instead of thirty-six, as at present. Dr. E. C. Levy, director of Public welfare, of Richmond, has been active in his work for the success of this institution. Dr. W. Nelson Mercer is chief visiting physician and is assisted by Drs. P. D. Lipscomb, G. A. Ezekiel and Wyndham B. Blanton as associate physicians, while

the consulting staff includes Drs. Dorsey G. Tyler, W. L. Mason, Henry S. Stern, R. Finley Gayle, J. Blair Fitts, Thos. S. Wheeldon, Ward H. Cooke, Joseph Bear, and J. L. Tabb, Jr.

Pine Camp established in 1910 and was first sponsored principally by the ladies of Ginter Park. The city took over the camp in 1915 and, since that time, improvements have been made as rapidly as finances permitted.

#### **Medical Examinations for Golfers.**

Dr. Matthias Nicoll, Jr., Deputy Health Commissioner of New York State, himself an enthusiastic golfer, in a bulletin issued recently states that there is no question that "golf may be and often is overdone." He accordingly suggested a few rules, applicable especially to the older golfers, and states that any one who can afford to play golf should be able and willing to pay for an annual scientific medical examination. There is no doubt of the fact that Dr. Nicoll's views should receive a recognition which the golf enthusiast may hardly wish, on first thought, to accord them.

#### **The American Gynecological Society**

Is to hold its annual meeting at Hot Springs, Va., May 21-23, under the presidency of Dr. John Sampson, of Albany, N. Y. Dr. A. H. Curtis, of Chicago, is secretary.

#### **McGuire Cot at Hospital.**

In memory of the late Dr. Edward McGuire, of this city, a cot was installed at Crippled Children's (Dooley) Hospital, Richmond, on the afternoon of May 8.

#### **Dr. and Mrs. John A. Gibson,**

Leesburg, Va., returned home about the first of May from a visit to Victoria, Va.

#### **The Valley Medical Society**

Meets in Winchester, Va., May 31. Dr. Hunter H. McGuire, Winchester, is president, and Dr. A. F. Roberston, Jr., Staunton, secretary.

#### **Dr. Payne to be Virginia Epidemiologist.**

Dr. Geo. C. Payne, of the International Health Board, has been appointed Virginia Epidemiologist and will shortly enter upon his duties in this State. He will, however, retain his connection with the International Board, coming to Virginia through the courtesy of that organization. Dr. Payne is at present doing post-graduate work in the Johns Hopkins

School of Hygiene and Public Health and will come to Virginia immediately after securing his degree as Doctor of Public Health, in June.

#### **Undergraduate School of Nursing at Yale University.**

The first university undergraduate school of nursing in the United States is to be established at Yale University, New Haven, Conn. The school is to have its own dean, faculty, buildings and budget, and the funds for its maintenance will be provided by the Rockefeller Foundation. It is planned to have the course cover about twenty-eight months.

#### **The Virginia Public Health Association**

Was reorganized at a meeting held in Richmond on April 17. Dr. W. B. Foster, Roanoke, the former president, presided. Dr. P. S. Schenck, Norfolk, was elected president; Dr. Roy K. Flannagan, Richmond, and Dr. W. S. Keister, Charlottesville, vice-presidents; Dr. L. L. Roper, Portsmouth, secretary-treasurer.

Over 300 persons actively interested in health problems throughout Virginia have signified their intention of joining the Association. Two meetings will be held each year.

#### **Doctors in Virginia National Guard.**

The Federalized National Guard of each State now constitutes, with the regular army, the first line of defense of our country and, as evidence of their patriotism and belief in preparedness for a national emergency, the following Virginia physicians have been commissioned in the Virginia National Guard:

In Richmond, Col. J. Fulmer Bright, Majors W. Nelson Mercer and John Blair Fitts, Captains Thomas F. Wheeldon and Ernest T. Trice.

In Danville, Major Henry A. Wiseman, Captains Clyde L. Bailey, Claude N. Rucker and Garnett W. Johnson.

In Norfolk, Captains Harry W. Boice and Albert V. Crosby.

In Roanoke, Captain Ira H. Hurt.

In Lynchburg, Captain James R. Gorman.

In Petersburg, Captain Herbert L. Wyatt.

#### **Dr. Louis L. Williams, Jr.,**

Who has been engaged in malaria control work with the Virginia State Health Department, has been designated to represent the United States on the epidemic committee of the league of nations. Twelve countries will be represented on the committee. Dr. Wil-

liams left the first of this month for Italy, where he will spend four months studying malarial problems.

### **Medical Aid Needed for Russia.**

An appeal comes from the American Medical Aid for Russia for food, clothing, instruments, supplies and medical books for the physicians of Russia, as well as for financial help to maintain their hospitals and help care for the complicated health problems of that country. Dr. Henry O. Eversole, a member of the Commission on Russian Relief, has sent advance information on the report of the Health Section of the Commission, showing that conditions are deplorable and help is badly needed. Great effort is being made to control epidemic diseases which are ravaging that country, but one of the most serious problems which confronts the medical profession is the care of millions of children whose health has been damaged by adverse social and economic conditions. Hospitals have been taxed to the utmost to meet epidemic situations and there is now a great lack of necessary equipment and supplies. Dispensaries which are running are hampered by lack of even the simplest drugs.

Some of the best known medical men in the United States are members of the Physicians' Committee of the American Medical Aid for Russia and endorse its work. Supplies or money should be sent this organization at either 1521 Cherry Street, Philadelphia, Pa., or 108 Dobbin Street, Brooklyn, N. Y. The American Medical Aid for Russia promises to apply all contributions to the relief of Russian institutions and medical personnel, without deduction for administration and transportation charges.

### **Course in Physiotherapy.**

The next course in physiotherapy which will be given at Walter Reed General Hospital, will begin October 5, 1923, and continue for four months. For information apply to the Commanding Officer, Walter Reed General Hospital, Washington, D. C.

### **The American Congress on Internal Medicine,**

Which convened in Philadelphia, April 2, elected Dr. Elsworth Smith, St. Louis, president, and re-elected Dr. Frank Smithies, Chicago, secretary-general.

### **Civil Service Examinations.**

Examinations will be held throughout the country on June 6, for men and women, to fill vacancies for trained nurse and trained nurse (psychiatric), in the Panama Canal Service. Full information and application blanks may be secured from the U. S. Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. Civil Service Examiners at the postoffice or custom house in any city.

### **Incidence of Diphtheria in City and Country.**

From investigations recently made by Dr. C. W. Kidder, of the U. S. Public Health Service, the following conclusions are deduced: that the susceptibility to diphtheria is higher among persons living in rural sections than among those living in cities; that it is much higher among the well-to-do than among the poor; and is more often found among the native born than among the foreign born. In view of the above, the Service stresses the value of the Schick test in determining those who are susceptible, thus enabling them to be immunized by the toxin-antitoxin. Particularly should this be a routine in the rural regions, where the degree of susceptibility was found to be greatest and where facilities for prompt and adequate treatment are frequently lacking.

### **Dr. J. Gordon Boisseau**

Has been named post commander of Post 151, American Legion, organized in Richmond, Va., early this month.

### **The Virginia State Dental Association,**

At its annual meeting held in conjunction with that of the North Carolina Dental Society at Pinehurst, the first part of this month, elected Dr. C. B. Gifford, of Norfolk, president, and re-elected Dr. Harry Bear, Richmond, secretary-treasurer. The Virginia Association will hold its next meeting during the Spring of 1924 in Norfolk, Va.

### **New Hospital at Stuart, Va.**

Dr. George T. Divers has placed contract for a new hospital to be erected at Stuart, Va., on the site of the Mother's Home, which was owned and operated by the late Dr. R. S. Martin. The building is to have four stories, will be modernly equipped and fireproof, and will have a capacity for thirty patients. It is expected that it will be ready for occupancy in August.

**Dr. L. T. Royster,**

Norfolk, Va., was elected one of the vice-presidents of the Virginia Conference of Social Workers, recently held in Charlottesville, Va.

**Dr. M. H. Eames,**

Lanexa, Va., was a recent visitor in this city.

**Broadcasting Public Health by Radio.**

The radio has now become a popular means of disseminating public health information. It is stated that broadcasting stations are so situated as to serve practically every portion of the United States. It is estimated that there are now more than 2,000,000 radio receiving sets within range of stations which release health bulletins. In this way health news is scattered with practically no additional expense to the Public Health Service.

**The American Drug Manufacturers**

Held their twelfth annual meeting in New York City, April 16-19. Important matters relating to narcotic drug regulations, legislation, pharmaceutical progress, scientific research, medicinal chemicals, etc., were discussed. Mr. A. S. Burdick, President of the Abbott Laboratories, Chicago, was elected president, and Mr. A. Homer Smith, of Washington, D. C., Secretary.

**Deaths of Physicians.**

*The Journal of the A. M. A.* reported deaths of 2,513 physicians during 1922, and, adding three per cent. for possible omissions or delayed reports, it is estimated that the total was 2,588. This rate of 17.73 per thousand was slightly higher than the 15.52 per thousand average for the previous twenty year period. The greatest number of deaths for a given age was at 66 years, at which age eighty-eight deaths were noted, and the largest number were due to diseases of the heart and circulatory system.

**Doctor!**

Do you want to locate in Tennessee? City of 4,000, eighty miles south of Nashville on L. & N. R. R. One of richest counties in State. Want to sell out and quit practice. \$4,500 cash to handle. Beautiful home and well-equipped office. Write for particulars to Dr. James A. LaRue, Pulaski, Tenn. (Adv.)

# Obituary

**Dr. McGuire Newton,**

Distinguished pediatricist and one of the most beloved doctors of Richmond, both by the profession and his clientele, died May 8th, after an illness of about seven months. His death was due to unusual heart complications accompanying inflammatory rheumatism. He was a son of the late Bishop John Brockenborough Newton and Mrs. Roberta Page Williamson Newton, and was born in this city 47 years ago. He graduated from the University College of Medicine, Richmond, in 1897, and joined the Medical Society of Virginia in 1898. Several years later he decided to limit his work to pediatrics and he had become one of the leading specialists in this branch in the country.

Dr. Newton was for some years professor of pediatrics at the University College of Medicine and, when that school combined with the Medical College of Virginia, he was placed in charge of the same branch in the consolidated schools. He was active in church and charity work, was an ex-president of the Richmond Academy of Medicine and Surgery, was a vice-president of the Medical Society of Virginia in 1910, and later a member of its executive council. He was also a member of the State Board of Health. He was prevented by the condition of his heart from entering the medical service during the World War, but continued his work at home with patriotic zeal. He was unmarried but is survived by a sister and several brothers.

**Dr. Samuel Lile,**

A prominent physician and surgeon of this State, died suddenly at his home, Lynchburg, Va., April 15. Dr. Lile was about sixty-two years of age and had practiced in Lynchburg for about twenty-five years. He studied medicine at the University of Louisville, from which he graduated in 1888. He joined the Medical Society of Virginia in 1894 and was much interested in its welfare, having been elected president in 1914. He was also an active church worker. Dr. Lile is survived by two daughters, his wife having died several years ago.

Dispensary and Hospital of Cleveland

## A FOOD TO KEEP BABIES AND YOUNG CHILDREN WELL

*Adapted to Mother's Milk*

**S.M.A.** is a simple and satisfying food for infants who are deprived of mother's milk, or who require food in addition to what the mother can supply.

S. M. A. contains the required food elements in proper proportions. It not only prevents, but cures, spasmophilia and rickets.

S. M. A. is a food which requires only the addition of boiled water to prepare, whether for the month-old infant or the infant a year old.

S.M.A. has contained, from the very beginning, a liberal amount of cod-liver oil. It offers a sure and simple means of providing infants with a constant supply of this valuable agent in sufficient and proper proportion.

S. M. A. makes happy, solid, breast-fed looking infants, and insures normal development.

S. M. A. is sold by druggists on the order of physicians.

*If your druggist cannot supply you with S. M. A. we would appreciate your sending us his name. And until he orders a stock, we shall be glad to supply you direct.*

# CALCREOSE

## Creosote in Pulmonary Tuberculosis

Powell, Latham, Ransome and other clinicians who have given the treatment of pulmonary tuberculosis special attention are of the opinion that creosote not only produces a beneficial effect on the digestive organs, and, so, on general nutrition, but also is of un- doubted value in lessening the cough and the amount of expectora- tion.

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime.

CALCREOSE has the pharmacologic action of creosote but does not have the untoward effects on the digestive tract that creosote has. Patients do not object to taking CALCREOSE.

Write for the "Calcreose Detail Man."

Francis H. Smith : 1829-1906  
Founder of The F. H. Smith Company

Fifty years ago the late Francis H. Smith, who was then employed in the House of Representatives and also a member of the commission appointed by President Grant to settle the Sioux Indian disputes, decided to go into business for himself.

Born and raised on a farm in Connecticut, he knew that the foundation of all wealth was land. He knew, furthermore, that the presence of the National Government in Washington, D. C., was a **guarantee of constantly increasing real estate values.** He knew that money would be needed to finance the Capital's expansion.

**Started in 1873**

So it was, in 1873, that Francis H. Smith opened an office and engaged in the real estate mortgage loan and investment business.

In 1873 there were no apartment houses in Washington and only thirty-three small hotels. Today there are approximately a thousand handsome apartment structures and some one hundred and twenty-five hotels, which rank with the best to be found in any city in the world.

**Developing Washington**

The F. H. Smith Company has played its part in this work of development. Buildings like these necessarily had to be financed in order to be built. Such financing in the

majority of cases has been in the form of mortgage loans.

It is these loans—loans on apartments, hotels, office buildings, etc.—that are offered by us to the investing public in the form of First Mortgage Bonds. The security back of them is Washington real estate—improved, income-producing property.

**Safe for 50 Years**

Our First Mortgage Investments have behind them a record of **no loss to any investor in fifty years.** Funds may be invested for as short a period as two years or as long as fifteen years, in denominations of \$100, \$500 and \$1,000.

**The interest return of 6½% is made all the more attractive by definite tax free features.**

Our Investment Savings Plan puts these investments within the reach of every-one who can save even as little as \$10 a month.

Let us send you a free copy of our Golden Anniversary booklet. It contains the illustrated story of F. H. Smith's remarkable career and of one of the most interesting periods in the Nation's Capital.

The F. H. Smith Company,  
Washington, D. C.

Without any obligation on my part, you may send me your Golden Anniversary booklet, together with information about first mortgage investments in the Nation's Capital.

### ADOMINAL PREGNANCY.\*

By J. BOLLING JONES, M. D., Petersburg, Va.

Though rare, with more frequent reports from year to year of cases of abdominal pregnancy, successfully handled both as to mother and child, the subject certainly demands some consideration at the hands of surgeons and obstetricians. It is evidently wise that all such cases be reported with results. The cases being rare, one can only be safely guided by the experience of others as well as his own, both as to diagnosis and treatment. I will not attempt to enumerate the number of cases that have occurred with living children in recent years. Horsley, in 1912, found in reporting a successful case of his own 138 babies living at time of operation. Forty-six of these had occurred in the previous fifteen years against 92 prior to 1897. Of the last 46 reported, 19 were still doing well at the time the report was made, and in many instances the children were over one year old. Eight were deformed and, as a rule, died early, 19 showed normal development but died in a few hours from various causes, such as prematurity, convulsions, bad surroundings, or some bad general conditions of the mother. No doubt with an improved diagnostic acumen and surgical technique, as we have today, a search of the literature of recent years would show a larger number of successful results; not that any more cases of abdominal pregnancy occur. The reverse should be true. With the exception of a few instances all abdominal pregnancies are of the secondary variety. There is usually a definite history of rupture in the early months. Most patients today are seen by some one capable of recognizing the true condition at the time, proper advice given, operation promptly done and no chance for

abdominal pregnancy to develop. These were the facts in the living baby I am reporting except that the mother refused the early operation. In a series of twenty cases of ruptured ectopic, all successfully operated on by me, there was another abdominal pregnancy of about four and one-half months. Who can tell what would have happened in the other eighteen had they not been operated on early, some just before, the others soon after rupture. I certainly would not advise any woman to take such a hazardous risk, however. The four and half months pregnancy was a poor colored woman. While there was a history of attacks of severe pain and faintness on former occasions, she had been seen by no physician until the day on which she was operated.

Diagnosis may be extremely difficult or very easy, depending upon the stage of development. Here, as elsewhere, mistakes will be seldom made if we have it in mind. Discrimination must be made between this condition and any intra-abdominal growth.

Pregnancy of this type will produce the same general picture as one perfectly normal. The menstrual history is particularly suggestive. It may be absent, irregular, scanty or too prolonged and profuse, with the passage of tissue, a history of at least much pelvic discomfort, and usually one or more periodic attacks of extreme pain attended by nausea and faintness of greater or less severity. With this early history we find, on physical examination, conditions depending upon the stage of development of the pregnancy. In the early months the abdomen will be enlarged below to right or left, and of smooth contour. The growth naturally will be higher and more in median line with the advance of pregnancy. At or near term there is little difference in its appearance from the normal. Uterine souffle occurs very much earlier than in a normal pregnancy, and will be a distinct guide long before the foetal heart sounds and foetal

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31-November 3, 1922.

movements are felt; once heard and felt, foetal heart sounds and foetal movements are more distinct than in the normal cases. On vaginal examination a mass will be found high up to the right or left, with uterus separate, somewhat enlarged, and pressed down to the opposite side. The findings in the pelvis will remain the same throughout. In the early months differential diagnosis is more difficult. The peculiar menstrual history, location of the growth, empty uterus, general pelvic discomfort, early appearance of the uterine souffle, would be guiding points. The main point in the early stages is, to my mind, not to misinterpret signs of rupture. This was my experience in the four and half months' pregnancy to which I have already referred. A diagnosis of ectopic with repeated ruptures was made; whereas at operation there was no blood in the abdomen, the foetus was in a perfectly formed glistening sac which ruptured when attempt at removal was made. The placenta was attached to the lateral wall of pelvis, underneath the broad ligament. Its vessels were ligated, and removal was without much difficulty. Remembering this mistake, I was the better able to handle the successful case now being reported. In the later months, if the child be viable, differential diagnosis is easy.

With the foetus dead, the X-ray would be an absolute guide. When in doubt, these cases should be watched and studied in the interest of both mother and child.

Treatment will depend on the stage of development, whether the foetus is dead or alive, and the general and local condition of the patient. The operative danger arises mainly in handling the placenta, and this is proportionate to the location and relatively vital structures to which it is attached, and not necessarily to the term of pregnancy. It is also well recognized that, in case of the foetus dying at any stage, changes immediately take place in the blood supply to the placenta, making the matter of its removal very much easier and safer: particularly if a period of a few weeks is allowed to elapse before the operation is undertaken. Consequently, in an advanced case, the foetus dead and the above changes having had time to occur, a section is indicated, removing the foetus, the placenta and membranes, with complete closure. With the child alive, or if recognized before time of viability, the mother's general condition good

and local condition not alarming, other considerations arise. In my judgment, these infants deserve to be considered just as they would be in threatened abortion. It has been proved by Cragin, Horsley, and by the case I report, that they can be perfectly normal in every way. These patients should be kept under the strictest surveillance. It might be slightly safer for the mother than for the child, to operate early, but this is questionable. In my cases the one at eight and one-half months was operated on as safely as the one at four and one-half. When the pregnancy is advanced, the danger of hemorrhage from rupture as in the early months is practically nil. Should the sac rupture with escape of amniotic fluid in the abdominal cavity along with the foetus, to my mind the shock would not be proportionate to that of hemorrhage. Under these conditions, of course, operation should be immediate. I have not read of such an accident occurring late, if handled promptly, as being disastrous.

According to Beck's statistics the best time to operate in the interest of the child is the thirty-eighth week. This was the plan we adopted in the case we today report. The mother's condition was good up to that time.

The question next arises how best to handle the placenta with the active blood supply. This is left to the judgment of the operator. Beck proved by experiment with dogs that three-fifths of the human sterile placenta could be handled readily by the peritoneum. He has collected a series of twelve cases where the child was removed, the cord cut close to placenta, the latter with its membranes left *in situ*, the abdomen closed without drainage. The mortality was a little over 33% as against the next and usually adopted plan of procedure, that of marsupialization, which carries a mortality of 39 per cent. It has been suggested this is probably not a fair test, as probably in a good many of the cases of marsupialization the operator had possibly attempted removal and, having failed, the patient had to stand the effects of the hemorrhage in attempts at removal as well as the long continued suppuration that goes with this method.

When, in the judgment of the operator, the placenta by virtue of its attachment can be safely removed, this should be done. This plan was adopted in both of my cases, both recovering.

Patient of Dr. F. J. Wright, Petersburg, Va.

Mrs. W. H. C., white, age 29, married 11 years, two children, first born in 1912, still born. In 1913 had laparotomy, median incision, removing right tube, ovary and appendix. In 1915 last child was born, forceps delivery. Since that time health fairly good. Menstruation regular but varied in amount and discomfort. The last regular menstruation was March 17, 1921. Present illness begun April 12, 1921, with severe pain in the rectum, extending through to front of lower abdomen, and lasting about fifteen minutes. No nausea, vomiting or fainting. About two weeks later, while at stool, the same character of pain occurred, but more severe, lasting a little longer, causing a feeling of faintness but no vomiting. About May 1st, the third attack occurred, and she was seen by Dr. Wright. There was pain in rectum and lower abdomen, very severe and persistent, causing thirst, nausea, blindness, air hunger and syncope. She was then in bed constantly for five weeks. The patient missed the April period due the 17th. Early in May begun menstruating and continued till June 8th. During May she suffered with intermittent cramping pains in the abdomen. They also disappeared about June 8th. On May 26th case was first seen by me with Dr. Wright, who suspected ectopic. This opinion was confirmed, based upon the typical history already given and pelvic findings, namely, a fixed mass to left of uterus, soft and elastic. Uterus quite tender and soft. There was no temperature. Immediate operation was advised but refused. On June 7th she was seen by another physician who questioned any form of pregnancy. He advised curettement which she also refused. On July 24th, two months later, she was seen the second time with Dr. Wright. The patient's general condition was then good but she had noticed her abdomen enlarging on one side and was concerned about herself. The growth then occupied the lower left abdomen and could be outlined above easily. Uterine souffle was loudly audible over the tumor. Digitally it was shown that the left side of pelvis was completely filled with a soft fixed growth. The uterus was easily defined to right but fixed; somewhat enlarged. All of the patient's functions were being well performed and vital organs in good condition. The patient was advised that the opinion given her two months

previously was correct; that nature had taken care of the situation to the extent of controlling hemorrhage, but that the foetus was alive and was growing. In view of the fact that her general condition was good, she was convenient to hospital care, and could be quickly handled in case of emergency, in the interest of the child we would await developments. I did not fear hemorrhage any further. She was from then on constantly under Dr. Wright's care; I saw her occasionally. Early in August, foetal movements were active and foetal heart could be heard.

On August 13th, patient had a severe fall. This was attended by marked abdominal pain, faintness and nausea. Fearing rupture, she was promptly sent to the hospital by Dr. Wright. When seen by me a little later, the picture did not look like shock from perforation but that from pain. Moreover, I remembered my first case referred to, where I made an error of judgment and consequently lost the baby. Her pulse was slow but of good volume. There was little anxiety in expression; considerable nausea; temperature normal; surface slightly cold, but soon responded to heat. There was extreme tenderness over the abdomen. Singularly, the foetal heart sound which had been distinct could not be found. The uterine souffle which had been extremely loud was very faint, there was extreme tenderness over the abdomen. What I feared was death of the foetus. The only drug administered was morphia to relieve pain. In 24 hours the patient's general condition improved, the foetal heart sounds were again distinct and souffle as pronounced as ever. She stayed in the hospital under observation twelve days and left in good condition.

From then on there was nothing unusual in behavior of the patient, only the necessary increasing enlargement of abdomen, the growth getting more in middle line, the increase in strength of foetal movements and heart sounds. We fixed the end of the 38th week to be about November 9th, taking this as a most propitious time for the child and as well for the mother. During these last weeks the case was properly safeguarded from an obstetrical standpoint.

Mrs. Cook entered the hospital November 8th and was prepared for laparotomy in the usual manner. Just prior to operation she was carefully gone over. Heart, lungs, blood pressure and kidneys were all normal; nutrition good; foetal heart sounds strong and move-

ments active. The tumor reached close to diaphragm, situated a little more to left of abdomen. On percussion, the entire left side was flat except an area of tympany extending from the left anterior superior spine upwards and over top of tumor. Otherwise, tympany only existed on extreme right in region of flank. Taken to operating room at 11:55 a. m., was back in room at 1:45 p. m. Time of operation one hour, thirty minutes. Anesthetic ether; anesthetist, Miss Spencer. Assistants in operation, Drs. F. J. Wright and F. Hinchman. The abdomen was opened and incision made through left rectus, extending from level of umbilicus to just above pubis. The left broad ligament was found spreading out over tumor as high as middle of incision. There were no adhesions at any point to abdominal wall, except small omental adhesion to old scar in middle line and independent of present condition. The placenta could be easily seen occupying the upper portion of sac and extending down on the left to the level of overlapping

Margaret Bolling Cook. Abdominal pregnancy baby, aged 11 months, 11 days.

broad ligament. On retracting abdominal wall to right, a clear thin portion of sac presented just under the middle line. Gauze padding was applied and the sac opened at this point. Amniotic fluid was abundant and apparently perfectly normal. The child was quickly extracted in perfect condition, in a few minutes' time crying lustily.

The cord was clamped and cut close to the placenta. On the removal of the child and amniotic fluid, the placenta immediately came down in easy access to field of operation. It was entirely arched over by the sigmoid, receiving its blood supply from the meso-sigmoid and left broad ligament. On picking up the sigmoid with the tissues now relaxed, it was

found that ligatures could be placed between the two. Complete enucleation was determined and accomplished without much difficulty. The upper half of broad ligament was removed with its enormously distended vessels. A small portion of membrane was quite densely adherent to the large iliac vessels. Fearing hemorrhage from this source in its removal, this small portion of membranous tissue was ligated and left *in situ*. Otherwise, the entire placenta and membranes were removed. The hemorrhage was at times considerable but at no time alarming. The uterus was pressed down below and to the right and was considerably larger than normal. I made no attempt to demonstrate the tube on the affected side. The abdomen was closed without drainage. The patient left the table in good condition. The baby, a girl, weighed four and three-quarter pounds, and was in apparently perfect state of development. Post-operative treatment was the same as in any abdominal incision. Salines by hypodermoclysis were given on account of the fact that we did not care to interfere with rectum or sigmoid. There was considerable uterine bleeding beginning soon after operation. It was as if it were an excessive menstrual flow. Patient's recovery was uneventful except after four or five days she ran a low grade temperature that we were unable to account for. My impression is that it may have been due to a mesenteric phlebitis. The kidneys acted well and bowels moved well by enema. There was little secretion of milk which made it necessary to feed infant artificially. The patient left hospital November 26th, in ambulance, but was soon up and around. The mother today, 11 months and twenty-four days after, is in perfect condition. A report of Dr. Mason Romaine, pediatrician, shows the baby to be perfectly normal mentally and it is physically above the average in development.

#### DISCUSSION.

DR. W. E. ANDERSON, Farmville: I want to congratulate Dr. Jones on the beautiful outcome of his case.

It has always seemed strange to me, how much a woman's abdomen and reproductive organs can stand. I had a case similar to that of Dr. Jones, only the woman carried the child for twenty-two months. She was a very big, stout woman, and she came a long ways across rough country roads to consult me. She arrived in pretty good condition.

The abdomen was so very thoroughly distended that I could not make a very thorough examination. I thought at first that it was an abdominal tumor and decided that it was too big a case for me. I referred her to Dr. Stuart McGuire, of Rich-

mond. The second day she went over to Richmond, and made the trip in perfect comfort. I went down to the operation. The whole staff of the hospital examined her, and no two agreed as to what the trouble was. One said it was a cyst. I said that she had abdominal tumor, the size and proportions of which I could not say.

We made the operation, and the first thing that popped out was the foot of a large child. We extracted the child and it weighed ten pounds. The patient said that she had not menstruated for twenty-two months and had considered herself pregnant. She had had twelve children before this. This may account for this condition. The woman made a good recovery and has not reproduced again.

I have seen cases of abdominal pregnancy and rupture, but I have not known any of them to die, if handled carefully.

DR. G. B. BYRD, Norfolk: Dr. Jones' case interested me because I have had some cases of abdominal pregnancy. I was not fortunate enough to get to see the patients until the sixth, ninth, tenth and eleventh months. Some of these were cases of abdominal pregnancy, some of extrauterine pregnancy. In the findings of these cases they give more or less the same history. They have been sterile until then, or they are rather late in reproducing, or they have had several years of sterility. All complained of pain in the pelvis, at one side or the other. Each was of the opinion that there was a possibility of her being pregnant.

In following up from time to time during the early months, I find that these patients do not enlarge as rapidly as you would expect them to at that stage. Each had a definite mass or tumor to be felt on one side or the other of the uterus. In the last three, after it was decided that the mass was increasing, they were advised to have an operation.

A patient I had gave a history of pregnancy, and she had been going to the doctor for two or three months, and had already engaged him to attend her in her confinement. I do not know whether he made a vaginal examination, but I assume that he examined the urine. About the eight and a half or ninth month, she had some pain in the pelvis, and sent for him, thinking herself in labor. He did not find any dilatation of the cervix, and told her that he did not think her in labor. That went on for perhaps a week. He saw her six times. The pain stopped and she was all right, although the tumor was still there.

When she was admitted to the hospital and I examined her, you could get a definite mass that felt like a baby, but was more freely palpable. We could not get any heart sounds. The operation was performed and the child weighed ten pounds and four ounces. The placenta was attached to the ovarium and came away easily. The child was in perfect condition. I fully believe that during her period of discomfort this woman had been in a position to have an abdominal operation performed.

DR. M. P. RUCKER, Richmond: I would like to ask that Dr. Jones say a few words in the description of the placenta and something about the length of the baby. His baby weighed four and one-half pounds. You would expect a larger baby at thirty-eight weeks. I would like to know whether he thinks it was the condition of the placenta or the interference with circulation that was responsible for the retarded growth of the baby.

DR. GEORGE T. MYERS, Norfolk: I think that abdominal pregnancy or extrauterine pregnancy requires all the skill of the obstetrician in making a diagnosis. Like a clap of thunder out of a clear sky are those cases in which this complication occurs in many cases.

I saw a woman about three months ago who was about the menopause; she had been menstruating regularly every twenty-eight days. At the time I saw her she had acute pain in the right side, no bleeding. I did not think that she had extrauterine pregnancy. It requires an astute diagnostician to recognize every case of tubal pregnancy before rupture. I diagnosed it as appendicitis. I decided to wait until the morning before operating. In the morning she was having extreme pain in the right side, and was passing a considerable amount of blood; this changed the original diagnosis. She was taken to the hospital and, when we opened the abdomen, we found it filled with blood, and a two-and-one-half months' foetus. We sewed the abdominal wound without drainage, and she made an uneventful recovery.

I had another case taken practically the same way. From a vaginal examination I could not find anything extraordinary. I took her to the hospital and found the same condition at operation. In both of these cases the tube had ruptured. I think it important to bear in mind that when a woman who has menstruated regularly, whether around the menopause or sterile, if the patient has possibly skipped one month or is a few days over her period and is taken with acute pain in the abdomen with or without bleeding, you may expect extrauterine pregnancy.

The removal of the placenta depends on the individual case, and the site of the placenta. I believe it preferable to leave it if it is attached to the stomach, or a large part of the intestines. If it is left, or adherent, you have to take it out later at a more favorable time, and you will not have the severe hemorrhage to contend with. I understood Dr. Jones to say that in his case he sewed the abdomen up without drainage, leaving the placenta. Of course drainage has been discussed and talked against, but I still drain where the placenta cannot be removed at the time of operation.

Early recognition is the important thing to remember in cases of tubal and abdominal pregnancy, operating before rupture takes place if possible.

DR. J. BOLLING JONES, Petersburg (closing): Babies of this type have been carried in the abdomens of women for years. They are like big ovarian cysts. How they can be carried and not cause more discomfort is more than we can see. The foetus is dead yet there is no infection.

Dr. Byrd speaks of a case of his in which the foetus was dead and the true condition was not recognized until the abdomen was opened. If we bear in mind there is such a thing as abdominal pregnancy, I do not think one likely to overlook it. The main point is to discriminate between evidence of actual rupture at any stage of development, which would require immediate section, and certain minor disturbances of the abdominal brain simulating rupture and requiring no interference. I was guilty of this error, opening the abdomen and finding the sac intact with foetus alive at four and a half months. I feel sure that this pregnancy undisturbed would have advanced to a safe time for operating in the interest of the child as well as the mother.

Dr. Rucker speaks about the placenta and the length of the baby. I am sorry we did not measure the baby. The placenta was smaller than usual, though it seemed especially large to me at the time.

There was not much difference otherwise. The mother is quite a small woman, which would necessarily affect the size of the offspring to a great extent.

Dr. Myers speaks of the early operation in ruptured ectopic. Of course we advise this in every case. In the abdominal case here reported, the woman refused early operation. The placenta was entirely removed, hence the abdomen was closed without drainage.

### PAINLESS LABOR.\*

By R. L. RAIFORD, M., D. Sedley, Va.

The intense interest manifested in recent years by all prospective mothers in twilight sleep and other forms of pain relieving methods advocated or used during childbirth forces us to realize the absolute necessity of abandoning the old "watchful waiting" method of handling our obstetric work and adopting in its stead an "up and doing" policy in these cases. It is true that nature will, unassisted, bring about delivery in a large majority of our cases and that the skill of the attending physician may be really needed only in the abnormal cases, but it is growing to be equally true that he who sticks to this policy will sooner or later find that, to put it mildly, he is not popular with this class of patients. They do not hesitate to tell you, and rightly so we believe, that they sent for you to help them and not to sit around and look at them.

Man's inhumanity to the pregnant woman is shown by his apparent, if not real, negligence in the study of the more refined methods of the practice of obstetrics, for until very recent years it has been deemed by many of the profession as well as the public that nature could care for all except abnormal cases of delivery, thus debarring the general practitioner from the refinements of skill which constant caring for normal cases will lend to the handling of those that are difficult. Many doctors will tell you openly that they detest the practice of obstetrics and, as a natural consequence, they are not taking the interest in this work that would carry with it the ability to help make all cases less painful and exhausting and make the difficult and serious cases much less so.

If pain were eliminated from the world, much that is best in the medical profession would pass with it, for it is pain in its broadest sense that brings most of our patients to us—either the pain they are then suffering or the pain they are afraid they will suffer in the future.

We rarely see an expectant mother, especially among the better classes, who does not dread the ordeal that is facing her, and this dread is increased to actual fear in many primipara cases and in patients of a nervous disposition. Here we are dealing with women who are hypersensitized to pain and who are approaching long hours of the most intense suffering human flesh is heir to. Furthermore, they have had months in which to learn from their fellow sufferers the horrors of child-bearing. They have also had three or four months of nausea and several months of embarrassment and separation from society and their usual avocations because of their condition.

When we consider these facts, it is little wonder that there should be just cause for discussions among the leaders of our country concerning race suicide and kindred subjects. It is little wonder that the discussions of twilight sleep in our leading periodicals, though they be fantastic and impractical, should arouse the interest of every normal woman to the point of demanding better and more humane treatment during this most trying period of her life. And it is little wonder that the specialist who is handling obstetric cases wisely and intelligently and meeting the desires and needs of the patient is keeping busy in spite of the handsome fee he gets when those of us who are paying no attention to these refinements of practice have plenty of time to burn, but little money to spend.

It is claimed that in the average case "Painless Labor" can be about as nearly approached as the much vaunted painless extraction of teeth. If we make an analogy of the two cases by comparing the preliminary discomforts of pregnancy to the discomforts that lead up to the point at which it is deemed necessary to extract a tooth; the pains of early labor to the pains which accompany the application of the remedy to relieve the pain of extraction; and the well handled case during the second stage of labor to the actual extraction of the tooth, it can be seen that, bearing in mind the relative seriousness of the two operations, one may experience as little relative discomfort in normal labor as in the tooth extraction.

Since this paper is meant to deal primarily with the problems of the general practitioner, there will be no attempt to discuss methods that can be used only in a well organized and

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31-November 3, 1922.

equipped institution. For this reason, since twilight sleep requires the constant presence of a trained attendant, and nitrous oxide oxygen must be given by means of apparatus that is not practical for him to use, we shall not discuss the use of these two methods of practice.

There is no doubt that the best method of making the expectant mother more comfortable is to gain, if possible, her perfect confidence. This can be done only by first becoming an intelligent and scientific obstetrician, and then by transmitting this knowledge of ability in a pleasant and unobtrusive manner to the patient. Frequent and painstaking inquiry as to the patient's health, careful and frequent analysis of the urine, correction of her ailments, if possible, however small they may be, and encouragement along the line of her ability to go through her confinement successfully, is the best way to build up confidence.

A sympathetic and firm handling of the case from the very beginning of labor pains, always keeping busy at something, if possible, while in the presence of the patient, never allowing her to get the impression that you are merely sitting around waiting for some complication to arise before doing anything, will cause a continuance of this confidence, and will often accomplish wonders in making your patient satisfied and comfortable. Some good men depend on this method entirely, but while it alone will act nicely in some cases, and will help immensely in all cases, we would hardly be justified in depending on this plan alone.

The drugs which have been used most successfully in alleviating pain during the first stage of labor are chloral, morphine, or morphine scopolamine combined. Most cases get on well enough not to require any treatment during this stage other than an occasional assurance that she is doing well. In others of a nervous or irritable disposition it will be well to give small doses of one or the other of these drugs as indicated. In some cases a little chloroform or ether during the latter part of the first stage, especially if pains are severe, the os rigid and dilatation slow, will not only make the patient immensely more comfortable, but will usually facilitate dilatation and thus hasten the progress of labor.

It is, however, at the beginning of the second stage of labor that the ability of the trained obstetrician has the chance to make a real home run. If called early in the case, it

will often tax the ingenuity of the most skilled physician to do enough to keep the patient satisfied that he is exerting his best efforts to help her, but after dilatation is complete and pains are strong and sufficiently frequent he should have plenty to do most of the time. Here the general anesthetic may be given with each contraction of the uterus, just enough to relieve the sharp edges of the pains but not enough to retard labor. This should be kept up until the head is well down on the perineum when it should be pushed to complete anesthesia, allowing the baby to be born without the consciousness of the mother.

In cases where the pains are not sufficiently strong unassisted we may, after dilatation is complete and if we are sure there is no mechanical obstruction, give small doses of pituitrin as indicated, to give tone and strength to the uterine contractions. But before giving this drug, we should always be prepared to give an anesthetic as needed, to hold the pains under proper control, for there is little doubt that the precipitous labors we hear about are due to the fact that the rapid action of pituitrin is not properly tempered by a skilful administration of chloroform or ether. After giving pituitrin the usual management in this class of cases is the same as in cases where pains are normally strong enough without its use.

By the careful use of chloroform or ether and pituitrin, if necessary, we will in most cases be able to perfect delivery with the mother so thoroughly anesthetized as to be unconscious of the fact that the infant has been born. Often, too, the placenta can also be delivered before complete consciousness is regained and it is not unusual for the mother to ask, after she has been dressed and fixed up nicely in a clean bed, how long it will be before she will get through, and it is always most gratifying to have her smile and thank you for having assisted her in getting over the dreaded ordeal so nicely.

We need not dwell on instrumental or other special forms of delivery as this paper is meant to deal primarily with the normal case. Potter's method which is designed to bring about delivery at a specified time by means of bags and podalic version may be used by one skilled in its methods and under proper conditions, but the method outlined in this paper is so simple and easy to practice that it may be used in any backwoods cabin with success.

When the general practitioner has given the question of obstetrics the thought and study due it, and acquired the skill to handle the normal case in such a way as to give the unqualified impression that he has given value received for the fee he gets for his services, the midwife problem will be largely solved. Let us always bear in mind that it is not the desire to save money alone that causes our women to have a midwife to attend them during confinement, but largely the idea that we have, through our negligence, allowed to become prevalent that in normal cases the midwife can be of about as much help as the doctor. All the abuse and criticism which can be heaped on the poor midwife who, in the present arrangements of society, seems to be with us as a necessary evil will have but little effect on her present status, for we may just as well sooner as later face the irrevocable fact that more intelligent and efficient service from the general practitioner in the normal case of obstetrics will be the ruling factor in solving this troublesome problem.

In conclusion, let me say that he who dons the garb of a practitioner of medicine, the highest calling save that of the ministry which it is our privilege to follow, and does not equip himself to relieve the suffering of the parturient woman in every possible manner in which he is capable, is guilty of the grossest neglect. To argue that labor is a natural process which demands no interference, except when an abnormality arises, should have about the same bearing as to say that our forefathers dwelt in caves, wore skins for clothing and ate their food uncooked. We must ever bear in mind that we are dealing with highly sensitized and often nervous women, the product of modern civilization, and, if we do our duty as obstetricians in such a manner as to gain their unqualified confidence and appreciation, we must treat them not as her forebears of medieval times but as what she is today. As a parting thought let me say that more scientific attention to the normal case of labor will not only be rewarded by the lasting gratitude of the patient and a better income for the physician, but will the better qualify us to handle our difficult cases with more skill and better results.

#### DISCUSSION.

DR. R. B. JAMES, Danville: Dr. Raiford, in referring to "Twilight Sleep," stated that it was neces-

sary to be on hand all of the time. I do not think that this is necessary.

I remember a case I had of a young woman with her first child, and, after getting her quiet and asleep, I went on into the next room and went to sleep. I always give adalin tablets. I find these very effective, and I think it a good thing. If you give her a hypodermic she will go on to sleep. Then if she makes more noise, give her some more. I do not see the necessity of being with her all of the time. To hold off the pain and let her go to sleep is better than to be watching all of the time.

If a woman goes into labor at ten p. m., and is not through until six o'clock the next morning, it takes a lot of ingenuity to find something to do all of that time.

DR. J. BOLLING JONES, Petersburg: I presume that a great many men do a lot of obstetrics. Personally, I have not done a large amount, but I have never had any more loyal patient than the woman I have delivered of a child. Deliveries can so easily be made practically painless.

In the operating room at the hospital (we have our delivery rooms near the operating rooms), and frequently when I am operating, I hear the screams of a woman being delivered of a baby, and I think how easy it would be to make that delivery painless.

I think Dr. Raiford is right when he says that it should be made painless. In the first dilating stage, I use a compound of chloral, bromide and mercury, with nearly one quarter grain of morphine. I do not hurry the labor, but give her plenty of time, and keep assuring her that I am going to make the labor painless.

Remember two things: you are to make it painless, and if she cannot have the baby, you can.

DR. W. E. ANDERSON, Farmville: I was impressed very favorably with Dr. Raiford's paper.

I just want to emphasize the point he made of keeping the confidence of the woman in labor. Primary to labor, I think it a good idea to have her in good trim, and keep assuring her that when the time comes you are going to see her safely and easily through.

I prefer chloral to morphine. I think the morphine hypodermic quiets the woman, but it postpones labor. I do not often find that they vomit the chloral. If she does vomit the chloral, I use chloroform, just enough to get the patient quiet. I find that chloral keeps the woman in a frame of mind to go on and have the baby.

DR. G. B. BYRD, Norfolk: Anesthesia with labor has always been a sort of hobby with me.

I think every woman ought to have as much relief at this time as she can get. It has been my custom to use nitrous oxide as a routine measure, not only in the hospital, but in the home. I think it depends on the training you have had in reference to nitrous oxide, if you use it. I give just enough to relieve pain. It has been my custom to give a dose of morphine when the patient begins to be uncomfortable. It does not retard labor. I believe it is a little quicker following a dose of morphine than if they did not get it.

The amount of morphine I use depends on the size and temperament of the patient. I had rather use small doses often, than to use a large dose. I usually use six milligrammes. Then you give the nitrous oxide, and the patient will go through it well, and come out in a frame of mind not to mind having another baby.

DR. R. L. RAIFORD, Sedley (closing): I wish to thank most heartily all the gentlemen who have spoken so kindly of the manner in which I tried to handle the subject in question. We do not find many men doing what Dr. Byrd says he does.

What I wanted to particularly impress on you, is to do what you already know how to do, instead of neglecting it.

### NASAL ACCESSORY SINUSES AND OPTIC NERVE DISTURBANCES.\*

By J. E. DIEHL, M. D., Norfolk, Va.

It is not my intention to discuss at length the various theories as to the effect of sinusitis in relation to optic nerve disturbances, but to confine my remarks to what I have found in my own cases, with a slight review of some of the literature. So what I may have to say is offered as an opportunity for discussion, and not with the idea of adding anything of material value to the subject.

There has been a great deal of literature written on this subject during the past few years, and I find on a careful review of the subject, that there is a remarkable unanimity of opinion among most of the writers as regards their findings. It is rather unusual and unique to find this harmony among a large number of enthusiastic workers.

If the close proximity of the posterior ethmoids and sphenoids with the optic nerve and also the close relationship between the vascular systems have any bearing in optic nerve disturbances, then the question naturally would confront us, how is it that the optic nerve is not involved more frequently in sinusitis, especially when we find nasal pathology well established? From what I can understand, the optic nerve is not involved so frequently in those cases where we find rather manifest pathology on inspection, which is usually confirmed by a roentgenogram and at times by the transillumination, but more often in those cases where the nasal pathology is more obscure and rather ill defined. This statement of course, does not hold true in all cases, but the tendency is fairly well established by those who have wide experience, and they offer evidence to prove their contention. I believe the early writers considered the close proximity of the sinuses to the optic nerve as the most plausible explanation of eye disturbances, but they did not offer anything more than this fact. From this view they have brought forth a number of well founded and explained etiologi-

cal factors. It is fairly well established that the more gross the nasal pathology the less apt are we to find eye disturbances and conversely, the less nasal pathology we find, the more apt are we to find eye disturbances. It is difficult to see why this should be, but this does not alter the situation one way or the other. Does the microscopic pathological picture throw any additional light on this subject? From the standpoint of pathology, both gross and microscopical, but little information is obtained. If the pathologist can enlighten us, very well and good, but if he can not, we seek solace by saying this seems to be the general belief among the rhinologists and our attention is directed to the remote and obscure pathology in the nose as a great potential factor in causing eye trouble.

When we speak of nasal pathology we are led into a broad field of interpretation and it is very hard, in borderline cases, to tell just where the normal ends and where the abnormal begins; this not only applies clinically, but is true regarding the laboratory findings as well. Climatic conditions have a certain influence, and the various stages of life also play a part, the characteristic anatomy of the nasal chambers, the question of free drainage and good ventilation, the position and shape of the turbinates, all of which have great potentialities in causing sinusitis and other more remote conditions.

While in the United States Army I had the opportunity and pleasure of examining a large number of soldiers, and my attention was particularly attracted to a large number of what I would term abnormal nasal septi, or septi that could cause local or general pathology. I believe that I am not exaggerating when I say that thirty to forty per cent were potential sinusitis cases. I have no figures to substantiate this statement, but I believe it is a conservative estimate. If this statement has any scientific value, then it would be the duty of the ophthalmologists to constantly bear this in mind and be on the lookout for nasal trouble that may account for the eye condition.

Now what are some of the most common eye disturbances attributed to the nasal accessory sinuses? The eye findings are fairly well set forth and they are not unlike those found in a number of other conditions. Some of the most constant findings are as follows: A central or paracentral scotoma, relative or abso-

\*Read at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31—November 3, 1922.

lute; enlargement of the blind spot, the vision not necessarily being disturbed, or slightly so, or there may be blindness. The ophthalmoscopic findings, as reported, may show little or no change in the disk. Some writers have reported finding one to three diopters of swelling of the disk said to be due to infection of the posterior ethmoids, and by subsequent operation on the nose the vision has returned to about normal and the swelling of the disk disappeared with only slight blurring of the edges remaining. I must confess that within my limited experience I have not found a case of eye disturbance that I was satisfied arose from the sinuses. The question may be asked, do I examine the fields in all my eye and nose cases? My answer is in the negative. However, I do make the confrontation and perimetric tests in all cases where I suspect optic nerve involvement. My omission may account for the failure in detecting some of these early and interesting cases, and I hope that by being more careful, and by mapping out all fields, I will be more fortunate in this respect than in the past.

Quoting Dr. Cushing, from an article in the *Journal of American Medical Association*, "When a retrobulbar neuritis is said to be accompanied by two or three diopters of swelling, we are certainly dealing with something which a hyperplasia of the mucous membrane lining the accessory sinuses is not capable of producing.

"During the course of the past twelve months many patients with brain tumor have appeared in the Brigham Hospital clinic who had recently undergone radical intranasal operations for assumed infection of sinuses. Were these operations done merely on the chance that the patient complained of obscure headaches or visual disturbances in the absence of choked disk, it would be understandable; but when these operations are performed on people with full blown changes in the optic nerve and with the idea that cleaning out the ethmoids and sphenoidal regions might check the process, we certainly have gone too far."

I appreciate the delicacy of making a diagnosis of optic nerve disturbance, due to an obscure nasal pathology, and we are not justified in so doing until we have exhausted every means available in making a diagnosis, and in order to reach this final analysis we must have the co-operation of the internist, neurologist

roentgenologist and ophthalmologist and, if we have failed to consult any one of these specialists, we have been derelict in our duty.

The future will be very interesting indeed to us all, especially to the men who have a number of cases on their records of diagnosed eye disturbances due to accessory sinuses, who had refused intranasal operations, as it is only a question of time until the rhinologist will determine whether or not his diagnosis was correct and the proper treatment advised. There have been a number of cases reported to show that the sinuses can and do cause eye trouble, and most of them that have been operated on have shown improvement or gotten well, and at some future time we may be able to tell the subsequent history of the cases who had refused operation.

337 *New Monroe Building.*

#### DISCUSSION.

DR. H. L. MYERS, Norfolk: I would like to say a few words on this very important subject. It should be emphasized.

Many conditions of the eye which we used to suppose were due to other causes, are almost certainly proven to be due to diseases of the nasal accessory sinuses. The examination of the anatomy of this region will satisfy anybody as to how easily disease of the walls of the sinuses can affect the optic nerve and other parts of the eye. I think that most of these cases show neuritis.

Dr. Cushing's summing up of the situation is the best to be found on this subject.

DR. J. E. DIEILL, Norfolk (closing): I brought up this subject to start a discussion, and I am sorry that there are not more here to discuss it. There have been volumes of literature written, both pro and con, and right at this time the pendulum seems to be with the pros. Personally, I feel like taking the mid-ground, at least until I have had more experience in this particular condition. It is the tendency of human nature to become over enthused at times, and, as time and experience grow, we often are led to modify, or at times change, our opinion entirely.

Dr. Myers' remarks are very important and instructive and I greatly appreciate his discussion.

### HYSTERECTOMY AND OVARECTOMY FOR BENIGN TUMORS AND SUPPURATIVE DISEASE IN SIX HUNDRED WOMEN.\*

By G. PAUL LA ROQUE, M. D., F. A. C. S., Richmond, Va.

The six hundred women herewith reported were encountered among fifteen hundred women operated upon for all types of pelvic disease during a period ending 1922. They have all been studied, operated upon and treated by myself personally in various hos-

\*Read by title at the fifty-third annual meeting of the Medical Society of Virginia in Norfolk, October 31-November 3, 1922.

pitals, and none have been excluded. There were ten deaths, a mortality of 1.6%: six of these among the first three hundred (2%) and four among the last three hundred (1.3%).

Two hundred and seventy-five (46%) had fibroids of the uterus, variable in size from that of a walnut to 16 pounds, and in number from one to as many as twenty or more. Over 60% of women with fibroids of the uterus also had ovarian cysts and 39% of fibroids were complicated by suppurative disease.

Four hundred and fifty (75%) women had ovarian cysts varying in size from that of an egg to 20 pounds in weight. Approximately 10% of the cysts involved both ovaries. Of women with ovarian cysts 25% had also fibroids and 33 1/3% of cyst cases were complicated by inflammatory disease.

Suppurative disease was present in three hundred and sixty-five (62%) of six hundred women and involved the uterus, both tubes and cyst. In 30% of these, pelvic abscess existed about these organs. Of the cases of suppurative disease in this series, 18% had previously existing fibroids of the uterus and 42% had ovarian cysts.

The pathological findings after the abdomen was opened were those of real pathology,—ovarian cysts and uterine fibroids of sizes, locations and numbers too familiar to need further mention: suppurative pathology seen as suppurating cysts, inflamed fibroids, old-fashioned dyed in the wool pus tubes and pelvic abscesses; these were the pictures exhibited.

More than half of the women in this series presented additional surgical pathology needing operation apart from that which called for the removal of the uterus or ovaries. In eighteen women tubal pregnancy was present; in fourteen the pathology had caused ulceration of the bowel in various parts necessitating bowel suture: more than three hundred had definite appendicitis which of itself needed operation; thirty had gall-stones; fifty hernia; more than a hundred required operation upon the cervix and perineum and rectum; in ten per cent of women there was present serious secondary anaemia, ranging from 21% to 50% hemoglobin; many cases presented heart and kidney disease and obesity, glycosuria and other non-surgical coincidental affections. In six women operation was performed during complicated pregnancy or labor.

Hysterectomy was performed in three hun-

dred and seventy-five women (63%), both tubes being invariably removed with the uterus. Hysterectomy was of the subtotal supravaginal type in three hundred and sixty-five and was complete, including the cervix, in ten cases. Ovaryectomy was performed upon four hundred and ninety (80%) of this series; 11% of the ovarian cases necessitated removal of both ovaries and 89% required the removal of only one. Combined hysterectomy and ovaryectomy was performed in two hundred and sixty-five of the six hundred women (46%). In one hundred and ten of the six hundred cases (20% of the three hundred and seventy-five hysterectomies) only the uterus was removed, the ovaries not being diseased. Of the four hundred and ninety women requiring ovaryectomy, 45% did not need removal of the uterus.

All deaths occurring before complete recovery from the operation and discharge from care regardless of the time and cause of death are charged to the operation. In no case has operation been declined because of desperate condition or for any other reason. One obese woman with large tumor and slight fever died suddenly of embolism two days after admission to the hospital while resting in bed the day before operation was contemplated. No other case died while waiting.

The ten deaths were as follows. Four of these were also reported in a separate contribution dealing with four hundred cases of suppurative disease.

12-1895. 45 years old, large fibroid cystic ovaries and dense adhesions; valvular heart disease. After hysterectomy, removal of both ovaries and appendix, she died the third day of acute dilatation of stomach and heart.

15-2344. 35 years old; fibroids and ovarian cyst. After complete recovery from myomectomy, removal of ovary and appendix, died in five minutes of cardiac embolism while sitting up in bed the twelfth day.

15-2426. 35 years old, pelvic abscess, large ovarian cyst ulcerated into sigmoid, single pus tube; pulmonary tuberculosis. After removal of ovarian cyst and left tube, suture of hole in sigmoid, appendectomy and drainage of pelvic abscess, died six weeks later of septic exhaustion and pulmonary tuberculosis.

16-2502. 35 years old, with large fibroids, ovarian cyst, pus tubes. After hysterectomy, ovaryectomy and appendectomy, died the 15th day of what seemed to be intestinal obstruction.

16-2537. 48 years old with gangrenous ovarian cyst, dense adhesions and bleeding of suspiciously malignant uterus. After hysterectomy, ovaryectomy and repair of sigmoid, died the third day of peritonitis.

16-2556. 25 years old, with double pus tubes, cystic ovary and pelvic abscess all acute and erroneously

- believed to be appendicitis or tubal pregnancy. After hysterectomy, ovariectomy, appendectomy and drainage of pelvic abscess, died of septic shock.
- 21-3838. 30 years old, with three weeks post-abortional, double pus tubes, pelvic abscess and cystic ovary. After three days without fever, double salpingectomy, partial hysterectomy, ovariectomy and appendectomy was performed; she died the fourth day of septic shock and suppression of urine.
- 21-3841. 40 years old with enormous double intraligamentary dermoid ovarian cyst and small fibroid. After removal of both large ovarian cysts, uterus and appendix, died fifth day of dilatation of heart.
- 22-3984. Fibroid uterus, ovarian cyst, ruptured extra-uterine pregnancy, non-suppurative inflammation. Hysterectomy, removal ovarian cyst, appendectomy, drainage. She died five days later. Autopsy showed pus imperfectly drained.
- 22-4030. 49 years old with small multiple fibroids, moderate inflammation of uterine and single ovarian cyst. Cauterization of cervix, subtotal hysterectomy and removal of one ovary and appendix was performed. She did well for a week, developed signs of peritonitis and died the tenth day following operation. Many consultations were held and we felt it might be a case of peritonitis from an infected cervix with possible small bowel adhesion.

Of the total deaths there were five in two hundred and thirty-five women in whom the pathology was non-suppurative (clean cases) (2.1%) mostly large tumors; and four of three hundred and sixty-five women with suppurative disease complicating fibroids and cysts (1.6%).

Considering the cases in which only the uterus was removed, leaving the ovaries, there were one hundred and ten women with no deaths; and in two hundred and twenty-five women in whom the ovaries were removed leaving the uterus, there was one death. Cases requiring combined hysterectomy and ovariectomy included two hundred and sixty-five women with eight deaths (3.4%); these were women critically ill with large tumors and suppurative disease needing operations technically difficult.

The women have welcomed operation as a last resort. The clinical story is that of recurrent attacks or alternate remissions and exacerbations of symptoms, periods of encouragement that they may be better, discouragement that for some usually assignable reason they have had a relapse and finally despair of being cured without "the knife." The operation is forced by serious illness from suppurative disease or large sized tumors. Broadly speaking, the larger the tumors, the less extensive the inflammatory disease and *vice versa*.

Those socially and financially "well to do"

have many times been "almost completely cured" by endocrinologists, electro-therapists and courses of "local treatments" by "office gynecologists." Those poor and less conspicuous socially have recited the same story of ups and downs characterized by remissions and exacerbations of symptoms independently of local treatment and endocri-organo-therapy, but in spite of Pink Compounds, Gold Discoveries, Wines of special designation, and home brewed teas and concoctions painstakingly prepared by friends and neighbors.

With the clinical story so familiar, it would seem quite superfluous to urge all women hastily to operation by the threat of impending death from the disease. The real advantages of early operation for obvious and symptom producing benign tumors of the ovaries and uterus are incident to the cure of suffering, checking extension of disease, preventive of the necessity for technically more difficult, more radical and more dangerous surgery on account of complicated pathology in women older and less healthy. The conservative purpose of treating benign tumors and inflammatory disease of the uterus and ovaries is directed by efforts to preserve menstruation, ovulation and the ability of the woman safely to bear children. The less extensive the disease, the more likely are we able to preserve uterine and ovarian tissue and with these menstruation and ovulation. Early operation is conservative surgery; late operation calls for radical surgery. And though it is clearly demonstrated that the longer they wait the more organs will have to be removed and though even for ancient and extensive disease the operation is not likely to be fatal, the disease may terminate fatally in spite of the operation in a few cases.

The urgency of immediate operation is an important question. Women rarely receive operation for the first "spell" of symptoms caused by pelvic tumor and inflammation save as a result of an erroneous diagnosis of appendicitis, the operation for which discloses a normal or diseased appendix and discovers disease of the pelvic organs. Uniformly good results following delayed operation upon previously unrecognized twisted ovarian tumors, ruptured tubal pregnancies, and appendicitis, under the erroneous belief that we were dealing with pelvic infection or fibroids; and hasty operation upon previously unrecognized pus tubes or pelvic abscess under the erroneous

belief that we were dealing with ovarian cysts or uterine fibroids; the results of such errors without gross differences in the results suggest that after a reasonable wait for sizing up the situation the time for operation is of minor importance as compared to the method of procedure and technic of operation.

There can certainly be no reason, if we permit experience to speak for itself, for "emergency" operations for tumors and inflammatory disease of the pelvic organs. On the other hand, there is the conspicuous observation that no case need wait long. In the cases here reported, errors have occurred in both directions; on the one hand waiting patiently for symptoms to subside and on the other proceeding expeditiously to do the job. There have been no conspicuous differences in the results of both plans of action. Broadly speaking it seems wise to get the patient and pathology ready then go ahead but never rush. Any case may without danger wait until they can be properly placed under the care of a skilled surgeon; many cases may quite properly be operated upon the day after admission; no case should be "emerged" upon.

A systematic thorough operative procedure is called for. In nearly all cases after the woman is anaesthetized the final examination is made. After cleansing the vagina of gross filth, the iodized cervix is well dilated and a dull spoon curette introduced for exploratory purposes and to remove loose material. In years gone by, we usually scraped about in the interior of the uterus. We have never felt any reason to believe that curettage does good. If the cervix is torn and hysterectomy is not necessary, we have repaired the cervix if it is not much reddened or infected; if badly infected or if hysterectomy is to follow, we prefer to amputate the cervix with the electric cauterizing knife. This practice was not pursued in the earlier cases and some of the women were annoyed by purulent vaginal discharge after operation. Since we have had satisfactory electric cauterizing knives, we have employed this method of destroying the cervix and the women have had after hysterectomy a dry vagina. We feel quite strongly that infected torn cervixes should not be neglected because "the abdominal work may be enough." Such lesions need treatment because of their own troubles regardless of abdominal disease.

After dealing with the cervix, lesions about

the vagina, vulva and rectum are scrutinized and dealt with accordingly.

The abdomen is usually opened by a vertical incision to one side of the middle line. In exceptional cases of excessively fat or greatly overstretched and prolapsed belly walls or of large fixed intraligamentary tumors, an elliptical cross cut of the abdominal wall has seemed to give more easy access to the pelvic pathology and left a good abdominal wall.

Before the pelvic organs are touched or closely inspected, the gall-bladder, bile duct and stomach are examined; usually both kidneys are felt to see if one may be absent and to detect lobulated kidney and palpable calculi. Inguinal and femoral hernia are removed by the intraabdominal method and umbilical herniæ are excised by prolongation upward of the vertical incision. The appendix is then removed and we are ready to go to work. In approximately twenty-five or thirty of the cases here reported, appendectomy had been performed by other surgeons before coming to me for pelvic disease. I have also operated upon many women for appendicitis after they had previously had pelvic disease operated upon by other surgeons. Three or four of the women in this series of six hundred seemed too sick to take the extra three minutes for normal appendectomy.

By proceeding in this manner curing the non-pelvic lesions before approaching the pelvic pathology, the woman is cured of all her disease thereby being given more nearly 100% efficiency of operation; second operations for appendicitis, hernia, lacerated cervix and perineal tears are forestalled; the operative procedure most apt to be productive of shock is reserved for the last so that she may be put without delay in a warm bed upon the treatment for shock. In dealing with gall stones, however, we have in thirty cases of this series operated upon the gall-bladder as the last act of the operation in cases of pelvic pathology of non-suppurative character. In the presence of pus in the pelvis we have usually deferred the gall-bladder work for a subsequent operation.

We have performed three types of ovariectomy and hysterectomy; partial, subtotal and total. Cyst puncture has long been abandoned. To clip from the uterus an innocent pedunculated fibroid is not designated as an operative procedure.

Partial or subtotal ovariectomy is employed for non-strangulated, single or multiple cysts with a respectable amount of normal ovarian tissue about the hilum and with little or no evidence of cyst infection. In such cases the remaining portion of the ovary is stitched with its sutured raw surface under the round ligament.

Total ovariectomy has been employed for the removal of ovaries and cysts hopelessly buried in inflammatory exudate or dense adhesions or obviously internally infected; in all cases showing at operation evidence of recent strangulation or gangrene resulting from torsion of the pedicle and for cysts in old women.

In four cases in which ovarian tissue was conserved in young women, we have had to re-operate after from one to three years on account of ovarian cyst, two of whom had tubal pregnancy and one suppurative salpingitis. Perhaps we have erred on the side of conservatism in other cases, but the great majority of women in whom ovarian tissue was thus conserved have remained satisfactorily cured and been most grateful that they continued to menstruate.

My standard reason for removal of ovaries is complete destruction of ovarian tissue either by suppurative inflammation or large cyst formation. Malignant disease, primary in the ovaries, calls of course for removal if recognized early; but I have not thus far been able to do this. Inflammatory disease primary in the ovary is exceedingly uncommon. In perhaps six cases of this series I have encountered small abscesses in ovaries in women with normal tubes. Practically all the ovarian abscesses I have seen have been ovarian cysts infected from adherent suppurating tubes, the appendix, caecum, sigmoid and small bowel. In fourteen cases we have been compelled to suture openings into the bowel at points of dense adhesions and in one case the bowel had been previously punctured by a gynecologist while puncturing an abscess in the cul-de-sac. All but one of these recovered though some had close calls. All cases of ovarian cysts to which the bowel had not ulcerated have recovered.

The fluid from the largest cyst of this series weighed twenty-one pounds. The large ovarian cysts are commonly not complicated by inflammation; if they were the women would

be so sick they would be compelled to be operated upon before the cyst becomes so large.

Over 90% of all patients in this series requiring operation upon the ovaries also required operation for other lesions of the pelvic organs; 60% required operation for displaced uterus; 30% required removal of tubes; 25% repair of lacerated cervix; 25% hysterectomy or myomectomy for fibroids. On the other hand 30% of women in whom we have corrected displaced uterus have needed also removal of cysts and over 60% of sufferers from fibroids of the uterus have also had ovarian cyst of operative size. The number of cases of ovarian cysts in women with uterine displacement or fibroids has so definitely increased with the age of the women that we are quite suspicious that in some way displacement favors the development of ovarian cysts. Certainly in such cases (a large proportion) a vaginal pessary, even though it may seem to hold the uterus forward, cannot cure the woman. For cysts existing in women with fibroids, advocates of light therapy by radium and X-ray have not yet offered claims of cure by these methods.

In no case have both ovaries been removed from any woman under forty-five years of age unless all ovarian tissue had been hopelessly destroyed by inflammatory disease and cysts. In all but 10% of the total cases I have found it practicable to save some portion of at least one ovary and avoid the production of artificial menopause. This practice has thus far been satisfactory and while a few women have failed to get perfect relief of symptoms and a small number have had second operations after a year or so, the number has been so small and the satisfaction to the women has been so great, I am satisfied to continue the purpose of sane conservation of ovarian tissue in young women. In women beyond the age of forty-five no attempt to conserve ovaries was made, unless they were unquestionably normal. I have not removed ovaries on account of pain. Women with pathology in the ovary who suffer pain have also uterine or tubal inflammation or painful tubal and uterine contraction incident to torsion of cysts or prolapsed ovaries. In my experience women with the largest ovarian cysts (five to twenty pounds) have not complained of pelvic pain and have shown at operation normal tubes and uterus free from inflammation. This observation and the dis-

covery of cystic ovaries incidentally during operations upon other abdominal organs which have no symptoms of pelvic disease has aroused in me a strong suspicion that ovarian cyst, unless complicated by inflammation of a tube or uterus or of the cyst itself, is a painless disease save only when twisted on its pedicle. We cannot concede to the wisdom of removing ovaries merely because hysterectomy is necessary. On the other hand it has seemed wise in a considerable number of cases in which double ovariectomy for cystic and suppurative ovarian disease and double pus tubes is called for, to remove the enlarged prolapsed or suppurative uterus.

We have employed two types of partial hysterectomies. Both suppurating tubes and the intervening portion of the fundus uteri removed in one piece makes easy the complete covering of all raw surfaces by a continuous stitch from one end to the other of the broad ligament over the uterus. The other type of partial hysterectomy or myomectomy consists of the deliberate excision of single, medium or small sized intra-mural fibroids, and a small amount of the adjacent wall of the uterus. After thus removing by means of a surgical incision fibroids of medium size, reconstruction by suture of the uterine incision seems superior to the less exact method of digging out fibroids, leaving a ragged bed which can rarely be neatly closed.

Subtotal hysterectomy removes all of the uterus above the level of the bladder attachment. This is the type of hysterectomy called for in the great majority of women with multiple fibroids, extensive suppurative disease, and in women at or beyond the menopause with enlarged sagging or prolapsed uterus from whom it is necessary to remove both tubes and suspend by suture the cervix, bladder, vagina and rectum high in the pelvis for the relief of prolapse. Preceding hysterectomy in women with large cystic, torn and infected cervixes, cauterization of the cervix has proved of great utility in destroying the diseased cervix without the necessity for the more tedious and perhaps slightly more dangerous total hysterectomy from above. The small remaining piece of thoroughly cooked cervix, after cauterization of the cervix from below and subtotal hysterectomy from above, serves nicely as holding material to which after being pulled as high as possible,

the round and broad ligaments may be sutured for suspension of the vagina. This combination of cauterization of the cervix and subtotal hysterectomy has so far, in approximately one hundred cases, served quite satisfactorily for the cases to which total hysterectomy is advocated by many. Menstruation is not stopped by this method. I have performed the complete hysterectomy from above in a few cases of this series without fatalities but much prefer the procedure as outlined above. I am aware that the practice of total as compared to subtotal hysterectomy is becoming increasingly popular and am open to conviction that the total operation from above is no more dangerous and more completely curative than subtotal hysterectomy preceded by cauterization of the cervix.

All abdominal hysterectomies have included removal of both tubes. I have seen a sufficient number of women re-operated upon for diseased tubes allowed to remain after hysterectomy to convince me of the wisdom of removing both tubes with every hysterectomy. Except in women beyond the menopause, I have succeeded in being able to leave one or a portion of one sound ovary in approximately 90% of cases of hysterectomy.

Twenty-five cases of myomectomy or partial hysterectomy are recorded, a small number (less than 10%) of the fibroid cases. Most of the fibromyomata upon which I have operated have been so large and so numerous as to leave little or no normal uterus above the cervix. There are cases in which myomectomy is definitely indicated but we must choose these with judgment if we would get the patients well.

Observation of the great frequency of ovarian and inflammatory disease in women with fibroids would seem to place great limitations upon the usefulness of the X-ray and radium to women with fibroid disease. There are few women to whom radiation is applicable, fewer to whom X-ray and radium applications can be assured of curative results and many to whom it is dangerous. The known effects of radium as an agent capable of producing "radium sickness," shock and definite immediate mortality; a burned, fibrous uterus (an "undesirable tenant"); occasional urinary and rectal fistulae (disagreeable sequelae), leads one to believe that the treatment of the few uncomplicated fibroids of moderate size in women beyond forty years of age, by dilata-

tion, curettage and application of radium is attended by higher mortality and fewer cures than the surgical operation.

Hysterectomy and ovariectomy for fibroid, cysts and suppurative disease of all grades of severity in all the women affected should yield complete cures in 98.5 per cent and a mortality of less than 2 per cent of women affected.

### THE SEHRT AORTA CLAMP FOR THE CONTROL OF POSTPARTUM HEMORRHAGE.\*

By M. PIERCE RUCKER, M. D., Richmond, Va.

Truesdale tells of finding in the German advanced dressing-stations, metal tourniquets of several sizes. The Germans evidently made wide use of this principle for the control of bleeding. It now appears that Sehrt was the originator of the instrument, and that he was driven to the invention of this substitute for the Esmarch tourniquet both on account of the lack of rubber and the fewness of assistants in the field hospitals.

In 1908, Momburg introduced his adaptation of the Esmarch bandage for the control of bleeding in the lower half of the body. The Momburg belt was quickly adopted by obstetricians as a help in the graver cases of postpartum hemorrhage. Sigwart, Hoehne, v. Reding, Fromme, Schestopal, Gogoberidze, Weber, van Erps, and others reported favorable results, Sigwart going so far as to recommend that midwives equip themselves with the necessary rubber tubing. On the other hand, according to Fleischer, Rielander noted circulatory disturbances and collapse after its use, and Riemann and Pagenstecher other untoward effects. Döderlein was able to collect from the literature seven deaths due to its use.

When the World War broke out, Gauss was engaged on the problem of compressing the abdominal aorta without exerting pressure upon other abdominal structures, and devised an apparatus for that purpose. In the meantime, Sehrt had extended the principle of his metal tourniquet to the abdominal aorta and developed an instrument that Gauss himself says is better than his, in that it is lighter and can be applied more quickly. In the last two years, there has been a great deal of favorable comment in the German magazines on the use of the metal clamp for compressing the abdomi-

nal aorta. In most cases, when the clamp is properly applied across the body just above the navel so as to occlude the aorta, either partially or totally, the hemorrhage promptly ceases. Gamper, however, reports three cases in which the compression stopped the pulsation in the aorta below the clamp, but not the bleeding from the uterus. He thinks that this was due to a collateral circulation through the ovarian arteries. Becker also reports some failures, but was able to reduce their number by fitting a special pad to the compression plate of the Sehrt instrument. Several patients upon whom the clamp was used have come to autopsy from one cause or another, and in none of them has there been any evidence of damage by the clamp.

There is nothing in the American literature about the clamp except a few abstracts of the German articles. Recent articles upon postpartum hemorrhage by Hornstein and Titus make no mention of the mechanical compression of the aorta for the control of the bleeding. The instrument that I show you tonight had to be imported, and from the difficulty I had in getting it, I would judge that there are few of them in this country.

I have used the instrument in ten cases. The technique is very simple. One locates the pulsating aorta between the recti just above the navel and applies the compression plate over it and compresses the aorta against the backbone until the hemorrhage ceases. The clamp can be left in place for twenty or twenty-five minutes. My patients have complained less of it than of vigorous massage of the uterus. Most of the cases were of only moderate severity, and the bleeding could probably have been controlled by massage of the uterus.

In one case, a difficult forceps delivery, bleeding began immediately after the delivery of the child. Both the mother and child needed my attention at the same time. I stopped the bleeding with the clamp, resuscitated the baby, expressed the placenta, changed gloves, repaired the cervix, and removed the clamp.

In another case, that of a large woman with a big fibroid, the bleeding started two hours after the delivery of the afterbirth. The interne controlled the bleeding partially with the clamp until he could get ready to pack the uterus, and completely stop the bleeding. One other patient was so large that I was un-

\*Read before the Richmond Academy of Medicine and Surgery, January 9, 1923.

able to apply the clamp. Her hemorrhage was controlled by a vaginal pack.

## CERTAIN PHASES OF ARTERIAL HYPERTENSION.\*

By W. W. HERRICK, M. D. New York, N. Y.

As has been well said, rise in blood pressure, either systolic or diastolic, is not a disease: it is a mere symptom. Like other symptoms its causes are multiple: they are also obscure. As in treating of other pathologic states, the etiology of which is unknown, one must fall back upon description of the associated conditions. With respect to hypertension, the more definite of these conditions are:

1. RENAL INSUFFICIENCY: In the majority of instances of nephritis with demonstrable incompetency of the excretory function of the kidney, there is a rise in both systolic and diastolic pressures. When accompanied by persistent increase in Urea N<sub>2</sub> and of Creatinin in the circulating blood, hypertension is usually serious and serious in rough proportion to the extent of the rise in pressure above the normal. Few of these patients who show both hypertension and persistent N<sub>2</sub> retention live more than two years. Occasionally, one sees cases with great retention of nitrogenous products from kidney impairment without concomitant hypertension. Such cases, in my experience, are usually either in the terminal phases of their malady and show evidences in the cardiovascular system of past hypertension, or are the victims of active, and often, terminal infection. It is well to remark, that so firmly fixed in the minds of the profession is the idea that hypertension signifies nephritis, that even yet, despite the mass of evidence to the contrary, it is difficult for many to realize that this is by no means true. To brand every case of hypertension as nephritic is almost as if one branded every instance of chronic fever tuberculous.

2. TOXEMIAS OF PREGNANCY: Hypertension, both systolic and diastolic, characterizes most cases of this baffling condition. The rise

\*Address delivered before the Tri-State Medical Association, High Point, N. C., February 22nd, 1923.

in blood pressure almost always precedes, by days or weeks, any albuminuria, casts, or any retention of urea, uric acid or creatinin in the blood. In fact, hypertension may be the sole evidence of the trouble. This usually declines promptly upon delivery, except when it has previously existed or when it has arisen on a basis of that vascular instability that so often presages hypertension. The kidney involvement, as shown by every known test of renal function, is secondary and usually late. No better instance of the extra renal origin of many cases of hyperpiesia is to be found. No other type of hypertension offers such attractive possibility of contribution toward the solution of the general problem, for no other is so definitely associated with a self limited state that can be controlled and observed in all its phases.

3. **ARTERIOSCLEROSIS:** Arteriosclerosis is more often a sequel than a cause of hypertension and may exist without any rise in blood pressure whatsoever. The association of sclerosis of the larger arteries with cardiac hypertrophy and a high pulse pressure is not infrequent. Cases of this type exhibit high systolic with normal or low diastolic pressures. The stroke volume output of the ventricle appears large. The smaller arteries seem less altered than the large trunks. A plausible explanation of the blood pressure findings is a large stroke volume output on the part of the ventricle into a relatively rigid arterial tree. Such cases are seen most commonly in those well past middle life and are comparatively benign. The high systolic pressure, characteristic of aortic insufficiency, is dependent upon the large stroke volume output of the ventricle, while the low diastolic pressure is largely, if not wholly, due to the relaxation of the peripheral vessels.

4. **THYROID DISTURBANCES:** Many cases of the so-called essential hypertension exhibit signs of excessive activity of the thyroid. Not only is the gland enlarged and its blood supply obviously increased, but tachycardia, increased metabolic rate and pressure of activity may be detected. In frank cases of thyroid toxicosis, the blood pressure is frequently above normal, rarely, however, ranging above 180 systolic.

5. **ESSENTIAL HYPERTENSION:** The importance of differentiating hyperpiesia from nephritis, though stressed by many writers, has

not had sufficient general recognition. It is to this group I would direct detailed attention. In essential hypertension there is entire absence of evidence of renal incompetency, inflammation or degeneration. A certain number, as years go by, develop an arteriosclerotic type of kidney with gradual impairment of function, but by far the larger part find their end stage in cerebral hemorrhage or myocardial insufficiency. Although occasionally found in those who are thin, the average person with essential hypertension is over-weight and inclined also to plethora. Many, in fact, exhibit the *polycythemia hypertonica* with increased hemoglobin, increased number of erythrocytes in the circulating blood, increased ratio of solids and increased blood viscosity. The activity, energy and capacity of these cases has been a matter of remark on the part of many observers. They have been classified with some reason as hyperthyroid cases. Not infrequently they show a heightened basal metabolic rate. In the earliest phases of the malady the blood pressure may be within normal limits excepting an exaggerated response to effort. One can frequently predict the eventual development of hypertension by observing an undue rise in systolic pressure after effort, interest or excitement. The diastolic pressure rises with the systolic and, when the latter exceeds 200 mm., the former tends to be about 100 mm. lower. As Mosenthal<sup>1</sup> has pointed out, rare examples of this condition have a diastolic pressure raised out of proportion to the systolic. In all of these vasoconstrictor phenomena, which supposedly form the background of high diastolic pressures, are prominent.

Arteriosclerosis is a late, but, I believe, almost constant development. It seems to involve primarily the small arteries rather than the large trunks. It can, of course, be best detected by careful ophthalmoscopic examination. Sclerosis of the cerebral, coronary and renal arteries and perhaps we may add those of the pancreas, is the common basis of the slowly evolving symptoms. The process may last for years without hampering the victim, but sooner or later the blow falls. It is of interest that persons of this type are peculiarly resistant to infections.

Laboratory studies in these cases may reveal information of considerable interest and value. Except in the later stages, when extensive

1. Mosenthal, H. O.; Med. Clin. No. Amer., 1139; Jan. 1922.

arteriosclerotic changes have taken place in the kidney, or when myocardial weakness has led to passive congestion, there is no albuminuria and very rarely casts. The phenolsulphone-phthalein test shows a normal output of this dye. The ability of the kidney to pass a concentrated urine is not impaired. Chemical examination of the blood reveals normal figures for creatinin and urea,  $N_2$ . A certain proportion of these individuals have a concentration of uric acid in the blood somewhat above the normal level, ranging from 3.5 to 7. mg. per cent. A considerable number have hyperglycemia—the blood sugar after a twelve hour fast being from .120 to .21 per cent. Many have a renal threshold for glucose above the average normal point at .17 per cent. In consequence, glycosuria is not always a reliable criterion of the state of the carbohydrate metabolism. As chemical studies multiply, I am persuaded that the essential hypertonias will be subdivided into different types. When such subdivision is brought about, I believe an important class will be those showing hyperglycemia. There are certain distinctive characteristics exhibited by this type. Elsewhere they have been classified as prediabetic. With the increase in blood pressure and the heightened concentration of glucose in the blood, one finds as associated features, overweight, plethora and arteriosclerosis. The interrelationships of this complex of symptoms are not without practical significance.

Attention has been called to a reduced tolerance for glucose in many cases with hypertension by O'Hare,<sup>2</sup> Botti,<sup>3</sup> Albertoni<sup>4</sup> and others.

Its cause is an interesting matter of speculation. Neubauer<sup>5</sup> in 1910 suggested that an increase in epinephrin might be the basis of this disturbance. Owing to the absence of any test for the quantitative determination of epinephrin in the circulating blood, this attractive theory remains unproved. The idea of Pierce and Keith<sup>6</sup> that hyperglycemia results because the damaged kidney does not utilize the normal amount of sugar presented to it, would claim more attention in the type of case under consideration, if hyperglycemia did not so often occur in cases without evidence of damage to the kidney. The work of Myers and Killian<sup>7</sup> upon the diastatic activity of the blood may have bearing on the hyperglycemia

of hypertension. These observers found that many "nephritics" have an abnormally high diastatic activity of the blood which they assigned to a probable renal insufficiency. Diastase mobilizes glucose from the glycogen of liver and muscle and, when increased, brings about hyperglycemia. The question as to what constitutes a "nephritic" must first be made clear. O'Hare<sup>8</sup> makes the interesting suggestion that the hyperglycemia of hypertension results from lessened functional efficiency of the pancreas through sclerosis of the pancreatic arteries. The latter theory is extremely plausible in view of the arteriosclerosis that is so inevitable in the later stages of the malady. In my opinion, a still more simple cause of the hyperglycemia of hypertension can be brought forward as applicable to at least some cases. Is it not possible that some are the result of an ill balanced diet with excess of carbohydrate? It has been a routine practice of many to restrict or prohibit protein in all cases showing high blood pressure without regard to the state of the kidneys. The excuse for this practice has been that traditionally hypertension has carried with it the idea of nephritis. Since the amount of fat one can take comfortably is limited, withdrawal of protein leads directly to increase in carbohydrate. An ill balanced ration with excessive carbohydrate brings in its train a certain tendency to overstrain of the pancreas and to obesity and a debatable tendency to flabbiness of tissue and to arteriosclerosis with circulatory insufficiency.

Is there any proof of an association of arteriosclerosis and hyperglycemia? I know of no experimental proof but on clinical grounds there is strong argument favoring such a view. In diabetes mellitus, even in the young, arteriosclerosis is almost a constant finding. There is no reason, at least in juvenile diabetes, to believe that the arteriosclerosis precedes the diabetes; rather does it appear to be a result of the prolonged metabolic disturbance of which hyperglycemia is the most obvious evidence. My own study of a group of hypertonias of middle age with hyperglycemia has led to an opinion that they all exhibit more arteriosclerosis than their years and their hypertension would seem to demand,

 8. O'Hare, Loc. Cit.

There is another avenue of inquiry. In cases in which hyperglycemia has been present, what is the effect upon arteriosclerosis of reducing the blood sugar to a normal level and keeping it there? In cases of diabetes mellitus we know that the effect of the maintenance of the blood sugar at a normal level upon the arteriosclerotic complications, such as gangrene and retinitis, is generally a happy one. My own study of a number of examples of hypertension with hyperglycemia has led to the finding that in a very considerable number,—not in all—the restoration of the blood sugar to an average normal level is accompanied by an appreciable fall in blood pressure and lessening of the symptoms of circulatory strain. In such a result, to be sure, the abolition of hyperglycemia is not the sole factor. Almost without exception these patients are overweight: diet that reduces glycemia reduces weight, and reduction in weight, as Rose<sup>9</sup> and others have shown, frequently reduces blood pressure. With such loss in weight, there are doubtless other factors, such as lessened volume of circulating fluid and decreased metabolism. The factors of rest, of release from business or domestic cares, which make data on blood pressure under institutional conditions so unreliable, do not obtain in these cases, since results were had in ambulatory patients going about their ordinary concerns. The literature dealing with the blood pressure of diabetes mellitus has been studied by Rosenbloom<sup>10</sup> who adds observations on 140 cases. From this material one can conclude that there is no change in blood pressure in the average case, but that in milder forms in stout elderly people, especially with evidence of chronic nephritis, or of arteriosclerosis, there is frequently hypertension.

It is certain that cases of severe diabetes mellitus, particularly in the young, are most prone to exhibit a low blood pressure. In the diabetes of late life, however, hypertension is very common and with it obesity and arteriosclerosis with their consequences. As Mosenthal<sup>11</sup> has suggested there are different types of diabetes. The diabetes of early life seems based upon profound functional disturbance or the results of infection; that of later life, upon the consequence of degenerative changes in structure, perhaps in the main, arteriosclerotic. This complex of hyperglycemia, obesity,

hypertension and arteriosclerosis is one of the most important of later life, for in it lie seeds of early decay. The early discovery of tendencies toward this complex is within the capacity of any clinician with adequate laboratory equipment and means much to the intelligent patient willing to co-operate in attempting to ward off the consequences of neglect or of ill advised treatment.

**TREATMENT:** In the management of essential hypertension much can be accomplished by education of the patient. Not infrequently, therapy is a problem in psychology. It is characteristic of patients with this malady to carry on under pressure. They work hard, and, if they play at all, play hard. They are those who get things done. Much of their energy is wasted in the mobilization of all their forces for trifles. One who always works "on his nerve" is laying the foundation of chronic vascular spasm that means eventual established hypertension. For such the explanation of this danger, the change in attitude toward the daily tasks, the cultivation of an equal mind, the avoidance of unnecessary expenditure of nervous and physical energy; these are all important.

**REST:** The influence of rest upon high blood pressure is well known and has been chiefly studied by Mosenthal.<sup>12</sup> Within a few minutes of relaxation, both systolic and diastolic pressures begin to fall; the drop in systolic pressure being much greater than that in the diastolic. If the rest is prolonged for several days, a still greater fall in pressure is had, but always the decline in diastolic pressure lags behind that of the systolic. Exceptional cases are little influenced. After resuming activity, the blood pressure tends to regain its former level but often some time elapses before this occurs. A period of rest and relaxation in the middle of each day is favorable. The growing habit of afternoon tea has much to recommend it. In cases exhibiting signs of cardiovascular strain—imminent or declared—the enforcement of a rest day once a week is of the greatest benefit. This may be spent in bed, or if the latter is irksome, in the quiet of a library or other environment, from which the ordinary irritations are excluded.

**EXERCISE:** Exercise, if well within the limits of circulatory capacity, lowers blood pressure. Strenuous forms of competition, such as tennis,

are to be avoided, but golf is ideal. Walking and riding are also of benefit. The effect of mild exercise, after a possible primary slight rise of blood pressure, is vaso-dilatation and a general fall which lasts for some time. The advice that the patient may safely exercise well

within the limits of dyspnoea or of fatigue can be given without hesitation.

Drugs: These are of minor importance. To aid in release from excessive nervous tension, chloral is useful and may be given over long periods without fear of impairment of myo-

cardial efficiency. Occasionally a case will seem to do well with small doses of the iodides, 5 to 10 grains daily. The nitrites are of little use except in the emergencies of the later stages of the disease. A drop of *spiritus glycerini* on the tongue at bedtime may hasten the vasomotor relaxation induced by rest.

**DIET:** Diet may be all important. The physician should be wary of prescribing an abnormal or ill balanced diet unless there is ample reason. Most adults, as most children, do best on a balanced ration. If chemical examination of the blood shows no retention of the products of nitrogenous katabolism, no excess of glucose or of chlorides, and, if survey of renal function exhibits no defects in the capacity of the kidney to excrete nitrogen or salts or glucose, there is no reason for depriving an individual of any important class of food material. Means are at command for adequate chemical control of diet and these should be used. If, under properly controlled conditions, there is excess of nitrogenous crystalloids, or of chlorides, or glucose, the indications are clear.

The question of weight in relation to cardiovascular, renal or pancreatic strain, needs little elaboration. Experienced actuaries are most hesitant in taking risks in those above weight. It has been well said that one should gain weight up to the age of 30; between 30 and 40, he may either gain or lose a little; but that, after 40 he should begin to lose; and, by 55, if he is to live long, should be real thin.

Such a life schedule of weight keeps pace with the average condition of heart, vessels, kidneys and pancreas. These vital organs undoubtedly reach their highest efficiency between 20 and 30. They probably maintain this efficiency but little impaired until 40. After 40 there is a decline, which after 50 may be quite steep. The wise man will adjust his bulk of body to the declining efficiency of the vital organs rather than heap up added burdens. In failure to heed such a simple law, many sow the seeds of arteriosclerosis, of myocardial failure, of diabetes, of hypertension.

The medicine of the future is preventive; curative medicine in most organic diseases is a failure. By the periodic survey, which any well trained practitioner with use of a few modern laboratory methods is competent to make, pathologic tendencies can be detected in their incipiency and often controlled. Such surveys are not the prerogative of any com-

mercialized institution, but should be a part of the routine care of intelligent individuals by the family practitioner or by some one selected by him. Responsible and authoritative opinions are not to be had from any other source. In the symptom quartet, hypertension, obesity, diminished tolerance for carbohydrate, and arteriosclerosis, lurk many of the dangers of middle life; the consequence of which can be postponed or abolished by scientific care.

**SUMMARY:** 1. Rise in either systolic or diastolic blood pressure is a symptom of varied, though unknown etiology.

2. The clinical conditions with which high blood pressure may be associated are: certain types of nephritis, some forms of arteriosclerosis, certain toxemias of pregnancy, examples of hyperthyroidism, of aortic insufficiency and of increased intracranial pressure.

3. A larger group exists independently of other conditions heretofore described. These are classified as the essential hypertonias. As clinical study develops, this group will doubtless be subdivided. Such an attempt is made in the present study.

4. A group characterized by the symptom quartet: hypertension, hyperglycemia, obesity and arteriosclerosis is considered in detail. The relation of these symptoms to faulty diet, particularly to an excessive ration of carbohydrate, seems clear in the cases cited. The importance of reducing the weight of the overweight hypotonias should be stressed.

5. Periodic health surveys should be part of the routine care of individuals by the practitioner. Such surveys are not the prerogative of any commercialized institution.

49 East 53rd Street.

### TRANSFUSION OF BLOOD.\*

By CARRINGTON WILLIAMS, M. D., Richmond, Va.  
Associate in Surgery, Medical College of Virginia.

The transfer of blood from one individual to another has been recognized since the earliest days of medicine as a valuable therapeutic procedure, and attempts to accomplish it have been made since the middle ages. In modern surgery the greatest improvement in technic was made by Crile when he introduced his cannulas for direct anastomosis of an artery of the donor to the vein of the recipient.

\*From the Department of Surgery, Medical College of Virginia.

Read before the Tri-State Medical Association of the Carolinas and Virginia, February, 21, 1923.

This method, or some modification of it, remained in quite general use until about ten years ago, when it was demonstrated that the transfer could be made safely by collecting the blood in a suitable receptacle and introducing it into the recipient before clotting occurred. At about the same time, it was found that anticoagulants could be added to the blood as it was collected, and the transfer made in a more leisurely manner. There has been during this time a vast amount of literature on the subject, written by advocates of many methods, among them Kimpton and Brown, Lindeman, Satterlee and Hooker, Lewisohn, Unger, and others too numerous to mention. These authors described methods which at once established transfusion as a practical and popular procedure. Moss added tremendously to the safety of the procedure by applying blood grouping as a necessary test before the transfusion.

The conception of the blood as an organ of the body should put transfusion of blood in the group of surgical procedures for organ transplantation. Fortunately, we are transplanting a part of an organ easily obtained, easily introduced into the recipient, and easily nourished. This conception of transfusion would seem to give a sounder basis for study of the procedure, and a safer attitude for the practitioner, for it is not devoid of danger, than would classing it with the many modern intravenous medications.

If, therefore, we class transfusion of blood with the transfer of tissue, we must recognize the unsatisfactory state of transplantation surgery, and recognize transfusion as one of its few satisfactory examples. For transplantation of tissue, the patient himself is usually the donor. We have all seen the unsatisfactory results of skin grafting with homografts even after matching the blood group of the recipient, yet autografts are almost always successful. In transfusion of blood, we must necessarily use the homograft except in rare instances, which will be mentioned later.

We know that the life of the red blood cell in the normal individual is quite short, yet the limits of our knowledge do not permit an accurate estimate of this time. Rous,<sup>1</sup> after reviewing the work done by others, concludes that about 1/15 of the total blood volume is destroyed daily; the average life of a cell must therefore be about fifteen days.

We know that introduction of foreign blood

into an individual stimulates certain functions of the blood, as the subcutaneous injection of a small amount of blood for hemorrhage of the newborn, accelerates clotting, and we believe that introduction of larger amounts of foreign blood stimulates the blood producing organs to greater activity. In addition to this stimulating action, however, we must consider the blood transplanted as an active part of the functioning blood. Ashby,<sup>2</sup> at the Mayo Clinic, has demonstrated that transfused cells live longer than the normal "home grown" cells, for she finds from 40 to 50 per cent. of these are present after 28 to 52 days, and some few cells after 100 days. It is safe to assume that cells surviving for this length of time must have had active function. This active blood is particularly important in the secondary anaemias, but it must also play a part in relieving the over-worked bone marrow in cases of pernicious anaemia.

Foreign blood is useful in diseases in which the blood is greatly depleted. It is the treatment of choice in pernicious anaemia. This disease, as is well known, is characterized by remissions at times of long duration, during which, the patient shows startling improvement. It is generally believed that transfusion of blood will initiate these remissions, and thereby prolong the life and usefulness of the patient. Anders<sup>3</sup> reports a typical case in which the red count rose from 720,000 to 2,050,000 after transfusion, and a similar improvement one year later. He collected 450 cases from the literature, 56 per cent. of which were much improved by transfusion. He very rightly warns us to use transfusion only as an adjunct to the usual medical and hygienic treatment of the disease.

In the leukaemias, transfusion seems to do harm rather than good.

In secondary anaemia, transfusion gives brilliant results, particularly where the cause of the anaemia can be corrected. It is not infrequently a life-saving procedure directly, or indirectly, by preparing a patient for a necessary operative procedure. Patients greatly debilitated by malignant disease can be temporarily made more comfortable by addition of blood to their circulation.

Transfusion is frequently necessary in shock, yet we must be extremely careful that we do not add to the shock by using incompatible blood.

In treating sepsis, transfusion of blood from

a donor immunized to the infecting organism has been tried with results no better than when the donor was not so immunized. Polak<sup>5</sup> reports favorable results from frequent small transfusions in puerperal sepsis. In general, however, transfusion does little good in treating septicaemia from other causes.

In the hemorrhagic diseases, the clotting time is shortened by transfusion or by injecting foreign blood under the skin.

The results of transfusion in general are admittedly good; what then are the objections? Aside from the technical difficulties, the dangers of transfusion, while few, are very real:

1. Emboli may be introduced, either air, clots, or small foreign particles. It is my own impression that many of our reactions are due to minute emboli. This danger should be eliminated by careful technic regardless of the method used.

2. Transmission of disease from the donor. This can be obviated by careful selection and examination of the donor.

3. Dilatation of the heart. We can avoid this by careful administration of the blood.

4. Reaction to incompatible blood.

These dangers have been enumerated by Pemberton.<sup>5</sup> The reaction of the patient is the most frequent and most serious danger. It varies in severity and duration. The typical reaction consists of a chill, rapid weak pulse, varying degree of collapse, difficult breathing, nausea and vomiting, and rapid rise in temperature. Severe reactions are usually due to hemolysis of red cells, and are followed by hemoglobinuria. Drinker and Brittingham,<sup>6</sup> after careful observations and experiments, conclude that reactions are due to changes in the red cells, and to some extent in the platelets which occur soon after removal of the blood from the circulation. A severe reaction in a greatly debilitated patient is a terrifying occurrence, and rightly so, for not a few deaths have resulted. Unfortunately, these deaths are usually not reported. Bernheim<sup>7</sup> reports two deaths and knows of four unreported. The author knows of four deaths in the hands of thoroughly trained men. All of these followed transfusion of citrated blood.

Patients who have had repeated transfusions, may develop a sensitization to the blood of a particular donor, or to any donor. In repeated transfusions, it is therefore quite important to repeat direct matching of the bloods for hemolysis and agglutination. Even when

no incompatibility is found by the laboratory, these repeated transfusions should be given carefully, and discontinued if the patient notices any unpleasant symptoms.

In contrast to this type of reaction, we have observed quite a favorable reaction in a number of patients. This reaction consists of a prompt decline of temperature after transfusion in febrile patients. One striking case, was a boy of ten years whose right kidney had been ruptured in an automobile accident. His condition was so serious from loss of blood, that an operation was considered not advisable. The hemoglobin was 12 per cent. with a correspondingly low red count. His temperature ran from 102 to 103 for several days until a transfusion of 500 c.c. of whole blood brought the hemoglobin up to 35 per cent., and the temperature to normal. After a few days, he bled again and the temperature rose, but promptly came down after another transfusion. This cycle was repeated twice again before his condition would permit an operation, which finally was successfully performed. Another case showing a similar favorable reaction, was a woman who had bled to a hemoglobin of 20 per cent. from an incomplete abortion. There was some delay in securing a suitable donor for her, and she ran a temperature from 102 to 104 without evidence of infection, until she was given 500 c.c. of whole blood, when the temperature rapidly became normal. One week later, she again bled freely, and with the bleeding had a rise of temperature. This time a similar transfusion from the same donor gave her a severe chill and sharp rise of temperature followed by a rapid decline to normal and good recovery. No infection was found to account for the fever in these patients. The intimate association of their anaemia and rise in temperature is extremely interesting.

The patient's own blood would be ideal for transfusion, but obviously is rarely available. Grant and Frazier<sup>8</sup> have reported cases where a long bloody operation was anticipated by bleeding the patient, citrating the blood and keeping it in the ice-box until needed. Schweister<sup>9</sup> has reported collecting blood from the abdominal cavity in cases of ruptured ectopic pregnancy, and introducing it into the vein of the patient. He reported one death following such a transfusion. This procedure seems to be quite unscientific, for much of this blood is already clotted, and minute emboli may

easily escape the filters which are available, while collecting and preparing the blood must severely damage the cells. It would appear quite unnecessary also, since Matthews<sup>10</sup> claimed years ago that much of this blood is returned to the circulation by absorption, and Siperstein and Sansby<sup>11</sup> have recently demonstrated that this absorption is probably quite rapid; they suggest the use of intraperitoneal injection of freshly citrated blood. The rapid absorption of saline solution from the peritoneal cavity has been amply demonstrated.

The selection of the donor is extremely important. In the Hospital Division of the Medical College of Virginia, we have a group of "professional" donors from the student body. These young men have been grouped by the method of Moss; the quality of the blood is tested and the Wassermann reaction is done. After typing the recipient, the bloods are matched against each other for hemolysis and agglutination. We do not accept a Group IV as a universal donor, and would use such a donor for another group only in an emergency. Occasionally, by direct matching of patient's and donor's blood, we find a donor unsuitable although in the same group with the patient. We have not had any severe reaction in a donor. Occasionally there is a short period of faintness, but even this is not observed if the donor is kept quiet. We rarely use more than 500 c.c. of blood, and let the donor go home after a few hours. We have used the same donor twice in one week without any unfavorable symptoms.

It is quite important to consider carefully the method to be used. It is safe to say that whole unadulterated blood is the method of choice by the great majority. It has been definitely proven that reactions are much more frequent after use of citrated blood. Bernheim<sup>7</sup> has studied the problem carefully, and says that after the citrate method, we may expect a reaction in 20 per cent. to 40 per cent. of cases, while after whole blood transfusion, there will be about 5 per cent.

It is impossible to give figures on mortality from transfusion, because deaths are rarely reported, but, as noted before, we must remember that no inconsiderable number have occurred. The small percentage of reactions to whole blood transfusion is the brief for this method. Against this, we must consider the ease and simplicity of the citrate method. It can be given by one man without assistance

if necessary, and under any conditions. To successfully transfer whole blood, the patient must be in a hospital and several assistants are needed. Bernheim says that the greatest good for the greatest number will come from the use of sodium citrate transfusion, but advises the use of whole blood where it is possible, and always in greatly debilitated patients. Our practice, in the hospitals of the Medical College of Virginia, is to use whole blood unless the patient is too ill to be moved to the operating room, and then we use citrated blood on account of the ease of administration.

The direct transfer of blood from artery of donor to vein of the patient is now rarely done. In expert hands, it may be satisfactory, yet even then we are ignorant of the amount of blood actually transferred. In view of the considerable technical difficulty of this procedure, and the trauma to the donor, it would seem that the more simple indirect methods should be used. Horsley, Vaughan and Dodson<sup>12</sup> have recently advocated the direct method and reported a number of favorable cases.

In conclusion, the methods used and found satisfactory should be briefly mentioned:

For the transfer of whole blood, we use the syringe-cannula method described by Lindeman<sup>13</sup> ten years ago. His cannulas should be used where it is possible in spite of the moderate difficulty in introducing them into the vein. Not infrequently we have to cut down on the vein in order to insert them, particularly in debilitated patients and in children. The syringes are the standard 20 c.c. Record. These syringes are filled rapidly and transferred to the patient before clotting can occur; they are then washed in three basins of salt solution and are again ready for use. From six to twelve syringes are necessary.

For the citrate method, we use the technic described by Farr and Gilroy,<sup>14</sup> in which the blood is collected in a flask containing the citrate solution. This flask is gently agitated as the blood runs in and is inverted when the blood is introduced into the patient by gravity.

To summarize, we believe that transfusion is of great value in the treatment of chronic anaemia and certain hemorrhagic diseases, and that it is a life-saving measure in acute severe anaemia from bleeding. The method of choice is that which transfers whole blood in the simplest manner with the least trauma to the donor and recipient. The value of the citrate method must be recognized, and it must be

used under certain conditions. Transfusion should be considered as a surgical procedure, and all of the preliminary tests and final technic should be carried out with the greatest care.

### TREATMENT AND PROGNOSIS OF CHRONIC CARDIAC LESIONS.\*

By T. N. DAVIS, M. D., Lynchburg, Va. --

Whatever the cause of cardiac disease, decompensation means failure of the heart's muscle. The treatment, whether aimed at prevention or restoration, should be directed first, to conserve the heart's energy and second, to build up a reserve to meet the varied demands made upon it under the ordinary conditions that a patient experiences; thus, the basic principle of treatment is rest, whether accomplished by avoidance of strain, slowing up of body functions, or digitalis. In the patient with a cardiac lesion already known but whose heart is functioning normally, there are certain rules to follow that he may control his reserve force and steer from decompensation.

We will consider exercise. It is known that careful and well directed exercise accomplishes several favorable ends, but before instituted, the presence of infection must be decided, as nothing would so readily bring on decompensation as the combination of infection and exercise. A leucocytosis and temperature over 99.6° per rectum for several days are clear signs of reinfection; with these findings absolute rest in bed is first and last the only treatment until the above signs are negative. The fact should be emphasized that broken compensation is practically always the direct

result of reinfection of the endocardium with physical strain acting secondarily, lowering the resistance of the myocardium. Having this in mind, how vital it is in our treatment that we remove diseased tonsils and teeth and clean up focal infection wherever apprehended. Without enumerating the usual advantages of muscular exercise, we know that the same physiological laws hold good in the cardiac patient whose compensation is intact; whether we use massage or active and passive motion, the first effect on the heart is increase in its rate, then quickened respiration and rise in the blood pressure; by resistance offered in the peripheral arteries the diastolic pressure is raised and the circulation in the coronary arteries is improved, there is increase of the flow in the coronary arteries out of all proportion to the pressure in them; the heart obtains a richer supply of blood and muscular tone is heightened. Thus by gradual exercise we can build up a reserve, not equal to the possibilities of the normal heart, but sufficient to meet the needs of a modified life. Appearance of the face, rate of respiration, the time it takes the pulse to return to normal are signs that determine the amount of exercise that is necessary. In the beginning, interruptions or rest periods must be frequent and the limit of toleration never approached; the patient should not talk while walking, or walk against the wind; as training improves his condition games without competition can be prescribed. In children a mild supervision of their play acts better than the attempt at repression. Inactivity and a sedentary life may prove as harmful to the patient as his zeal that urges him to reach a former level of activity in work and recreation. When exercise has been instituted it must be regular and frequent.

In impending or actual decompensation get the patient to bed. Orthopnoea may prevent complete dorsal relaxation; here a semi-erect position will be of advantage in gravitating the contents of the blood vessels to the lower extremities; this posture permits the blood to drain from the myocardium. Such grave signs as cyanosis and collapse call for venesection; the withdrawal of as much as thirty ounces will give time for quicker stimulation as ether or caffeine, etc.

Rest alone may be all that is necessary to control symptoms; it gives the heart time to hypertrophy to meet the new situation. Where there is dropsy or anasarca, digitalis will act

\*Read as part of symposium on Chronic Cardiac Lesions at the meeting of the South Piedmont Medical Society in Lynchburg, November 21, 1922.

more quickly when effort is made to eliminate through the bowels; calomel first, then magnesium sulphate, an ounce in black coffee every morning for three days, when digitalis is commenced. I believe it is fairly well comprehended that larger doses of digitalis must be administered; when so given there is a saving of several days in the approach to compensation. The massive dosage advocated by Eggleston is not suitable usage outside the hospital. Remember that ordinarily it takes two to three drops as measured by a medicine dropper or from the bottle to make the official minim of the U. S. P. tincture. Ten minims should be given three or four times a day, until digitalization is attained or signs of heart block—nausea, vomiting, dropped beats—appear. The ventricular rate should be around seventy; other signs of effectiveness of the drug are increase in the output of urine and increase of pulse pressure. After the above has been established, a proper dose to keep up the good result must be continued. The elimination of digitalis or average rate of disappearance from the body is twenty-two minims per day, so that ten minims morning and night can be safely given indefinitely. The patient may find that he cannot be comfortable without a daily dose of digitalis, probably ten minims. It is remarkable how in some cases the cardiac equilibrium is kept by a daily dose, and upset when left off. If digitalis fails to keep the patient comfortable, it may be tried intravenously for several doses; a new hold, so to speak, may be gained, the myocardium once more responding. Subsequently oral administration may be resumed.

Edema if uninfluenced by elimination through the bowels and digitalis medication may be overcome by the administration of theobromin sodio-salicylate. Twenty grains should be given every four hours for four doses the first day; the following day four doses of thirty grs., then stop for several days, when it can be given again if edema accumulates.

Morphine should never be withheld from these patients; it is supreme for the psychic and physical distress, relieving pain and allowing sleep which is the thing most desired. Nitroglycerine can be relied upon to allay lesser symptoms of dyspnoea, anginoid and constrictive sensations in the chest. When the outlook is hopeless on account of absolute ex-

haustion of the heart, morphine and nitroglycerine still relieve until the end.

The Karel treatment, consisting of milk about six ounces every four hours, is an ideal diet when the patient is first seen; it may be reinforced by the addition of milk sugar, a teaspoonful with each feeding, the sugar giving more nutrition and enhancing the diuretic action of the milk. Often the cardiac patient has a renal insufficiency and acidosis may be a factor in the production of dyspnoea. The addition of sodium bicarbonate and milk sugar with the four hour feedings increases the therapeutic value of the treatment. The Karel diet can be given five or six days if of benefit. When a change is decided upon, the choice would be a baked potato replacing one or two feedings of milk. Gradually other articles are added; a small piece of steak or lamb chop and a slice of tomato are particularly appetizing after the milk cure. Salt should not be allowed except what is naturally contained in the food. Diet is next to exercise in importance. A cardiac patient should have small meals, four to five a day, rather than three of the usual size. Over filling of the stomach may be disastrous; a patient should so eat that on arising from the table he is not conscious of his stomach; on the other hand, going a long time without food is equally as bad as over eating. Try to keep the patient ten to fifteen pounds under his former weight.

Prognosis should be based more on the cause and type of heart lesion. In the rheumatic heart the number of attacks and number of valves involved concerns us first; then the age of the patient. Prognosis is better if the patient is beyond twenty-one, as reinfection is less apt to occur. Involvement of the mitral valve-stenosis, the usual lesion of rheumatic endocarditis, while crippling the heart, not necessarily limits a patient's activity. It is possible for him to go on through several decades without symptoms at all; indeed it is only where arterio- or cardio-sclerosis sets in that there are objective symptoms of a heart lesion. Many women pass through pregnancy without their physician aware of this lesion in them. On the whole, though men tolerate valvular defects far better than women, the latter withstand hypertension and cardiac hypertrophy with little inconvenience.

Height and weight should be taken into account. Generally the tall and large person has

not the same prognosis as the small and lean type. This latter individual is almost, sure to live longer.

In the luetic heart which practically is secondary to a luetic aortitis, basing the prognosis on the morbid anatomy,—aneurism with rupture, coronary involvement with occlusion, you can say the outlook is bad. If anticipated, the arteriosclerotic or degenerative type of heart offers a better outlook; unless interrupted by the advent of apoplexy, angina pectoris or nephritis, these patients have few discomforts, except those of encroaching old age.

Prognosis in the hypertrophied heart of chronic nephritis is entirely dependent upon the extent of disease in the kidney. If the heart is normal, with the exception of enlargement, it does not give cause for concern, death usually being due to uremia, or apoplexy the result of rupture of an artery from hypertension. Much can be learned from the response of a heart to rest and digitalis. The result of treatment is in direct proportion to the integrity of the cardiac muscle; when drug and dosage are potent and there is little or no response, the prognosis can be counted poor. Response also to exercise, by the degree of dyspnoea, gives valuable information.

Where foci of infection are discovered concomitant with the heart findings, not only is their removal indicated but the prognosis is usually bettered likewise.

No single symptom or sign that we assume points to an ill functioning heart can enlighten us in regard to termination; the physician should determine prognosis from the signs and symptoms as a whole which is equivalent, practically speaking, to the patient's response to the routine of his daily existence. The one exception to the above statement is the finding of pulsus alternans which is ominous, death occurring generally within two or more years.

### CHRONIC CARDIAC DISEASES—PATHOLOGY AND DIAGNOSIS.\*

By F. C. Rinker, 'A. B., M. D., F. A. C. P., Norfolk, Virginia.

Chronic valvular heart disease is found in general practice to exist in about five per cent. of all cases.

I will attempt to consider first the pathology and diagnosis of the various valvular lesions, confining myself entirely to the heart proper, and lastly, I will take up the general patho-

logical effects of these lesions on the musculature of the heart.

It is frequently argued that careful study of valvular lesions, from the standpoint of differentiation of the various valves affected, is of minor importance and that loss of compensation is the all important feature. While this is true to a certain degree, there are differences in the symptoms and signs of the many lesions and, therefore, differences in the resulting pathology and the prognosis. This should impress upon us the necessity of closely studying each valve lesion.

Let us consider the valvular lesions in the following order:

1. Mitral Stenosis.
2. Mitral Insufficiency.
3. Aortic Stenosis.
4. Aortic Insufficiency.
5. Tricuspid Stenosis.
6. Tricuspid Insufficiency.
7. Pulmonary Stenosis.
8. Pulmonary Insufficiency.

#### I. MITRAL STENOSIS.

*Pathology:* There are three varieties (a) Infections, (b) Arteriosclerotic (c) Congenital.

Of these, the first is the most common. In this type the edges of the mitral valves are roughened by vegetations, the result of endocardial inflammation. In addition, there is thickening of the valves which results in difficulty in closure.

The arteriosclerotic type is met with more commonly in old age and is merely a thickening of the valve leaflets due to the tissue change of age.

The congenital form is rare and may be due to mal-development during fetal life or may be due to hereditary syphilis.

The earliest effect of mitral stenosis is hypertrophy of the left auricle followed by dilatation and finally there is hypertrophy and dilatation of the right ventricle.

*Diagnosis:* There is usually little difficulty in making a diagnosis in cases of mitral stenosis. The thrill and presystolic murmur heard over the precordial area not transmitted are the main diagnostic points. We must always be alert, however, for the murmur is variable as to time; it may be presystolic or it may be heard in diastole, it is *not* transmitted.

Mitral stenosis is to be differentiated from:

1. That of aortic regurgitation.

\*Read as a part of a symposium on Chronic Cardiac Lesions, before the South Piedmont Medical Society, November 21, 1922, Lynchburg, Va.

2. The Graham Steele murmur which is heard over the left third and fourth interspaces.

3. The murmur of pulmonary insufficiency which cannot be differentiated from the Graham Steele murmur.

4. Tricuspid stenosis, a very rare condition.

5. The so-called Austin-Flint murmur heard in some cases of advanced aortic regurgitation.

## II. MITRAL INSUFFICIENCY.

*Pathology:* The post-mortem changes found are; sclerotic, vegetative and ulcerative alterations of the mitral cusps. The left auricle is at first hypertrophied and then dilated and there is dilatation and later hypertrophy of the ventricle.

Mitral regurgitation may also be the result of dilatation of the heart without endocardial disease known as relative insufficiency.

*Diagnosis:* Systolic murmur heard best over the apex of the heart and transmitted to the left axilla and to the angle of the left scapula are diagnostic signs. The murmur may, however, be heard best at the base of the heart in some cases. In addition to these signs there is usually enlargement of the left heart, and a marked accentuation of the second pulmonic sound.

The murmur of mitral regurgitation is seldom mistaken for any other organic heart lesion. It must, however, be differentiated from the hemic murmurs, the functional murmurs due to cardiac position adhesions, etc., and from arteriosclerotic murmurs, heard so frequently at the base of the heart, none of which are transmitted. It must also be distinguished from the cardio-respiratory murmur which is frequently transmitted but is heard only during respiratory excursion. In rare instances acute pericarditis and patent ductus arteriosus offer puzzling differences, but the nearness of these murmurs to the ear and the to-and-fro quality distinguish mitral insufficiency from them.

## III. AORTIC STENOSIS.

*Pathology:* The aortic leaflets are found to be thickened and covered with vegetations or ulcerations; in some instances there are found calcareous deposits in the cusps. The valves feel hard and sclerosed.

The left ventricle first hypertrophies and may later dilate. When dilatation of the left ventricle does occur there results a relative mitral insufficiency.

*Diagnosis:* The region of the base of the heart has been well named "the region of romance." Aortic stenosis is the one organic heart lesion in which the greatest care should be exercised in diagnosis. The murmur is heard best over the second interspace to the right and is transmitted to the vessels of the neck; it is systolic in time and there can usually be felt a thrill over the aortic area. The second aortic sound is feeble or absent, and the left heart is enlarged.

Atheromata of the aorta, pressure on the aorta from mediastinal tumors, hemic murmurs and pulmonary stenosis must be differentiated from aortic stenosis.

To repeat, there are four findings which are requisite as a basis for the diagnosis of aortic stenosis, as follows:

1. A systolic thrill at the base.
2. A slow deliberate pulse.
3. A systolic murmur heard at the second right interspace and transmitted to the vessels of the neck, and
4. A feeble or absent second aortic sound.

## IV. AORTIC REGURGITATION.

*Pathology:* The pathology differs somewhat with the cause. In the syphilitic cases there is an inflammation of the small arteries at the base of the valves and plaques are found on the valves. In the *infectious* cases vegetations are found on the valve edges, and in the *arteriosclerotic* types there is a sclerosis of the cusps. The left ventricle first dilates and then hypertrophies. Aortic insufficiency causes more marked enlargement of the left ventricle than does any other heart lesion.

*Diagnosis:* The diagnosis of aortic insufficiency is usually easily made. In no other cardiac lesion are there as many peripheral vascular signs which aid in the diagnosis as are found in aortic regurgitation. The cardinal points in diagnosis are:

1. A murmur, occurring during diastole, heard best over the second right costal cartilage and transmitted downward and to the left, to the apex of the heart.
2. Marked increase in left cardiac dullness.
3. Peripheral signs: (1) Corrigan's water-hammer pulse, (2) Blood pressure changes in arm and leg, (3) Capillary pulse, (4) Duroziez sign (pistol shot murmur).

This murmur is sometimes taken for mitral stenosis, pulmonary insufficiency, aneurysm, and mediastinal tumors.

*Electrocardiogram* is of value and shows

evidence of left ventricular preponderance of marked degree.

**V. TRICUSPID STENOSIS.** The pathological findings are identical with those found in mitral stenosis affecting the tricuspids.

*Diagnosis:* This valve lesion is rarely recognized except at autopsy.

The region of the heart dullness is increased to the right due to dilatation of the right auricle, sometimes there is a presystolic thrill. There is a short presystolic murmur heard just to the right of the sternum in the fifth interspace.

Mitral stenosis is frequently associated with tricuspid stenosis and it is most difficult to differentiate the two. In the former the murmur is heard loudest about the left nipple region of the chest while in the latter the murmur has its greatest intensity to the right of the sternum and in the mid-sternal region in the neighborhood of the fifth interspace.

**VI. TRICUSPID INSUFFICIENCY.** The pathology is similar to that described under mitral insufficiency.

*Diagnosis:* 1. There is bulging of the precardial region at times. 2. Cyanosis and venous engorgement are present. There is marked venous pulsation. 3. A systolic pulsation can frequently be felt over the right side of the heart. 4. Pulsation of the liver when felt is pathognomonic. 5. Enlargement of cardiac dullness to the right. 6. The electrocardiogram shows right ventricular preponderance.

**VII. PULMONARY STENOSIS:** This lesion is almost always congenital.

*Pathology:* The post-mortem changes are identical with those found in aortic stenosis. Hypertrophy of the right heart occurs and is soon followed by dilatation of the auricle and ventricle.

*Diagnosis:* A systolic thrill felt at the base of the heart, increased cardiac dullness to the right, and a systolic murmur with its maximum intensity heard over the second left interspace close to the sternum constitute the cardinal signs of diagnosis.

Basal heart murmurs should always be carefully studied before making a diagnosis of pulmonary disease because this condition is rare and functional basal cardiac murmurs are frequent.

**VIII. PULMONARY REGURGITATION:** This condition is rare. Up to 1910 Norman Pitt

had been able to collect only ten cases reported in the literature.

*Pathology:* The changes found in the pulmonary cusps are identical to those found in cases of aortic regurgitation.

*Diagnosis:* A diastolic murmur, best heard at or near the left second costal cartilage transmitted downward only slightly with increase in dullness to the right at the base of the heart, is the diagnostic sign.

The absence of left ventricular hypertrophy and the peripheral signs of aortic regurgitation assist in differentiating it from this lesion.

Having considered each valvular lesion of the heart separately, let us now turn our attention to the effects of these various conditions upon the nervous mechanism and musculature of the heart.

To quote Mackenzie: "Unfortunately, most of the changes that occur in the myocardium show no signs or symptoms by which we can recognize them. Nevertheless, there are a number of manifestations which we can refer to the muscle of the heart, such as various irregularities of the heart's action, changes in the size of the organ, and it may be the character of the sounds." (Mackenzie, Sir J., *Lvd.* 1916. 121.)

Definite evidences of these changes may not be demonstrable, but by study of the heart's efficiency we are able to obtain indirect evidence.

The most important pathological conditions arising in the myocardium are dilatation and hypertrophy. These frequently result in irregular action of the heart rhythm.

*Dilatation of the Heart* is manifested by dyspnoea, vomiting, syncope, and the usual decompensating signs of acute cardiac failure.

This condition may result from sudden strain or it may be the result of valvular incompetency occurring particularly early when strain is thrown on a chamber of the heart during diastole, as in aortic regurgitation.

The diagnosis of such a condition is not difficult.

*Hypertrophy of the Heart:* Clinically, this condition renders a more difficult problem than does dilatation. The electrocardiogram furnishes an important means of determining the preponderance or hypertrophy of a given chamber of the heart and renders information valuable from the viewpoint of both therapy and prognosis. For example: In

cases of left ventricular hypertrophy or preponderance there is an inversion of the R-wave in the electrocardiogram in Lead-*three*, and where there is hypertrophy of the right ventricle the electrocardiogram shows inversion of the R-wave in Lead-*one*. Should the auricles be hypertrophied, then the P-wave of the electrocardiogram is of high amplitude and peaked in more than one lead. These conditions cannot be determined definitely by any other means.

*Irregularity in Rhythm*: There are two distinct pathological varieties of irregularities which may occur in the heart: Auricular Fibrillation and Heart Block.

*Auricular Fibrillation* is, as the term implies, a fibrillation of the auricles which beat much more frequently than the ventricles. This is associated with ventricular irregularity. It is due to some alteration or interference with the sino-auricular node or pace maker. The impulses arising in this node are too frequent to be transmitted by the auriculo-ventricular bundle and consequently ventricular irregularity occurs. The auricles do not contract but remain in a state of twitching and act only as reservoirs.

*Heart Block*: The transmission of impulses through the auriculo-ventricular bundle of His may be interrupted by the invasion of disease in the bundle, or in either of the bundle ventricular branches.

Heart block is complete or partial dissociation of His bundle action. The ventricle does not receive the impulse from the pace maker but assumes an impulse and beats independently, slowly and at times irregularly.

One may assume heart block as a diagnosis whenever the heart rate is less than forty beats per minute. The condition, however, frequently exists with a much more rapid pulse rate and can only be definitely determined by the electrocardiogram.

There are other conditions affecting the cardiac rhythm but time does not permit a discussion of them in this paper.

In conclusion, let me urge that whenever possible, in the study of chronic cardiac lesions, all means of precision be used and that a careful consideration be given the efficiency of the heart muscle in each case.

## X-RAY AND RADIUM TREATMENT OF THE INFECTED TONSILS AND ADENOIDS \*

By E. U. WALLERSTEIN, M. D., Richmond, Va.

The subject is one that demands our attention for the tonsil question is one of the most important in our specialty. Daily we are called upon to decide whether tonsils are diseased, their relation to a systemic disorder, and what procedure should be initiated.

At present the standpoint of a large majority of us is that if the tonsil is chronically infected surgical removal is advised, provided there is no grave contra-indication to operation.

A tonsillectomy both from the standpoint of surgical technique and possible complications is a major operation. This idea now obtains in the profession and is gradually being recognized by the laity. Therefore, if there is a non-surgical procedure that will cure infected tonsils it is a most important step forward.

Until recently the other means employed in treating tonsils when tonsillectomy was not done have been tonsillotomy, cauterization, electric desiccation, suction, massage, and topical application of medicaments. These are unscientific from a pathological viewpoint and are rapidly going into disuse.

In studying the effect of X-ray on the susceptibility of experimental animals to cancer it was discovered that cancer could be produced in radiated animals, whereas this was not possible in controls. In seeking for an explanation, it was found that the blood underwent changes: that in the animals treated with X-ray the lymphocytes were markedly decreased in number; and that probably the mononuclear elements of the blood stream bore some relation to cancer immunity.

It was further shown that the roentgen ray has a selective affinity for the lymphoid elements. By properly graduated dosage it was demonstrated that this class of cells could be made to disappear from the blood, leaving the other elements unaffected. This fact was taken advantage of in the treatment of lymphatic leukemia. Based upon these observa-

\*Read before the Richmond Society of Ophthalmology and Oto-Laryngology.

tions, Murphy, Witherbee and others at the Rockefeller Institute determined to apply X-ray to the tonsils.

The tonsil parenchyma consists of lymphoid cells arranged in lymph nodules. The character and number of nodules vary in the different types of tonsils. In the large soft tonsil of simple hypertrophy the number and size of the germinating follicles are increased; whereas in small fibrotic tonsil the lymphoid cells are decreased, due to the encroachment of connective tissue.

In the original article Murphy and Witherbee report forty-six cases of infected tonsils treated by the roentgen ray. They pointed out that lymphoid tissue is the most susceptible to X-ray of all tissues except the sex glands. In this series treatment consisted of a single long exposure to the X-ray in all cases, except one which was more frequently treated. The cases were not selected from any special group as far as age or disease due to infected tonsils. A cure was reported in all but four cases. In general there was a definite decrease in size of the tonsil within two weeks, with a further decrease for one to two months.

In a study of the bacteriology made by cultures of the crypts and naso-pharynx in thirty-six cases, the streptococcus and staphylococcus hemolyticus was found in thirty-two cases. These organisms disappeared within four weeks. The beneficial results of treatment are explained by the authors thus, "It seems probable that the disappearance of infection of the tonsils and changes in the bacteriological flora after X-ray treatment are due to the opening up and proper drainage of the crypts which follow atrophy rather than the actual removal of lymphoid tissue." An advantage is claimed over surgical removal in that X-ray treatment completely removes the lymphoid tissue from the lateral and posterior walls of the pharynx.

The adenoids are inaccessible to X-ray treatment on account of their position. To quote the above article "The adenoid tissue is, as expected, in view of the portal of entry used for the X-rays, not so uniformly reduced as the tonsil. This particular aspect of the problem of reducing excessive lymphoid tissue in the naso-pharynx through X-rays is one to which in the near future especial attention will need to be given."

The objections that there is danger of setting up a parotitis or that neighboring tissues will

be injured is not a real one, according to these authors, as the dosage is no higher than that used in therapy of enlarged glands of the neck.

They draw the conclusion, "The X-ray method of treating chronic focal infections of the throat, namely tonsils and adenoids, is not only safe and permanent but will more thoroughly and completely remove this focal infection than any other method yet devised, surgical or otherwise, and furthermore the contra-indications for operation in no way interfere with this procedure."

Since this original article appeared reporting the results of using a single large dose, Witherbee has changed the dosage. He now advises multiple applications, the average case requiring eight treatments at two weeks intervals.

Waters and his associates at Johns Hopkins conducted an investigation and report less favorable results than Witherbee. The number of cases studied was twenty-one, including ten children. Seven patients were lost sight of and fourteen were studied thoroughly. Treatment consisted of four X-ray exposures, about two a week for two weeks then a rest of two weeks and a second course of four treatments. Anatomically, by actual measurement, the tonsils were reduced in size in all but one case. The clinical symptoms in the cases of the ten children subsided.

Among the cases treated was one of Sydenham's chorea which was much improved and a case of chronic arthritis in a woman of fifty-six was benefited locally and generally. In this case, interestingly enough, the tonsils were not reduced in size and streptococci were still present at the end of treatment.

An interesting case showing the effect of the roentgen-ray on tonsillar tissue was that of a student with acute catarrhal otitis media. X-ray was applied and after the fourth treatment an X-ray dermatitis developed. Twenty-seven days after the fourth treatment, the tonsils were enucleated and examined by the pathologist. The report was "Pathological section of one of the tonsils showed that apparently the germinal centres were not affected by the X-rays but that the lymphoid cells between the germinal centres disappeared and their place was taken by fibroblasts."

The Hopkins group report "forty per cent. successes of which we have no proof of per-

manence." Their attitude towards the present use of X-ray of systemic absorption is as follows; "It will require many cases to determine the effectiveness of roentgenotherapy in removal of chronic focal infection in tonsils that are giving rise to a general constitutional malady, such as arthritis, glomerular nephritis, etc. In view of results as brought out in the section on bacteriology, it would amount to malpractice to resort to X-ray treatment alone when surgical removal might save the patient."

By careful and repeated serial cultures it was shown that the X-ray cannot be relied upon to cause the disappearance of streptococci.

Eight cases were studied bacteriologically of which seven were found to harbor the streptococcus. In three cases the streptococcus persisted weeks after the termination of treatment.

That cultures from the crypts cannot be depended upon was shown by Pilot and Davis who, out of a series showed sixty-one per cent. streptococci by crypt culture. The cases were later operated upon and cultures taken directly from the interior of the enucleated tonsils showed ninety-seven per cent. streptococci. Furthermore, Bloomfield and Davis have shown that a normal individual, if serially cultured, will eventually show the presence of streptococci in the throat. In the summary they state "It is possible when the technique is perfected roentgen ray or radium treatment will entirely supplant surgical measures in children."

Pacini, in the *Journal of Radiology* for April, 1922, states that the roentgen ray alone is not capable of counteracting all types of infection. He divides abnormal tonsils into three groups and gives a different kind of treatment for each. To the first group belongs the simple hypertrophies of children. X-ray alone is advised for this group. The second he terms the immunological active which he would have us treat with X-ray and the violet ray. The third group is the infected, and for this he advises surgical removal.

The obvious objection to this plan of treatment is that it is impossible to correctly determine to which group any one tonsil belongs.

Simpson, in an article in the *VIRGINIA MEDICAL MONTHLY*, November, 1921, advises the conjoint use of X-ray and radium. He con-

cludes, "I am positive that I can cause a complete atrophy and disappearance of any tonsil in one to three treatments."

Withers, in the *Laryngoscope* for March, 1922, advocates the use of radium. He points out that radium has the advantage over the X-ray in that the quantity of radiation is not so variable and that use can be made of the beta rays which have a direct bactericidal effect. Moreover, its use, he claims, has none of the dangers of roentgen-therapy.

At variance with the findings above quoted is that of Lederer of the clinic of Beck at Chicago. He writes, "In no case in our series were there any very marked changes and only in children with typical hypertrophied tonsils have we been able to note even a slight change in size." He reports that the bacterial flora was not changed in the cryptic type and that fibrotic tonsils were not affected. It is further pointed out that often a "dry throat" results from treatment.

Coakley, in the latest edition of his book, says "Radiotherapy has been recently advocated, but from our observations and those of others, it may reduce the size of the tonsil, more or less, yet it has not resulted in freeing the tonsil from harboring pathogenic organisms and the consequent local and constitutional effects thereof."

It will be seen that there is no unanimity of opinion. In fact, views are antipodal, varying from that of some who claim that X-ray is an infallible therapeutic measure of universal application to that of others who believe it valueless.

What then should be our attitude? Granted that the roentgen ray and radium can effect a reduction in size of the tonsil, does the simple reduction of size effect a cure? Granted that streptococci can at times be made to disappear from the crypts, has it not been shown that this does not mean a disappearance of bacteria from the parenchyma of the tonsil?

The adenoids, on account of their location, are not greatly affected by the X-ray. Are they not as important or more important than the tonsil in many cases, especially in children?

Consequently, from the evidence adduced to date, I cannot see any indication for the use of either X-ray or radium in the treatment of tonsils, except in those cases in which operation is contraindicated. In such constitutional diseases as diabetes, advanced pulmonary tu-

berculosis, severe cardiac decompensation, hemophilia, etc., it may possibly be of value but otherwise surgical removal is indicated.

114 North Fifth Street.

### THE BACTERIOPHAGE.\*

By E. C. L. MILLER, M. D., Richmond, Va.  
Professor of Bacteriology, Medical College of Virginia.

As you are all probably aware there has been discovered recently what seems to be a disease which attacks and destroys bacteria. The organisms are too small to be seen with the microscope and will pass through filters which hold back all bacteria. Bacteria attacked by this disease are not only killed but are completely disintegrated or dissolved; hence, the name, bacteriophage from the Greek phagein which means to eat or devour. The organisms seem to be strictly parasitic, growing only in young cultures of bacteria. If a young bouillon culture of bacteria about three or four hours old be inoculated with a suitable bacteriophage, the growth soon ceases and the cloudy bouillon becomes clear. Some of the clear material added to another young culture again causes the bacteria to dissolve and disappear. This sort of transplanting can be continued indefinitely. Already 1500 consecutive transplants have been made and the activity of the bacteriophage tends to increase rather than diminish in spite of the enormous dilution. If such a dissolved culture be greatly diluted and then added to an agar culture heavily inoculated on the surface with the bacteria, certain spots appear on which the bacteria are unable to grow, presumably, because at these points bacteriophages lodge and destroy the bacteria. If one attempts to make subcultures of the bacteria from one of these spots, no growth results; if from a remote area, normal growth results; and if from the edge of the spot, a ragged and irregular growth is produced indicating a mixture of bacteria and bacteriophage. Ordinarily, a bacteriophage attacks only one kind of bacteria though it is possible to train it over gradually to attack another species, especially a closely related species. Bacteriophages seem to be entirely indifferent to oxygen; they act just as well in the absence as in the presence of air.

Such, in a summary way, are the essential facts which have been discovered recently;

now something about what this discovery may signify.

### WHERE IS THE END?

Bacteria have seemed to us right small creatures and if bacteria can have parasites and diseases it reminds us of de Morgan's lines:

"Large fleas have little fleas  
Upon their backs to bite 'em;  
These little fleas have lesser fleas  
And so ad infinitum."

Can this thing go on ad infinitum? Can these parasites of the bacteria in turn have lesser parasites on them? To help answer this question I wish to build a stair-case down into the world of the minute. (See table page 181).

The large protein molecules are probably about one micro-micron in size so that there is only one order between a protein molecule and the limit of the microscope in which this bacteriophage can be placed (0.01) micron. Being only ten times the diameter of a protein molecule it could contain only 1,000 protein molecules or their equivalent. Can life with all of its complex activities be organized out of the equivalent of 1,000 molecules of hemoglobin? Possibly, but this certainly seems to be the minimum and it does not seem possible that this parasite of the bacteria can have a "lesser flea" to bite it.

### IT MAY SIMPLIFY THE STUDY OF FILTRABLE VIRUSES.

As you are well aware, it has been known for several years that many of our common and important diseases are caused by the filtrable viruses, that is by organisms too small to be seen with the microscope. There are about forty of these and among them are measles, scarlet fever, mumps, smallpox, typhus fever, trench fever, acute anterior poliomyelitis and rabies.

Very little progress has been made in the study of these organisms because they can be recognized only by allowing them to produce the disease in animals which is a very slow and unsatisfactory procedure. Here seems to be a similar organism which can be recognized in a few hours by simply adding it to a culture of bacteria. This greatly simplifies the technique and may result in a rapid increase in our knowledge of these creatures.

### IT MAY ASSIST US IN COMBATING PATHOGENIC BACTERIA.

If we have discovered a natural enemy of bacteria, one that can destroy them promptly

and effectively in the body, it may, in time, prove a valuable ally in our fight against disease. It is easy to see that such co-operation between man and the bacteriophage would place the bacteria in a very difficult situation, between two fires, as it were, being obliged to fight, not only the defensive operations of the patient's system, but also this insidious enemy in their own midst. From our standpoint as physicians, it opens the possibility of being able to supply, to the patient, a quantity of these creatures all trained to destroy any particular bacterium that may be trying to injure the patient.

#### IT MAY CONTROL EPIDEMICS.

Very little has been accomplished so far in the direct treatment of disease in man, by bacteriophages, but some progress has been made in studying epidemics among animals. The first bacteriophage found was recovered from the stool of a human patient convalescent from dysentery and it is generally true that the best place to find any particular bacteriophage is the stool of a patient recovering from that disease. A portion of the stool is suspended in salt solution, incubated over night, and filtered to remove all bacteria. The clear filtrate contains the bacteriophage. In an epidemic it frequently happens that no bacteriophage can be found in the early cases; later when the epidemic is on the wane bacteriophages can be found. A few naturally occurring epidemics among animals have been rather carefully studied and the role of the bacteriophage seems to be about as follows: In the healthy animal the bacteriophage seems to be living in a sort of quiescent equilibrium with the host. It may be confined to the intestinal tract or it may be scattered all through the body. When the new bacterium (the cause of the epidemic) invades the animal, the bacteriophages at once begin to adapt themselves to this new germ which has appeared in large numbers. They probably do not help that first case any, but before that case dies, they have acquired some

adaptation to the new germ, they have increased in numbers and they are scattered, along with the epidemic bacteria, to other victims. Here, they again increase in numbers, they become better adapted to the new germ and they are more widely scattered to other members of the community. Thus it comes about that after a time many, or most of the individuals in the community are supplied with bacteriophages able to cope with the new germ and the epidemic dies out. In an epidemic of fowl-typhoid the stools of the sick and dying chickens were examined daily for bacteriophages. At first, none are found that would attack the organism causing the epidemic, but as soon as a virulent one was found the epidemic died out and the survivors then all showed virulent bacteriophages for that bacterium. A number of similar epidemics have been cut short by injecting all the chickens with a bacteriophage virulent for the causative organism.

Some work has been done in protecting the water buffalo from an epidemic disease called "barbone." This is caused by a germ belonging to the hemorrhagic-septicemia group. Several epidemics have been cut short by injecting a bacteriophage virulent for the barbone bacillus. It has also been shown that not only are the buffalo protected against the natural infection, but they have been able to resist an injection of an enormous dose of the bacteria—in fact they have withstood the injection of 1000 times the known fatal dose of the bacteria.

If this work is confirmed, it will provide us with an explanation of why an epidemic stops of its own accord. In the laboratory we know that pathogenic germs tend to increase in virulence when they are passed through a series of animals. From this, we would expect an epidemic to keep getting more and more virulent. As a fact, it does not do so, but quite to the contrary, soon gets less virulent and dies out of its own accord. Even the

world-wide influenza epidemic instead of completely exterminating the human race, as we might have expected it to do, quietly died out or died down to very modest proportions. In the past all we have been able to say in explanation has been that all the susceptible material had been used up; but why one person should be susceptible and another not, we could not say. Now it appears that one was susceptible because he had no bacteriophage to guard him and another was immune because he was equipped with a bacteriophage able to destroy the epidemic organism. If it is correct to call such resistance immunity and if we recall that the bacteriophages are scattered to the members of the community much as are the bacteria, then we can say that one "catches" his immunity in the same sense that he "catches" the disease. Whether he really has the disease or not depends on which he "catches" first.

#### IS IT ALIVE OR NOT?

So far, I have assumed that this bacteriophage is an organized living creature of minute size because that seemed the simplest way to present it. However, it is no more than fair that I should inform you that the scientific world is by no means agreed that it is living. Many of those who have worked with it regard it as an enzyme. Dr. Herrell, who was the first to work with it, and who has done far more than anyone else, is fully convinced that it is living. Most of the American writers consider it an enzyme.

The two strongest points in favor of its being a living organism are its ability to increase indefinitely ( $10^{1500}$ ) and its ability to adapt itself to changes in its environment (adaptation to a new bacterium). In favor of its being an enzyme are first, the fact that in its resistance to certain antiseptics it resembles an enzyme more than any known living organism; second, the fact that similar lytic agents have been found or produced in cultures of bacteria under circumstances which seem to preclude previous contamination. This, of course, means spontaneous generation and it is easier to consider the spontaneous production of an enzyme than it is to consider the spontaneous generation of life; and third, its very small size seems to accord better with an enzyme molecule than with an organized living being. Every one admits that it is capable of perpetuating itself indefinitely and it is rather

difficult to think of an enzyme doing this. We have usually considered self perpetuation as one of the prerogatives of life. However, it may be possible to have a self perpetuating enzyme.

It is rather interesting from a biological standpoint that the scientific world cannot determine whether the thing is living or not.

However, from a practical standpoint, it does not matter. All are agreed that it does the work: it destroys bacteria and it can be trained to destroy any particular kind we desire. Hence, whether alive or not, we should be able in time to utilize its power to destroy our constant enemies—the germs.

#### DENTAL RECLAMATION THROUGH MEDICAL REVOLUTION.\*

By JOHN BELL WILLIAMS, Ph. G., D. D. S., Richmond, Va.  
Professor of Dental Pathology, Medical College of Virginia,  
School of Dentistry.

"I have always thought it a greater happiness to discover a certain method of curing, even the slightest disease, than to accumulate the largest fortune."  
—*Sydenham*.

With the trend toward organized group practice in our hospitals, the necessity for procuring the benefits of dentistry has been so amply displayed that it would appear presumptuous for him whose name is here subscribed to imagine himself capable of adding anything new to so exhausted a subject. This necessity in the treatment of disease is not at this time subject to controversy!<sup>1</sup>

Step by step, dentistry and medicine have developed apart and have come back to the same road from which they both started, amongst the early Egyptians when there were "those practitioners for the eyes, those for the head, some for the teeth, others for the belly and for occult maladies."<sup>2</sup>

According to tradition, dental surgery had its origin with Aesculapins, the god of medicine.<sup>3</sup> Hippocrates invented forceps and other dental instruments and established principles of interdental and inter-maxillary fixation for treating fractures of the maxilla and mandible which are used by modern practitioners. These principles of Hippocrates have stood the test of the ages, being proven anew with each recurring war. Although they strongly opposed bandaging, there are those who still cling to this antediluvian method of extra-oral fixation. One would almost suspect such persons of cher-

\*Read before the Virginia State Dental Association in Richmond, October 19, 1922.

ishing a surreptitious belief in "touching" for "the King's Evil." Aristotle included the mouth in his studies. It may have been for purely personal reasons that the importance of this indispensable factor to politics was perceived, but it was for scientific reasons that his research was pursued. Cornelius Celsus emphasized the danger of the performance of mouth operations by unskilled men. While Galen contributed much to dental knowledge, his error in dubbing the pulp "nerve" remains as a monument to ancient science and as an antiquity to modern science.

Abulcasis, the medieval genius of Arabian surgery, attached great importance to scrupulous mouth hygiene and the early treatment of pyorrhea, while the English representative of this period, John Gaddesden, recommended the application of cow's dung to correct dental disorders.<sup>4</sup> However, we do not consider this seriously, regarding it rather as an Englishman's weakness for advertizing all products of John Bull than as a constructive step in dental history. The greatest surgeon of the middle ages, Guy de Chauliac, was the first to recognize dentistry as a specialty of medicine, but his treatment of the medical offspring thus sent into the world to gain his spurs, was rather of tolerance than serious consideration. Hence, dentistry may be considered the forerunner of the modern tendency toward specialization in medical branches and, up to recent years, has been treated by the parent profession with the condescension bestowed upon dissenters.

During the sixteenth century Fallopius gave to us an account of the dental follicle and Eustachius occupied himself in the study of the teeth writing the first book on their anatomy. Ambrose Paré, the father of modern surgery, acquired his first technical skill from the performance of mouth operations. The layman's attitude toward the profession during this period was anything but complimentary, for Shakespeare designated the dentist as a "tooth drawer" and described his profession as "a kind of unconscionable trade, because his trade was nothing else but to take away those things whereby every man gets his living." An interesting commentator relates that surgeons as "uneducated men and associated with barbers as well as apothecaries were prohibited from practicing physic." Even prior to this Chaucer had not spared the physician and his description is anything but flat-

tering. "The English physician according to the poet was a man addicted to astrology and magic; glib of speech, with abundant assurance; in league with the apothecary to make the most out of his patients; indifferent to religious matters; avaricious to acquire and eager to keep." But these comments are mild, if we may be permitted to use Moliere's comedies as a mirror of the French mind, when he holds the whole medical faculty up to ridicule. While we do not deny his courage, we cannot admire his taste. Regardless of the condition of the medical art at that time, no man should attack a great profession which has always labored conscientiously in the service of humanity. The expression of such a sentiment as "a dead man is but a dead man, and of very little consequence; but professional etiquette neglected does great harm to the whole body of physicians," may have been immensely amusing to the vulgar populace, but immensely abusing to serious thinkers.

Dentistry of the twentieth century is the product of American dentists. The honor of our first dentist goes to New England, but as a consolation we may remind ourselves of the fact that the first American jury sat in Virginia and that this jury had the honor of convicting a "Doctor" (degree unknown) for horse stealing. In 1840 it became necessary for Drs. Hayden and Harris to establish the first dental school in the world when medical schools refused to include dentistry in their curriculum. For some time it was considered a great disadvantage to be thus severed. But "sweet are the uses of adversity" for the far reaching effects of this separation could not be foreseen by these pioneers. From that time the dental profession of America ceased to be held back by the parent profession and has developed as a separate entity far beyond the dentistry in those countries where the medical school has complete dominance. With the slowly revolving years we were coming back on a higher plane to an age of specialization as the age of our infancy among the early Egyptians. Dentistry had either to be rejected as a menace or accepted as a working part of the medical machine.

With the high development of the profession the desirability of hospital affiliation became apparent and dentists were appointed to hospital staffs. The harvest to be gleaned from such an association was soon indicated by the

innovation of ether anesthesia at the Massachusetts General Hospital by Morton in 1846. It is a great source of pride to note that it was in Richmond, Virginia, in 1881 that the American Medical Association met and passed a resolution creating a section on dental and oral surgery.<sup>5</sup> This movement was introduced by S. D. Gross, a luminary of American surgery, and warmly supported by the illustrious Davis.

At the first meeting of this section in 1882, emphasis was laid upon the necessity of establishing chairs on dental diseases in medical schools, to be filled by practicing dentists.<sup>6</sup> This resolution met the same fate as the one passed by the American Medical Association in 1887, providing for those holding the D. D. S. degree to become members.<sup>7</sup> We note in passing that "many are called but few are chosen."

As early as the year 1801, Benjamin Rush reported in his brilliant conclusions the miraculous cure of "rheumatism," "dyspepsia" and other disorders, by the removal of diseased teeth, remarking "I have been made happy by discovering that I have only added to the observation of other physicians in pointing out a relation between the extraction of decayed and diseased teeth and cure of general diseases.<sup>8</sup> And so it appears that the genius of Dr. Rush lent itself as readily to establishing dental reclamation in medicine as his personality lent itself to establishing Thomas Sully's reputation as a painter.

Although physicians and dentists, have builded their history from the same traditions, laws, ethics and a mutual ambition for knowledge and skill to benefit mankind, it was not until the collective influence of the foregoing observations of Rush in 1801, Riggs revolutionary paper in 1875,<sup>9</sup> the report of a committee on rheumatic fever of the British Medical Association in 1889,<sup>10</sup> and William Hunter's indictment in 1910 was assimilated, that the importance of mouth pathology in the diagnosis and treatment of disease was accredited by the medical profession. As a result, and true to man's immemorial custom, there developed within the ranks of both professions a number of faddists, the culmination of whose genius seemed in a fair way to make the twentieth century go down in history as the TOOTHLESS AGE. Arrayed against these were the ultra-conservatives whose motto seemed to be "no harm is done where no hurt

is felt." But the vast majority of both professions held fast to the steady influence of the old while reaching out for inspiration from the new.

From a clinical viewpoint the relationship between ill health and defective teeth was unquestionably demonstrated. But the belief that ill health was the result of the inefficiency of carious teeth in the process of mastication, causing indigestion, and that infectious food and the swallowing of pus was the sole factor, was not compatible with the fact that a healthy gastro-intestinal tract can usually tolerate poorly masticated food and as a rule destroy septic material when swallowed. The soil was tilled for the experiments of Rosenow, Billings and others to show the result of chronic mouth infections being distributed by metastasis to remote organs. Following thereupon, the medical parent began to turn a more tolerant eye upon the disenherited offspring. When a child begins to show intelligence a father straight-way claims it as his own. And so, as "the old order changeth," the birth-right was restored and a common interest recreated. Thus the day when dentistry was judged in terms of gold crowns and false teeth was relegated to the past, and rests in the archives with that era in medicine when calomel was king and blood-letting the anchor of hope.

At the present time hospital dental service has developed to such an amazing degree that some American hospitals require a dental staff of twenty-five persons. A report on dental needs and dental facilities prepared by the service bureau on dispensing and community relations of hospitals of the Americal Hospital Association shows that dental service is either definitely established or well under way in more than one-third of the two hundred and eighty-two general hospitals of the United States. On the basis of this survey and the studies of dental work made in connection with other surveys this report emphasizes:

1. "A dentist competent as a dental diagnostician should be recognized with adequate rank on the staff of the hospital, and should be given the necessary facilities such as access to the X-ray and to beds when necessary.

2. "The primary responsibility of the hospital in dental care is the dental diagnosis of patients whose mouth conditions are involved as a factor in the disease for which the hospital accepted these cases and for whom dental

treatment is necessary in order that the hospital medical and surgical work shall attain satisfactory results. In other words, a hospital cannot carry out adequate diagnosis and treatment without undertaking dental diagnosis and in some instances, dental treatment also.

3. "A routine dental examination of hospital cases should be included as a part of the physical examination."<sup>11</sup>

In accordance with a resolution passed by the American Dental Association with regard to the development of dentistry in the hospitals of each state, the President of the Virginia State Dental Association, requested that a survey be made of the hospitals in Virginia. A letter was sent to sixty-two hospitals with the following questionnaire: "Is there a regularly appointed or permanently employed dentist on your staff? Does he examine the mouths of all patients? If so, to what extent? If not examined by a dentist, are the mouths of all patients? If so, to what extent? What is the extent of this examination?"

Of the hospitals addressed, forty-eight, or 77 per cent replied. This shows a most gratifying interest in dental service on the part of our hospitals. Fifteen hospitals, or 31.2 per cent, reported a dentist on their regular staff. Three hospitals, or 6.2 per cent, advised that they have under consideration the appointment of a staff dentist. A consultant dentist was acclaimed by seven hospitals, or 14.6 per cent. From the preceding conclusions we see that dental service is actually established or recognized as necessary in twenty-five hospitals or 52 per cent of those answering the questionnaire; this being forty per cent of those addressed in Virginia. Comparing our findings with the survey conducted among the larger general hospitals of the United States, it developed that the hospitals of Virginia, though comparatively small and frequently located in rural districts, are keeping pace with the progress of dental advancement. Encouraging as this may seem, the fact remains that in only nine hospitals, or 18.8 per cent, are the mouths of all patients examined by a dentist.

Further observation of the replies shows that in twenty-eight hospitals, or 60.4 per cent, an inspection only is made by a physician followed by a Roentgen ray examination

if deemed necessary. But little mention is made in these reports of a clinical examination or interpretation of the X-ray examination by one trained in mouth diagnosis. From our view point a professional diagnosis cannot be satisfactorily determined except by one so trained, but, of course, every question has two sides. It makes some little difference to the fly, however, which side of the "tanglefoot" he lights on.

The most surprising fact disclosed in this survey is that in this day of highly developed medical science one-fifth of the hospitals recorded apparently do not consider the mouth as a factor in disease since they report no examination at all. This deficiency has been explained by some as due to "the war," but they neglected to make clear whether they referred to the Spanish-American or the Civil War.

The ideal of our hospitals is no longer merely to put the patient back on his feet; to restore the patient to his normal self is the goal. To realize this ideal, the mouth examination is one of the elements from which the complete diagnosis is made.

"Men have found that mastery comes through limitation of field and concentration of interest and effort; coincident, however, with this increasing division of labor, provision must be made for the synthesis of results of special workers into harmonious wholes. For this integrative function, men of wide training and sympathies, with comprehensive grasp, possessing the so-called encyclopedic type of mind, will be needed more than ever before, to sift the essentials from the non-essentials, to arrange, classify and reduce to manageable volume the total results of special workers."<sup>12</sup> At their disposal must be "those practitioners for the eyes, those for the head, some for the teeth, others for the belly and for occult maladies."

### CORRELATION OF DENTISTRY AND THE PRACTICE OF MEDICINE.\*

By MANFRED CALL, M. D., Richmond, Va.  
Dean and Professor of Clinical Medicine, Medical College of Virginia.

The opportunity to appear before an association of the dignity and importance of the Virginia State Dental Association is an honor to be coveted, and I wish to convey to you this acknowledgment of my appreciation of your invitation to read before you a paper on a subject of interest to the allied professions of Medicine and Dentistry.

It would be presumptuous for me, granting that I had the technical knowledge, to attempt to enlighten you on the fundamentals of your own profession; nor can I attempt, as a representative of the medical profession, to bring to you the consensus of opinion on the Correlation of Medical and Dental Practice. While this interdependence has been recognized, in the abstract, for some time, an appreciation of this relationship is now of increasing importance if we are to reach an approximate solution of diagnostic and therapeutic problems that concern both professions; if we are to be reciprocally helpful in developing a broader professional vision, and in acquiring a more comprehensive understanding of the present trend in medical and dental education and practice; and, finally, if we are to realize that the individual and collective efforts of the teacher, the research worker, and the practitioners of medicine and dentistry are proceeding, not in diverging lines, nor yet in parallel lines, but in lines that converge to a

common point and that represent the consummated ideal of both professions, preventive medicine and dentistry.

We can appreciably add to the impetus of this movement by a more wide-spread acceptance of the fact that the knowledge of the one profession is complementary to that of the other and by the utilization of this knowledge in a more detailed and frequent contact of the two professions at the bedside, in the clinic and in open discussions.

I will present some evidence to illustrate the present trend so far as it affects the undergraduate of both professions and in what manner specialization in effort has been the inspiration to progress in both professions. By specialization, I refer to a definite, intelligent, and sustained endeavor by one who, fundamentally grounded in the principles of his profession, preferably with a background of a well ordered and carefully analyzed general experience, has the ability, the aptitude and the enthusiasm to concentrate all of his powers, analytical and constructive, for the more complete understanding of a more or less circumscribed field of medicine or surgery.

Specialization in medicine has existed for a longer period of time than has specialization in dentistry, and this specialization has played a most important role in the extension of medical knowledge. By the operation of individual thought in the laboratory and in the clinic, by scattered observers over long periods of time, has resulted in large part the generalization and collective medical knowledge of today. From the same source we may expect the enlarged knowledge of tomorrow.

Dentistry is following the same cycle, and, like medicine, producing its practitioners, its research workers and its teachers. The last two classes, the research worker and the teacher, definitely link our two professions. The research workers in the two professions are actuated by the same desire, they have the same fundamental training and they are solving very similar problems, for they are primarily concerned in a study of the causation and prevention of disease. The teachers are primarily concerned in the dissemination of the methods adopted by the research workers and the results achieved by the practitioner in the alleviation and cure of disease.

If the practitioner, medical or dental, is to keep in touch with the advanced thought of

\*Read before Virginia State Dental Association in Richmond, October, 18-21, 1922.

his profession, if he is to give to his clientele the benefit of improved diagnostic methods and refined therapeutic procedures, he must establish some contact with the source from which this information continually flows.

My own experience in medical teaching and practice (for 22 years) has naturally led to a crystallization of opinion along this line. Not the least important of these conclusions has been a recognition,

*First*, of the deadening influence that follows a voluntary or involuntary professional isolation in the practice of medicine, whether in the heart of a congested city, or in the sparsely settled country districts;

*Second*, a corollary of the preceding, the stimulating effect of daily contact with fellow workers, and young enthusiasts, and the great benefit to be derived from a critical review of the weekly, monthly, or quarterly; summaries of the achievements of fellow workers, or an account of the origination of researches in new fields;

*Third*, is the necessity for a co-ordination of thought and opinion in the allied realms of general medicine and its specialties: general surgery and its specialties: dentistry and its specialties, in the light of a more illuminating physiology, pathology, bio-chemistry and pharmacology.

If we follow the present trend of the educational movement in Medicine and Dentistry, we must be impressed by the similarity of purpose and identity of expression by the leaders in these great spheres.

For example, Eycleshymer, University of Illinois, in an address on "Liberalization in Medical Education" has this to say: "In human progress there are two fundamental processes which sometimes proceed equally, but usually one or the other is dominant. . . . These two processes are extension and consolidation. In the past medicine was largely restricted to the diseases of mankind. At present she recognizes the ultimate relationship of the diseases of plants and animals to those of mankind. In the near future she must take into consideration the diseases of metals: ultimately her domain will extend over both the organic and the inorganic world. . . . In the growth of knowledge in all of its special fields and great provinces, and, a whole, the same two processes stand forth, specialization and generalization. The vitalizing factors in

these are individual thought and collective thought. Greater men in medicine must come through great liberty in medical education. The practitioner of the future, either general or special, not only must measure up in self reliance, responsibility and judgment to the practitioner of the past, but also must be better trained and more thoroughly imbued with the investigative spirit. Acuteness in observation, precision in experimentation, and caution and judgment in deduction, are the essentials for the interpretation of disease."

Now as a parallel idea the following excerpt is taken from an editorial in one of the dental journals. (*The Dental Cosmos*, Aug., 1922).

"If one were seek for the principal underlying cause of the revolutionary change that has led up to present day dental science and art. . . . the germ theory of disease should rank first in importance. From the light thrown upon the etiology of dental caries by Miller to the present day knowledge of the bacteriopathology of the oral cavity and the causal relation of mouth infection to systemic disease, the science and art of dentistry have experienced a new birth. . . . the objectives of dental practice are primarily vital rather than mechanical. The basis of dentistry is now biologic and its mechanical procedures are not ends in themselves. . . . The training of the latter day dental student must include a practical acquaintance with the broad underlying generalizations of science and the methods of reasoning by which these fundamentals have been evolved. In dental teaching there is needed a curriculum that will be educative as a whole, not merely informative."

If these educational principles are desirable for the undergraduate body, their continued application is essential for us, who have left the doors of our Alma Mater, but who are still students attempting to acquire a much desired post-graduate culture while in the service of a jealous mistress.

Both professions in this State have worthy practitioners and eminent teachers: both professions for their highest development need to produce more research workers. With vocational teachers in our state medical and dental colleges and teaching hospitals, with unlimited laboratory facilities and abundant clinical material, can we not feel reasonably assured that the day is not far distant when our undergraduate and graduate student body

will feel the call to this higher professionalism and, by their efforts, place Virginia schools and the Virginia professions in the forefront of investigative work?

The progress of dental science has been most closely watched and evaluated by your own leaders. The recognition of this progress by the medical profession was fairly sudden and coincident with the demonstration of the importance of oral sepsis.

I do not for a moment minimize the part played by our medical leaders in demonstrating the existence of oral sepsis and its relation to systemic conditions, but I would point out that the reaction of the medical mind, when it had once accepted as a possibility the importance of oral sepsis, varied somewhat, according to its professional age and to the criteria the individual had assumed as necessary to prove the efficacy of any therapeutic procedure. The practical application of this principle of oral sepsis was possible only with the aid of the dental practitioner. Frequently the combination of the two, enthusiastic disciples of new thought, let credulity run away from judgment. In this connection we remember the acceptance by many of the profession of the role allotted the amoeba in the production of pyorrhoea and the brief reign of glory enjoyed by emetine in the treatment of the condition. The sober consideration that followed the shattering of many ill-considered but optimistic prognoses and the realization that multiple foci of infection might exist tended to stabilize the medical and dental enthusiast on this engrossing subject.

The graduate of recent years, well trained in laboratory methods, in the theory of infection and immunity, is better aware of the possibility of multiple foci, other than the mouth, and also of the fact, that while foci of infection may originate and tend to perpetuate systemic disorders, yet, in many cases, secondary intoxication, metabolic rather than infectious, may assume the dominating role and perpetuate a vicious circle. It is in this type of case, for instance hypertrophic arthritis, that great disappointment has followed a failure to obtain relief after the surgical removal of one or more septic foci.

I doubt if there is any one subject on which there is such unanimity of opinion in the two professions, or any subject which has been more thoroughly discussed in all its ramifica-

tions than the subject of oral sepsis. Aside from its manifestations as a frank sepsis, we have had our attention directed to the role it may play in the essential anemias, achylia gastrica, certain forms of insanity, various arthritides, vascular and renal degenerations, and endocrine dyscrasias. The importance of oral prophylaxis and hygiene is so well established that it does not require further mention in this particular paper.

At this time, attention may be focussed not on the teeth as such, but on the mouth and all of its structures, mucous membrane, submucosa, the osseous tissue of the maxillae, the mandible, the teeth and the alveolar structure, the blood and lymph supply, the innervation; the functional ability of the mouth structures and jaw musculature, together with a consideration of developmental anomalies, acquired defects, the effect of traumata and bad habits and the modification in function that accompanies retrogressive tissue changes in the body, however induced, and systemic states as reflected in the mouth.

This enumeration opens a field of far greater dimensions than that of oral sepsis. For the whole, obviously, is greater than any of its parts, no matter how important a fraction may be as compared to the whole. Oral sepsis is concerned with the principles of infection and immunity, with predisposing and active agents, with local and general tissue resistance. This larger field, in addition, is concerned with the findings of embryology, and the application of the principles and teachings of physiology and biochemistry. It emphasizes the interrelation of organ function to organ function as part of a general whole. It calls for as liberal a fundamental training on the part of the dentist as is now given to the medical man.

If it is essential that a physician should have some knowledge of the mouth changes that accompany Addison's disease, primary anemias, arsenic and lead poisoning, the mucous membrane changes of pellagra, purpura, scurvy, the exanthemata, syphilis, parasitic infections and various dermatoses, is it not also necessary that the dentist have an understanding knowledge of these general conditions that give such mouth manifestations?

It can be demonstrated that, even in the absence of infection, mouth conditions can produce systemic states to the point of incapacity.

city. If the early recognition of these clinical possibilities gives the opportunity for a more reasonable prophylaxis, and a less extensive pathology in consequence, should not both professions be on the alert for the early manifestations of such states? Let us illustrate this point by rickets, a deficiency disease in which faulty bone formation may occur with a resulting faulty shape of weight-bearing areas and an insufficient support of structures designed to bear appreciable stresses from the application of varying muscular forces. I venture to say that the physician would be more impressed with the resulting visible bony changes in the extremities and thorax than he would be in the possible bony changes in the head and face with their resulting effect on dentition and mastication.

Cryer in various reviews has presented a study of the developmental changes in the bones of the face and the embryonic relationship of the mucous lining of the mouth, nasal cavities and all the internal surfaces of the face, the teeth and the alveolar process. He points out that at the age of five or six years, forty-eight teeth are in various stages of transition: that with normal development the jaws are in typical relationship the one with the other, and the teeth erupt with typical alignment and occlusion and with typical arches.

With pathologic conditions subsequent to the eruption of the deciduous teeth, structural alterations and misplacement of the permanent teeth may occur with modification in the shape of the jaw, face, maxillary sinuses, and even in the nose and its accessory sinuses. Viewed in this light, rickets has a new significance and abnormal mouth mechanics loom as a potential etiologic factor in diseases of the gastro-intestinal and respiratory tracts.

Disharmony of structure must be associated with disharmony of function. As the salivary and mucous glands arise from the same embryonic tissue as the teeth and the alveolar process, perverted development of the one should leave some impress on the development and functional ability of the other. If then insalivation and mastication are important steps in the digestive cycle, any perversion of form or function may initiate a change in the whole digestive cycle.

Green recognizes this when he states that "Loss of the means of mastication may lead ultimately to partial or complete loss of func-

tion of the glands which furnish certain important digestive hormones." (Medical Diagnosis).

Lorand, in *Old Age Deferred*, speaks of its onset, even before thirty years of age as being "accompanied by loss of the teeth, the gums also are retracted from the teeth, which consequently appear greatly lengthened: later on the teeth become loosened and fall out. This then causes the jaw bone to atrophy, the face becomes sunken and the individual appears many years old. There is a tendency to constipation, nutrition is below normal," etc.

For the maintenance of any function, constant exercise of such a function is essential, and the state of the general vitality of the patient conditions the functional activity of each organ. Glands must receive their normal stimuli: the digestive glands have their chemical hormones, secretory impulses along the nerve paths as well as the physical presence of the food. Inhibition of function, even in the normal organ, may be variously induced.

The function of motility is often of greater importance than the function of secretion. Diminished motility may result in stasis; increased motility in hyperperistalsis and even spastic obstruction. With the former, abnormal fermentation or putrefactive changes may be induced, while in the latter, diarrhoea may result: in the former toxemia and malnutrition, while in the latter is the tendency to diarrhoea and asthenia. The character of the food ingested is determined to a large extent by mouth mechanics: the number of teeth, their occlusion, the sensitiveness of the gums and the peridental tissues.

Cannon, in his "Mechanical Factors of Digestion," gives a summary of what occurs in normal mastication; postulating a normally developed bone and muscular apparatus his reference to the secondary events induced by the initiatory act are of great interest, for from it we can readily deduce that just in proportion as mastication is interfered with, whether by structural alteration or defects, or by painful phenomena associated with the act of mastication or deglutition, the whole cycle of digestion and assimilation may be unfavorably influenced.

"The freedom of movement of the lower jaw permits a wide variety of relations between the upper and lower row of teeth: they can be brought together, separated or pressed

with a sliding motion one row upon the other, either forward and backward or from side to side. The up and down motion is essential to the use of the biting front teeth: the side to side motion is more useful in the later process of chewing: the tongue and cheeks act like the hopper of a mill, and force the food between the grinding facets until it is broken up or torn into fragments of proper size for swallowing.

"The duration of mastication varies with appetite, age, the demands of business, the quantity of food in the mouth, and especially with the nature of the food, whether fluid or gummy, moist or dry, crisp or tough. The amount of mastication given any food is related to the readiness with which a mass is comminuted, insalivated and gathered into a bolus, and is not related to the degree of salivary digestion.

"The effect of the mechanical treatment in the mouth is the production of a semi-fluid mush in which there are likely to be particles of varying size, less than 2 m.m. in diameter. Such comminution must result in an enormous increase in the surface exposed to the action of the digestive enzymes and thereby promote the rapidity of their action. The secretion of saliva, which softens the hard particles in the food and with its ptyalin starts the digestion of starches, is also promoted by the movements of mastication. The pressure exerted in the process of mastication may be surprisingly great. The pressure which the molars are capable of exerting, for example, as determined by a spring dynamometer may be as high as 270 lbs. With a direct thrust the crushing point of cooked meats has been found to vary between fifteen and eighty lbs., of candies between thirty and 110 lbs. and of various kinds of nuts between fifty-five and 170 pounds.

"The voluntary act of chewing has been found to have much significance for the proper initiation of gastric digestion. During mastication substances of pleasant taste are brought in contact with the gustatory organs of the tongue and cheeks and odors released from the separated food rise to the olfactory region of the nose and, through the pleasurable sensations aroused by this stimulation, the gastric juice is reflexly started flowing in preparation for gastric digestion. As has been proved by experiments of Pawlow

and Elkins, this initial 'psychic juice' may be a prime condition for the co-ordination of gastric and intestinal digestive processes.

"Still another remote effect which may result from the chewing of agreeable food is the development in the stomach of a condition of tonic contraction, a state of sustained shortening of the circular muscles, which nicely adapts the capacity of the organ to the contents, whatever the amount swallowed. The peristalsis of the stomach, which churns the food with the gastric juice and pushes the chyme onward into the duodenum, is dependent on the tension developed in the muscular wall as a result of its tonic state. Although these secretory and motor activities of the stomach are not, as we are aware, directly subject to voluntary control, they are capable of being profoundly influenced, favorably or unfavorably, by the character of the experiences, agreeable or disagreeable, that attend the process of mastication."

Is any further evidence needed to indicate the role that mouth mechanics play in the digestive act? Deduction readily indicates the functional changes that may occur and it is a well known fact that functional disorders, perpetuated, finally resolve into true pathologic states. A similar relationship applies to the respiratory tract.

Mouth conditions, aside from oral sepsis, that induce respiratory affections, are operative chiefly in that they produce changes that mechanically impair proper ventilation of the upper air passages, induce mucous membrane changes, lower tissue resistance, conduce to infection, and result in marked irritation of the respiratory bronchial tract with subsequent pathology.

The normal protective mechanism of the lungs is so efficacious that, according to F. Muller, the contents of the alveoli and of the bronchi, even as far as the trachea, are sterile, under physiologic conditions.

That part of the protective mechanism we will consider lies in the area and arrangement of the mucous membrane of the nose. Here we find an enormous area of mucous surface in a relatively small space, due largely to the shape and formation of the turbinate bones, producing approximately one and one-half pints of secretion daily. In normal nasal breathing the air is warmed, filtered and saturated with moisture in its passage through

the nose before it enters the lungs: foreign bodies of small size, dust, soot and bacteria are entangled in the surface mucous: the current of air passing backward is deflected at an angle by the pharyngeal wall with further opportunity for the deposition of foreign particles, and it then enters the lower respiratory tract where the second part of the defensive mechanism becomes operative. Conditions, then, that lead to mouth breathing negative the first part of the protective mechanism of the lungs and thus may induce disease.

In this connection, Cryer states that abnormal deposits of lime salts may prevent the teeth from erupting into their normal positions, fixing the cancellated tissue of the alveolar arch, forcing the tongue back into the pharynx, carrying the soft palate upward and plugging the posterior nares, producing mouth breathing and blocking nasal drainage.

I have been impressed with the number of cases, even in early adult life, that present anatomic nasal changes, not the result of traumatism, and not, necessarily, the result of infection, even though accompanied by infection. I refer to distorted nasal septi, with resulting mucous membrane changes and the conditions that produce mouth breathing.

Dewey states that "the distance between the floor of the nose and the roof of the nose is dependent upon the development of the lateral wall of the nose, the principal part of which is the superior maxillary bone. If any condition arises that interferes with the growth of the superior maxillae, it necessarily will cause a shortening between the floor of the nose and the roof of the nose and the nasal septum, continuing to grow downward, as it meets with resistance from the floor of the nose, will become deflected."

This statement tends to answer the question as to whether the nasal condition is a primary one, or secondary to abnormal mouth development in a certain number of cases, and also to answer the question "Should these patients have been referred in early life to a rhinologist, a pedodontist or an orthodontist?"

The rhinologist would probably have advised a period of watchful waiting, certainly until fifteen years of age, and then, if necessary have adopted an operative rather than a prophylactic procedure. In this connection I can heartily endorse the opinion expressed by Dr. Liles before this Association at its last

meeting, "That it is a duty to be alert to diagnose and treat causes rather than symptoms and that preventive dentistry must start with the child even before the teeth are erupted."

I believe dental consultation should be a routine procedure in early life, even in children supposedly normal.

The relationship of mouth conditions to manifestations on the part of the nervous system is not so apparent, but, when we consider the innervation of the teeth and associated parts by the sensory branches of the fifth cranial nerve and note the relationship of the nuclei of the fifth nerve with those of the sixth to the twelfth cranial inclusive, as well as the ganglionic communications of the fifth nerve, we find an explanation for many of the reflex phenomena originating along some of these branches.

Conditions producing irritation along one small portion of its many branches and subdivisions give varying manifestations in the central nervous system or the organs of special sense—optic, olfactory, auditory—as well as in the gastro-intestinal and respiratory tracts. Among the causes producing such manifestations may be listed, mechanical compression of the nutrient foramina, however induced, impinging on nerve or vessels, shocks from blows upon the mandible or from an abnormal degree of concussion in mastication, chemical irritants, metabolic or bacterial toxins, unerupted or impacted teeth.

The resulting symptoms will vary with the intensity of the exciting cause and the duration of its action and will include vaso-motor, secretory and trophic, as well as painful phenomena, from the mild neuralgias to the severe neuritides.

While the areas of pain reference to the head and face have been worked out for the various teeth such as fronto-nasal, maxillary, mandibular, temporal, mental, naso-labial, and superior laryngeal, the same areas may be involved in diseases of the eye, the nose and its accessory sinuses, and certain thoracic and abdominal viscera supplied by the vagus,—especially the lungs and the stomach. A discriminating judgment and a most careful analysis of the evidence would be called for in establishing the true etiology of such manifestations.

An illustration of a trophic manifestation

from dental irritation is of interest. Le Clercq, in discussing Chronic Gingival Irritation in the etiology of Alopecia Areata, shows that in 105 of his cases it was the sole determining factor: in twenty-five per cent. it was the preponderating factor: and in sixty-five per cent. it was a more or less important factor. The alopecia was limited to the side of the dental lesion, it was characterized by a limited number of areas, generally but one, with two areas as a maximum where only one tooth was involved: it was peculiarly benign and yielded readily upon cessation of the irritation.

The evidence I have presented to stress the analogy in the fundamental training of the medical and dental student: and the points of contact chosen to illustrate the correlation of medical and dental practice could be indefinitely extended.

My own attitude is one of profound respect for the achievements of dentistry and a realization of the fact that dental diagnosis requires for its fullest development, and has produced, men as well trained for the purpose as can be found in any medical or surgical specialty. That in its therapeutic procedures, prophylactic or curative, it calls for the mechanical skill of the artisan and the imagination and perspective of the artist for accomplishment of results necessary, not only for the comfort and appearance of the patient, but for the preservation of most important body functions. And, that until such qualified dental representatives are added to the staffs of all general hospitals, or included in any group of men who offer a complete diagnostic clinic, a most essential factor is lacking in what otherwise might be a complete organization. The practical operation of such dental contact can probably be best worked out by hospital and out-patient organizations. The establishment of such a dental department and the appointment of a chief of such service, with full responsibility for the development of the department, has at once a tremendous educational value on the entire hospital staff.

In a teaching hospital, the qualifications for such a chief should closely parallel those required of the head of a surgical division, including aptitude as a teacher, interest in pedagogic affairs and research, large clinical experience, and general proficiency as a practical dentist. Such a chief should have the authority to nominate to the governing board

all associates and subordinates and should be held personally responsible for the character of their work.

In our own hospital, a private institution, a routine inspection of the mouths of all hospital cases is made by Dr. Guy Harrison, head of the Department of Oral Surgery. He indicates on a special form to be attached to each chart whether or not a complete mouth examination is indicated. The signature of the attending physician on this attached report authorizes or declines such complete examination. This procedure was adopted because many of our cases are from the city in which the institution is located, have their own dental affiliations, and might prefer to have such examination completed by men of their own choice, and at some future time.

In a general hospital, certainly on its charity wards, such a degree of ethical consideration would not as a rule be necessary for obvious reasons.

When the volume of the hospital clinic justifies the service, appointment of dental internes must be considered.

I might say, that, so far as the teaching hospitals of the City of Richmond are concerned, the Memorial and St. Philip's, we are now making a critical survey of each hospital teaching department, its organization, its teaching methods, and its functional efficiency as it pertains to the department as such and also as an integral part of the Medical College. As chairman of its Medical Staff, I feel that a sympathetic and understanding co-operation of this staff with the representatives of the dental faculty will, in the near future, result in a most satisfactory and constructive development along this line, and include in addition an opportunity for the training of the entire nursing corps in essential mouth prophylaxis.

The value of our own staff meetings has been materially enhanced by the presence of our dental confreres. Their discussion of our work, and our discussion of theirs, the exhibition and reviews of cases, has resulted in a better balanced viewpoint that would otherwise be possible, and has been of enormous informative value.

Until all patients, charity or pay, can have the benefit of such talent, and the staffs of all general hospitals are strengthened by the addition of such men, we as a profession have

failed in an obligation to the patient, the institution and ourselves.

*Stuart Circle Hospital.*

### ETHMOIDITIS: DIAGNOSIS AND TREATMENT.\*

By ELBYRNE G. GILL, M. D., Roanoke, Virginia.

Medicine arose out of the primal sympathy of man with man; out of the desire to help those in sorrow, need and sickness. This knowledge must have been brought very strongly to the attention of the Program Committee when they selected this subject for the symposium, for one has to be in practice only a short time to realize that the problem of "Ethmoiditis" is one of the most perplexing and oft times disappointing in the whole category of our specialty.

Before entering into a discussion of the subject, the anatomy of the ethmoidal labyrinth will be briefly reviewed. These cells are present at birth, being hollowed out in the foetus at the third embryonal month and develop simultaneously with the frontal sinns. The latter is but an offshoot from the ethmoid, which forces its way into the diploe of the nasal portion of the frontal bone. Curran has proven that all of the cells are present at birth as well as those which afterward go to form the sphenoid.

The ethmoid labyrinth embraces all that portion lying between the two lateral plates of the orbit. It is composed of two capsules, with a partition between; normally, the cells of the ethmoid labyrinth are contained within the limits of the ethmoidal capsule but, under certain circumstances, they may extend far beyond these boundaries into the frontal, maxillary and sphenoid bones.

We are now brought face to face with the problem of diagnosis. When a patient presents himself (A) for examination with the history of sneezing, loss of sense of smell, dull headache, mouth breathing and bronchial asthma, and a rhinoscopic examination reveals the presence of a nares filled with polyps, the diagnosis is apparent even to the most superficial observer. The treatment is obvious. This type of case is frequently encountered and the results from surgical treatment are universally good when a complete operation has been performed. By a complete operation is meant a

thorough removal of all ethmoidal cells (anterior and posterior).

Now another patient (B) presents himself for examination, giving the history of having a post-nasal discharge particularly annoying in the morning on account of the glue-like secretions which accumulates in the throat and naso-pharynx. Are we dealing with a discharging ethmoid, sphenoid, or maxillary sinus? How can we convince ourselves the ethmoid is the offending sinus? Needle puncture will reveal the contents of the antrum. What a joy and relief it would be to all rhinologists if the sphenoid could be eliminated as readily. We are told that a cotton-tipped applicator introduced into the opening of the sphenoid will disclose the nature of its contained secretions. This statement is easily made but difficult to substantiate.

For making a differential diagnosis, Skillern suggested the following technique: "Introduce a small quantity of powdered methylene blue on a cotton pledget into the sphenoid after thorough cleansing and drying. Into the maxillary sinus, it can be insufflated through a Lichtwitz needle. The patient is instructed not to blow the nose or clear the throat as far as possible until next morning. Then use a large cloth or towel. Comparison of the masses of blown or hawked out secretions will at once show the amount that is tinged with blue and that which is clear of coloring matter, thus giving one reliable data from which to draw a conclusion. If it is shown that the mucosa of the sphenoid or maxillary is secreting a considerable amount, a differential diagnosis between these two can be made by alternating the application of the methylene blue between them." This suggestion is worthy of careful and thorough trial as the sphenoid is a stumbling block to all of us when called upon to say whether it is diseased or not. Even when we have the assistance of a skilled roentgenologist.

After weeks and sometimes months of careful and painstaking treatment of these cases (which usually are patients of prominence), we find that the annoying post-nasal discharge continues. We have satisfied ourselves that the sphenoid, maxillary and frontal are not diseased. What is our next procedure?

We are now presuming that all palliative measures have been exhausted. Should we advise operation on the sinus? This question

\*Read before the Virginia Society of Oto-Laryngology and Ophthalmology at its meeting in Norfolk, November 1, 1922.

can best be answered by individualizing every case. What is best for one patient will not always apply to another. Age, temperament, vocation, all have to be considered. In case an operation is performed, conservation should be the "guiding star." It is better to do too little at first and if necessary do a secondary operation, for if too much is done at first the opportunity may not be given for the second operation.

In the writer's opinion, the operative procedure required for this type of case is a correction of any existing septal deformity and a middle turbinectomy. This will provide ventilation and drainage. We should begin anew our palliative treatments; namely, daily irrigations with saline solutions and suction. If this procedure does not effect a cure after a reasonable time, it is doubtful whether further operative procedure would be justifiable. Vaccine therapy in my hands has been a disappointment and its use has been discontinued.

Having briefly discussed hypothetical cases A and B, let us turn our attention to hypothetical case C, who presents himself for an examination of nose and accessory sinuses at the instance of an ophthalmologist. The patient hasn't any subjective symptoms referable to the nasal sinuses such as existed in cases A and B, but has optic neuritis or some other kindred lesion and the nasal sinuses are suspected as being the etiological factor. The rhinologist is asked to state if the sinuses are the sources of the infection. Rhinoscopic examination reveals a deviated septum which wedges the middle turbinate firmly between the ethmoidal labyrinth and sphenoid. Examination otherwise negative. Shall we report negative nasal findings because pus was not evident and the X-rays negative?

Stark answers this as follows: "From a nasal standpoint we must not expect to find the common symptoms of sinus infection, pus polyps, history of nasal discharge, etc., as we are dealing with a closed sinus; otherwise, we should not have pressure. The deflected septum and middle turbinate tightly pressed against the lateral wall should always be suspected." How shall we now proceed? Advise immediate operation or a more careful search for other foci of infection? Beck says: "I often wonder if in some of these cases it would not be wiser to operate immediately and then

take a Wassermann or other diagnostic measures, because while waiting to make a diagnosis by exclusion the nerve may be irreparably damaged by the swelling. It will be admitted that a latent lues may exist in a non-luetic sinus disease, and many a so-called toxic amblyopia has been treated by withholding tobacco and alcohol and has gone blind while the sinus disease was not taken into consideration, because there was no pus in the nose or the X-ray was negative."

The appropriate treatment would be as in the former case, a submucous resection and a removal of the middle turbinate, as ventilation and aeration will have been established. This statement is well illustrated by the report of the following case, taken from my records:

CASE REPORT: R. G. C., age 35, consulted me November 21, 1920. Occupation, farmer. Gave the following history: Twelve years ago right eye became blind (has been this way ever since). Onset sudden, without any apparent cause. Three years ago left eye became partially blind. Had to give up his work as clerk. Condition remained this way for about six months. Under treatment vision improved to such an extent that he resumed his duties as a clerk. For past three months vision in left eye has been failing rapidly and now only sees fingers at close range. Results of my examination are as follows:

Vision O. U.—Form at close range.

Vision O. D.—Total blindness.

Vision O. S.—Form.

External Examination—O. S. Pupils react to light and accommodation. Cornea, heavy deposits on Descemet's membrane. Tension normal.

Fundus Examination—O. D. Rupture of choroid and retinae in macula region. O. S. Numerous and heavy vitreous opacities. Impossible to see nerve head.

Sinuses—All clear to transillumination.

Nose—Septum deviated to left side coming in contact with middle turbinate. No pus or secretion of any kind present.

Throat—Tonsils cleanly removed.

Ears—O. K. Stereoscopic X-ray plates reveal cells of ethmoid and sphenoid perfectly clear.

This patient has been through the hands of three competent ophthalmologists who had made careful and painstaking search for some

foci of infection. Every test, including Wassermann, was negative. Tonsils had been removed, along with several teeth, with the hope of finding the source of infection, but the vision continued to fail. In spite of the negative X-ray findings of the sinuses and the absence of pus in the nose, I advised opening the ethmoidal labyrinth and the patient like "The drowning man" readily consented. On November 22, 1920, I performed a submucous resection. Middle turbinectomy and opened the ethmoidal labyrinth. Mucoid material was present but no pus. No attempt was made to curette all of the ethmoid cells as ventilation drainage had been established. Also we felt that it was almost a physical impossibility to remove all of the cells as we may cause a spread of the infection or exaggerate it by leaving a mass of macerated tissue. The progressive improvement of the patient's vision reveals the wisdom of the position taken. The patient left the hospital November 25, 1920, and returned to his home in the country. Only medication was iodid pat and nasal spray. On January 15, 1921, (two months after operation), patient's vision was greatly improved. This improvement continued until he returned to my office, May 20, 1921. Vision O. D. Nil. O. S. 20/20-2. Fundus O. D. Same. O. S. Vitreous clear. No opacities.

I mentioned this case for two reasons: first, to show the seriousness of a latent infection of the ethmoidal sinuses, and secondly, what may be accomplished by simply establishing ventilation drainage through removal of the middle turbinate and the correction of the septal deformity.

This patient was seen again September 15, 1922; condition was the same, vision O. S. 20/20-2.

We have touched upon the three types of chronic ethmoiditis which we encounter in our daily routine. No effort has been made to present any one in all of its phases as space and time will not permit, and furthermore it is not so much my desire to present my views as it is to elicit a full discussion from the members of the Society.

There is another type, Acute Suppurative Ethmoiditis, which has not been mentioned. When a patient presents himself for examination giving the history of severe sub-frontal headache, worse in the mornings, nasal discharge, following "cold," one immediately thinks of sinus involvement. Again we are

called upon to say whether we are dealing with a maxillary, frontal or ethmoid. Needle puncture will eliminate or condemn the antrum. A differentiation between frontal sinus empyema and suppuration of the anterior ethmoidal cells is more or less of a rhinological nicety. It is now generally conceded that when frontal sinus cells are involved the ethmoid cells are similarly affected. Since the therapy in both instances is practically the same (daily saline irrigations and suction), further consideration will be useless. If these cases are treated at the onset, fully ninety per cent. will clear up under the above mentioned treatment. In the few cases that do not respond to this mode of therapy, operative interference will be required. All that is necessary in most cases is a fracture of the middle turbinate which provides drainage with the aid of suction.

In the presence of acute suppuration, one should do as little surgical work as possible. A sub-mucous resection, turbinectomy and ethmoidal exenteration is only indicated when there is an invasion of the orbital tissue by the infectious process or symptoms of impending intracranial involvement.

From my brief remarks on this all important subject, one may infer that I shun too readily major surgery on the ethmoid. It is not the major surgery I shun but the major failures it entails. No less an authority than Skillern says, "Operative procedures upon the ethmoid, unless slowly, carefully and systematically carried out, are most apt to spell disappointment, and radical operations upon this structure do not by any means end in radical cures."

#### CONCLUSIONS.

1. Complete exenteration of ethmoidal cells in cases B and C should be the court of last resort.

2. If we will spend as much time and patience treating these cases before operation as we do following the operation, fewer would be necessary, as there is no part of the human anatomy which possesses more recuperative powers than does the nose and its accessory sinuses.

3. Before any operation is done, one should always study carefully stereoscopic X-ray plates of the affected parts. Bacteriological examination of the secretions or pus should be made.

4. If by the presentation of this subject we

will have learned to respect the "virginity" of the ethmoidal labyrinth. it will not have been in vain.

### ETHMOIDITIS.\*

By W. L. MASON, M. D., Richmond, Va.

In reviewing the literature upon this subject one finds very little written in the past few years on ethmoiditis alone, except as it occurs in children. Much work, however, has been done upon it in conjunction with other accessory sinuses in relation to eye disturbances, and it is possibly this phase of it that is being most actively studied today. We already hear criticisms of the unwarranted opening of accessory sinuses in cases of lowered vision due to some cranial condition or undiscovered foci of infection. Thus it behooves us to give these cases particular study, using every means at our disposal to arrive at an accurate diagnosis.

In considering ethmoiditis, it is important to bear in mind the anatomical position of the ethmoid, its relation and proximity to other sinuses, and, when we do, we are at once confronted with the fact that it is almost a matter of impossibility to have an ethmoiditis without some inflammation or suppuration in the adjoining sinus or sinuses. The ethmoid is really more a part of the nose. The inhaled air comes more in contact with it, is warmed and moistened more by it; hence, it is hard to conceive of even an acute coryza without involvement of the ethmoid. In fact, I believe that in every acute catarrhal process of the nasal mucosa all sinuses are more or less involved, because of continuity. Consequently, an ethmoiditis cannot be diagnosed by simply looking up the nose and finding pus, nor can it be said to be clear if not seen. We are all well aware of the fact that the easiest ethmoid condition to diagnose is frequently the hardest to treat.

Involvements of the ethmoid may be acute or chronic, which in turn may be either suppurative or non-suppurative. Skillern, in his book on accessory sinuses of the nose gives the following classification:

1. Acute Catarrhal Inflammation.
2. Acute Suppurative Inflammation.
3. Chronic Catarrhal Inflammation, or Hyperplastic Ethmoiditis.

\*Read before the Virginia Society of Oto-Laryngology and Ophthalmology at its meeting in Norfolk, November 1, 1922.

4. Chronic Suppurative Inflammation.

5. Chronic Catarrhal Inflammation with Suppuration.

I. *Acute Catarrhal Inflammation* occurs more or less with every acute coryza, depending upon the severity of the attack. The mucosa of the uncinat process, bulla and external surface of turbinates become swollen, having the appearance of a myxomatous degeneration with punctiform hemorrhages. The interior of the cells shares in these changes and resolution occurs more slowly than in the general nasal mucosa. This condition may be the result of irritation alone.

II. *Acute Purulent Inflammation* is unusually associated with acute frontal sinus empyema; if arising idiopathically, it may be traced to one of the infectious diseases. Resolution occurs more readily than in other sinuses on account of the relatively good drainage of each cell, together with the action of the cilia. In this form of ethmoiditis the mucous membrane is deep red and covered with thick purulent secretion and is directly due to micro-organismal invasion. In general, it may be compared to a particularly severe cold in the head.

In absolute occlusion of the nares, headache is constant with occasional neuralgic outshoots toward the deeper structures of the eyes. Ocular symptoms are prominent, such as pain on rotating, epiphora, orbital neuralgia on reading or otherwise concentrating the gaze. Anosmia is marked as long as nasal obstruction exists. Each attack predisposes toward another, leaving the disintegration of the mucosa more marked until a condition of chronicity develops, together with a marked tendency toward catching cold. Therefore, it is wise during the interim between attacks to make a comprehensive examination of this region with the view of ascertaining and correcting the cause.

III. *Chronic Catarrhal Inflammation, or Hyperplastic Ethmoiditis* is a result more of protracted disturbance in the nutrition of the ethmoid capsule than of inflammatory changes with bacterial invasion. Mechanical causes would seem to be pre-eminent. Continual slight irritation of a certain portion of the mucosa causes at first hyperaemia with subsequent out-flowing of serum into the interstitial spaces of the connective tissue. If the irritation be mild, the hypertrophy will tend to spread itself over a broad area, gradually los-

ing its polypoid character. If, however, it be great, the continual collection of serous elements, assisted by gravity, will soon cause the appearance of a true mucous polyp.

In the early stages of hyperplastic ethmoiditis, a condition resembling chronic coryza predominates; later on in the disease, headache above and below the eyes, radiating towards the temples, is a predominating symptom. The exudate is of a thin watery consistency, assuming a purulent character during attacks of acute coryza.

The most common bronchial affection is asthma, while granular hyperplastic pharyngitis as well as eustachian catarrh may be classed as concomitant affections.

IV. *Chronic Suppurative Inflammation* occurs in two forms: (1) open or manifest empyema: (2) closed in on latent empyema. In the first instance the purulent secretions forming in the cells escape through the ostia and appear in the nose, while in the latent variety some occlusion prevents the pus from escaping, so that it gradually is secreted under pressure until it bursts or is evacuated by artificial means.

Suppuration in the ethmoid cells usually is an accompaniment of empyema in one of the larger cavities. Acute infectious diseases seem to exert a peculiar influence toward ethmoidal suppuration. The condition is invariably due to bacterial invasion of the secretions and is distinctly purulent with a tendency to drying and forming crista not only in the nares but in the pharynx and even the larynx. The headache in these cases, when free drainage exists, is frequently nil, while in the closed in variety it is sometimes unbearable, occurring over the root of the nose and directly on the vertex. Deep seated pain in the eyes is not present unless stagnation and pressure occur.

V. *Chronic Catarrhal Inflammation with Suppuration.* This classification has found considerable opposition, most observers contending that the suppuration precedes and does not follow polypoid hypertrophies. It has been an old and accepted view that the constant drainage of purulent secretions over a given area of nasal mucosa gives rise to polyposis, and therefore these hyperplastic structures are the results of secondary irritation due to the outflow of secretion; while occasional dissertation was made, it was not until Uffenorde states that the suppuration was more

often secondary to the polyposis that interest was given this thought. He re-assures us as follows: From repeated attacks of simple catarrh numerous polyps made their appearance until a greater portion of the nasal chamber was occluded, and the possibility of cleansing was so seriously interfered with that the continually forming secretions became stagnated between the polyps, putrefaction followed, and infection resulted, particularly during an attack of acute coryza. It might be added that most writers do not accept Uffenorde's view in entirety, but believe nasal polyps, under certain circumstances, result entirely from the irritation of the purulent secretions exuded from diseased sinuses.

#### REPORT OF CASE OF ETHMOID ABSCESS WITH RUPTURE INTO ORBIT.

Colored male, age 30, seen in October of 1921. Past history with reference to any sinus or eye trouble negative. There was marked displacement of eye forward and to the right. Pupil dilated and vision reduced to light perception. Movements of eye-ball extremely limited. Conjunctiva markedly swollen. Nerve atrophied. Through upper lid to inner side was a small sinus which discharged an almost constant drip of thick creamy yellow pus. Examination of nose in that side showed mucous membrane so much swollen that chamber was entirely blocked to respiration. Patient stated that trouble followed an attack of grippe, through which he suffered terrific headache and did not send for doctor until eye began to bulge and pain became unbearable.

I removed a portion of mid-turbinate the day he was brought in, establishing drainage by nasal route. One week later swelling of interior of nose was much reduced and eye had receded. At this time, I enlarged opening into ethmoid and cleaned out considerable thick cheesy substance. Small curved probe passed through opening in lid could be seen in nose. Ethmoid cavity was swabbed daily with two per cent iodine in glycerine solution and, at end of three weeks, discharge through lid was only intermittent, and at end of six weeks had stopped and opening closed. The eye on the affected side is blind due to atrophy of nerve and, while mucous membrane of nose at the end of two months was still somewhat thick, there was no excessive amount of drainage and sense of smell very little affected.

*Stuart Circle Hospital.*

## A CASE OF COMPLETE HETEROTAXIA WITH ELECTROCARDIOGRAPHIC AND X-RAY STUDIES.\*

By W. E. KILLINGER, A. B., M. D., Victoria, Va.

In reviewing the literature on the transposition of the viscera, we find that the cases are classified into four groups depending on the character and the amount of transposition.

GROUP 1.—Complete heterotaxia in which all the organs are transposed. This misplacement is more frequently found than any of the conditions mentioned in the following groups. It is not necessarily associated with any defective organ, or any symptoms referable to the changed position. The five cases recently reported by Willius, had no complaint traceable to the abnormality.

GROUP 2.—Dextrocardia; or incomplete heterotaxia, in which the heart alone is transposed.

By recalling the embryological development of the heart, we can readily understand how transposition of this organ occurs. The two primitive cardiac tubes fuse into one about the fifteenth day, and auricular, ventricular, and bulbar subdivisions become evident. The tube soon becomes bent on itself which determines largely the axis of the heart. In congenital dextrocardia the tube bends in the opposite way instead of the normal S manner. Abbott explains this position by assuming that the embryo lies in an abnormal position within the chorion, so that its right side instead of its left side lies closer to the blood supply. Dextrocardia with the other organs normally placed is a relatively rare condition and, while the heart may be perfectly developed itself, according to Parsons and Smith the resulting disability may be serious. The liver and right lung impede the cardiac movements and hence result in incompetence. Smith state that patients with this anomaly are likely to complain of pain both locally and referred, which is the result of pressure on the intercostal nerve, the vagus, or its intercardiac endings. Later, there is a tendency for dyspnea and faintness to appear.

GROUP 3.—Incomplete heterotaxia in which all the organs except the heart are transposed.

This condition is very rare or, perhaps better, the condition is rarely recognized, as we do not have a displaced heart to lead us to

suspect transposition of the other organs. One case has been reported in recent literature by Royer and Wilson. However, the normally placed heart in their case showed transposition of the auricles, a rudimentary left ventricle, and a patent foramen ovale. The patient died at the end of six years.

GROUP 4.—Heterotaxia, complete or incomplete, with or without cardiac misplacement, associated with various congenital lesions of the heart and great vessels.

A good example of this is the case reported by Nanages in the *Anatomical Record* for 1920-21. In this case the patient only lived four days. There were only three cardiac chambers, the right and left auricles, and a considerably enlarged ventricle. What should have been considered the trunk of the pulmonary artery with its prominent anterior position and left upward course, was really the ascending group of the aorta with its wide communication to the single ventricle. The real pulmonary artery was poorly developed and found on the left anterior side of the aortic trunk, and apparently continuous with the base of the ventricle. We find many cases of mono-ventricular hearts reported, especially among the Philippino babies, in whom it apparently is not so very rare.

The case of complete heterotaxia reported in this paper belongs to the first group mentioned and came under my observation while making an electrocardiographic study.

### REPORT OF CASE.

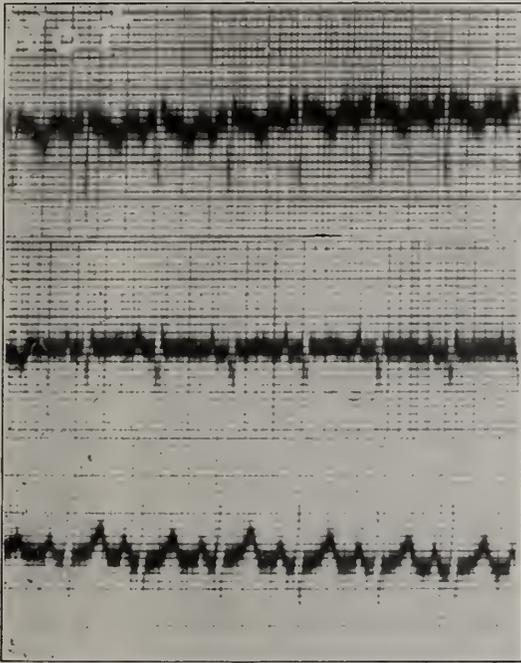

Female, white, age 14, referred to Kendig Hospital Clinic by Dr. W. J. Ozlin, for electrocardiographic examination. Family history revealed nothing important, she being one of six healthy children. She was a full time baby, normal delivery. Had measles, mumps and chicken-pox in infancy; since then has been in good health until one year ago when she began to suffer with a slight shortness of breath, and a persistent cough. Has lost some weight in past year.

She is slightly under-nourished, skin and mucous membranes good color, no cyanosis nor oedema, slight acne over back. Head of normal contour, and no tenderness over the sinuses or mastoids. Eyes and nose negative. Teeth in poor condition, tonsils cryptic, and injected. Neck is rather long but showed nothing of note. The chest was normal in contour, rather marked supraclavicular retraction,

\*Read at the meeting of the Southside Virginia Medical Association at South Hill, Va., December 12, 1922.

equal in expansion. The lungs were negative to palpation and percussion, but a few rales were audible over the hilus of the left lung, posteriorly.

At rest the cardiac impulse was not visible, but after a little exercise the apex beat was clearly visible in the fifth interspace on the right side. By palpation and percussion the apex was definitely located in the fifth right interspace two c.m. outside the mid-clavicular line. The left border of the heart corresponded to the left border of the sternum. In the fourth interspace the right border of cardiac dullness was ten c.m. to the right of the sternum. A slight systolic murmur was heard over the apex; the other sounds were of normal quality.

Complete inversion of all deflections in Lead I. Simple tachycardia. Occasional ventricular premature contraction not shown in this plate.

Examination of the abdomen revealed the hepatic sign on the left side. The spleen could not be palpated, nor splenic dullness definitely made out. However, as we know, this is a difficult task in a normal subject, unless there is an enlarged spleen.

The extremities and reflexes were negative.

Blood and urine examinations showed nothing abnormal.

Roentgenograms of the chest revealed a clear cut dextrocardia. The barium meal showed the stomach on the right, with the pylorus

pointing toward the left, also the shaded area of the liver to the left, with the sigmoid colon on the right.

Electrocardiographic studies revealed a complete inversion of all the waves in lead I, a simple tachycardia, and an occasional ventricular premature contraction.

The child has always been right handed.

#### COMMENT.

Transposition of the viscera is reported much more frequently now than formerly. This is not necessarily due to a more careful physical examination, but rather to the extensive use of the X-ray and electrocardiograph in examination. Where formerly the cases were found by the pathologist and the anatomist, now they are recognized by the clinician. Again due to life insurance, and public health examinations, many more people are examined by the physician than a few years ago.

The complete types of heterotaxy are not easily overlooked, it is the incomplete types that are apt to escape our recognition. In both types dextrocardia is almost the rule, and its discovery directs attention to the possibility of transposition of the abdominal organs, as was the experience in the case reported. Congenital misplacement of the heart is rare compared to acquired displacement, and the X-ray and electrocardiograph must be used to diagnose correctly. The most frequent cause for an acquired displacement of the heart is gross lesions in the respiratory tract, and these can usually be demonstrated. Schussler reports a case of acquired dextrocardia in a girl eleven years old. When the girl was two years old she contracted a severe pleural pneumonia, which was followed by extensive pleuritic adhesions in the right thoracic cavity. The heart was pulled over by these tough adhesions. And in the case reported by Carnot and Friedel, the acquired dextrocardia was due to the presence of a megacolon, which also displaced the liver and spleen.

Transposition of the abdominal viscera alone offers much difficulty without the aid of the X-ray. The left sided liver may be mistaken for a splenic enlargement, such as occurs in leukemia, Banti's disease, and other pathological conditions. In fact, Nadger reports a case in the *Indian Journal of Medicine*, that was treated for some time as a case of Banti's disease, until it was found that the left-sided mass felt was not the spleen, but the liver.

Again, Tanner reports a case in the *Long Island Medical Journal*, that was operated for a left salpingitis, and revealed a transposed viscera with a gangrenous appendix.

Labdeau, the French internist, suggests that these cases of transposition of the abdominal organs are not so rare as generally supposed. Their causes are not so easily explained as a simple dextrocardia. In the embryo the two gastric curves are situated on the same vertical medial plain and the two halves of the stomach are arranged symmetrically. Later the stomach is twisted in a manner so that its posterior border, the larger curvature, becomes convex and bulges toward the left, while the anterior border is concave and is turned to the right. This torsion causes the right part of the small intestine to be carried to the right. The various parts of the mesentery which attach the various segments of the intestinal tract to the vertebral column are more or less elongated. This explains the inversion of those portions of the intestinal tract that arise from the entoderm. The adnexa organs of the entodermic tube, the lungs, larynx, and trachea, the liver, and pancreas, are also changed; this would explain the sinistral position of the liver. In these cases the right lung has two lobes while the left has three.

With the introduction of the electrocardiograph, studies on congenital and acquired dextrocardia were begun. In 1911 Nicholai reported two cases of congenital dextrocardia in which the electrocardiogram showed a complete inversion of all the waves in lead I. Hoke reported the same findings a little later. Owen in 1912 reported a case of complete transposition of the viscera with the electrocardiographic studies made by Lewis, who states that the cardiograph offers a ready and certain method of diagnosing transposition of the heart.

If in the normal subject we take lead I from the left arm to the right arm, instead of from the right to the left as we usually do, an inverted picture will be obtained similar to that found in dextrocardia. This inverted picture applies to lead I alone, according to Lewis, because it is the only symmetrical lead. Acquired dextrocardia never gives the completely inverted electrocardiograms found in congenital dextrocardia.

Willius reports cardiographic studies in three patients in whom transposition was present. In the first patient there was complete

inversion of lead I and II. In the second and third patients there was inversion only in lead I. He explains that the inversion of lead II in the first case was due to the exaggerated inclination of the heart to the right. Willius states that inversion of the deflection in lead I is definite evidence of congenital dextrocardia, and that his experience confirms the value of the electrocardiogram in the differential diagnosis of cardiac displacement.

Calvin Smith reports a case in which the long axis of the heart pointed toward the right side, and yet the electrocardiograms were normal. In this case, however, the dextrocardia was the result of dextroversion rather than inversion of the heart due to abnormal embryonic development. The striking differences in the electrocardiographic studies of congenital dextrocardia are easily understood when it is remembered that there exist two forms of this condition. In the one form the heart is not transposed, but rotated on its vertical axis, from left to right, as a result of a persistence of the embryonic stage, in which the apex was formed by the right half of the common ventricle. In this form the cardiograph shows no inversion of the waves in lead I. In the second one, represented by my case, transposition mirror picture rather than rotation is present.

It is in this form that the electrocardiogram shows inversion of all the waves in lead I. So we must conclude that the electrocardiogram affords the best method of differentiating the acquired displacement from the congenital misplacement, as well as the two types of dextrocardia from each other, while, of course, the X-ray gives a clear-cut picture of the abdominal organs.

### THE PHYSICIAN AND THE QUACK.\*

By J. E. RAWLS, A. B., M. D., F. A. C. S., Suffolk, Va.  
Senior Surgeon to Lakeview Hospital.

Perhaps there are some present who would think that an apology would be in order to read a paper entitled "The Physician and the Quack," but not so. The subject of "the true orthodox physician and quackery" has not only interested each member and the medical societies of our profession, but the public at large. This relation or concern that exists between the Physician and Quack on the one side, and the laity or the public on the other, engendered

\*Read before the Southside Virginia Medical Association at its meeting in Norfolk, June 13, 1922.

the paper's caption and the comments therein.

Members of the profession and the medical associations have been concerned greatly, and especially of late, as to the rapid spread of quackism. The remedy for this evil has been earnestly sought and at times apparently found, but so far the remedy or medicine has not had the desired effect, as the pandemic of quackery continues to spread. So we would like to take up this subject for a few moments under the following heads:

- 1st. The Physician and the Public as it is.
- 2nd. The Quack and the Public as it is.
- 3rd. The Physician and the Public as it should be.—The Remedy.

#### THE PHYSICIAN AND THE PUBLIC AS IT IS.

1st. The Physician is looked upon by the public as in the profession primarily for a livelihood, regardless of the arguments to the contrary. Verbal argument does not change the public mind.

2nd. The Physician is looked upon by the laity as a person to cure the sick, and the physician, as a rule by silence or otherwise, encourages this primarily, and his friends ignorantly advertise him as such, and his worth is in proportion to the number of his supposed cures.

3rd. The Physician is looked upon by the public for obvious reasons as a competitor with his brother physician, and with the quack.

#### THE QUACK AND THE PUBLIC AS IT IS.

1st. The Quack is looked upon by the public as in his profession primarily for a livelihood—regardless of the argument to the contrary. Verbal argument does not change the public mind.

2nd. The Quack is looked upon by the laity as a person to cure the sick. He encourages this by word and act, and his friends ignorantly advertise him as such, and his worth is in proportion to the number of his supposed cures.

3rd. The Quack is looked upon by the public as a competitor with his brother quack, and with the true physician.

If the foregoing be true, then the public so far has seen no difference between the physician and the quack. Then the question would naturally arise, why should the public not license and patronize the quack and call him doctor. And the public does all three, regardless of legislature and law. Why? Because of an improper relation between the Public and

our Profession. This brings us to our third heading:

#### THE PHYSICIAN AND THE PUBLIC AS IT SHOULD BE. THE REMEDY.

The true relation of Physician and Public can only be brought about by a process of proper education, that we may know each other better.

1st. The Profession should be properly educated.

2nd. The Public should be properly educated. The physician should be better educated in the way of diagnosis. He should not only be able to recognize diseases of a definite visible or macroscopic pathology, but also diseases of an invisible, microscopic or psychopathic pathology.

We, as a profession, have become accustomed, since John Hunter's time, to think of diseases in terms of definite gross pathology. Symptoms without a definite gross pathology existed above the eyes of the patient. We diagnose such symptoms as essential, idiopathic, pseudo-bilious, neurotic, "hipped," hysterical, hypochondriac and the like. These terms are used in the presence of the patient with an air of wisdom, but in reality are dump heaps of professional laziness or ignorance.

Such a diagnosis, as nervousness, "hipped" and hysteria, feeds the quack, and we find that he is growing fat at our expense and humiliation. The physician usually loses interest after thoroughly examining a patient, when he is unable to find any definite pathology to account for the symptoms. This loss of interest is quickly observed by the patient and the patient begins to lose interest in the doctor. Finally, the patient asks the doctor what is his or her trouble. In reply he with a Solomonic air uses a few technical terms and ends by saying "nervousness or hysteria." These terms mean to the patient that the doctor's interpretation of her trouble is imaginary—she is faking. What happens? "The parting of the ways." In a few days she consults the quack. The physician sent him a patient. The quack through mental suggestion or otherwise relieves the patient of her symptoms. The patient is grateful and tells her friends: in a short while the quack's office and pockets are filled, and then we as a profession get busy with our legislature and medical societies in an attempt to prevent the influx of patients to the quack,—but still they go.

We are glad to see some of our profession, in the form of the psychiatrist, recognizing diseased entities without a definite gross pathology, and cures or relief brought about without grease and pills. In recent months we have seen quite a number of articles in medical journals and some books written on "Psychoanalysis," which is a sign that the profession is beginning to recognize diseases not based on gross pathology.

Psychopathology is a specialty within itself. We cannot all become experts in this line, but we should recognize psychopathic patients and, if unable to relieve them, they should be referred to some reputable expert. In this way the charlatan will be robbed of his gold and silver, and the patient and public will rise to a higher level of knowledge and respect as to the real worth and mission of our profession.

Our profession in a general way should become acquainted with the vices and virtues (if there be any) of the various popular methods used by the various charlatans or quacks. We cannot meet their supposed cures and popularity by negation. The public will not swallow negatives, abuses and prosecutions. We can only meet this by a knowledge of what the quack can do and cannot do. *The way to conquer evil is by fairness and by the truth.* To do this, we, as a profession, must be in possession of the facts, and the public must come to know these facts or truths either directly or indirectly.

The profession must conquer patent medicine by a similar process—by a process of truth and not by the method of negation. Our profession should become acquainted with the ingredients of patent medicine formulae and their therapeutic value, and give this information to the public either directly or indirectly, as occasion demands. Treat the virtues and vices of the patent medicines with absolute fairness, and this will appeal to the public, and will not appeal to the patent medicine man. *Truth throws on light, and light banishes the halo of mystery that shrouds the average patent medicine formula.* The quack and patent medicine man do not want us to use the method of truth and fairness, but want us to use the method of negation, abuse and threats. *Why? Because the process of truth turns on light and dries him up, while the negative and abusive method advertises him, and darkness prevails and he grows fat.*

*One of the greatest paying advertisements for the quack is the average physician. We discount and abuse him to the public with negations. Just what the quacks want—it pays. Allow the most insignificant, unknown, incapable physician in a city to get in a controversy with and be abused by one of the leading and most competent physicians of that city and it would immediately bring him into the lime-light—would give him prominence. This method of quack advertisement, we, as a profession, should wisely avoid.*

We have considered some of the information the profession should know. Now we will consider some knowledge the public should know.

*The public should know the true mission of our profession.*

*They should know the true mission of the physician is an educator and not a pill-roller.* The mission of the physician is to educate patient and public as to the laws governing physical health and happiness. The old proverb "an ounce of prevention is worth a pound of cure" should be reinterpreted in its true significance. The laity should look upon the physician as a consultant, as an advisor and a friend and a father against diseases, rather than mysterious and all-wise person to cure diseases. The first attitude strikes at the very cause while the latter strikes at the the effect. The first is more effective and this is where we should spend our time and the public should know it.

*The charlatans or quacks do not spend their energy in the human prevention of diseases but are only known by their so-called cures and fees.*

The subject of cure has always been more or less shrouded in mystery so far as the public is concerned, and our profession has done very little toward clarifying or unveiling this mystery. As a result, the public's estimate of the real value of a "doctor," whether a true physician or quack, is in proportion to the number of so-called cures. The quack takes advantage of this in his advertisements, and we fear that many of our profession are stained with the same vain-glory.

*The public should know that a great number of diseases are self limited and that they terminate of their own accord, regardless of physician or medicine.* They should be taught that such diseases as measles, and the like, run a definite course, and terminate at a definite time, whether at such a time paregoric or dish-

*water is given, or whether it is administered by Dr. A or Dr. B.*

This false idea as to the cure of diseases has given us many remedies in the profession, and has not stopped here, but has fattened the patent medicine man.

The true doctor should teach the patient and public that the true physician's mission is primarily to prevent diseases, and then to pilot the patient through the storms of his disease, giving aid in the way of medicine as indicated until its course has terminated. The public should know that there is no "typhoid medicine," no "pneumonia medicine" and the like. They should know that specifics are few in number.

We must cease to mystify the medical art. Mysticism has served its purpose. It has made many of us appear wise when we were mostly otherwise. It has done more. Through this mystery and ignorance on the part of the public, quacks and patent medicines have sprung up and flourished.

Let us turn on the light of truth, and quackery and its remedies will gradually shrink. Let the public know that we, as a profession are broadminded, and possess, or are willing to possess, all known truth, so far as remedial agents are concerned, and are willing to compete fairly and in the open with any professional sect, cult or creed. Even the devil can be conquered by truth.

## Proceedings of Societies

### The Piedmont (Va.) Medical Society

Met at The University of Virginia Hospital, Saturday May 26th, with a registered attendance of thirty-eight physicians.

Among the cases shown at the clinical demonstrations was one of Multiple Exostosis, by Dr. I. A. Bigger; Osteitis Fibrosa Cystica, Dr. S. H. Watts; Endocarditis, Dr. H. B. Mulholland; Some Common Eye Diseases, by Dr. R. F. Compton; Types of Paralysis Due to Syphilis, by Dr. D. C. Smith; Rectal Examination in Prostatic Obstruction, by Dr. J. H. Neff; Pernicious Anemia; Pneumonia Simulating Typhoid, by Dr. J. S. Davis.

After the banquet, Dr. J. C. Flippin read a paper entitled "Some Types of Purpura with Report of Cases," and Dr. W. H. Goodwin one on "Syphilis of the Bones."

Election of officers for the ensuing year was as follows: President, Dr. E. D. Davis, of Standardville; Vice-Presidents, Dr. J. F. Thaxton, Tye River and Dr. M. L. Rea, Charlottesville, Va.; Secretary-Treasurer, Dr. Lewis Holladay, (re elected) Orange, Va. The next meeting will be held in Charlottesville the last Saturday in November.

LEWIS HOLLADAY, *Secretary.*

### The Accomack (Va.) Medical Society

Held a meeting in Onley, Va., May the 3rd. This was the first meeting of the Society since 1919 and was a most enthusiastic one. There were eighteen members and several visitors in attendance. In the absence of the president, Dr. W. F. Kellam, Onley, the meeting was called to order by Dr. W. W. Kerns, of Bloxom. Dr. J. Fred Edmonds, Accomack, was elected a member, and Dr. John O. Gaston, recently elected County Health Officer, and Miss Sarah Crosley, County Nurse, were elected to honorary membership. Talks were given by Dr. Gaston, Mr. A. H. Straus, of the State Board of Health, Richmond, Dr. Geo. C. Payne, recently elected State Epidemiologist of Virginia, and several others.

Dr. J. L. DeCormis, Accomack, was elected president, Dr. W. M. Burwell, Chincoteague, vice-president, and Dr. John W. Robertson, Onancock, secretary-treasurer.

### The Medical Society of Virginia, Maryland District of Columbia

Held its spring meeting May 16, at Manor Club, near Norbeck, Md., with members of the Montgomery County (Md.) Medical Society as hosts. The papers were of a high type and most interesting. The following officers were elected for the ensuing year: President, Dr. William J. Mallory, Washington, D. C.; vice-president, Dr. Jacob W. Bird, Sandy Spring, Md.; recording secretary, Dr. W. T. Davis; corresponding secretary, Dr. Joseph D. Rogers; treasurer, Dr. Robert Scott Lamb. The last three are of Washington, D. C., and were re-elected. Arrangements for this meeting were in charge of Drs. Joseph D. Rogers, of Washington, and J. W. Bird, of Sandy Spring, Md.

### The Graduate Nurses' Association of the State of Virginia and the State League of Nursing Education have Annual Meetings.

The Graduate Nurses' Association held their annual meeting in Richmond, May 23 and 24,

Miss L. L. Odom, of Sarah Leigh Clinic, Norfolk, presiding. The sessions were interesting and largely attended. One of the interesting matters brought up for attention at this meeting was the endorsement of resolutions for the establishment of a chair of nursing at the University of Virginia, in connection with the University Hospital. While no action was taken other than endorsement of the resolutions, the nurses are already making plans for raising the \$50,000 it is estimated such a chair will cost. Miss L. L. Odom, of Norfolk, was re-elected president; Miss Marie Baptiste, Richmond, and Miss Mary Cowling, Lynchburg, vice-presidents; Miss Blanche Webb, Norfolk, secretary; Miss Margaret Cowling, University of Virginia, treasurer; and Misses Agnes Randolph and Elizabeth Webb, Richmond, directors.

Miss Virginia Thacker, of Lewis Gale Hospital, Roanoke, was president of the State League of Nursing Education, which held its meetings on the evening of the 24th and morning of the 25th. At the closing session of the League, Miss Martha Baylor, of St. Luke's Hospital, Richmond, was elected president for the coming year.

#### **The Southwestern Virginia Medical Society**

Held its semi-annual meeting in Christiansburg, May 17 and 18, under the presidency of Dr. R. H. Woolling, of Pulaski. The program was most interesting. Fourteen new members were received at this time. The next meeting is to be held in Abingdon, September 19 and 20. Dr. E. G. Gill, Roanoke, is secretary of this Society.

#### **The Medical Association of The Valley of Virginia**

Met in Winchester, May 31, under the presidency of Dr. Hunter H. McGuire, of that place. Dr. Alex. F. Robertson, Jr., Staunton, was in his accustomed place as secretary. Dr. George Stragnell, of New York City, was an out-of-State visitor at this meeting, and read a paper on "Psychology in Medicine." There were fifty members and one visitor in attendance. Eight new members were elected. The next meeting is to be held at Staunton, in September, 1923.

#### **Walter Reed Medical Society.**

The Spring meeting of this Society was held at Hampton, Va., May 2 and 3, at which time

a most interesting program was enjoyed by those in attendance. Col. Louis A. Thompson, Hampton, was elected president; Dr. Harry D. Howe, Hampton, vice-president, and Dr. L. E. Stubbs, Newport News, was re-elected secretary-treasurer.

#### **State Society News.**

GOLF TOURNAMENT BEING ARRANGED TO BE PARTICIPATED IN BY MEMBERS OF THE MEDICAL SOCIETY OF VIRGINIA UPON FIRST DAY OF MEETING.

The Committee of Roanoke Academy of Medicine has completed the formulation of plans for a Golf Tournament to be held on the opening day of the meeting, and with this in view notices have been sent to the Secretaries of the different local organizations throughout the State requesting lists of such members as may be interested, and already replies have been received from twenty-four members who hope to participate.

The contest will be for a cup which will be presented by the Roanoke Academy of Medicine and will be over thirty-six holes. It will be announced later as to whether the awarding of the cup shall be for the one contest or whether it will be of more interest to plan this over a three year period. The handicaps are being worked out and will be reported in detail at a later date.

The Committee wishes to make it clearly understood that the schedule will not in any way interfere with the scientific program for the reason that the tournament will begin on the morning of Tuesday the 16th and will be completed in plenty of time for the opening session in the evening.

The railroad schedules fit in very nicely for those in different sections of the State who are unable to leave home until Monday evening since sleeper accommodations can be had from various directions so that members may arrive here on the early trains of Tuesday. Further details of the contest will be announced later and it is hoped that the tournament may be an enjoyable feature of the meeting.

J. W. PRESTON,  
*Chairman Publicity Committee.*

ROANOKE HOTELS AND THEIR RATES FOR THE MEETING OF THE MEDICAL SOCIETY OF VIRGINIA.

Chairman of the Hotel Committee, Dr. E.

G. Gill, announces the names of the following hotels in Roanoke and the rates they will give for our convention. He suggests that the members make their reservations direct with the hotel managers, and that they make these at an early date. If there is any trouble, however, write the Hotel Committee, Dr. E. G. Gill, MacBain Building, Roanoke, chairman.

**Hotel Roanoke,**

Single rooms without bath ----\$1.50 and \$2.00  
 Single rooms with bath -----\$3.00 and \$4.00  
 Double rooms with bath -----\$5.00 and \$6.00  
 Double rooms without bath ---\$3.50 and \$4.50

**Shenandoah Hotel,**

Single room with bath -----\$2.00 and \$3.00  
 Single room without bath -----\$1.50 and \$2.00  
 Double rooms without bath ----\$2.50  
 Double rooms with bath -----\$3.00 and \$4.00

**Ponce de Leon Hotel,**

Single rooms with bath -----\$3.00  
 Single rooms without bath ----\$2.00  
 Double rooms without bath ---\$2.50  
 Double rooms with bath -----\$4.00

**Lenox Hotel,**

Single rooms with bath -----\$2.00  
 Double rooms without bath ----\$4.00

**Raleigh Hotel,**

Single rooms without bath ----\$1.25 and \$1.50  
 Single rooms with bath -----\$2.50 and \$3.50  
 Double rooms with bath -----\$3.00  
 Double rooms without bath ---\$2.50

Tablets Neutral Acriflavine—Abbott, 0.03 Gm. (½ Gr.)  
 Enteric Coated Tablets Neutral Arciflavine—Abbott, 0.03 Gm. (½ Gr.)  
 Hynson, Wescott & Dunning  
 Phenoltetrachlorophthalein—H. W. & D.  
 Ampules Phenoltetrachlorophthalein—H. W. & D.  
 Mallinckrodt Chemical Works  
 Carbon Tetrachloride Medicinal—M. C. W. Merck & Co.  
 Skiabaryt (for Rectal Use)—Merck.  
 Skiabaryt (for Oral Use)—Merck.  
 Powers-Weightman-Rosengarten Co.  
 Carbon Tetrachloride C. P.—P. W. R.  
 Nonproprietary Articles  
 Neutral Acriflavine  
 Carbon Tetrachloride Medicinal.

NEW AND NON-OFFICIAL REMEDIES.

Tincture No. 111 Digitalis—P. D. & Co.—A fat-free tincture of digitalis which, standardized by the minimum lethal dose frog heart method of Hough-ton, is 50 per cent. stronger than tincture of digitalis—U. S. P. The actions and uses of tincture No. 111 digitalis—P. D. & Co., are the same as those of tincture of digitalis. It was introduced at a time when the "fat" of digitalis was believed to cause gastric disturbances. This claim of superiority is not tenable and the preparation is sold simply as a standardized tincture of digitalis. To minimize deterioration through light and air, the preparation is marketed in one ounce amber vials and saturated with carbon dioxide. Parke, Davis & Co., Detroit, Mich. (Jour. A. M. A., April 7, 1923, p. 1003).

Borcherdt's Malt, Cod Liver Oil and Iron Iodide.—Each 100 Cc. contains ferrous iodide 0.88 Gm. (4 grains per fluidounce), cod liver oil, 25 Cc. and Borcherdt's malt extract (plain) 75 Cc. Borcherdt's Malt Extract Co., Chicago. (Jour. A. M. A., April 21, 1923, p. 1143).

Carbon Tetrachloride Medicinal.—Carbon Tetrachloride has narcotic and anesthetic properties somewhat similar to those of chloroform. It has recently come into use as a vermifuge in the treatment of hookworm disease. It also removes some intestinal parasites other than the hookworm. It is reported that usually about 95 per cent. of the hookworms are removed by the first dose. Its use appears to be relatively safe, but serious symptoms and even death have been reported. It is administered in water, milk or gelatin capsules on an empty stomach, followed by a purgative dose of magnesium sulphate.

The dose is from 2 Cc. to 3 Cc. (30 to 45 minims) for adults. Carbon tetrachloride is a heavy liquid, having an odor somewhat like that of chloroform. It is almost tasteless and almost insoluble in water.

Carbon Tetrachloride Medicinal—M. C. W.—A brand of Carbon Tetrachloride Medicinal—N. N. R. Mallinckrodt Chemical Works, St. Louis.

Carbon Tetrachloride C. P.—P. W. R.—A brand of Carbon Tetrachloride Medicinal—N. N. R. Powers-Weightman-Rosengarten Co., Philadelphia. (Jour. A. M. A. April 21, 1923, p. 1143).

Modified Pneumococcus Vaccine.—A vaccine or "antigen" prepared by digesting a suspension of pneumococci, types I, II, III and Group 4 at 37 C., until about 95 per cent. of the organisms have become gram-negative and the mixture is relatively nontoxic to guinea pigs. It is believed that this method yields a vaccine with greater protective power. There is some evidence that this vaccine is of value in the treatment of lobar pneumonia. It is not intended for prophylactic use.

Pneumococcus Antigen—Lilly.—A modified pneumo-

## Miscellaneous

### THE OLD TIME COUNTRY DOCTOR.

Gone is the old time country doctor.

You see him now no more.

With many other old time folk,

He's pass'd to another shore.

Don't you recall the faithful nag

He rode o'er hill and dale?

The saddle bags, too, that always held

The pills that never did fail?

None were so poor, but he would go,

No matter where, nor when.

And we may surely safely say,

He was loved by all good men.

If there's a home across the stream

For saints immortal fair,

That good, old country doctor then,

Is in his home and happy there!

—Edward Madison Jones.

## The Truth About Medicine

During April the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Non-official Remedies:

Abbott Laboratories

Neutral Acriflavine—Abbott

coccus vaccine—N. N. R. It is marketed in 5 Cc. vials, each Cc. containing twenty billion partially autolyzed pneumococci. Eli Lilly & Co., Indianapolis, Ind. (Jour. A. M. A., April 21, 1923, p. 1143).

Sulpharsphenamine-Squibb.—A brand of sulpharsphenamine—N. N. R. (See Jour. A. M. A., March 31, 1923, p. 919). It is supplied in ampules containing respectively, 0.1 Gm., 0.2 Gm., 0.3 Gm., 0.4 Gm., 0.5 Gm. and 0.6 Gm. E. R. Squibb & Sons, New York City. (Jour. A. M. A., April 21, 1923, p. 1143).

Neo-Silvol.—A compound of silver iodid with a soluble gelatin base containing 18 to 22 per cent. of silver iodid in colloidal form. Neo-silvol, even in concentrated solutions, causes neither irritation of mucous membranes nor coagulation of albumin. It does not stain the skin. It is claimed that neo-silvol in laboratory tests for germicidal value has been found as effective as phenol in its action on bacteria. Neo-silvol is intended for the prophylaxis against, and treatment of infections of accessible mucous membranes and is claimed to be indicated in affections of the genito-urinary tract and of the eye, ear, nose and throat. Parke, Davis & Co., Detroit, Mich. (Jour. A. M. A., April 28, 1923, p. 1213).

Phenoltetrachlorphathalein—H. W. & D. A dibasic dye formed by the condensation of phenol and tetrachlorphthalic acid or its anhydride. Phenoltetrachlorphathalein has been used for the determination of the functional output of the liver. It can be used, *in the form of the sodium salt, intravenously*; but cannot be given subcutaneously or intramuscularly. The substance may also be obtained in the form of Ampules Phenoltetrachlorphathalein containing a solution of disodium phenoltetrachlorphathalein. Hynson, Wescott & Dunning, Baltimore, Md. (Jour. A. M. A., April 28, 1923, p. 1218).

#### PROPAGANDA FOR REFORM.

Alcohol and Disease.—Recently a statistical report regarding the possible influence of alcohol on the prognosis of pneumonia in a large municipal hospital has been published. The data for nearly 3,500 cases of lobar pneumonia showed that, with reference to the patient's habits of indulgence in alcoholic drinks, the mortality was higher in moderate users than in light users or abstainers, and that the mortality is much higher in excessive users than in moderate users. It must be borne in mind, however, that these statistics have no bearing on the use of alcohol in therapy. (Jour. A. M. A., April 7, 1923, p. 1007).

Incompatibility of mercurochrome—220, soluble with local anesthetics and alkaloids.—An accident from the precipitation of mercurochrome-220 soluble by procain has been reported. The A. M. A. Chemical Laboratory has confirmed the incompatibility. The following local anesthetics were found to give precipitates when treated with mercurochrome-220 soluble solution: alypin, apothetin, benzocain, butyn, cocain, hydrochlorid, B-eucain lactate, phenacain, procain, propaesin, quinin and urea hydrochlorid, tropacocain hydrochlorid and stovain. Many vegetable alkaloids were also found to be incompatible with mercurochrome-220 soluble. (Jour. A. M. A., April 14, 1923, p. 1091).

A rapidly eliminated digitalis body.—At the request of the Council on Pharmacy and Chemistry, Dr. R. A. Hatcher undertook to elaborate a digitalis preparation that would be stable, that would contain a definite amount of the readily absorbable principle and that would be suitable, if possible, for intravenous administration. As a result of his work he has isolated a digitalis body which behaves unlike any constituent of digitalis heretofore described. A nearly fatal dose is eliminated within a few hours

after its introduction into a cat. It remains to demonstrate the therapeutic value of this new digitalis preparation through the co-operation of the clinician and the pharmacologist. The intravenous administration of digitalis is rarely necessary if digitalis is properly given by mouth. For rare cases in which intravenous medication administration is indicated, it appears that Dr. Hatcher has prepared a drug whose action is less persistent than other digitalis preparations now available and which is simply and inexpensively prepared. (Jour. A. M. A., April 14, 1923, p. 1072).

Nephritin (Reed and Carnrick), was reported on by the Council on Pharmacy and Chemistry in 1907. The following is a summary of this report: The advertising claims for Nephritin are based on the theory that certain granules in the renal cells, called "grains of segregation" and claimed to have been observed microscopically, carry on the secretion of urinary constituents and that a deficiency of them is the cause of nephritis. While Renaut, who formulated the theory, recommended as a cure for nephritis the maceration of fresh kidneys in physiologic sodium chlorid solution, Reed and Carnrick urged objection to the maceration and explained that nephritis represents all the action of the maceration, but is fifty times as potent. Nephritin is stated to be "the grains of segregation from the cortex of the pig's kidney, the renal connective tissue being eliminated." It appeared impossible that the microscopic structures claimed to be present in nephritin could be isolated as such from the connective tissues, and, on inquiry by the Council, no information on this point was to be had. Further, the firm presented no evidence for the claimed action of nephritin or for the claim that it was fifty times stronger than the maceration. (Jour. A. M. A., April 21, 1923, p. 1167).

The treatment of syphilis.—The general view is that neither mercury or arsphenamin positively cures in cases in which the disease has existed long enough to become well established as a systemic disease, but that they both tend to cure and that both are valuable in treatment. It is the general opinion of syphilologists that when chancres are seen that are unmistakable, these cases should be vigorously treated and that there is a good chance of aborting the disease at this time. If early cases are not treated until the Wassermann reaction has become positive, there is a difference of opinion as to treatment. There are syphilologists who believe that these early cases are better treated by mercury alone until the patient has had an opportunity to develop all the immunity of which he is capable. After the patient has established all the resistance of which he is capable, these syphilologists would treat with mercury and arsphenamin. It is becoming increasingly apparent that the advantages of the new method of treating syphilis in which arsphenamin plays the larger part, are by no means certain. The trend of the last few years has been in the direction of placing more reliance on mercury and the older methods in the treatment of syphilis. (Jour. A. M. A., April 21, 1923, p. 1167).

Herradora Specialties not accepted for N. N. R.—Early in 1922 the Scientific Chemical Co., New York City (Marcus Aurelio Herradora, M. D., President), requested the Council on Pharmacy and Chemistry to consider his intravenous preparations. The firm sent specimens of the following products "for Intravenous Use": Herradora's Arsenic Compound, Nos. 1 to 6, Herradora's Arsenic and Hypophosphites, Herradora's Arsenic and Iron Compound, Herradora's Calcium Compound, Herradora's Calcium-Sodium-Glycerophosphate, Herradora's Chlorids Compound, Herradora's Chlorids with Iron Compound, Herra-

dora's Creosote Compound, Nos. 1 and 2, Herradora's Digitalin Compound, Herradora's Glycerophosphate-Iron and Nickel Compound, Herradora's Guaiacol Compound, Herradora's Iodids Compounds, Herradora's Hexamethylenamine and Guaiacol Compound, Herradora's Iron, Manganese and Nickel Compound, Herradora's Mercury Compound, Herradora's Quinine Compound, Nos. 1 and 2, Herradora's Sodium Iodid, Herradora's Sodium Iodid-Salicylate-Guaiacol Compound.

After examining the submitted evidence the Council concluded that the Herradora Specialties were inadmissible to New and Nonofficial Remedies for the following reasons:

1. The therapeutic claims advanced for them are unwarranted and exaggerated, and there is no evidence to warrant the intravenous administration of them.

2. With one exception ("Herradora's Sodium Iodid"), the preparations are mixtures of drugs, the administration of which is not in the interest of sound therapy, particularly when these preparations are intended for intravenous use.

3. Herradora's Sodium Iodid is marketed with unwarranted therapeutic claims.

4. With the exception of Herradora's Sodium Iodid, Calcium Compound, and Iodids Compound, all of the Herradora Specialties are claimed to contain ingredients, the identity and uniformity of which are not insured by their inclusion in the U. S. Pharmacopoeia, National Formulary, or New and Nonofficial Remedies.

The Council submitted its objections to these Herradora Specialties to the Scientific Chemical Co., to permit the firm to meet these objections so far as possible. However, advertising mailed in February, 1923, convinced the Council that the propaganda contained in the firm's advertising is detrimental to the rational practise of medicine and the public welfare. Therefore, it authorized publication of its report. (Jour. A. M. A., April 28, 1923, p. 1259).

## Book Announcements

**Clinics and Collected Papers of St. Elizabeth's Hospital, Richmond, Va.** Vol I, 1922. Contributed by the Staff. Illustrated by Helen Lorraine. St. Louis. C. V. Mosby Company. 1923. Cloth. 8vo. 560 pages. Price \$7.50.

The demand for such volumes as this is no longer questionable. They have appeared at intervals from various hospitals throughout America for many years. The older title "Hospital Reports" has in some cases been changed first to "Collected Papers" and now to "Clinics and Collected Papers." The older reports were printed in limited numbers and save in few cases were not offered for sale. These of the present day are printed in large numbers, extensively advertised by publishers, and are easily accessible to purchase.

The present volume is the first of its kind emanating from a Southern city and for this reason is the cause of peculiar local and regional pride. It is of convenient size, 560 pages,

easily readable, comprehensive and beautifully and abundantly illustrated by Miss Helen Lorraine's superb drawings and many photographs, Roentgenograms and charts. The table of contents is arranged in parts and chapters according to subjects. The index appears to be one hundred per cent perfect. The subjects considered are met with frequently in practice. To read it has been a great pleasure, considerable profit and genuine inspiration. We commend it highly.

Of the total sixty-six contributions, thirty-eight are from Dr. Horsley Sr.; one with the late Dr. R. H. Whitehead of the University of Virginia, one with Dr. Vaughan, and one with Drs. Vaughan and Dodson. Dr. Warren T. Vaughan contributes thirteen papers, one with Dr. Horsley, one with Drs. Horsley and Dodson, one with Miss Van Dyke. From Dr. Austin I. Dodson there are six papers, one with Dr. Vaughan, one with Dr. Ashworth and one with Drs. Horsley and Vaughan. There is one contribution from Dr. Paul C. Colonna, one from Dr. J. S. Horsley, Jr., and one by Dr. O. O. Ashworth. None of these three are listed among the members of the staff but are or have been internes.

The book is made of case reports not hitherto published and reprinted journal contributions from various members of the staff. The first 31 pages, introductory in purpose, are occupied by short papers from the Superintendent, Miss Stone, the business manager, Mr. Todd, the Dietitian, Miss Van Dyke, and a charming story by the Illustrator, Miss Lorraine, giving a brief outline of the history of medical illustrating.

The short article by Miss Stone is especially valuable for the spirit of human kindness exhibited by the Superintendent and all internal officers and employees toward patients and should be read and emulated.

Miss Van Dyke, the dietitian, reminds us that many human beings "live to eat;" and applies to hospital management the idea embodied in an axiom from the commercial world, "A satisfied customer is the best advertisement." She might also have reminded us that

"We may live without music,  
We may live without books,  
But civilized man  
Cannot live without cooks."

There is also an interesting article by Miss Van Dyke and Dr. Vaughan on Postoperative

Dietotherapy. This should be studied especially by nurses, to learn the harmfulness of the pernicious practice of spoiling delicious lemonade by decorating it with white of egg.

This being the first volume, opportunity was taken for preservation of some of the older contributions of Dr. Horsley, some of which date back as far as 1910.

There are reports of much research work on the part of Dr. Horsley, especially in operative technique upon the stomach, intestines and blood vessels, and one instructive report showing the negative results of experimental reconstruction of the common bile duct.

Considerable text and many beautiful illustrations are devoted to plastic work about the face and neck, cancer in general and of the breast and skin. In this part of surgery Horsley is an artist in the class with Miss Lorraine.

On pages 365 and 366 are two photographs of a remarkable case of a patient weighing 105½ lbs. before and after being removed from an ovarian cyst weighing 116½ lbs.

The oration, "The Ideals of the Surgeon." is a genuine and eloquent inspiration and should be read and re-read by every aspiring surgeon.

The writings of Dr. Vaughan are extremely interesting and show thorough study. Especially instructive are the case reports of "Allergic Headache" and a paper on "Lead Poisoning from Drinking Moon-Shine Whiskey."

The anatomy of a six-legged dog by Dr. J. S. Horsley, Jr., written while a student at the University of Virginia, is a remarkable study by this scholarly son of the elder Horsley.

The volume before us, like much of current literature, shows progress in standardization of surgeons and we hope that the time is not far distant when we will have a report entitled "Clinics, Collected Papers and the Immediate and Ultimate Effects of Surgical Operation and Medical Treatment in Every Patient Treated." In this way and in this way only, can doctors have a real basis upon which to refer patients for superior special treatment and hospital managers a real basis upon which to appoint staff members. We welcome this volume and wish for speedy progress in this direction on the part of every surgeon in every hospital in America.

Dr Horsley has issued at least two annual reports of St. Elizabeth's Hospital, 1921 and

1922. The "Clinics and Collected Papers" would have been improved by the inclusion of these two reports. We hope this will be done next year.

G. P. LA ROQUE.

**Dreads and Besetting Fears.** Including States of Anxiety, Their Causes and Cure. By TOM A. WILLIAMS. M. B., C. M. Membre Correspondant Etranger de la Societe de Neurologie de Paris. Membro Correspondente Academia Nacional de Medicina do Rio de Janeiro, etc. Neurologist to Freedman's Hospital. Boston Little, Brown, and Company. 1923. Mind and Health Series. 12 mo. Cloth. 217 pages. Price, \$1.75 at booksellers.

**The Unadjusted Girl.** With Cases and Standpoint for Behavior Analysis. By WILLIAM I. THOMAS. Foreword by MRS. W. F. DRUMMER. Boston. Little, Brown, and Company. 1923. Criminal Science Monograph No. 4. 3vo. Cloth. 261 pages. Price \$3 net.

**Applied Psychology for Nurses.** By DONALD A. LAIRD, Assistant Professor of Psychology, University of Wyoming; Lecturer in Nursing Psychology, Ivinson Memorial Hospital School of Nursing. J. B. Lippincott Company. Philadelphia and London. Lippincott's Nursing Manuals. 1923. 8vo. Cloth. 236 pages with 49 illustrations. Price \$2.50.

**Senile Cataract.** Methods of Operating. By W. A. FISHER, M. D., F. A. C. S., Chicago, Ill. Professor of Ophthalmology, Chicago Eye, Ear, Nose and Throat College, etc. With the collaboration of PROF. E. FUCHS, Vienna, Austria; PROF. I. BARRAQUER, Barcelona, Spain; LT. COL. HENRY SMITH, London, England; DR. H. T. HOLLAND, Shikarpur, Sind, India; DR. JOHN WESTLEY WRIGHT, Columbus, O. 256 pages. 160 illustrations, 112 of which are colored. Published by Chicago, Eye, Ear, Nose and Throat College, Chicago, Ill. 12mo. Cloth. Price \$2.50 and will be sent postpaid on approval.

**Merck's Manual of the Materia Medica.** Fifth Edition. A Ready Reference Pocket Book for the Physician and Surgeon. Compiled and published by Merck and Company. New York, St. Louis, Montreal. Works at Rahway, N. J. 1923. 581 pages. Flexible linen cloth, 50c; artificial leather, \$1.00.

**Veneral Disease in the American Expeditionary Forces.** By GEORGE WALKER, M. D., Late Colonel, Medical Corps, U. S. A. Medical Standard Book Company, Baltimore, Md. 1922. 8vo. Cloth. 237 pages.

## Editorial

### Influence of Insulin on the Symptoms of Diabetes Mellitus.

From the time of Celsus and Aretaeus, who lived in the first century of the Christian era, to the present time, the ugly symptoms of diabetes have all but baffled the best efforts of the medical profession. The dieting of diabetics, in late years, however, has enabled physicians to assuage the course and modify the degree of severity of some of the more harassing symptoms of this ancient disease, but it is only with the advent of this potent extract of pancreas, insulin, produced in a form innocuous to the body, when subcutaneously injected in properly guarded dosage, that the physicians have come into the possession of an agent of unsurpassed metabolic importance. This new product possesses the power accurately to reduce, for definite periods of time, the severity, and often altogether, remove the ugly symptoms of diabetes. The voracious appetite, the extreme thirst, the copious secretion of urine, and the emaciation of the body, no longer need be dreaded, because insulin will drive "these wolves" away. Before the hypodermic syringe of insulin, properly administered, even coma relaxes its grip upon the brain. Insulin displaces the anesthetizing poison of perverted fat metabolism for carbohydrate metabolism.

#### THIRST

Thirst has always been one of the most annoying symptoms of diabetes. Many of

these patients only begin to recognize that there is something wrong with them when they realize that they have an unusual and insatiable thirst. This symptom is quickly alleviated by the use of insulin; it disappears as the blood sugar curve falls toward the normal level. In connection with the disappearance of thirst, there is marked relief from dryness of the mouth and viscosity of the saliva. The whole status of the mouth improves at once with the use of insulin. Our experience of the use of insulin justifies the assertion that, for the alleviation of this group of symptoms, alone, the discovery of insulin should rank high in the list of important medical discoveries.

#### APPETITE AND HUNGER

The administration of insulin, in connection with the adjustment of a diet suitable to the needs of the patient, is attended by a distinct surcease from the "bread riot" that is ever raging in the epigastrium of the diabetic. Physiologically, there may be a difference between appetite and hunger, or, at least, they may be explained on different theories, but in the life of a diabetic, appetite is more than a "complex of sensations operating in the nervous system along with memory impressions of the sight, taste, and smell of palatable food," an empty stomach. Appetite and hunger operate upon the mental and moral attributes of the diabetic with profound effect and any agent that may help lessen the gnawing appetite and relieve the pangs of hunger by the normal intake of food is worthy of honorable mention in the category of therapeutic agents. As insulin reduces the hyperglycemia, the distressing hunger is relieved and the appetite is more normally appeased. In all our cases, this remarkable effect has been observed. The patients comment themselves with gratifying satisfaction upon the great relief felt in the liberation from constant and unremitting sensations of recurring hunger, so long an annoyance.

#### POLYURIA

The enormous quantity of urine secreted by diabetics, in some cases, amounts to a consideration of great importance in its symptomatology. This symptom, while not always of paramount importance with the patients, is one that stands out as significant and is, indeed, discomforting as it is characteristic. Some

patients are so pressed by the desire to void a distended bladder of urine, that they must urinate at very short intervals. Such an exigency amounts to a serious symptom. This, also, is one of the unpleasant features of the disease that yields to the use of insulin in connection with diet. Few patients fail to remark that the night's sleep is no longer interrupted by the necessity of voiding large amounts of urine, as was the case before insulin and diet were begun. Most of our cases have secured relief from this symptom and its companion symptom of thirst as the high blood sugar level yielded to the influence of insulin.

#### STRENGTH AND EMACIATION

Languor and weakness, along with loss of weight, have long stood out as a group of symptoms more or less constant in diabetes, varying in degree with the type and severity of the disease. In mild or incipient cases, the emaciation and body-strength are not so obtrusive as in the severe or malignant forms. But nevertheless, in diabetes, weakness and loss of weight rather uniformly appear and are important evidences of the disease and serve to subjectively affect the patient profoundly. One of our patients has repeatedly expressed the opinion that, following her daily dose of ten units of insulin, she feels for four to six hours a definite and clear-cut exhilaration of body and mind. This patient has said that the ten units given to her before noon "stimulates" her until bedtime and that now her mind "works better" than it has for years. But in nearly all cases, the patients say that they feel stronger and have more endurance than they had before the use of insulin. In this respect, our patients have commented more emphatically than they have during the course of the mere dietary treatment in which the urinary-sugar examinations served as a guide for the amount of carbohydrate given. Probably, the same wholesome effect of increase in strength would have been gotten had the blood sugar curve been as carefully lowered by fasting and slow-carbohydrate feeding in dietary treatment. The insulin and diet treatment give control over hyperglycemia and in that way favorably affect the strength and well-being of the diabetic to a remarkable degree. Again, the gain of weight, within limits in selected cases, may be permitted with the administration of the carbohydrate-oxidizing-

insulin. This fact, if proven to be uniformly so, will be a decided advance in the management of diabetics on the low-maintenance and under-nourishment regimes. It would seem then that insulin offers the diabetic the opportunity to increase his weight, without running the risk of further weakening his carbohydrate mechanism.

#### SCALP-SKIN-NAILS SYMPTOMS

Symptoms of the scalp, skin and nails are indeed definitely benefited and healed by the use of insulin. Dryness and itching of the scalp and skin yield to insulin. Eczema and pruritus, boils and carbuncles, hang nails, and ulcers in the scalp—conditions that have annoyed the patient for years—yield to the adequate and carefully controlled administration of insulin. One of our cases had suffered for years with rodent ulcers of the scalp which had denuded areas of the scalp of hair the size of a dime. The administration of forty units of insulin daily brought his blood sugar from 460 milligrams of blood sugar per 100 c.c. of blood to 160 milligrams of blood sugar per 100 c.c. of blood and with a complete cure of the ulcers and the formation of cicatricial tissue.

#### DIABETIC ACIDOSIS AND COMA

We must remember that the acidosis of diabetes, unlike that of nephritis, is due to the formation of aceto-acetic and beta-oxybutyric acid in the tissues and body fluids as a result of a faulty fat metabolism. The faulty fat metabolism is the result of the effort of the body to employ fat as a substitute. As complete combustion of fat is dependent upon a "flame of burning sugar," and as in diabetes this necessary bed of burning sugar in the body furnace is very dull, and sometimes all but "out," the effort to use the substitute fat fuel is attended by the smoke of incomplete combustion.

From this condition, ketone bodies show in the urine of the diabetic and indicate that the patient is in a state of acid poisoning. This is the forerunner and ultimately the cause of diabetic coma. In our patients who have shown the presence of an excess of ketone bodies, the use of insulin was attended by prompt improvement. Two of our cases gave evidences of profound acid poisoning. A woman of 65 years was in profound coma with marked ketonuria and a blood sugar of 580 milligrams of blood sugar per 100 c.c. of

blood. The patient's blood sugar fell in the course of two days to 360 milligrams per 100 c.c. of blood. The dose of insulin used in this case was large and repeated every hour. The patient received also the usual water and fruit juice treatment.

In another case of beginning coma, the patient responded to insulin, fruit juice, water treatment. The ketones disappeared from the urine, the bad mental symptoms disappeared, and the patient quickly showed sugar free urine.

In the milder cases of diabetes with ketonuria, the patient may be prepared for dietary treatment by a temporary insulin treatment. Such patients, with the careful use of insulin, may become free of acidosis, and the maintenance diet required for the patient may be more quickly learned. It is probably not an overstatement to say that, in this phase of diabetes (ketosis and coma) insulin exerts its most spectacular power. For this dangerous condition, the physician now possesses in insulin an antidote of a definite potency, it seems.

Finally, upon all the cardinal symptoms of diabetes in man insulin exerts an immediately favorable influence for short period of time. To remove the symptoms of diabetes altogether and permanently to rid the diabetic body of the harassing symptoms that characterize the disease, it is necessary to inject into the body at intervals certain unit doses of this potent extract of the pancreas, and to restrict the introduction into the diabetic body of carbohydrate food, and to adjust this restriction in connection with the fat and protein of the diet, with a view to meeting the requirements of the nitrogen balance, ketogenic—antiketogenic balance, and total (caloric) body needs.

## News Notes

### Commencement Exercises of Virginia Medical Schools

Brought with them this year, as in the past, mingled joy and sorrow for the fulfillment of aims and ambitions and because it was the parting of the ways to those who have been closely associated for several years. However, an opportunity for the renewal of these relations is to be had through medical societies and, for this purpose, if no other, we wish to emphasize the need of all members of the

graduating classes affiliating themselves with the county and State organizations in the communities in which they locate.

### MEDICAL COLLEGE OF VIRGINIA

Exercises commenced Saturday the 2nd, with a minstrel show by the students in John Marshall High School Auditorium. On Sunday, Rev. Fred R. Chenault, D. D., of Broad Street Methodist Church, delivered the baccalaureate sermon. Alumni day was observed on Monday, June 4, Dr. Manfred Call, Richmond, presiding and a reunion dinner was held at Commonwealth Club that evening. At the meeting of the alumni it was planned to have a drive to raise \$3,000,000 for a proper expansion of the school. A part of this is to be raised for immediate uses.

At the meeting of the Board of Visitors on the same day, Dr. St. George T. Grinnan, acting professor of pediatrics, was elected to fill the vacancy caused by the death of Dr. McGuire Newton. Dr. Grinnan will take up his duties in this new position at the opening of the school in September.

A business meeting of the General Alumni Association was held on Tuesday morning, the 5th, and this was followed by a luncheon in the College building.

Commencement exercises at Strand Theatre, on the evening of the 5th, were followed by a reception and dance at Commonwealth Club, in honor of the graduates in medicine, dentistry, pharmacy and nursing. There were 43 graduates in medicine, 36 in dental surgery, 34 in pharmacy, and 9 in nursing—the largest number of graduates from the Medical College of Virginia since 1913.

Hospital appointments are as follows:

*Memorial Hospital, Richmond*—Drs. Rowland H. Edwards, Palls; John A. Mease, Jr., Sandy Level; Louis Perlin, Richmond; Lee S. Liggan, Richmond; Leta J. White, Greenwood, S. C.; Cornelia W. Segar, Hampton; Joseph P. Treccise, Butler, Pa.

*Johnston-Willis Sanatorium, Richmond*—Drs. Bolling J. Atkinson, Champe, and William P. Bittinger, Gerrardstown, W. Va.

*Retreat for the Sick, Richmond*—Drs. Percy R. Fox, Penola; Samuel P. Hileman, Rockbridge Baths; Henry H. Menzies, Richmond.

*Stuart Circle Hospital, Richmond*—Drs. Emerson M. Babb, Ivor; Earnest M. Wilkinson, McKenney, and undergraduate R. B. Groves.

*St. Luke's Hospital, Richmond*—Drs. Joseph T. Graham, Draper, and Rogers N. Harris, Whites.

*Pine Camp Hospital, Richmond*—Dr. Francis J. Clements, Cartersville, and undergraduate H. T. Garriss.

*City Home Hospital, Richmond*—Undergraduates F. Norman Bowles, G. T. Colvard and W. F. Matthews.

*Mercy Hospital, Baltimore, Md.*—Dr. Robert R. Jones, Walnut Cove, N. C.

*Long Island Hospital, Boston, Mass.*—Dr. Churchill Robertson, Salem.

*C. & O. Hospital, Clifton Forge, Va.*—Dr. Robert P. Hawkins, Jr., Clifton Forge.

*Pittman Hospital, Fayetteville, N. C.*—Dr. John N. Robertson, Charlotte C. H.

*St. Francis Hospital, Jersey City, N. J.*—Drs. Wyatt S. Beazley, Jr., Richmond; Sam R. Cozart, Stem, N. C.; Homer B. Luttrell, Amissville.

*Elizabeth Buxton Hospital, Newport News, Va.*—Dr. Waverly Randolph Payne, Midlothian.

*City Hospital, New York City*—Drs. Fielding Combs, Honaker, and Joseph E. Burns, Goldston, N. C.

*Gouverneur Hospital, New York City*—Dr. Phil H. Neal, South Boston.

*Lenox Hill Hospital, New York City*—Dr. William I. Owens, Richmond.

*Northwestern General Hospital, Philadelphia*—Dr. Clarence E. Perkins, Newport News.

*Philadelphia General Hospital, Philadelphia*—Dr. Edwin R. Mickle, Nathalie.

*Muhlenberg Hospital, Plain Field, N. J.*—Dr. Benjamin E. Glass, Carteret, N. J.

The other graduates in the School of Medicine are:

Benjamin F. Bailey, Ft. Defiance.

William H. Batte, Jr., Jarratt.

John G. Davis, Jr., Roanoke.

Honston L. Gwynn, Yanceyville, N. C.

Frank E. Handy, Emory.

Hummie Z. L. Horton, Apex, N. C.

Robert S. Kyle, Woodlawn.

John P. Lilly, Athens, W. Va.

John W. McNabb, Belleville, Pa.

Harry T. Schiefelbein, New Lisbon, Wis.

Archer A. Wilson, News Ferry.

#### UNIVERSITY OF VIRGINIA.

Commencement exercises at the University of Virginia began on Sunday, June 10, with the

Baccalaureate Sermon by the Rev. Walter William Moore, President of the Union Theological Seminary, Richmond, Va. The graduating class, including the Doctors of Medicine, attended this exercise in a body in academic costume.

At 7:30 p. m. on the same day, there was an organ recital in the McIntire Theatre by Mr. Henry H. Freeman, Director of St. Paul's Choir, Washington, D. C., assisted by Elizabeth Bernadine Thornberry, Soprano.

On Monday, June 11, Departmental Alumni Meetings were held in Peabody Hall at 9:30. Dean Hough outlined the growth of the Medical School during the past fifteen years and the plans for its future development.

These departmental meetings were followed by the Annual Alumni Meeting in Peabody Hall at 11, and this meeting was followed by the Alumni luncheon at the University Commons, the alumni orator being the Hon. Mendel L. Smith.

At 8:15 p. m. the Phi Beta Kappa address was delivered in Madison Hall by the Rev. Beverley Dandridge Tucker, Jr., of St. Paul's P. E. Church, Richmond, Va. On this occasion the Phi Beta Kappa keys were delivered to the initiates of this session. Among these initiates were the following members of the graduating class in medicine:

Vincent W. Archer, Monroe J. Epting, Robert B. Hiden, John P. Williams.

Other members of the graduating class who had previously been initiated into Phi Beta Kappa upon graduating from the college were:

Eugene L. Lowenberg and Caldwell J. Stuart.

Six members of the graduating class had also been initiated on April 12, into the honor medical society, Alpha Omega Alpha, as follows:

Silas E. Chambers, Monroe J. Epting, Robert B. Hiden, Eugene L. Lowenberg, Caldwell J. Stuart, John Powell Williams.

On Tuesday, June 12 at 10 a. m. the graduating classes of all departments joined in the class exercises held in the McIntire Theatre, and at 5 p. m. the final exercises and conferring of degrees took place. The graduating class was addressed by Mr. Homer S. Cummings, of Stamford, Conn. The names of the graduating class are given below. These exercises were followed at 7 p. m. by a reception

to the graduates, their relatives and guests in Madison Hall.

In addition to these exercises, a number of athletic and social events were held. On Saturday afternoon, June 9, was the Varsity-Alumni baseball game, and on the afternoon of Monday, June 11, there was a game between the University of North Carolina and Virginia. Both of these were played on Lambeth Field.

The Alumni Ball was held on the evening of Monday, June 11, and the Final Ball on Tuesday, June 12. The graduates in medicine with their hospital appointments are as follows:

V. W. Archer, B. S., Black Mountain, N. C., Roentgenologist, Black Mountain Sanitarium, Black Mountain, N. C.

Walter Weyman Benton, Winder, Ga., Ancon Hospital, Ancon, Canal Zone.

Launcelot Minor Blackford, B. S., University, Va., Union Memorial Hospital, Baltimore, Md.

Louis Christian Brand, Staunton, Va., University of Virginia Hospital, University, Va.

Albert A. Creecy, B. S., in Medicine, Norfolk, Va., Sarah Leigh Hospital, Norfolk, Va.

E. P. Cardwell, Wilmington, N. C., Orange Memorial Hospital, Orange, N. J.

S. E. Chambers, Basic, Va., Mercy Hospital, Baltimore, Md.

Samuel Wesley Eason, B. A., Norfolk, Va., Jersey City Hospital, Jersey City, N. J.

Monroe Jacob Epting, Jr., B. A., Savannah, Ga., St. Luke's Hospital, New York City, N. Y.

Richard T. Ergenbright, Charlottesville, Va., Worcester City Hospital, Worcester, Mass.

Richard Dulany Gill, Leesburg, Va., University of Virginia Hospital, University, Va.

William H. Glass, Gainesville, Fla., Orange Memorial Hospital, Orange, N. J.

Robert B. Hiden, A. B., Pungoteague, Va., Instructor in Physiology and Biochemistry for 1923-24, University of Virginia.

Clack D. Hopkins, Richmond, Va., Flushing Hospital, New York City, N. Y.

W. B. Hubbard, Broadway, Va., Instructor in Anatomy for 1923-24, University of Virginia.

Charles I. Johnson, B. S., Montgomery, Ala., Kenmont Coal Co., Jeff, Ky.

Thomas Duckett Jones, B. A., Petersburg, Va., University of Virginia Hospital, University, Va.

Eugene Lowenberg, B. S., Norfolk, Va., Lenox Hill Hospital, New York City, N. Y.

Ray Jackson Neff, B. A., Chillhowie, Va., University of Virginia Hospital, University, Va.

H. Lamont Pugh, Crozet, Va., U. S. Navy.

Willard G. Rainey, Greensboro, N. C., St. Elizabeth's Hospital, Richmond, Va.

Samuel Harvey Rivers, B. A., Dryden, Va., University of Virginia Hospital, University, Va.

C. J. Stuart, B. A., Washington, Va., U. S. Navy.

Charles W. Scott, Port Republic, Va., University of Virginia Hospital, University, Va.

Richard Green Waterhouse, B. A., Emory, Va., St. Elizabeth's Hospital, Richmond, Va.

William Weston, Jr., B. A., Columbia, S. C., Johns Hopkins Hospital, Baltimore, Md.

John Powell Williams, B. A., Richmond, Va., St. Luke's Hospital, New York City, N. Y.

#### States Advance in Safeguarding Health of Working Children.

Twenty-two States now require the physical examination of every child applying for an employment certificate, according to the newly revised edition of a bulletin on "Physical Standards for Working Children," issued by the U. S. Department of Labor through the Children's Bureau. The bulletin contains the recommendations of a committee of physicians who were appointed by the Bureau to prepare a standard form for use in examination of children seeking to enter employment.

Since the publication of the first edition of the bulletin, two years ago, a considerable number of changes have been made in the various State laws with reference to such examinations, and the summary of legal provisions which it contains has now been brought up to date. One State, Virginia, is said to have advanced in this respect to a stage beyond that of the other States, in that it now requires the examination of every working child at regular intervals during the years when he is especially susceptible to the strains of industry. It should thus be possible to determine whether the work at which he is engaged is injuring his health or interfering with his normal development. In certain other States a child must be re-examined when he goes from one employer to another, but since he may remain with his first employer until

he passes the certificate age, the bulletin points out that this is not so adequate a provision as the new Virginia law.

In addition to the twenty-two States requiring a physical examination for every child before an employment certificate is first granted, eight others and the District of Columbia allow the certificate-issuing officer to require an examination when he is in doubt as to the child's physical fitness, but many officers, it is said, do not realize the importance of this phase of their work. In eighteen States there is still no legal provision of any kind for examination, even when a child first enters employment.

#### Age Old Quackery Still in Use.

As several cases have recently come to the attention of the State Bacteriological Laboratory where persons bitten by mad dogs had resorted to the mad stone for cure instead of taking Pasteur treatment, A. H. Straus, director of the State laboratory, applied to the Attorney-General of the State for an interpretation of the law as to whether people applying the mad stone for pay could be prosecuted under the Medical Practice Act, for practicing medicine without a license. Attorney-General Saunders gives the following opinion:

"After examining Section 1622 of the Code of 1919, I am of the opinion that any person who attempts to cure the bite of a mad dog by the use of a mad stone, for compensation, is engaged in the practice of medicine within the definition found in this section of the Code, and that in all such cases, where the person is not a licensed practitioner, you should report the facts to the attorney for the Commonwealth of the county in which such offense occurs, with the request that the party be prosecuted."

In view of the above, we would suggest that if any of our readers know of cases where the mad stone is applied for compensation, they report name of person using it to this office that the Medical Society of Virginia may assist the Medical Examining Board of Virginia in prosecuting such person.

#### Memorial to Dr. McGuire Newton.

A number of the friends and admirers of the late Dr. McGuire Newton, noted child specialist of Richmond, have secured a charter for the McGuire Newton Foundation. It is the purpose of this Foundation to create a \$100,000 children's clinic in Richmond, as a

memorial to Dr. Newton, which will be known as the McGuire Newton Memorial Clinic. To assure the permanency of the Clinic, which is to be operated exclusively for the treatment of children's diseases, it is provided that only the income from the endowment can be used in maintaining the Clinic, and, in case of the resignation or death of any member of the board of trustees, of the Foundation, his or her successor is to be named by the board of trustees, which is to have sole power in the administration of the funds. H. W. Ellerson is chairman of the Foundation, and temporary offices are at 1010 Floyd Avenue, this city, the former home and offices of Dr. Newton.

The new class formed at the spring reunion of the Ancient and Accepted Scottish Rite Masonry, the day of Dr. Newton's funeral, took the name of "McGuire Newton Class." This name was adopted in honor of Dr. Newton and symbolizes the work which this class will do toward the relief of crippled children, a movement which the Scottish rite has long fostered.

#### Dr. Charles A. Young,

Formerly House Surgeon of the Wills Eye Hospital of Philadelphia, is now located in Roanoke, Va., with offices at 612-614 MacBain Building.

#### Dr. W. V. Atkins,

Blackstone, Va., was called to Front Royal, Va., the first of this month on account of the illness of his granddaughter.

#### Results of T. B. Seal Sales.

Salem led all the cities in the State of Virginia in the per capita sale of Christmas Seals during the last campaign with a per capita sale amounting to over 13 cents. Petersburg, the second city, had a per capita sale of nearly 10 cents. In county sales, Henrico won first place with a per capita sale of 4 cents.

In Virginia 63 counties increased the amount of their sales over the past year. Some of the larger cities, however, showed a decrease.

The Virginia Tuberculosis Association has received to date the sum of \$55,045.56 from the sale of Seals with \$200 yet to be transmitted. The sale will exceed that of last year by about \$1,000. Out of the sum raised, \$36,543.28 will be distributed to the counties and cities for local tuberculosis work, \$15,750 going to the Virginia Tuberculosis Association and \$2,752.28, representing 5 per cent. of the

gross proceeds, going to the National Association.

### The Virginia Pharmaceutical Association

Is to hold its annual meeting at Virginia Beach, June 25, 26 and 27. H. E. Orchard, of Lynchburg, is president, and A. L. I. Winne, of Richmond, secretary.

### High Rate of T. B. in Porto Rico.

Dr. J. G. Townsend, of the U. S. Public Health Service, who recently returned to this country after a five months' study of tuberculosis in Porto Rico, states that there is a high tuberculosis death rate in this island. The rate is a little more than 200 per hundred thousand, which is greater than in any State in the Union except Colorado, where the tuberculosis death rate is enormously increased by the constant immigration of tuberculous patients, many in the last stages of the disease. The high rate in Porto Rico is especially among the laboring class and is largely due to the housing and diet conditions under which they live.

### Dr. Charles K. Mills,

Philadelphia, was elected president of the American Neurological Association, at its meeting in Boston, early this month. He will preside at the jubilee celebration in Philadelphia, next year, on the occasion of the fiftieth anniversary of the society.

### Cost of Operating a Ford.

Tabulations as to the cost of operating a Ford car have just been completed by the State Board of Health, which has since May 1, 1919, been using Fords in its rural sanitation work through Virginia. Excluding garage rent and depreciation, it is seen that the average driver, a man normally careful, can at this time expect to run his Ford over *country* roads, taking the good with the bad and encountering all kinds of weather, at a cost not to exceed \$35 a month, if he has a mileage of approximately 900. Gasoline and oil account for about one-half the total upkeep, the remainder, slightly under fifty per cent, being chargeable to repairs, tubes and tires.

### Dr. S. E. Massey,

Recently of Martinsville, Va., has located in Roanoke, Va., with offices in Anchor Building. He will limit his work to diseases of the eye, ear, nose and throat.

### Dr. Claude M. Lee

And family are spending the month of June with relatives in Culpeper, Va., before sailing for their home in Wusih, China, where Dr. Lee is a medical missionary.

### Married.

Dr. William Benjamin Hopkins, Richmond, Va., and Miss Mary Courad Nicholson, Littleton, N. C., May 6.

Dr. Oscar Bruton Darden, Richmond, Va., and Miss Mary Wyckoff Dunlap, Dunlap, N. C., June 12.

### Fresh Air Camp for Crippled Children.

Westhampton College buildings, belonging to the University of Richmond, have been offered to and accepted by a committee in charge of securing quarters for a fresh air camp for the crippled children of Richmond during the summer months. Funds are to be raised by the various committees for the maintenance of the camp during this time.

### Dr. William R. Aylett,

Of Newport News, Va., who was recently quite sick at St. Elizabeth's Hospital, Richmond, is now much improved and has returned home.

### Dr. William Banner Moore,

Member of the Medical Society of Virginia, for sometime located at Smith, N. C., has moved to Browns Summit, N. C.

### Dr. Tom A. Williams,

Washington, D. C., was an invited guest at the meeting of the New York State Medical Society in New York City, May 23rd. The subject of his address was "Besetting and Other Morbid Fears," on which subject he has just published a book.

### Work of the Rockefeller Foundation.

On May 14, the Rockefeller Foundation passed the ten-year milestone in its work. Though its chartered purpose, broadly stated, was "the well-being of mankind throughout the world," the work of the Foundation has become chiefly centered upon public health and medical education. The expenditures for the first decade have amounted to \$76,757,040, roughly divided as follows:

Public Health .....	\$18,188,838
Medical Education .....	24,716,859
War Relief .....	22,298,541
All Other Philanthropic Work...	10,445,628
Administration .....	1,107,174

Contributions outside the field of public health and medical education were made, for the most part, during the war and during the earlier years of the Foundation's work, before its policies and program had become clearly defined. There has been an increasing concentration upon medical education and public health.

#### **Civil Service Examinations.**

The U. S. Civil Service Commission, Washington, D. C., announces open competitive examination for reconstruction aide (physiotherapy) and reconstruction pupil aide (physiotherapy), applications to be rated as received, until further notice. Vacancies are to be filled in the Public Health Service and Veterans' Bureau throughout the United States. Competitors will not be required to report for examination at any place, but will be rated on their physical ability, and education, training and experience. For full information and blanks, apply to the above named commission or the secretary of the board of U. S. Civil Service Examiners at the post-office or custom house in any city.

#### **Dr. B. B. McCluer,**

Speedwell, Va., recently visited his parents at Bon Air, Va.

#### **Dr. Lester A. Crowell,**

Lincolnton, N. C., was elected president of the North Carolina Hospital Association at its recent meeting in Asheville.

#### **Dr. Margaret P. Kuyk,**

Richmond, after attending the A. M. A. meeting in San Francisco, this month, will go on to Portland, Ore., for the meeting of the American Association of University Women, to be held there in July.

#### **Dr. D. A. Stanton,**

High Point, N. C., has been appointed a member of the N. C. State Board of Health, to fill the unexpired term of Dr. Fletcher R. Harris, Henderson, resigned.

#### **Dr. D. W. Draper,**

Of Newport News, Va., is spending some time in Philadelphia, doing post-graduate work in pediatrics.

#### **Dr. Walter E. Dandy,**

Of Johns Hopkins Hospital, Baltimore, by invitation delivered an address before the Nor-

folk County (Va.) Medical Society, his subject being "The Localization of Brain Tumors by Air Injections in the Brain."

#### **Dr. Charles R. Robins,**

Richmond, was appointed one of the delegates to represent the Society of the Sons of the Revolution in the State of Virginia at the triennial meeting of the General Society of Sons of the Revolution in Boston, June 18 and 19.

#### **Dr. F. O. Plunkett**

Has been elected president of the Men's Club of Court Street Methodist Church, Lynchburg, Va.

#### **Officers in the Society of Colonial Wars.**

At the annual election of officers of the Society of Colonial Wars of the State of Virginia, held in Richmond, the middle of May, Dr. Alexander G. Brown, Jr., was elected surgeon, and Drs. Francis Whittle Upshur and J. Shelton Horsley gentlemen of the council.

#### **Dr. Roshier W. Miller**

Has been re-elected a member of the City School Board of Richmond.

#### **Dr. Benjamin Carroll Henson,**

Roda, Va., has been attending the Trudeau School of Tuberculosis, at Saranac Lake, N. Y., but will return home the first of July.

#### **Dr. C. L. Bailey,**

After practising for twenty-one years at Quinton, Va., has located at Sandston, Richmond, R. F. D. 3, Va.

#### **Dr. H. T. Hopewell,**

Strasburg, Va., who recently suffered a stroke of paralysis, has sufficiently recovered to be at his work again.

#### **Dr. and Mrs. J. W. Holmes,**

Pulaski, Va., have been on a visit to their son at Kenova, W. Va.

#### **Miss Loula L. Odom, R. N.,**

Superintendent of Sarah Leigh Hospital, Norfolk, Va., has been appointed by the Governor as a member of the State Examining Board for Nurses, succeeding Miss Elizabeth Harrison Webb, of Richmond. The appointment is for a term of four years.

#### **Dr. E. T. Trice**

Has returned to his home in Richmond, after a visit to Rochester, Minn.

**Dr. C. W. Massie,**

Of this city, who has been quite ill at St. Luke's Hospital, Richmond, is now much improved.

**Dr. Harry B. Taylor,**

A graduate of the Medical Department of the University of Virginia and president of the class of 1902, recently delivered an address in this city, on "Medical Missions in China." After graduating, Dr. Taylor spent several years in hospital training, following which he went to China as a medical missionary under the Episcopal church. He is in charge of St. James Hospital, Anking, China.

**Appointments in National Guard of Virginia.**

Dr. Herbert R. Drewry, Norfolk, who served as captain with the medical corps in the Twenty-ninth Division in France, has been made major and assigned to the medical corps of the 111th Field Artillery.

Dr. Harry M. White, of Fishersville, Va., who also served with the rank of captain in the Twenty-ninth Division, has been appointed major and assigned to the 116th Infantry.

Major Herbert R. Drewry and Captain Harry W. Boice, both of Norfolk, have been elected medical officers of the 111th Field Artillery, and Captain Walter E. Miler, also of Norfolk, Staff dentist.

**Dr. R. H. Woolling,**

Pulaski, Va., has recovered from a recent illness. He spent several weeks recuperating at his former home in Fluvanna County, Va.

**Dr. W. T. Graham,**

Richmond, has been appointed by Governor Trinkle as a member of the State Board of Health, to fill the vacancy caused by the death of Dr. McGuire Newton. Dr. Newton's work was with particular reference to children, and Dr. Graham will continue that line of work as a member of the Board.

**Dr. John R. Blair,**

For many years a resident of Church Hill, Richmond, has sold his home and will shortly move to Ginter Park, this city.

**Dr. and Mrs. C. W. Astrop,**

Of Surry, Va., were recent visitors near Fork Union, Va.

**Dr. Robert Whitehead,**

Meherrin, Va., who recently underwent an operation for appendicitis, returned to his

work in May, after spending sometime recuperating at his father's home in Amherst, Va.

**Delegates to Social Workers' Conference.**

Drs. R. L. Raiford, Sedley, and P. K. Graybill, Fincastle, were among the delegates appointed by the Governor to represent Virginia at the annual meeting of the National Conference of Social Workers in Washington, in May.

**Experimental Laboratory Destroyed by Fire.**

Fire of undetermined origin recently destroyed the new animal experimental laboratory on the estate of Dr. C. H. Mayo, three miles south of Rochester, Minn. The loss was estimated at \$150,000.

**Dr. Paul E. Redd,**

Of Richmond, recently paid a short visit to Mathews County, Va.

**Dr. L. K. Leake,**

East Leake, Va., has been elected a member of the board of directors of the State Bank of Goochland, which was recently organized in that County.

**Elected Members of The Raven Society.**

The middle of May, Dr. D. C. Smith, instructor of dermatology at the University of Virginia and the following students from the Department of Medicine were among those initiated as members of the Raven Society at the University: Frederic G. Dorwart, Newport News, Va., Luther W. Kelly, University, Va., Winston U. Rutledge, Anchorage, Ky., and John Powell Williams, Richmond, Va.

**The Richmond Chapter, Alumni Medical College of Virginia,**

At a meeting held recently, elected Dr. Manfred Call president, for the ensuing year; Elam C. Toone vice-president; Dr. Harry Bear secretary; and Dr. Frank S. Johns treasurer.

**Dr. and Mrs. James Bordley,**

Baltimore, Md., were recent visitors at the home of friends in Winchester, Va.

**The Community Hospital**

Will be opened at Greenville, N. C., September 1. It will be in charge of Dr. E. T. Dickinson, formerly in charge of Wilson (N. C.) Sanatorium. The last named institution was closed the first of June.

**Crippled Children's Hospital at Shreveport.**

The Shrine Hospital for Crippled Children,

at Shreveport, La., was dedicated in April. This was erected at a cost of \$300,000.

#### **The N. C. Public Health Association,**

At its annual meeting in Asheville recently, elected Dr. Charles W. Armstrong, of Salisbury, president, and re-elected Dr. Frank M. Register, of Raleigh, secretary.

#### **Dr. G. F. Simpson,**

Parcellville, Va., with a party of friends, motored to Harrisonburg, Va., and attended the Shriner's meeting held in that place on June 1.

#### **Dr. Thomas M. Winn,**

After a year's service at Physician's and Surgeon's Hospital, Wilmington, Delaware, has located at Millboro, Va. Dr. Winn, formerly of Palmyra, Va., graduated from the Medical College of Virginia last June.

#### **Dr. W. B. Carr,**

Recently of Warrenton, Va., has a position on a Fruit Boat between Brazil and New York City.

#### **The Medical and Chirurgical Faculty of Maryland,**

At a recent meeting, elected Dr. Philip Briscoe, of Mutual, Md., president, and Dr. Joseph A. Chatard, Baltimore, secretary.

#### **Dr. Thomas A. Groover,**

Associate professor of roentgenology at George Washington University Medical School, Washington, D. C., recently had his left hand and two fingers on his right hand amputated, owing to extended exposure to the roentgen rays.

#### **Dr. Henry A. Christian,**

Physician-in-chief at Peter Bent Brigham Hospital, Boston, by invitation, delivered an address before the Alumni Society of Randolph Macon College, Ashland, during commencement week, his subject being "Public Health Problems of Virginia." Dr. Christian is an alumnus of Randolph Macon College.

#### **St. Luke's Hospital to be Enlarged.**

The management of St. Luke's Hospital, Richmond, expects shortly to enlarge that institution and make a number of changes for the greater good of the hospital. To this end, the three residences just west of the hospital on Grace Street have been purchased.

#### **Members of N. C. State Board of Health.**

Drs. J. Howell Way, Waynesville, and A. J. Crowell, Charlotte, have been reappointed by the Governor as members of the N. C. State Board of Health for a period of six years.

#### **Dr. C. B. Crute,**

Farmville, Va., last month assisted in Powhatan County in holding chest clinics, under the auspices of the Tuberculosis Association.

#### **Dr. Roy K. Flannagan,**

Richmond, represented the Virginia State Health Department at the thirty-eighth annual conference of State and Provincial Health Authorities of North America, which convened in Washington, last month.

#### **Dr. L. H. Apperson,**

Who has been practicing roentgenology in Danville, Va., early this month moved to Petersburg, Va., where he is associated with Dr. Wright Clarkson in the same specialty.

#### **Dr. Paul C. Brittle**

Has moved from Conway, N. C., to Burlington, N. C. Dr. Brittle is a member of the class of '07, of the former University College of Medicine, Richmond.

#### **Dr. J. Rainey Parker Honored.**

Elon College, N. C., at its commencement this year, conferred upon Dr. J. Rainey Parker, Burlington, N. C., the honorary degree of LL. D., in recognition of the work he has done in Alamance County as a surgeon and citizen. He is head of the Rainey Hospital in Burlington and has been doing a big work there.

Dr. Parker has many friends among our readers as he was a former student in Richmond, having graduated from the University College of Medicine in 1901.

#### **Dr. and Mrs. J. Allison Hodges,**

Richmond, are leaving the middle of this month to attend the A. M. A. convention in San Francisco. They will be away for about five weeks during which time they will visit many places of interest in the West.

#### **The Alonzo Myers Orthopedic Clinic, Inc.**

Dr. Alonzo Myers announces the association with him in the practice of orthopedic surgery of Dr. J. Stuart Ganl, recently of Walter Reed General Hospital. They opened a clinic the middle of May, at 8 West Seventh Street.

Charlotte, N. C., which is known as The Alonzo Myers Orthopedic Clinic, Inc. This has complete departments of physiotherapy, brace making and fitting, and orthopedic equipment.

#### **May Have Health Station for Mothers and Children in Virginia.**

Representatives of the American Child Health Association recently spent several days at Charlottesville and the University of Virginia, in an inspection which may lead to the location of a demonstration station for health work among mothers and children. This Association, with headquarters in Washington, has already established two stations, and they propose to establish a third in the Southern States. Virginia is very anxious to have this one.

#### **Roanoke Meeting, Medical Society of Virginia.**

Under the heading of "State Society News," in this issue, we give information about the golf tournament to be held on the 16th of October, and also the names of Roanoke hotels, with their rates.

Begin now to make your plans to attend this meeting. The dates are October 16, 17, 18 and 19, a lovely season of the year, and the meeting promises many interesting features. To add to the success of the meeting, we want the interest and attendance of every member of the Society.

#### **Hospital Buyer,**

Which started publication last Fall, is devoted to all departments of hospital buying and should be of interest to those engaged in this work, as it conforms to the highest standards demanded.

#### **The San Francisco Meeting.**

If preparing to attend the American Medical Association in San Francisco, June 25-29, do not fail to carry your blue fellowship card. General headquarters, registration and information bureaus, all meetings and commercial exhibits will be in the Civic Auditorium. There will also be in this building a branch post-office, so, if you do not know where you will be stopping, you may arrange to have your mail sent you "Care the American Medical Association, Civic Auditorium, San Francisco, California."

#### **Hydatidiform Mole.**

A further study of hydatidiform mole has

been undertaken at this hospital, especially in regard to the frequency of malignancy following this condition. An attempt is being made to collect case reports from outside physicians. Cases reported by physicians will be greatly appreciated and the physician will be given due credit in any literature published.

Address communications to

ROBERT B. KENNEDY, M. D.,  
*Chicago Lying-in-Hospital,*  
*Chicago, Ill.*

#### **The South Carolina Medical Association,**

At its seventy-fifth annual meeting in Charleston, elected Dr. Leland O. Mauldin, Greenville, president, and re-elected Dr. E. A. Hines, Seneca, secretary-treasurer.

#### **The American Laryngological, Rhinological and Otological Society,**

At its annual meeting held last month, elected Dr. Hanau W. Loeb, St. Louis, president, and re-elected Dr. William H. Haskin, New York City, secretary.

#### **Doctor!**

Do you want to locate in Tennessee? City of 4,000, eighty miles south of Nashville on L. & N. R. R. One of richest counties in State. Want to sell out and quit practice. \$4,500 cash to handle. Beautiful home and well-equipped office. Write for particulars to Dr. James A. La Rue, Pulaski, Tenn.

#### **For Sale.**

West Virginia village and country practice and residence: prosperous churches, high school with normal training course, bank, three lodges, rich agricultural section, on class A road. Price \$5,000; residence alone worth the price. Address No. 264, care this journal.

#### **Wanted.**

Physicians (Mental Diseases)—\$1,800 to \$2,000 a year and institutional maintenance. Apply State Employment Commission, 22 Light Street, Baltimore, Maryland.

#### **Good Location For Sale.**

A splendid private hospital containing fifteen rooms and fully equipped with all modern conveniences. This property is beautifully located, fronting Lee Highway, in the new residential section of Christiansburg, Va. Will sell at a reasonable price and on easy terms. If interested, apply for further particulars to W. L. Pierce, Agent, Christiansburg, Va. (Adv.)

## Obituary

### Dr. William Beauregard Ashburn,

South Norfolk, Va., died at his home in that place May 17, at the age of 61 years. Dr. Ashburn studied medicine at the Medical College of Virginia, from which he graduated in 1889. He had been health officer for Berkley and South Norfolk as well as for a time physician to the county almshouse. At the time of his death he was physician to the relief association maintained in Berkley for the benefit of employees of the Virginia Railway and Power Company. Dr. Ashburn was a member of the Norfolk County Medical Society and of the Medical Society of Virginia. He is survived by his wife and two sons, one of them Dr. Horace G. Ashburn of South Norfolk.

### Dr. Samuel Saunders, Jr.,

A former resident of this State, died in Binghamton, N. Y., May 8. He was 36 years of age and studied medicine at the University of Virginia, from which he graduated in 1915, at which time he was appointed an interne at University Hospital. Later he entered the U. S. Public Health Service and at the time of his death was a member of the staff of the Binghamton State Hospital. Dr. Saunders' death was due to a relapse following a severe attack of influenza. Within twelve hours after his death, his mother died at her home at University, Va., and the interment of mother and son occurred simultaneously in Washington, D. C.

Dr. Saunders is survived by his wife, formerly Miss Nan Harding, a graduate of the Training School at University Hospital, a small daughter, and two sisters.

### Resolutions on Death of Dr. McGuire Newton.

The following was adopted at a meeting of

the Richmond Academy of Medicine and Surgery held on May 8, 1923:

*Be it Resolved*, That in the death of McGuire Newton, the Richmond Academy of Medicine and Surgery has lost one of its foremost members.

The profession of this city and State has lost its leading pediatrician; and the people a friend whose loyalty was sublime, and a citizen whose value was immeasurable; a unique character—wise, generous, fearless, rigidly honest; a man to whom the word "duty" was all but a religion.

He gave unstintingly of himself to the mothers and children of this community, and reaped a rich reward in undying affection and deep appreciation. He has left behind the memory of a life that all might do well to emulate; and his loss will long be keenly felt among us. *Be it further*

*Resolved*, That these resolutions be spread upon the minutes of this body, that a copy be sent to his family, and that they be published in the VIRGINIA MEDICAL MONTHLY.

J. G. NELSON,

W. L. PEPEL,

A. L. GRAY,

*Committee.*

The following resolutions were adopted at a meeting of the Medical Faculty of the Medical College of Virginia, Richmond, at a meeting held May 17, 1923:

WHEREAS, The Medical Faculty of the Medical College of Virginia has lost in the death of Doctor McGuire Newton one of its most valued and beloved members. Therefore, be it

RESOLVED, That we, the Medical Faculty of the Medical College of Virginia, feel with deep regret the death of our colleague and friend, Doctor McGuire Newton, whose long, efficient and faithful service to the College, to the children's wards of the hospitals and to the children of the city and State will be missed for years to come. His frank and true personality, his unflinching sense of duty, his great intelligence, his untiring endeavors, his loving kindness in his contact with his little patients and the confidence he instilled in the parents have made him one of the most beloved physicians that has ever lived in Richmond and will leave an enduring impression upon this whole section of the South. For these things and other sterling qualities, we shall miss him in our counsels, in our practice and among us as a friend and advisor. Therefore, be it further

RESOLVED, That in presenting these resolutions the Faculty extend to the family of Doctor McGuire Newton their heartfelt sympathy and that a copy of these resolutions be spread upon the minutes of the Faculty, sent to the daily press and published in the Bulletin of the Medical College and the VIRGINIA MEDICAL MONTHLY.

BEVERLEY R. TUCKER,

ROSHIER W. MILLER,

*For Committee.*

## A FOOD TO KEEP BABIES AND YOUNG CHILDREN WELL

*Adapted to Mother's Milk*

**The importance of fat in the diet of infants**

One of the nutritional principles upon which S. M. A. is founded is that the fat content in the diet of infants is of vital importance in building up their resistance.

**The fat in S. M. A. resembles the fat of breast milk**

S. M. A. meets the need for an artificial food which contains as high a fat content as breast milk, and whose fat is comparable not only in quantity with the fat of breast milk, but also in *physical* and *chemical* properties.

*If you have not had the opportunity to observe the results of feeding S. M. A. in your practice, we shall be glad to send you, free of charge, a supply sufficient to enable you to do so.*

**THE LABORATORY PRODUCTS CO.**  
1111 Swetland Building ∴ Cleveland, Ohio

*Formula by permission of The Babies' Dispensary and Hospital of Cleveland*

S. M. A. fat, in addition, has the advantage of being markedly anti-rachitic and anti-spasmophilic. It thus marks a distinct advance in infant feeding, since it prevents the development of these two nutritional disturbances.

**S. M. A. fat is anti-rachitic and anti-spasmophilic**

S. M. A. also resembles breast milk in its protein, carbohydrate, salt and water content, and, in the hands of a constantly increasing number of physicians, is producing happy, healthy, breast-fed looking infants.

**S. M. A. contains all the required food constituents**

# CALCREOSE

## Intestinal Antisepsis

THERE is good evidence that creosote acts as an intestinal antiseptic but patients object to its use because of its taste and the untoward effect on the stomach.

CALCREOSE (calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium, possessing the pharmacologic activity of creosote but free from its untoward effect on the stomach, therefore,

CALCREOSE lends itself admirably to the treatment of intestinal infections in which it is desired to administer creosote. Patients do not object to its use even when taken for comparatively long periods of time and in large doses.

# A New Arsphenamine Compound

*May be Administered Subcutaneously or Intramuscularly*

**SOLUTION** of Sulpharsphenamine is prepared by breaking the neck of the ampou and introducing with a syringe the required quantity of sterile water.

**COMPARISON** of volume of solutions of leading Arsphenamines ready for administration. Dosage of Sulpharsphenamine shown is for subcutaneous or intramuscular injections.

Arsphenamine 80 Cc. Neoarsphenamine 10 Cc. Sulpharsphenamine 1.6 Cc.

## Sulpharsphenamine Squibb

**A** DEFINITE compound of arsphenamine containing 22 to 24% of arsenic. Marketed in nitrogen-filled ampoules. Higher therapeutic index, more stable and less toxic than neoarsphenamine.

*Note the marked advantages*

- 1.—May be administered subcutaneously or intramuscularly as well as intravenously.
- 2.—Has a higher therapeutic index than neoarsphenamine, plus constancy of therapeutic action.
- 3.—Less toxic than any other arsphenamine compound. Less danger to the patient.
- 4.—Most stable of the arsphenamines. Its solutions do not undergo change as rapidly as solutions of neoarsphenamine.
- 5.—More prolonged in action than neoarsphenamine, and therefore less apt to be followed by reactions.

### ALLERGY IN ASTHMA AND HAYFEVER: A RESUME FOR THE PRACTITIONER.\*

By RICHARD A. KERN, M. D., Philadelphia.

From the Medical Division of the Hospital of the University of Pennsylvania.

It has been estimated that allergy in some form or other occurs in ten per cent. of the white population of this country. Every tenth person is perhaps hypersensitive to some one or more foreign, usually protein substances, and is therefore a potential victim of asthma, hayfever, urticaria, angioneurotic edema or other allergic disease. The American Hayfever Prevention Association† has placed the number of hayfever sufferers in the United States at over one million. Here, then, is a group of conditions that because of its enormous prevalence commands the attention of every practitioner.

Our conceptions of asthma and allied conditions have undergone profound and fundamental changes in the past few years. Let me illustrate by referring briefly to the description of asthma as given in a well known textbook. In the 8th edition of Osler's Practice,‡ published in 1912, we read:

"As to the etiology, all writers agree that there is in a majority of cases of bronchial asthma a strong neurotic element. Many regard it as a neurosis. Of the numerous theories the following are most important: (1) Spasm of the bronchial muscles. (2) Swelling of the bronchial mucous membrane. (3) A special form of inflammation of the smaller bronchioles. Other theories which may be mentioned are that the attack depends on spasm of the diaphragm or a reflex spasm of all the inspiratory muscles." We read further: "One of its most striking pecu-

\*Read before the Walter Reed Medical Society, September 15, 1922, at Smithfield, Va.

†Scheppegrell: Hayfever and Asthma, Phila. and New York, Lea and Febiger, 1922.

‡The Principles and Practice of Medicine: Sir William Osler, New York and London, 1922.

liarities is the bizarre and extraordinary variety of circumstances which at times induce a paroxysm. Among these local conditions, climate or atmosphere is more important. A person may be free in the city and invariably suffer from an attack when he goes into the country, or into a special part of the country. Breathing the air of a particular room or dusty atmosphere may bring on an attack. Odors, particularly of flowers and of hay, or emanations from animals, as the horse, dog, or cat, may at once cause an outbreak. Fright or violent emotion of any sort may bring on a paroxysm. Uterine and ovarian troubles may induce attacks in rare instances. Diet, too, has an important influence and in persons subject to the disease, severe paroxysms may be induced by overloading the stomach, or by taking certain articles of food. Many cases are associated with affections of the nose. Briefly stated, then, bronchial asthma is a neurotic affection, characterized by hyperemia and turgescence of the mucosa of the smaller bronchial tubes and a peculiar exudate of mucin. The attacks may be due to direct irritation of the bronchial mucosa or may be induced, reflexly, by irritation of the nasal mucosa, and indirectly, too, by reflex influences from stomach, intestines, or genital organs."

Contrast these vague speculations of the 8th edition with what we find in the 9th published two years ago: "Hayfever and Asthma: A reaction of anaphylactic nature in sensitized persons, in others possibly a reflex neurosis, characterized by swelling of the nasal or respiratory mucosa, increased secretion, and in asthma spasm of the bronchial muscles with dyspnoea. There are no essential differences between hayfever and asthma: in the one the nasal portion of the respiratory tract is affected, and in the other the bronchial, in many instances both."

Then follow two pages discussing the

various types of sensitization, and as for the possible reflex origin of the disease, there are only these few closing lines:

"Prior to the recent studies, this disease was regarded as reflexly following irritation in various localities: nose, stomach and bowels, etc., and the subjects were regarded as neurotic. Emotional disturbances as fright, apprehension, the smelling of an artificial rose in persons subject to 'rose cold' may cause attacks and it is difficult to bring such cases into the anaphylactic category. The prompt relief that sometimes follows the removal of irritation, for example, a polypus of the nose, support the view that this factor may prevail in cases not sensitive to animal or vegetable proteins."

You see, the chapter on asthma has been entirely rewritten.

Whenever our knowledge of a disease undergoes such a fundamental change, it is inevitable that there be a transition period of confusion. Much that is written is speculative and hypothetical, often exaggerated or even erroneous. It takes time and careful observations to correctly evaluate the various factors. Old ideas, that were unceremoniously discarded in the enthusiasm over the new, at times come back into their own, and assume a new significance. It took years to determine the true value of salvarsan, and that it had not displaced mercury. It is advisable, therefore, from time to time to review such fields of recent advance and to note that which a widened experience has firmly established. Such a survey in the domain of asthma and hayfever is perhaps not untimely.

Certain questions naturally present themselves: Are all cases of asthma due to sensitization? If not all, then what proportion of cases are due to this cause, and to what types of substances are they sensitive? How is sensitization to be determined? What of the role of what used to be called reflex causes, such as nasal conditions, gastro-intestinal and pelvic disorders: do they still play a part? What shall be the treatment of the cases, and what greater hopes can we hold out to our patients? These are the questions that are uppermost in the practitioner's mind and these I shall consider as fully as possible in the time available.

At the outset let me say that the discussion is confined to true bronchial asthma: an affec-

tion in which there is dyspnoea that tends to be more or less paroxysmal, with bronchial spasm that may be relieved by antispasmodics such as adrenalin; a condition in which the dyspnoea is not traceable to other causes, such as evident cardiac disease, either valvular, or the failing myocardium in patients with the high blood-pressure of arterio-sclerosis or nephritis; cases of mediastinal tumor; other forms of lung disease such as advanced stages of pneumoconiosis. It may seem unnecessary to state these diagnostic precautions, yet such cases are constantly being referred to asthma clinics for sensitization tests. For example, a man of fifty-nine was recently sent in for study of his so-called "asthma." The history was that he was a coal miner, twenty-nine years underground; that ten years ago he began having winter colds, worse recently, with dyspnoea induced by paroxysms of coughing, especially at night. On physical examination marked emphysema and a weak myocardium were found, and X-ray showed advanced pneumoconiosis. He had "miner's asthma," but certainly not bronchial asthma. A woman of forty had been treated six years for a supposed asthma. Physical examination showed slight thyroidal enlargement and a large substernal goitre, the removal of which effected a prompt cure.

**INCIDENCE OF SENSITIZATION.** Sensitization is by far the most important single cause. According to various observers from fifty to seventy per cent. of all cases give positive skin tests and clinical proof. Of the remainder it is probable that an increasing proportion will be found sensitive on more careful study, and as our knowledge of sensitizing substances increases. Cases that develop in childhood are practically all allergic; the proportion of positive skin tests gradually falls with a rising age of onset. Of patients developing asthma under twenty-five, fifty per cent. are found sensitive: under thirty, twenty-five per cent. Allergy very rarely manifests itself for the first time over the age of fifty.

**TYPES OF ALLERGENS.** The substances to which patients react may be divided into those which are *ingested* and those which are *inhaled*.

**I. Ingested Allergens.** Foods are far less commonly the cause of asthma than some of the earlier observers would have us believe, and more recent figures put the incidence well

under five per cent. Food-asthma is met with chiefly in early life, and even here it is not a predominant factor. Furthermore, the finding of a positive skin test is not sufficient to assign to that food a definite causal relation: in each case there must be clinical proof that exposure to the food in question will produce an attack, and that withdrawal of the food will improve the patient's condition. It is conceivable that a food, even though it causes a reaction when introduced into the skin, is rendered harmless on ingestion by the processes of digestion. The foods most commonly the cause of asthma are egg, milk and the cereals; then come shell fish and fruits. In the group of ingested substances may be placed drugs. As a rule, drug allergies appear in the form of urticaria or angioneurotic edema, involving the skin or gastro-intestinal mucosa, but in occasional cases drugs produce asthma.

II. *Inhaled Allergens.* Of far greater importance are the inhaled allergens. These may be classified as follows:

(1) Animal emanations. Most frequently to blame are hair or dandruff of horses and cats, and the feathers of chickens or geese. Rabbit hair is often used in pillows by the foreign-born in our cities. Occasional causes are duck, canary, and parrot feathers, dog and guinea-pig hair.

(2) Pollens. Forty per cent. of hayfever patients suffer from asthma during some portion of the season. The offending pollen varies with season and locality. In Virginia, the principal cause of spring hayfever and asthma (May 15 to June 30) is grass pollen, notably Kentucky blue grass, timothy, red-top and orchard grass. Minor causes are sheep sorrel, worm seed, horseweed, and in some localities the pollens of black willow, black walnut, red maple and the oaks. Fall hayfever and asthma (August 15th to October 15th) is almost wholly due to common ragweed, occasionally giant ragweed and marsh elder.

At this point let me call your attention to a fundamental principle of plant pollination, ignorance of which has led to many erroneous beliefs. All flowering plants fall into two groups, the wind-pollinated, and the insect-pollinated. Wind-pollinated plants have inconspicuous flowers that form a very profuse pollen of exceedingly small size—fifteen microns for ragweed. Such pollens have a

wide range of wind convection—a quarter to half a mile for the grasses and five miles or more for ragweed. Insect-pollinated plants on the other hand have bright colored, conspicuous, at times scented flowers to attract insects. Their pollen grains are large and heavy and their range of wind convection is at most a few feet. When it first became generally known that pollens bore a relation to hayfever and hayasthma, people began to observe what plants were in bloom during the season of illness. So in the fall suspicion at once fastened on goldenrod, while the inconspicuous ragweed was for years overlooked. It is quite true that roses, primroses, goldenrod and the like may be responsible for an occasional attack but it is only when the patient comes in direct contact with the flowers. For the overwhelming majority of cases the insect-pollinated plants have no significance. The importance of corn pollen as a cause of trouble has been emphasized by several writers. Here, it is true, we are dealing with a wind-pollinated plant, but its pollen grains are so large that they are not carried over a few hundred feet and only persons in close proximity to cornfields can be affected.

(3) Dust. This term covers a most important group of factors. Most asthmatics say that dust of any kind causes them trouble and it is easy to understand how in an asthmatic patient, at a time when there is bronchial infection and a congested mucosa, together with a "hair-trigger" vasomotor system, the inhaled dust acting simply as a mechanical irritant may precipitate an attack. It is, however, a significant fact that the dusts to which we are exposed are commonly of an organic nature. They contain varying amounts of protein and may, therefore, act as antigenic substances in producing a true sensitization. Commonly, then, we find that asthmatics are sensitive to a particular dust. This may be a dust to which they are exposed in their occupation. A baker may become sensitive to the proteins of wheat or rye flour, a tailor to sheep wool, jewel polishers and woodworkers become sensitive at times to wood dusts, and boxwood seems to be the commonest offender. Various face powders and toilet preparations, particularly those in which orris-root is an ingredient, may play a part. These are clearly defined specific dusts. But commonly the patient is sensitive to the dust of a particular room, usually the

bedroom. At times this may be traced to an ingredient of room dust derived from such substances as feathers, a wool rug, a grass rug, or wall paper. More often, however, we find sensitization to only "dust." Extracts of dust in these cases will give positive skin tests and avoidance of the particular dust gives the patient relief. These dust cases are extremely common. Cooke\* has recently reported positive skin tests to a stock dust extract in over thirty per cent. of his cases. In my own experience I have found this to be true.

How do people become sensitive to dusts? It is an interesting fact that bedroom dusts are those most often concerned. It is also a matter of common observation that asthmatic patients date the onset of their trouble to an acute infection of the respiratory tract, and one is led to speculate as to a possible connection between these two. Influenza is often mentioned by patients as the starting point of their trouble. In others it is severe bronchitis, bronchopneumonia and in children whooping cough. These are all conditions in which there is present a considerable bronchiolitis. Lobar pneumonia, on the other hand, is rarely an antecedent of asthma. One must admit the probable tendency to sensitization in these individuals as evidenced by the commonly positive family history for allergic disease. But we do know that an inflamed mucosa is more permeable to foreign substances than a normal one. Egg albumin fed to an animal with enteritis will pass unchanged through the intestinal lining to the blood and can be found in the urine. It is conceivable, therefore, that in these cases of acute bronchial infection the inflamed mucosa offers a portal of entry for the sensitizing dose of a foreign protein. Since the patients are usually confined to their bedrooms during such illnesses, bedroom dusts should be the commonest offenders.

(4) Bacterial Sensitization. Much was written several years ago on sensitization of asthmatics to the proteins of the bacteria with which they were infected and skin tests were performed with bacterial extracts and suspensions. More recently, a number of observers have reported their failure to get positive reactions and it is probable that an actual sensitization in asthmatics to bacterial protein does not exist.

How shall we find out to what a patient is

sensitive? This is accomplished by a careful history and skin tests. There is no disease in which a detailed history is more essential than asthma, and I know of no type of history that is harder to take. We must go into every ramification of the patient's life, activities and surroundings. The significance of the age of onset has been referred to. Among the circumstances of the attack we must consider:

(a) *The nature of the attack.* This includes a description of its onset, duration and termination, its relation to cough or exertion. The more definite the paroxysmal nature of the attack, characterized at the onset with dyspnoea not induced by cough or exertion, the more likely is the case to be allergic.

(b) *Seasonal Variation.* Pollen cases obviously fall in this group, but we must also keep in mind the seasonal occurrence of certain foods, for example, strawberries. Many non-sensitive cases have also a seasonal variation usually being worse in winter, or in the early spring and late fall, at the times of transitional weather between warm and cold.

(c) *Time of day of the attack.* The attacks of dust asthma and those due to feathers are usually nocturnal. However, it is a fact that all asthmatics have more trouble at night.

(d) *Place of the attack.* Are the attacks limited to or distinctly worse in a particular room or locality? Has the patient ever experienced relief by leaving his house or neighborhood and going on a vacation or a visit?

(e) *Relation to food.* Has the patient ever noticed any relation between the taking of any particular food and the occurrence of the attacks? Here again we must guard against error; it is a common experience that asthmatic attacks are prone to follow a heavy meal, simply a matter of overfilling the stomach.

(f) *Exposure to animal emanations.* In this connection, it is not enough to take the patient's word as to contents of pillows, mattress or upholstery, but he should be required to submit specimens. An intelligent patient, a woman of forty-five, last winter consulted me because of asthma each winter for the past three years. She gave a history of asthmatic attacks fifteen years ago whenever she rode horseback and was forced to give up her horses on that account. Further questioning showed that her recent attacks have occurred only when occupying a certain apartment each winter. She brought a sample of the mat-

\*Journal of Immunology, I, 147, March 1922.

tress stuffing which she had thought to be wool but which she found to be horsehair. The removal of the offending mattress of course gave prompt relief.

(g) *Occupational dusts.* This needs no explanation.

(h) *The effect of antispasmodics.* If adrenalin fails to give relief in an attack of dyspnoea, there is little likelihood of uncomplicated allergy.

The family history is of importance. Fully fifty per cent. of all asthmatics give a positive family history of allergy in some form or other. Thus, one person may be subject to hayfever, another has a food rash or is sensitive to drugs and the like.

**SKIN TESTS.** These are indispensable in the study of a case of asthma. The physician who expects to investigate many asthma cases must have in his possession suitable preparations of practically all substances that we know can cause asthma: their number mounts into the hundreds. And right here the practitioner is confronted by his greatest difficulty. He asks, "Is it worth my while to acquire all these substances for the comparatively few cases of asthma that I see?" and he promptly answers his question by "No." Experience has, however, shown us that the great majority of cases are due to a comparatively small number of substances. It is possible, therefore, to draw up a small list of proteins which it is worth every practitioner's while to acquire. With these he can test the patients and frequently arrive at a correct diagnosis. Only when he has failed in this is it necessary to refer his patients to someone more fully equipped. Of the foods he should have the following proteins; egg, milk, rice, wheat, corn, buckwheat, oat, rye, bean, pea, potato, strawberry, lamb, pork, beef. Of the animals emanations are necessary horse dander, chicken feather, goose feather, cat hair and dog hair. Orris root is also desirable. The above preparations can be obtained in powder form and retain their potency for a considerable time, at least a year. For Virginia the following pollen extracts are needed: Kentucky blue grass, timothy, red top, orchard grass, sheep sorrel, black willow, black walnut, common ragweed, giant ragweed, and marsh elder. These pollen preparations tend to deteriorate and should be renewed in the spring of each year. Room dust preparations for sensitiza-

tion tests may be prepared in the following manner: Sufficient dust is placed into a wide-mouthed two ounce bottle to fill it half way and enough fourteen per cent. alcohol added to just cover it. This is allowed to stand for three or four days being shaken vigorously two or three times a day. A drop of the resultant fluid is sufficient for a test. It has been the experience of the writer and others that when a particularly active dust solution is found it may be used routinely in the testing of other patients.

Tests may be performed by two methods—intracutaneous in which the substance in solution is injected into the skin, and cutaneous, in which the dry powder is placed upon a shallow cut or abrasion, usually on the flexor surface of the forearm, and the substance brought into solution by the addition of a drop of tenth normal sodium hydroxide (0.4 per cent.). In each case a positive reaction is characterized by an urticarial wheal, one-half centimeter or more in diameter, and a surrounding zone of erythema. The intracutaneous method is undoubtedly more delicate but it presents certain difficulties and dangers. The proteins to be tested must be in sterile solution and such solutions are not now commercially available. Furthermore, intracutaneous tests are sometimes followed by severe general reactions and only recently there was reported the death of a child three minutes after the test injection. The method, therefore, is only safe in the hands of those specially trained and the practitioner should content himself with the cutaneous method.

So much for sensitization: what of other etiologic factors? Second only to sensitization in importance is infection. Bronchial infection may itself cause asthma; repeated winter colds may prepare the soil for a dust sensitization. Infection sooner or later complicates all cases of asthma, whatever be their cause, and the prognosis in any case depends largely on the amount of permanent lung damage that infection has produced. Cases that begin as a seasonal pollen asthma are frequently prolonged into the fall and winter and finally become perennial because of superimposed infection. And the infection must be sought for throughout the whole respiratory tract, including the nasal sinuses and tonsils as well as the bronchi.

What of the so-called reflex causes? Cases

of gastro-intestinal origin are due to ingested substances and cannot be considered reflex. Rarely there are cases of pelvic origin and in these an endocrine disturbance must be suspected. Rose and Rolleston\* recently reported the case of a woman in whom asthma developed promptly after the production of an artificial menopause with radium. Sensitization studies were negative and for a year all methods of treatment failed. Three days after the administration of ovarian and mammary extracts was begun the asthma ceased and after eleven months the patient was still free of symptoms. In a small number of asthmatics, nasal disorders, notably polypi and infection of the ethmoid sinuses, seem to be the only etiologic factor, the operative treatment of which is followed by a prompt and permanent cure. Unfortunately, these cases are very few, and it is the experience of everyone who sees many asthmatics to get a history of one or more futile nasal operations in nearly every case. For the rest, reflex causes have little significance. A patient with asthma due to sensitization has as a result an autonomic nervous system that yields more readily to stimulation than normally. Thus, excitement or an over-filled stomach may precipitate a paroxysm of asthma. The heightened nervous instability so common at the menses is quite sufficient to account for the greater frequency of asthmatic attacks in women patients at that time. Prevent exposure to the underlying sensitization factor—a pollen, feathers, etc., and the secondary reflex causes are inert.

TREATMENT may be considered under the headings specific and adjuvant.

*Specific Treatment:* At the outset it must be stated that by far the best results are obtained when the offending substance can be avoided. Active desensitization (or as Cooke has more aptly termed it, hyposensitization) is much less satisfactory, its results variable and as a rule not permanent. Foods can usually be avoided. At times, cooking renders the food inert. Patients mildly sensitive to one of the wheat proteins can take small quantities of toast without trouble. If an individual is sensitive to only the lactalbumin of milk and not to casein, the lactalbumin can be removed by boiling and skimming off the coagulated protein. If the food in question is a common article of diet, such as egg or

milk, then active desensitization must be attempted. This may be done by repeated subcutaneous injections of increasing amounts of the protein, or (and this is the method of choice) by the feeding of gradually increasing amounts. Thus, a child may be given a few drops a day of a cow milk solution sufficiently dilute so as not to cause a reaction. Each day the quantity and strength is increased until the child is able to take a fair amount of whole milk. Should any dose be followed by a reaction, the subsequent dose must be smaller. Such a patient must continue to take a given amount of the particular food every day in order to retain a state of diminished sensitization. The animal emanations are usually avoided; for example, feathers in pillows, animal pets and the like. There is one exception, namely horse emanation. Street dust may contain sufficient horse emanation to produce asthma in very sensitive individuals, and in such cases active desensitization is necessary. Fortunately, the results are usually good.

When a patient is sensitive to room dust, a complete change of his surroundings is advisable. He should use another room, preferably without floor covering and a complete change of bedding. Pillows, stuffed with silk floss or cotton are preferable to feathers. Such a change is commonly followed by prompt relief. This relief, unfortunately, is very often only temporary. After four or five months the patient has a return of asthma usually introduced by an acute respiratory infection and it is often found that he has become sensitive to the dust of his new surroundings; another change is then indicated. Attempts to desensitize by the injection of dust extracts have been made and with promising results. The method is, however, yet in the experimental stage.

In pollen cases the avoidance of the causative factor is practically impossible and desensitization must routinely be used. Patients are commonly sensitive to several of a group of related pollens. For instance, patients with early summer hayfever are usually sensitive to a number of the grasses. Under these circumstances one should select for treatment the pollen which gives the strongest skin reaction and is at the same time the commonest in the patient's surroundings. The grasses are biologically so closely related that desensi-

\*British Medical Journal, 1, 12, January 7, 1922.

tization to one pollen offers considerable protection against the whole group. Prophylactic injections should be begun, preferably three months before the beginning of the season, and given at intervals of five to seven days, using the successive doses as outlined and recommended by the various biological products houses. The results of pollen injections are as a rule quite satisfactory in the early summer forms of hayfever and asthma, and the patients usually have complete relief. The autumnal form is, however, much more refractory. Only an occasional case experiences complete relief when treated with the usual commercial products. In the majority of instances, however, the disease is greatly ameliorated and less than ten per cent. experience no improvement at all. There remains considerable room for improvement in both the pollen preparations and our method of treating these autumnal cases. Pollen injections during the hayfever season should be given very cautiously and in small doses. An overdose may do considerable harm. No injections should be given during the season when the patient is free of symptoms. Desensitization must as a rule be carried out each year. In a small number of cases one or two series of treatments have succeeded in giving permanent relief.

A point that is commonly overlooked in the management of hayfever and hayasthma cases is the avoidance of exposure to large quantities of pollen. Patients should be told to keep down the weeds in their neighborhood. By a thoroughgoing antiweed campaign in the City of New Orleans, Scheppegrell and his associates were able to reduce the incidence of spring hayfever by fifty per cent. In rural communities the difficulties are, of course, almost insurmountable.

*Adjuvant Treatment.* Of first importance is the treatment of infection. This includes the elimination of infected foci, such as sinuses and tonsils. An autogenous sputum vaccine in asthma or one prepared from the nasal secretions in hayfever is of great value. It is to be remembered, however, that the bacterial flora of the sputum often change and fresh vaccine must consequently be prepared from time to time.

*Drugs.* The time honored antispasmodics, belladonna, lobelia and stramonium, are of great value. Calcium lactate in doses of ten

to fifteen grains three times a day has proven efficacious in both asthma and hayfever. Much was hoped for from the recently introduced drug benzyl benzoate but unfortunately the results have not been very encouraging. Perhaps one case in thirty is strikingly benefited while the rest are not helped at all. Nevertheless it is worth a routine trial. Potassium iodide is indicated in practically all cases. To obtain the best results it should be given in small doses, not over five grains two or three times a day, and its use should be continued over long periods of time.

A change of climate helps in asthma as it does in tuberculosis, chiefly by its curative effect on secondary infection. A warm, dry equable climate at an altitude not over 3,000 feet is the most advisable, for example Southern New Mexico.

*TREATMENT OF THE ATTACK.* Here by far the most useful drug is adrenalin. It should be given early in the attack and doses of 2 to 4 minims of a 1 to 1,000 solution are quite adequate. The common mistake is to give too much, thereby producing disagreeable secondary after-effects. When patients administer the drug to themselves, ten to fifteen minims of a 1 to 10,000 solution should be used. It was formerly believed that the prolonged use of adrenalin gave rise to serious troubles such as arteriosclerosis. Clinical experience has shown, however, that this is not the case. Hoxie and Morris\* have reported the case of a woman who for a period of six years had taken an average of 7 c.c. of adrenalin hypodermatically each day. The patient died suddenly and autopsy showed practically no vascular change.

The use of the various asthma powders and smoke inhalations is to be condemned. It is true these substances give temporary relief but their continued use results in additional bronchial irritation and only increases bronchial infection.

*RESULTS OF TREATMENT.* Do we cure asthma patients? If by cure is meant the rendering of the patient non-sensitive, then the answer must be "No." Sensitive patients will always develop asthma if exposed to the substance to which they are sensitive in sufficient concentration. We can, however, completely relieve the patient of his asthma if the sensitizing substance can be completely avoided and if no permanent lung damage has been done. And

\*Endocrinology, IV, 47, 1920.

that for practical purposes constitutes a cure. The results of pollen and horse emanation desensitization have been referred to. In the non-sensitive cases and in those sensitization cases in which there is prolonged secondary infection, emphysema and resultant secondary myocardial weakness, the outlook is not good. It is important, therefore, that these cases be diagnosed and thoroughly studied as early as possible and this is the responsibility of the general practitioner.

### LEPROSY—REVIEW AND REPORT OF A CASE.\*

By DUDLEY C. SMITH, B. S., M. D., Charlottesville Va.  
Instructor, Dermatology and Syphilology, University of Virginia.

The reasons for this review and report are mainly three in number. First, leprosy is a rare disease in Virginia. Second, increasing immigration may make it more common. It is a fact that at present leprosy does not begin in this climate, but it is entirely possible for the organism causing it to change its characteristics by evolutionary processes in such a way that it will attack persons in this climate. Third, during the last few years marked advances have been made in the treatment of leprosy.

CASE REPORT: Mr. O. K., whose address is 631 W. Main St., Charlottesville, Va., presented himself at the Out-Patient Department of the University of Virginia Hospital on September 2, 1921. He was admitted to the hospital for further observation. He had been admitted to the hospital on two occasions previously; March 9, 1916, and November 20, 1918. On these occasions his complaint was "rheumatism" and his diagnosis was syphilis. Following each admission he received a series of intravenous injections of arsphenamine with only very slight improvement. The records on both of these occasions give approximately the same data, except certain signs and symptoms were more marked on the latter admission.

Patient is a Syrian about fifty years of age, is single, was born in Syria, came to New York City about 1900, lived there a short time, then came to Virginia with his brother. They kept a small store and peddled their wares.

FAMILY HISTORY: Father and mother dead, died of old age, cause not known. Questioning gives no information as to the cause of their death. No sisters. One brother about five or six years younger, living, and in good health. He knows of no other members of family having trouble similar to his.

PAST HISTORY: Was a healthy child and young man. Does not remember having had any illnesses. Worked as "day laborer" until 1908, from which time patient dates his present illness. Has had headache since 1915; this is almost constant with paroxysmal increases. Hard indurated lumps began to appear on forehead at this time. These were not very tender. Has vertigo. Vision has been poor for several years. Some pain in eyes. Hearing has diminished in acuteness. Never any discharge. Lumps began to appear on ears in 1914. Began to have chronic cold in 1914; soon following this he had several attacks of nosebleed (fresh blood). Later the bleeding was less, but more constant, almost daily; blood was brownish with some flakes from nose. Rarely any sore throat, some hoarseness. No palpitation. No dyspnoea except in the attacks of pain. Some precordial pain which does not radiate. Feet, legs, arms, hands, and face have swollen for several years. No chronic cough, hemoptysis, night sweats, or loss of weight. Appetite and digestion good. No constipation. Urinates five to six times at night, this began about two years ago, amount passed each time is small, some difficulty starting stream. No hematuria. No incontinence. Denies venereal infections. No convulsions, memory good, sleeps well, for several years has had "girdle pains." Habits are not unusual, uses tobacco and coffee in moderate amounts, drinks very little, seems to have some idea of sanitation and infection.

PRESENT ILLNESS: Patient dates his present trouble since about 1908. At that time he began to have "rheumatism," thinks his joints swelled, he felt stiff and had much pain. Before this he had been in good health. The trouble began in his right arm, then involved his shoulder, left leg, right leg, and left arm in this order. Was confined to bed three weeks. Similar attacks have continued to present time except they have been of shorter duration. About 1915 he began to have darting and lancinating pains in arms, legs, abdomen, and chest. At times these were stinging in char-

\*From the medical service, division of dermatology and syphilology, University of Virginia Hospital.

Read before semiannual meeting of Piedmont Medical Society, November 5, 1922.

acter, at other times burning sensations were severe. The "shooting" pains were worse in legs. In abdomen it feels as though some one grabbed him "in the stomach" and pulled and twisted. Does not vomit. About 1914 he noticed the appearance of nodules in the skin. These appeared in head, neck, arms and legs. These caused very few symptoms, nor were they tender. No ulceration. Patient says his feet feel dead. The skin on legs and arms is not as sensitive as normal, can strike or cut skin without pain. He has some trouble walking in the dark, legs feel stiff. The pains are worse in cold weather and at night. These are not affected by diet or exercise.

**PHYSICAL EXAMINATION:** Patient is a well nourished Syrian about fifty years of age. Answers questions slowly but seems to have average intelligence. Speaks English fairly well. Complains of frequent, shooting pains. He has leonine face. Fairly marked ragged alopecia of scalp and eyebrows. Almost entire skin is covered by maculopapular eruption. The eruption is "ham-colored" and splotchy. The areas are confluent. The thickness of the skin varies from slight to nodules from two to four centimeters in diameter, especially about the face. These nodules are intradermal, only slightly tender, are not painful, and are most prominent on the forehead and ears. On the arm just above the bend of the elbow is a round area four centimeters in diameter which is whitish and atrophic. There is a similar area three centimeters in diameter about the middle of the outer surface of the forearm. Most of the first phalanx of the right forefinger is absent, the patient says due to injury. There is marked diminution of senses of touch and pain over the body, which increase on extremities toward the hands and feet. Over the forearms, face and legs there is almost complete anaesthesia. Pupils contracted, are equal and normal, react to light and distance. There is mild conjunctivitis with some pustular discharge. Nose flattened, nodules in skin, and shows bloody scales in nares. Teeth poor. Small nodule the size of a pea on the tip of the tongue. Pharynx slightly congested. Tonsils enlarged and cryptic. Expansion of chest good and equal. Lungs clear. Heart not enlarged, no adventitious sounds. Abdomen normal. Penis normal. Left testicle atrophied. There are palpable lymph glands in the neck, axillae, ingui-

nal regions, and epitrochlear regions. Some of the glands are as large as a lima bean. They are smooth, rather hard, and discrete. The patella, Achilles, and triceps reflexes are absent. Babinski negative. Romberg moderately positive. The ulnar nerve is palpable in both arms.

**LABORATORY FINDINGS:** White cell count is 8,500; red cell count is 5,000,000; hemoglobin eighty per cent. Differential shows polymorphonuclears 60.5 per cent.; lymphocytes 29.3 per cent.; large mononuclears 4.4 per cent.; transitionals 2.4 per cent.; mast cells 0.8 per cent.; eosinophiles 2.6 per cent. Wassermann was strongly positive on several examinations. Blood pressure is a hundred and forty systolic and eighty diastolic, Phenolsulphonphthalein kidney functional test gave thirty-five per cent. excretion in the first hour. Spinal fluid examination normal. Urinalysis showed specific gravity of 1020, acid reaction, no sugar, a trace of albumin, a few hyaline and finely granular casts, no blood or pus. Acid fast bacilli corresponding to morphology of Bacilli leprae were found in nasal secretion, nodules in skin and venous blood. These were found in smears made directly from nasal secretion, venous blood and serum from nodules; in the case of venous blood, several cubic centimeters of blood were laked by adding to solution of acetic acid, the mixture centrifugalized and smears made from sediment (method used by Rivas.)

Diagnosis on last admission was *advanced maculopapular and anaesthetic leprosy*.

No claim is made to anything original in the following review, it is gathered from the accepted authorities. It is not even attempted to make a complete review of leprosy, this would require a monograph.

The cause of leprosy is generally recognized to be a slender acid-fast bacillus, very similar to the tubercle bacillus.

It was discovered by Hansen in 1871. It is very difficult to grow in culture media or in animals; in fact some claim that it has never been grown outside the human body. The arrangement of these bacilli in large plasma cells is characteristic, the protoplasm of the cell is packed with these bacilli and the bacilli are in bundles. These cells are called "lepra cells." The bacilli may also be found in lymph spaces. They invade practically any tissue of the body, but have a predilection for the skin and nerves.

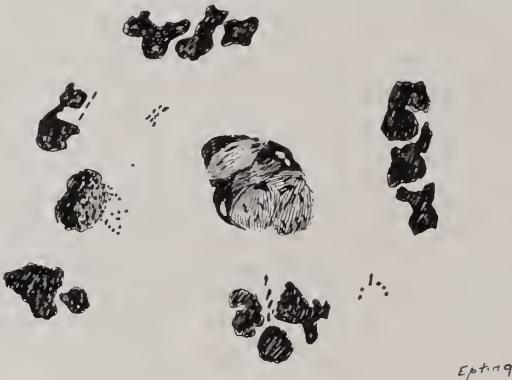

Practically nothing is known in regard to the immune reaction. A positive Wassermann is present in about sixty per cent. of cases. The disease is most probably spread by contact. It is not known whether the contact is direct or indirect, evidence seems to point to direct contact transference. The blame is put on air, dust, water, food, insects, rodents, etc., without conclusive proof. The main factors in infection are: number and virulence of organisms; environment, including climate; and individual susceptibility. The latter may be either acquired or hereditary. A metabolic deficiency may be a factor in the individual susceptibility. Prolonged contact seems to be essential to transmission. Age has a bearing, the child or young adult being more suscep-

that the bacilli multiply rapidly and are soon disseminated over the body, probably through the lymph and blood.

The lesions of leprosy are characterized by a particular type of granuloma. This granuloma shows mononuclear (lymphocytes, plasma cells and mast cells) infiltration usually about the blood vessels. The vessel walls are thickened. The infiltration replaces the normal elements of the tissue to a certain extent. Numerous bacilli are found in the lesion. A characteristic finding is the "lepra cells." Leprous tissue may change into scar tissue without ulceration, or ulceration may occur. Involvement has been found in practically all the tissues of the body. The bacilli within or near the nerves cause a neuritis with hyperesthesia at first, followed by degenerative changes in nerve fibers.

The stage of invasion usually presents prodromal symptoms. These vary in intensity and kind, sometimes few and mild, at other times more severe. This period varies from a few months to a year in length. A list of prodromal symptoms includes malaise, lassitude, chilliness, intermittent fever, mental depression, epistaxis, rhinitis, hoarseness, superficial and deep neuralgic pains, alteration in cutaneous sensibility, tingling, itching, burning, localized tenderness, numbness, stiffness, vertigo, and headache. A few or several of these symptoms may be present. In localities where leprosy is rare the diagnosis is rarely made in the early stages.

Three forms of leprosy are described; the tubercular or nodular, the anaesthetic, and a mixed type. In the first the skin is involved, and in the second the nerves. Most cases actually belong to the mixed type. In the tubercular form the first thing noted in the skin is patchy brownish-red or fawn colored maculopapular eruption on the exposed surfaces. The elevation of the skin may be very slight. The erythematous area may be from two to three centimeters in diameter. These may disappear and leave white spots, or there may develop definite nodules in the skin. The eruption sometimes becomes generalized. The nodules are seen frequently in the eyebrows, on the forehead, the alae of the nose, lobes of the ears, cheeks, back of the hands and on the feet. They vary from the size of a pea to a thickened area of skin several inches in diameter. The nodules may be generalized. The

Nasal smear, showing "lepra cell" filled with acid-fast bacilli.

tible. There are two males affected to one female. All races are susceptible. Most of the cases in this country occur in Louisiana, Minnesota, California, and Florida.

The incubation period is not definitely known, probably a few to several years. Granting that the patient whose case is here reported got his initial infection in his homeland and that the first evidence of the trouble was in 1908, the minimum time of incubation in his case is seven years. Both statements can be challenged, but are reasonable suppositions. The average length of incubation is stated as being two to three years.

The method of invasion is also unknown. The theories are that the bacillus enters the body through the skin; the mucous membrane of nose, pharynx, or bronchi; the gastrointestinal tract; or the generative organs. Most authorities feel that the nasal passages are the site of the initial lesion. The character of the primary lesion is not known, but it is known

nodules cause irregularities in the skin which on the face produce the leonine appearance. They may ulcerate. The subjective symptoms may consist of any of those mentioned under prodromal symptoms. There is often a generalized enlargement of lymphatic glands. These are moderately enlarged, elastic, and painless. The mucous membrane of the nose, mouth, pharynx, and larynx may be involved. There is usually some conjunctivitis, sometimes a keratitis and abnormalities in the deeper structures of the eyes.

In musculo-anaesthetic or nerve leprosy the bacilli cause changes in the nerves. At first there is irritation causing shooting pains, sensory, vasomotor, and motor disturbances. Later

cases that show both nodules and nerve leprosy. It may begin as either or both types.

The essential in prophylaxis is to prevent the bacilli being distributed from diseased individuals to those not infected. Complete isolation of lepers has proved a practical procedure in diminishing and ultimately exterminating the disease. Of course, a remedy that would quickly and efficiently destroy all the bacilli in an infected person would be a great aid to prevention of the disease. This goal has not been reached but several steps in that direction have been taken.

A malady as old as leprosy and with its characteristics has necessarily been treated in numerous ways. A list of drugs used in its

Photographs of patient taken in 1901 and 1921.

there occurs macular eruption. This may be red, pigmented, or light spots. The areas are sometimes several inches in diameter. The process progresses, the nerves become palpable, the skin becomes anaesthetic and the patient gets a paralysis of certain muscles. The nerves most commonly involved are the ulnar and peroneal. The paralysis produces the "claw hand." Reflexes are at first exaggerated, later they are diminished. Trophic lesions may occur in the tissues supplied by the affected nerve; this may go as far as actual loss of a portion of an extremity. It is characteristic of this type that the progress is slow.

The third, or mixed type, includes all the

treatment would be very long. Yet, in spite of the numerous remedies recommended, it has been considered practically a hopeless condition.

Most consideration has been placed on the segregation of those afflicted to prevent normal persons becoming infected. This alone has proved in several instances to be an efficient method of reducing the number of lepers. The reduction is slow, decades are required to free a country of the infection.

Proper treatment of the disease consists of general measures and medicinal treatment. The general measures employed are change in environment, hygienic surroundings, good

food, fresh air, freedom from mental worry, tonics, etc. It frequently happens that a patient shows marked improvement following admission to a leper colony when only general measures are used. Spontaneous recovery is said to occur occasionally. Surgical and other measures are taken advantage of when indicated. Leprasoria are necessary for the proper handling of lepers, both from a prophylaxis and treatment standpoint. The remedies recommended in treatment of leprosy include drugs, glandular extracts, vaccines, and serums. The agent which has stood the test of time and experience is chaulmoogra oil, or its derivatives. This oil contains substances which have a specific action on acid-fast organisms, especially the leprosy bacillus. Large amounts of the oil over long periods cannot be given on account of the gastric disturbance. The crude oil when given by intramuscular injections is very irritating. During the last few years it has been found that certain fractions of the oil contain the active principles. The unsaturated fatty acids, chaulmoogric and hydnocarpic, or some associated substances are the active bactericidal substances. The ethyl esters of these acids are recommended by McDonald and Dean: the sodium salt of these acids is used by Rogers. The ethyl esters are given in one to five cubic centimeter doses intramuscularly. The sodium salt is given intravenously in two grain doses after being dissolved in citrated salt solution. McDonald and Dean make the following statement: "The intramuscular injection of the ethyl esters of the fatty acids of chaulmoogra oil usually leads to a rapid improvement in the clinical symptoms of leprosy. In many cases the lesions disappear, except for scars and permanent injuries, and the leprosy bacillus can no longer be demonstrated." Rogers and others come to the same conclusion. Undoubtedly a marked advance has been made in the last few years in the treatment of leprosy.

#### PRELIMINARY NOTE ON A NEW THERAPEUTIC AGENT, THE THERAPEUTIC SWING.

By P. B. BARRINGER, M. D., Charlottesville, Va.

Some ten years ago with a weight of 225, and height five feet, eight inches, the writer began to show periodic glycosuria. Always a trencherman, it was hard to quit old habits among which were midnight meals after the

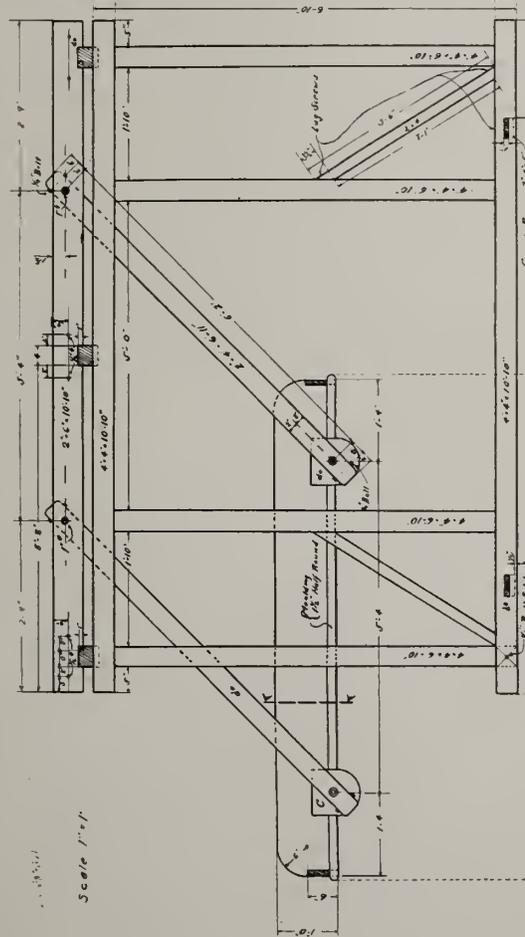

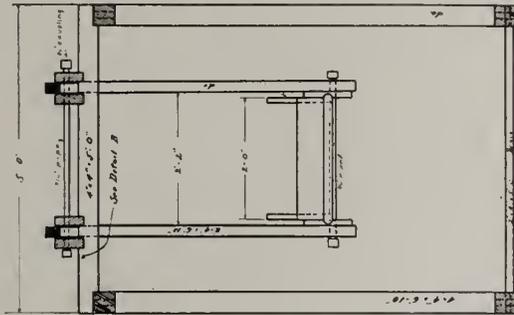

midnight oil. With these attacks came distressing nightmare, not dreams but the old primitive night terrors, going back to the weary winged pterodactyle and the sabretoothed tiger snarling and snapping below. I soon found that sleeping on my belly stopped the nightmare and I in time assumed this sleeping posture habitually. In less than five years' time, with little or no medication and only a temporary change in diet, the sugar disappeared absolutely, but not until I had dropped to 169 in weight. Midnight mincepie is still a satisfying and soothing solace.

I began to wonder if this change in sugar toleration was due to decline in "obesity" or was it due to change in sleeping posture. I recalled that we were quadrupedal long before we were bipedal, that the natural sleeping posture of the child is also on its belly, that there must be a better visceral circulation when on the belly because then the "posterior" ligaments which carry the blood supply hang vertical and straight, just as they were evolved. Further, I had observed that many members of a wonderfully long-lived family slept that way. Moreover, there had been a steady fall in blood pressure, with my loss of weight, amounting to some 30 mm. in four years. As a working hypothesis I decided to assume that it was increased intra-abdominal pressure, pressure on the pancreas, sympathetics and vessels, that produced my trouble. When lying on the back, obesity, heavy meals, too much water in the stomach and even gastric gas all give an increased pressure on pancreas, etc., while if on the belly only the latter oppressed. This was my case.

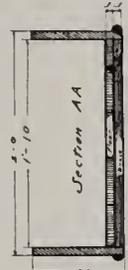

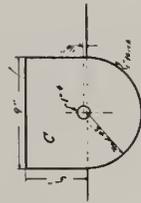

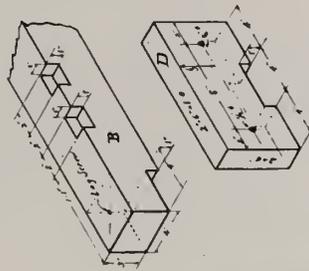

I had the Taylor Instrument Company, Rochester, N. Y., make me a special U-tube manometer, mercury or water, zero in the middle, sliding scale, etc. With Y-tube, bulb pump, connected manometer and long rectal tube I in turn tried many experiments, but one must suffice here. With a large soft rubber "condom" slipped over the terminal end of a rectal tube tie firmly in place. Pump this condom up until  $1\frac{1}{2}$  or 2 inches in diameter. Read the manometer and it will be about 10 mm. plus. Open, let condom become flaccid, oil, and introduce as high in rectum as possible, then very slowly pump up to 10 mm. Very variable manifestations appear, but in a few minutes a subconscious mechanism will adjust the abdominal muscles and the mercury

NOTE -

- 2x6s removed to cross members
- 2x6s held together by 1/2" bolts passing thru spacer shown in detail-D. Omitted in profile for clearness
- Braces and outside floor boards held by nailing to s. sheboards
- All 4x4 uprights marked 4 into pen.
- ends 4x4 1/2 in horizontal 4x4s, and retained by 1/2" bolts as shown in elevation
- All pipes shown are 3/4" external diam
- Retained at ends by 3/4" coupling
- Sideboards natched 1/4" to receive pipe
- 4x4x5' cross members leg screwed to 4x4 horizontal (See Detail-B)

BARRINGER'S THERAPEUTIC SWING

Scale 1/4" = 1'

will come to rest somewhere—say about 12 mm. plus. The subject is on his right side, loosen scale and slide it until the zero is brought to the level of the mercury as it stands. Now make patient stand up and we read about 40 mm., the measure of the bipedal burden borne daily. A good husky laborer can blow this mercury “over the top” on demand, few women can. (Is this one of the causes of feminine constipation?) Now put patient on all-fours, after a time, negative, again depending on tone. Now put him in a knee-chest posture and an invariable negative. Now put him in the quadrupedal sleeping posture, which I found so valuable and have so long used, and nearly always negative. A gas-laden gut gives plus anyway you fix it but in this posture the average man, not too fat, gives a negative. The posture is as follows:

On a fairly firm, level bed extend the body prone, flex the left lower leg, and then draw up this thigh to a right angle, with the weight on left knee, tilting pelvis to the right. Next, draw right elbow down under the thorax, flexing forearm until palm of the right hand rests against manubrium. Then draw the left elbow down until at right angles with the body, tilting shoulder girdle also to the right. Fat men may find that a pillow under the left elbow helps at first.

This is a good and comfortable posture of rest, many more people sleep that way now than one would think and all of us once could sleep that way easily. It is primitive, infantile, but we would be better off had we not turned our backs on mother earth too soon.

With an apparent explanation for the benefits accruing from sleeping on the belly, I began to wonder what more belly rest would do for any one. Would a daily seance with the belly hanging free help? To this end I had built a wooden cot, 2x8 feet, with a hole 18x24 inches to receive the belly, and tried it. Sleep on such a device is an impossibility and resting is a mere matter of vigor. The hole seemed too large and even when adjusted to comfort you could not approach sleep. But a most interesting observation followed. Lying prone on the “big hole” gives a natural posture for trying one’s pulse and I was soon struck with the fact that pronounced changes in rhythm, and particularly pressure, took place when the belly hung free. Turning over, and dropping my lowered back through the hole, brought no

such results. I tested it often and it was as certain as things physiological can be.

Pondering these facts, I determined to see what increasing the gravitational pull by swinging the patient would do, shortening the time. I then had built a strong frame from which I suspended my cot by four equal rods of about 7 feet radius, and then tried it without a “sphyg.” But a man can’t trust his finger or take his own pressure, so I asked two colleagues to come out and test the machine, predicting to them the result. From notes of the time I read as follows:

	Age	Wt.	Before swinging	After swinging
Dr. H. T. M.	42	150	125-70	110-65
Dr. M. L. R.	40	185	118-65	108-60

Each of these gentlemen took the other’s reading on a good mercurial manometer and read closely. Dr. M’s systolic fall was 15 mm. on eighty swings, and Dr. R’s was 10 mm. with 5 mm. each diastolic. As the swing was rough and poorly padded, I swung Dr. R. only 75 times, nearly four minutes. This double result was interesting but I had no idea of its real import until, trying their pressures four hours later, we found no rise at all with a slightly lower diastolic.

As these were men approaching middle age, and of professional habits of life, I determined to try it out first, as a physiological problem on youth and the vigor of athletic training. I got out a number of students and internes. One fell 18 mm. in five minutes and all but one fell some. He, about 25 years of age, was hard and thin. From all forms of tests I am convinced that to get a pressure response one must have a real “belly,” that is one you can see, with weight enough in the abdominal wall, or loose inside, to feel the gravitational and centrifugal pull of the swing. Fortunately, most patients of this class have such bellies and I have learned to make them where needed (1) by drink water or enemata, (2) by attaching weights, by suction, to the ventral face, and (3) by relaxing with dry or moist heat.

I then tried to find a patient of high tension, with still good vessels and such good general health as to give no risk. This theoretical ideal was never found but a near approach is here given: Mrs. R., age 65, weight 170, height 5 feet, 6 inches, married with seven children, six living in good health. On arrival, systolic 255 mm. Her family physician re-

ported "running from 250-260." Face splotted and turgid, much dizziness and extreme constipation. Vessels seemed sound but as she had had a "leg-arm" paralysis some four years ago from which not fully recovered, they were risky. One or more severe attacks of epistaxis. No albumen, no sugar, nocturnal urine 360-400, specific gravity 1025-1030. Family history diabetic, father and brother. I decided to handle her as if made of glass.

For blood pressure results a seven foot swing gives a physiological response in six minutes or 120 swings. By a full physiological response I mean that the average person, of fair weight of belly and a normal pressure, will give all the fall at the end of this period that you could safely exact, say 5-10 mm. diastolic and 10-20 mm. systolic. Now let us see what does this? Theoretically, a 7 foot swing has 14 feet of horizontal traverse and 18 in vertical. In practice this is cut down to 10 feet horizontal and 12 in vertical. Forty times a minute, with this traverse, you start and stop and rise and fall with your abdominal viscera shooting back and forth like a shuttle in a loom. Every movement throws blood towards the splanchnic area and the valves of the veins check its return, except for the head. Moreover, it is a "force pump" as each blood vessel, for each viscus now hangs vertical, big end up, and it holds what it gets, while the lower viscera are also free from that 40 mm. pressure found in the rectum when standing. Even intra-capillary conditions favor filling the "splanchnic lake."

Having gotten these facts from the safe and sound, I felt justified in starting this patient with twenty swings of low vertical. Invoking the saints of gravitation, I put her in. As a posterior bearing I pad the ant-sup-spinous processes of the illium (pubes free) while anteriorly she was padded under the sternum and the elbows and forearms drawn far back against the sides. Well padded everywhere we buckle a canvas cover over her. This is imperative as they may slide, get scared and try to jump out. With a rope attached to the front of the cot I swung her gently 20 times, largely to get confidence, etc. From notes of the time I read as follows: Second day two periods 50 each, not over 10 inches. third day 75 each, 10 inches, said she was "surprised how much better she felt," fourth day 100 morning and evening, 12 inches. Face no longer turgid

but now soft and elastic, pronounced tingling face, neck and mammae as the pressure subsides. At the end of the first week systolic 210 mm. and diastolic 105 mm. Without drugs or enemata bowels have begun to move, can walk upstairs without balustrade, can take off a ring not removable in years, lost one pound and "wonderfully better." Now looks quite pallid showing color on arrival due to superficial blood. To make a long story short, she had to leave at end of month when she had a systolic of 185 mm. and a diastolic of 90 mm. The last week I gave 120 swings twice a day, "hitting the ceiling," and this with rectum and stomach both full of water. Color now fine, bowels regular, almost free, walking 400 yards twice a day. I advise exercise as a vessel built up to stand high pressure is safe on a 40 mm. drop and will soften without work. Today, about 15 months after leaving me, while her tension is climbing back to where it was, she is vastly improved, works, eats and sleeps well, cheerful and hopeful. Bowels as regular as when she left, one or more actions daily.

There are 1,000 cases of constipation for each hypertensee, and I was much impressed with the marked improvement in a colon you could trace, from end to end, in a fleshy woman through the abdominal wall, the marked improvement, at the end, in haemoglobin content and the whole change in mental status. I am persuaded that it will excite every function in this seemingly hopeless cavity if kept up long enough. I now use water only in the rectum, and it is its weight that counts. The heavy liver, at the other end, is all that is needed. Between these two we can knead the dough and splash the splanchnic lake.

Several times I have thought I knew how this machine worked. Today I am uncertain. For instance if a "swing" is made with the radius pivoted below, with the arc of traverse above, it aids constipation but does not influence blood pressure. One can not say why. The fall in blood pressure is often so sudden that it appears to be a vasomotor. For instance, when a large party of medical friends were at my house, we found one with high tension (190), and as a demonstration I reduced this case 15 mm. in less than one minute. As he had just had supper I was afraid to try more. In considering a vasomotor fall we must recall that while there is a vasoconstrictor center in the medulla, the analogous dilator

center is not there. The vasodilator ganglia all seem to be in the abdominal cavity and most abundant on the inferior face of the diaphragm. Repeated visceral impact on this inviolate region might give such a result at once. But the slow and consistent improvement always seen in abdominal power must be due to vascular changes from other causes. Systematic and regular engorgement of the abdominal vessels would be expected to promote just such changes.

I always advise the prone sleeping-posture, already given, for all patients using the swing, although it need not be limited to them. It seems to prolong the swing action. As we have seen the body weight in this posture is borne chiefly by the pelvic and shoulder girdles, the strong lumbo-dorsal spine easily carrying the weight between. The viscera hang well nigh vertical, although the belly spreads out somewhat to the left. In many people the belly hangs free from the umbilicus back to the pubes and this gives a grateful rest to the biped's weak spot, the lower abdominal area.

This machine, starting in the mental recreation of a retired physiologist, has reached a practical turn little expected. It opens an almost unlimited field for further study. I am anxious that my colleagues in Virginia should take up this work and I come to this journal for this purpose. I will gladly show my machine and its results to all who come but I would advise a careful testing of longer radii. Perhaps you should learn the short before experimenting with a more potent form. To this end I will gladly furnish free, to a few interested internal men, the blue prints for the present machine. It has one great fault: it takes a house to house it. With gross dimensions some 11x8x5 feet, it practically requires a room at least 25x12. The floor on which it is placed must be strong. A patient weighing, say 200 pounds, and we are treating a heavy class, when moving at nearly 500 feet per minute, is not quite safe on flimsy apparatus. I am convinced that no one will ever have more than one accident with the same patient. When properly made and handled "it runs as easy as a rocking-chair" and it gives results. It would be an ideal addition to the armamentarium medicum of any institution.

At present I can only suggest this classification as a guide for its use:

(1) Abdominal muscles can be given "set-

ting up exercises," light and heavy "duty work" at will. It is really good here.

(2) Constipation can be influenced both by improving digestive power as well as nervous and muscular tone.

(3) Anemias, of a feculent type, improve rapidly, possibly others, as it alters temporarily circulation in viscera, bones, etc.

(4) Hypertension, if carefully and gradually approached, can be much reduced for considerable periods and in some cases perhaps permanently. Even when lowered temporarily it causes a most marked improvement in general health.

Of course I would suggest that, after the experimental stage is past, we should use with it all other hygienic and therapeutic agents which are found to act synergistically. As an example, bran, taken as a breakfast food, is almost a purgative when used during heavy swinging while fruit salts act as usual. In short the Therapeutic Swing is offered as an agent giving a new line of approach, whose limitations and possibilities have yet to be very largely worked out by critical experimentation.

#### CASE OF DIVISION OF POSTERIOR SENSORY ROOT OF GASSERIAN GANGLION FOR TRIFACIAL NEURALGIA.\*

By M. D'ARCY MAGEE, M. D., Washington, D. C.

I feel a hesitancy in presenting to this society the result of one attempt at the division of the sensory root of the gasserian ganglion, realizing the larger scope and experience of many present; but, since the subject grows daily in importance, I regard it timely to bring before you the progress made by neurological surgery for the relief and radical cure of trigeminal neuralgia.

Neuralgia, as such, is described by one author (Starr) as a disease of a sensory nerve characterized by pain in the course of the nerve or its peripheral distribution. Surgeons have cut out both nerves and ganglia for relief of neuralgia, and much information has been obtained as to its pathology. All the various processes of neuritis with degeneration and atrophy have been seen. The most important lesions appear to be in the neurone bodies which lie in the ganglia: these undergo stages of degeneration such as chromatolysis, vacuolation and atrophy.

The connective tissues about the neurone

\*Read before Medical Society of District of Columbia, November 22, 1922.

bodies are found to be increased in density. The small blood vessels in the ganglia are sometimes closed and all forms of atheroma or sclerosis have been seen in the large vessels. (Keen and Spiller). While these changes are characteristics of chronic and long-standing cases of neuralgia, but not especially in acute and transient cases, they are, however, indications of a long continued malnutrition.

The causes of neuralgia in general are due to toxic agents of external or internal origin, causing an irritation of the neurones or of their axones; it may be caused by congestion without or within a serous exudation in the sheath of the nerve and consequent compression and irritation of the nerve fibres. Many cases of neuritis are preceded by neuralgia. It is not uncommon to be due to pressure from without, as tumors or bone formations, or by disorder of nutrition, gastro-intestinal diseases, infections, diabetes, anemia, malaria, syphilis, and lead poisoning.

**ETIOLOGY**—The pathogenesis of trigeminal neuralgia is not uniform. Excluding primary or secondary involvement of the ganglion by malignant tumor, there are a number of instances of genuine major neuralgia in which demonstrable lesions of the ganglion or its divisions have been conspicuous by their absence. On the other hand, certain cellular changes have been found in the ganglion of patients suffering from tic douloureux, while precisely the same changes have been found when tic douloureux did not exist. (Caminiti). The disease may be of central origin, that is from a lesion in the pons, in the sensory root, or in the ganglion itself; the ganglion may be involved primarily or secondarily to diseases of the peripheral branches. In a word, there remains to be found a lesion, either central or peripheral, which is either constant or characteristic. This view is held by authorities, as Spiller, Hutchinson, and Krause. Women are more frequently affected than men. Age has no exemption. Majority of cases occur in middle life. Heredity plays a part, although some authors differ on this point. During Fall or Winter are seen greatest number of cases, and climates of low damp localities are prolific sources: neurasthenic types with gouty antecedents and diabetes are also among many of its victims.

The early surgical measures employed to meet cases of major neuralgia were confined to

the peripheral filaments and intracranial ganglion of the fifth nerve, such as neurectomy excision, and evulsion of one or all three of the divisions; likewise in 1903 Schlosser, of Munich, described injecting the branches of the trigeminus with alcohol within their exit from the cranium. He had tried injections at the supra-orbital, infra-orbital, and middle foramina and thinking that he would be more successful if the nerve trunks could be reached, central to their important branches, he devised a method of injecting the third branch at the foramen ovale, the second at the foramen rotundum, and the lacrimal and the frontal branches of the first as they enter the orbit at the sphenoidal fissure. His technique was simplified by Levy and Baudouin and their modification has been used with success by Harris in England, and was introduced in this country by Patrick. The method of Levy and Baudouin has been tested by many operators in all parts of the world, and there can be no doubt of its value (page 341, Vol. IV, Billings' Forchheimer).

In inveterate neuralgia of one or two of the branches of the trigeminal nerves, a peripheral operation may cure the case but seldom does. It often gives relief, perhaps a few months or sometimes a few years, but invariably returns. All such methods seem to fail as a permanent cure, and bring us to consider the intracranial method of attack.

In 1884 Mears, of Philadelphia, suggested the removal of the gasserian ganglion as a cure. Horsley was experimenting on lower animals, the feasibility of such a suggestion, and in 1890 William Rose, a pupil of Horsley attacked the ganglion of a patient by removing the upper jaw and drilling through the base of the skull at the foramen ovale, and succeeded in removing the second and third division of the ganglia. In 1891 Horsley approached from the side of the skull, opened the dura, lifted the temporal lobes and severed the posterior sensory root near pons. Patient died, never regaining consciousness, although it had been successfully performed on lower animals.<sup>1</sup>

Andrews, of Chicago, among others, exposed and excised the ganglion through pterygoid fossa. These radical operative steps were followed by extremely high mortality. Two years later Hartley and Krause advocated an osteoplastic flap in front of the ear exposing the dura, known as the high temporal operation, in

contradistinction to a later method proposed by Cushing, in which the line of incision was somewhat lower. The gasserian ganglion was excised, evulsed and pulled out but, owing to the danger from hemorrhage and too much trauma, was abandoned.

In 1898, after careful histopathological studies of the ganglia removed from cases of trigeminal neuralgia, and after animal experimentation combined with histological studies, Spiller proposed simple division of the sensory root for the relief of the pain. Frazier carried out this idea and, in conjunction with Spiller, was able to show conclusively from an experimental and clinical standpoint that regeneration of a completely divided sensory root never occurs. In spite of this fact it is only within the past few years that simple division of the sensory root has been generally adopted. Even at the present time, avulsion of the root, instead of a clean division by the scalpel is sometimes done.

Frazier, in 1903, at the suggestion of Spiller, began to cut the sensory root in preference to removal of the ganglion which, with additional refinement of technique, is the accepted operation in the United States, assuring permanency and having the lowest mortality. In reply to a recent letter seeking information in regard to the results of radical operation of trigeminal neuralgia, he states, "In some 315 operations, I have been called upon to reoperate three times. We have lost one case in these 315 operations; in 121 consecutive cases we have had no deaths. Of course, as you know from your knowledge of physiology of the sensory root, there can be no regeneration after the root has been severed so that the operation is in every way a radical one in its effects."

Adson, of Mayo Clinic, in a recent article in the September number of *Surgery, Gynecology and Obstetrics*, under heading of preservation of the motor root of the gasserian ganglion, describes the technique employed since last March in nine consecutive cases, exposing the ganglion through an oblique incision of the skin; temporal fascia and temporal muscle situated 1 c.c. in front of the ear and extending upward and backward from the zygoma for 7 c.c.; this is followed by a decompression opening in the skull which is about 3 c.c. in diameter, after which the dura is elevated, the middle meningeal is ligated, the third branch identified and dissection carried upward, ele-

vating the dura from the arachnoid which is attached to the ganglion until pulsation can be

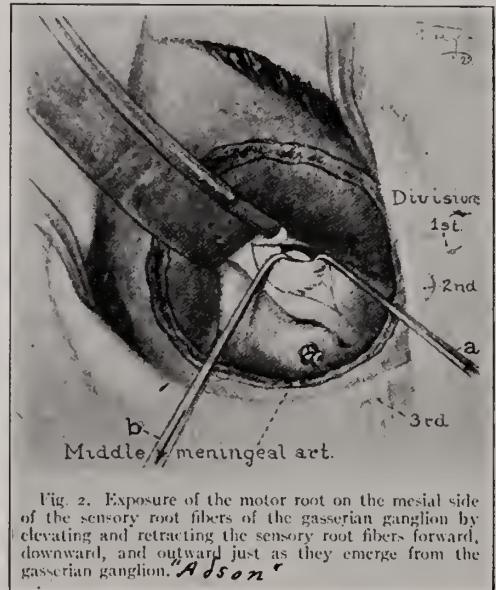

Fig. 2. Exposure of the motor root on the mesial side of the sensory root fibers of the gasserian ganglion by elevating and retracting the sensory root fibers forward, downward, and outward just as they emerge from the gasserian ganglion. Adson

Fig. 1.

seen above the ganglion. (Fig. 1). The arachnoid is then opened exposing all sensory root fibres and the outer part of the ganglion. After bleeding is controlled, the retractor exposes the posterior margin of the ganglion, along with the sensory root; a small dissecting hook, placing it over the small root fibres, is retracted gently downward and forward, elevating the ganglion on the mesial side. Hook B catches the mesial side of the sensory root and is elevated by retractions downward and upward to expose the motor root lying in a fasciculus underneath and independent of the sensory fibres, as will be shown on a slide. The sensory roots are divided and the motor tract recognized first as to its location, again by having a distinct sheath apart from sensory bundle of fibres. In a recent letter from Dr. Adson relative to the result of operations of trigeminal neuralgia, he informs me that "In two hundred and eight patients operated upon for trifacial neuralgia, there were two who suffered a return of pain, and these two cases were not true recurrences but the result of failure to resect all of the root, which operations were performed during my first year of experience in this type of surgery. I hardly feel that the word 'recurrence' can be used in connection with this disease for when once the root is divided it never regenerates, and the return

of pain must be caused by the failure on the part of the surgeon to divide all of the fibres. These patients in whom the pain returned were among the cases operated when the old technique was followed, in which a headlight was used. Since adopting the illuminated retractor, however, I am able to see all of the fibres and we have not had any cases of patients returning complaining of pain. We have also perfected the preservation of the motor root."

At present, approach to the ganglion and sensory root is made through the temporal bone at the level suggested by Cushing and Lexer. The incision used by the authors is a longitudinal one extending upward for about three inches from the preglenoid tubercle on the zygoma. A simple trephine opening is made through the squamous portion of the temporal bone, and the opening enlarged with bone-biting forceps. The method of making a large flap of muscle periosteum and the bone is quite unnecessary, since the longitudinal incision obviates injury to the temporal branch of the facial nerve and assures a disappearing scar in the hair line. The operative opening is enlarged downward as far as possible rather than upward, as the field is better exposed thereby and less retraction of the temporal lobe of the cerebrum is necessary. Upon raising the dura mater by sponge dissection from the floor of the middle cranial fossa, it may become necessary to identify several landmarks. These are (1) the foramen spinosum, through which the middle meningeal artery enters the cranial cavity; (2) the foramina ovale and rotundum containing the mandibular and maxillary divisions of the trigeminal nerve; and (3) the gasserian ganglion with its sensory root.

In a few operative cases I witnessed, and one I performed, the grayish pink color of the sensory fibre was in contrast to the white glistening fibres of the motor tract. Frazier uses faradization in determining the complete severance of the sensory root.

In the March number of *Surgery, Gynecology and Obstetrics*, Kanavel and Loyal E. Davis, of Chicago, have given some valuable data as to the topographical anatomy, which I will take a few minutes of your time to describe.

The anatomical landmarks are of invaluable aid to the successful operator. The principal landmarks, as stated before, are (1) the preglenoid tubercle of the zygoma about 1 c.c. from the external auditory canal; (2) the foramen

spinosum through which the middle meningeal artery enters the cranial cavity; (3) the foramen ovale and rotundum containing the mandibular and maxillary division of the trigeminal nerve; (4) the gasserian ganglion.

In a hundred skulls examined, the average distance from the internal surface of the squamous portion of the temporal bone opposite the preglenoid tubercle to the foramen spinosa is 2.47 c.c., the minimum distance is 1.9 c.c. and the maximum distance 3.4 c.c. The foramen spinosa in four per cent was continuous with the foramen ovale.

Anatomical specimen of the temporal bone, which I shall exhibit later, shows the foramen spinosum within the squamous portion of the temporal bone at its articulation with the great wing of the sphenoid. This anomaly is well to note since the foramen spinosum is usually found in the great wing of the sphenoid and to the sphenosquamous articulations the dura is more adherent, and such a diversity could confuse the operator. Again marked grooves running anterior-posteriorly are present. These depressions of such depth caused by cerebral convolutions of the temporal lobe are readily mistaken for the true operative field and serve

Fig. 2. Showing incision used by the author.

as attachments to the dura. The middle meningeal artery divides as it leaves the foramen (Fig. 2) into six distinct variations, the larger percentage gives off single anterior and posterior branches. (This is a valuable point in approaching the meningeal artery at its root). Furthermore, there is the bony prominence overlying the foramen spinosum just anterior to it, found in 41 per cent of the cases,

which makes it difficult in tying the middle meningeal at its base. The distance from the foramen spinosum to the gasserian ganglion in 40 skulls examined is 1.66 c.c. at an angle of 20 degrees occipital from transverse diameter through the foramen spinosum. The foramen ovale is 0.7 c.c. at an angle of 30 degrees frontal from the transverse diameter and the foramen rotundum 2.27 c.c. at an angle of 36 degrees frontal from transverse.

With anatomical points anticipated, the safety and speed of an operation is assured. The danger of this operation is hemorrhage, which may be venous or arterial. The venous hemorrhage occurring in the field of operation from the middle meningeal plexus can be controlled by use of small cotton sponges (small

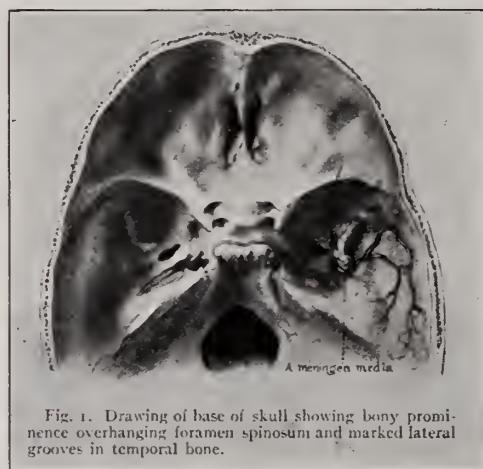

Fig. 3. Drawing of base of skull showing bony prominence overhanging foramen spinosum and marked lateral grooves in temporal bone.

Fig. 3.

dental cotton sponges) or small strips of gauze. In lifting the dura, the petrosal sinus can be injured, or when cutting the posterior sensory root of the ganglion, there may be injury to the cavernous sinus. Arterial hemorrhage can be controlled by ligating the middle meningeal artery and with due regard to a contributory branch found coming through the foramen ovale. Most operators ligate only once. In our case we ligate below and above, and cut between. The first branch of the facial nerve is exposed at the hiatus fallopii and the greater superficial petrosal nerve, and crosses the field of operation to the sympathetic plexus, or sometimes makes an exit from the foramen ovale which would account for temporary facial paralysis in some cases recorded. The upright position is likewise an aid to diminish hemorrhage. Another danger is injury to the brain

by possible retraction or perforation of the dura when separating it from the floor of the middle fossa, and finally misinterpreting the anatomical anomaly so frequently encountered. Speed of the operator must be considered as a factor, as well as a well chosen anesthetist. In the case I am about to report, nitrous oxide oxygen was employed by Dr. Warner, an expert on Providence Hospital staff.

Traumatic keratitis is overcome by immediate protection of the cornea from abrasion,

Fig. 4. Foramen spinosum showing course of middle meningeal artery.

during and following the operation. A well supplied shield worn for ten days to two weeks, followed by the use of protective glasses, has brought the patient up to the present time free from any trophic disturbance.

Dr. U. T. Coughlin in an article (S. G. O. 1921), describing section of the sensory root of the fifth cranial nerve under local anesthetic, claims he had trouble with bleeding and trying to maintain the head in position by the general anesthetic; however, my preference would be nitrous oxide oxygen or ether, since the danger of secondary hemorrhage following local anesthetic is greater. I will state that at no time during my operation was I concerned about the anesthetic given and, furthermore, after severing the sensory root the patient came out from under the anesthetic sufficiently to determine by the insensibility of the cornea and side of the face, that complete severance of the sensory root was affected.

Mrs. M. V. B., age 70, born and lived all life in Alexandria, Va., was first seen in July 1920.

FAMILY HISTORY: Father died at age of 30, cause of death unknown but had been victim of neuralgia several years before death. Mother

died of influenza at age of 75. Paternal grandfather and grandmother died of old age, cause not known. Maternal grandparents, cause of death unknown.

One sister died, age 45, of child birth. Another, age 39, died from influenza. Brother died from bloodpoisoning. Does not recall any gonty ancestry.

Fig. 5. Showing foramen spinosum in the squamous portion of temporal bone.

**PERSONAL HISTORY:** Previous state of health, aside from an attack of whooping cough, remained well until the age of 13 years when she was ill with an infected arthritis. She had subsequently malaria and suffered from attacks of sick headaches which continued after her marriage. Had three children, all normal births.

**PRESENT HISTORY:** Fifteen years back had a sudden intense shooting pain along the supra- and infra-orbital branch of the fifth nerve,

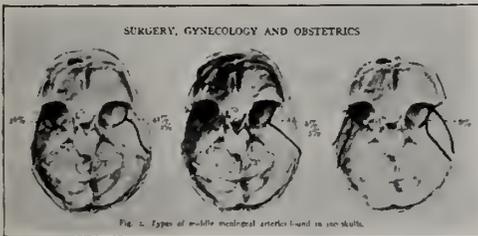

Fig. 6.

which lasted several hours and recurred at intervals of three to four weeks—longest interval three months; during the winter on damp cold days, pains were more intense and more frequent. The taking of food or drinking of cold water excited the paroxysms and kept

her in mortal terror of recurrent attacks. Eleven years ago she had her teeth extracted and finally submitted to injections of alcohol into the supra- and infra-orbital branches, which afforded her relief for several years but later recurred with greater intensity.

**PHYSICAL EXAMINATION** showed patient undernourished, evidence of intense suffering, face drawn to right side, and hypersensitive even to light and gentle touch of skin, lacrimation and increase of buccal secretions attended attacks. Subsequent X-ray investigation eliminated any sinus involvement. Wassermann test negative; urine contained indican and serum albumen but M. E. negative; blood pres-

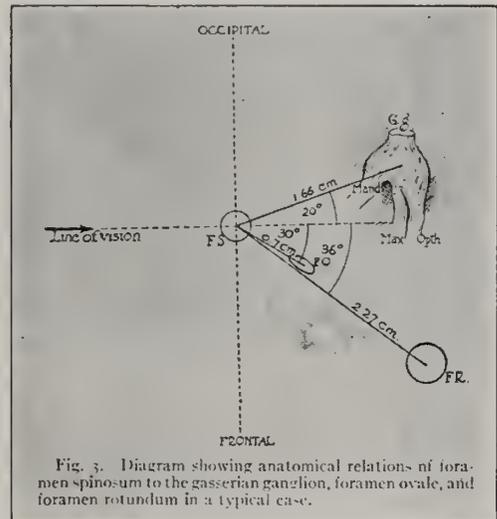

Fig. 7.

sure systolic 250, diastolic 100, was given butyl chloral hydrate (B. C. H. 5, glycerine 10, aquae qs. ad 60.) with caution during attacks, which gave transitory relief. Blood pressure after attacks was systolic 162 and diastolic 85. After observing that the attacks continued with unabating violence and patient was growing weaker, I decided to operate by severing the posterior sensory root.

Patient was admitted at Providence Hospital, May 25, 1922, and was prepared for operation. The right side of skull was shaved and usual preparations instituted.

Patient was placed in extreme Fowler position and head supported with a head-rest; nitrous oxide oxygen was administered by Dr. Warner, of Providence Hospital staff; a longitudinal incision was made extending upward about 8 c.c. from the preglenoid tubercle of

the zygoma, temporal fascia was opened obliquely, exposing the temporal muscle, and the fibres separated, exposing the pericranium to increase the exposure of the skull; the temporal fascia was cut along the upper border of the zygoma. A simple trephine opening was made through the squamous portion of the

interrupted sutures and the skin closed by a subcuticular suture.

Direct reflected light with a head mirror was all the illumination necessary.

Fig. 8. A dissection of ganglion showing the motor root with its distinct fasciculus.

Fig. 9. Showing multiple bundle of nerve fibres in ganglion with motor root obscured.

temporal bone, and the opening enlarged downward as far as possible, rather than upward, thus avoiding the posterior branch of the middle meningeal artery and giving a better field and less retraction of the cerebrum; upon raising the dura by sponge dissection of the middle cranial fossa, there was more or less hemorrhage which was easily controlled. The branch of the middle meningeal artery was traced back to the foramen spinosum and a small amount of surgery wax inserted around its base. A small blunt hook with an eyelet carrying a silk ligature was placed around the vessel and tied. Further dissection upward and to the left disclosed the ganglion. The covering of the ganglion was opened after locating the superior and inferior maxillary branches and the fibres of the sensory tract separated in mass from the motor root and severed by a right angle knife. At this stage the patient came from under the anaesthetic sufficiently to determine the insensibility of the conjunctiva and gave assurance that the operation was successful. The fascia of the temporal muscle was closed with several

The right eye was protected and drops of fresh solution of 5% argyrol instilled after irrigating twice daily with 4% boric acid. There were no complications and the patient left the hospital eight days after the operation. Her freedom from pain was attended with an increase in metabolism: has gained eight pounds in weight; her blood pressure systolic 135 and diastolic 80.\*

Fig. 10. Showing no paralysis of facial muscles.

**DEDUCTIONS:** It does seem that severance of the sensory root of gasserian ganglion should

†Since above report, three other cases have been successfully operated upon.

be thought out and performed more frequently than heretofore, in view of the diminished risk attending operation, improved technique, and low mortality.

The lack of sensibility and anaesthesia on one side of face as a result of these operations does not in the least incommode the activity of future good health and the gratitude of relief overshadows the few after cares of the eye that are entailed.

Results to date show that the best that can be accomplished in extra cranial surgery is relief for a time but no assurance of a cure and a

Fig. 11. Showing absence of scar above hair line—final result.

certainly of a return of symptoms in greater magnitude than before. To doom a patient to the eternal hell of morphine for relief is cruel, unscientific, and should meet with a determined stand on the part of the medical and surgical profession.

Finally, if neurological surgery never reached beyond the achievement of a successful relief to these most unfortunate individuals, it has triumphed in this sphere, to command your strongest support.

1623 Connecticut Avenue.

## THE ACTIVITIES OF THE TUBERCULOSIS DIVISION OF THE HEALTH BUREAU, DEPARTMENT OF PUBLIC WELFARE, RICHMOND, VIRGINIA.\*

By W. NELSON MERCER, M. D., Richmond, Va.  
Director, Tuberculosis Division, Health Bureau.

This paper is intended to emphasize the advantages to be gained not only by the private practitioner and the community in general but also by the tuberculous patients themselves, when the full co-operation of physicians is given with various activities of the City Health Bureau.

It is interesting to quote from an editorial appearing in a recent issue of a publication of the National Tuberculosis Association† concerning this very subject, as follows:

"While efficient antituberculosis work is carried on in nearly all cities by some agency, the municipal health department plays in most cases a very small part in this important field of public health. In only 46 out of 83 cities (largest in the United States) are there municipal tuberculosis clinics; in only 45 are there tuberculosis nurses; in only 29 has the health department any specific appropriation definitely earmarked for tuberculosis work; and in only 13 is there a separate bureau of tuberculosis, and in only 6 a full time director. The budgetary allotment for 23 cities having a definite allowance is 4.9 cents per capita. We believe that every health department in a city of 100,000 population should include on its staff an expert, specifically charged with the supervision and co-ordination of the campaign against the most deadly of preventable diseases, for, whatever aid may be offered by private agencies, the strategy of a widely conceived antituberculosis campaign can be fully executed only by the official health authorities of the community." Quoting again from the same editorial: "In other words, what is needed in the tuberculosis field is a more definite emphasis on the need for strong, technically efficient, and properly financed municipal and county health departments as the first and most important essential in the ultimate control of tuberculosis in the community."

The Tuberculosis Division of the Health Bureau, Department of Public Welfare, Rich-

\*One of a series of lectures and demonstrations to a class of physicians in tuberculosis, held under auspices of the Health Bureau Department of Public Welfare, Richmond, Va., February 15, to April 15, 1923.

†Read at a meeting of the Richmond Academy of Medicine and Surgery, June 12, 1923.

‡Journal of the Outdoor Life, March 1923.

mond, Virginia, has a well organized and efficient free tuberculosis clinic; it has two full-time tuberculosis nurses and eight other nurses who devote part of their time to this work; a specific appropriation for tuberculosis work; a full-time Director of a separate Division of Tuberculosis; and a municipal sanatorium for white, and one for colored tuberculous patients.

This organization is the result of the foresight and progressiveness of Dr. E. C. Levy, Director of Public Welfare, and Dr. C. C. Hudson, Health Officer of Richmond.

The City Law (Code 1910, Chapter 25, Section 95) requiring reporting of cases of pulmonary and laryngeal tuberculosis is as follows:

"Every physician practicing in the City of Richmond, who shall be in attendance upon a patient affected with small-pox or varioloid, cholera, scarlet or yellow fever, diphtheria, measles, pulmonary or laryngeal tuberculosis, or typhoid fever, shall report the name and location of the patient to the board of health in writing within twenty-four hours after he is satisfied of the existence of such disease, and he shall also report the recovery or death of every such patient under his charge; and for his failure to comply with either of these requirements, the physician so offending shall be fined ten dollars for every twenty-four hours he so fails to report concerning such patient." This has been in effect since August 17, 1906.

The State Law (Chapter 226, Acts of 1916) regarding the restraint of careless consumptives is as follows:

"1. Be it enacted by the general assembly of Virginia, That all persons who are suffering from tuberculosis, who shall violate the laws prohibiting expectoration in public places and vehicles, or who shall deliberately and continuously place the health of any person in danger of infection with such disease, shall, upon motion of any member of the Board of Health of any county or city in the Commonwealth, before the circuit court of said county or city, be summoned to appear before said Court to answer said charges, and if, after hearing, it be found that such person is guilty of the conduct charged and is a menace to the health of the public, or is unnecessarily exposing other persons to infection with tuberculosis, the said court may order such person to be restrained and detained

for a period not exceeding twelve months, in some suitable place, or be required to give bond in a penalty to be determined by said court conditioned upon a cessation of the practices complained of, for such period not exceeding twelve months, as the court may determine. Said court may at any time, for good cause shown, rescind or modify such order, or make such disposition of said person as may be authorized by existing laws."

The regulations of the State Board of Health require that all cases of tuberculosis be reported to the local authorities who shall send copies to the State Board of Health.

The following agencies are supplied by the Richmond Health Bureau, in the fight against "the great white plague":

- A. Director of the Tuberculosis Division.
- B. Preventive Measures.
  1. Printed Precautions.
  2. Instructions to Patients and Others at Home and Clinic.
  3. Milk Pasteurized, or from Tuberculin-Tested Cows.
  4. Sputum cups and Paper Napkins.
- C. For Diagnosis.
  1. City Laboratory.
  2. Tuberculosis Clinic (Including Nutrition Clinic).
  3. Tuberculosis Clinician (Consultant).
  4. X-ray (through Clinic and Hospitals only.)
- D. For Treatment:
  1. Tuberculosis Clinician.
  2. Nutrition Expert.
  3. Tuberculosis Nurses.
  4. Tuberculosis Sanatoria.
  5. Tuberculosis Literature.

The Director of the Tuberculosis Division of the Health Bureau is also the City Tuberculosis Clinician, and, as such, is in charge of the operation of the Clinic and of the consultation service in special cases. He is also the Chief Visiting Physician to Pine Camp Sanatorium and to the colored Tuberculosis Pavilion.

Instruction in the prevention of tuberculosis is given by the clinic staff to all who attend the clinic. The nurses impress upon all patients visited in their homes the proper method of disposal of sputum, care of the person, bedding, clothing, etc.

During the past winter a course of instruction in the diagnosis, prevention, and treatment of tuberculosis was given to a class of

physicians, weekly, at the clinic, and practical demonstrations of selected cases served to make the course of more practical benefit.

All milk sold in the city is pasteurized or comes from tuberculin-tested dairy cows, and infection from this source is thereby prevented.

The City Laboratory offers facilities free of charge for the examination of sputum, spinal fluid, blood, exudates, transudates, tissue, and guinea-pig inoculation with post-mortem findings as an aid in the diagnosis of tuberculosis.

The Tuberculosis Clinic, located at 1108 Capitol Street, is open from 11:30 A. M. to 1:00 P. M. on Tuesday and Thursday, for white patients; on Monday and Wednesday from 11:30 A. M. to 1:00 P. M. for colored patients.

Physicians may accompany or refer their patients for a thorough examination of the chest and throat. Advice is given to each patient individually concerning his hygienic, dietetic, medicinal, occupational, and social regimen to be followed at home, or while awaiting admission to a sanatorium, or after his return therefrom. A very practical and complete pamphlet, entitled "The Treatment of Tuberculosis in the Home," issued by the Richmond Health Bureau, is given to every patient who is to be treated at home.

In those cases who are unable to purchase medicines, the Clinic furnishes tonics and cough mixtures, if they are deemed necessary.

Paper sputum cups with metal holders and paper napkins are furnished at the Clinic to all patients diagnosed as tuberculous. Thorough instruction in their use is also given.

The Nutrition Clinic is held weekly, at 1108 Capitol Street, from 3:00 to 5:00 P. M., on Friday, for undernourished children. Each child is given a chest examination by the Tuberculosis Clinician, and then a general examination by the Nutrition Expert. Special attention is directed to the general development, per cent underweight, glands, teeth, tonsils, skin, bones, and joints. Abnormalities are noted and their correction recommended.

An arrangement has been perfected whereby diseased tonsils and adenoids, of those patients who are unable to pay more, are removed at the City Hospitals for a fee to cover the operating expenses only. The nose and throat specialists of the city give their time and skill freely to this worthy cause.

A diet list is prescribed for every under-

nourished child, showing the amount of each article of food to be eaten, its preparation, and the time for feeding.

Graphic notation of the physical examination is made in each patient's chart whenever he visits the Clinic, X-ray, laboratory, and nurses' reports are attached, and the progress of the case is entered. These reports are strictly confidential. Mothers are urgently requested to accompany their children to the Nutrition Clinic in order to become familiar with the instructions given.

Several chest and nose and throat specialists render valuable services voluntarily in the Clinic on regular days.

In Richmond, during 1922, there were 77 deaths from pulmonary tuberculosis among white people and 125 among negroes, which will throw some light upon the incidence of tuberculosis among the white and colored population of the city. It is estimated that for every annual death from pulmonary tuberculosis, there are 10 active and 10 arrested cases in the community, or approximately 4,040 cases.

The inverse ratio between the number of visits to the Clinic by white and colored patients and the death rate in each race illustrates conclusively the different results obtained among people who want to co-operate and those who fear to know their true condition until too late for hope of recovery.

	Number Visits		Death Rate
	To Clinic	No. Deaths	Per 100,000
			Population
White	1625	77	62
Colored	435	125	229
Total	2060	202	113

*Private Consultation in Special Cases:* The service of the City Tuberculosis Clinician is available for consultation with private physicians throughout the city in those cases of suspected or complicated tuberculosis who are confined to their homes, or unable to go to the Clinic. Every effort is made to reach a correct diagnosis, advice is given to the physicians concerning the treatment to be followed and what disposition is thought best for the patient, whether sanatorium, home, or special treatment. In those cases which require artificial pneumothorax treatment, this can, upon the family physician's request, be continued as long as necessary by the patient visiting Pine Camp Sanatorium, or the Colored Tuberculosis

Pavilion, at regular intervals for refills, after he has remained the allotted time as a patient in either of these, or in any other sanatorium, and has undergone this special treatment along with the routine treatment for all tuberculous patients.

Patients who are unable to pay, and patients presenting surgical or other complications needing correction, are admitted to the city hospitals, if necessary, when this action is sanctioned by the attending physician. Here the patient is treated by the city attending staff of specialists free of charge.

X-ray examinations are made only of those persons who attend the Clinic, or of patients in the city hospitals and sanatoria, and for these only when it is a necessary aid to diagnosis.

*Tuberculosis Nurses.* At present there are two nurses of the Health Bureau who devote their entire time to tuberculosis activities, and eight other nurses, a part of whose time is spent in tuberculosis work. Their function is to visit in their homes all tuberculous patients reported to the Bureau of Health, where instruction in the proper care of the patient can best be given, the home conditions noted and improved, and precautionary measures instituted. They also arrange for institutional care when deemed advisable. When needing financial aid the case is referred to some public or private agency. When needing bedside care the patient is referred to the Instructive Visiting Nurses' Association.

These nurses also instruct the other members of the family or any suspicious cases, and wherever contacts are found, they refer them to the family physician or to the clinic for examination. Each patient examined at the clinic is visited at the home by a nurse.

It would be of great assistance in the fight against tuberculosis for physicians to be perfectly frank with their patients by telling them of the true nature of the disease, not a "spot on the lungs," or "weak lungs," its treatment, and how to prevent its spread to others. In this way the duties of the tuberculosis nurses would be made much less arduous and the co-operation of the patients much more easily obtained.

At the Clinic the tuberculosis nurses assist in the examination of the patients, thereby becoming more familiar with their condition and any complications which may exist, thus en-

abling them to carry out the home treatment and give advice more intelligently.

The Clinic follow-up system is carried on by these nurses, who visit any patient who fails to appear at the clinic on the day scheduled for his return. In this manner an accurate check on the progress or retrogression of each patient is made effective, and it is largely to the careful supervision and personal interest of these tuberculosis nurses that the present arrested condition of many clinic cases is due, for otherwise they would probably be helpless invalids and charges on the charity of the city. The number of visits paid during 1922 by nurses doing tuberculosis work was 6,330.

*Admission to City and State Sanatoria.* Before a person is eligible for admission to Pine Camp Sanatorium, operated by the Department of Public Welfare of Richmond for white tuberculous patients who are unable to pay for treatment elsewhere, or to the Tuberculosis Pavilion at Second and Hospital Streets, for colored patients, each applicant must be examined by a member of the City Tuberculosis Clinic Staff and passed upon by the Director of the Tuberculosis Division. This is necessary to determine whether or not the case is suitable for sanatorium treatment.

In addition to the physical examination, a thorough social and financial investigation is carried on by social investigators, the object of which is to prevent non-residents of Richmond, and those who are able to pay their way to other sanatoria, from becoming charges on the city. In this manner only the worthy cases needing sanatorium treatment are admitted to the free city institutions. Each applicant is put on the waiting list as soon as found qualified, and each must await his turn for admission, no favoritism being shown.

The State Sanatoria for white tuberculous patients are operated for *bona fide* residents of Virginia, in the early or moderately advanced stage of the disease. The cost to the patient is one dollar (\$1.00) a day, the State making up the difference in actual operating expenses. Blue Ridge Sanatorium is located near Charlottesville, and Catawba Sanatorium near Salem, both in the mountainous section of Virginia. Piedmont Sanatorium, at Burkeville, is operated by the State for native colored tuberculous patients. The cost to the patient here is only fifty cents (.50) per day,

the State making up the difference. Only early and moderately advanced cases are accepted for treatment.

Whenever an eligible early or moderately advanced case of tuberculosis is found at the city clinic or in consultation, he is advised to go to a State Sanatorium if able to raise the necessary funds. But if a resident of Richmond with pulmonary tuberculosis, and he is financially unable to pay, or is too far advanced for the State Sanatoria, he is admitted as soon as possible to a City Sanatorium.

Frequently money is provided by one of the welfare agencies of Richmond to pay the expenses of a patient in a State Sanatorium while awaiting admission to Pine Camp, thereby removing the danger of infecting other people, and allowing the patient to start "the cure" under ideal conditions at once.

It is expected that when the new buildings at Pine Camp Sanatorium are completed and the capacity is increased to 92 patients, this present unavoidable delay will be removed.

*Examination of Contacts.* It is the duty of every physician to examine every six months all persons exposed to a case of tuberculosis, and if the least uncertainty arises as to the condition found, he is urged to call in consultation the City Tuberculosis Clinician, who will assist the physician to arrive at a correct diagnosis and advise proper disposition of the case.

*Post-Sanatorium Care of Arrested Cases.* The arrested cases of pulmonary tuberculosis constitute a problem all to themselves, and frequently tax to the limit the resources of the physician, their families, and the municipal and welfare agencies concerned in their condition and livelihood.

Fortunately for Richmond, only a few indigent migratory consumptives pass through or locate here, but occasionally we have to provide treatment and support for such cases when they have acute exacerbations of this disease in our midst. As soon as their condition permits, however, these transients are returned to their original locations.

The resident cases of arrested tuberculosis are followed-up by the tuberculosis nurses, and examined periodically at the clinic or by their own physician. According to their physical findings and general condition, advice is given them concerning the regulation of their daily life, suitable occupation, amount of exercise,

proper food, and living conditions. Sleeping porches are constructed whenever possible.

The question of suitable employment is ever-present in patients just returned from sanatoria, and not infrequently they are, of necessity, forced to change their occupation to one more healthful and less apt to cause a recurrence of activity. This, in many cases, is almost impossible, due to lack of sufficient education or resourcefulness. Many arrested cases have found suitable positions through the Employment Bureau of the City, and others by means of private agencies and friends.

During the first year of post-sanatorium life, all ex-patients are directed to be examined every month either at the clinic or by their own doctor and, should unfavorable signs or symptoms develop, they are advised at once what is best to be done.

Supervision of these arrested cases is never entirely given up, for some of them would very probably break down if not checked up at intervals.

*Room 409, City Hall.*

## THE ROENTGEN RAY IN THE TREATMENT OF CERTAIN TYPES OF METRORRHAGIA.

By FRED M. HODGES, M. D., Richmond, Va.

In metrorrhagia, with or without fibroids, the action of the X-ray or radium is twofold: There is (1) the direct action on the tumor or enlarged uterus, and (2) the action on the ovaries. In the tumor itself the ray causes an edema of the endothelial lining of the capillaries, followed by an obliterative endarteritis and anemia of the tumor. In the tumor the cell nuclei show hypertrophy, then coagulation necrosis and destruction, later to be replaced by connective tissues. This is not only due to the results of an obliterative endarteritis, but also to the direct action of the ray on the cells. The effect on the ovary is first on the ripe Graafian follicles, then on the primordial follicles, and lastly on the interstitial tissues.

The action of the X-ray and radium is identical, except that the X-ray is slower in fat patients and is much more reliable in large tumors.

Corscaden in a study of 250 cases treated with the roentgen ray and radium found that bleeding ceased or became normal immediately after one radium or one X-ray series in forty per cent. of the cases; within one month,

twenty-one per cent.: within two months, thirteen per cent.: within from three to six months, ten per cent. Further treatment was necessary in fourteen per cent. There were one and one-half per cent. failures.

Dysmenorrhea stopped in every instance. In 105 fibroids with masses large enough to measure there was reduction in all but one. This patient had only one moderate radium treatment. The most rapid reduction was in a mass 20 cm. in diameter which disappeared entirely in six months; the one least affected was reduced from 15 cm. to 8 cm. after three years and, after seven years, is about the same size.

After the use of radium, thirty patients had discharge. The watery discharges were stopped by the X-ray. The others were mucopurulent and thought to be due to the ulceration caused by radium.

There has been no inflammation in cases treated with the X-ray. Corscaden believes these infections are usually due to faulty technique in the application of radium and not to the action of the rays on latent foci. He went very carefully into the effect of artificial menopause in these women. Hot flushes were the most constant symptom, but usually did not give a great deal of trouble. There was no effect on sexual desire. In two this seemed to be increased; in two, decreased. About an equal number gained and lost weight. There was no effect on the appearance of age. In the large majority of instances the patients were in better general health and less nervous. A few were more irritable and nervous.

Of the various accidents and changes which might occur in fibromyoma (toxemias, degeneration, inflammation, sloughing, etc.) none was noted. The treatment was unqualifiedly successful in ninety-one per cent.

Beclere, in 709 metrorrhagias due to fibroid treated with the X-ray alone, reported ninety-eight per cent. good results. In this series of 700 cases, eighty-eight per cent. were forty years of age or over; and twelve per cent. were under forty years of age. Eighty-four and a half per cent. of his patients had palpable abdominal tumors. He gives the following table showing the number of cm. which the tumors extended above the symphysis pubis:

25-30 cm.	9	2.66 per cent.
20-24 cm.	25	7.39 per cent.
15-19 cm.	51	15.08 per cent.
10-14 cm.	111	32.84 per cent.
5-9 cm.	104	30.76 per cent.
1-4 cm.	38	11.29 per cent.

Prolonged metrorrhagia and the tumor were usually the cause of medical advice being sought. Pressure on the bladder was occasionally noted. In some catheterization was necessary. Reduction in the size of the tumor in many cases was as rapid as 1 cm. per week and took place from two to three months before cessation of menses.

Clark, in an analysis of 527 cases of myoma uteri and myopathic lesions treated with radium, concludes that, "Irradiation is the treatment of choice for the smaller myomas in women approaching or within the menopausal years whose only symptom is hemorrhage." In this large series only fourteen operations were necessary. There was one death. He believes that if all of the patients had been operated upon there would have been ten or more deaths anyway. He states that after irradiation the majority of tumors shrink greatly or disappear entirely. Malignant changes rarely occur, and after all symptoms are relieved he considers them cured.

Geist says: "To my knowledge there are no cases in which after or during the roentgen treatment a malignant condition has developed locally. It cannot be argued that the bad results have not been recorded and we must, therefore, alter our point of view as regards the roentgen ray treatment of fibroids. If after irradiation and prolonged periods of observation, no malignancy develops in the uterus and no metastases occur, then we are bound to say, not only that the roentgen ray caused a beneficent result in fibroids, but also in cases complicated by sarcomatous change or those cases of sarcoma not diagnosed."

Graves, of Harvard, feels just about as Clark does toward the irradiation treatment of metrorrhagia.

We have treated fifty-eight cases with the X-ray. Nine of these were very large fibroids, the tumor extending above the umbilicus; sixteen were smaller fibroids; and the remainder were cases with marked bleeding but no demonstrable tumor. Two patients were more than sixty years of age, had large tumors, and had been bleeding profusely for several years. One of these has had no trouble for

more than a year. The other case has had radium twice and X-ray and is very much improved, but is still having some trouble. She is a very poor surgical risk and an extremely fat woman, weighing around 250 pounds. The large powerful machines may get results in such cases, but the present ten inch gap machines will not. Several factors in this case make it a very difficult one: (1) the effect which castration has on these tumors is lacking, and (2) the extreme obesity makes it impossible to get a full dose of ray into the tumor. This is the only complete failure in the series.

Three patients have had a recurrence of the bleeding and required further treatment. Two of the very large fibroids, though markedly reduced in size, can still be palpated through the abdomen. There is no bleeding and the subjective symptoms have been relieved. The other seven large fibroids have either entirely disappeared or are so small they cannot be palpated.

We have treated six patients under thirty with the X-ray. In five of these the periods have been normal for more than a year; and in one, on account of severe loss of blood and an extreme anemia, the treatment was pushed to castration. This girl has hot flashes, but is in far better health in every way than she has been in years.

Considering the entire series from the standpoint of results in percentages, the treatment was entirely successful in ninety-three per cent. of the cases. In five per cent. the subjective and objective symptoms were relieved, but small tumors persisted, and in two per cent. the treatment was a failure. In patients more than thirty-five years of age our results have been almost perfect. Occasionally a patient is more or less knocked out by the treatment, but this is only temporary. No accident of any kind has occurred. If a patient lives out of town, radium is preferred unless there is some contra-indication to its use. If hemorrhage is not entirely controlled by the radium, a few X-ray treatments are given.

In every patient a pelvic examination by one experienced in this work and a diagnostic curettage are made, if deemed necessary, before X-ray treatment is undertaken. Some experienced in the use of radium but with no knowledge of the X-ray do not believe that a case which has been a failure with radium

should then have X-ray. We can see no possible logical reason for this and have successfully treated four patients who had had one or more radium treatments. These patients were sent us by competent surgeons who considered them very poor surgical risks.

In the excessive loss of blood at the time of the menopause, irradiation therapy acts almost as a specific. I have been unable to find a single authentic report of a failure where a case was properly treated. The results are spectacular and permanent.

As to the degenerative changes, malignant changes, accidents, etc., which occur in the uterus or in fibroids treated with the X-ray or radium, they are practically nil. (Clark, one-half to one per cent.; Corscaden, 0 per cent.; Hanks, 0 per cent.). At Mt. Sinai in New York, they had no malignant changes occurring in a large series of fibroids treated with the X-ray.

In women past forty years we use heavy treatments and finish the treatment in a short time, but in younger women treat them for several months in order to avoid nervous troubles as much as possible.

In young women several short X-ray treatments will almost invariably control the bleeding for a long time, and in several patients it has been unnecessary to stop menstruation entirely. When menstruation has been stopped entirely, it will practically invariably return unless further treatment is given after several months have elapsed. If it is too copious at this time, an operation or castration by the X-ray can be considered.

We feel that in young women with fibroids a myomectomy should be done if possible; if the fibroids are fairly large and cannot be removed, a hysterectomy leaving the ovaries should be done; if, however, there are no fibroids but profuse menstruation, an attempt should be made to control the hemorrhage with the X-ray or very small doses of radium. In large fibroids in patients who are good surgical risks or where there is other pathology present, surgery is naturally the method of choice and X-ray therapy should not be considered. If the patient is a bad surgical risk, irradiation will in the majority of instances give a symptomatic cure and should be used.

In the idiopathic or simple metrorrhagias at the time of the menopause, irradiation will give almost 100 per cent. good results. In

small fibroids with hemorrhage during the menopausal years, irradiation also offers excellent results.

### THE IDENTIFICATION OF CLOSTRIDIUM TETANI (*Bacillus Tetani*).\*

By GEORGE F. REDDISH, Ph. D., Richmond, Va.  
Associate Professor Bacteriology, Medical College of Virginia.

Interest in the study of the anaerobic bacteria has increased very considerably within the past few years, especially during and since the last war. Very extensive studies were made during this time on the war wound anaerobes, particular attention being given to pure culture studies for classification purposes to facilitate the identification of those species found in war wounds. These intensive efforts brought forth much new material of great value and have put the classification of anaerobes on a more sound basis than they had ever been before. As a result of certain phases of this work, a clearer understanding of the identity of *Clostridium tetani* (*Bacillus tetani*) has been made possible.

In the text-books of today, even those revised this year, little or no light is thrown upon two species, *Clostridium putrificum* and *Clostridium tetanoides*, which resemble *C. tetani* very closely morphologically and which are easily confused with it in microscopic appearance. In text-books, the drumstick spore form of *C. tetani* is given as characteristic of this species alone. Therefore, the form of spore is still greatly emphasized in the identification of this deadly organism, and very often microscopic appearance of the spore is the only basis upon which diagnosis is made in the examination of pathological material. In the

light of recent investigation, it is found that such preliminary observations of morphology constitute but the beginning of the identification of the tetanus bacillus; other more distinctive characteristics are necessary for this purpose.

In the same year that Nicolaier (1884) discovered the tetanus bacillus, Bienstock (1884) observed another anaerobe very similar to it morphologically, but which lacked completely any pathogenic property. This organism Bienstock named *Bacillus putrificus* because it was strongly proteolytic and caused distinct putrefaction in protein materials. It has been reported that *Clostridium putrificum* (*Bacillus putrificus*) has been found in much the same habitat as is *C. tetani*, namely, in soil, dung heaps, dust, in the intestines of many,—especially of herbivorous,—animals, etc. It is entirely possible, therefore, that many of the observations in which positive findings of *C. tetani* have been reported may have been, in reality, *C. putrificum*, for undoubtedly the presence of round, strictly terminal spore forms has been considered sufficient evidence to claim positive diagnosis of the presence of *C. tetani* in many instances. Certainly the tendency among most bacteriologists is to consider this drumstick spore form as characteristic of the tetanus bacillus.

During the war, Adamson and Cutler (1917) isolated from war wounds an anaerobe which shows spores very similar to those of *C. tetani* and *C. putrificum*, but which resembles the former even more culturally than does *C. putrificum*. However, it is non-pathogenic, and for this reason has been given the name *Bacillus tetanoides*. This organism, even more than *C. putrificum*, might be easily mistaken for the tetanus bacillus because of its cultural similarities and because it is found closely associated with it in wounds. It may, however, be found in wounds in which *C. tetani* is not present.

Pathogenicity is the most outstanding property of the tetanus bacillus; the type of spore is even secondary to it as a diagnostic feature, for the reaction in laboratory animals is characteristic. It is apparent, then, that *C. tetani* cannot be identified by observation of the spore form alone, but that toxicity tests must be made. When tetanus toxin is injected into the muscles of the thigh of the white mouse, for example, stiffening of the muscles

\*Read before the meeting of the Association of Virginia Biologists, November 29, 1922.

Note: The genus name "*Bacillus*" has been supplanted by the term "*Clostridium*," according to the new classification scheme adopted by the Society of American Bacteriologists.

takes place within twenty-four hours, causing the animal to lose all use of the limb; death results within 48 to 72 hours. This reaction is typical of tetanus in laboratory animals; similar injections of cultures or culture filtrates of *C. putrificum* or *C. tetanoides* produce no symptoms whatever. Therefore, toxicity tests differentiate *C. tetani* from these two similar anaerobes. In order to prove conclusively that an organism is *C. tetani*, it is necessary to show that tetanus antitoxin protects against its toxin. However, simple toxin tests, showing typical reaction, serve sufficiently well for routine laboratory practice. If, on the other hand, the pathological material is from an undoubted case of tetanus, the finding of drumstick spores in such material might be considered tentative proof of the presence of the tetanus bacillus.

In the present work the object has been to determine cultural and biochemical differences between these three anaerobes which will identify them with a definiteness commensurate with their importance. Studies of colony form on agar, cultural observations in meat medium, milk, broth, gelatin and blood serum were given especial attention. Biochemical studies on the changes induced in peptone broth, showing by accurate chemical methods the peptolytic activity, and also quantitative determinations of the amount of dextrose consumed in dextrose broth by these three organisms were carried out in detail. The fermentative reactions in twenty-six test substances were also determined. These observations will be given in the order indicated above.

Surface colonies of *C. tetani* on dextrose agar are delicate, thin and spreading. They have a slightly raised central nucleus, but the surrounding area is flat and almost transparent in young cultures. There are short, irregular, large, forked projections which radiate out from the central mass in an intertwining fashion. The colonies of *C. putrificum* on dextrose agar are smaller, more delicate and almost transparent; they are irregularly dented, though not deeply so, and there are no outgrowths or fringe. *C. tetanoides* colonies, on the other hand, are dense, whitish, and glistening and have a wavy edge. There is also a tendency to form a filmy growth over the surface of the agar. These differences are distinct, and sufficient in themselves to distinguish the three species.

In meat medium (egg-meat medium, Rettger, 1906), *C. tetani* proves to be only slightly proteolytic; there is some disintegration of the meat particles, but no reduction of the bulk of the medium, no putrefactive odor and no other signs of visible proteolysis. *C. tetanoides* causes a reaction in this medium very similar to that of *C. tetani*, except that a white precipitate is formed throughout the medium, which is a distinct feature. The medium, like that of *C. tetani* cultures, becomes reddened, but never brown or black. *C. putrificum*, on the other hand, after about ten days' incubation at 37° C., shows definite signs of putrefactive decomposition of the meat. At first there is reddening of the medium, which gradually becomes darker, then brown and finally almost black in old cultures. Putrefactive odors are evident as soon as digestion progresses to the point at which the bulk of the medium is reduced. The putrefactive decomposition is so pronounced that the organism has been given a name which indicates that this property is dominant.

In milk there is no evidence of noticeable change on the part of *C. tetani* and *C. tetanoides*, but *C. putrificum* brings about almost complete digestion of the casein within three weeks. There is only moderate growth in broth by all three species, *C. tetanoides* producing a heavier turbidity than either of the other two. In gelatin, *C. tetani* produces only slight liquefaction, while *C. putrificum* liquefies gelatin readily and completely. *C. tetanoides*, however, is non-liquefying. *C. tetanoides* does not liquefy blood serum, even after long incubation at 37° C.; *C. tetani* liquefies it slightly after twelve days; *C. putrificum*, on the other hand, digests blood serum completely. There is some correlation between these reactions on the various protein media, the meat, milk, gelatin and blood serum; this is of value in showing the consistency of the results.

As regards the biochemical reactions, the differences are equally distinct. Of the twenty-six test substances used, including monosaccharides, disaccharides, polysaccharides, glucosides, and alcohols, *C. tetanoides* formed acid from three, but no gas from any of them. *C. tetani* produced only a fair amount of acid from dextrose, and only slight acid from two others, while *C. putrificum* formed only slight amount of acid from dextrose alone; no gas was formed from any of the test substances.

These reactions, though definite, are not so marked as to be of classification value. However, quantitative determinations of the amount of dextrose consumed by the three organisms is of more value. *C. tetanoides* reduces this sugar from 0.7% to 0.47% within 60 hours under optimum conditions for growth. *C. tetani* reduces dextrose from 0.7% to 0.58% within the same period; *C. putrificum* consumed this sugar only slightly, from 0.7% to 0.64% in 60 hours. These differences are definite and quantitative, and are of classification value. Determinations of the action of these organisms on peptone show equally marked differences. Four tests were employed to show the progress of peptolytic action, namely, quantitative biuret, amino nitrogen, ammonia, and Sorensen figure. Reduction of biuret figure, and increase of amino nitrogen, ammonia and Sorensen figures is indicative of peptolytic action. *C. tetani* was shown to be less peptolytic than either of the other two organisms, giving only a slight decrease in biuret, and a corresponding slight increase in ammonia and Sorensen and amino nitrogen. *C. tetanoides* showed greater decrease in biuret, and greater increase in the other three figures. *C. putrificum* was found to be decidedly peptolytic, as might be expected from its extreme proteolytic activity. The biuret figure decreased very considerably, while the ammonia and Sorensen figures increased proportionally and to a high degree. The amino nitrogen was further reduced to form ammonia, and did not show a high final figure. Therefore, *C. putrificum* is decidedly more peptolytic than either *C. tetani* or *C. tetanoides*, and *C. tetanoides* is slightly more peptolytic than *C. tetani*.

In a detailed study of *C. putrificum* (Reddish and Rettger, 1922) the writer showed that the above characteristics are of definite classification value, and indicated furthermore that distinction between closely related species might be more clearly illustrated by such biochemical methods. In the present work, it has served to point out quantitatively certain fundamental differences between it and *C. tetani* and also *C. tetanoides*.

For purposes of identifying *C. tetani*, the toxicity test with characteristic reaction in laboratory animals is sufficient when quick results are necessary. When time and materials are not factors to be considered, some such procedure as outlined above should be em-

ployed. This would necessarily demand pure cultures of the organism, and the procuring of such is not always an easy task. At least, two courses are open for the accurate identification of *C. tetani*, and either may be used to suit the convenience and equipment of the particular laboratory. Certain it is, however, that observation of the spore form is not to be considered sufficient for positive diagnosis, but simply as a preliminary step.

#### SUMMARY AND CONCLUSIONS.

*Clostridium tetani* cannot be identified by observation of spore form alone, because of the close similarity of the spores of *C. putrificum* and *C. tetanoides*. The latter organisms are non-pathogenic; therefore, a differentiation can be made between *C. tetani* and these two species by toxicity tests. The reaction of tetanus toxin in laboratory animals is characteristic, a stiffening of the musculature into which the toxin has been injected being a distinct feature by which the organism can be recognized. For final identification, it is necessary to show that tetanus antitoxin protects against this toxin. The observation of drumstick spore form, then, is but a preliminary step; the toxicity test is necessary in routine pathological work of this kind.

Where possible, or feasible, cultural and biochemical properties can be used for identification, and these are even more accurate, in that the various tests made should corroborate the findings in the other cultural tests. It is found that the tetanus bacillus differs very markedly from both *C. tetanoides* and *C. putrificum* in the various standard culture media, and also in their action on peptone and dextrose. Colony forms on dextrose agar are also distinctive. It is necessary that pure cultures be used in the latter method, but in testing for toxin reaction, mixed cultures will suffice for toxin production.

*C. tetani* may be identified as follows:

1. It is anaerobic.
2. It is pathogenic, producing typical symptoms in laboratory animals.
3. It is only slightly saccharolytic and slightly proteolytic, forming small amounts of acid from only three sugars, and breaking down meat, casein, serum albumin, gelatin and peptone but sparingly.
4. It forms drumstick spores, that is, round, strictly terminal spores in a slender rod.

## REPORT OF CASE OF RUPTURE OF THE UTERUS.\*

By R. H. DUNN, M. D., South Charleston, W. Va.

Mrs. A. E. H., white, married, age 26 years. Mother living and healthy at age of fifty-three years. Father died of organic heart disease, at age of thirty-eight. Has three sisters and two brothers living. One sister died at age of fifteen of typhoid fever. One sister died of tuberculosis at age of twenty-two, following previous attack of influenza in 1919.

Patient has had ordinary diseases of childhood. She began to menstruate at the age of fifteen, was often irregular and generally suffered severe pains and cramping at menstrual periods. Medical attention had to be secured quite often at times.

Was married at the age of twenty-two and became pregnant after the first month. Health was good while carrying baby until term. The family physician was in charge of the patient and was called to deliver her on March 28, 1919, and he was unable to do so with forceps. I was called in consultation and a Cesarean section was advised. Patient was moved to Dunn Hospital in early morning of March 29th and was delivered of eight and a half pound baby girl by Cesarean section. Mother and child progressed very rapidly and were able to leave the Hospital on April 12, 1919.

Patient's health continued good until April 26, 1921, at which time she began to suffer severe pain in the right lower abdominal region. I was again called in consultation and the diagnosis of acute appendicitis was made. She was again brought to the hospital and operated on April 28, 1921. Her recovery was rapid and patient was discharged from the hospital on May 10, 1921.

**HISTORY OF LAST ILLNESS:** Menstruated last, September 14, 1921. Felt foetal movement

first some time in January. General health was delicate, suffered much with gas and indigestion, had pains occasionally in shoulder and arms and some slight pains in lower limbs. Placed herself in the care of her family physician after the first month.

Macerated appearance of uterus at removal.

On May 7th, patient walked out in the garden to pick some lettuce and while out there she noticed considerable pain in the abdomen and vomited quite a bit. This vomiting continued at intervals and her physician was called. Patient was put to bed and palliative remedies were used to relieve her. Patient's general condition did not improve and on May 11th, I was called to see her with her physician.

On Thursday, May 11th, patient was extremely distended, vomiting and bowels had not moved for four days; temperature 100 and pulse from 90 to 100; pain generalized over abdomen; respiration rapid and patient perspiring profusely at times.

Distention was so extreme that nothing could be determined by palpation, not even the position of the foetus. On vaginal examination the head was low down in the pelvis, L. O. A. There was no discharge, cervix was soft and about one finger dilatation.

Patient stated that first time she noticed the extreme shocked condition was on Wednesday, the 10th, when she was raised up to take some water at which time she became unconscious for a short time. Patient complained of a burning pain down low in both sides of abdomen,

\*Read before the Kanawha Medical Society, November 28th, 1922.

not sharp, but she described it as a miserable feeling. Patient stated that at no time did this pain resemble any of the pain that she had experienced at the beginning of her last term of labor. Treatment given at this time was colon irrigation with good results; morphia was given at intervals and hot stupes were applied to abdomen.

Patient stated that a few days after this attack she could feel the movements of the child but is not positive as she thought that this movement may have been produced by her turning from side to side in the bed. Neither her physician nor I was able to hear any foetal heart sounds at this time and her physician stated that he had not noted them at any time from the 11th to the time of her operation, the 27th of May.

The diagnosis at this time was diffuse peritonitis, with a guarded prognosis.

Looking into fundus.

On May 12th, I was called out of the city for several days and on my return the physician informed me that the patient was gradually recovering. In about ten days from the onset she was able to sit up at short intervals and even walked to the bath room, when necessary. Patient, however, experienced a fullness of the abdomen and said that when on her feet she felt as if her abdominal muscles would give away and on lying down that she had a sore dull ache low down in both sides.

On May 27, 1921, she again began to suffer with pain in the lower abdomen, hips and back, and I saw her at her home and advised immediate operation. She was brought to the Hospital where the following symptoms were noted:

Patient suffered with pain in lower abdomen; abdomen had lost its general contour,

and had more of a flattened appearance, and almost a doughy feel; very little rigidity; child high up in abdomen; pulse 100; temperature 99.3; respiration 20.

Uterus split from cervix to fundus.

Vaginal examination showed cervix about one finger's dilatation; body of uterus to the left and low down in pelvis; on account of tenderness foetus could be felt but high up and to the right.

Operation May 27, 1921.

Old scar of previous operation in median line was excised and opened to peritoneum in usual manner. Peritoneum was picked up with Kelly's and opened with scissors; the first tissue encountered was placental tissue and the escape of considerable amount of coffee black fluid. The opening was enlarged and the foetus was delivered by feet. The placenta was attached to the anterior abdominal wall and partly incarcerated by the greater omentum. The placenta including the cord had a very dark putty appearance, as well as the viscera. This was carefully removed with practically no effort and very little if any bleeding from the omentum. Hot tapes were then introduced, and after the old clots and fluid were removed, the uterus was down low in the left pelvis with the whole fundus looking like a black cauliflower mass, practically contracted and very little bleeding.

The uterus was then caught with two large Kelly's, one in the anterior wall and one including the posterior wall, and a supra-vaginal hysterectomy was rapidly done. Both ovaries were in healthy condition but both tubes adjacent to the ruptured portion were very fragile and had the same putty appearance that

the uterus had. A great deal of care was taken in ligating the tubes, as the sutures if drawn usually taut would cut through the tissues. The tubes were not removed and were brought together and treated in the usual manner. Two omental adhesions to the abdominal wall were ligated.

Three pints of normal saline were put into the abdomen and the incision closed in the usual manner with drainage.

Supra-vaginal hysterectomy.  
Uterus split after removal from cervix to fundus.

The foetus was a male of 8 pounds and evidently had been dead for some time, as in removing it from the abdomen, although sterile towels were used in order to hold it, the skin and flesh slipped easily.

The patient was put to bed and saline by rectum was given at intervals of four hours. She made a slow but gradual recovery and was discharged on June 28, 1921.

A few questions that may be asked in this case are:

At what time did this uterus rupture?

If this uterus ruptured on May 7, 1921, did it empty itself at once or did it do so gradually?

This pregnancy dated from September 14th, and would be due ordinarily June 21st. Was not patient evidently mistaken in the length of her pregnancy?

What effect did her former Cesarean section have on the case?

Were the pains that patient had on May 11th due to labor, to possible rupture at that time, or to an infection?

What would have been your position in the case on May 11th?

Would not this patient have had even more shock and pain from a severe hemorrhage on

that date than was indicated by pallor and pulse, or emptying of uterus?

How long had this uterus been ruptured from the appearance of uterus, fluid, viscera, and foetus?

#### CONCLUSIONS

Uterus ruptured on May 7th, but evidently emptied itself very slowly.

From appearance and size of foetus this patient was evidently pregnant a month sooner than stated.

The usual technic was used as in a number of other cases and we expected to do a Cesarean on this patient at term.

Had this patient been operated on May the 11th, I do not believe that she would have survived the operation.

From appearance of viscera, etc., this uterus evidently was ruptured three weeks before operation.

### THE IMPORTANCE OF THE EARLY RECOGNITION, DIAGNOSIS AND TREATMENT OF MENTAL DISORDERS.\*

By W. C. ASHWORTH, M. D., Greensboro, N. C.  
Medical Director, Glenwood Park Sanitarium.

My subject for this paper has been selected on account of the far-reaching evil influence of the failure to fully appreciate the importance of recognizing and treating the incipient mental disorders. It is a well recognized fact that our whole social structure, to a large extent, depends upon the effectual treatment of those who are mentally defective. It is a sad commentary on our boasted civilization that a large per cent of our mentally deficient are languishing in our jails, so-called "county homes," etc. The appalling number of inmates of our State institutions is significant because of the fact that it clearly indicates a failure on the part of our profession to diagnose and successfully treat the mental disorders from which these unfortunate people are suffering, during the curable period of the disease. The medical profession fully recognizes the importance of early diagnosis and recognition of physical disease, whether amenable to medical or surgical procedure, but has not yet been fully aroused to the great importance of early diagnosis of mental cases. If we, as a profession, would exercise the same diagnostic acumen in the diagnosis and treatment of our

\*Read before the North Carolina Hospital Association, at Wilson, November 2, 1922.

mental cases as we exercise in our medical and surgical cases, the results would be very materially different.

The mental delinquent is not only a menace to society, but has no earning capacity, therefore is a parasite on his or her family. We must also take into consideration that a mentally incompetent person oftentimes, in fact, generally, disrupts the family, and, therefore, lessens the earning power of those who are responsible for his behavior and conduct. The moral derelict is a dangerous person to his associates and the community, hence, the importance of finding the physical cause (most usually focal infection) responsible for his dereliction, since more exact scientific study has shown that at least six criminals out of ten are mental defectives, and that the same estimate, approximately, applies to paupers, habitual drunkards and dissolute women. In fact, mental deficiency underlies, to a large extent, our most troublesome social problems. The so-called "half-wits," or moral derelicts, are in effect high grade imbeciles, or, more properly speaking, morons, since their mental development corresponds to that of a normal child of twelve or fourteen years. It will be found, on close observation, that they lack judgment and reasoning power, and, as a natural consequence, their actions are inspired and directed by unregulated impulse. In other words, if untrained and uncared for, the mental defective becomes a criminal, a vagabond, a pauper, or a vicious and dangerous person, a constant menace to the community in which he lives.

It is obvious to my mind that the crime wave, which at the present time is exciting such widespread and justified alarm in the United States, is attributable, largely, to the activity of the high grade imbecile, who, in common parlance, has "gone bad," and is, therefore, a pronounced enemy of society. If, however, the mental defective were wisely and carefully trained during the acute stage of the disease he, ordinarily, would become somewhat useful to society; or, at least, partly selfsupporting; or, be transformed into a harmless person. The difficulty, however, of the problem of treating this large and increasing class of cases is greatly accentuated on account of the great number of mental defectives who are unrecognized, therefore, untreated during the curable stage of their disease. It is a lamentable fact that they are becoming more numerous every day, since

each succeeding generation produces a larger percentage of them, relatively speaking, to the total population. Their defection is markedly hereditary, and, unfortunately for society as a whole, they usually propagate their species very rapidly. It is a well established fact that criminals usually marry each other, therefore criminality is the natural and inevitable offspring of such marriages. I am reminded, just at this time, of a statement made by our own Rupert Blue, former Surgeon General of the U. S. Public Health Service, namely; "A true race of feeble minded people is being developed among us."

I believe the time is rapidly approaching when every municipal court will have in constant attendance a physician well versed in the diagnosis of mental disorders. The reason for the above statement is obvious if the premises of this paper are correct, since a large percentage of the criminals, who are daily arraigned before our municipal judges, will be found to be mentally incompetent on account, probably, of some physical disease—may be focal infection—which properly treated would obviate the necessity of the municipal judge passing a road or jail sentence to an individual who is both physically and mentally sick rather than a criminal *per se*. I have often thought of the great injustice, I might say unfairness, to the youthful criminal who receives such a sentence, and is, therefore, forced into the ranks of hard and seasoned criminals. If the youthful criminal is found, after a careful and painstaking examination by a physician who is an expert in the diagnosis of early mental diseases, to be suffering from some underlying physical or mental disease, he should be sent to a reformatory rather than have for his companions criminals and moral degenerates of our jails, etc.

I think the medical profession is in a position to help our municipal courts in meting out justice to our youthful criminals, and, thereby, will be able to save a large percentage of our mental defectives who, at present, are being classed as incorrigible youthful criminals. If we, as a profession, fully recognized the danger involved in the neglect of our mental defectives, I think the legislature of our State would soon enact laws requiring scientific treatment of weak-minded persons. If such law were enacted and systematically applied, it would be of inestimable benefit in the

way of reclaiming a large percentage of our mentally incompetent individuals.

Our State institutions, at the present time, are fairly groaning under the weight of the burden of undertaking to care for the chronic insane, hence the importance of the early recognition of mental disorders while the patient can be cured. It is well known that the facilities of our State institutions for the care of the insane are inadequate, notwithstanding huge appropriations from our State Treasury, to care for a large number of patients whose admissions are being constantly sought by their physicians, relatives and friends. The congested condition of our institutions is largely due to the fact that they are filled with the chronic insane, who are incurable, and, therefore, little room is left for the incipient cases, which might be cured.

The thought has occurred to me that a large mental clearing house, so to speak, controlled by experts on mental disease, would save the State much expense. The service of this board of experts on mental disease would save the embarrassment to the superintendents of our State hospitals and private institutions before the criminal courts, where the mentality of the criminal is questioned. The members of the board could pass upon the insanity of the criminal independent of the court room, and, in this way, the grilling examination by our attorneys, and, the oftentimes consequent humiliation to members of our profession would be avoided. A recent experience in our State has proven very conclusively to my mind the necessity of the so-called clearing house for mental cases, whether criminal or otherwise, and the need to secure admission for those who are really in need of treatment. It is true, however, that we have made rapid strides in this respect, as evidenced by our epileptic colony at Raleigh and vocational training for our mild mental cases.

I do not think that we can praise too highly the splendid work that is being accomplished by our State institutions for the care and treatment of the insane, and I seldom meet the superintendents that I do not feel disposed to congratulate them for the unstinted service which they are rendering the state. A very illuminating article, written by Dr. Albert Anderson and his associate, Dr. Victor R. Small, appeared in a recent issue of *Southern Medicine and Surgery*. I think every mem-

ber of our profession should read the article carefully in order to combat criticism of the management of our institutions, if for no other reason.

### MINISTERS TO THE SICK.\*

By WILLIAM J. MALLORY, A. M., M. D., F. A. C. P.,  
Washington, D. C.

"Is my strength the strength of stones? or is my flesh of brass? Is not my help in me? and is wisdom driven quite from me? To him that is afflicted pity should be shewed from his friend."—Job. VI, 12:14.

Since the time when Job, being smitten with boils, cursed his day, man's need of moral and spiritual support as well as physical relief in the presence of disease has been recognized, and it has fallen to the lot of the minister of religion and the doctor of medicine to meet these two requirements.

It is only in recent years that law and medicine have become associated in an effort to deal in a constructive manner with the social problem of disease, delinquency, and crime, aiming at prevention and cure rather than simple punishment; whereas the relation between religion and medicine is older than civilization, the spiritual and physical welfare of mankind originally being in the hands of one man, the priest-physician.

With the increasing complexity of the social order and the resultant specialization in all activities, the work gradually became divided in such a manner that the priest concerned himself more particularly with ethical, moral and religious matters, and the physician with the physical aspects of disease. But specialization without co-ordination tends to limit the intellectual horizon, and so there developed what has been called the disharmony between science and religion; not that they are incompatible, for truth is unity, but because they saw each other "as through a glass, darkly," and not face to face.

Recognition of a common purpose should bring the minister and the physician together, not for fusion or reversion to a primitive type, but for mutual understanding and co-operation in human welfare work—ministration to the sick. Consideration of the subject from the dual view of science and religion may therefore be justified.

That the view should be different is natural.

\*Address delivered before a joint meeting of the clergy and physicians at Trinity Episcopal Church, Washington, D. C.

for one is not born a physician or clergyman, but becomes such by calling, training and experience. The calling is similar in that both have the ideal of service; the training and experience are widely different. An important point of similarity not usually recognized is that of faith, for although physicians themselves little realize it, the main spring to all their professional activities is an abiding conviction in the existence of a universal law, both natural and divine, which rules in the physical and spiritual universe.

The words of Prince Gautama, as interpreted by Sir Edwin Arnold in his "Light of Asia," may well be taken as part of the physician's creed:

"Before beginning, and without an end,  
As space eternal and as surety sure,  
Is fixed a Power divine which moves to good,  
Only its laws endure.

This is its touch upon the blossomed rose,  
The fashion of its hand shaped lotus leaves,  
In dark soil and silence of the seeds  
The robe of spring it weaves.

That is its painting on the glorious clouds,  
And these its emeralds on the peacock's train;  
It hath its station in the stars, its slaves  
In lighting, wind and rain.

It spreadeth forth for flight the eagle's wings  
What time she beareth home her prey; it sends  
The she-wolf to her cubs; for unloved things  
It findeth food and friends.

This is its work upon the things you see;  
The unseen things are more; men's hearts and  
minds,  
The thoughts of peoples and their ways and wills,  
These, too, the great Law binds.

It will not be contemned of any one;  
Who thwarts it, loses, and who serves it, gains;  
The hidden good it pays with peace and bliss,  
The hidden ill with pains."

Physicians are governed by the conviction that there is an understandable cause back of all changes; that changes occur as a result of an orderly sequence of events which may be investigated and understood. The knowledge so obtained is the rational basis for purposeful action in dealing with disease. So they investigate and by study and training avail themselves of the knowledge and experience so gained by others, striving to learn as much as possible of the normal functions of the human body and the changes that occur in it as a result of disease, in order that they may work intelligently to prevent, cure, or alleviate such conditions.

We all recognize that there is a natural tendency to recover from injury and disease, for we see wounds heal without the attention of the surgeon and we see people recover from infectious diseases without treatment of any kind. But by investigation of the changes which take place in tissues during healing, as well as the conditions which interfere with healing, the surgeon is now able to produce healing in wounds which would be mortal if left unattended, and to prevent or correct deformities otherwise hopeless.

As a result of the attitude of inquiry and long and painstaking investigation, the causes of many diseases have been learned and their mode of transference understood, and so it is now possible to prevent typhoid fever, small-pox, malarial fever, yellow fever, and many others. There are, however, some morbid conditions, due to heredity, previous disease, and age, which it is impossible at present to prevent or cure. But by understanding the normal function of organs and the character and degree of the impairment which occurs in these conditions, it is possible to do much to prolong life and increase efficiency by intelligently adapting the life, work and habits of the patient to a handicap which cannot be removed.

What has been said so far refers only to the more obvious aspect of disease. There is, however, another phase which, while less apparent, is of very great importance; that is, the manner in which the sick person reacts to the condition in which he finds himself. This is naturally not such an important feature of acute illnesses as it is of chronic impairment of health, or those permanent deficiencies which handicap one in the battle, without destroying life.

All of us have seen people slightly impaired in health who are a burden to themselves and an affliction to all who love them, while we know of others suffering from a long and painful illness who still do all that they can in the useful work of life and bear their affliction with such cheerful fortitude that they are an inspiration and blessing to all who come in contact with them.

As Montaigne says, "Men are tormented by the opinions they have of things and not by things themselves." A psychiatrist of wide experience points out how one man who has lost an arm becomes a beggar, while another

with the same impairment will readapt himself to the new condition and carry on successfully.

An inspiring example of successful adaptation of life in the face of great physical infirmity is found in the life of Edward Livingston Trudeau. When, as a young man at the beginning of his career, he came to Saranac, ill with tuberculosis, he did not resign himself to invalidism and moping, but, observing the effects of climate and right living on the course of the disease, extended his interest beyond himself to the help of other sufferers and found his life work, of which he wrote: "The struggle with tuberculosis brought me experiences and left me recollections which I never could have known otherwise and which I would not exchange for the wealth of the Indies."

Robert Louis Stevenson repeatedly found the way to a chosen profession barred by chronic ill health, but despite physical pangs and mental anguish he wrote such stories and verse as have lightened the burden of sickness for thousands of men, women and children.

It is in this domain of adaptation that the wise clergyman may be of the greatest assistance to the sick. But it is said that if Christ himself came to the world, he would not be permitted to heal the sick. To those who would follow his methods it may be said that he never violated any law or advised anyone else to do so. When he healed the sick, the Mosaic law was the sanitary code and the priests were health officers and quarantined infectious diseases. After the Sermon on the Mount, when he healed the leper, he said, "See thou tell no man, but go thy way, shew thyself to the priest, and offer the gift that Moses commanded, as a testimony unto them." So, if He were here today, I see no reason to doubt that he would comply with the law of the land now, as he did then.

If the physician can believe what he sees and what patients tell him, there are still many afflicted with torments of the mind and possessed by devils. The young lady who says she is "so nervous she could just scream" also states that she loves a man whom she may not marry because he is of a different faith: and the woman who tells her physician that she contemplates seeking a divorce and desires a letter stating that she is justified in such a course—both of these need the clergyman

rather than the physician. But now, as in the time of Macbeth, the physician is asked to

"\* \* \* minister to a mind diseas'd;  
Pluck from the memory a rooted sorrow;  
Raze out the written troubles of the brain;  
And, with some sweet, oblivious antidote,  
Cleanse the stuff'd bosom of that perilous stuff  
Which weighs upon the heart."

And when he replies, "Therein the patient must minister to himself," he is told to "throw physick to the dogs, I'll none of it."

But we must not forget that physical disease may be largely if not wholly the cause of abnormal mental condition and unsocial behaviour. Many of the downcast and heavy hearted are so because of physical impairment and the fretful wife or irritable husband may not be possessed by a devil, but may be suffering from no worse demon than can be extracted by a dentist's forceps. Auto-intoxication, focal infection and other chronic physical disorders may so impair the nervous system that the reactions will be very abnormal, and before attempting to remove an evil spirit or produce healing by an act of faith it would be well to attack the evil at its source and remedy physical conditions found to be defective.

Some one has asked, "When should the minister be called?" I would reply early and often. Not once in a lifetime and that so late that the toes are cold. Only too frequently the sequence of events is as follows: We see the physician going into the house next door and we say, "I see Mrs. Brown is ill," but we feel no apprehension. Next day, when two physicians enter the house, we say, "I fear Mrs. Brown is worse, for they are having a consultation." We feel anxiety, but still have hope. But when we see the minister leaving the house, we say, "I fear they have given up hope of Mrs. Brown for I saw the minister coming out of the house today." The sad and depressing atmosphere on such an occasion should not be charged to the minister's visit any more than the death should be ascribed to the last dose of medicine taken. Both the physician and the minister too often have to deal with an end result of events belonging to an irrevocable past.

Some people refer to the deformed and mentally defective as "the afflicted of God," thereby leaving the blame and burden to Him. The cynical Oriental poet makes the "vessel of more ungainly make" say:

"They sneer at me for leaning all awry.

What, did the hand of The Potter then shake?"

But in our day and land we believe that our vessel is subject to good and bad influences, which may be modified favorably, so we organize means for the care and education of mothers, study prenatal influences, and advocate child welfare work, the training of defectives and the reclaiming of the delinquent, considering ourselves instruments in the hands of the great Artist, to be used in shaping the vessel in symmetry and strength for beauty and service.

What should the minister do when called? This is for him to determine. To the man devoted to his calling, and possessed of the available knowledge of the material with which he must work, there is no conceivable limit to the good he may do for mankind. As its guide, philosopher and friend, his teaching should lead to wholesome living, right thinking, and self restraint. These alone would prevent many of the diseases which mar the body and cloud the mind, for "Unnatural deeds do breed unnatural troubles." There is an old writing which says, "He that sinneth in the sight of his Maker shall fall into the hands of the physician," while "length of days and long life and peace" are promised to those who "forget not the law but keep the commandments." (Ecclesiasticus 38:15.) "Hear ye children, the instruction of a father and attend to know understanding." Then, as in the olden days, the hearth will be indeed an altar, and the worthiest sacrifice to the gods the perfect physical sanity of young men and women which the scrupulous ways of pure religion tend to maintain.

But this is not easy, and so, from the childhood of the human race, mankind has sought for some royal road to wisdom and a sudden, easy, and happy issue from affliction. The idea of being healed of a mental or physical affliction by an act of faith, such as a pilgrimage to some sacred spot or the offering of a gift to some shrine, is very beautiful and appeals to something deeply implanted in all. Even the most material-minded are charmed by the new and strange and it seems good to them to leave their native city and journey to a distance, even to a foreign country, where a strange man in a novel environment may treat them, perhaps cure them, and certainly give a new name to the disease.

The earliest historical records reveal the

care of the sick in the hands of priests or priest-physicians and among the primitive people existing at present the priest is the medicine man. But even in very early times, in Egypt, India and Babylonia, there gradually grew up a body of lay physicians who dealt with disease more particularly from its physical aspects. Between them and the priests there existed in Greece the most cordial and helpful co-operation. These groups of lay physicians gradually increased in size and importance and admitted to their ranks acceptable ones who wished to become physicians. They formed schools or guilds where the theories and practice were taught by discourse and at the bedside.

It was in such an environment, near the temple of Esculapius that Hippocrates laid the foundation for rational medicine, and Galen, when a young man, served at such a temple. The modern physician who reveres the names of these fathers may well be reminded that their education was not purely technical, but that physical training was practiced for the development of the body, and rhetoric, poetry and music cultivated for the humanizing of the soul.

We see that the head hunter and South Sea Islander have their priest-medicine-man and that the cultured pagan had temples dedicated to the healing of disease. But before we encourage the modern man to expect a miraculous intervention in the laws of nature for his personal benefit it would be well to consider the physical and spiritual consequences.

Uncleanliness now, as in the days of Moses, has something to do with disease. Bad habits and the violation of the laws of physiology produce very distressing results in this world, however much the consequences may be mitigated in the world to come. But, on the other hand, by means of personal and communal sanitation, health is nowadays in a great measure a purchasable commodity, and a high typhoid rate, the prevalence of malaria, and a high death rate in general should not be blamed on God, on the local Saint or on the minister, but on the city fathers and the citizens themselves. So let us co-operate with the health officer in enforcing the laws providing for our own safety.

The man who is taught that God or the minister may cure his ills will rationally ask, "Why, then, were they not prevented?" and if

what he calls Christian Faith does not produce a remedy, he may try what someone else calls Christian Science. The steps are then short and easy to the wizard, the Ouija board and the newest novelty that promises the most for the least inconvenience. Such an one will be fickle in faith and subject to unpleasant, gusty changes of temperament. We may imagine him saying in the words of Kipling's Pagan:

"How can the skin of a rat or mouse hold  
Anything more than a harmless flea?  
The burning plague has taken my household.  
Why have my gods afflicted me?  
All my kith and kin are deceased,  
'Though they were as good as good could be.  
I will out and batter the family priest  
Because my Gods have afflicted me."

The rational attitude of mind and one leading to more productive results is expressed in another verse:

"This was none of the good Lord's pleasure,  
For the spirit He breathed in man is free;  
But what comes after is measure for measure,  
And not a God that afflicteth thee.  
As was the sowing, so the reaping  
Is now and evermore shall be.  
Thou art delivered to thy own keeping,  
Only thyself hath afflicted thee!"

This virile doctrine is such "strong medicine" that all will not accept it, so the miracle worker on the one hand and the scapegoat on the other will ever be the resort of the weak and timid.

In the olden days when Moses was trying to make a nation of a people who had recently been slaves, though he fed them with manna from heaven, his public cried to him for the flesh pots of Egypt, and when he came down from the mountain with the Ten Commandments for guidance and mutual protection he found them worshiping a golden calf. In modern times, the public of Metchnikoff, Pasteur and Reed will drink sour milk to prolong life, but to rout out the rats, destroy mosquitoes and flies, and keep their milk bottles clean does not appeal to the imagination, at least not to a degree sufficient to arouse enthusiasm.

If we might speak of a medical problem in terms of theology, we would say that faith is essential but faith should lead to works and the works should be "meet," that is, there should be a rational relation between the character of the works and the end desired to be accomplished.

To the observant all life is a miracle, and to the pious all healing is from God. A holy book tells us:

"The Most High hath created medicines out of the earth, and a wise man will not abhor them. Was not bitter water made sweet with wood? The virtue of these things is come to the knowledge of man, and the Most High hath given knowledge to men, that He may be honored in his wonders. By these He shall cure and shall allay their pains and of these the apothecary shall make sweet confections, and shall make up ointments of health, and of His works there shall be no end." As for the physician, "\* \* \* \* \* for the Lord created him; and let him not depart from thee, for his works are necessary. For there is a time when thou must fall into his hands."

But do not expect too much of him. At best, the physician can only point out the relation between cause and effect, and with the aid of an intelligent public opinion prevent some diseases, cure some others, and fortunately, ameliorate all. Under his directions we may undoubtedly have life a little longer and, what is more important, "more abundantly," that is, live more efficiently while here. He may win many battles, but must ultimately lose the war, for to all must come the

"\* \* \* reaper whose name is Death,  
Who, with his sickle keen,  
Reaps the bearded grain at a breath,  
And the flowers that grow between."

The physician attempts to teach man how to live cleanly, sanely, long and usefully. Religion must show him how to meet ir retrievable loss and death.

"In the hour of death, after this life's whim,  
When the heart beats low, and the eyes grow dim,  
And pain has exhausted every limb,—  
The lover of the Lord shall trust in Him.

When the will has forgotten the lifelong aim,  
And the mind can only disgrace its frame,  
And a man is uncertain of his own name—  
The power of the Lord shall fill his frame.

When the last sigh is heaved and the last tear shed,  
And the coffin is waiting beside the bed,  
And the widow and child forsake the dead,  
The angel of the Lord shall lift his head.

For even the purest delight may pall,  
And power must fail and the pride must fall,  
And the love of the dearest friends grow small—  
But the glory of the Lord is all in all."

## THE CONSERVATION OF LIFE.\*

By R. H. GARTHRIGHT, M. D., Vinton, Va.

The soundest and healthiest body is the one most capable of performing useful mental and physical work.

Few men are perfect. For one who is strong and virile, there are many weaklings. Stand on the street corner, if you please, and study the passing crowd. The pale and pinched faces, the limping gait, the stooped shoulders and contracted chests, prove the truthfulness of this assertion.

Men do not realize what a great privilege it is to be alive. Deaths are entirely too frequent. Hundreds of thousands cease to exist long before attaining their majority; millions "pass over the river" in the meridian of life, and few reach the allotted "three score years and ten." Drink, abuse of the digestive organs, impurity, unnecessary exposure to contagious diseases, and excesses that cripple the heart and kidneys, send them down to untimely graves.

Nature is a fighter. The law of antithesis is a natural law. We know that two forces are continually at work in the body of every creature: the one endeavors to keep it alive, the other to kill it.

Because men fail to appreciate the value of life, sooner or later they suffer.

"Fools, because of their transgression and because of their iniquities are afflicted." How long the vital principle will be retained in the material parts is often dependent upon the individual's volition. A man may possess perfect organs, functioning physiologically, the light of life ablaze throughout his complex organism, and still be inclined to abuse the "tenement of clay." He may will to yield to appetite until his material parts are wrecked beyond restoration.

No man comprehends the height and depth, the length and breadth of this marvelous principle denominated life. With it the whole creation teems and throbs. It breathes upon the earth, and fields of green and flowers of varied hues appear; and other things come forth to please the eye and delight the ear with beauty and with melody. It glows upon the cheeks of maidens, gives strength and grace to the forms of men, converts the inorganic into the organic, makes flesh and bone and brain from senseless dust. It dwells in

the tiny blade of grass and in the cedars of Lebanon, the earth worm in its feebleness and Behemoth in his might.

Let me venture a definition of human life. It is that invisible force which sensitizes and prepares the organs for the reception of impressions, making man capable of seeing, hearing, feeling, thinking and working. Dr. William E. Mumsey, defines it, "An invisible, imponderable, intangible, immaterial energy."

This energy permeates every cell of the organism. It accumulates in the ganglia, shoots along the nerve fibers throughout their ramifications, stimulates the blood currents, the respiration and the elimination of waste products. It touches and revivifies organs that are about to perish: thus restoring the physiology of tissues on the border of pathological decay. From occipito-frontalis to plantar fascia, into the recesses of every nook and corner of man's anatomy, its light and power penetrate. Into the hundreds of bones, cartilages and muscles, the skin, the brain with its fissures and convolutions, its hallways and apartments curtained by soft and delicately woven tissue—into all these it enters to assist in balancing and harmonizing the body's organs. It is this energy, aided by other forces, which brings together the various atoms, resulting in the formation of compounds, that uniting, make man a conscious, active being.

This principle manifests itself in the embryo. Then the mystery of reproduction goes on until all the organs are formed and a human being, endowed with an immortal soul, is ushered into the world. To wantonly destroy a life in its incipency, is "murder most foul and damnable." If all men and women of sound minds and bodies would organize for the purpose of studying the laws of life preservation, pledging themselves to the strict observance of the same, coming generations would be stronger and happier.

One way in which lives can be saved and health preserved is by a systematic distribution of doctors. The average Virginia city contains a plethora of physicians, the average country community contains a paucity. Indeed the condition is so serious that medical men need to be offered special inducements to locate in the country. Strong and progressive men should practice in rural districts. Health conditions will improve and the mortality

\*Read before the Roanoke Academy of Medicine, October 16, 1922.

rate decrease perceptibly when country work is given more thorough and systematic attention by the profession.

The introduction of automobiles stimulates the building of good roads through sections formerly inaccessible. With traveling on smooth highways in vehicles that save time, there will come many rural improvements, better houses, better school facilities, better land producing better crops, and better sanitation, and with doctors more accessible, life's conservation will be greater.

With one or more small hospitals established in every county, chemists, bacteriologists, physicians and surgeons can give almost ideal service to the rural population without the danger and time required to move patients' long distances to hospitals in the cities.

Statistics show that seventeen thousand parturient women die annually in the United States, and approximately, two hundred and fifty thousand babies die before they reach the age of one year. In our own state the report of the Health Board shows that three times as many mothers succumb to child-birth as would if they were properly cared for. Prospective mothers' lives are sacrificed because they neglect to receive treatment at the critical period.

In the county of Pittsylvania under the supervision of Dr. W. P. Caton, there were 5,978 school children inspected, 1353 of whom had defects of vision, 546 beginning to be deaf, 2,214 enlarged tonsils, 1,091 adenoids, 4,609 decayed teeth, and out of 1,847 children examined for hookworms and other parasites, 356 had hookworm, showing an aggregate of 10,169 defects. Isn't that alarming for a single community? It exists perhaps almost as bad over the entire state and country.

An evil abounds that is wrecking the health and destroying the ability of many. I refer to the drug habit. The Harrison Act does not seem to be diminishing the number of addicts, for it is said that there are more than one million in this country. Half of them are women. Lemuel L. De Bro believes these sufferers should be treated in well appointed hospitals. Sad it is to know that there are unscrupulous men and women going up and down the land selling morphine and cocaine to these weak and miserable creatures. Can it be that some members of our exalted profession are so degraded in mind and morals as to become engaged in this hellish traffic?

Lord have mercy on them, and bring them back to a state of decency!

The Doctor should watch his middle-aged patients and have them undergo a thorough examination once or twice a year. He will often find beginning organic diseases which, if attended to in time, will lengthen life. Heart, lungs, and kidneys are often crippled before their owners suspect they are diseased.

The cancer problem needs to arouse the active interest of every member of the profession. This insidious disease continues to destroy tens of thousands annually. The people ought to be taught how to recognize its incipient symptoms, and submit to the X-ray, radium, or surgical treatment before it advances beyond the curative stage.

Why is it that we have so few cases of typhoid fever to treat today? Because health boards and family physicians have taught them how to prevent it.

How is it that so many children still acquire measles? Because we have not impressed the heads of households with its dangers. The idea exists that measles and whooping-cough must at some time attack every body, and mothers wishing to have it over with actually make no efforts at prevention.

One of the greatest hindrances to progress along this line is the blind submission of hundreds to the methods of the numerous medical cults that are continually springing up in every quarter. Our convalescent patients are persuaded to submit to their manipulations, and then if by chance improvement continues, they proclaim through the press, and with loud voices, their marvelous success! And people believe them and crowd their offices. Special bills are passed by legislatures and approved by governors permitting *poropaths*, *chiropractics*, cancer quacks, D. C.'s, C. Q.'s, *et cetera*, to practice on the bodies of human beings without submitting to examination before the State Boards. Who is responsible for this condition? The problem is unsolved. Our efforts to protect the people from quacks do not seem to be appreciated and sometimes we are tempted to say, "Ephriam is joined to his idols, let him alone." But while we feel this way, really we should redouble our efforts to eliminate medical pretenders and thus fight unceasingly for the protection of the ignorant and thoughtless.

Perhaps the most effectual as well as the

most ghastly and rapid example of plague extermination in history is described in the Book of Numbers. The children of Israel committed whoredom with the Midianitish women at Beth Peor. Soon syphilis ran riot among the hosts, and many died with the disease. Terrific battles were fought and thousands killed and cities destroyed. Israel returned with the spoils of war and captured women. Moses' wrath was kindled, and he ordered the slaughter of every woman who had known man and all the men who had cohabited with women. The slaughter was terrible, but it saved the nation. Israel was cleansed of the plague and the taint ceased to be transmitted.

Dr. Thomas W. Murrell, of Richmond, says, "He, (Moses) looked down on the ages. He was as surely protecting the Hebrew boy and girl playing on the steps of Solomon's Temple, and the men and women who gathered in the stable at Bethlehem, as those who now sleep under the stars by Jordan." That was indeed radical treatment. How would Dr. Moses handle the situation today?

Impress the young with the importance of life's conservation and good results will follow. "The seeds of first instruction are dropped into the deepest furrows." If future generations are to be healthy and wise, the living youths of today must absorb and demonstrate these lessons.

The preservation of health and the prolongation of life should constantly occupy the mind of the doctor. The various methods of helping the individual to keep his physical parts in good working condition should be daily impressed upon his mind by the family physician. Health Boards are accomplishing a great deal, but more satisfactory results would be in evidence if they received the full co-operation and help of doctors in general practice. Life is tenacious and persevering. Since the dawn of history it has met various antagonistic forces. War and pestilence have driven out the vital spark from the bodies of millions, but other sentient beings have quickly taken their places.

Periods of cessation from wholesale turmoil and destruction have obtained, and prosperity returned. But for its wonderful tenacity and revivifying properties, dire destruction would quickly come to a large portion of the earth's inhabitants.

Look at France: Charles IX, Catherine de Medici, Louis XIV, and Napoleon Bonaparte kept its soil deluged with blood through long years; but from the almost chaotic condition to which that fair land was reduced, living men and women bestirred themselves, and speedily rebuilt the nation.

Permit me to say that in our observations on life we, as men who are somewhat scientific, should seek to avoid conversion to the ideas of those scientists who see nothing immaterial in man, but rather look upon the human frame as composed of body and soul, one part of which parallels eternity. The thought of death is repugnant; as expressed by Charles Lamb, "We do not want to go down into the cold and muddy grave even though we have kings and princes for our bed fellows."

"Cold in the dust the silent heart may lie,  
But that which warmed it once can never die."

In the beautiful drama of *Ion*, the instinct of immortality so eloquently uttered by the death-defying Greek finds a deep response in every thoughtful soul. When about to yield his young existence as a sacrifice to fate, his beloved Clementhe asks if they shall not meet again; to which he replies "I have asked that dreadful question of the hills that look eternal, of the clear streams, flowing forever, of the stars among whose fields of azure my raised spirit hath walked in glory. All were dumb, but while I gaze upon the *living* face, I feel that there is something in the love that mantles through its beauty that cannot wholly perish. We shall meet again, Clementhe."

The fear of what will come after death induces some men to observe hygienic rules, and thus prolong their earthly existence. Shakespeare has this idea in mind when he writes:

"For in that sleep of death what dreams may come  
When we have shuffled off this mortal coil,  
Must give us pause.

For who would bear the whips and scorns of time,  
The oppressor's wrong, the proud man's contumely,  
The pangs of despised love, the law's delay,  
The insolence of office, and the spurns  
That patient merit of the unworthy takes  
When he himself might his quietus make  
With a bare bodkin?"

Who'd these fardels bear,  
To grunt and sweat under a weary life,  
But that the dread of something after death,  
The undiscovered country from whose bourne  
No traveler returns, puzzles the will,  
And makes us rather bear those ills we have,  
Than fly to others that we know not of?"

Sometimes when we think of present con-

ditions, of the men who are disregarding the rules of decency and the laws of the land, of the large number of children appearing daily in our juvenile courts, of the unrest in Europe and other foreign countries, the degrading, inhuman outrageous actions of the bloody Turks, we are inclined to view the future with a feeling of dread. But if we will consider what has been done by determined and optimistic workers in the midst of distressing conditions in the past and realize what many are doing to uplift humanity today, we will not despair, but will be encouraged for the future. I believe that life is too powerful and man too far advanced in civilization to retrograde—that individuals are going to increase in mental and physical vigor, nations move on towards perfection, and universal justice prevail.

Sitting in my office not long ago and thinking over these questions, I looked at some of the pictures on the wall. Before my eyes were the fine and noble features of Gen. Robert E. Lee, the great soldier, the matchless leader of men, the splendid teacher of youth, the Christian gentleman, who wore always the "white flower of a blameless life;" an engraving of John W. Daniel, the statesman and Virginia's gifted orator, the great constitutional lawyer, the honest man; another picture—the first meeting of the Medical Society of London in 1773, composed of prominent physicians and surgeons of the day, who wrought to benefit their kind. In the group is seen the modest face of Jenner whose discovery has saved the lives of multiplied thousands. Then I looked at the features of a brave young soldier who fought in France for his native land and for the world's freedom. There was also a photograph of the cottage home of a superannuated Methodist preacher. Standing in the front yard by the fence, leaning on his staff, is the preacher himself, gray headed and bent with age, realizing the sweet consciousness of duty done, who has "fought a good fight" and almost "finished his course," calmly awaiting the call to his eternal reward. And I felt that there are still many men and women faithful and true, in every section of our beloved land, preaching the gospel of health, and unselfishly working with all their powers to strengthen character and uplift humanity.

Let us hope that the time will come, and come soon, when wars will cease, contagious

and infectious disease be conquered, and Hygeia, robed in garments of spotless purity, will walk in queenly strength and dignity through all the lands of this big round world.

### THE ETIOLOGY OF BENIGN STRICTURE OF THE ESOPHAGUS.

By PORTER P. VINSON, M. D., Rochester, Minnesota.  
Division of Medicine, Mayo Clinic.

Approximately eight per cent of esophageal obstructions are due to cicatricial stricture. Most such strictures are the result of ingesting caustics, usually a solution of lye, but a fairly large number are caused by other factors. The strictures that follow the swallowing of lye are most common in children, but those due to accidental burns from this caustic and from swallowing it in attempts at suicide are often seen in adults. A patient who has had such an accident in childhood occasionally is able to swallow with comparative comfort until adult age, when a bolus of poorly masticated food, usually meat, may lodge in the esophagus above the stricture. In removing this bolus, sufficient traumatic edema may be produced to cause complete esophageal obstruction. During the past two years, thirty-seven patients with benign stricture of the esophagus have been observed in the Mayo Clinic. I shall discuss these cases from the standpoint of etiology.

Nineteen of the thirty-seven patients had strictures resulting from the ingestion of a solution of lye. Eleven of these had swallowed the lye before they were ten years of age, but two of them were more than fifty years before they came for examination. Eight of the patients were adults, four of whom had attempted suicide, and four had swallowed the solution accidentally. One stricture in an adult had been caused by the accidental swallowing of a solution of silver nitrate in infancy. Hydrochloric and sulphuric acids had been responsible for three of the strictures seen in adults. One of these resulted from an attempt at suicide.

One patient aged seventy-five years had had a thrush infection four years before, and a stricture in the upper portion of the esophagus was attributed to the effects of the disease. Scarlet fever was the etiologic factor in two cases, and in one other, the stricture had followed an attack of typhoid fever. Three of the strictures had occurred during pregnancy and were evidently the result of ulceration

of the esophagus caused by pernicious vomiting. Seven of the patients had strictures for which no cause could be ascertained. They had evidently resulted from a mediastinitis, or from the healing of a simple ulceration in the esophagus.

#### SUMMARY

Of thirty-seven patients having benign strictures of the esophagus, twenty-three had acquired them after eighteen years of age. The remaining fourteen strictures had occurred in patients under ten years of age.

Five of the strictures seen in adults had resulted from unsuccessful attempts at suicide.

Of the strictures that had occurred in childhood, eleven had resulted from lye, two followed scarlet fever, and one was caused by the ingestion of a solution of silver nitrate.

Twenty-three strictures observed in adults were produced by the following causes: eight from the swallowing of lye, three from the vomiting of pregnancy, two from the ingestion of hydrochloric acid, one from sulphuric acid, one from thrush, one followed typhoid fever, and in seven the cause could not be determined.

## Proceedings of Societies

### Wise County Medical Society.

At the meeting held in Norton, June 27, papers were presented by Mr. Aubrey H. Straus, director of the State laboratory, on "Diphtheria Immunization;" by Dr. Thomas F. Staley, Bristol, on "Eye Strain and Results of Accurate Refraction;" and by Dr. C. B. Bowyer, Stonega, on "House Fly." Meetings are held bi-monthly and are interesting and well attended.

Officers elected for the ensuing years are Dr. W. G. Painter, Big Stone Gap, president, and Dr. C. B. Bowyer, Stonega, secretary (re-elected).

### The Southside Virginia Medical Association

Met in Lawrenceville, June 12, with a full attendance, Dr. W. C. Harmon, of Dolphin, presiding. The program was unusually good and the free discussion which followed each paper showed that the doctors of our territory are taking much interest in the newer things in medicine and surgery.

The next meeting will be held in Emporia in September.

R. L. RAIFORD, Sec'y.

### The Norfolk County Medical Society,

At its annual meeting in June, elected Dr. Charles W. Doughtie president; Dr. R. L. Payne, vice-president; and, re-elected Dr. Lockburn B. Scott, secretary-treasurer. All are of Norfolk.

### The Southampton County Medical Society

Held its regular monthly meeting in Courtland, June 7, with a full attendance. Mr. Aubrey H. Straus, State Bacteriologist, had charge of the program, and talked on the Schick test and the administration of toxin-antitoxin. Several children with typical Schick reactions were exhibited and some of the doctors present took the test at the close of the meeting.

## The Truth About Medicine

During May, the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Non-official Remedies:

#### PROPAGANDA FOR REFORM.

The intracardiac injection of epinephrin.—Recently much publicity has been given to the power of epinephrin, when injected into the heart, to produce a response resulting in revivification when the heart has apparently ceased its action from certain causes. Of the many cases which have been reported, a remarkable one is that in which collapse occurred during an examination for extra-uterine pregnancy. After other methods had been tried without avail, an intracardiac injection of epinephrin was given. In ten seconds the heart sounds became perceptible. Four weeks later the patient was discharged as well. It must be borne in mind that the instances in which such restoration can be utilized are rare.

When death comes as the result of the wearing away of tissues, as the result of toxic action of either bacterial or metallic poisons, or as the result of destruction of vital organs, it would be cruel and futile to arouse false hopes by what could only be a sensational experiment. (Jour. A. M. A., May 5, 1923, p. 1314).

**Intravenous therapy.**—For some years the Council on Pharmacy and Chemistry has urged conservatism in the adoption of the intravenous method of administering drugs. It has been necessary to do this to offset the propaganda of proprietary firms that, for commercial purposes, feature the indiscriminate use of intravenous therapy. In order that the status of this form of drug administration might be presented to the profession, and that it might be made clear under just what conditions the intravenous administration of drugs is warranted, the Council publishes a report prepared by a committee which studied the problems involved. The report discusses the fallacy of the arguments commonly advanced by those who advocate intravenous therapy as a routine. The Council has no desire to discredit the rational use of drugs by intravenous injection, but, on the contrary, it seeks to avoid the accidents and disappointments that must follow the abuse of a method which, rightly employed, may be a life-saving measure. The Council places itself on record as opposing the reckless and indiscriminate use of drugs by intravenous injection with its attendant dangers and increased needless expense to the patient. However, the Council recognizes the legitimate, life-saving nature of the intravenous administration of drugs in extreme cases. (Jour. A. M. A., May 5, 1923, p. 1331).

**Fleischmann's Yeast** not admitted to N. N. R.—In March, 1921, the Council on Pharmacy and Chemistry took up the consideration of Fleischmann's Yeast on account of the extensive and extreme therapeutic claims which were made for this preparation. Since then the Council has given much attention to the subject of yeast therapy. After consulting with eminent students of nutrition and clinicians qualified to speak with authority on questions of nutrition, dietotherapy and pediatrics, the Council concluded that there was little likelihood that the administration of yeast or yeast preparations will be of therapeutic value in many cases for which they are advised. The Council finds that many advertisements for Fleischmann's yeast are misleading in that they tend to create the belief that many diseases are prevented or cured by its use. Advertisements addressed to physicians are likely to lead to the belief that the efficacy of yeast therapy in many conditions has been established. Advertisements addressed to the public are bound to create the opinion in the mind of the lay reader that reliance may be placed on yeast in many conditions. The Council refused recognition to Fleischmann's Yeast (1) because it is advertised by means of unwarranted and misleading therapeutic claims, and (2) because it is advertised to the public with unwarranted therapeutic claims that may become a detriment to the public health. (Jour. A. M. A., May 12, 1923, p. 1398).

**The Standardization of Pituitary Extract.**—Pituitary extract—a solution containing the water soluble principle or principles from the fresh posterior lobe of the pituitary body of cattle—is official in the U. S. Pharmacopeia as Solution of Hypophysin, and a method of standardization is prescribed. In practice the pharmacopeial standard has been found unreliable and manufacturers have adopted various modifications. Further, the pharmacopeial solution has been found too weak, and stronger preparations

are being marketed. Some of these have been accepted for New and Non-official Remedies. The wide variation in the strength of pituitary extracts and the unsatisfactory character of pharmacopeial assay method are shown in a study carried out by Erwin E. Nelson, and a study by Morris I. Smith and Wm. D. McKlosky. The next pharmacopeia should provide a pituitary solution of satisfactory strength and an assay method which will insure a satisfactory control of this important medicament. Until such a standardization is provided, the physician will do well to use one of the pituitary preparations accepted for New and Non-official Remedies, which he has found to be satisfactory. (Jour. A. M. A., May 19, 1923, p. 1473).

**Tryparsamide.**—The Council on Pharmacy and Chemistry publishes a preliminary report on the experimental status of Tryparsamide. The drug is an arsenical developed in the Rockefeller Institute for Medical Research. Pending the outcome of clinical studies, the substance is not offered for sale. Tryparsamide is primarily a trypanocidal agent, but it possesses some spirocheticidal activity. It is said to produce "tonic" effects. It is proposed for use in the treatment of trypanosomiasis, syphilis of the central nervous system and late stages of syphilis with inactive or indolent lesions, and it is said to be specially indicated in the treatment of cachectic individuals. The Council states that the favorable reports of the effect of Tryparsamide on trypanosomiasis and neurosyphilis appear to warrant controlled trials of the drug in these conditions, but also warns that the possibility of harm to vision must be given due consideration. The Council postponed the acceptance of Tryparsamide for New and Non-official Remedies until its therapeutic value and safety are established, and until it is on the market. (Jour. A. M. A., May 26, 1923, p. 1521).

## Book Announcements

**Cerebrospinal Fluid in Health and Disease.** By ABRAHAM LEVINSON, B. S., M. D., Associate in Pediatrics, Northwestern University Medical School; Attending Physician, Department of Contagious Diseases, Cook County Hospital, Chicago, etc. With a Foreword by LUDVIG HEKTOEN, M. D. Second Edition, thoroughly revised. St. Louis. C. V. Mosby Company. 1923. 267 pages with sixty-nine illustrations, including five color plates. 8vo. Cloth. Price \$5.00.

**New and Nonofficial Remedies 1923** Containing Descriptions of the Articles which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on Jan. 1, 1923. Cloth. Price, postpaid, \$1.50. Pp. 415+XXXVI. Chicago: American Medical Association, 1923.

New and Nonofficial Remedies is the publication of the Council on Pharmacy and Chemistry through which this body annually presents the American medical profession with disinterested, critical information about the proprietary medicines which are offered to the profession, and which the Council deems worthy of recognition. In addition to the descriptions of proprietary preparations, the book contains descriptions of those nonofficial

remedies which the Council deems deserving of consideration by the profession.

A valuable feature of the book is the grouping of preparations in classes. Each of these is introduced by a general discussion of the group. Thus the silver preparations, the iodine preparations, the arsenic preparations, the animal organ preparations, the biologic products, etc., each is preceded by a general, thoroughly up-to-date discussion of the particular group. These general articles compare the value of the products included in the group with similar pharmacopeial and other established drugs which it is proposed that these proprietary preparations shall supplant.

The preface of this volume shows that the book has been extensively revised.

Physicians who wish to know why a given proprietary is not described in *New and Non-official Remedies* will find the *References to Proprietary and Unofficial Articles* not found in *N. N. R.* of much value. In this chapter (in the back of the book) are given references to published articles dealing with preparations which have not been accepted.

*New and Nonofficial Remedies* should be in the hands of all physicians who prescribe drugs. The book contains information about the newer *materia medica* which cannot be found in any other publication.

**Epidemiology and Public Health.** A Text and Reference Book for Physicians, Medical Students and Health Workers. In three volumes. By VICTOR C. VAUGHAN, M. D., LL.D., Emeritus Professor of Hygiene in University of Michigan, Assisted by HENRY F. VAUGHAN, M. S., DR. P. H., Commissioner of Health of City of Detroit, and GEORGE T. PALMER, M. S., DR. P. H., Epidemiologist for Department of Health of City of Detroit Vol. II. **Nutritional Disorders. Alimentary Infections. Percutaneous Infections.** St. Louis. C. V. Mosby Company, 1923. 8vo. 917 pages. Cloth, \$9.00.

**The Tonsils.** Fauical, Lingual, and Pharyngeal. With Some Account of the Posterior and Lateral Pharyngeal Nodules. By HARRY A. BARNES, M. D., Instructor in Laryngology, Harvard Medical School; Laryngologist, Massachusetts Charitable Eye and Ear Infirmary, and Massachusetts General Hospital, etc. Second Edition. St. Louis. C. V. Mosby Company, 1923. 8vo. 217 pages. Illustrated. Cloth, \$5.00.

**Tonsillectomy.** By Means of the Alveolar Eminence of the Mandible and A Guillotine. With a Review of the Collateral Issues. By GREENFIELD SLUDER, M. D., F. A. C. S., Clinical Professor and Director, Department of Rhinology, Laryngology and Otology, Washington University School of Medicine, St. Louis, Mo. St. Louis. C. V. Mosby Company, 1923. 8vo. 176 pages, with ninety illustrations. Cloth, \$5.00.

**A Text-Book of Therapeutics.** Including the Essentials of Pharmacology and *Materia Medica*. By A. A. STEVENS, A. M., M. D., Professor of Applied Therapeutics, University of Pennsylvania, Philadelphia. Sixth Edition, entirely reset. Philadelphia and London. W. B. Saunders Company, 1923. 8vo. 793 pages. Cloth, \$6.25 net.

**Regional Anesthesia.** Its Technic and Clinical Application. By GASTON LABAT, M. D., Lecturer on Regional Anesthesia at New York University and Bellevue Hospital Medical College; Laureate of the Faculty of Sciences, University of Montpellier; Formerly Special Lecturer on Regional Anesthesia, The Mayo Foundation, University of Minn. With a Foreword by WILLIAM J. MAYO, M. D. Philadelphia and London. W. B. Saunders Company, 1923. 8vo. 496 pages with 315 original illustrations. Cloth, \$7.00 net.

**Transactions of College of Physicians of Philadelphia.** Third Series. Vol. LXIV. Philadelphia. Printed for the College. 1922. 567 pages.

**Catalogue of Macmillan Publications And Imports.** May, 1923. The Macmillan Company, 64-66 Fifth Avenue. New York. Part I, 141 pages, Publications alphabetically arranged under authors' names; Part II, 28 pages, Series, with titles included in each; Part III, 97 pages, Publications classified by subjects.

### Permanent T. B. Clinic Established in Loudoun County.

A permanent tuberculosis clinic has been established in Loudoun County, Va., through the efforts of the county branch of the Virginia Tuberculosis Association. It will be conducted in conjunction with the county health department, directed by Dr. P. M. Chichester, formerly of the Richmond Health Bureau, who was several months ago appointed county health officer of Loudoun County, with headquarters in Leesburg. Dr. H. A. Latane, of Alexandria, is acting as clinician at this clinic.

### The U. S. Civil Service

Announces open competitive examinations for Junior Medical Officer (Pathologist), \$2,000 a year, and Junior Medical Officer (Assistant Anesthetist), \$1,000 a year, the receipt of applications to close July 24; also for Junior Pathologist at an entrance salary of \$1,500 a year, this examination to be held throughout the country July 25. In addition to the basis salary, appointees may be allowed the increase of \$20 a month granted by Congress for all positions.

Full information and application blanks may be obtained from the U. S. Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. civil-service examiners at the post-office or customhouse in any city.

## Editorial

### Cerebrospinal Considerations.

Internal medicine greets with a high degree of interest the recent reports<sup>1</sup> in the current medical publications of the apparent success of a new drug-treatment of paresis. If a discovery of a drug, innocuous in its effect upon the body but highly noxious to the etiologic factor in this dread disease, has been made, another mile-post has been reached on the road of therapeutic conquests over syphilis-manifestations in the nervous system. Internal medicine must await further experiments and experiences with the new "arsenical," before accepting as final the favorable results of this recent work.

It seems worth while to remark upon the simplicity of the method. Every effort that results in simplifying both scientific inquiry and scientific treatment naturally, in these times of multiplicity and intricacy of the elaborate diagnostic side of medicine, elicits the favor of clinicians everywhere. This is particularly true in the instance of cerebrospinal therapy. Attempts at simplification and improvement in the treatment of cerebrospinal diseases justly claim the appreciative attention of medical men of every sort and location. Since the days of Swift-Ellis (1912), this subject has been widely investigated and only a partial success has attended the methods heretofore elaborated in the treatment of paresis. This new method leaves the

intraspinal route and relies on the intramuscular injection of the drug and its penetration to the cerebrospinal fluid. If this proves to be effective, a decided advance has been made.

The necessity of intraspinal treatment of meningococcic meningitis, of pneumococcic meningitis, of streptococcic meningitis, of tubercular meningitis, of poliomyelitis, and of tetanus by sera makes the study of therapy by the spinal canal route extremely important, to say nothing of the study of the cerebrospinal fluid for diagnostic purposes. So that in our brief mention of new treatment for cerebrospinal syphilis, we shall call attention to some considerations now commonly used by clinicians in dealing with both the therapy and diagnosis of diseases related to the spinal fluid.

### CEREBROSPINAL FLUID

The anatomy and physiology of the cerebrospinal fluid, in relation to the ventricles of the brain, the chorioid plexus and subarachnoid spaces, is of interest in this connection. Levinson<sup>2</sup> in his book, second edition, points out with clearness the following interesting facts:

1. "The cerebrospinal fluid is contained in the ventricles and the subarachnoid space of the brain and cord.
2. "There is a free communication between the fluid contained in the ventricular system and the fluid in the subarachnoid spaces of the brain and cord.
3. "The cerebrospinal fluid has a circulation.
4. "The rate of formation of normal fluid is unknown: likewise is the rate of absorption.
5. "Absorption seemingly takes place by a process of diffusion from the subarachnoid space of the brain and of the cord. Some absorption also takes place by the lymphatics draining into the deep cervical glands, into the lymph vessels of the nose, perilymph spaces of the labyrinth and into the perineural sheaths of the cranial nerves.
6. "The meninges and the chorioid plexus are not permeable, or very little so, under normal conditions.
7. "The fluid exerts a mechanical function in that it equalizes the cerebrospinal pressure. The numerous other functions attributed to the fluid need further substantiation.

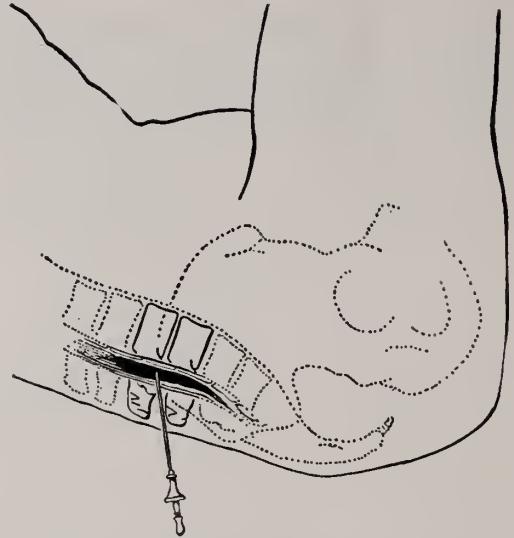

1. Lorenz, W. F. and others. J. A. M. A., Vol. 80, No. 21, page 1498, and Vol. 80, No. 22, page 1620.

2. Cerebrospinal Fluid in Health and Disease, by A. Levinson, B. S., M. D. C. V. Mosby Company, St. Louis, 1923.

8. "The origin of cerebrospinal fluid is unknown. There is some evidence pointing toward the theory that the chorioid plexus is the seat of origin of the fluid. There is also evidence pointing to the assumption that the fluid is a direct product of the blood or the brain tissues."

### LUMBAR PUNCTURE

From the day of Quincke (1891) to the present time, lumbar puncture for diagnostic and therapeutic purposes has held the interest of the medical profession. Always the removal of the spinal fluid by lumbar puncture should be made only when strongly indicated and should be considered an operative procedure in internal medicine for the purposes of diagnosis or treatment. It is not a measure that should be instituted without careful consideration and without adequate experience; on the other hand, it is a procedure of diagnosis and treatment that should be em-

Lumbar puncture. Introduction of the needle when the patient is in the sitting position. (From Barker's Clinical Diagnosis of Internal Medicine. Vol. I, pg. 73).

ployed where and when indications are positively for it. Therapeutically, lumbar puncture may be performed for the relief of intracranial pressure in hydrocephalus, delirium tremens, eclampsia, encephalitis, for the introduction of serum in meningococcic meningitis and for the intraspinal treatment of cases of neurospinal syphilis. For diagnosis, lumbar puncture may be performed in cerebrospinal syphilis, hemorrhage of the brain, tumors of the cord, poliomyelitis, and meningitis.

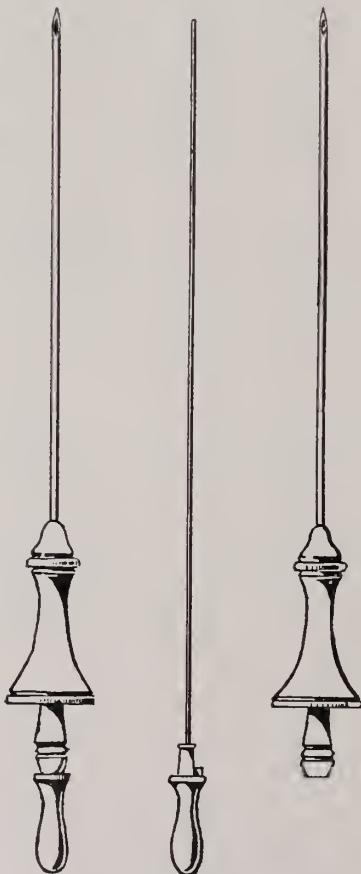

Levinson has summarized the following conditions for the use of the lumbar puncture:

#### In *diagnosis*,

1. Suspicious meningitis.
2. Suspicious poliomyelitis.
3. Hemorrhage of the brain.
4. Neurosyphilis.
5. Coma.
6. Convulsions.

#### In *treatment*,

- I. For relief of intracranial pressure
  - (a) Meningitis.
  - (b) Meningism.
  - (c) Poliomyelitis.
  - (d) Encephalitis.
  - (e) Hemorrhage of brain.
  - (f) Delirium.
  - (g) Convulsions.

Trocar for lumbar puncture showing the stylet in place, and withdrawn. (From Barker's Clinical Diagnosis of Internal Medicine. Vol. I, pg. 72).

## II. For intraspinal injection in serum treatment

- (a) Antimeningococcus.
- (b) Pneumococcus serum Type I.
- (c) Influenza.
- (d) Poliomyelitis.
- (e) Tetanus antitoxin.
- (f) Horse serum.

## In chemical treatment,

- (a) Neosalvarsan.
  - (b) Mercury.
  - (c) Optochin (ethyl cuprein hydrochloride).
  - (d) Magnesia sulphate.
  - (e) Novocaine.
  - (f) Adrenalin.
- (miscellaneous) general edema, diabetes insipidus, uremia.

## CONTRAINDICATIONS AND EFFECTS OF LUMBAR PUNCTURE

In tumors of the cerebrum and cerebellum, lumbar puncture is contraindicated. Sudden death may result when it is employed in these conditions. Lumbar puncture should not be performed on patients with infections of the skin over the region of the lumbar spine. In such cases as erysipelas, or exanthematous infections over this area, the risk of infecting the cerebrospinal canal is great. The routine use of the lumbar puncture may be practiced in cases indicating its use, but a certain skill is necessary and the procedure should be employed only under favorable conditions. The following cautions should be observed by clinicians:

- (a) In patients highly nervous, gas anesthesia may be better than local anesthesia.
- (b) The strictest sterilization of the instruments and field of operation should be made.
- (c) If possible, the patient should be in lateral recumbent position on left side. The sitting position should be avoided. Death has occurred as a result of the patient being in a sitting or erect position.
- (d) The patient should remain in bed, with head on level with the body, for at least twelve hours following the puncture.
- (e) Caution should be exercised in the rapidity and in the amount of fluid removed; small amounts of fluid should be removed, except in meningitis.
- (f) Headache and insomnia resulting from the procedure may be relieved by codein.

The marked relief derived by the removal of excess of cerebrospinal fluid in meningitis, in pneumonia, in influenza with meningeal complications, is immediate often times. One patient seen in consultation during the influenza epidemic (1918), with violent delirium and other meningeal symptoms, was instantly relieved by the removal of the fluid taken for diagnostic purposes. Upon entering the canal, the fluid was found under high pressure and in great excess. Considerable amount was removed with the above noted result.

## TRYPARSAMID AND ITS PENETRATION INTO THE SPINAL FLUID

Tryparsamid, the sodium salt of *N*-phenylglycinamid-*p*-arsonic acid, has been observed experimentally in animals infected with trypanosomes and with spirochetes of relapsing fever and of syphilis. From the experimental work done on animals and on patients, it has been found that a single dose of tryparsamid, up to 5 grains, can be given with safety to the patient. In some cases, the transient disturbance of vision is observed, however.

The use of the drug has caused old and indolent lesions of syphilis to disappear; has changed a positive Wassermann reaction to negative.

The use of tryparsamid in syphilis has been adopted not because of its spirocheticidal action, for this is quite weak, but because of its unusual "toxicologic and therapeutic action observed in experimental animals, such as the promptness of recovery from toxic injury, tolerance to repeated doses, a marked tonic effect, and the ability of the drug to induce resolution and healing of syphilitic lesions, even the presence of actively motile spirochetes, but without increasing the liability of the occurrence of a general disease."<sup>3</sup>\*

In addition to the above noted findings, its use in syphilis of the central nervous system has been especially favorable because of the apparent revelation that the drug appeared to possess "an affinity for the tissues of the central nervous system." Further, it has been learned that "the difficulties of penetration into spinal fluid" heretofore experienced with arsenicals and other drugs, might be overcome.

Referring to the report of the University of Wisconsin investigators, a recent editorial<sup>†</sup>

<sup>3</sup>Lorenz, W. F., *J. A. M. A.*, Vol. 80, No. 21, page 1497.

<sup>†</sup>*J. A. M. A.* June 2, 1923, page 1621.

says "Of forty-four patients who were in an advanced stage of general paresis, twenty-one had been discharged from the hospital and were earning a living. Of twelve other much agitated patients in an acute stage of the disease, seven recovered normal mentality and were earning a living. The remaining five mentally were in condition to work but had not been discharged on account of the serologic findings." The Wisconsin men summarized their article in the following significant language:

"Tryparsamid and mercuric salicylate given according to the method herein described is especially effective in early paresis and neurosyphilis. In our experience it is more effective than any other form of treatment used. We also recommend its trial in cases that are 'Wassermann fast' and in syphilitic patients showing a poor state of nutrition and those beyond middle age. Tryparsamid, when employed in dosage of 3 gm., produces no local or general symptoms, either immediate or late, and can be used to advantage in cases where the patient can not tolerate arsenicals."

As pointed out in the article referred to, paresis develops in approximately five per cent of syphilitics; although between thirty and forty per cent of all syphilitic patients show "positive spinal fluid findings some time in the course of the disease." The inference drawn from these observations is that, although a large number of syphilitics at some time become infected in the cerebral spinal system, only a small per cent of all syphilitics go to the maximum manifestation of the disease as seen in paresis.

To sum up: Tryparsamid is a new arsenical preparation developed in the Rockefeller Institute for Medical Research. Powers-Weightman-Rosengarten Company is manufacturing it for the Institute. It is not on sale for general use. The drug is under the control of the Institute during the period of investigation and is, apparently, receiving that careful, scientific consideration given to the development of insulin in diabetes.

Tryparsamid is a trypanocidal rather than a spirocheticidal drug, although it appears to exert some spirocheticidal powers. The drug produces apparently decided tonic effects in patients debilitated by the late manifestations of syphilis, in patients suffering from syphilis of the nervous system, and in paretics.

The Council on Pharmacy and Chemistry

of the American Medical Association has postponed the acceptance of tryparsamid for New and Nonofficial Remedies; confirmatory evidence is awaited of its therapeutic efficacy and of its innocuous properties. In the report of the Council on this subject in the *Journal of the American Medical Association*, Volume 80, No. 21, page 1521, besides the current observations, a reference list of the literature on this new arsenical is given.

#### **The High Blood Pressure Issue of American Medicine.**

The June edition of *American Medicine* giving the present day conception of a group of men in various fields of medicine and surgery on the subject of high blood pressure is a valuable collection of papers on this question. Such a presentation should be of interest to doctors everywhere.

It is important that the profession shall crystallize its ideas on this symptomatic phenomenon, high blood pressure. It is unquestionably of paramount importance that fundamental factors back of the symptom shall be understood and classified. The presentation of this subject in a group of unrelated papers may not give us an orderly treatise on the perplexing condition, but it serves to present the many sides of the problem and points of view from which it may be considered. Some of the titles are: "On High Blood Pressure." (Sir Clifford Allbut); "Variation in Blood Pressure, Its Causation." (Sir W. Arbuthnot Lane); "The Relation of the Thyroid to High Blood Pressure." (George W. Crile); "Blood Pressure in Pregnancy." (John N. Upshur); "The Relationship of High Blood Pressure to Other Impairments." (Eugene Lyman Fisk); "Blood Pressure in Infancy and Childhood." (George Daw Scott); "Retinitis of Hypertension." (W. L. Benedict). This partial list shows that one may read this edition of *American Medicine* and obtain the best thoughts on this subject from some of the foremost men in medicine today.

---

## News Notes

### **Plan Your Vacation to Include Attendance at State Society Meeting.**

The Roanoke committee in charge of arrangements for the annual meeting of the Medical Society of Virginia, October 16, 17,

18 and 19, has sent out cards to all members, urging them to bear in mind attendance upon the State meeting in making plans for their vacations. Don't forget it. A large attendance adds to the interest of the meeting and you will miss a good time if you are not there.

The Program Committee has selected "The Pancreas" as the subject for the general symposium at our Roanoke meeting. This is to be discussed as follows:

*Anatomy and Physiology of the Pancreas* by Dr. Theodore Hough, University;

*Pathology of the Pancreas* by Dr. K. D. Graves, Roanoke;

*Diagnosis and Medical Aspect of Diseases of the Pancreas* by Dr. James H. Smith, Richmond;

*Surgery of the Pancreas* by Dr. Joseph T. Buxton, Newport News.

These are only a few of the subjects of interest to be discussed.

Dr. John Staige Davis, the president, will shortly announce names of his invited guests.

Make your plans to attend and bring the ladies in your families.

### **Penetrative Powers of Arsenicals.**

The probable reason why the chances for the complete cure of a generalized syphilitic infection are poor, says the U. S. Public Health Service, is because the usual remedies (arsphenamine, nearsphenamine, and silver arsphenamine) all lack the power necessary to enable them to penetrate the infected tissues in sufficient amounts to destroy the last remaining parasites. Other arsenicals, supharsphenamine, tryparsamid, and 3-amino-4-oxyphenol arsonic acid, have superior penetrative powers and their use as remedies is suggested.

The report was made by Carl Voegtlin, M. I. Smith, Helen Dyer, and I. W. Thompson, all of the U. S. Public Health Service, after prolonged experimentation, both chemical and bacteriological, on rabbits. While the authors admit that results so obtained cannot be transferred without reservation to the treatment of human syphilis, they nevertheless advance several reasons that cause them to believe that a clinical trial of the more penetrative preparations named is strongly indicated.

In conclusion they express as Ehrlich did, their belief that no matter what arsenical may be used better results will be obtained from single large doses a week apart than from smaller doses given at shorter intervals.

### **Dr. L. L. Williams Returns from Malaria Study Abroad.**

Dr. L. L. Williams, Jr., of the malarial control bureau, of the Virginia State Board of Health, is home again, after attending the epidemic commission of the league of nations, as the representative of the United States in the study of malarial control work. This study began in Italy the latter part of May, with representatives from the countries in the league of nations. Dr. Williams, the only representative from the western hemisphere, represented the United States through the courtesy of the league, as the United States is not a member of that body. Although no methods of control are used in Italy which are not known in this country, Dr. Williams states that Italy's malarial problem is much greater than the one faced here, since that peninsula has malignant and fatal types not prevalent in the United States.

### **Leprosy Amenable to Treatment.**

Leprosy is in a measure amenable to treatment, according to reports issued by the U. S. Public Health Service. During the last ten years (1912-21) a considerable percentage of the lepers segregated at the Kalihi Hospital near Honolulu and on Molokai Island have been paroled; that is, they have been released as being "not a menace to the public health." but have been required to report for examination at certain intervals which vary with the individual case. Of those paroled about 13 per cent have relapsed and have returned to segregation; but about one-fourth of these were later paroled for the second time. In all, 242 lepers were paroled: 31 relapsed and seven of these were later paroled. Ten were completely released from parole.

The chance of arresting the disease decreased with the length of time that it had been allowed to go without treatment, unless this period was seven years or more. Apparently patients who survive without treatment for seven years possess powers of resistance that slightly increase their chances for marked improvement under treatment.

Those who desire it are treated with chaulmoogra oil and its derivatives.

The parole system was begun in 1912 and has worked admirably. Those paroled appear to have told their friends that the conditions existing at the hospital were good; and the mere fact that they had been released has

shown that segregation might lead to cure and not to lifelong confinement, as it almost invariably did previous to 1912. As a consequence many lepers, instead of concealing the disease up to the last possible moment (and thereby spreading it through the community) are now surrendering of their own accord and taking treatment. This earlier surrender and earlier treatment hasten the degree of improvement that will secure parole and will later, perhaps, complete release. About 70 per cent of those who have been paroled were in segregation for less than two years.

#### **Dr. O. O. Ashworth,**

Who has been doing special work in tuberculosis at Catawba Sanatorium, Va., for the past year, became a member of the staff of the Medical Department of St. Elizabeth's Hospital, Richmond, July 1. Dr. Ashworth formerly served as interne at this hospital.

#### **Dr. H. C. Beckett**

And son of Chase City, Va., are visiting Bluefield and a number of other West Virginia cities. They expected to be away from home a month or more.

#### **The American Gynecological Society,**

At its annual meeting held at Hot Springs, Va., recently, elected the following officers for the ensuing year: President, Dr. Barton Cooke Hirst, Philadelphia; vice-presidents, Drs. John O. Polak, Brooklyn, N. Y., and Herbert M. Little, Montreal, Canada; secretary, Dr. Arthur H. Curtis, Chicago; treasurer, Dr. Charles C. Norris, Philadelphia.

#### **Progress in X-Ray Therapy.**

The extraordinary development of the X-ray as a therapeutic agent is unquestionably one of the most important outstanding achievements of the day. The recent perfection of new machines of immense power has expanded the field so considerably that it is impossible at this time to predict what the ultimate scope of this imponderable but powerful force will prove to be in the field of treatment; but it seems safe to say that it will finally mean as much here as it has meant for years in the field of diagnosis.

It is a source of satisfaction to the Virginia profession to realize that roentgenologists here will maintain in therapeutics the very high standard they have already established for themselves in diagnosis. Dr. Fred M.

Hodges of Richmond has just installed a 300,000 volt apparatus which has been in operation a few days. This is the first of the great new machines to appear in Richmond. It is understood that plans are now being projected by other X-ray men in Richmond and elsewhere in Virginia to make similar additions to their equipment. It is also gratifying to know that the benefits of the new apparatus will be available to all sufferers, whatever their financial resources. Dr. Hodges has just announced that he is arranging hours for a free clinic at his offices for those who are unable to pay.

The application of the X-ray in therapeutics is being guarded by careful painstaking work in which the leading roentgenologists of the country are in close co-operation. No claims are made for it until its efficiency has been tested many times, by many men, under many circumstances. It is nevertheless rapidly reaching out into new channels. Perhaps its greatest promise is in the dreary field of malignancy. Its value in surface malignancy has long been recognized; the new machines of great penetrating power apparently enable it to reach the deeper growths. In the treatment of toxic goitre, uterine fibroids, menorrhagias, certain skin affections, and various other conditions, very notable work has been done.

#### **Married.**

Dr. Hunter McGuire and Mrs. Jane Love Baker, both of Winchester, Va., in Asheville, N. C., June 12.

Dr. J. Edwin Wood, Jr., and Miss Emily Mildred Battle, both of Charlottesville, Va., June 28.

Dr. Lawrence Hiter Hoover and Miss Flossie Webster McFarland, both of Clarksville, Va., in Richmond, June 17. Dr. Hoover is a member of the class of '20, Medical College of Virginia.

Dr. Kemp P. B. Bonner, Raleigh, N. C., and Miss Clara Bell Martin, Beaufort, N. C., June 4.

Dr. Fred Wharton Rankin, Louisville, Ky., and Miss Edith Mayo, daughter of Dr. and Mrs. Charles H. Mayo, Rochester, Minn., June 12. Dr. Rankin was formerly of Mooresville, N. C., but has recently been appointed professor of surgery in the University of Louisville, Medical School.

**Dr. and Mrs. Arthur Bryan Carr,**

Of War, W. Va., have returned home after a visit to Mrs. Carr's family in Richmond. Dr. Carr is a graduate of the Medical College of Virginia in the class of '21.

**The Association of Surgeons of The Southern Railway**

Held a most interesting and pleasant meeting in Charleston in May, under the presidency of Dr. W. M. Cunningham, of Corona, Ala. The three prizes offered by the *International Journal of Surgery* each year for the three best papers were awarded respectively to Dr. Edward T. Newell, Chattanooga, Tenn., for his paper on "Traumatic Shock;" Dr. H. S. Black, Spartanburg, S. C., for his paper on "The Transfusion of Blood;" and Dr. W. H. Frampton, Charleston, S. C., for his paper on "Fractures of Joints."

The following officers were elected: President, Dr. Edward T. Newell, Chattanooga, Tenn.; vice-presidents, Drs. Edward F. Parker, Charleston, S. C., Dr. Crosson, Leesville, S. C.; Dr. Jeff Davis, Toccoa, Ga.; and Dr. T. F. Elkin, Tupelo, Miss.; historian, Dr. George Ross (re-elected), Richmond, Va.; recording secretary, Dr. W. S. Nash, Knoxville, Tenn.; executive secretary-treasurer, Miss Edith A. Foltz, Washington, D. C.

**American Medical Association.**

The meeting in San Francisco was a largely attended and most successful one. Dr. William A. Pusey is president-elect for the next meeting, which is to be held in Chicago in 1924. Only fifteen Virginia doctors registered attendance.

**Dr. and Mrs. P. E. Tucker,**

Buckingham, Va., have been on a visit of several weeks to West Virginia.

**Dr. E. R. Ferguson**

Announces that he has moved from Toms Creek to Inman, Va.

**Dr. J. E. Wood, Jr., Instructor at University of Virginia.**

At the June meeting of the Board of Visitors of the University of Virginia, Dr. J. Edwin Wood, Jr., B. S. 1918, M. D. 1921, University of Virginia, was elected instructor in Internal Medicine in the Medical Department of the University. Since his graduation in medicine, Dr. Wood has served as interne and house officer at Massachusetts

General Hospital, Boston, specializing in Internal Medicine. At University of Virginia, in addition to assisting in the instruction of the medical students, Dr. Wood will have special charge of electrocardiograph work of the University Hospital.

While at Massachusetts General Hospital, Dr. Wood published several papers giving the results of investigations in Internal Medicine.

**Highsmith Hospital Installs New X-Ray Apparatus.**

The Highsmith Hospital, Fayetteville, N. C., announces that it has added a Victor Deep Therapy X-Ray machine to its equipment. This gives the hospital a most complete X-ray laboratory for diagnosis and treatment.

**Extension Work for Physicians of North Carolina.**

What is termed as the largest single extension teaching project in the United States was launched by the Extension Division of the University of North Carolina, when during the week beginning June 18 over 350 physicians began a twelve weeks' postgraduate course which is being given in eighteen cities distributed throughout North Carolina. C. D. Snell, director of the University' Extension division, stated that "While nearly all State universities now have extension divisions, this is the first attempt by any University to hold extension classes on such a large scale in every section of the State. The success of our work is entirely due to the splendid co-operation of our progressive North Carolina physicians at whose instance this work is being carried on."

Three courses will be given in Internal Medicine this summer on three circuits of six towns each, and beginning July 16 on another circuit composed of Winston-Salem, Greensboro, High Point, Salisbury, Concord, and Charlotte, a course will be given by Dr. B. T. Terry, of Vanderbilt Medical School, on the subject of General Pathology. The plan this summer calls for a lecture and a clinic a week in each of twenty-four cities which will be attended by groups of physicians numbering from fifteen to thirty.

What is called the Mountain circuit will have as instructor Dr. Frank A. Chapman, of Rush Medical College, Chicago. The places of the meetings on this circuit were Waynes-

ville, Asheville, Rutherfordton, Morganton, Hickory and Statesville.

Dr. F. Demette Adams, of Washington, D. C., instructor for the Sandhill circuit, had meetings at Raleigh, Sanford, Carthage, Hamlet, Lumberton, and Fayetteville.

Dr. Sidney Burwell, of Johns Hopkins, had charge of the Tidewater circuit, meetings on this circuit being held at New Bern, Washington, Williamston, Tarboro, Greenville, and Kinston.

This is the third summer of postgraduate medical extension courses as given under the auspices of the Extension Division and Medical School of the State University. They are growing in popularity each year, and already plans are being laid for a series of courses to be given during the summer of 1924.

#### **Dr. Rhodric W. Browne,**

Member of the Medical Society of Virginia and at one time stationed at Norfolk, Va., with the U. S. Public Health Service, has been transferred from U. S. Veterans' Hospital, No. 36, to U. S. Veterans' Bureau at Lake City, Fla.

#### **Dr. M. A. Lackey,**

Recently of Portsmouth, Va., is now at Mooresville, N. C.

#### **Dr. Lawrence T. Royster,**

Norfolk, Va., has been appointed by Governor Trinkle as a member of the State Board of Health, for a term of four years beginning July 1, 1923.

#### **The National Tuberculosis Association,**

In recent session at Santa Barbara, California, elected Dr. Livingston Farrand, president of Cornell University, Ithaca, N. Y., president. Memphis, Tenn., was selected as the 1924 convention city.

#### **The Virginia Pharmaceutical Association,**

At its meeting held at Virginia Beach, the latter part of June, elected S. C. Brooks of Purcellville president for the coming year.

#### **The West Virginia State Medical Association**

Held a most interesting and enjoyable meeting at Beckley, June 12, 13 and 14. Wheeling was selected as the 1924 place of meeting and the following officers were elected: President, Dr. Robert A. Ashworth, Moundsville; vice-

presidents, Drs. Charles S. Smith, Beckley, R. H. Dunn, South Charleston, and S. B. Lawson, Logan; secretary, Dr. D. A. MacGregor, Wheeling; treasurer, Dr. Hugh G. Nicholson, Charleston; editor of journal, Dr. J. R. Bloss (re-elected), Huntington; delegate to the A. M. A., Dr. H. P. Linsz, Wheeling; alternate, Dr. A. P. Butt, Elkins.

Councilors are: *First District*, Dr. Charles G. Morgan, Moundsville, elected; *Second District*, election deferred, Dr. J. C. Irons, Dartmoor, holds over; *Third District*, election deferred, Dr. C. R. Ogden, Clarksburg, holds over; *Fourth District*, Dr. G. D. Jeffers, Parkersburg, elected; *Fifth District*, Dr. Harry G. Steele, Bluefield, elected; *Sixth District*, Dr. C. A. Ray, Charleston, elected.

Among the Virginia doctors registered at this meeting were Drs. Manfred Call and Paul V. Anderson, Richmond; Hugh H. Trout, Roanoke, and E. E. Watson, Salem.

#### **W. Va. State Alumni Association of Medical College of Virginia.**

Prior to the meeting of the West Virginia State Medical Association in Beckley, the middle of June, a call was sent to the alumni of the Medical College of Virginia, the University College of Medicine, Richmond, and the Medical College of North Carolina, practicing in West Virginia, to attend an alumni meeting and luncheon to be held in Beckley during time of the State Society meeting. This meeting was quite a success, thirty-one of the alumni being present. The name of the Association was changed from the Alumni Association in Southern West Virginia to the above name. Dr. Manfred Call, of Richmond, made an address before the Association.

Officers for next year were elected as follows: President, Dr. John E. Cannaday, Charleston; vice-president, Dr. Robert A. Ashworth, Moundsville; secretary-treasurer, Dr. Walter E. Vest, Huntington. The next meeting is to be held in Wheeling at the 1924 meeting of the West Virginia State Medical Association.

#### **Dr. R. J. Wilkinson,**

Huntington, W. Va., has been spending a vacation with his brother at Bedford City, Va.

#### **Dr. J. S. Horsley, Jr.,**

Finished his internship at St. Elizabeth's Hospital, Richmond, the first of July, after

which he left for the Mayo Clinic, Rochester, Minn. He expects to do special work in surgical pathology, for several months.

#### **Dr. W. J. Marquis,**

Who has been an interne at St. Elizabeth's Hospital, Richmond, since July 1, 1922, also left the first of July for the Mayo Clinic. While there he will take up work in roentgenology as a Fellow.

#### **Woman Physician for Coast Guard Duty.**

Dr. Blanche N. Epler, residing at Hatteras, N. C., has been appointed by the U. S. Public Health Service as contract physician to furnish professional services to Coast Guard stations Nos. 181-185 inclusive.

Dr. Epler is engaged in private practice among the inhabitants of this somewhat isolated and exposed region. She will be prepared to respond at any time, day or night, to calls arising out of any serious accidents happening to Coast Guardsmen in the course of their arduous tasks, and will also conduct the visual and other physical examinations of applicants for admission to the Coast Guard service at the stations under her medical supervision. Dr. Epler was chosen for the work after she had proved that she was fitted to meet the requirements of the post and had been recommended for the duty by the local District Superintendent of the Coast Guard.

#### **Corner-Stone of Hospital Laid.**

July 3 was a gala day for the Eastern Shore of Virginia, when the corner-stone was laid at Nassawadox, for the \$150,000 Accomac-Northampton Memorial Hospital to be located at that place. There were speeches and a ball game, and dinner and supper were served on the hospital grounds at a nominal price. Work is progressing well on the hospital and it is expected that it will be completed by the first of the coming year. It is of brick and stone, fireproof, modern and up-to-date in every respect, and will be a credit to those who have promoted its construction.

#### **Dr. and Mrs. A. W. Rusmiselle,**

Waterford, Va., are home again after a visit to friends in Strasburg, Va.

#### **Dr. William H. Parker,**

Richmond, returned home the latter part of June, after a visit to Rochester, N. Y.

#### **Dr. W. C. Moomaw**

Has been elected one of the directors of the Petersburg (Va.) Y. M. C. A., for a period of three years.

#### **Dr. Weymouth's Home Struck By Lightning.**

Lightning struck the home of Dr. S. E. Weymouth, Callao, Va., the latter part of June, and did considerable damage.

#### **Dr. Carrington Williams**

Has been elected first vice-president of the newly formed Civitan Club of Richmond, Va.

#### **Dr. William F. Drewry,**

Petersburg, Va., in June attended the annual meeting of the American Psychiatric Society in Detroit. Dr. Drewry is an ex-president of this Society.

#### **American Medical Aid for Russia.**

Again an appeal comes from the American Medical Aid for Russia, 103 Park Avenue, New York City, for money, clothing, instruments, books and journals for the medical men in Russia. It is stated that they not only lack the barest necessities of food and clothing, but are terribly in need of drugs, medical and surgical instruments, and of scientific books and journals in English. Contributions will be promptly and efficiently distributed in Russia. Send the things you can not and do not use yourself, to the New York office for distribution to points where most needed.

#### **Dr. R. L. Raiford,**

Of Sedley, Va., spent a part of June visiting Dr. Henry A. Cotton, of Trenton, N. J., and the clinics of several of the larger Northern cities, making a special study of focal infections and allied diseases.

#### **Dr. and Mrs. J. C. Coulter**

And daughter, of Charlottesville, Va., returned home the middle of June, after their annual visit to Dr. Coulter's parents near Pittsburgh, Pa. They visited a number of places of interest in West Virginia and Pennsylvania, while away.

#### **Dr. Charles A. Easley**

Is now well and has resumed his practice in Bluefield, W. Va., after having been away for several months on account of his health.

**Dr. Edward B. Broocks,**

Of the class of '16, Medical Department of the University of Virginia, is visiting at his former home in Chase City, Va. Dr. Broocks has, for the past two years, been connected with the pediatric work of a hospital in Toronto, Canada.

**Dr. Allen W. Freeman,**

Formerly of Richmond, but now professor of Hygiene and Public Health in the Johns Hopkins School of Hygiene and Public Health, delivered an address on "Health Administration in Rural Districts" before the annual conference of sanitary officers and public health nurses of New York State, the latter part of June. In this address he urged the importance of appointing full time health officers on a county basis.

**Dr. and Mrs. James K. Corss,**

Newport News, Va., who started last January for a trip around the world *via* Panama and San Francisco, left Paris the latter part of June and were expected home early in July.

**Dr. and Mrs. J. Shelton Horsley**

Returned to their home in Richmond the first week in July, after attending the meeting of the American Medical Association held in San Francisco. Dr. Horsley was chairman of the Scientific Assembly of the Association and read a paper before the Section on Obstetrics, Gynecology, and Abdominal Surgery.

On their way west, they spent several days in El Paso, Texas, where Dr. Horsley practiced for five years, having operated the first private hospital in that city. They also stopped for a few days at Albuquerque, New Mexico, where Dr. Horsley read a paper before the New Mexico State Medical Society.

**Dr. Banting listed for Annuity.**

It is announced that Dr. Frederick G. Banting, discoverer of the insulin treatment of diabetes, has been listed for an annuity of \$7,500 in the Canadian parliament, that he may devote the rest of his life to medical research. If parliament approves the budget, as it is expected to do, Dr. Banting, yet a young man (only 30 years of age), will be free from the struggle for existence to devote his life to research work.

This is a fitting tribute paid by the Canad-

ian government for the great benefit Dr. Banting is rendering humanity.

**Dr. R. W. Selby**

Has returned to his home at Middleburg, Va., after a visit to his former home in Northumberland County, Va.

**Dr. Charles W. Pritchett**

Has been elected president of the Lions Club of Danville, Va.

**Results of Nutrition Classes Organized in Richmond.**

Fine gains in weight have been made by the boys and girls in the nutrition classes organized in Richmond, this spring, by Dr. William R. P. Emerson, of Boston, noted authority on malnutrition among children. In one class, three children are reported to have gained eleven pounds each in eight weeks. Another class shows an average gain of 20 ounces a week per child, which is ten times the normal gain for children of the age in this class.

Dr. Emerson, in his talks demonstrated the necessity for the removal of physical defects, that the child may be fit to gain. Other causes of malnutrition given by Dr. Emerson were lack of home control, over fatigue, faulty food habits, faulty health habits, and insufficient food.

A movement has been launched throughout the State to further nutrition work in the rural schools by providing scales for weighing pupils, to ascertain if their weight is correct for their height.

**Dr. and Mrs. A. B. Householder**

Recently returned to their home in Lovettsville, Va., after a visit to Washington, D. C.

**Dr. C. D. Kunkel,**

Pulaski, Va., in June visited a daughter living in Lynchburg, Va.

**Cancer Workers Meet in San Francisco.**

In response to a call issued to state and provincial chairmen and regional directors, by the American Society for the Control of Cancer, a number of "cancer workers" met during the A. M. A. meeting in San Francisco, and heard accounts of the work being done throughout the country and had presented them an explanation of the District Cancer Campaigns to begin next Fall, together with a full discussion of organization plans

and the activities proposed to be carried out. The meeting was considered fully "worth while" by those who were fortunate enough to be able to attend.

#### **Doctors in Political Offices in Loudoun County.**

At the elections held in Loudoun County, Va., in June, the following doctors were elected: Drs. J. B. Hackley and G. F. Simpson, as members of the council of Purcellville; Dr. H. A. Spittler as member of council of Middleburg; and Dr. L. T. Rasmuselle as a member of the council of Waterford.

#### **Dr. Julius H. Taylor,**

Columbia, S. C., a member of the class of '01. of the Medical Department of the University of Virginia, has been appointed a member of the State Board of Medical Examiners of South Carolina.

#### **Dr. Archer A. Wilson,**

Of News Ferry, Va., a graduate of the class of '23, Medical College of Virginia, has located at Oxford, N. C.

#### **Dr. George C. Payne**

Has entered upon his duties as epidemiologist with the State Board of Health. Prior to this, he visited a number of Northern cities, studying modern methods used in the investigation and prevention of epidemics. Dr. Payne has just taken his degree as doctor of public health from the Johns Hopkins School of Hygiene and Public Health and has previously had several years' experience as a practicing physician.

#### **Dr. B. C. Crowell Professor of Pathology at Jefferson Medical College.**

Announcement has been made of the election of Dr. Bowman C. Crowell, lately professor of pathology in the Medical College of the State of South Carolina, at Charleston, as professor of pathology in Jefferson Medical College, Philadelphia. He succeeds to the position formerly occupied by Dr. Wm. M. L. Coplin, who resigned one year ago. Professor Crowell is a native of Nova Scotia and a graduate of McGill University, Montreal. His experiences as teacher, pathologist and investigator have been varied and interesting and Jefferson College is to be congratulated upon having secured his services.

#### **Dr. Daniel S. Lamb Honored.**

In commemoration of his fifty years of ser-

vice in Howard University School of Medicine, Washington, special exercises were held for Dr. Daniel S. Lamb, June 7 and 8. At this time, the honorary degree of Doctor of Science was conferred upon him. Dr. Lamb is now professor of anatomy at the University.

#### **Dr. James A. Hayne,**

Columbia, State Health Officer of South Carolina, delivered the address before the graduating class of the Richmond School of Social Work and Public Health, held in this city last month. Dr. Hayne is an attractive speaker and has many friends in this State, having attended the academic department of the University of Virginia, prior to studying medicine at the Medical College of the State of South Carolina.

#### **Dr. George W. Crile,**

Cleveland, was elected president of the American Surgical Association, at its annual meeting recently held in Rochester, Minn.

#### **Dr. D. Hunter Marrow,**

Daytona, Fla., is spending the summer at his old home, Union Level, Va.

#### **Dr. James F. Terrell,**

Of the class of 1918, Medical College of Virginia, is now a lieutenant in the Medical Corps of the U. S. Navy and stationed at Submarine Base, Coco Solo, Canal Zone.

#### **Dr. Howard Urbach,**

Richmond, was elected State physician of the Maccabees at their convention held in Alexandria, the latter part of June.

#### **Dr. B. P. Seward,**

After a year's service as interne at Stuart Circle Hospital, Richmond, has located at Surry, Va., where he will continue the practice of his profession.

#### **Dr. S. C. Draper,**

After a short time at Inman, Va., will resume practicing at his former home, Pulaski, Va.

#### **Appointments on State Board of Health.**

Dr. Isaac Peirce, Tazewell, Va., has been reappointed by Governor Trinkle, a member of the State Board of Health from the Ninth Congressional District, and Dr. A. L. Tynes, Staunton, has been appointed a member from the Tenth District. Both appointments are for a term of four years, beginning July 1, 1923.

**Dr. and Mrs. J. W. Hannabass,**

Of Richmond, recently had a very pleasant trip visiting Northern cities.

**Dr. H. S. Daniel,**

Louisa, Va., left early in June for Baltimore, where he expected to take a special course at Johns Hopkins University. While he is there, Mrs. Daniel is visiting her old home in Pennsylvania.

**Dr. George C. Snead,**

Trammel, Va., was a recent visitor at his former home in Lynchburg, Va.

**Dr. F. W. Lewis,**

Moratico, Va., went to Baltimore, recently, for hospital treatment.

**Dr. Clarence Porter Jones**

And son, of Newport News, Va., have been spending a couple of weeks fishing at Nimrod Hall, in Bath County, Va.

**Wanted:**

Physician for hospital work in small town in Virginia. Must be capable of doing X-ray and laboratory work. Reply, stating salary wanted and references, to No. 217, care this journal. (Adv.)

**For Sale.**

West Virginia village and country practice and residence: prosperous churches, high school with normal training course, bank, three lodges, rich agricultural section, on class A road. Price \$5,000; residence alone worth the price. Address No. 264, care this journal. (Adv.)

**Nurse Wanted.**

Nurse wanted in Industrial village of 2,000 people, no negroes and no foreigners. Work consists of prenatal, maternity, school and social work. Have well equipped nurse's office, and congenial living quarters will be arranged. Position open at once. Address applications, together with credentials, to "Nurse," care this journal.

## Obituary

**Dr. William Elbert Killinger,**

A prominent young physician of Victoria, Va., connected with Kendig Brothers' Hospital, was accidentally drowned while in bathing near his home on June 17. Accompanied by his wife and a friend, Dr. Killinger went to the pond and, leaving them on shore, rowed to the middle of the pond and dived off the boat. On rising to the surface, he called for

help but was drowned before any one could go to his rescue. Dr. Killinger was born at Rural Retreat, Va., twenty-nine years ago. After several years at Yale, he took up the study of medicine at Tulane University of Louisiana, from which he graduated in 1921. After an internship at Sarah Leigh Hospital, Norfolk, he became a member of the Kendig Brothers' Hospital staff, with which he was connected at the time of his death. He was a member of the Medical Society of Virginia. Dr. Killinger married about a year ago and is survived by his wife, parents and several brothers and sisters.

**Dr. Richard Curd Bowles,**

Of near Kents Store, Va., died June 7, at the age of 86 years. Dr. Bowles was widely known throughout the State and was an honorary member of the Medical Society of Virginia. He graduated in medicine from the University of Maryland in 1861 and immediately entered the Confederate service in the War between the States. Later he was made an assistant surgeon in the Confederate States' navy. After the war, he returned to his native county, where he practiced his profession for a long number of years. He is survived by his wife and several children.

**Dr. Robert R. Jones,**

A highly esteemed and beloved physician of Brunswick County, Va., died at his home at Diamond Grove, June 7, from old age. Dr. Jones was eighty-eight years of age. He studied medicine at Jefferson Medical College, Philadelphia, graduating in the class of 1855. He had practiced his profession in the county of his birth for sixty-eight years, with the exception of a short time, while acting as druggist at Camp Lee, near Richmond, during the Civil War. He retired only a few years ago. Dr. Jones is survived by three sons, one of them Dr. R. R. Jones, Jr., of Lawrenceville.

**Dr. Lawson Betts Moore**

Died July 3 at his home in Charlottesville, after a lingering illness. Dr. Moore was born in Berryville, Va., 61 years ago and, upon completing his academic education, entered the University of Virginia, where he commenced the study of medicine, later receiving his diploma from the University of Maryland in 1887. Dr. Moore was a member of the Medical Society of Virginia. For some years he resided in southwest Virginia.

# Answering an Important Question

**The Question**—“Why is it possible to feed S.M.A. with good nutritional results to normal, full-term infants of varying ages (from birth to one year, or even longer if desired), without dilution or change?”

**The Answer**—This is possible because S.M.A. resembles breast milk, both physically and chemically, in all important respects. In other words, S.M.A. resembles breast milk not only in the quantity of protein, carbohydrate and salt—it also resembles breast milk so closely in the *character* of its *fat* that it is possible for S.M.A. to contain the same *quantity* of fat as breast milk. S. M. A. is also markedly anti-rachitic and anti-spasmophilic. S. M. A. thus offers the physician a means of supplying infants of all ages with the food elements in the same proportion as they would obtain them from breast milk. And this is why, in feeding S.M.A., it is only necessary to increase the *amount* of the prepared food as the infant grows.

S. M. A. is sold by druggists on the order of a physician. If you cannot obtain it from your druggist, please give us his name, and we will furnish you direct till he gets a supply. Complete literature for physicians on request—THE LABORATORY PRODUCTS CO., 1111 Swetland Building, Cleveland, Ohio.

# CALCREOSE

## Intestinal Antisepsis

THERE is good evidence that creosote acts as an intestinal antiseptic but patients object to its use because of its taste and the untoward effect on the stomach.

CALCREOSE (calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium, possessing the pharmacologic activity of creosote but free from its untoward effect on the stomach, therefore,

CALCREOSE lends itself admirably to the treatment of intestinal infections in which it is desired to administer creosote. Patients do not object to its use even when taken for comparatively long periods of time and in large doses.

### THE TREATMENT OF LOBAR PNEUMONIA.

By RUSSELL L. CECIL, M. D., New York City.

In the treatment of lobar pneumonia we are governed by the same general principles that apply to the treatment of all serious infections. These principles have to do with rest, ventilation, proper diet, catharsis, and the control of various symptoms as they arise.

Rest is particularly important in the treatment of pneumonia. Too much physical examination, having the patient sit up in bed, and other such procedures are not only bad for the heart, which is already under strain, but may be responsible for the spread of the disease into other lobes. Since death in pneumonia is generally due to extension of the disease, everything should be done to limit the infection to the original lobe, and complete rest and quiet are important factors in achieving such a result. It is very important for the patient to get plenty of sleep, and the physician should not hesitate to employ codeine or morphine for this purpose.

Proper ventilation is very important for the pneumonia patient. Anoxemia is a common symptom in pneumonia and can be combated in part by a generous supply of fresh air. There is still difference of opinion as to whether pneumonia patients should be put out on balconies when the temperature is freezing. Perhaps it is better not to be dogmatic on this subject, but to use the fresh air treatment when the patient wishes it and when he feels better out doors. It is generally agreed that cold air is injurious in broncho-pneumonia, particularly the type following measles.

The diet in pneumonia should be liquid, but the choice of articles may be left in large part to the taste of the patient. A limit, of course, must be put on carbohydrates, as an excess of sugar would tend to produce tympanites. For the same reason, I am opposed to a high calory diet in pneumonia. Pneumonia runs a

short course, and a high calory diet is entirely unnecessary. It is most important that patients with pneumonia should drink large amounts of water, particularly if they have a high temperature, or appear toxic.

The bowels are best regulated by salts and daily enemas. In many cases enemas alone are not sufficient to prevent distention and even with the addition of Epsom salts by mouth the distention may become so great that turpentine stupes are necessary. Magnesium sulphate is probably the best of the various mineral salts and should be given in fairly large doses.

Pain in the side is best controlled by codeine administered every two or three hours, either by mouth or subcutaneously. In cases where the pain is very severe, morphine should be used without hesitation, not only to relieve the pain, but to give the patient rest and sleep. The drug treatment may be supplemented by hot poultices and by strapping with adhesive plaster if necessary. The last procedure interferes somewhat with the examination of the patient and should be avoided if possible.

Cough is often a very distressing symptom in pneumonia, and here again we must depend on codeine and morphine not only to control the cough but to give the patient opportunity for sleep. When the sputum is extremely viscid, ammonium chloride may be administered with advantage.

Stimulation in some form or other is usually desirable in the course of pneumonia and the most popular cardiac stimulant at the present time is digitalis. A good tincture is usually easiest to obtain and should be given in fairly large doses at the outset. (1 dram, b. d). On the second day the dosage may be cut to 20 mms. t. i. d. In cases of emergency, ouabin, one-half mg., may be administered intramuscularly. As much as two and one-half mg. may be administered within twenty-four hours. This is a very powerful stimulant, but in most cases where cardiac failure has set

in we have found that the benefit derived from cardiac stimulation is only temporary at best. Alcohol is still used by some good clinicians, but the trend of opinion seems to be against its use in pneumonia. Camphor, strychnin and caffeine may also be employed, but probably have very little therapeutic value.

**SERUM TREATMENT.** I believe that Type I anti-pneumococcus serum is of benefit in pneumococcus Type I pneumonia, when administered early in the disease and in large doses. This form of treatment, however, has not proved to be altogether practical for the general practitioner. The chief reason for this is the difficulty and delay connected with the proper typing of sputa. The statistics reported from the Rockefeller Institute by Cole and his co-oworkers showed a death rate of only 7.5% in cases of Type I pneumonia which had been treated with serum, whereas the control cases ran a death rate of 25%. Recent reports from other hospitals, however, do not show such a striking difference. In the first place, the death rate for untreated Type I pneumonia appears to lie between 20 and 25%, depending on the season, etc. Dr. Edwin A. Locke, of Boston, recently collected a large series of Type I cases which had been treated with Type I anti-pneumococcus serum in various hospitals where the records were accurate and the treatment had been faithfully carried out. In Dr. Locke's series there was practically no difference in the death rate between treated and untreated cases, except in a comparatively small group which had received serum treatment early in the disease. In the cases treated early the death rate was only about 9%.

During the last two years we have been working with a modified anti-pneumococcus serum at Bellevue Hospital. This preparation was first worked out by F. M. Huntoon, and is nothing more than a water solution of the immune bodies originally contained in polyvalent anti-pneumococcus serum. By a very ingenious procedure, Huntoon was able to extract the immune bodies from the anti-pneumococcus serum and redissolve them in water. This product is known as pneumococcus antibody solution and contains protective substances against pneumococcus Types I, II, and III.

The advantages of this preparation are:

1. It is polyvalent; that is, it is aimed against the three fixed types of pneumococcus, and according to our figures it has shown itself to be of distinct value in the treatment of Type IV pneumonia. By reason of its polyvalent character, typing of the sputum is no longer absolutely necessary, and treatment of the patient can be instituted as soon as the diagnosis of lobar pneumonia has been made. This, of course, is a great advantage over serum.

2. Pneumococcus antibody solution is practically free from horse proteins, hence there is no danger of anaphylaxis or serum sickness. This removes a great source of worry for the physician and discomfort to the patient, and there is, therefore, no reasonable limit to the amount of antibody solution that can be administered.

3. Pneumococcus antibody solution contains a certain amount of pneumococcus protein which may conceivably act in the capacity of a vaccine.

4. The fact that the preparation is a water solution renders it very soluble and easy to absorb and possibly presents the immune substance to the body in a form more acceptable than that of serum.

The antibody has usually been administered intravenously in doses of 50 to 100 cc., the technique being similar to that of serum administration. Injections are given once or twice, sometimes three times a day. The reaction produced by antibody is very characteristic and striking. In 20 to 40 minutes after the injection the patient usually begins to shiver and is soon in the midst of a hard chill, which lasts from 15 to 20 minutes. At its conclusion the patient complains of fever and the temperature may have risen to 106° F., or even to 108 or 109. This high temperature usually persists for only a short time, 30 to 60 minutes. The rapid fall is accomplished by a profuse perspiration, which may continue for several hours. The fall in temperature may be slight, but is often extensive, amounting to 8 or 10 degrees. It may be temporary or permanent, depending on the stage of the disease. These reactions are very similar to the so-called "foreign protein" reaction, and are probably due to a disturbance in the colloid equilibrium of the blood. The dose of antibody administered does not bear any close relation to the character or severity of the re-

action. In one patient 10 cc. may produce a severe chill, while another patient may tolerate 100 cc. without any reaction whatever. The reactions are more severe when treatment is started late in the disease.

During the past two and a half years this solution has been tested on a large scale in the wards of Bellevue Hospital. Through the kind co-operation of the various directors all cases of lobar pneumonia admitted to the twelve medical wards were studied bacteriologically, and on six of the twelve wards practically every case of lobar pneumonia was treated with intravenous injections of pneumococcus antibody solution. The other six wards were used as control wards. In these wards patients with pneumonia received no antibody but in other respects were treated in practically the same way as the patients who received antibody. Specific treatment was started as soon as the diagnosis of pneumonia was made. The result of the experiment are shown in Table I.

TABLE I.  
COMPARISON OF DEATH RATE IN TREATED AND CONTROL SERIES.

Type	CASES TREATED WITH ANTIBODY			CONTROL CASES		
	Cases	Deaths	Rate%	Cases	Deaths	Rate%
Pneumococcus I	157	21	13.4	175	41	23.4
Pneumococcus II	78	22	28.2	76	31	40.7
Pneumococcus III	57	20	35.	60	24	40.
Pneumococcus IV	109	17	15.6	137	31	22.8
Total	401	80	19.9	448	127	28.3
Strep. Hemolyt.	21	10	47.6	21	9	42.8
Strep. Viridans	7	1	14.2	10	1	10.

It will be observed that 401 cases of pneumococcus pneumonia were treated in the antibody wards, and 448 in the control wards. There was considerable difference in the mortality rate for Type I cases, 13.4 per cent. for the 157 treated cases, as compared with 23.4 per cent. for the 175 untreated cases. In the Type II groups the treated cases showed a death rate of only 28.2 per cent., as compared with the control death rate of 40.7 per cent. In the Type III series, the percentage of fatalities was more nearly the same for the two groups, 35 per cent. for the treated; 40 per cent. for the untreated cases. Strangely enough, a considerable difference in mortality rate was noted in favor of the treated Type IV group, 15.6 per cent. against 22.8 per cent. Altogether, the treated pneumococcus cases showed a death rate of 19.9 per cent., while the control pneumococcus series represented a rate of 28.3 per cent. Streptococcus pneumonia was not bene-

fited in the least by antibody treatment. In fact, the death rate was higher for the treated series (39.3 per cent.) than it was for the untreated series (32.2). The number of cases, however, in the streptococcus group is too small to permit of accurate conclusions.

TABLE II.  
DEATH RATES FOR PNEUMOCOCCUS PNEUMONIAS RECEIVING ANTIBODY ON OR BEFORE THIRD DAY OF DISEASE. CONTROL SHOWS DEATH RATE FOR PNEUMOCOCCUS PNEUMONIAS ADMITTED TO CONTROL WARDS ON OR BEFORE THIRD DAY OF DISEASE

Type	CASES TREATED WITH ANTIBODY			CONTROL CASES		
	Cases	Deaths	Rate%	Cases	Deaths	Rate%
Pneumococcus I	56	5	8.9	68	16	23.5
Pneumococcus II	24	5	20.8	25	8	32.
Pneumococcus III	10	1	10.	19	7	36.8
Total	90	11	12.2	112	31	27.6
Pneumococcus IV	24	4	16.6	45	11	24.4
Total	114	15	13.1	157	42	26.7

The results of treatment with antibody were much more striking in cases that were treated early in the disease. For example, in Table II it will be noticed that the death rate for Type

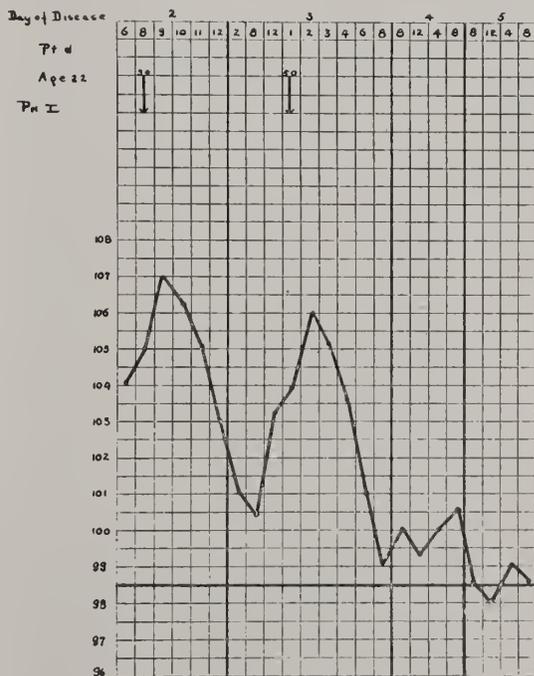

Fig. 1. Temperature Chart of Pneumococcus Type I Pneumonia.

I pneumonias treated during the first 48 hours of the disease was only 8.9 per cent., while controls admitted to the hospital during the first 48 hours of the disease showed a death rate of 23 per cent. Similar reductions are

noticed in the other types. Altogether, 114 pneumococcus pneumonias treated with antibody during the first 48 hours of the disease showed a death rate of only 13.1 per cent.; whereas 157 pneumococcus pneumonias in the control series ran a death rate of 26.7 per cent., more than twice as high.

Figure 1 shows the temperature chart of a Type I pneumonia treated with antibody. The case was that of a young man, aged 22, who came in with a consolidation of the right lower lobe. Antibody was given on the second day of the disease, 50 cc. intravenously. Following the injection, there was a rise of 3 degrees in the patient's temperature, followed by a characteristic fall. On the following morning the temperature rose to 104°, and another injection of antibody was given. This injection was also followed by a reaction with a fall of temperature to normal, where it remained. Figure 2 shows a Type II pneumonia treated with antibody solution, with reactions and results similar to those in the Type I case. Figure 3 shows a Type III case; Figure 4 a Type IV infection treated with antibody solution.

stance against Type IV pneumococcus. Evidence is accumulating, however, to show that pneumococcus Type IV is made up of atypical fixed types; in other words the Type IV strains represent aberrant forms of Types I, II or III. If this hypothesis is correct, it would readily explain the beneficial effect of antibody on Type IV pneumonia.

Upon the evidence which has been presented we must conclude that pneumococcus antibody solution is a therapeutic agent of considerable power. The effect is most striking when the antibody is administered early in the disease, but it may also be of value in the later stages by neutralizing the circulating toxins. The most dramatic effects are observed in Type I infections, but good results can also be obtained in the other types when antibody is used early and in large doses.

More recently we have been studying the effect of antibody when administered subcutaneously. By this procedure, one avoids entirely the severe reactions which are often very uncomfortable and, in certain cases, actually dangerous to the patient. It has been claimed,

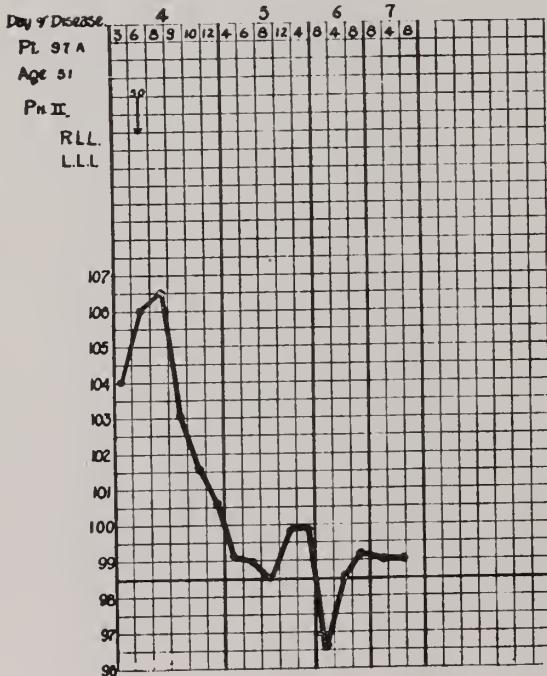

Fig. 2. Temperature Chart of Pneumococcus Type II pneumonia.

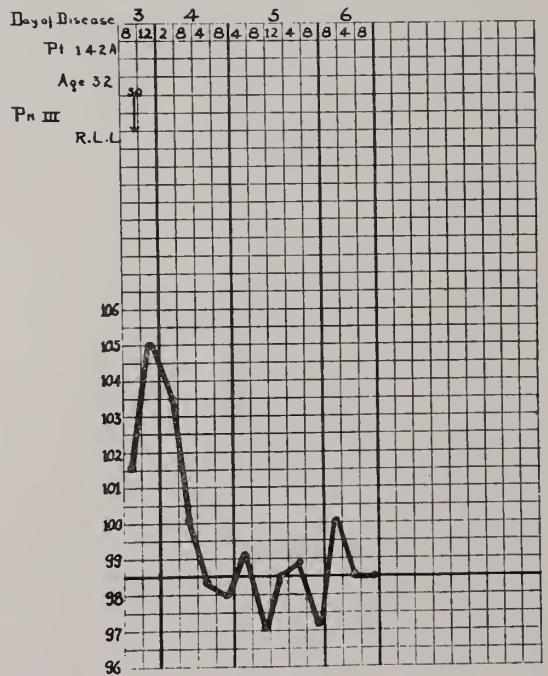

Fig. 3. Temperature Chart of Pneumococcus Type III pneumonia.

It is difficult to explain why Type IV pneumonia should be favorably influenced by pneumococcus antibody solution, as this agent is not supposed to contain any immune sub-

of course, that foreign proteins have therapeutic value in pneumonia and other infectious diseases. There is little evidence in our studies to support such a theory in respect to pneu-

monia. In the streptococcus pneumonias treated with antibody the death rate was higher in the treated cases than in the untreated cases. The proper time to administer the specific agent in pneumonia is during the first twenty-four hours of the disease. When antibody is given within twenty-four hours

This preparation is still a new remedy and will certainly be subjected to further improvements as time goes on. A method must be devised for still further concentrating the antibody, and it would also be desirable to eliminate the shock reaction which follows the intravenous injection. Even in its present form, however, pneumococcus antibody solution marks an important step in advance in the specific treatment of pneumonia, and I believe that it will be along this line that an efficient mode of treating this disease will ultimately be worked out.

*33 East Sixty-first Street.*

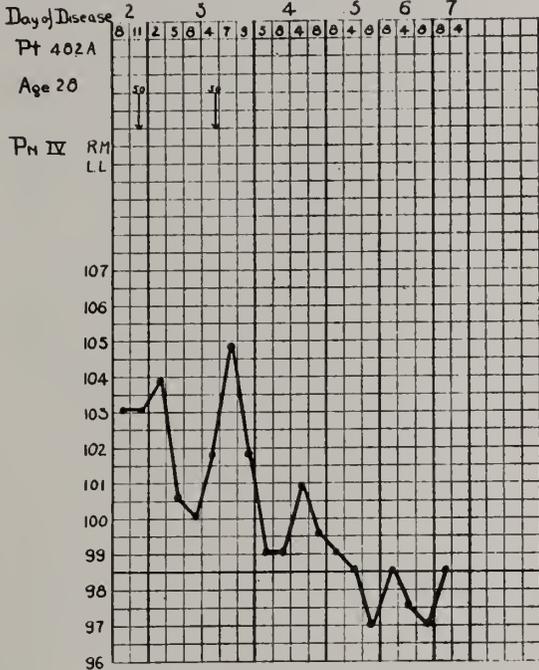

Fig. 4. Temperature Chart of Pneumococcus Type IV pneumonia.

after the chill, an aborted form of the disease is often produced, with the temperature going down to normal on the third or fourth day.

Contraindications to the intravenous injection of antibody are:

1. Cases complicated by severe systemic disease—cardiac, renal or vascular.
2. Cases seen late in the disease, when the patient's strength is well-nigh exhausted by the infection.
3. Pneumonia in the aged.

There is, of course, no contraindication to the subcutaneous administration of antibody, as it produces no constitutional reaction. The advantages of antibody, as already mentioned, are:

1. Its polyvalency, which makes it amenable for the treatment of all types and eliminates the necessity of typing the sputum.
2. Its freedom from horse protein and the danger of anaphylaxis and serum sickness.
3. The fact that it is water-soluble and readily absorbed when injected subcutaneously.

### SOME SOURCES OF ERROR IN THE INTERPRETATION OF THE PHTHALEIN TEST, WITH SPECIAL REFERENCE TO THE EFFECT OF EXERCISE.\*

By WILLIAM H. HIGGINS, M. D., Richmond, Va.

Sufficient time has elapsed since the introduction of the phenolsulphonephthalein test by Rowntree and Geraghty to classify it among our most reliable diagnostic methods. Its absorption and excretion have been so thoroughly studied and verified by numerous observers that it is now universally accepted as the most accurate and practical of all the functional kidney tests so far proposed.

However, in spite of its unsurpassed value in renal diagnosis, startling discrepancies occur with sufficient frequency to warrant an inquiry into the factors concerned in the mechanism of the test. These factors may arise in part through carelessness in technique. In many instances the administration of the dye is left to a nurse or technician and there may be some doubt as to the exact amount given or whether the injection was made intramuscularly or subcutaneously. Any laboratory method which is as free from complicating steps as the one under discussion is likely to suffer because of its simplicity from apparently unimportant but in reality damaging alterations in its application. In the light of knowledge brought out subsequent to the introduction of this test, we must also consider the more deeply hidden agencies involved in tissue chemistry in their relation to absorption and excretion.

In the earlier studies by Rowntree and Geraghty, and more recently by Braasch and

\*Read before the Richmond Academy of Medicine and Surgery, Richmond, Va., November 30, 1922.

Kendall, the influence of various conditions on the elimination of the dye were pointed out. Although these observations are more or less familiar, their practical bearing on the amount of phthalein excreted in a given period may bear repetition at this time. These factors are of particular importance where the clinician finds variations in the functional output of the kidneys in successive readings and is in doubt as to their significance.

#### THE INFLUENCE OF THE ROLE OF ABSORPTION ON THE RATE OF EXCRETION.

Meltzer and Auer<sup>1</sup> were the first to demonstrate that absorption from the intramuscular tissue is much more rapid than that from the subcutaneous tissues. According to these investigators, rapidity of absorption from intramuscular injection is dependent not on the puncture of small veins in the muscles as held by others, but is due to the direct absorption through the walls of the blood vessels.

Following this work, Rowntree and Gerahty<sup>2</sup> showed by carefully controlled animal experiments and verified clinically that absorption for one hour from the subcutaneous tissues averages 5 to 10 per cent less than from the intramuscular, while at the same time considerable variation (37 to 62 per cent) existed in the absorption from the same dog. On account of these large variations, due apparently to tardiness of absorption, this method was subsequently discontinued. They accordingly investigated the intramuscular method (gluteal and lumbar) and found an average of 51 per cent elimination during the first hour by the gluteal route as compared with 57.5 per cent when the injection was made in the lumbar region. Intravenously the output of dye for the first hour averaged 67.9 per cent., considerably higher than that from other methods of administration. By studying the curve of excretion for 5 and 10 minute intervals it was found that from 30 to 35 per cent is excreted in the first 10 minutes after appearance, this being half the total excretion for one hour. The striking rapidity of elimination in the first few minutes following intravenous injection results, of course, from the concentration of the drug in the circulation. Their conclusion was that the intravenous method is not as accurate as the intramuscular, especially where ureter collectors are employed. The normal variations in the functioning power for

such short periods as 15 minutes or one-half hour are too great for accurate readings. In view of these studies they considered the intramuscular injection in the lumbar region the most desirable mode of administration.

Emphasis has been made on this point in technique as failure to take cognizance of these observations unquestionably introduces a source of error in the results.

The influences controlling the absorption from the site of injection are not entirely clear. It has been observed at the Mayo Clinic that in patients with urinary obstruction of long standing who were being prepared for operation the phthalein return by intramuscular injection was frequently lower than other clinical data would indicate. When the dye was given intravenously, the output was often nearly normal. This was particularly marked in patients undergoing preliminary treatment for prostatectomy, who were suffering from the reaction following drainage.

#### FACTORS INFLUENCING ABSORPTION AND EXCRETION.

More recently a clinical investigation of the phthalein test has been made by Braasch and Kendall<sup>3</sup> at the Mayo Clinic. They make the inquiry whether in all cases of low phthalein output, the kidney is the only factor involved. If conditions should exist in the body whereby the injected phenolsulphonephthalein is absorbed and retained in transit to the kidney, this action might result in delaying or indefinitely holding up a certain amount of the dye, so that the problem is not only one of whether the kidney can or can not excrete it, but whether or not the kidney has a chance to excrete it. Acting upon these premises, they showed first that the type of food and the capacity of each animal to carry out the reactions occurring in the metabolism of sugar and amino acids are among the factors determining the output of phenolsulphonephthalein. They pointed out also that although the body as a whole eliminates the dye to a high degree, tissues other than the kidney have some upper and lower limits of saturation which must be satisfied before the kidney even begins to excrete it.

It is known, of course, that a small part of the phthalein is eliminated through the bile ducts, but to what extent and under what conditions the liver may act as a storehouse for

the dye is not clear. Besides the question of the mere retention of phenolsulphonephthalein in the body, it can be shown experimentally that it is actually destroyed in the body tissues in the absence of oxygen. This destruction within the tissues not properly oxygenated is rapid and complete. Braasch and Kendall undertook to determine to what extent the destruction may take place clinically. Their results indicated that only in very marked cyanosis is the dye destroyed and, if the patient is able to be up, it is doubtful whether destruction of the dye within the tissues plays a very important part in the lowered output.

In investigating the possibility of the retention of the dye in tissues other than kidneys, it was shown by Kendall that if the tissues of dogs are rendered alkaline, phenolsulphonephthalein will be more readily given up. Clinically, it was found that after alkalinization of the urine, the phthalein output was increased from 10 to 50 per cent, largely in patients suffering from urinary obstruction or renal infection; in other words, when the impairment in renal function was temporary and dependent on these factors. If, however, the impairment was permanent, as in advanced chronic nephritis, little difference was found in the output following the administration of an alkali.

The condition of the circulation of the blood may also influence the excretion of the dye. In cardiac insufficiency, the functional output may be greatly reduced although the kidneys may show only minor changes. This low output may be explained by delayed absorption as the phthalein return intravenously is much higher than when given intramuscularly. The effect of diuretics may be mentioned briefly. Rowntree and Geraghty carried out extensive experiments with various kinds and their conclusions were that only those drugs which exert their effect on the renal secreting cells increase slightly the phthalein output.

#### EFFECT OF EXERCISE ON THE PHTHALEIN OUTPUT.

After giving the usual instructions to patients upon whom the phthalein test is being carried out, the question is frequently asked, to what extent is exercise permissible? I took occasion about one year ago to search rather carefully through the voluminous literature for any reference to this point, but without avail.

In a personal communication from Dr. Geraghty, he stated that so far as he knew no effort had been made to determine the effect of exercise on the excretion of the dye.

The difficulties of determining this point are obvious. Aside from the influence of one or more of the sources of error referred to in this paper, it must be remembered that there are rather wide variations within the normal limits. Consequently, any comparative results can at best show only the general tendency of the renal function during a period of rest as following exercise.

Although the total number of observations is too limited in this preliminary report to draw definite conclusions, the patients were selected with considerable care in order that sources of error might be reduced to a minimum. No patient was examined whose illness was likely to fluctuate during the period of testing and no one showing evidences of any enlarged prostate was included. The phenolsulphonephthalein was administered and determinations were made according to the usual technique described by Geraghty.<sup>4</sup>

The patients' records are grouped on the two charts according to the degree of exercise. Those on Chart I refer to healthy students, and patients at the City Home Hospital, where the opportunities for exercise were unusually good. The nine students included in this test actually walked continuously during the two-hour period with the exception of the few minutes necessary at the end of the first hour to collect the specimens. The others were either nurses on duty, or patients who were cooking, cleaning, etc., during the test.

On Chart II is the record of observations taken at the Memorial and St. Philips Hospitals, where the exercise consisted largely of walking and sitting in the wards.

Of the twenty-one patients recorded on Chart I, sixteen gave lower readings after exercise, three showed higher readings and two gave the same for both periods. It should be added that one of the three secreted an alkaline urine and gave an abnormally high reading (90 per cent) after exercise. According to Braasch and Kendall, the soda which she was in the habit of taking introduced a source of error. Studied collectively, this group excreted on an average of 6 per cent less dye after exercise.

Of the twenty-two patients recorded on Chart II eight showed a decrease after exer-

cise, twelve gave an increase after exercise and two were the same for both periods. In this group there was an average of 3.2-3 per cent. increase after moderate exercise as compared with the 6 per cent decrease after rather vigorous exercise.

According to these two series of observations, there appears to be a difference between the functional output of the kidneys following moderate exercise and that following vigorous exercise. In the former series, there was no definite trend in the variations between the two periods and apparently the type of exercise taken by those recorded in Chart II, had no appreciable effect on the excretion of the dye.

In Chart I, however, the phthalein return showed a general tendency to be less after vigorous exercise in sixteen of the twenty-one studies, while two of the others remained the same.

An explanation of this probable influence of vigorous exercise on the output of phthalein is not altogether clear. We, of course, know that not infrequently a transient albuminuria, together with casts, occurs following strenuous exercise, but it has not been our experience to find evidences of renal irritability after the type of exercise described in these experiments. It is conceivable that other urinary solids are temporarily withheld by the kidneys following vigorous exercise. So far as I have been able to ascertain, no one has published any data bearing on the effect of exercise on the excretion of urea, sugar, creatinine, etc. We are now conducting experiments covering this point.

CONCLUSIONS.

I. The phenolsulphonephthalein test is an index of tissue absorption and retention as well as renal excretion. Any deviation from

## SOME UNSOLVED PROBLEMS IN NEUROLOGICAL SURGERY.\*

By ERNEST SACHS, M. D., St. Louis, Missouri.  
Professor of Clinical Neurological Surgery,  
Washington University School of Medicine.

The title of this paper implies that there are some problems in neurological surgery that have been solved, but when I say solved I do not mean that every phase of those subjects has been cleared up and settled, for it will always remain one of the great charms of our profession that practically everything is still in a state of flux. Our most cherished theories of but a few years ago have to be discarded. Neurological surgery has been developed in such very recent times that many of the views its exponents hold have not been sufficiently tried and tested to make them as positive as some of the fundamental theories of, for example, bacteriology.

The treatment and permanent cure of major trigeminal neuralgia (tic douloureux) we do

\*Read before the Richmond Academy of Medicine and Surgery, March 27, 1923.

understand, and these pathetic cases can be promised permanent relief by severing the sensory root of the fifth nerve from its origin in the pons. No case of tic douloureux that has had this operation done properly ever gets a return of pain. If the pain remains, the operation has not been completely done or the diagnosis was wrong; and we know now that pains occur in the face which are not true trigeminal neuralgia. But of the pathology of the disease we know nothing. There is no demonstrable pathological lesion, and the disease may be due to some physiological or chemical disturbance, or mayhap it is due to one of these greatly overworked causes, vitamins, ions or ductless glands. While the treatment of spinal cord tumors is perfectly clear and their removal is comparatively simple, the diagnosis and localization still offer many pitfalls, but of this I shall speak later. The treatment of certain types of brain tumor, the benign encapsulated endotheliomas, is also quite clear though here, too, both the diagnosis and treatment offer many difficulties.

But of the subjects that constitute our unsolved problems the following are a few:

The treatment of gliomas of the brain, of hydrocephalus, of mental deficiencies, and certain types of spastic cases both of cerebral and spinal origin. I shall, of course, not attempt to take up all these subjects, but shall confine my remarks to but three of them—the gliomas, hydrocephalus and spinal localization.

Forty-five to fifty per cent. of all brain tumors are gliomas. Gliomas are usually considered malignant tumors. Were this so, the problem would indeed be a desperate one; but gliomas lack one of the most characteristic signs of a malignant tumor: they never metastasize, they never invade the dura, but some of them infiltrate the adjacent brain tissue. It is a local disease and, if the tumor can be removed, there is no danger of its recurring elsewhere. This, then, is the crux of the problem, can the tumor be removed completely, and, if so, what are the best methods of doing this?

The first point to emphasize is that there are different kinds of gliomas—the solid and the cystic. The cystic gliomas are of three types. First, the simple cysts containing yellowish, gelatinous fluid with a small solid

gliomatous mass in one spot of the wall, but the rest of the cyst wall is not composed of gliomatous tissue; second, the single cysts composed of gliomatous tissue with no single nubbin of gliomatous tissue; and thirdly, the cases of multiple gliomatous cysts in a mass of solid tumor.

Of these three types, the first is the most favorable tumor we have in the brain. The emptying of the cyst or removal of the wall with the nubbin of tumor effects a permanent cure. At times the nubbin may be inaccessible or only partially removed, and then the cyst may refill in the course of months. Occasional evacuation of the cyst may keep the patient comfortable for a long time. Sometimes they cease to secrete and the patient remains well. Under what circumstances this happens and what factors influence this fortunate outcome we do not know.

The second type of gliomatous cyst in which the wall is all gliomatous is less promising, though here, too, removal of the cyst wall or destroying it by some cell fixative, as Zenker's solution, may give a permanent cure. If the cyst refill, it may be retapped but at times these cysts change into solid gliomatous tumors. The cases with multiple cysts must be considered with the solid tumors.

With the solid gliomas, the problem is a different one; can one remove a solid glioma? I have been struck by the fact that not all gliomas are infiltrating, but some have a definite line of demarcation though not a true capsule. My policy at present is, and has been for a number of years, to attempt to remove a tumor if I possibly can, for to leave a tumor means ultimate death; however, I do not attempt to remove every tumor. I have no rule of thumb by which I determine which tumor I shall remove and which I shall leave in even after I have exposed it. No two surgeons will absolutely agree on this point, for that rare indefinable quality known as surgical judgment, a twin of that rapidly disappearing quality known as the art of medicine, must be our guide. The two extremes at present, I think, are represented by the Mayo Clinic and the Baltimore Clinic. The former leave gliomas alone surgically; the latter attempt to remove everything. I agree with neither of these two policies but steer a middle course. To remove a tumor completely but leave the patient so seriously disabled that he is a burden to him-

self and his family, is a questionable triumph of surgery. It is similar to some of the victories in the recent war when conquered cities were mere smoking, battered walls. What is occupying my attention at present is trying to determine, if possible, either before or at the time of an operation, which are the removable gliomas. Diagnostically as yet we have not found any means of differentiating the various types of gliomas, but at operation a fairly accurate differentiation is possible. It is not even always possible to know before operation if one is dealing with a glioma, regardless of the type. A case that rapidly develops tumor symptoms is almost certainly a glioma, but I have seen cases that could readily be enucleated in spite of their very rapid growth.

Before taking up the second subject, it might be of interest to dwell for a few moments on certain factors that make these operations fairly safe, far safer than they have been in the past. These factors may be summed up in a few words.

1. Expert anaesthesia controlled by careful, frequently repeated blood-pressure observations.

2. A trained corps of assistants.

3. Improvements in the technique of the surgical procedures, and, if necessary, doing the operation in several sittings.

4. Making free use of blood-transfusion as a post-operative stimulant.

For the anaesthesia, I believe a trained anaesthetist is essential, one who knows how to handle cerebral cases, for these are different from the ordinary surgical cases. The depth of anaesthesia must be much lighter than for an abdominal case. We have found the Connel percentage ether apparatus particularly valuable. With an expert anaesthetist, I have not felt the need of using local anaesthesia except very occasionally.

As regards the other three factors, I just want to say this. Work in the intracranial cavity is enormously simplified if the problem of the cerebrospinal fluid is properly handled. The free use of ventricle-puncture is a *sine qua non*. I have never seen any harmful effects come from the withdrawal of cerebrospinal fluid by ventricle puncture. The reduction of intracranial pressure by withdrawal of cerebro-spinal fluid is essential. Occasionally the ventricles are collapsed, and then the surgeon faces a most difficult situa-

tion. Hypertonic salt solution or even lumbar puncture may be necessary, though the latter procedure I consider very precarious in cases of increased intracranial pressure.

Blood transfusion we are using very freely. In the past two years we have transfused twenty per cent. of all craniotomies and, of the eighty tumor cases in this series, thirty-one and a third per cent. were transfused. Blood is certainly a much more effective post-operative stimulant than normal saline. If the patient's blood pressure has dropped markedly at the end of the operation, we usually give 500 c.c. of blood by the syringe method. We prefer this to citrated blood as we get far fewer reactions. I am quite sure that on a number of occasions we have given blood when salt solution might have accomplished almost as much, and consequently we have been criticised for this, but the remarkable effect it has on patients after a long operation makes me continue this practice.

---

Hydrocephalus still remains a difficult problem. The cases of hydrocephalus associated with cerebellar tumors I shall not consider, for the removal of the tumor relieves the hydrocephalus. I refer to the case of hydrocephalus due to obstruction by inflammatory processes around the fourth ventricle or aqueduct of Sylvius, and those cases of hydrocephalus now called communicating hydrocephalus. The type of hydrocephalus must first be determined. Dandy's method of injecting a neutral dye into the ventricle and observing its excretion I have discarded, as we had such alarming temperature reactions from the injections. I have returned to the old method of doing a double puncture, ventricular and spinal, and connecting each needle with a glass tube and noting if the fluid rises to the same height in both tubes. If it does, we have a communicating hydrocephalus; while if the fluid stands at different levels with the patient lying on the side, we have an obstructive hydrocephalus. For the latter type I have been doing an operation for the last seven or eight years which is comparatively simple and seems to be effective. I make an opening over the fourth ventricle and allow the fluid to escape into the subcutaneous tissues where it can then be absorbed. If the obstruction is above the fourth ventricle, some such method as Dr. Dandy has described must be used to

open the aqueduct of Sylvius. This increases the danger of the operation tremendously, and has thus far not led to very good results. I have tried it two or three times but have no successful case.

The treatment of the communicating hydrocephalus is indeed an unsolved problem. Dandy's suggestion of limiting the source of the cerebro-spinal fluid by removing the choroid plexus seems the only rational one, but it is a severe surgical interference. I have done it four times. In one infant the head ceased to enlarge, but five months later the child died of a pyelitis, so that I cannot express a positive opinion about the permanent value of the method.

Hydrocephalus may properly be called an unsolved problem, but now that we know how to differentiate the various types, we can deal with these cases more intelligently. A recent experience illustrates this very well. A child of four weeks began suddenly to develop hydrocephalus. It had been a premature infant and had a temperature of  $107^{\circ}$  the day after its birth. The temperature then fell to normal. The child did not gain and there was constant feeding difficulty. At four weeks, Dr. Tuttle, who referred the case to me, noted hydrocephalus. Lumbar puncture revealed a yellow fluid full of flocculi; culture was negative. Removal of spinal fluid did not influence the hydrocephalus. Spinal puncture, the next day, yielded only a few drops. Ventricle puncture showed the same yellow fluid. We evidently were dealing with an intraventricular birth-hemorrhage which had caused an obstructive hydrocephalus. As the child was failing rapidly, I attempted something that, as far as I know, had not been done before. A ventricle needle was put into each lateral ventricle and the ventricles were irrigated out with normal saline. Following this, lumbar puncture yielded a copious flow of cerebro-spinal fluid, and now the cerebrospinal fluid is normal, the head has ceased to enlarge, and the child is gaining steadily.

---

Spinal surgery offers us a number of problems on which we want more light, but it also has reached a far more satisfactory stage than the surgery of hydrocephalus. Spinal tumors are favorable cases for operative removal as the majority of them grow from the meninges, and though they may compress the cord very

markedly, they do not destroy the cord as a tumor growing in the substance of the cord may do.

Our greatest difficulty still consists in determining whether the symptoms of a focal spinal lesion are due to tumor or some other process. In the first ten or fifteen years, when spinal tumors were being operated upon, following the epoch making monograph by Victor Horsley and Gowers, two points were considered essential to warrant the diagnosis of spinal tumor. One was pain, the other was the progressive character of the disease. If a case did not present one of these two features the diagnosis was not deemed justifiable. We know today, however, that a patient may have no pain and still have a spinal tumor; and there may be a remission of symptoms and the spinal symptoms nevertheless be due to a spinal tumor. It has been claimed that only those spinal tumor cases have no pain that are intramedullary, that is, have their origin in the substance of the cord. To determine that point, some years ago I reviewed all my spinal tumor cases and found that in my own series pain was not such a prominent symptom and that quite a number of extra-spinal tumors, that is, meningeal tumors, produced no pain. In addition to this, I found that even in those cases that had pain this symptom was not the initial or most prominent one. I believe that pain in spinal tumors only occurs when the posterior nerve roots are involved or pressed upon, while if the tumor lies between roots (and this may occur particularly in the dorsal region where each segment is rather long) there may be no pain. In my series the initial symptom was some form of paraesthesia: burning, pins and needles, or formication, and this symptom is so indefinite that not a few of the cases, before they finally get relief, have become so discouraged that they consulted osteopaths or chiropractors. These paraesthesias have preceded objective findings, such as pathological reflexes or anaesthesia, by many months; and on purely subjective symptoms none of us would be willing to make a positive diagnosis.

The remission in symptoms may well be explained by changes in the vascularity of the tumor. Two cases in my series illustrate this point strikingly. One was a fibroma. On removing the tumor it was found to have practically no blood supply, and microscopic

sections showed very few and extremely minute vessels. At one time this patient had been totally paralyzed but, when he came under observation, he had some sensation and some movements in his lower extremities. While this tumor was growing I believe it had a good blood supply, and then the tumor had cut off its own blood supply by pressure and consequently had shrunk, thus giving more room to the spinal cord. The other case was that of an angioma of the cord. This patient had periods of complete paralysis, and then again marked periods of remission. She had consequently been diagnosed as an hysterical paralysis by her physicians in Russia, and they had employed on her the drastic methods that had been used in the army on functional cases, but of course without avail.

If pain need not be present and the symptoms are not continuously progressive, how shall we determine if the picture of a transverse myelitis is due to tumor? One point is of great value. Cord tumor symptoms come on fairly slowly, at least in the course of a few weeks, while myelitic symptoms from other causes usually develop much more rapidly. The character of the line which marks the beginning of the disturbed sensation is sometimes said to be different in tumor cases than in myelitic cases. Increased reflexes, paralyzed muscles and disturbed sensations are observed in focal spinal lesions regardless of the cause and therefore they will not assist in the differentiation. The history of the case and the character of the line of changed sensation are almost the only points of value; there are cases in which it is impossible to determine if the paralysis is due to a tumor or not. In these cases the injection of air into the spinal canal and taking an X-ray picture may be of value, or the test of Ayer, of Boston, by which he determines if there is a spinal block; but Ayer himself has pointed out that spinal tumors do not always produce such a block. I still feel, therefore, that the old dictum of Victor Horsley should not be discarded, that every patient with the symptoms of a focal spinal lesion has not been given a fair chance unless he has been explored.

The determination of the exact level at which a lesion is located requires a most careful study of the disturbances in sensation as well as changes in reflexes and motor power. I find that there is a surprising carelessness

on the part of many men in making sensory examinations. If there is merely diminution in sensation, not complete loss, the greatest care has to be exercised. To examine a patient with but part of his clothing removed may lead to serious error for, where fine distinctions in sensation are being studied, the weight of the clothing may confuse the most intelligent patient. In finding the region in which normal sensation begins one should always examine from the abnormal to the normal area. The patient must always be lying down, and the examining room should be warm. The usual tests, of course, are made with a needle and cotton wool, and, as a rule, these are much more satisfactory than testing disturbances in temperature sense, but occasionally temperature disturbances are more valuable guides. I recall one instance where I was only able to establish the sensory level by means of a piece of ice.

These remarks about methods of examination no doubt seem very elementary to most of you. My reason for mentioning them is that they are so frequently disregarded.

I have endeavored this evening to outline for you some of the solved and unsolved problems which are occupying the attention of neurological surgeons. It is one of the most fertile fields for clinical research. It has made great strides in the last decade, and during the next decade unquestionably many of the unsolved problems will be still further elucidated.

### THE GROWING IMPORTANCE OF MAPPING FIELDS OF VISION.\*

By W. E. DRIVER, M. D., Norfolk, Va.

It is almost impossible to over-emphasize in treating diseases of the eye today the importance of locating in its earliest stages any form of progressive trouble with the optic tract as well as with the eye proper. In other words, the eye surgeon, or oculist, is the guardian of the whole eye apparatus when the sight is in jeopardy. The value of his service to his patient is in direct proportion to his ability to *determine* the source of every interference with the vision and his ability to remedy such defects.

The fact that an oculist will examine a patient and fit glasses to his eyes that enable

\*Read at the meeting of the Virginia Society of Otolaryngology and Ophthalmology in Roanoke, April 13, 1922.

him to see does not demonstrate by any means that he has gone to the seat of the trouble and found the underlying causes of the symptoms manifested. This is often shown by the continued trouble a patient may have, as headaches, the necessity for frequent change of glasses, and increasing hyperopia. It is now a well established custom that persons suffering from headache for any considerable length of time, or other troubles that seem due to the eyes, consult an oculist at once, without reference to the family or general physician, to learn whether or not the trouble may be due to the eyes. This, obviously, has increased to a large extent the responsibility of the oculist in making his examinations.

Certainly it has been conclusively demonstrated in the last half century that the mapping of the fields of vision is the most illuminating of all methods of recognizing interference with the visual tract. The careful plotting of the visual fields in securing reliable records of affections of the eye and optic tract requires both time and patience, but after years of experience in this work, I can only repeat that such mapping is the *most accurate* means of estimating the need for specific treatment.

If, in the case which I am citing below as an example of my point, the patient had been under careful observation, and accurate charts of his field of vision had been plotted at the time he was first sent to the hospital, probably his sight could have been saved.

The following is the history of a case which came under my personal observation and one which particularly illustrates my argument.

"Hypophyseal struma with primary optic atrophy and bitemporal hemianopsia. Dyspituitarism with evidences of former activity. High sugar tolerance. Chronic hypoglycaemia. Operation. Partial extirpation of growth.

HISTORY: June 1, 1910. B. C., a coach painter, was referred to the hospital by Dr. C. M. C., complaining of loss of vision. One of a large family of healthy children, he enjoyed a fair measure of health himself until his present trouble. The usual infantile infections were followed by a very severe typhoid and a secondary pneumonia at 14. He subsequently grew very rapidly, and at 17 measured six feet in height. At 23 he had another attack of typhoid and at 28 pleurisy.

Apart from these illnesses the patient has been well; a hardworking man of more than average physical strength. He has used tobacco to excess and alcohol abundantly, but otherwise has had no vices. Though he works constantly with white lead and oil, he has never had any occupational colic or neuritis. He has been married five years and has one healthy child.

PRESENT SYMPTOMS: In March 1909 he accidentally observed that vision in the left eye was dim. It has progressively failed. He has had occasional temporal headaches, but they have not been frequent or severe, no nausea or vomiting. Photophobia, with aching pain in the eyeballs, has been his chief source of annoyance.

At the time of his first admission in June, 1910, although the fields of vision aroused some suspicions, the X-ray plate was inconclusive, and expert ophthalmological opinion was emphatic that the condition was a typical lead or tobacco amblyopia. A gloomy prognosis was given; he was given large doses of potassium iodide and discharged, the visual acuity in the left eye having dropped markedly during the two weeks he was under observation.

August 10, 1911. Readmission. The patient, by good fortune, was seen by Dr. W., who found a typical bitemporal hemianopsia, and he was advised to re-enter the hospital."

Mapping fields of vision, to be sure, is subjective, but it is not as misleading as one would suppose when it is done by skilful persons. Dr. Cushing, in his article entitled "Distortions of the Visual Fields in Cases of Brain Tumor"<sup>2</sup> (1911), mentions the fact that patients had brought to him charts on which the fields of vision had been plotted elsewhere, but as a rule they had been so casually mapped that they were too unreliable for diagnosis. He says: "Too few circumferential points are usually taken, and the cards, as a rule, are so small that the color interlacing, on which we have come to lay such stress, is not apparent. Furthermore, a number of our best illustrations of hemiachromatopsia were entirely overlooked on tests made shortly before the patients' admission to the hospital, the fields of form alone having been recorded."

Albrecht Von Graefe<sup>3</sup> was the first to call attention to the importance of testing the visual field in ophthalmic practice. He showed that for many intra-ocular diseases there are special varieties of contraction of the visual field, which are more or less characteristic of these diseases, and can be utilized for this diagnosis. Since then (about 1860) the visual field has been much cultivated, so that at present its examination has great significance, both for diagnosis and prognosis.

The importance of mapping fields of vision in diagnosing intra-ocular diseases was conclusively demonstrated by Von Graefe, and since that time much has been added to the methods used in the accurate plotting of the visual fields. Among those who have followed Von Graefe's discoveries along this line and perfected the methods of plotting have been Soelberg Wells, Donders, Bjerrum, de Schweinitz, Wilbrand, Cushing and Walker.

In his *Treatise on Diseases of the Eye*,<sup>4</sup> Soelberg Wells (1868) says: "Besides examining the acuteness of vision, it is often of much importance to ascertain with accuracy and care the condition of the field of vision." Wells did not use the graduated disks in determining the field of vision, but plotted the periphery of the field of vision on a blackboard by using chalk held in a dark handle while having the patient keep his eye on a certain spot in the center of the board.

De Schweinitz (1892-1916) plots a field of vision in much the same manner as Wells, when he wishes a field not larger than  $45^\circ$  in extent. For a larger field, in determining the periphery of the retina, he uses the perimeter. This, as is well known, consists essentially of an arc marked in degrees, which rotates around a central pivot, that at the same time may be the fixing point of the patient's eye. The test object, 1 to 2 cm. in diameter, affixed upon a carrier, is moved from without inward and the point noted on each meridian where it is recognized.

"Bjerrum, in 1899, proposed an addition to the usual method of examining the field of vision. The addition consists in making use of white objects which subtend a very small visual angle. The examinations are made at a distance of two meters, using a large black screen two meters in breadth, which can be let down from the ceiling to the floor. At this distance, the blind spot, instead of measuring 2.5 mm., as on an ordinary perimeter, measures 20 mm. in diameter, and everything else in the same proportion.

"The objects used by Bjerrum are small circular disks of ivory fixed on the end of a long black rod. They vary from 10 to 1 mm. in diameter.

"The examination is begun in the ordinary manner (at 30 cm.) with the 10 mm. disk, and then continued at two meter distance with a 3 mm. disk. In the first case the visual angle approximately is two degrees, in the second five minutes. This method is valuable in finding section-shaped defects, irregular limitations, and scotomas, and should supplement ordinary perimetric work in all important examinations."<sup>5</sup>

Clifford B. Walker, in Harvey Cushing's service, in his examinations of patients with intracranial lesions, finds it necessary to investigate the field of vision for test objects

varying in visual angle from one or two minutes to about  $8^\circ$ , and has designed a series of circular rimless colored and white disks, supported on wire handles, which cover the required range, taking the "normal" of 5 mm. disk as the unit. In this series the smallest disk is 0.15 mm. and the largest 4 cm. in diameter. His special perimeter has a radius of 28.6 cm. and a large working surface  $66^\circ$  by  $130^\circ$  in extent.<sup>6</sup>

Clifford Walker has gone further than this in the study of defective retinal areas with a series of large disks.

Although there is more labor involved and in some instances there seems little to be learned in a further plotting of the fields, as a matter of fact there is much more to be learned, though the information obtained throws more light on the prognosis than on the diagnosis. The large disk is rather of more value in advanced cases which are to be carefully watched before and after operation; even though the small or normal disks may show very little change, although active changes may be going on in those parts of the retina found to be defective to the normal disk, both before and especially after operation.

Examination with large disks should be made on all field defects whether of anterior or posterior origin. The results are much more striking in anterior lesions than in posterior, and this is true to such an extent that it is useful as a diagnostic point in differentiating anterior and posterior lesions.

In the instance of cases presenting themselves for operation with rather damaged fields and a diagnosis of a lesion in the chiasmal region, all knowledge possible is necessary concerning the visual prognosis and the state of the defective retina before operation. After operation it is necessary to detect the earliest improvement in the defective area and to follow its progress. The very small disks may show very little change, while a series of large disks may show marked improvement in the field. The inner field represents the normal disk. The next larger field is taken with a disk twice the normal diameter; the third outer field is taken with a disk of twice the diameter of the previous disk or four times that of the normal disk, and likewise the outermost disk is twice the diameter of the next inner or eight times the normal disk.

The small disks are not shown in this first series, but the same relation between disks holds down to the smallest which has a visual angle at perimetric distance of about 1.7 minutes, close to the limit of visibility. Of course, when there is scotoma, the order of the disks is reversed, the inner border representing the larger disk, and the outer border the normal disk, so that if there are less than four margins in a scotoma, it means that a corresponding number of the largest disks are seen in the scotomatous areas and therefore are not recorded.

Some of the diseases most readily diagnosed by examination of the visual fields, with details of diagnosis, are briefly described as follows:<sup>7</sup>

**GLAUCOMA SIMPLEX:** A form of glaucoma with no pronounced inflammatory symptoms, but attended with progressive loss of vision.

The contraction of the visual field begins most frequently on the nasal side. A very frequent, according to some, constant, change is an up-and-down elongation of the blind spot, so that a sickle-shaped scotoma is produced (Bjerrum) arching above or below round the fixation point and even reaching the horizontal meridian on the other side of the latter (Ronne). In this way an annular scotoma may ultimately develop. In glaucoma simplex central scotomata may occur, so that with a large field of vision the central visual acuity is impaired early. The reverse also occurs; that is, a marked concentric contraction with good central vision.

**OPTIC NERVE ATROPHY:** The atrophy of the optic nerve fibres is the most important cause of the decrease of visual power which accompanies the elevation of tension. Impairment of both direct and indirect vision occurs. The former finds expression in the gradual diminution of acuity of central vision, the latter in the limitation of the field, which begins in the majority of cases on the nasal side, as the temporal side of the retina becomes insensitive first. Finally complete blindness supervenes.

With the diminishing sight is associated progressive restriction of the visual field (usually under the form of progressive concentric contraction or of sector-like defects, rarely under that of a central scotoma).

The field of *colors* is affected before that

for white objects, the field for red and green disappearing early, and later that for blue.

By this fact **ATROPHY** is distinguished from **GLAUCOMA SIMPLEX**, which sometimes shows much resemblance to it, but which is not ordinarily associated with color blindness till late in its course.

Atrophy of the optic nerve due to disseminated sclerosis is characterized by an irregular course, at times by transient improvement of sight, and rarely leads to complete blindness. It is unilateral. The field varies, but a central scotoma is relatively frequent.

**OPTIC NEURITIS:** Subjective symptoms consist in defective sight; in severe neuritis complete blindness. Marked swelling with normal sight does also occur. Characteristic of many cases of neuritis is a sudden and momentary obscuration of sight, repeated often. Contraction of the *field of vision* is often found, sometimes under the form of hemiopia. Sometimes the only anomaly of the field is an enlargement of the blind spot.

Brain diseases are by far the most frequent cause of optic neuritis. They lead to disease of the optic nerve, either through producing congestion or transfer of inflammation.

The diseases of the brain which are complicated with *optic neuritis* are partly focal, partly diffuse affections. Above all it is the tumors of the brain which result in neuritis, usually under form of choked disk. Neuritis in this case is so frequent, said to be wanting in only ten per cent., some say more, of cerebral tumors, that it forms one of the most important symptoms. Accordingly, in every case in which there is a suspicion of the existence of a cerebral affection, the fundus of the eye should be examined with the ophthalmoscope.

In a report by Cushing, 1911, he mentions that cases of brain tumor causing visual defects seemed rapidly increasing, as of the 200 cases reported on, covering an interval of five years, eighty-two of them had come under observation during the last twelve months.

**TUMOR OF THE BRAIN:** Von Graefe was the first to distinguish the inflammations of the optic nerve *accompanying diseases of the brain* into congestive neuritis (choked disk) and descending neuritis.

**RETINITIS PIGMENTOSA:** A special variety of atrophy which runs a very chronic course is the pigmentary degeneration of the retina.

It is marked by such characteristic subjective symptoms that the diagnosis can be made almost from them alone. Persons affected with this disease complain that they see worse at night, or whenever illumination is reduced. Examination of the field of vision discloses the cause of this phenomenon.

In the beginning of the disease the visual field, when taken with good illumination, shows a broad blind zone between the center and the periphery (an annular scotoma). Central vision is good, because the periphery of the retina functions, orientation is good too, so that the ring-shaped defect in the visual field is not noticed. The peripheral portion of the retina, however, is undersensitive and, when illumination is diminished, it no longer functions, and then the periphery of the visual field disappears just like the portion that corresponds to the ring scotoma, so that the patient has left only the small central portion lying inside the latter.

In feeble illumination, therefore, orientation is no longer possible for him. And even the central portion of the retina is damaged, because the light sense in general is reduced, and hence the liminal stimulus is increased; that is, the minimum quantity of light required to stimulate the retina is greater than in a normal eye. As the disease advances, the periphery of the retina becomes entirely blind, so that even in good illumination nothing but a small central portion of the visual field is left, and the patient can scarcely guide himself alone even in daytime. At the same time direct vision may be so good that the patient may be able to do fine work. Finally, central vision too is lost, so that complete blindness supervenes, but not usually until late in life.

**DETACHED RETINA:** The retina separates from the pigment epithelium even more readily than the choiroid separates from the sclera (as it does for example after operation); and the dreaded detachment of the retina is nothing but the retransformation of the virtual cavity of the ocular vesicle into a real one.

Detachment of the retina is diagnosticated by means of the ophthalmoscope, which shows the detached retina under the guise of a delicate gray membrane that rises above the level of the normal fundus and projects toward the vitreous. Exteriorly the eye looks normal. Only the anterior chamber is often

strikingly deep and the tension is diminished.

The subjective symptoms of detachment of the retina consist in the disturbance of vision that it causes. This is characterized above all by a limitation of the field of vision, corresponding in location to the detached portion of the retina, which has partially or entirely lost its sensitiveness to light. If, as is so frequently the case, the detachment lies below, the patient complains of a dark curtain which veils from him the upper part of objects. For instance, he does not see the head of a man standing in front of him. Hence, the examination of the *field of vision* is of great importance for the diagnosis of detachment of the retina.

**STRABISMUS:** The vision of those who are affected by strabismus is distinguished from that of one-eyed people by the greater extent of the *field of vision*. In the case of a person who squints with his right eye, the exclusion of the right eye from the visual act is done only to avoid diplopia, and hence, is limited to those objects which throw their images in both eyes at once, that is, to those which are found in the portion of the visual field common to both eyes. The case is otherwise when the object passes into the temporal field of the squinting eye where it can no longer be seen by the other eye because hidden from it by the nose. Then the image of the object is not suppressed by the squinting eye. Hence, the field of binocular vision of a man with squint is about as large as that of a normal man.

The temporally situated portion of the visual field, for which there is no suppression of the images, corresponds to the innermost portions of the retina of the squinting eye.

**CHOROIDO-RETINITIS:** An inflammation that affects predominantly the outer layers of the retina, adjoining the choroid, will scarcely run its course without implicating the choroid too. Conversely, it is obvious too that choroiditis cannot exist without the portions of the retina immediately adjacent participating in the process. From an anatomical standpoint, every choroiditis is a retinochoroiditis, or chororetinitis, although the term is not generally used unless ophthalmoscopically visible signs of inflammation can be demonstrated to exist both in the retina and in the choroid.

In this disease the exudates from the choroid pass not only into the superimposed retina,

but also through the latter into the vitreous. Opacities thus produced are hence almost a constant accompaniment of choroiditis.

The vision is diminished as a whole on account of the cloudiness of the vitreous and the hyperaemia of the retina. But in those spots in which inflammatory foci exist, sight may be entirely abolished, so that scotomata are present in the field of vision. Owing to the fact that the retina over the focus of inflammation is pushed forward and its elements are displaced from their normal situation, objects whose images fall on the retina may appear distorted (*metamorphopsia*); straight lines, for instance, appear bent in various directions. Frequently also objects appear smaller than they really are (*micropsia*), or in the atrophic stage look larger than they are (*retinal macropsia*).

When, after the subsidence of the inflammation, atrophy of the choroid and of the superimposed layers of the retina has taken place, signs of absence of function, *gaps in the field of vision*, take the place of the signs of irritation.

This disease is chiefly dangerous because of its tendency to recur, in consequence of which new foci of inflammation are constantly developing in the choroid. With this is ultimately associated atrophy of the retina and optic nerve, so that obstinate cases of choroiditis terminate in partial or total blindness.

**METAMORPHOPSIA:** Is the condition in which objects appear distorted. It is found in pre-choroido-retinitis.

Metamorphopsia may be due to defects in the refractive media (astigmatism, especially of the irregular kind), refractive metamorphopsia, or to displacement of the retinal elements. The latter occurs when the retina is lifted up by an exudate (retinitis, choroiditis) or an underlying liquid or growth. If the process is such that the retinal elements are spread apart, as for instance occurs in a recent choroiditis or retinitis, an object looked at will look smaller than it is (*micropsia*). This is because a retinal image, that would normally occupy three retinal elements, now owing to the distention of the retina, occupies but two, and hence affords an impression corresponding to that afforded by an object of two-thirds the actual size of the object looked at. On the other hand, when the retinal elements, are abnormally crowded together, as occurs in the atrophic stage of retinitis and

choroiditis, objects look larger than they really are (*macropsia*).

In the beginning of detachment of the retina objects frequently appear crooked, in consequence of the oblique position of the pericipient retinal elements.

**EFFECTS OF DRUGS ON THE FIELD OF VISION:**  
*Strychnine:* This exerts an excitant action upon the optic nerve, so that even in normal eyes it produces a slight, although not permanent increase in the visual acuity and an enlargement of the field of vision.

It acts best in disturbances of vision unattended by changes visible with the ophthalmoscope, especially in hysterical and neurasthenic forms, which, however, generally afford a good prognosis anyway. In serious lesions of the optic nerve, as in progressive atrophy, we often obtain with it an improvement in the sight and especially an enlargement of the *field of vision*; but these changes are not permanent.

*Quinine:* In acute quinine poisoning (after doses of less than one to three gm. or upwards), sudden blindness sets in with hardness of hearing. In most cases the blindness disappears again gradually but incompletely, amblyopia and a markedly contracted *field of vision* remaining permanently.

Anatomical investigation shows in the first days of quinine poisoning a destruction of the ganglion cells of the retina, and as a result of the death of the ganglion cells a degeneration of the nerve fibres of the optic nerve very soon sets in.

*Tobacco and Wood Alcohol:* Nicotine and alcohol amblyopia are due to chronic poisoning by these substances, nicotine poisons more often than alcohol. In this country there have been many cases of methyl-alcohol poisoning—in a few cases this has occurred from inhalation of the vapor (as shellac workers), but generally from drinking cheap liquor, jamaica ginger, or other liquids which have been adulterated with deodorized wood alcohol. Blindness is almost always complete and permanent.

In nicotine poisoning, disturbance of vision sets in very gradually. The reduction of the visual acuity is most always the same in both eyes, a fact that distinguishes this from other intra-ocular affections, such as cataract, choroiditis, atrophy of the optic nerve.

In this poisoning, objective examination shows but *slight ophthalmoscopic change*.

Examination of the *vision* shows a moderate diminution of the visual acuity which has its cause in central scotoma. No gap is found in the field of vision if tested by means of a white object, but a red or green mark undergoes a change of color in the region of the scotoma. The outer limits of the visual field always remain normal and complete blindness is therefore not to be apprehended, but direct vision is destroyed, and with it the ability to carry on any fine work.

**ENLARGEMENT AND TUMORS OF THE HYPOPHYSAL GLAND:** With tumors of the brain there may occur not only congestive neuritis, but also descending neuritis and simple atrophy of the optic nerve. Simple atrophy may be produced because a tumor exerts a direct pressure upon the chiasm or the optic tracts, and thus causes their effacement.

An example of this is furnished by the interesting cases of tumor of the hypophysis, which, by pressing upon the chiasm causes atrophy of the optic nerves with temporal hemiopia.

In all cases in which the defect in the visual field is contained in one eye only, or in which, while there are defects in both eyes, they are not symmetrically situated, the lesion must be situated in the *optic nerve* itself, that is, in front of the chiasm. In temporal hemiopia the lesion is seated in the chiasm itself and is so placed that only the decussating fibres are affected by it. It most often occurs as an enlargement of the hypophysis cerebri. The symptoms vary, depending on whether the degeneration affects the glandular or the nervous portion of the hypophysis.

Unquestionably the hypophyseal gland is capable of great histological alteration at different ages and under different stimuli. Even in the case of actual enlargements to which the gland is subject and the tumors peculiar to its vicinity, there has been great disparity in the interpretation as well as in the nomenclature applied to the lesions.

Degeneration of the hypophysis causes the eye to suffer, although indirectly, owing to pressure of the enlarged gland upon the optic nerve. Thus it is often the case that the ophthalmologist is the first to discover a diseased hypophyseal gland.

One can readily see the growing value from the diagnostic point of accurately mapping the field of vision. As an aid to diagnosis its value can be compared to the X-ray and the

Wassermann test in other branches of medicine. The neurological surgeons have emphasized the importance of this subject more than the eye surgeons, up to this time, which is an unwarrantable position.

In connection with the foregoing effort to demonstrate the importance of examining the field of vision, especially for diagnostic purposes, I wish to mention the investigations made by Dr. C. E. Finley, of Havana, Cuba. In his paper, "Bitemporal Contraction of Visual Fields in Pregnancy," presented before the International Congress of Ophthalmology in Washington, April, 1922, Dr. Finley clearly demonstrates that the "normal hypertrophy of the pituitary body which takes place in connection with pregnancy," in about seventy per cent. of such cases, produces "a compression of the chiasm which manifests itself by changes in the visual fields, in the nature of a bitemporal contraction, which varies in degree according to the amount of compression suffered."<sup>8</sup> Such contraction, however, it should be clearly understood, is the result of the state of pregnancy, and not the indication of permanent interference of the optic tract.

Besides the accurate mapping of the visual fields and the careful diagnosis that may be derived therefrom, I wish to stress particularly the fact that the eye surgeon should be able to remove and clear obstructions from the eye tract. There should be no part of the eye or its appendages with which he is not familiar enough to administer surgical and medical treatment.

For instance, in gumma, a syphilitic condition affecting one of the extra ocular muscles, the eye surgeon will not think for a moment of calling in outside assistance, but on the other hand, usually when he has determined from the mapping of the field of vision that a patient has an interference of the optic chiasm by an enlarged hypophyseal gland, he throws up his hands in horror and immediately calls upon the neurological surgeon, or the endocrinologist, for assistance. Diseases of the hypophyseal gland affecting the optic tract are so eminently a part of the eye surgeon's field that he should without question be qualified to cope with them.

### MATERNAL MORTALITY IN RICHMOND: A PRELIMINARY SURVEY.\*

By C. C. HUDSON, M. D., Health Officer,  
and

M. P. RUCKER, M. D., Chairman, Midwife Examining Board,  
Richmond, Va.

"Maternal Mortality, a Crime of Today" is the title of a recent paper by C. Henry Davis.<sup>1</sup> That the high maternal mortality which still pertains in spite of the tremendous advances in the medical science of the past fifty years is a reflection upon the medical profession, public health work and the public in general, we all agree, but that it is a modern crime is open to considerable doubt. Maternal mortality certainly existed in the time of the patriarchs, for it is recorded<sup>2</sup> of Rachel that "when she was in hard labor, that the midwife said unto her: Fear not; thou shalt bear this son also. And it came to pass, as her soul was in departing (for she died), that she called his name Benoni; but his father called him Benjamin." How frequently such calamities occurred in ancient times it is, of course, impossible to tell. The earliest records available for such a study are those of the Registrar General for England and Wales, and these, according to Victor Bonney,<sup>3</sup> show that the death rate, directly and indirectly attaching to pregnancy and labor, has diminished woe-fully little in the last seventy years. A study of the maternal mortality in the United States from 1890 to 1913, by Grace L. Meigs,<sup>4</sup> of the Children's Bureau, U. S. Department of Labor, indicates that there is, if anything, a slight increase. She makes the statement that "child bearing in this country is a greater hazard to women of child bearing age than any disease except tuberculosis." Louis I. Dublin,<sup>5</sup> the statistician for the Metropolitan Life Insur-

ance Company, says that deaths of women from puerperal causes affect the community deeply, because they occur at periods of life when each death involves serious loss, often causing a dissolution of the family.

The actual risk of child bearing cannot be determined exactly from statistics, as they have been kept. Rongy<sup>6</sup> makes the suggestion that birth certificates should have on the back spaces for certain facts about the mother and child, such as presentation, instrumentation, duration of labor, eclampsia, placenta previa and (we might add) pituitrin. There are, however, a number of ways more or less accurate of arriving at some conclusions. Davis<sup>1</sup> went over 5,000 consecutive life insurance examinations in the office of the Northwestern Mutual Life Insurance Company, and found that one applicant in seven had a mother or a sister or both to die from the immediate effects of childbirth, one in 27 from tuberculosis, and one in every 47 from malignant disease. Rongy<sup>6</sup> compared the number of deaths from puerperal causes to deaths from all causes and found that in the Bronx, in every 1,000 deaths, 7.3 were due to childbirth, and 8.7 if we include abortions. Another way of studying this question is to compute the mortality rate for women between the ages of 15 and 44. This was done by Dublin.<sup>5</sup> His material consisted of 14,694,260 women carrying industrial insurance in all states of the Union, and he found a death rate of 68.4 per 100,000 women between the ages of 15 and 44, 66.1 for white women and 82.3 for negroes. Septicemia was responsible for 43% and toxemias for 26.4%. Harrar<sup>7</sup> studied the records of 101,197 deliveries at or near term at the New York Lying-in and found one maternal death in 317 out-patient deliveries and one in every 212 hospital cases.

Death rates from puerperal causes are usually computed in one of two ways by Health Departments. The usual way is to calculate the rate as so many deaths per 100,000 population. Another way is to use the number of births as a basis for calculation. The number of live births reported are now reasonably accurate. Howard<sup>8</sup> states that a truer rate would be obtained by comparing the maternal deaths with the actual number of deliveries. This is what he calls the real risk-rate of maternity. There are various sources of error inherent in either method. The principal sources of error for Richmond are as follows:

1. The deaths in our hospitals of compli-

\*Read before the Richmond Academy of Medicine and Surgery, February 13, 1925.

cated cases brought in for treatment from outside the city.

2. Deaths from infection following abortions and stillbirths. (21.7% of all puerperal deaths).

3. Incompleteness of birth records in estimating maternal deaths per 1,000 births. (Probably 5%).

4. Multiple births.

5. Acute and chronic diseases complicating pregnancy and labor.

In the past three years a special study of all deaths from puerperal causes in Richmond has been made by the Health Bureau and it has been found that 14.7% of all puerperal deaths belonged in class 1. These were complicated cases brought to the various hospitals on account of the complications. In the same three year period 21.7% of the puerperal deaths were incident to abortions and premature deliveries. This causes an unduly high rate when the rate is based upon the number of live births. Both of these factors are very important in increasing the death rate from puerperal causes in Richmond. The incompleteness of birth records, amounting possibly to 5%, still further increases the death rate when computed on the basis of 1,000 live births reported. The error occasioned by the birth reports of multiple births, amounting to about 1 to 2%, works in just the opposite way from the preceding three years, and would tend to slightly lower the rate. The fifth source of error, that is patients dying from acute and chronic diseases in either pregnancy, labor or the puerperium, and classed by the International Classification of Causes of Death under puerperal conditions, was quite an important source of error in the recent epidemics of influenza. Under normal conditions this error is probably almost completely neutralized by real puerperal conditions being incorrectly reported and thereby being incorrectly classified.

The record of deaths in Richmond is complete as far back as 1907. In considering the death rates from puerperal conditions for this entire period, we have used the rate per 100,000 population as being the best method available. For the more recent years we have computed the rate per 1,000 births as approaching more closely the real maternal risk-rate.

Many people do not fully appreciate the importance of the puerperal state as a cause of death. As may be seen from Table I, more

deaths were caused by the puerperal condition in Richmond during 1922 than were caused by typhoid, malaria, diphtheria, scarlet fever and measles combined.

TABLE No. I.  
SHOWING COMPARISON OF PUERPERAL  
CAUSES WITH OTHER CAUSES OF  
OF DEATH—1922.

Cause of Death	Deaths	Death Rate Per 100,000 Population	
		White	Colored
Typhoid	8	4.5	
Malaria	4	2.2	
Diphtheria	16	9.0	
Scarlet Fever	3	1.7	
Measles	2	1.1	
All Combined	33	18.5	
Puerperal	34	19.1	

Table No. 2 shows the deaths and the death rate per 100,000 population, white, colored and total, from puerperal causes, beginning with 1907. As may be seen from this table, the white death rate from puerperal causes has declined from an average rate of 22.2 in the five year period 1907-1911 to 17.9 for the five year period 1917-1921, while the white rate of 10.5 for 1922 is the lowest rate on record. The colored death rate from the puerperal causes has increased from 31.7 to 42.5 for the above periods. The rate for 1922 is 38.4, which is nearly four times the white rate.

TABLE No. II.  
DEATHS AND DEATH RATES, WHITE, COLORED  
AND TOTAL FROM PUERPERAL CAUSES,  
RICHMOND, VA.

Year	Deaths			Death Rate Per 100,000 Population		
	White	Col.	Total	White	Col.	Total
Average 1907-1911	16.8	14.2	31.0	22.2	31.7	25.7
Average 1912-1916	19.2	16.0	35.2	20.1	32.7	24.4
Average 1917-1921	20.8	23.2	43.8	17.9	42.5	25.7
1922	13.0	21.0	34.0	10.5	38.4	19.1

Table No. 3 shows the death rate per 100,000 population from puerperal causes with the two principal causes, septicemia and albuminuria and convulsions, separated. As may be noted from this table, there has been a decrease in the death rate from puerperal septicemia during the last fifteen years. The death rate from albuminuria and convulsions on the other hand has remained practically the same, while the death rate from other causes has shown a slight increase.

TABLE No. III.

DEATH RATES PER 100,000 POPULATION AS CLASSIFIED BY CAUSE, 1907-1922.

Year	Puerperal Septicemia	Puerperal Albuminuria and Convulsions	Other Causes
1907	10.6	7.9	0.9
1908	13.1	10.4	8.7
1909	11.2	9.5	7.7
1910	8.6	10.1	1.6
1911	9.2	11.5	7.6
Average	10.5	9.9	5.3
1912	9.0	4.5	10.6
1913	10.3	8.8	8.1
1914	15.1	8.6	9.4
1915	6.3	5.6	6.3
1916	7.4	7.4	4.9
Average	9.6	7.0	5.8
1917	9.8	7.9	5.5
1918	7.8	8.9	11.9
1919	2.3	11.2	5.4
1920	10.4	11.6	8.1
1921	6.3	8.5	12.5
Average	7.3	9.6	8.9
1922	6.2	5.0	7.8

The following table shows the percentage of deaths in Richmond for each cause during the last sixteen years.

CAUSE	PER CENT OF ALL PUERPERAL DEATHS
Accidents of Pregnancy	10.7
Puerperal Hemorrhage	6.3
Other accidents of Labor	9.1
Puerperal Septicemia	35.3
Puerperal Phlegmasia, Alba Dolens, Embolus and Sudden Death	3.1
Puerperal Albuminuria and Convulsions	35.1
"Following Childbirth"	.4
100.0	

Any consideration of maternal deaths from puerperal causes at once brings up the midwife question. Dr. Julius Levy,<sup>9</sup> of Newark, N. J., in a recent elaborate study, has considered the statistics of New Jersey from this standpoint. His figures would seem to show that the results obtained by midwives are much better than those obtained in hospitals and in the private practice of physicians. During the last three years every death in Richmond from puerperal causes has been investigated by one of the infant welfare nurses of the Health Bureau. All deaths in which a midwife had been in attendance were charged to the midwife. There were during this period 19 deaths among 2,813 patients attended by midwives, giving a maternal mortality of 6.7 per 1,000 births. Excluding the deaths of imported cases and the deaths following abortion, there were seven deaths among 9,069 births attended by

physicians, the maternal mortality being 7.3 per 1,000 births. The apparent slight increase in deaths of mothers attended by physicians may be attributed to several causes: First, in one case at least, a midwife was called and, upon seeing the patient's condition, refused to assume the responsibility of attending her; secondly, in all cases of convulsions physicians were called or the patients were sent to hospitals; thirdly, pregnant mothers who either have chronic impairments or have acute diseases always call physicians; fourthly, cases of pregnancy in very young girls are usually treated by physicians. The following table shows the percentage of births attended by midwives for each year beginning with 1907:

TABLE No. IV.

ATTENDANT AT BIRTH.

Year	Births Reported		Per cent. Attended	
	Physician	Midwife	Physician	Midwife
1907	1375	936	59	41
1908	1621	1185	58	42
1909	1577	1262	56	44
1910	1504	1230	55	45
1911	1701	1239	58	42
1912	1814	1255	59	41
1913	1981	1154	63	37
1914	2019	1136	64	36
1915	2290	1183	66	34
1916	2689	1213	69	31
1917	2758	1079	72	28
1918	2778	1070	72	28
1919	2845	1170	71	29
1920	3231	1147	74	26
1921	3472	909	79	21
1922	3366	757	82	18

In 1921 all midwives in Richmond were required to take a course of instruction arranged by the Health Bureau and were further required to pass an examination before the midwife examining board, before being granted a permit to practice midwifery in Richmond. As the result of this work the number of midwives was reduced from 105 to 47. As may be seen from the above table, the number of births attended by midwives has shown a very great decline in the past two years.

Coincident with the decrease in the percentage of births attended by midwives, there has been a decline in the maternal death rate from puerperal causes among the whites and an increase in the maternal death rates among the negroes. The coefficient of correlation between percentages of births attended by midwives and the colored maternal death rate is -.4. The probable error of the coefficient of correlation is 0.1416. The coefficient of correlation is just

three times the probable error and is therefore insignificant.

During the last three years there have been 134 deaths from puerperal causes in Richmond. The following table shows the summary of the deaths by color, and the maternal rate per 1,000 births for the three years. It also shows the true city rate after excluding the cases brought to the city with complications and those deaths due to abortions.

TABLE V.

MATERNAL DEATHS PER 1,000 BIRTHS, EXCLUDING DEATHS OF IMPORTED CASES AND ABORTIONS, 1920-1921-1922.

	White	Col'd	Total.
Total births reported	7,541	4,341	11,882
Total deaths	57	77	134
Excluding deaths of imported cases (9 W., 10 C.)	48	67	115
Excluding abortions (10 W; 15 C.)	38	52	90
Maternal death rate per 1,000 births.			
Total	7.6	17.7	11.3
Excluding imported cases	6.4	15.5	9.7
Also excluding abortions	5.2	12.0	7.6

Nineteen of these deaths were of imported cases, and only incomplete histories could be secured. The cause of death of the 115 city cases may be classified as follows:

			Per Cent	
	White	Col.	Total	of all
Post-abortion infection	10	15	25	21.7
Post-partum infection	8	11	19	16.5
Toxemia of pregnancy (eclamp.)	13	14	27	23.5
Hemorrhage	9	7	16	13.9
Exhaustion and Shock	6	2	8	7.0
Other infectious diseases	5	7	12	10.4
Ectopic gestation	3	4	7	6.1
Chr. Heart disease	0	1	1	.9
Total	54	61	115	100.0

A further study was made of these deaths in an effort to find out what type of prenatal care the patient had received. We realize that this information must necessarily be incomplete, as the person who could have given definite information along this line was dead. However, the information that we could obtain gives us some idea as to what had taken place.

	Per Cent
Engaged physician before onset of labor	30.0
Prenatal instruction given	24.0
Preparations made for delivery	27.0
Urine examined	23.0

A special study was made of the births reported from that part of the city west of First and lying between Broad and Main streets. This study was undertaken for the purpose of seeing what maternal mortality may be expected among a fairly large group of mothers, all of whom would be likely to engage physicians early enough for them to be given a certain amount of prenatal care. No births were reported from this area by midwives, and all negro births were excluded. In this area all deaths of mothers who were brought to the hospitals within this area from other parts of the city or from outside the city were excluded, as were also the deaths from abortion. All deaths of mothers from this section in hospitals outside this area were charged to the area. In other words, we have made an effort in studying the statistics in this area to find out what we may expect from a physician, if given a fair chance. While this study has not been carried on long enough to arrive at any definite conclusions, the results are very striking. The following table shows the results in detail:

TABLE VI.

PUERPERAL STATISTICS FOR SELECTED AREA

Year	Births	Maternal Deaths	Maternal Death Rate Per 1,000 Births	Births Per Maternal Deaths
1920	441	1	2.3	441
1921	462	1	2.2	462
1922	429	1	2.3	429
Total	1,332	3	2.3	444

Of the three deaths from puerperal causes from this area, only one occurred in the 1920 influenza outbreak from pneumonia; one of the deaths was due to embolism and the third death was due to eclampsia and post-partum hemorrhage. In addition to the above deaths, there was one death due to sepsis following an abortion of two months, where no physician had been called.

CONCLUSIONS.

1. The white death rate from puerperal causes has been gradually reduced in the past sixteen years.
2. The colored death rate from all puerperal causes has shown a decided increase.
3. The death rate from septicemia has shown a decided decrease.
4. The death rate from toxemia has remained approximately the same.

5. In computing city mortality from puerperal causes, deaths from complicated diseases brought into the city should be eliminated.

6. In computing rates per 1,000 births, deaths following abortions should also be eliminated, as we have no means of knowing the total number of abortions.

7. The midwife in Richmond is not an important factor in the maternal death rate.

8. Nothing approaching adequate prenatal care and instruction is given to a large part of the prospective mothers in the city. Our study would indicate that there is a large field for further development in this respect.

9. The results in the section west of First street (1 death per 444 births) approach very closely to what Dublin has stated as being the ideal for obstetrics (1 death per 500 births).

## CHRONIC ULCERATIVE COLITIS AND ITS TREATMENT.\*

By WALTER HUGHSON, M. D., Baltimore, Md.

Chronic conditions of an uncertain or even unknown etiology still form a considerable part of our list of diseases despite the steady advance in knowledge which has been made in recent years. Unfortunately, these same diseases are of a complex nature, respond poorly to most suggested forms of treatment, and are a constant source of embarrassment to the physician realizing, as he must, how little hope

he can offer to his patient of even an alleviation of the distressing symptoms. The very multiplicity of the therapeutic measures employed is the surest indication of the futility of most of them. How eagerly the profession grasps at each new idea that may be offered, willing, and quite properly so, to employ any measure that may promise relief to the patient. Unfortunately, many of these suggestions are based on far too inaccurate observation and in many instances represent the result of some chance benefit derived from an entirely random use of medical or surgical measures. Such a condition as I have described is chronic ulcerative colitis. From the literature on the subject one gains a confused idea of various medical and surgical procedures, vouched for by their sponsors as furnishing a beneficent if not a curative effect on the disease. The only unanimity discoverable is in the matter of the relative value of strictly medical or surgical procedures held as one would expect by medical men and surgeons respectively, but after finding agreement in the broader principle it is immediately lost in the maze of detail, varying always with the individual. In this paper no effort is made to add to the already confused state of affairs by further suggestion, but rather by an analysis of present methods and theories to reach some conclusion as to the proper manner of handling the condition. Lacking an etiologic basis, which is always the prerequisite of intelligent treatment, we can but weigh the respective merits of methods already employed and endeavor to strike an average between the various radically different modes of approach to the subject.

The disease as an entity was first recognized by White in 1888 and his paper apparently aroused considerable interest in England, judging from the amount published on the subject in the next few years. During this period and indeed until comparatively recently there persisted confusion between the colitides or dysenteries of known etiology but distinct chronicity, and this particular type to which we can assign no definite causal factor. Indeed so recently as in the 1908 edition of Osler and McCrae's *Modern Medicine* the assertion is made that "there is not as yet sufficient evidence to warrant the separation of the condition from dysentery."

A clear idea of the nature of the disease is given by Logan<sup>1</sup> in an admirable review of a

\*Read before the York County, (Pa.) Medical Society, November 2nd, 1922.

large series of cases treated in various ways at the Mayo Clinic. He says, "Under the heading of Chronic Ulcerative Colitis I shall consider only those cases for which no definite etiology has yet been found," and Yeomans<sup>2</sup> describes his paper as being "based on sixty-five cases of chronic ulcerative colitis of unknown etiology." Those two words "unknown etiology" being used to describe the condition, necessarily limit our discussion of this particular factor, but they require a certain amount of elucidation. The point is this, a chronic colitis to which we can assign some definite cause and thereby apply a rational therapy cannot be considered in the group under discussion. We can accept as belonging to this group only those cases in which none of the usual, or for that matter, unusual causes of chronic ulcerations of the colon can be assigned. This point cannot be emphasized too strongly. Much of the confusion existing in the matter of treatment is due to the fact that in discussion of papers, methods used successfully in the treatment of the ordinary bacillary dysenteries and colon infections are represented as being curative for this variety of unknown origin. Probably the most likely factor in its causation is some previous intestinal infection, either bacillary or of the parasitic variety, which perhaps leaves the intestines in a condition of lowered resistance. Thus Logan describes cases following ptomaine poisoning but with no significant bacteriology; he also suggests hyperacidity of the intestinal contents by citing relief of symptoms following alkali therapy. In Yeomans' series a majority occurred in the first three decades—this was also true of Logan's cases—and he mentions dietary and other youthful indiscretions as being a possible cause. Several writers have mentioned a previous history of amoebic dysentery but with no amoebae or cysts present at the time of examination. Yeomans gives a list of conditions preceding the actual disease in his series but concludes that these various factors—infections, operations, pregnancies, etc.—can only have played a part in that they lowered the individual's general resistance. The disease is not transmissible. Examination of the intestinal flora seldom shows anything more than the usual types of organism. Kendall feels that "Normal intestinal organisms, or types indistinguishable from them by ordinary methods of study, may multiply with abnormal luxuri-

ance through unusual conditions; extend their normal habitat and crowd out some of the existing organisms, eventually leading to abnormal reactions in the alimentary canal which may be detrimental to the host." The possibility of some anaerobic organism being responsible for the disease has been frequently considered. The tubercle bacillus cannot be found in the stool. Yeomans found a positive Wassermann in only 3 of 58 cases examined in this way and very properly concluded that syphilis could not be regarded as an etiologic factor.

The gross and microscopic pathology is little more helpful. The picture depends entirely on the extent and duration of the disease. Yeomans gives an excellent pathological classification of the superficial changes in the mucosa. Primarily there is present a simple chronic inflammatory process, characterized by different types of ulcers in various stages of development. These ulcerations as seen through the sigmoidoscope range from the superficial discrete variety to those with a deep hemorrhagic or necrotic base. Perforations occasionally occur through this latter type. The mucosa may be uniformly thickened or thrown into the form of polypoid tumors; this latter condition has been mentioned as a complication. The submucosa and muscular coats may be thickened or thinned and, though the intestinal mucous membrane is fortunately prone to repair, the new formed connective tissue may undergo slight or marked cicatricial contraction. Under these conditions stricture may develop. Logan lays considerable emphasis on this scarring and consequent smoothing out of the mucosa. It has been generally believed that the ulcerations are present in greater numbers along the taenia coli, but Logan states that this was present in only four of his reported series of 117 cases. The rectum and sigmoid are most frequently affected though the caecum is often found to be definitely involved, suggesting the greater susceptibility of the fecal reservoirs. The entire colon in late cases shows ulceration and, when the disease has progressed very far, the entire large bowel may be simply a long, ulcerated pus discharging tube.

As might be expected, there is present microscopically a general round cell infiltration of the mucosa; the glandular epithelium is frequently destroyed and the glands themselves filled with leukocytes. Numerous chronic

ulcers of the mucosa are seen which, as stated above, after extending through the entire bowel wall may lead to perforation. These ulcers present no peculiar characteristics.

However obscure may be the etiology, certainly the disease presents symptoms which when combined with adequate laboratory examination will leave little doubt in the physician's mind as to its true nature. The outset is invariably marked by a diarrhoea. Logan and Yeomans both analyze their cases from the standpoint of symptoms presented. The stools may range in number from three to twenty in 24 hours. The character of the stool varies from time to time but in general is watery and contains varying amounts of blood and mucus. Blood is almost constantly present and the patients soon develop a secondary anaemia. There is sometimes an eosinophilia (these cells may occasionally be found in the bowel wall). Yeomans found an average loss of weight of about 20 lbs. Occasional cramp-like pains are felt, burning pains in the abdomen, indeed all the signs of inflammation. Abdominal rigidity is not a marked symptom. The disease is a distinctly chronic one, prone to remissions sometimes seasonal in character, and extremely likely to recur—a fact which should be borne in mind when analyzing the results of different treatments. In Yeomans' series again the average duration was two years and two months and these figures indicated the period the disease had existed before coming under his observation. In Logan's series only 18 had had symptoms for less than one year and only thirty under two years. Fever is a late manifestation. Up to a certain point the patients manage to maintain their usual activities in life, but unless given relief there develops a progressive weakness and prostration.

The diagnosis is readily made when all other conditions have been ruled out and, as I have indicated above, this process of elimination requires facilities which unfortunately are not always at hand. The bacteriology of the gastro-intestinal tract presents difficulties and problems of a very special nature. The methods and equipment for isolation and identification of the intestinal flora can be found only in especially equipped laboratories under the direction of trained bacteriologists. The history may be typical. The following case will illustrate it:

The patient, an undernourished, anaemic young man, 19 years of age, came under observation after suffering from a colitis for four years. The trouble had started with what seemed to be a mild dysentery which failed to clear up in the usual time; diarrhoea persisted in a moderately severe form for several months when mucus appeared in the stools in considerable quantity and soon after blood was found. Therapeutic measures were adopted which proved beneficial for about six months when the trouble returned as severely as before. Ten stools a day with abdominal pain and rectal tenesmus were the principal features. Medical treatment again brought about some relief for nearly a year when there was a second recurrence which persisted until the patient came under our observation. At this time there were about 15 stools a day with large quantities of blood and mucus. He presented all the characteristic clinical and laboratory findings of chronic ulcerative colitis.

The outset may be associated with some definite disease attack or there may be elicited some clear cut story of dietary trauma or privation.

Laboratory studies invariably fail to show any of the usual parasitic or bacterial invaders in the feces. This part of the diagnosis must be thorough and exhaustive as it is only after elimination of every known cause that we are justified in placing the case in the class under discussion. Syphilis must be ruled out by careful blood examination and tuberculosis by examination of the lungs and intestinal flora. In the opinion of both Logan and Yeomans, direct inspection of the rectum and sigmoid are of the greatest aid in diagnosis. If the case is seen early the upward invasion from the recto-sigmoid junction can be followed—a fairly typical occurrence—and the general appearance and growth of the ulcerations observed. Benign and malignant tumors, strictures, etc., can also be ruled out in this way. These two authors are also agreed on the value of X-ray examination. The extent of the process can be seen when the transverse and ascending colon are involved, a point which the sigmoidoscope fails of course to show. Early there appears the typical picture of an irritative condition with increased peristalsis. But with the advance of mucosal involvement and the resultant thickening and fibrous tissue formation, peristalsis becomes

much impaired. The waves are flattened out, as it were, and "the colon becomes a stiff walled tube without haustrations." (Logan). Stricture may follow. Yeomans states that in none of the sixteen cases examined by X-ray "were upper segments of the colon demonstrated to be implicated without the descending colon and sigmoid." The disease is primary in the rectum and sigmoid.

Logan summarizes the diagnosis as follows: (1) The history of an intractable diarrhoea which in the large majority of cases contains blood, pus and mucus; (2) by not finding any parasitic or known bacterial cause in the stool; (3) by the proctoscope showing involvement in the rectum and lower sigmoid, or (4) by the X-ray showing the characteristic changes in the colon.

Obviously the prognosis must be a guarded one. As we shall see presently in the discussion of treatment no single therapeutic measure has been of value in all hands. When apparently cured, the disease is prone to recur and not infrequently the individual fails to respond to any measure adopted whether medical or surgical. Complete cures are very much the exception. Alleviation of severe symptoms and control of any further extension should constitute our preliminary prognosis. Even this may be too sanguine. The subject of treatment is a vast one. Special therapeutic measures have been suggested, tried, and reported with extraordinary regularity. Surgeons and medical men have been equally prolific in their suggestions and in many instances have combined each other's ideas, thereby offering an appalling number of possible methods of treatment.

Treatment of diseases of the alimentary tract is a difficult problem. Unlike similar conditions on the surface of the body, which we can deal with more or less in an individual way, our attention, in organic disturbances of the digestive apparatus, must be divided between the local condition and the elaborate physiological mechanism of the structures involved. This point is often lost sight of. No where, not even excepting the urinary apparatus, is treatment made so difficult by functional activity as in the intestinal tract. While dealing with the lesion our therapy is constantly interfered with by the passage of irritating fecal material over the raw and bleeding surface of the ulcers. Little wonder is it that

these conditions become chronic. A similar problem is met effectually in the case of ulceration of the stomach and duodenum by the almost universally used gastro-enterostomy which in the last analysis is simply a mechanical side-tracking of the the stomach content. It has been everyone's experience that large indurated ulcers of the stomach fairly fade away after the irritating action of food mixed with gastric juice has been removed. Local applications here would hardly be considered. Furthermore, unless we have the benefit of some specific drug, such as emetin, how useless must most of our attempts be to sterilize that part of the tract where bacterial and parasitic growth is so luxuriant. How difficult we frequently find sterilization of the male urethra whose comparatively simple mucous membrane and glands offer few of the difficulties of approach found in the elaborate rugae and secretory apparatus of the large and small bowel.

As in every problem connected with the gastro-intestinal tract, there are two distinct forms of therapy, medical and surgical. Zealous proponents of one or the other tend to be intolerant of any but their favorite measure.

The basis of all the medical therapy of chronic ulcerative colitis is irrigation with antiseptic or healing solutions. Medication by mouth would hardly be considered as a possibility, though of course diet in that it changes either the consistency or reaction of the fecal material may be of benefit. Rectal and colonic irrigations have long been employed as therapeutic measures—instillations of solutions of the silver salts,  $\text{AgNO}_3$ , arygyrol and protargol in mild cases which have not extended any great distance upward seem to have been of some benefit; so too, the use of a bland, non-irritating oil which so lubricates the bowel wall that the irritative action of the fecal material is partially allayed. This oil should be retained over night if possible. Other irrigations used are solutions of the common salts, sodium chloride, sodium bicarbonate, boracic acid solution, potassium permanganate, hydrogen peroxide (I have seen such an irrigation cause perforation of the bowel where a large ulceration was present) quinin and chloramin-T. The irrigations should be given in the knee chest position with the proper precaution observed against over distending the

bowel. Yeomans considers peroxide in two per cent. solution the best; Logan prefers argyrol but said the best results were obtained from enemata of hot water 120° F. In one case he secured healing with complete disappearance of symptoms after four months of such treatment. Bassler<sup>3</sup> feels that "enemata are not apt to be helpful and are often harmful" and states, "If the bowel cannot be irrigated from above, such as by the duodenal tube, the intestinal tube of Einhorn or by operation, it had best not be irrigated at all." Direct local treatment of individual ulcers through a sigmoidoscope is another method which is of course distinctly self-limited.

Oral medication may be said to begin with diet which in general should be such as to eliminate all irritating and highly fermentative articles and those which have any rough residue. Bassler gives this subject of diet considerable attention. He advocates a high protein diet of the usual meats, fish, eggs, green vegetables, butter, milk, cream cheese, gelatin foods, etc. And despite the diarrhoeic condition, he has cured a few cases by the simple use of an anti-constipation diet of bran t. i. d. in various forms, stewed prunes, heavy molasses, petroleum, vaseline, senna leaves and a liberal amount of water. Oil by mouth in addition to being a good tissue builder serves much the same purpose as a rectal irrigation. Bassler has had good results from the use of gentian violet in enteric coated pills each containing 0.016 gm. This procedure is based on the selective bactericidal action of gentian violet. Churchman<sup>4</sup> considers that the dye has a bacteriostatic action on the organisms, that is the dye suspends reproduction without implying that the organisms are necessarily killed. Spores are also affected by the dye. Many of the intestinal flora are susceptible.

An interesting procedure is that which has been used successfully by Einhorn<sup>5</sup> in two cases of ulcerative colitis. I speak of the Einhorn intestinal tube by which true colonic irrigations can be given without the aid of surgery. The time consumed in passage of the tube is one week—for withdrawal three days. The treatment lasted for 46 days—several types of irrigations were used the most efficacious being calcium carbonate and water 0.5:1000 c.c. with 15 gtt. of ichthyol in the latter part of the drip. He also used mercurochrome one per cent. solution *zii q.d.* for one week. The patient gained 23 lbs. and was considered

cured. Bassler prefers irrigation through a simple duodenal tube. Autogenous vaccines have been used with success by Yeomans but Bassler found little to recommend them and Logan feels the same way. Intravenous therapy has been used. A negative Wassermann is, of course, not necessarily final and when other stigmata of syphilis are present salvarsan should be tried. Dr. Thomas R. Boggs, of Baltimore, tells me that in some of the intractable cases at the City Hospital he has used intravenous injections of 10 c.c. of a ten per cent. solution of calcium chloride with quite remarkable results. The bleeding is arrested almost immediately and subsequent healing takes place in over fifty per cent. of the cases. This is an interesting lead and one which deserves considerable attention and further trial.

It is more or less agreed that after a thorough trial of any or all of the above procedures and that after they have failed to give permanent relief resort should be made to surgery. Bassler, however, is not in complete accord with this general statement. He says, "The necessity of irrigation for months makes the Einhorn tube impractical. However, the duodenal tube method should supplant the operation for irrigations, especially since many of those treated by operation are improved only as long as irrigations are kept up and when the fistula is closed the re-performance of operation for the original purpose is not fair to the patient, especially when the results by duodenal or intestinal tube are every bit as efficient and can easily be resumed at any time."

Surgical methods employed are appendicectomy, first suggested by Wier; cecostomy; ileostomy; Brown ileostomy and appendicectomy; iliocolostomy; resection of sigmoid and colectomy. From the first three there is little to choose, the technique of the operation is simple, the object gained from each one practically the same. Any one of these openings simply furnishes a direct means of irrigating the affected portion of the bowel with the various healing solutions, but the procedure has no effect whatever on the downward passage of fecal material other than to hasten its discharge. The usual solutions prove efficacious,—potassium permanganate 1-10,000 increasing up to 1-5000, tannic acid 1 dram to the quart, plain water and salt solution either iso- or hypertonic all have a good effect. The

stools promptly decrease in number, their character is changed and the patient finds great relief. Little discomfort is experienced from the opening and the patient soon learns how to take care of himself. There is but slight discharge and, when the proper time arrives, healing is usually spontaneous. If occasion demands, the bowel can be reopened with very little difficulty and simply by the use of a local anaesthetic. This operation cannot in any way be considered a difficult or dangerous one and hardly seems to warrant Bassler's opinion of it. Frequently the bowel or appendix following closure will be found immediately beneath the skin when occasion for reopening it arises. Immediate relief of symptoms sometimes follows opening of the bowel. This suggests that the simple introduction of oxygen into the diseased colon may have a beneficent effect and, in conjunction with the theory that the causative organism might be an anaerobe, I have injected oxygen through the appendicostomy opening allowing it to bubble through very slowly and to remain in the bowel as long as possible. No cures were effected but there was marked relief in two of three cases after other irrigations had failed. In one the relief has been, so far as I know, permanent; in the second case there was a recurrence, and in the third no relief whatever was experienced.

Going a step further, and I think in the right direction, is the procedure first described and advocated by Brown, of St. Louis. Payne,<sup>6</sup> in an article entitled "Physiological Rest to the Large Bowel by Surgical Intervention," takes the matter up in detail. The operation consists in making a complete severance between the ilium and cecum. The stump of the ilium is brought out through the flank and the cecum is fixed to the abdominal wall and a cecostomy made. Thus the colon is entirely relieved of the necessity of functional activity and in addition to being given a complete rest can be treated exactly as in the other types of operation. Payne says the discharge from the small intestine is not particularly irritating to the skin and interestingly enough that in time the discharge becomes semi-solid. This may possibly be a somewhat too optimistic view to hold in regard to ileostomy as the discharge is undoubtedly irritating and certainly retains its fluid character for many weeks. After a rest period of 90 days, or however long a time is necessary to complete the heal-

ing, the ends of the bowel are sutured and the cecostomy opening closed if necessary. Payne has had excellent results in several cases. Iliocolostomy is an operation of some difficulty and at best relieves that portion of the colon which is usually the least severely involved.

Colectomy and resection of the sigmoid are emergency measures and should only be undertaken when all hope of relieving the ulcerated condition of the bowel has been given up. This point is reached only when the colon has undergone such marked structural change that it is simply a pus forming tube. Naturally, any such condition greatly increases the gravity of an operation which at best has a forbiddingly high mortality.

General hygienic measures must be adopted whether the patient be medical or surgical. A careful life, rest, sleep and fresh air will prove of benefit in this as in any other disease.

Statistics of improvements, cures and failures by the different methods advocated are of very doubtful value as there have been so far no consistently brilliant results from any one form of treatment. Yeomans, using only appendicostomy, cured approximately the same percentage of his surgical cases as those which he treated medically and constitutionally. He had one death in nine surgical cases. Logan using all types of operations claims no cures for surgery but reports many with marked improvement. His immediate surgical mortality was 11.8 per cent. but the variety of operations used was great and he had several colectomies. In his list Logan had seven cures in 38 patients treated medically, not by any means a brilliant showing but quite as good as any other reported series.

From this great amount of material we cannot help but feel the probable futility of much of it. However, lacking anything better we must make the best use possible of the means at hand. Whatever unanimity of opinion there is in regard to possible benefit from the various measures suggested would seem to justify our selecting as most valuable the following: Rectal and colonic irrigation except in very early cases can hardly be a method of any great value but should be made use of if the case can be diagnosed promptly. It represents the only means of treatment at hand for the general practitioner and for this reason can certainly not be ignored. Diet as prescribed by Bassler and whatever oral medication seems appropriate should be given a thorough

trial. The Einhorn tube, were it not for the natural hesitation one would feel in using it, is the soundest of the non-surgical procedures. It is difficult to see the value of the duodenal irrigation as advocated by Bassler which in regard to the colon can amount to but little more than irrigation of the large bowel with dilute small intestine contents. Drinking considerable quantities of salt solution or whatever the irrigating fluid might be would probably answer the same purpose. Autogenous vaccines should be tried as their administration is easy, they cause no discomfort to the patient and have been reported as giving beneficial results in some cases. Intravenous therapy wherever indicated should be adopted, particularly calcium chloride.

Of the surgical procedures, the Brown operation is undoubtedly the soundest from a physiological standpoint. Many patients would probably be much opposed to a fecal fistula even though assured of its ultimate closure and under such circumstances an appendicostomy or cecostomy would be the second choice. Colectomy would be justified under the rarest circumstances.

In conclusion we can say that:

(1) Since chronic ulcerative colitis is a disease of unknown etiology, its therapy cannot be definitely established beyond each individual case.

(2) Medical treatment should be instituted immediately the diagnosis is made; and should be continued only so long as the patient is deriving from it actual benefit.

(3) Physiological rest of the ulcerated bowel should be the aim of any surgical procedure adopted; and the more complete the rest obtained the better the possibility of a cure.

(4) If this is impossible the colon should be irrigated from above downwards through an opening in the appendix, caecum or terminal ilium. There is no peculiar virtue in any particular irrigating fluid.

(5) Due to the recurrent character of the disease, a case can be regarded as cured only after complete relief of symptoms for at least a period of one year.

(6) The prognosis should be an extremely guarded one.

## A CONSIDERATION OF SYMPTOMS AND HISTORY IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.\*

By DEAN B. COLE, M. D. Richmond, Va.

With a realization of the need of an accurate history in the diagnosis of pulmonary tuberculosis, and an appreciation of the needs of the busy practitioner, we will briefly consider the symptoms of pulmonary tuberculosis.

### LOCALIZING SYMPTOMS.

1. **COUGH** is frequently the earliest symptom of pulmonary tuberculosis and almost always occurs at some stage of the disease. Any cough lasting more than three weeks should be looked on with suspicion.

2. **EXPECTORATION**—As a rule expectoration is closely associated with cough but may occur independently, the sputum being raised by hawking or clearing of the throat. In the early stages of tuberculosis the sputum is usually slight in amount and is frequently raised only early in the morning.

3. **HEMOPTYSIS**—Any hemorrhage of a dram or more should be attributed to pulmonary tuberculosis until proven otherwise. A tentative diagnosis will do no harm and may be the salvation of the patient. From 80 to 90 per cent of pulmonary hemorrhages are caused by tuberculosis and most of the remainder by bronchiectasis, lung abscess, malignant diseases of the lungs, and various mycotic infections, all of which will be benefited by a tuberculosis regimen until definite diagnosis is made.

4. **PAINS**—Most tuberculous patients suffer from chest pains, either pleuritic or toxic, or both. Pleurisy is always a suspicious symptom and, if an effusion be present, the cause is almost always tuberculosis.

\*One of a series of lectures and demonstrations to a class of physicians in tuberculosis held under auspices of the Health Bureau, Department of Public Welfare, Richmond, Va., February 15, to April 15, 1923.

5. **HOARSENESS**—This is frequently the first intimation of the presence of pulmonary tuberculosis and may occur for years before other symptoms become manifest. It is most likely to be transient rather than persistent, and frequently is only present after prolonged use of the voice. A laryngological examination is important in these cases.

6. **DYSPNEA**—Shortness of breath is a common symptom among those suffering from pulmonary tuberculosis, and is sometimes the first symptom noticed by the patient. There are many factors that may cause this symptom, and for that reason dyspnea bears little relation to the amount of pulmonary involvement.

#### CONSTITUTIONAL SYMPTOMS.

1. **FEVER**—An afternoon rise in temperature of one to two degrees or even less should lead one to suspect tuberculosis as the cause. As a rule, rest in bed will cause a lowering or disappearance of fever, in the tuberculous, while exercise produces an elevation. However, temperature of pulmonary tuberculosis may resemble that of pneumonia, malaria, or even typhoid fever, depending on the stage of the disease, resistance of patient, complications, etc. To be of most value in diagnosis, readings should be taken at two hour intervals over a period of at least three days. Remember a normal or even temperature does not rule out tuberculosis.

2. **LOSS OF WEIGHT**—A gradual and progressive loss of weight is characteristic of tuberculosis.

3. **INTESTINAL SYMPTOMS**—Loss of appetite, indigestion, and epigastric fullness usually accompany loss of weight, but all or any may be independent of the others. Either constipation or diarrhea may be present. These symptoms may be present for months before others are complained of.

4. **ACCELERATION OF PULSE** may be the first symptom of tuberculosis. In these cases the differentiation between tuberculosis and thyroid disturbances is most difficult.

5. **NERVOUSNESS** is a most frequent symptom of pulmonary tuberculosis, and only too often is tuberculosis overlooked as the causative factor. Many so called nervous breakdowns are in reality manifest tuberculosis.

6. **SUPPRESSION OF THE MENSES** may be the

first tangible symptom of an oncoming tuberculosis.

#### HISTORY TAKING.

The following facts should be obtained as far as possible, it matters not whether you are taking an elaborate history or simply questioning your patient either before or after examining him.

1. **COMPLAINTS**—Ask patient why he came to the office. Without asking leading questions, see if the patient complains of any of the following: cough, expectoration, hemoptysis, loss of strength, pleurisy, indigestion, etc.

2. **FAMILY HISTORY**—Question patient closely as to whether or not there has been a death in the immediate family, and, if so, was the cause tuberculosis. Do not simply take the patient's word for cause of death, but question him regarding symptoms, cause of disease, etc., so as to be, as far as possible, sure in your own mind that it was not tuberculosis. Family history of this disease probably is not a great factor except in the immediate family of the patient, unless he has closely associated with some distant relative who had tuberculosis. Of course, in that case, it is a question of association and not family relationship.

3. **PAST HISTORY**—General health; work; when patient began work; type of work; environment; amount of rest patient gets; home conditions; whether or not married; children—how many; past diseases—measles, pertussis, typhoid—these are unquestionably the three most important: measles, due to the fact that it so frequently leaves lung complications; whooping cough, for somewhat the same reason; typhoid has no particular bearing on tuberculosis except that frequently the diagnosis of typhoid is made when the patient was simply suffering from tuberculosis, and a period of weeks in bed was sufficient for the patient to temporarily recover. On the other hand, occasionally a case of typhoid is diagnosed tuberculosis. General questions on the circulatory system—as palpitation of the heart, dyspnea; on gastro-intestinal system—as to appetite, bowels, etc., should always be asked, and any suggestive symptoms should be closely followed up. Of course, questions on the nervous system and the genito-urinary system should not be overlooked, even in a patient known to be suffering from tuberculosis any more than in any other patient.

**HABITS**—The habits of the patient are most important and are frequently overlooked. Questions relating to the use of alcohol, drugs, and excesses of all kinds should be asked.

**EXPOSURE TO TUBERCULOSIS**—Has there been any intimate exposure? If so, when, and for how long?

**PRESENT ILLNESS**—Here we are trying to determine the onset of the disease. When were you last perfectly well; the illness began how and when; acute or gradual? Try to ascertain if illness began with any of the following: cold, gripe, pleurisy, hemoptysis, fever, or simply with fatigue and loss of strength. This is determined in order that we may classify onset of disease under one of the following: *Insidious*—in which the patient complains of fatigue, lack of endurance, as probably the earliest symptoms, and gradually develops other symptoms over a period of months, or perhaps a year or more. *Catarrhal*—here the usual onset is a cold, so-called bronchitis which, in reality, is simply tuberculosis manifesting itself in this way. *Hemoptotic*—here we have frank hemorrhage manifesting itself as the first symptom. In many cases, of course, patient had symptoms but never realized it until after he had had his hemorrhage. *Pleuritic*—here the onset is with pleurisy and frequently pleurisy with effusion, sometimes following pneumonia. *Febrile*—This type is less frequent, and not infrequently the patient comes to the doctor suffering from some condition other than tuberculosis and the physician discovers that the patient has been running a temperature that he cannot account for, and this leads to a diagnosis of tuberculosis. Of course, there are many other ways in which temperatures are discovered, and in an effort to discover the cause the diagnosis of tuberculosis is made.

"It is no exaggeration to state that from the history alone the vast majority of cases of early tuberculosis can be recognized definitely, or at least the presence of the disease can be strongly suspected."\*

## DIET IN TUBERCULOSIS.

By H. R. EDWARDS, M. D., Richmond, Va.

Clinician, Bureau of Tuberculosis Education, State Board of Health.

If there is one thing in particular that has

been neglected in the treatment of diseases, it is diet. Tuberculosis is no exception to this rule; in fact, we might even say that the diet for tuberculous patients has not only been neglected but abused as well. This abuse, which was intended to accomplish much good, was the result of an accepted theory regarding its treatment. In consumption there is a great wasting away of tissue and, because of this fact, it was thought that a heavy diet, consisting usually of excessive amounts of protein, would correct this condition by replacing the lost tissue. Our ideas, however, have changed quite materially in the therapy and diet of tuberculosis and rest is now considered the first essential in its treatment. With this thought in mind, I shall try to show how the best results may be obtained by a properly regulated diet.

Diet, for the normal man as well as for those suffering from disease, has been given very little attention in the past and we have only to look about us to see the results of such carelessness. The digestive apparatus of the average American has some impairment or definite loss of function. Rheumatism, arteriosclerosis and many other diseases are traceable to a faulty diet. There is no land on the globe that has the great variety of food that we have from which to select and none could have a more perfect diet. The lack of interest, almost utter indifference to the whole subject, seems to arise from the very fact that our food resources are so abundant. Also, many of the foods that we do use are spoiled in preparation, to say nothing of the vital elements that are wasted by boiling and discarding the juices.

It was found at the Phipps Institute in Philadelphia, that 80% of tuberculous patients showed some impairment of kidney function. A less percentage showed definite tuberculous involvement. We know that the kidneys are one of the most important excretory organs of the body and any impairment of their function is sure to have an effect on the elimination of poisons that are so numerous in tuberculosis. The unusually high protein diet, generally used in the treatment of this disease, is a direct tax on the excretory organs and also has a definite relation to the metabolic rate, of which I will speak later. The liver is another vital organ for the excretion of waste products and we find it also very often impaired in function.

I am sure that you are all aware of the experiments with low protein diets that were made some years ago by Chittenden of the Yale Scientific School. He selected several professors, college athletes and a group of soldiers, loaned by the Government for this purpose. From the experiments, which were conducted over a period of several months, he found that less than half the accepted amount of protein is sufficient to keep the body in vigorous activity and good health. Such experiments have been repeated many times since and the accuracy of Chittenden's findings, proven beyond a doubt. We only need to observe the Chinese coolie to understand that high protein is not essential to endurance. Those men run for hours throughout the day with their rickshaw loads and never tire. The same is true of the natives of India. They run for miles without ever tiring and their diet is essentially a very low protein one. The Japanese soldiers out-marched any others during the Russo-Japanese War and their diet is noticeably low in protein, meat being eaten only occasionally.

Dr. R. A. Kocher reported in the *California State Journal of Medicine* some metabolism studies that he had made on pulmonary tuberculosis at Trudeau Sanatorium, Saranac Lake, New York. In brief, his conclusions were as follows: In fifteen cases of afebrile pulmonary tuberculosis, eight of which showed active lesions, the metabolism was basal, that is, within a few per cent above or below the average normal. On two patients the effect of giving a meal of 400 grams of lean beef was determined.

The metabolism was raised 25 to 30 per cent, due to the so-called specific dynamic action of the protein. The effect of a high caloric diet on the rate and depth of respiration was determined. A mixed meal of one thousand calories increased the ventilation of the lungs, measured as minute volume, 18 to 20 per cent. These facts prove that a high caloric or a high protein diet have the same effect as muscular work on the patient and, as rest is the chief factor in the treatment of tuberculosis, we defeat our purpose when we feed excessive amounts of protein, thus greatly overtaxing the lungs; the very organs that we are most anxious to have at rest. Janney and Newell have shown that cases of pulmonary tuberculosis complicated by diabetes, or *vice versa*, are favorably influenced by the state of under-

nutrition resulting from a rigid adherence to the proper diabetic diet.

To quote further from the experiments of Kocher at Trudeau, with relation to the creatinin co-efficient, we find that four subjects were selected and the creatinin co-efficient was studied, first on a low, then later on a high protein diet, over an extended period; starting from early convalescence, when the patients had just completed the bed rest, through a period of moderate exercise. At the time muscular activity began, the creatinin co-efficient was uniformly low. With the increase in weight, the co-efficient was practically stationary or even decreased on a low protein diet, where there was a substantial gain in weight. It is plainly evident that the gain in weight was a gain in adipose and not in muscular tissue. During the period on a high protein diet, when the patients were on moderate exercise, there was a very decided rise in creatinin co-efficient in every case. This showed that there had been a nitrogen retention and synthesis of new protein, or active functioning in muscular tissue. We have then, in creatinin estimation, a simple means of determining, at any time, whether a patient is making a substantial, or only a spurious gain. The creatinin output is the index of the functional efficiency of the body. We learn from these facts that superfluous fat merely adds to the metabolic rate and respiratory rate without adding to the functional efficiency of the organism.

Uhldom claims that passive congestion of the liver is found in nearly every case of tuberculosis. This, of course, is a result of diminished respiratory function which, he says, is brought about by the fact that the venous circulation of the liver is influenced largely by the movements of the diaphragm and he claims that it is possible to have this movement diminished and yet have more rapid respirations.

Dr. Lawrason Brown warns against high protein diets, claiming that they do not lead to permanent results and success and are likely to give rise to toxic action of the liver and kidneys. Again, he has shown that a diminished alkalinity of the blood stream does not favor the healing process and this condition is brought about by using high protein dietaries, especially those with an excess of meats.

Degeneration of the thyroid gland, concurrent kidney diseases, disease of the adrenals, all show some relation to the tuberculous pro-

cess and the foods ingested. We should understand then, that the diet in tuberculosis should be given careful thought and attention and, if we wish to save the body as much energy as is possible and facilitate the healing process, we must use every precaution to eliminate anything that will tax the system unnecessarily. Care should be given to the teeth as it has been found that many of the cases that have been starved of lime for long periods are those that have very poor teeth; consequently, the powers of mastication are impaired, resulting in poor digestion. The digestion of proteins is mostly in the stomach and the action of the ferments found there is greatly enhanced by the presence of some alkali like that which is found in the saliva.

Attention should be given to the intestinal tract. The intestinal flora is of such a character that putrefaction is inevitable if this organ of elimination is neglected. It is not necessary to go into detail to prove how injurious such neglect may be to the entire system. Buttermilk prepared with *B. Acidophilus* will help greatly to correct any condition of the intestinal flora that may result from such carelessness. This will also often relieve much of the constipation that exists in this disease which is, of course, a direct menace to the progress of the case.

Now that we know what may be expected of the ordinary case of pulmonary tuberculosis (which may be summarized generally as impaired organs for the elimination of waste products, caused by the foods ingested) we should understand that the course which should be followed in diet is to use only the minimum amount of food and especially a restricted protein dietary. The diet of our sanatoria throughout the country is all, more or less, at fault in this respect; though many are showing some progress by discontinuing the usual nourishment between meals. Most patients are firmly convinced that they must eat large portions of meats, eggs, and milk in order to get well. This is not true but it will require much time and education to change such erroneous ideas. Many of them do not feel that they are making any progress unless they are gaining a considerable amount in weight. It is well, of course, to gain a certain amount but excessive weight is burdensome besides being a hindrance to the success of the cure. It is far better to gain slowly, at the same time gain-

ing strength, than to gain large amounts of adipose tissue and no strength. An effort should be made to gain from about five to ten pounds in excess of a patient's usual weight, not the estimated weight for height and age. Always remember that high caloric value of foods increases the metabolic rate, consequently increasing the respiratory rate with a lessened amount of rest to the diseased lung, the very thing about which we are most concerned.

Too much care cannot be given to the amount of protein used in the diet for tuberculosis. It should be rich in fats and carbohydrates, vitamins, iron and lime, a minimum amount of protein with sufficient bulk to insure two bowel movements a day. During the active stages of the disease, when there is a great body loss, more protein should be fed than later when the disease is arrested, but this should never be in excessive amounts as is now practiced so freely. If it were possible to obtain and prepare the protein for this purpose without using meats, we would make another great advance in this most important branch of tuberculosis therapy.

Some of the advantages of a vegetable, over a flesh protein dietary are as follows: vegetables do not readily undergo putrefaction and decomposition. Flesh proteins contain a great amount of toxin that is present from the usual metabolism going on in the body of the animal at the time it is butchered and putrefactive, as well as other organisms are allowed to grow to enormous amounts. These affect the intestinal flora and favor auto-intoxication. However, at this time, it is not possible to change from one to the other in the ordinary home or many of our sanatoria because they are not prepared to offer proper substitutes: not that we lack such materials but the majority of people are not educated in their use and selection. It is needless to say that whatever protein we do use should be in as small amounts as possible. An increased amount, as is customary, involves grave dangers to the patient by decreasing his vital resistance and imposing unnecessary burdens on the excretory organs which are already overtaxed and often seriously crippled. Men who have been associated with this work for many years have given us definite evidence that patients receiving high protein diets do not make the best progress. The additional toxins that result from excessive amounts of protein, together with those of the

tubercle bacillus, materially handicap the healing ability of the blood stream by reducing the alkalinity of this fluid.

We shall now consider, more in detail, some of the various food principles that are necessary to the normal organism as well as to the diseased one. As a rule, only a slight change in the amounts is necessary to adapt them to all conditions.

During the stage when the patient is having active symptoms, the diet should be of a different character than when the case is quiescent and the patient is exercising. Three meals a day are usually quite sufficient but, if the digestion is impaired greatly, it will be found necessary to feed oftener. Foods requiring little effort on the part of the body to assimilate them are the most advisable. While in the arrested stages, the diet may be largely that of the normal person, the meals should have as much variety as possible and should be spaced about five hours apart. If the patient is forbidden food between meals, his appetite will be more acute at the regular meal time and he will doubtless eat more than he otherwise would. From observation, I have found it most interesting to note that very often the case that complains of a loss of appetite is one that is gaining steadily; making it very evident that, previous to that time, he or she had been eating too much. This has been a great help in preaching the principle of a low protein diet, because the patient unconsciously proves to himself the disadvantages of over-eating.

McCann and Barr, of the Russell Sage Foundation at Bellevue Hospital Medical College of New York, have shown in their metabolism studies of pulmonary tuberculosis that the amount of food required by the consumptive need not be more than 20 to 25 per cent above that which is required for a normal person, about 500 calories above that required when at rest.

Much of the natural salts, as iron and lime, are lost in our modern methods of cooking. This is largely due to boiling vegetables and throwing away the water which has absorbed a large proportion of these most vital elements. We know that in the healing process of the most favorable cases much calcium is deposited in the tubercles. The usual diet for ordinary needs is, as a rule, low in calcium and this is greatly decreased when an extra amount is re-

quired for deposition in the tubercles. Milk which contains much lime and should be used freely, together with greens, buttermilk, whole wheat breads, cottage cheese and soy beans, contain 99% of the day's supply of calcium. Meats, as a whole, are deficient in this salt element.

In a man weighing 150 lbs., we find 1 oz. of iron and there is a loss of about 1/7 of a grain of iron each day in the usual functioning of the body. As we know, this important element is needed to make hemoglobin, without which bodily activity could not continue. It is not possible to take this iron into the system in the form of inorganic iron and it has been found that the usual medicaments containing such iron are not as easily assimilated as they were thought to have been, so the chief amount of this iron must be supplied by foods and taken into the system through organic action. In tuberculosis, where there is lessened space in the lungs for the exchange of gases, it is most important to have the highest number of red cells possible to facilitate the combination of CO<sub>2</sub> with oxygen. Natural food stuffs contain this iron in the best form and the one that can be absorbed easiest. When we consider the amount of iron, or percentage of the day's ration, contained in one ounce of material, we find that the legumes (averaging 11.35) produce more than we get from any other source. Greens contain 4.29, cereals 3.9, nuts 3.49, eggs 5.67, fruits 1.74, vegetables 1.46, milk products 1.05, and milk .47, or less than half of one per cent of the daily requirement. Considering the per cent of iron per 100 calories of food, we find that greens come first with 46.4, then meats with 15.6, legumes 13.7, vegetables 10.4, fruits 5.6, cereals 4.3, nuts 2.67, and lastly eggs 1.36.

There is not much use of elaborating on the vitamins in general. We know that there are three chief varieties; the fat soluble "A," which has to do chiefly with growth; water soluble "B," or the one that gives rise to beriberi; water soluble "C," or the antiscorbutic vitamin. Boiling and baking damages these vitamins, so, to insure the proper amount of them in the dietary, a certain amount of raw food stuffs should be eaten each day. In general, fats and oils are rich in the fat soluble "A" and almost nil in the other vitamins. Meats, fish and milk products are more or less divided equally among the three vitamins and cereals

and vegetables have the greatest amount of the antiscorbutic factors. Alkalies destroy vitamins as does the high milling of cereals. Antiscorbutic factors are damaged at the usual temperature of pasteurization of milk. New processed corn meal is deficient in this respect and, to a certain extent, may be the cause of pellagra, for this disease is not found in mountainous regions where the farmers are still grinding their grain on the old burr mills, thus preserving the outer coating of the grain which contains a liberal supply of vitamins. The tomato is perhaps the best single source of vitamins that we have, for it contains all three varieties; therefore, it should be used extensively. The acid is not injurious as it was once thought to be. The potash salts, of which it contains more than most fruits and many other vegetables, tend to alkalinize the blood stream.

Cereals, which are one of the most important sources of foods, have been used for ages but, like many other foods, have suffered much at the hands of modern methods of preparation; for instance, rice is polished, destroying the outer coating and, when eaten alone, is apt to cause a deficiency disease as beriberi. Wheat and other cereals are highly milled, removing the outer coating and destroying the part that contains the salts and life-giving properties. The Scotch use oats as a cereal almost exclusively. They consider scalding the proper method of cooking this grain and, because of this, none of the nutritious elements are lost in preparation. This, together with their buttermilk, has made them a very healthy race of people. We should profit by this knowledge and cultivate a greater liking for such simple foods. The protein of cereals is very good and easily digestible. More whole wheat bread, which contains much bran, would eradicate much of our constipation.

Vegetables are used far too little in the national dietary and we should eat more of them than is customary. The white potato, which is used far too little, is a valuable source of food. The majority of uncooked vegetables should be put through some sort of cleansing process before being used as they are often contaminated by many kinds of bacteria. The taste or quality of the food is not affected by using a weak solution of lye or hydrogen peroxide. Vegetables contain mostly water and their chief use is to supply carbohydrates,

alkaline salts, vitamins and cellulose. Starch is the basic substance of the carbohydrates and, in this form, is most easy to assimilate.

Legumes are very rich in lime, iron and vitamins. The protein in them is inferior in quality to that which is found in meats, milk, eggs, cereals, potatoes and nuts. The soy bean is not included in this category for its protein is of a high quality. Perhaps the reason for the difficulty in digesting them lies in the fact that they are not carefully chewed before swallowing and the close network of cellulose, enclosing the protein substance, is not acted upon in the stomach but in the intestines. These beans should be cooked quickly, instead of over long periods, and this is more easily done with superheated steam than by other methods.

It is hardly necessary to say much about fruits. They are one of the most readily absorbed forms of food and are rich in vitamins and salts with starch and small amounts of protein, of which the apple contains most and, when sufficiently ripened, requires practically no digestion whatever. They are most valuable for cases that are unable to take much solid food. Fruit juices should be used frequently. The acid of fruits, which has been thought detrimental to our balance of alkali and acid in the body, has been proven to be very valuable in alkalizing the blood.

Nuts are used more as a dessert but, as they are rich in excellent protein, fats and mineral salts, their great food value should be recognized and their use made more common. One pound of walnut meat is equal in food value to from three to twenty-five times as much as any other food or meat except nuts. An almond milk can be prepared by grinding the meats and slowly emulsifying them with water to the consistency of milk. This closely rivals cows' milk and is a good substitute to use for the cases requiring this form of nourishment that have tired of the cows' milk.

Animal foods are considered the chief constituent of our daily diet and it is needless to say that they have been used far in excess of their requirement. Plants are food producers and animals are food users. I have mentioned before that, at this time, it is not advisable to swing from a meat to a strict vegetarian diet, but it is my thought to promote and encourage a much lessened meat diet than that to which we are accustomed at the present time. Meat is chiefly protein in nature and practically all of

it is absorbed but, as the body can handle only a certain proportion of this, the excess is a direct poison to the system which the kidneys and liver must eliminate. We have already seen how greatly over-worked those organs are and we know that they should be saved all unnecessary effort possible. Beef, mutton, fish and fowl are all quite easily digested and, when used as the sole source of protein, their daily requirement, for the average individual, is about one to two ounces.

Animal products, such as milk, eggs and butter, have been considered for ages some of our chief sources of food supply. In milk we have an almost complete protein. Vitamines, organic salts and so forth are there in abundance. This protein is of excellent quality and is more easily absorbed than any other. If taken with vegetables and cereals, we have no need for further food articles. The lime content is higher in milk than in any other single food element. Cottage cheese, buttermilk and similar products furnish not only a good grade of protein but also help to acidify the intestinal flora which is usually teeming with putrefactive bacteria that are apt to lead to many ills. Milk and eggs furnish an excellent form of nourishment for the case that has poor digestion and requires frequent feedings. The whites of eggs are more digestible when only slightly coagulated (as in poached eggs) but the yolk should be thoroughly cooked. Milk is intended to be a perfect food, that is, it has the various elements necessary for the life of the young. It is not necessary to mention that milk should be obtained from tuberculin-tested cattle and, if the bacterial count is very high, it should be pasteurized before using.

In conclusion then, we would say that the diet in tuberculosis should be that of a low protein ration in general and that the protein which is used should be preferably that which is found in milk, vegetables, eggs and fruits; using only as little meat as is absolutely necessary. Increased ingestion of proteins, or high caloric diets, increases the basal metabolic rate of the body with a consequent increased respiration, giving more work to the lungs which are the very organs that we are most anxious to save any unnecessary labor. It also gives extra work to the excretory organs, as the kidneys and liver, causing definite impairment of function in a large majority of cases.

## NERVOUS, MENTAL AND ENDOCRINE MANIFESTATIONS IN MENOPAUSE.\*

By HOWARD R. MASTERS, M. D., Richmond Va.

Instructor in Nervous and Mental Diseases.  
Medical College of Virginia.

The normal menopause, or "third phase of life," is accompanied by a train of annoying symptoms that are well known, yet there are a number of cases which become pathologic, possessing varied nervous, mental and endocrine conditions which not infrequently enshroud the approaching change in such a manner that diagnosis is difficult.

The age limit of occurrence may be said, generally speaking, to be between thirty-five and fifty-five; about fifty per cent. taking place between forty-five and fifty, twenty-five per cent. between forty and forty-five and most of the remaining twenty-five per cent. above and below the limit given. One often encounters menopause occurring early in life and, on inquiring into the family history, finds the condition to be familial. Less frequently the onset takes place after the age of fifty-five. It must not be overlooked that artificial menopause from partial or total oophorectomy bears the same marks as that of physiological menopause and should be included. The average age of the true climacterium according to Sanes<sup>1</sup> in an analysis of the literature from thirty-two nations, is 47.1 years.

Concerning the physiology of the ovary, we believe that there are at least two internal secretions, one the corpus luteum derived from the Graafian follicles after their rupture, the other the interstitial secretion derived from the interstitial cells. However, the exact chemical substance or active principle, according to Vincent<sup>2</sup>, like that of iodine from the thyroid and epinephrin from the adrenals, is unknown. It is probable, as suggested by Gustave Bond, that corpus luteum contributes to the fixation of the impregnated ovum and the experimental work of Marshall and Jolly<sup>3</sup> would seem to confirm this. These investigators extirpated the ovaries of dogs known to be pregnant and in every case but one pregnancy was discontinued. It is also said that injection of corpus luteum inhibits ovulation. The general view now held by most writers is that the interstitial cells control the nutrition of the reproductive organs and contri-

Read before the Richmond Academy of Medicine and Surgery, June 12, 1923.

bute to the development of the secondary sex characteristics. Experimental castration tends to bear out this statement.

I have ventured to call your attention to the normal function of the ovaries and mention several facts concerning the interruption of this function. Such an interruption is evidenced by the approach of menopause and by the castration of women. A dysfunction of the ovaries is brought about by the menopause. Should pathological conditions exist, the organisms fail to respond, or should it become over-active, then certain syndromes follow unless there is a physiological adjustment.

While the symptoms of the various types of menopause over-lap there are certain syndromes which are outstanding and suggest to us the following classification:

**I. NORMAL PHYSIOLOGICAL MENOPAUSE.** The onset of this class occurs between the ages of forty-four and forty-seven with gradual decrease in menstrual flow until cessation. Next in order of frequency are the vasomotor symptoms which usually come on shortly before permanent amenorrhoea is established. These consist of hot flushes, sweating, faintness, vertigo, "crawling sensations," cold clammy feet and hands and epistaxis. Intestinal symptoms are not uncommon. Emotional upsets and apprehension are frequent. This type usually has a good physical status and has been a stable individual throughout her life, possesses a strong resistance and is able to throw off untoward symptoms. The degree of intensity of the manifestations varies, and a number of women pass through this phase almost unmolested. Increase in body weight, atrophic and fibrous changes and gland cell obliteration mark the close of menopause and the beginning of the senile era. Little or no treatment is needed.

**II. CASTRATES—PARTIAL AND COMPLETE.** Artificial menopause is usually produced between the ages of twenty and forty-five on account of the existence of some functional or organic surgical condition. Most frequently it is followed by a period in which there is an amelioration of the patient's symptoms after which the onset of the menopause syndrome is very sudden and accompanied by various physical, nervous, mental and endocrine upsets. Menstruation stops completely except in cases where the uterus and an ovary, or part of an ovary, are left intact. The usual

menopause symptoms are somewhat exaggerated. General or localized obesity begins, the skin becomes smooth and soft, frequently losing much of its pigment, and the growth of the head hair may become luxuriant. In the younger individuals there is often a change in personality. They become "flashy" in their dress, loud, talkative, silly and appear to be more easily attracted by their opposite sex. Vincent states that after castration there may be a temporary increase in sexual desire. The change in personality is somewhat similar to the precocity of adolescence and may be due to endocrine imbalance. Atrophic changes of the genital organs and mammary gland usually follow, though the latter occasionally hypertrophy, a condition often confused with obesity of the breasts. It is said that an increase in the growth of hair on the face and other portions of the body takes place; however, this may be evidence of adrenal involvement. Male secondary characteristics may develop especially during senility, numerous cases having been reported.<sup>4</sup>

**III. NERVOUS SYMPTOMS ASSOCIATED WITH MENOPAUSE.** It may be said that the greatest percentage fall under this class. The principal symptoms complained of are tachycardia or bradycardia, headache, vertigo, insomnia, irritability, tremors, functionally exaggerated reflexes and paresthesias, of which numbness and tingling are most common, and not infrequently pruritus. The vasomotor disturbances probably have a close relationship to the nervous manifestations, especially the paresthesias. The mechanism is probably through the sympathetic nerves of the arterioles and the capillary reflex arcs.\*<sup>5</sup>

**IV. MENTAL SYMPTOMS ASSOCIATED WITH MENOPAUSE.** A number of climacteric cases show mental symptoms, while in the neighborhood of thirty to forty per cent. have psychic manifestations of a milder degree and will be discussed in a later paragraph. In some of our series definite psychoses have been noted. Mental symptoms such as depression, excitement, visual and auditory hallucinations, delusions of persecution, sense of unworthiness, suicidal tendencies, violence and maniacal states have been observed. Those cases showing psychic changes often have apprehension, phobias, emotionality, instability, are self

\*Wright believes that on stroking the skin lightly a white line appears, while deeper pressure brings forth a red line. This phenomenon is analogous to the vasomotor flushings and blanching but being produced by local stimulation and is due to the degree of stimulation of the capillaries.

centered, anxious and possess what are termed "envies," or "inclinations" similar to those occurring during pregnancy. The lack of gratification of these inclinations sometimes leads to anxiety states. A thorough investigation of the patient's past mental history, family history and psychic stability is all important. Some cases have had recurrent depressive psychosis, some mixed manic psychosis, and others anxiety and varied psychotic states previously, and it is in these cases we feel that menopause is contributory only as an exciting cause. The patient possibly has a lowered resistance and generally has a psychotic constitutional or hereditary make-up. Mental disturbances associated with menopause sometimes clear up in a relatively shorter time than true psychoses.

V. ENDOCRINE DISTURBANCE ASSOCIATED WITH MENOPAUSE. Since we have concluded that the ovary is an organ of internal secretion which is essential to the body, we must further conclude that all menopause cases become endocrinous because of the withdrawal of the ovarian secretion. Atrophic changes of the gland begin to take place, menstruation slows down and finally permanent amenorrhoea is established. E. Novak<sup>6</sup> states that not infrequently is there an increase in menstrual flow during climacterium associated with endometrial hyperplasia and probably due to hypersecretion of the ovary, even in the demonstrable absence of anatomic diseases. The writer believes that this functional bleeding may be greatly influenced by increased activity of the anterior lobe of the pituitary or a hyposecretion of the thyroid gland which is secondary to ovarian hypofunction. Atrophy of the external genitalia, the uterus and at times the breasts, are other signs of ovarian deficiency. Atrophy of the ovaries, sclerosis or cystic formation may take place. On the other hand obesity changes are observed and may be general or localized. Abdominal obesity and trochanter padding are attributed to ovarian hypofunction while other types are said to indicate involvement of the pituitary or thyroid. This increase in fat is in all probability due to lowered metabolism. The body hair is often scant and pigments may be lessened. The patient is frequently languid, sluggish and drowsy.

There seem to be secondary changes, especially in the pituitary, thyroid and adrenal glands during and following menopause.

Tucker tells me that he has observed certain acromegalic changes such as enlargement of the superior maxillae, clubbing of the fingers, broadening of the hands, etc., in some of these cases and in 1917 Emil Goetsch<sup>7</sup> mentioned that definite hypertrophy of the pituitary gland and enlargement of the sella turcica followed castration both in the humans and other animals. In other cases hyposecretion of the posterior lobe of the pituitary is evidenced by the obesity of the breast girdle and flank padding and increase in the size of the extremities, sparse body hair distribution, scanty perspiration, decreased involuntary muscle tone, subnormal blood pressure, temperature and pulse rate and lowered metabolism.

Thyroid involvement is frequently associated with menopause changes, the characteristic hypothyroid features being dry, scaly skin, slow pulse, low blood pressure, obesity about the face, chin and neck and dry hair. These patients are sluggish and complain of constipation. This type occurs more frequently between the ages of from forty-five to fifty-five in contrast to those who show hyperthyroid symptoms in which the onset of menopause is between thirty-five and forty-five. In the cases of over-secretion of the thyroid, obesity is usually absent, the patient is slender, the pulse rapid, perspiration free, vasomotor symptoms exaggerated, tremors in evidence, and nervous manifestations such as irritability, restlessness and phobias are present. Here we not infrequently find foci of infection as a contributory cause. The blood pressure may be elevated.

Association of adrenal involvement is not uncommon. Low blood pressure, increased pigments, increase in face and body hair and asthenia are said to be indications of hypoadrenalism. This condition is sometimes accompanied by mild depressive phases. Increased blood pressure, irritability and nervousness are evidences of hyperadrenalism. We have noticed that in some of our menopause cases with hypertension the administration of ovarian extracts caused a definite lowering of the pressure. Other organic causes contributing to the elevation of the blood pressure should be eliminated before attributing the rise to increased adrenal secretion.

VI. GENERAL PATHOLOGICAL CONDITIONS ASSOCIATED WITH MENOPAUSE. The physical

condition of the patient at the onset of menopause is important and apparently bears a close relationship to the difficulty that is encountered by the individual in passing through the "third phase of life." Focal infection, whether it be teeth, tonsils, fistulae, or what not, seems to contribute largely to the involvement of endocrine system, urinary system and joint conditions. Hyperthyroidism and hypoadrenalism not infrequently follow infected teeth and tonsils. Other causes which tend to lower the resistance are cardio-vascular diseases, and chronic pelvic conditions, especially those of inflammation. With a lowered resistance, a fertile field is produced and the individual is susceptible to almost any disease. It is here that we must not overlook the fact that the close of the menopause marks the beginning of senility. Elimination and treatment of diseased conditions during this period seem to be an ideal time to attempt prevention of the infirmities of old age.

The prognosis of menopause cases, where organic diseases have been excluded, may be said to be good. Seventy to eighty per cent. of these recover, becoming stable and useful women. With castrates the outlook is less encouraging. They continue to be nervous, have vasomotor symptoms and the onset of pathological conditions is difficult to ward off. Those with nervous manifestations can be controlled to a great extent. In those who have a mental disturbance there is a tendency to recurrence or a continuation of the psychic instability with the development of a psycho-neurosis, and recovery in most cases is slow. Those showing definite endocrine conditions improve greatly while the doubtful ones respond poorly. Symptoms of organic conditions may be alleviated to a moderate degree but in many cases are not especially satisfactory.

Specific organo-therapy is of great value and should be used in those cases experiencing any difficulty. It is particularly useful in the amelioration of vasomotor symptoms. Good results have been obtained from the use of corpus luteum, whole ovarian extract and ovarian residue. It is difficult to suggest the dosage because of the lack of standardization by the various manufacturers. The usual amount given represents five grains of the dried extract administered three or four times daily. The extracts may be obtained in tablet and capsule form and a soluble extract in

ampules for hypodermic injection. In our hands we have obtained the best results with the use of one ampule of the soluble ovarian extract given hypodermically three times a week, or daily, for a period of two to six weeks and followed by the extract in tablet form, five grains three times a day, over a period of one to three months, or longer when indicated. In cases where prolonged dosage is necessary, it is well to give the extract on alternating weeks or months, other symptoms being treated according to their nature. In many cases the use of ovarian extracts is surprising and usually very gratifying.

#### NUTRITION AND LIFE.\*

By. LAWRENCE T. ROYSTER, M. D., Norfolk, Va.

You have honored me with an invitation to address you this evening. I have accepted because of my appreciation of the honor; because I hold the practitioners of orthodontia in high esteem and because I think the medical and dental professions should work in close and cordial co-operation.

The strides which have been made in medical and allied sciences in the past twenty-five years well-nigh stagger our sensibilities when we make even a casual survey of the progress of this period; in fact, the panorama is now passing before our eyes with such amazing rapidity that no man can maintain even the most superficial acquaintance with all the branches, and must of necessity restrict his reading to more or less narrow lines and con-

\*Delivered before The Eastern Association of Graduates of the Angle School of Orthodontia, at Norfolk, Va., March 24, 1923.

concentrate his efforts to a limited field. If we consider this discovery as prophetic, it requires no stretch of the imagination to see that the medical student of the near future must determine at some time during his college course which branch of the profession he will follow, and complete his course with that end in view.

For example, he must determine before graduation whether he will choose internal medicine, surgery, obstetrics, pediatrics or dentistry, with its subdivisions, oral hygiene, oral surgery or orthodontia. You will notice of course that I have placed dentistry in the curriculum of medicine, and this is as it should be.

Whatever branch of the healing art, with its prophylactic, corrective or curative phases, is chosen, an intimate knowledge of the fundamental sciences is absolutely essential to the production of the highest type of professional man.

This vast increase of knowledge with a consequent diversity of interest has developed the specialist, highly trained and exceptionally proficient in a more or less limited field, with the result that all specialties are dependent on each other. Out of this condition has arisen the popular group practice so familiar to us today. Whether group practice is conducted by a number of men closely associated through business affiliation, or whether the opinion of several different men, not actually associated, is sought in the diagnosis of a single case, the effect is the same. Regardless of how well specialized one's knowledge and experience may be, it is necessary that there be the same training in the fundamentals and sufficient understanding of the work of the consultant, in order that his findings may be interpreted intelligently.

But let us bear in mind that specialism is apt to narrow vision as well as activity. Are we not apt to become so intent on the problem, whether it be diagnosis or cure, that we lose sight of the relation of the immediate condition to the individual, and in turn, the individual to society? Are we not apt to content ourselves with the relief or amelioration of the acute condition and forget to consider the future carrying-on power of the patient?

The specialty which requires the broadest vision of life is, perhaps, pediatrics. Not pediatrics as usually defined as "the study and

treatment of disease as manifested in children," but rather a much broader conception—the making of the best possible citizen out of the material as it comes to us during childhood. Diagnosis and treatment of acute conditions alone is not sufficient. To be sure we must treat and aid in the cure of acute disease and save life, and this must be our immediate care; but do we fulfill our duty if we discharge the patient at this point? Most assuredly not! Have we determined what bearing the acute condition has on the future health and earning capacity of the patient? Have we taken advantage of the opportunity thus afforded for a thorough examination with a view to determining his state of nutrition, mental status, condition of tonsils, whether teeth are decayed or maloccluded, and in fact everything which may in any way affect the future of the patient? If we have not done this we have failed in our duty.

Pediatrics, then, in this broad sense is not limited to the pediatrician, but must include the obstetrician, who cares for the child *in utero* through its mother; the family physician, who of necessity treats a majority of the children, and observes the health of the other members of the family which may in turn affect that of the child; the surgeon who operates for an abdominal infection or a hernia; the orthopedist who corrects deformities, thereby making a self-supporting individual out of one who might otherwise become a crippled dependent; the orthodontist, who corrects malocclusions, thus not only preventing early loss of teeth through disuse, but also changing a repulsive countenance into a pleasing one, an important economic factor.

I have said that the pediatrician should concern himself with making the best possible citizen out of the material as it comes to him during childhood. The importance of this phrase must be stressed. According to the laws of biology and heredity, all the possibilities of the adult structure are inherent in the cell at the moment of fructification. Heritable factors we cannot alter but nutrition, on which their development depends, we can control.

The newer knowledge of the chemical composition of food and its relation to the animal economy and the results produced by intelligent application of this knowledge may in truth be termed the "science of nutrition," while the employment of the recently discov-

cred vitamins in promoting growth and development and in correcting abnormal states suggests the term "wizardry of nutrition."

When we observe cases of rickets developed in breast-fed infants, who have been reared in an unsanitary environment and suckled by a mother whose food has been poor in certain food elements, or more frequently, an infant fed artificially on a food poor in these elements, and see this child gradually overcome the rachitic deformity through either the application of sunlight, or the administration of cod-liver oil, or more quickly by both; when we see an infant, who has been fed on condensed milk, or certain dry products high in carbohydrate and poor in fat and protein content, or an insufficient supply of cow's milk, swollen, tender and racked with the pain of scurvy, relieved by the administration of the juice of a few oranges; when we see the symptom complex known as pellagra, with its eruption, wasting, diarrhea and mental disturbance, change from a state of apparent hopelessness to one of comfort and happiness through the administration of a well-balanced ration, particularly one rich in protein; or a pitiful and helpless neuritic of the beri-beri type restored to usefulness and contentment through the administration of the polishings of rice; or again witness the cure of a xerophthalmia (formerly considered infectious) through the administration of a small amount of cod-liver oil, we are almost convinced that the day of miracles has not passed or that necromancy has returned.

Or let us observe the malnourished school child, that child who is fidgety, unable to concentrate, who becomes easily fatigued, is fractious and impatient under restraint, cross with his companions at play, and lags behind in school work, and with all is considerably below the average weight for his age and height; or that other child who has a peculiar temperament and in whom we recognize there is something wrong, though nothing tangible is present except perhaps decayed or irregularly shaped teeth to point to a malnourished state in the past. It is most interesting to see these children change into perfectly normal ones in a remarkably short time through the prescribing of a rationally balanced diet *at regular intervals*, combined with the regulation of habits of life, particularly a sufficient amount of rest. Sometimes in these cases the diet is

rational and results may be obtained by simply regulating the hours, putting a stop to eating between meals, thereby creating an appetite which induces the child to take a sufficient amount of food at meal-time.

To be sure the picture drawn above may result from chronic infections, from teeth, tonsils, etc., and it is presumed that these defects are to be corrected. The same picture with or without low-grade fever may be produced by tuberculosis, and the utmost care must be taken to rule out this condition.

The question naturally arises why the people of former generations and more remote periods of civilization did not suffer from these nutritional disturbances. The answer is paradoxical: They did, and they did not. Some of these conditions have been coexistent with history, some have developed in the course of, and as a result of the progress of civilization. When our domestic animals ran wild and roamed the plains they were compelled to forage for their own food, and this they did with a selective instinct and chose what was good for them and produced the best milk for their offspring, and with almost unerring accuracy rejected what was useless or positively harmful in open seasons. During the rigorous seasons, however, they were often compelled to eat whatever could be found, and as a result many fell victims to a general state of malnutrition. Likewise as they became domesticated as the servants of man their food was selected for them. Instead of the plains and fertile fields they were restricted to the narrow confines of inclosed pastures and compelled to subsist on whatever vegetation could grow there, and when this failed, on dry provender which deteriorated from drying and aging.

So it has been with man. We see him during his savage and semi-barbaric existence, feeding on fresh vegetation in its natural state and on animal food which was consumed almost as soon as it was killed; and having no fixed habitation he moved when food became scarce in one locality to a new home where food could be secured with ease again. And even when grain was first used in powdered form it was milled in a mortar just before cooking. So as civilization advanced through a slow and steady development the food question changed but little until man began to live in cities. Till then, he was troubled little by the problems of nutrition except during times

of famine, drought or war, when the food supply was all but cut off, and invariably under these conditions scurvy developed. Even in the early stages of urban life proximity to the country districts made it easy to obtain the necessary provender within a few hours of production. It was in about this stage of civilization economically, though not socially, that the early settlers in this country found themselves, and so they lived until density of population and economic conditions favored a change which was far more abrupt than any which the world has ever known.

This period of comparative simplicity of living has occupied the greater proportion of civilized life on the American continent. Meat was secured by hunting, or later, by the slaughter of domesticated animals as the need arose, and consumed while fresh because of lack of facilities for keeping, and what small quantity was kept was preserved by a process of smoking which retained the nutrient qualities that would have been destroyed by aging. Vegetables were consumed within a short time from gathering; dairy products were utilized almost as fast as they could be produced and prepared for the table, while grain was harvested and garnered in comparatively small quantities, and milled within walking distance of its source and consumed as soon as milled. And of as great importance these forefathers of ours were housed in primitive structures which prompted an outdoor life in mild weather and were exceedingly well ventilated in winter, for it must be recalled that the almost airtight and overheated homes with which we are familiar are of quite recent development.

But gradually and inevitably increase in population, change from country to city life, and rapidly developing economic exigencies wrought their changes. The vast majority of heads of families ceased to produce their food and depended on the purchase of such commodities as were needed from the small farmer, who, as he rose in the scale of production, grew crops of limited variety, eventually restricting his efforts to the output of a single article. The farm receded farther and farther from the center of consumption, thereby causing delay in transit and the necessity for storage with its consequent aging. Grains of every kind, instead of being produced, milled and consumed within a radius of a mile or so, are

sent several thousand miles and returned to be consumed, after months of delay, thus impairing the vitamin values of the fresh product.

With civilization also came a departure from the simple life, with its simple tastes, and certain refinements of diet were demanded by the upper classes, and this was quickly imitated by the humbler classes, so that white-flour bread, almost devoid of anything but the starchy content, was substituted for the seconds of an earlier period. During this earlier period were developed also certain methods of preparation, made necessary by the limited variety of food products, which formed rational, balanced diets of almost scientific precision, such as the once famous, but now often spurned, corn pone and "pot liquor," the latter being little less than a concentrated essence of vitamins.

These changes in handling the preparation of food products with the consequent diminution of food values have taken place with such rapidity that the human economy has not had time to adjust itself to the change—for a century or two is a very short time in the development of a race—with the result that deficiency diseases have become exceedingly common, and malnutrition almost the rule rather than the exception.

It would appear, then, by the application of the knowledge we now possess we were about to enter a metabolic utopia; this is, however, very far from the case. However much has been learned during the recent past on this subject, it is exceedingly small in comparison with what yet must be learned before we reach this state. A total of three vitamins is now definitely known, with a probable fourth just discovered, and as yet each of these has been studied in relation to a single condition. Each of these may have an influence, probably all have, on metabolism in many other conditions, and it is almost certain that numerous other vitamins exist, concerning whose nature we as yet know nothing. The metabolism of certain of the earthy salts has been studied extensively, and the relation they bear to several abnormal conditions has been definitely determined, while the processes of digestion of the three cardinal food elements, fats, proteins and carbohydrates, have been understood for a number of years. Beyond these facts practically nothing is known.

It is entirely likely that those mysterious organs known as the ductless glands—or when grouped, form the so-called endocrine system, about which so much is written and so little known—play a role, perhaps an important one, in the process of metabolism. The activity of only one, the thyroid, has as yet been measured even partially; and yet it is supposed that one or more of these glands determine the size and shape of one or another of the body tissues, which means that they direct the ability of this or that tissue to assimilate or fail to assimilate, ingested food. It is supposed that each of these glands either stimulates or retards the activity of another of the group. Who knows but that some chemical combination of inorganic material or some unknown vitamin contained in the food we consume either activates or inactivates these glands, and so indirectly governs our growth and development?

The crowning achievement of scientific thought up to the present time is the biological cell doctrine, and to Gregor Mendel we owe the discovery of the fact that various characteristics which pass from generation to generation do so not by chance but by definite rule, in definite proportion and orderly sequence. This is now known as the Mendelian law. Through intelligent application of this law the control of plant and animal life has been made practical, and the development of desirable and suppression of undesirable qualities has reached the stage of scientific accuracy. Could we but control the mating of human stock the effect on the race would not be difficult to visualize.

The factors which determine stature, physique, muscular activity (hyper- or hypo-kinetic), the color of the hair and eyes, the shape of the teeth and contour of the jaw and even the characteristics of temperament, through whatever organ or organs they act, are inherent in the cells and can be controlled only by inbreeding on the one hand and cross-breeding on the other. Yet the activity of these cells and their contained factors are obviously dependent on the soil in which they develop, the food which they assimilate. Therefore who can tell at the present time to what extent all of these matters are influenced, yes, even controlled by the quantity, quality and proportion of food products with which the growing organism is supplied?

In laboratory animals it may be shown that the offspring of a mother fed during pregnancy on food which is adequate for her maintenance, but deficient in a single element, or one marked by the total absence of one vitamin, are undersized at birth or of normal size at birth, yet reach adult life with stature stunted (the small size being out of proportion to a possible application of the law of filial regression), or do not live out the natural span of life. All of these characteristics are familial ones and therefore produced by heritable factors, and yet are unquestionably modified by an unbalanced diet. Which simply means that the cells containing these factors were so poorly nourished that they were incapable of functioning to the full extent of their inherent powers.

Similar experiments show that in animals born of properly fed mothers and themselves robust at birth, when food is supplied in sufficient quantities to meet the caloric needs of the growing organism and apparently perfectly balanced, with the exception of a single element, change in weight and stature takes place in a remarkably short time. If the lacking factor is supplied again within a certain time the animal soon regains its normal strength and development. If its administration is delayed beyond this time, however, regeneration does not take place. The application is too obvious for explanation.

It must be apparent that in whatever field we work, which bears directly on the development of human beings and the maintaining of virility after the period of development is past, knowledge of the science of nutrition is essential. The obstetrician must know what food to supply the expectant mother, so that at birth the offspring will be physically perfect. The physician must know what food is required by the nursing mother to supply the infant with a sufficient amount of fat, carbohydrate, protein, salts and vitamins. Likewise the dairyman must know what forage to supply the cow in order to produce the same quality of milk for the benefit of the artificially fed infant.

The dentist must know the food adapted to the production of teeth of good quality; to prevent deformities of the jaw from mechanical influences and to harden the jaw after correction of malocclusion, thereby preventing a recurrence.

The director of a school lunchroom must possess the same knowledge to adapt the lunches to the needs of the growing child. In fact, every one who deals with "man in the making" must possess this essential knowledge in order that definite ends may be attained.

It may be said that all this calls for such profound knowledge of an intricate scientific problem that it is out of the reach of the average person, but fortunately this is not the case. It is true that fundamental principles should be known, but only a small amount of actual knowledge is needed. What we call a balanced ration, i. e., one which contains a sufficient amount of the tissue-building, energy- and heat-producing elements, together with a liberal supply of the essential vitamins, is all that is needed to carry into practice the principles involved, and any one of a number of small and readable books can supply this. Man can live and thrive on milk, eggs, leafy vegetables and fruits, but of course these would become monotonous, and therefore a variety in food is desirable, but the essentials have been stated. We get what vitamins we need from common, everyday, simple food, and do not have to resort to proprietary preparations and yeast to supply them.

When we recall the fact that at the moment of conception our control of heritable characteristics ceases, that we then must deal with good and bad alike, and that with few exceptions we cannot tell in early life the desirable from the undesirable, but from the palace may go out a fool, and from the cabin may arise a genius, it must be clear, then, that all must be cared for alike and that our duty is to make the best possible citizen of the next generation out of the material as it presents in childhood. Since at present we cannot control the production of the cells making up the human organism, we must do the next most important thing—supply these cells with the best nutrition. Thus we become the moulders, in large measure, of the social fabric of the next generation, and the next; the makers of history through the better-nourished bodies of its citizens, doing our share in the advancement of civilization, and writing the romance of nutrition.

## ACUTE OSTEOMYELITIS.

### The Differential Diagnosis and Treatment.\*

By LOUIS A. McALPINE, M. D., Portsmouth, Va.

Of all the acute diseases there are few that are more serious, both from the standpoint of mortality and ultimate morbidity, than acute osteomyelitis. This is true because of the fact that unless an early diagnosis is made septicemia frequently develops or, if the victim of the disease escapes this, widespread necrosis of the bone occurs or secondary foci of osteomyelitis may occur in the other bones. The disease is also serious in that it is rare that the diagnosis is made early enough to institute the proper treatment in order to prevent the morbid changes in the structure of the bone.

In consideration of the seriousness of this infection and on account of the wide diversity of opinion as to what is the proper treatment at the proper time, I have prepared this paper, hoping to stimulate some discussion regarding the differential diagnosis and the treatment of the infection.

In order to consider carefully the diagnosis and treatment, it is necessary to mention the etiological factors concerned in the production of the disease. Acute osteomyelitis is hematogenous in origin, occurs most frequently in children, and is not uncommon in infancy. It follows the acute infectious diseases and is a frequent complication of typhoid fever. In the writer's experience, acutely infected tonsils have furnished the source of the infection in several cases. Local infections, such as otitis media, abscesses, carbuncles, pimples and the like, are sometimes responsible for the production of the disease. Exposure and trauma may be predisposing causes; however, the writer believes that trauma has very little bearing on the development of the disease, although most cases have some history of traumatism. This view is taken by reason of the fact that it is believed, if trauma were a predisposing cause, often we would have osteomyelitis with simple fractures. This, I believe, all will agree, is very rare.

The staphylococci, and principally the staphylococcus aureus, are the infectious agents most often met with, although the streptococcus is sometimes the invading germ. The

\*Read before the Seaboard Medical Association at Newbern, N.-C., December 1922.

histological anatomy of the bone marrow is unfortunately concerned to a great extent in the development of the disease. The extremely fine and "loop the loop" blood vessels furnish excellent places for the germs to lodge and the marrow itself furnishes rare culture media for them to flourish upon.

On account of the difficulty of early diagnosis and on account of the difference in the treatment of early and late cases, I prefer to discuss the symptomatology, differential diagnosis and treatment of first, the early cases, and second, the late cases. And when we speak of "early" and "late" in reference to acute osteomyelitis, we are speaking, as a rule, not in terms of days, but we are speaking in terms of a few hours, and we are dealing with an extremely ill patient. Let us qualify "early" as meaning the period from the time the infection of the marrow takes place to the time this infection spreads through the Haversian canals to the subperiosteal tissue; and "late" as the infection of the subperiosteal tissue or the formation of a subperiosteal abscess.

The pathological changes that take place within the cavity of the bone are rapid and extensive. The invading organism usually enters the bone at the epiphysis and inflammatory processes are at once inaugurated. There is vascular distention, associated with thrombosis of many of the vessels, leucocytic infiltration, coagulation necrosis, followed by liquefaction of the intercellular substance, and destruction of the tissue leading to purulent foci. Extension of these areas along the tract of the marrow leads to degeneration of the substance. This constitutes the pathology of the early case, or the first few hours of the disease.

Later, the infectious process spreads into the Haversian canals to the subperiosteal region. The blood vessels of the bone canals become thrombosed or blocked from pressure, and the circulation to the bone is destroyed. There is beginning bone necrosis and finally the formation of a subperiosteal abscess.

The differential diagnosis of the early case is frequently very difficult although the writer believes that, by careful study and painstaking examination, the correct diagnosis can be made in a greater number of cases.

*Acute arthritis* is the disease which is most often confused with acute osteomyelitis, and this is due to the fact that the infection of

the bone commences at the epiphysis and the symptoms and signs are more or less referable to the joint. However, if the following points are borne in mind, this differentiation will become more apparent. In osteomyelitis, the source of the infection can usually be determined. The disease comes on suddenly with immediate pain in the affected part, pressure or percussion reveals an area of marked tenderness at some point in the bone, and not the joint; the examiner by easy manipulation can move the joint without giving the patient pain. In addition there is high fever, and very severe constitutional symptoms, with a pronounced leucocytosis. In acute arthritis the swelling of the joint coincides with the appearance of the pain and the joint cannot be moved without great pain to the patient. The disease is likely to be poly-articular. The leucocytosis is insignificant and the constitutional symptoms very much less severe.

The early, very serious case of osteomyelitis that immediately overcomes the patient, producing stupor or delirium, is sometimes confused with other infections such as typhoid fever, meningitis or septicemia. These, however, are diagnosed by blood culture or spinal puncture, providing of course, the patient survives long enough for this to be done. In these cases of general infection, Lexer has pointed out that it cannot be decided whether the general infection has developed from the bone suppuration or whether the latter is only an incidental localization of the severe general infection.

Scurvy produces a painful and very tender swelling in the shaft of the bone with mild constitutional symptoms, such as pallor and slight fever, but the severe toxic symptoms are totally lacking.

The late cases of acute osteomyelitis give a much clearer clinical picture. The subperiosteal abscess has usually ruptured through the periosteum and there is extension into the soft tissues, giving all the signs of a very acute inflammatory process. The differential diagnosis in this case is the same as in the early case, with the exception that the examiner has the added advantage of the extensive local signs such as swelling, redness, tenderness and heat.

In the diagnosis of acute osteomyelitis, it must be remembered that X-ray examination is always negative for at least the first ten

days of the disease and must not be considered a factor in the diagnosis.

#### TREATMENT

The first thought in the treatment of acute osteomyelitis should be that it is an emergency condition and should be dealt with by immediate surgical procedures as soon as the diagnosis is made and, even in those suspicious cases where the diagnosis is not entirely clear, an exploratory operation is not amiss.

Poultices and plasters have no place in the treatment of a suspected infection of a bone and such temporizing measures cannot be too strongly condemned.

Review of the literature brings us face to face with conflicting opinions regarding the extent of operative work to be done in the acute cases. Many authorities advise simple incision over the point of greatest tenderness, and trephining two or three openings in the bone, while others advise the troughing of the shaft for the entire extent of the infection.

Halle even goes so far as to advise only incision of the soft parts and division of the periosteum with drainage, and quotes statistics to show that in 304 acute cases there was a mortality of 16.66% in 144 cases in which the bone was opened, and 7.59% in 79 cases in which there was simple drainage of the soft parts. He believes there is ample drainage through the Haversian canals. Of course he concedes that a secondary operation is always necessary. While bearing these opinions and statistics in mind, it is the humble opinion of the writer that the method of treatment to be employed in a given case should be determined by the extent of the pathology present and not by set rule to cover all cases. Thus, in the early case, that is before the infection has spread through the Haversian canals, a small opening through the cortex of the bone, into the marrow cavity, and drainage will frequently suffice to cure the acute process and make secondary operation unnecessary. Also in the late case, that is, after the infection of the Haversian canals and subperiosteal tissue, it is necessary to open widely the marrow cavity and to remove the spongy infected bone, and drain thoroughly. Frequently this procedure will cure the acute case and sequestration will not take place.

The early case should be drained with either a gauze wick or tube but should not be packed. The late case should be either

packed with gauze saturated in dichloramin-T or Dakinized. There is not much choice between the use of dichloramin-T, packing and the Carrel-Dakin treatment, as far as final results are concerned. There might be a slight advantage in Dakinizing in that there is not the pain and discomfort of frequently removing packing from the wound.

In reference to the use of dichloramin-T, the writer has observed that frequently the solution used is put up in a clear glass bottle and the specimen has undergone chemical reaction on exposure to light, causing a change in color and a precipitation. Any solution of dichloramin-T that has a red clay color and a precipitate in the bottle has either been exposed to light, or improperly prepared and is absolutely useless. A 5% solution of dichloramin-T in chlorocastane oil has about the same color and consistency as castor oil.

In the operation on either the early or the late case, no curretting of the marrow cavity should be done, as this destroys the osteogenetic cells and delays regeneration of bone. A very important point in the treatment of any case is that the primary focus of the infection should be removed, if possible.

#### CONCLUSIONS

1. Acute osteomyelitis is a serious disease, occurring generally in childhood, and frequently causes death or permanently disables the victim.

2. The disease may be divided into "early" and "late" cases according to the extent of the pathological processes taking place in the bone. The "early" cases are those in which the inflammatory reaction is confined to the marrow cavity and the "late" are those in which the inflammation has spread through the Haversian system to the subperiosteal tissue.

3. The differential diagnosis of the "early" case is sometimes difficult but can be made more often by painstaking examination and a critical analysis of the symptoms and signs of the disease. The "late" case presents a more definite symptom complex and the diagnosis is more readily made.

4. The treatment of "early" cases consists of opening the medullary cavity and drainage of the infected area by means of gauze or a tube. The "late" case is treated by means of widely opening the medulla, removing the infected bone, and packing with gauze satur-

ated in dichloramin-T, or by Dakinizing. These methods frequently will cure the acute osteomyelitis and sequestration will not take place.

### SOME ESSENTIALS IN FRACTURE WORK.\*

By GEORGE H. REESE, M. D., Petersburg, Va.

As indicated by the title of this paper it is limited in scope to general principles, being a crystallization of my observation and experience derived from four years of industrial surgery at Hopewell, and at Old Hickory Works, near Nashville, Tennessee. At the end of this period I had the satisfaction of emerging without a lawsuit to my discredit, or a broken bone treated of which I had reason to be ashamed. The factors contributing to this measure of success I shall endeavor to set forth, as space permits, for the consideration of others engaged in the same kind of work, with no more training or experience than I had when I assumed this obligation.

It is self evident that the first important requisite in the treatment of fracture is that the surgeon should have an accurate mental picture of the condition with which he has to deal. He must have a sound knowledge of anatomy, physiology, and pathology; for it is upon these essentials that all diagnostic measures are reared. He must have mechanical skill. Without these three fundamentals no one can ever hope to treat fractures successfully.

With this equipment assumed, we may ask, what are the diagnostic points in fractures? and answer: preternatural mobility with bony crepitus, and X-ray confirmation. Deformity, ecchymosis, and persistent pain are highly suggestive, and I would urge for them, careful consideration; but they may attend other traumatism or be the result of an old disease or injury, or be the simulation of a skilful malingerer. All the other symptoms and signs of fracture unaccompanied by the above may, for all practical diagnostic purposes, be forgotten.

All cases of traumatism should be X-rayed. Do not confine the X-ray to known fractures or suspicious cases, otherwise fully 10% of fractures will go undiagnosed as such. Have them X-rayed in two or more positions. One

picture is useless as a rule, for either scientific diagnosis or treatment. The information gained by the surgeon who has cases thoroughly X-rayed is amazing to himself and of untold value to his patient. He finds a fracture where he could hardly notice a contusion. He finds a known or suspected fracture associated with another fracture, or an unsuspected dislocation. He may have a slight or serious laceration, which is really a compound fracture, and fail to treat it as such without X-ray confirmation. He may have an impacted fracture which it would be unwise to disturb; or a transverse fracture without displacement, to say nothing of other fractures, which might result in confusion to himself and disaster to his patient should manipulative attempts be made under ether or otherwise, to elicit the pathognomonic signs of fracture. Comminuted fractures, linear fractures, impacted and all other fractures, are revealed by the X-ray and differentiated as by no other method.

Should open operative treatment be in mind, its character will be determined by radiographic findings, or the necessity or the advisability of this form of treatment indicated. The advantages to both patient and surgeon of thorough radiography, before the injury is further manipulated, are so many and so vital, that it is amazing to find in most books the statement, that if only one X-ray picture can be had, it should be taken after the fracture has been set. This is a negation of the value of accurate diagnosis, without which there can be no assurance of proper treatment; it is utterly selfish and to our way of thinking the most pernicious idea ever advanced about a condition, where diagnosis often means everything.

When a fracture is encountered it should be treated with the utmost gentleness and the least possible movement of the bones permitted before the final dressing is ready to be applied. If in great pain or shock the patient should be given morphine at once, and the limb gently straightened and splinted before transportation is undertaken. No attempt should be made at reduction until everything is ready for the permanent dressing, unless the fragments are threatening to erupt, or are impinging upon blood vessels, nerves or other important structures.

All fractures should be set as soon as possible. Delay is often convenient for the surgeon, but

\*Read at a meeting of the Southside Virginia Medical Association in Petersburg, March 1923.

inevitably adds to the distress of the patient and to an increase in his pathology. In severe shock, in fractures associated with burns, severe abrasion or lacerations, often this rule has to be evaded. A complicating hematoma may be aspirated under aseptic conditions, a compressive dressing applied, and fixation proceeded with as usual.

In all compound fractures great care should be taken not to add to the existing infection. Consequently it is of the greatest importance not to let the exposed bone ends retract until they and the surrounding wound have been thoroughly disinfected. This should be done with full strength iodine and an aseptic dressing applied before the patient is moved. If this is impossible, he should be hurried to the operating room as gently as possible, the wound thoroughly scrubbed clean of all foreign matter with gauze sponges saturated with iodine; bone fragments, etc., removed with sterile instruments, and proper drainage provided. If necessary, enlarge the wound to any extent demanded for thorough inspection and removal of all suspicious material.

I mentioned iodine as the initial disinfecting agent because it is time honored, efficient, and almost universally available. Other disinfectants may be used and some of them are doubtlessly as good as iodine.

As a secondary disinfectant of compound fractures, nothing has a superior record to Dakin's solution. Other chlorine compounds are highly efficient. We found them more troublesome to obtain, keep fresh, and to administer, however, than our old routine of iodine followed by apinol. This latter made its own way with us as a highly efficient, un-irritating antiseptic. It is efficient as a cleansing or antiseptic agent, either alone or combined with 10% tr. of iodine. For the treatment of lacerated wounds, it gave us most excellent results.

The above remarks presuppose a rigidly aseptic technique. Under no circumstances should any unsterile object be brought into contact with a compound fracture. Only in unavoidable conditions should even the gloved finger be introduced into the wound. Cleaning the injury with sterile instruments, gauze and antiseptics, should be accomplished without any unnecessary digital invasions. To ignore this rule is to invite trouble.

In setting a fracture of consequence, general

anaesthesia is usually indispensable. This should be insisted upon by the surgeon and the blame for its omission placed squarely upon the patient. Exact approximation of the fragments is the ideal to be attained, and the surgeon is entitled to every aid in his effort to secure a perfect anatomical and functional result. This attainment is impossible when combated by spastic muscles and a resisting patient. It is not always easy to secure accurate reduction even by open operation under general anaesthesia; hence the folly of attempting the reduction of any major fracture without deep narcosis.

Most fractures are best set under the fluoroscope. If this is impossible, set them as usual and check by radiograph before completing the operation. If unsuccessful in the first attempt, repeat the performance as often as necessary in order to secure a good result. If such cannot be approximated after repeated trials, open operation may be justified, provided surrounding conditions are such as to warrant so radical a procedure.

The conversion of a simple fracture into a compound fracture is a step to be taken only as the last resort. This is rarely necessary in the fractures of long bones but, strange to say, this is where most of it is done, and where most of the wiring and plating is perpetrated.

There are some fractures that demand open operation for successful reduction; for example some fractures of the jaw, some fractures of the patella, olecranon, and some fractures with dislocation. When such lesions are encountered, they should be operated upon at once and the fragments neatly approximated. If any internal fixation is necessary, it should be accomplished by an autogenous bone graft, bone peg, chronic gut, or kangaroo tendon. If wire or plates are ever used, they should be inserted with the understanding that they are to be removed as soon as the bone has united. When left, they almost invariably give trouble. This should be borne in mind whenever any unabsorbable material is used.

There is scarcely any justification in modern surgery for the use of wire in fractures, and but little more justification for the use of plates. Used surgically, they are intended merely to approximate the fractured bone ends, not to splint them. The splinting has to be done by other methods; hence the need of wire and plates for purposes of approximation vanishes.

In the application of external dressings, everything depends upon the skill and ingenuity of the operator and scarcely less upon well trained assistants. Every surgeon has to adapt himself and methods to meet the variations of each individual case. He cannot do his best unassisted and should not from a medico-legal standpoint undertake to set a major fracture alone.

The immediate complications of fracture, such as injury to the brain, bladder, nerves, and bloodvessels, of course, require added attention to each specific need.

The late complications, such as necrosis, ulceration, gangrene, paralysis of nerves, and excessive atrophy and paralysis of muscles, are usually due to faulty methods of fixation or to improper or neglected after treatment.

After treatment is a factor of prime importance in the successful management of fractures. The splints should frequently be removed, the skin inspected for trophic disturbances, the parts bathed with alcohol, and gentle massage and passive motion instituted. Stiffness of joints can be eliminated almost entirely by early passive motion. This should be commenced within a week or ten days of the injury, under gas if necessary, and be gently and gradually increased, until full movement is attained. Suppurative wounds of the joints were found by the war surgeons to be highly benefited by this simple procedure. By persistent effort, the joints in simple fracture should be normal in motion, or nearly so, by the time the bone has solidly united. This means a great deal to the manual laborer.

In the old and the debilitated, in those contused about the thorax, ether, as an anaesthetic, should be avoided, if possible. Gas oxygen or chloroform should be used instead. These patients are prone to develop hypostatic or traumatic pneumonia and nothing should be done to increase this tendency.

In splinting the fracture, leave the patient mobile, support him by appropriate constitutional measures and circulatory stimulants, elevate his body, if feasible, and as soon as possible get him up and about on ambulatory splints. Treating the patient in the aged is of far more importance than treating the injury. The syphilitic may require anti-syphilitic treatment, while the alcoholic may spring delirium tremens, or traumatic insanity develop in any

severe case, necessitating control before successful union is secured.

Success in fracture work is won by the taking of infinite pains. This paper is a plea to the general surgeon and practitioner to bestow a greater skill, consideration and effort, upon this neglected branch of surgery than has been given in the past.

Many surgeons, for reasons best known to themselves, are disinclined to engage in traumatic surgery. Some have referred to their war experience as blunting their technique and tending to unfit them temporarily for work in private life. In this connection it may be well to note the one great surgical achievement of the war. Dr. Alexis Carrel, already a surgeon of world-wide fame, being dissatisfied with his own technique and that of the French and British surgeons, set about to discover a better method of treating infected wounds. As a result of his labors, hundreds of lives have been saved, and thousands of limbs are sound and well that otherwise would have been lost.

### X-RAY IN THE TREATMENT OF CANCER.\*

By DANIEL D. TALLEY, JR., M. D., Richmond, Va.

In this paper some attempt will be made to outline the problems attendant upon the employment of the rays in malignant disease, to comment upon the measure in which these problems have been overcome and to discuss briefly the relations of the rays to the other principal methods now used in treating cancer; not so much with an idea of establishing the superiority of any one method or agent, but with regard to the co-operative use of all.

That both the X-rays and the rays of radium have the power of causing destruction of cancer cells within the living body, if applied to the involved area with sufficient intensity, has been well established and is universally admitted. The desiderata therefore have been (1) the constant production of rays powerful enough to produce desired effects in the deepest tissues of the body, (2) the accurate measurement of such applications, (3) the complete destruction of the irradiated pathological condition without doing injury to the skin and healthy tissues around or above the growth, and (4) the avoidance of harmful constitutional effects or alarming symptoms which

\*Read in the Symposium on Cancer at the meeting of the Tri-State Medical Association at High Point, N. C., February 22-23, 1923.

may follow the use of the more penetrating rays in large quantity, over areas of considerable size.

The advent of the Coolidge tube approximately one decade ago was a great step in the advance of Roentgen ray therapy, in that it made possible the constant production of rays of deeper penetration than could be produced previously for practical purposes. This widened the field of this therapy, since it enabled us to influence malignant cells in the deeper tissues to an extent hitherto impossible. Less than five years ago the German roentgenologists began to employ apparatus capable of delivering rays of a far greater penetrating power than anything previously produced and with these rays of powerful penetration still more satisfactory results began to be reported. The use of this method of technique, at least to any considerable extent, has in this country been limited to a period of less than two years, but apparatus for its employment is coming into more and more general use.

As many readers may be unfamiliar with certain principles in the production, employment and effects of the X-rays, it is believed that a few words of explanation here may be helpful: (1) The rays produced from any X-ray tube are heterogeneous. That is, no matter how high the penetration of some of the rays may be, there will also be produced at the same time rays of lower penetration which would naturally be absorbed by the skin and superficial tissues and thus damage same in attempting to produce deep effects. In order to obviate this damage, filters are interposed in the path of the rays which allow only the more penetrating ones to pass through and thus reduce skin absorption to a minimum. Aluminum and copper are the most common filter materials now in use. (2) The rays of higher penetrative power are of relatively short wave length and are produced by currents of much higher voltage than are those of lower penetration. (3) From the primary X-rays entering the tissues, so called secondary rays are produced in the tissues themselves, to which a considerable proportion of the destructive effect is due, though the primary rays also contribute to the result. (4) The intensity of the rays varies inversely as the square of the distance of the tube focus from the area treated. This law is responsible for the fact that the further away the tube is

from the body surface the more nearly equal will be the intensity of the rays in all the tissues irradiated. (5) If a deep lesion be irradiated from several different directions or through several so-called "ports of entry," a maximum effect may be produced in the lesion with a minimum skin damage, as a different skin surface is exposed each time.

Experience has shown that the ideal way to treat malignancy with radiation is to destroy it as quickly as possible by attacking boldly, and if possible, administering a lethal dose to every part of the growth at one sitting, or in a few treatments given over a very short period of time. The reason for this is that incompletely irradiated growths tend to acquire increased resistance to repeated radiation, and it has been claimed that a very small dose will stimulate instead of destroy.

The application of this principle may require many hours of treatment at one time or spread over a few days and has brought several new problems for solution. One of its results is the more or less profound condition of radiotoxemia characterized by nausea and vomiting, diarrhea and extreme weakness and possible rise of temperature. These symptoms may be especially profound after extensive abdominal radiation. Symptoms usually last only a few days but may be prolonged, and large doses or overdoses have even led to occasional fatalities. As the blood stream passes beneath the irradiated areas, its cellular constituents receive the effect of the radiation and certain changes take place which may require weeks or even months to become restored to normal. Other changes may take place in normal organs and tissues. These facts render the administration of intensive deep roentgen therapy a procedure requiring careful and intelligent consideration and study, and make it increasingly dangerous if the general vital forces are not up to normal. It is contraindicated if cachexia has begun.

Another problem is the question of dosage. For instance, not only does carcinoma require a different dose for its destruction from sarcoma, but one type of either of these tumors may respond to a dose which would not destroy another type. Furthermore, it has been pointed out that the kind of normal tissue in which a tumor grows may have a marked bearing upon the radiation susceptibility. In treating malignant growths which involve deep

tissues, it is ideal to give a radiation dose which will be just sufficient to destroy all the pathological cells without producing damage in the surrounding or overlying healthy tissues, it being a well established fact that cancer cells are less resistant to the rays than normal tissue cells. Irreparable injury may be produced if the dosage is sufficient to destroy normal structures. As a result of extensive experimentation and study, both on the part of the physicists and the clinical workers, the question of accurate measurement of dosage in the deeper parts of the body is being worked out, this problem being by no means a simple one. It is further complicated by the fact that the power to diagnose the entire extent of the malignant growth is limited, especially in the more deep seated lesions.

The problems of ray therapy have likewise been taken up by the pathologist and biologist notably with regard to the tissue changes produced by irradiation and the reaction of the normal tissues, which may be an important factor.

The foregoing remarks are intended to show that careful study and special medical knowledge are required to employ the roentgen ray proficiently and that much concerning its effects and methods of administration has yet to be learned. The remainder of my remarks will tend further to bear out these facts.

The two most efficient methods in the treatment of malignant disease today are surgery and radiation, or radiotherapy. Radiotherapy includes the use of both the X-rays and radium. The effect of these two agents upon cancer cells is practically identical and they should be considered rather as adjuncts to one another than as rival forces. Without going into physics, it may be said that X-rays may be produced in far larger quantities than radium rays and are thus more useful for application to large and deep areas. Radium may be introduced into cavities or in various forms may be buried in the pathological tissues, and when so used in more or less close contact with the area diseased may be more efficient than the X-ray. Its destructive power is limited, in the amounts available for use today, to a distance of a few centimeters into the tissues. The advantages of the X-ray, therefore, are in external radiation, those of radium where the salt or the emanation may be brought into contact with the malig-

nant tissue. It will thus be seen that there are many types of malignancy where the X-ray and radium can be used to the best advantage in conjunction with one another. Certain of the gamma rays of radium are of shorter wave length than any known and are more efficient in their effects on malignancy. In order to compete externally with the X-rays as now produced, however, huge amounts of radium would be required at a prohibitive cost. Schmitz believes the ideal would be to produce with the X-ray the effect of the gamma ray of radium. As the apparatus is at present constructed, the X-rays produced are not of short enough wave length to do this but the opinion is held by some that for practical purposes they are efficient.

What relation does radiotherapy bear to surgery? Surgery in malignant disease may in a sense be regarded as a finished product, in that as far as we can now see, no new methods of technique are likely to influence cancer mortality to any great extent. That the practitioners of surgery themselves are far from satisfied with the results of their art as applied to cancer is well known to anyone at all familiar with operative statistics of this disease.

The conscientious surgeon, therefore, should welcome and does welcome any agent whereby the cancer mortality may be reduced for use (1) in cases where the results from its employment may be superior to those obtained by operation, (2) in cases where a combination of methods may promise a cure, unobtainable by either method alone, and (3) in cases where surgery cannot be employed with any reasonable hope of success. Reliable opinions seem to justify the belief that radiotherapy comes nearer to filling this need than any other known agent.

No argument will be here set forth to advance claims for radiotherapy in those cases which are really operable; that is, where there is reasonable assurance that the whole of the cancer tissue may be removed without recurrence or metastasis. There are exceptions to this rule, as for example in most cutaneous cancers, where X-rays or radium occupy an established position, and in the first stage of cancer of the cervix uteri where statistics of five year results show that even at the present day radium alone or in conjunction with intensive X-ray therapy can compare favorably

bly with surgery, so that some surgeons prefer the former method. In those cases of malignant disease which are on the borderline of operability, it is fairly well established that more satisfactory results have been obtained by surgery when either preoperative or postoperative radiations, or both, are used. The instances in which apparent arrest of the disease has been secured in inoperable cases by radiation alone are many; its use in the treatment of local recurrences after operation is gratifying; and the palliative and occasionally permanent results after deep metastases are worthy of note.

Of the high voltage X-rays of short wave length and deep penetration above referred to, it may be said that the results reported by foreign observers have been generally received in this country with a commendable conservatism. It has been believed that some of these reports have been much tainted with over-enthusiasm and they have been correspondingly discounted. Furthermore, sufficient time has not elapsed since the inception of the newly modified form of therapy to speak of what the real and final results from its use may be and many problems of its administration yet remain to be solved. It may be admitted that the dangers do not seem to be contraindicative to its use in competent hands, and that many of its problems seem possible of solution, but the time is not yet ripe for positive statements.

Giving the foreign reports a reasonable amount of credence, however, and judging from the statements which come from those who have had any considerable experience with the use of such rays in America, it would seem that the results are superior to any obtained previously, and that the outlook is favorable for still more gratifying achievements.

That any achievements from radiotherapy will be enhanced by earnest co-operation between surgeon and radiologist in selecting cases for treatment, in planning this treatment, and in carrying it through is believed to be obvious and unnecessary of further comment.

### THE "CATTLE-TRUCK" SYMPTOM.

By COURTNEY EDMOND, M. D., F. A. C. S.,  
Clifton Forge, Va.

Mrs. "B.," naturally much agitated, 'phoned that a spot had suddenly come before her right

eye and that it would not go away, asking what should be done. The reply was that she should first come to the office, allow the trouble to be determined and then be advised as to treatment. She came within about thirty minutes, stating that the spot was enlarging, the vision worse, and that she could see but imperfectly in an upward direction only. Suspecting closure of the retinal artery, the following brief history was quickly obtained:

Age 26, healthy, married, two children. On other occasions for many years, at long intervals, the same kind of spot had appeared before the right eye, only to promptly disappear with slight annoyance. The present attack was different because of the greater visual disturbance and the longer duration.

*Macroscopically:* The affected eye presented a pupil a trifle larger than its fellow, reacting to light somewhat sluggishly. Intraocular pressure unchanged to palpation. Vision greatly reduced centrally with a kind of ebb-and-flow of peripheral vision.

*Ophthalmoscopically:* Right pupil noticeably larger; fundus-reflex whiter than normal; ocular media clear; papilla pale; retina ischemic, particularly about the macula where the smaller vessels stood out more clearly than usual; no hemorrhages; no visible embolus. The macula was a red spot in marked contrast with its paler environment, the "cherry-red-spot." The classical symptoms of occlusion of the central artery were well developed. The retinal vessels were but slightly narrowed, with the following striking picture in the upper temporal artery and vein: The blood-stream in these two vessels was broken up into hundreds of minute moving segments, or cylinders, of blood-cells with intervening clear spaces of plasma; a kind of slowly moving procession of beads of blood, which has been designated the "cattle-truck" appearance.

This procession of cylinders represented a diminished blood-stream and all were moving at about the same rate of flow, without jerking or hesitation, outward in artery and inward in vein, or according to the natural current. Where the vein crossed over artery, with a distinct bend in the former, the little cylinders could be observed to hurry, or "speed-up," as if wishing not to be seen while coursing the bend of the vessel. It appeared as if gravity might be having special effect at this point.

At the papilla the cylinders piled end-on-end, forming a continuous blood-stream but without visibly elongating the stream during the interval of observation. The motion described was not the result of digital pressure except that the patient stated she had been rubbing the eye rather frantically in efforts to dissipate the cloud. In fact, I could not determine at the time of the office visit that such pressure had any appreciable effect upon the moving cylinders. The following morning there was no "cattle-truck" symptom.

This simile, no doubt, is of English origin, as I am informed that the American cattle-car, or its equivalent, in England, is called "cattle-truck." While a bit fanciful, a train, or procession, of reddish cattle-cars reduced to ophthalmic proportions might prove a close resemblance to the remarkable picture referred to, the writer shall lay no claim to the discovery of the analogy.

There is, perhaps, little to justify this report. It may but enroll another upon the list of those who have observed this well known phenomenon which is diagnostic of arterial occlusion. Attention, however, might be directed to the history of previous transient obscurations of vision in the right eye, when, no doubt, the lumen of the artery was threatened; the excellent physical condition of the patient, without heart-lesion or other apparent source of embolus, and the reduced blood-stream as seen with the ophthalmoscope. These would appear to be points against embolism and in favor of an endarteritis or thrombotic process. Not all are in harmony with an eminent authority who surmises that emboli may circulate normally, or in those but slightly ill, lodging often where no notice can be had of their situation, the patient, of course, being unable to escape attention to an embolus affecting vision.

In the several cases of so-called embolism occurring in my practice, none before has given history of prodromal attacks of fleeting blindness, although I am aware that such history is not unusual. It was my first opportunity to observe the "cattle-truck" symptom, and I could but meditate upon what a perfect, vivid demonstration was afforded of the circulation of the blood and the differing directions of arterial and venous flow. It was an ophthalmoscopic entertainment and the one good "movie" I have seen.

## Analyses, Selections, Etc.

### **The Pathogenesis of Subacute Combined Degeneration of the Spinal Cord, with Special Reference to its Connection with Addison's (Pernicious) Anaemia, Achlorhydria and Intestinal Infection.**

The authors point out that, in the past, the nervous system in this combination has been studied chiefly by neurologists little interested in the anaemia; or by physicians whose attention was focused on the anaemia largely to the exclusion of the neurological aspect of the subject. They refer to the increasing frequency with which spinal cord symptoms are recognized in Addison's anaemia as they have become more systematically looked for, the later reports placing the figure at approximately 80 per cent. On the other hand, they note an increasing tendency toward recognition of the anaemia associated with this lesion of the cord as belonging to the Addison type of anaemia. They so regard the blood picture in the eight cases of the degenerative cord condition reported by themselves.

Having thus related these two syndromes to each other, they consider achlorhydria as a link in the chain of pathogenesis. Achlorhydria is the most frequent of all the ear-marks of Addison's anaemia, not excepting the classical blood picture, occurring in about 96 per cent of cases. Furthermore, they consider it firmly established as a condition precedent to the blood changes. Likewise they found an achlorhydria persisting throughout digestion in each of their eight cases of subacute combined cord degeneration; whereas its frequency in other conditions is shown in the table given on next page.

In three cases suggestive of subacute combined degeneration, but with a normal gastric acidity curve, the diagnosis eventually proved to be syphilis of the spinal cord.

The authors' ideas as to pathogenesis are clearly stated. They believe that Addison's anaemia only develops in individuals who have achlorhydria. The anaemia is caused by haemolytic toxin absorbed from the intestine, where it has been produced by the action of bacteria coming originally from the mouth, the presence of achlorhydria having deprived the stomach of its antiseptic powers, which normally exert a powerful influence in protect-

TABLE III. RELATIVE FREQUENCY OF  
ACHLORHYDRIA IN VARIOUS  
CONDITIONS.

ing the bowel from such infection. In addition to the haemolytic toxin, there is a neurotoxin. Although one or the other may appear to be present alone in the early stages, it is rare for the haemolytic toxin, and still more rare for the neuro-toxin, to continue to be produced without the other throughout the course of the illness.

Naturally, in treatment, these authors emphasize the most painstaking and complete eradication of dental, tonsillar, and sinus infection: the administration of dilute hydrochloric acid in sufficient dosage, usually 1½ drachms in 4 oz. of water, preferably with lemon juice and sugar. The acid is to be sipped during and for half an hour after the meal, and continued during life.

Active lactic acid milk, and a vaccine from any streptococcus obtainable from the mouth, duodenum, faeces or urine, are also recommended. Transfusions when indicated, and arsenic, with due care lest an arsenical neuritis be obscured by existing cord lesions, are of value. Little can be expected in the matter of cord symptoms beyond arrest of their progress, though some improvement may be obtained by systematic exercises. (*A. F. Hurst, M. D. Oxon and J. R. Bell, M. D., Melb.: Brain, XLV., Part II, page 268*).

J. H. S.

## Proceedings of Societies

### The Augusta County Medical Association

Held its annual meeting and members were entertained at the home of the retiring president, Dr. J. B. Stone, of Churchville, Va., August 1. There was an attendance of about 30 members and visitors and 25 ladies. Dr. John Wilkins Brodnax, of the Medical College of Virginia, delivered an address on "Art as Applied to Medicine," which was illustrated by lantern slides. Dr. J. C. Flippin, of the University of Virginia, the other invited guest, was prevented by death in his family from attending. A paper was also read by Dr. Kenneth Bradford, of Staunton, on "Infectious Diarrhea in Children." The treasurer, Dr. J. F. Fulton, of Staunton, reported a balance of \$100 in the treasury.

Officers elected for the coming year are: President, Dr. Alex. F. Robertson, Staunton; vice-presidents, Drs. F. E. Hamlin, Staunton, Thornton Hankins, Fordwick, Harry White, Fishersville; secretary, Dr. H. G. Middlekauff, Weyers Cave; treasurer, Dr. J. L. Alexander, Staunton, new member of board of censors, Dr. R. S. Griffith, Basic.

### A Delegate's Notes from the National Women's Medical Auxiliary.

The American Medical Association at the Convention in St. Louis in 1922 adopted a resolution presented by the Texas delegation that a Woman's Auxiliary should be formed in each state. A temporary organization was formed by the women who attended that meeting, and a permanent organization was effected at the recent San Francisco Convention.

Mrs. Red, of Texas, the president, called an informal meeting on Tuesday morning, June 26, to discuss the constitution and policies of the Auxiliary, about twenty ladies being present. The first regular business meeting took place at the beautiful Fairmont Hotel, Thursday morning, June 28, with a large number of ladies in attendance, representing many states. Mrs. Red gave all a most cordial welcome, and presided with grace and dignity, and explained the object of the meeting. Her report of the work that had been accomplished during the past year, especially that of the Texas Auxiliary, which was organized five years ago at the suggestion of Mrs. McReynolds, was most interesting and inspiring. There were four past

state presidents, and three recording secretaries from Texas present.

Dr. Southgate Leigh, of Norfolk, Dr. Seale Harris, of Birmingham, and Dr. McReynolds, of Texas, all spoke briefly on what the Auxiliary could do to help the medical profession, such as getting better sanitation in the schools and in the homes of the poorer classes, and creating a sentiment against the various fads, fakes, and cults, that are sweeping over the country and deceiving so many of the uneducated.

After the addresses, Mrs. Red stated that fourteen states were represented at this meeting, that ten were already organized, and that much interest was being manifested in this pioneer work to aid the physicians. Mrs. Red told of her visit to Birmingham, where she, with the able assistance of Mrs. Seale Harris, had organized a very enthusiastic auxiliary, and at the invitation of Dr. Long, the president of the North Carolina Society, she attended the State convention last May in Asheville, and organized its auxiliary, Dr. Long giving many valuable suggestions, and this movement now has the enthusiastic co-operation of the women of that state.

The business session was followed by the election of officers, which are: Mrs. S. C. Red, of Houston, Texas, president; Mrs. J. Allison Hodges, of Richmond, Va., president-elect; Mrs. Southgate Leigh, of Norfolk, Va., Mrs. Robert E. Farr, of Minneapolis, Mrs. Seale Harris, of Birmingham, and Mrs. F. P. Gegenback, of Denver, vice-presidents; Mrs. W. A. Wood, of Waco, Texas, recording secretary; Mrs. H. L. D. Kirkham, of Houston, Texas, corresponding secretary; Mrs. A. E. Baker, of Charleston, S. C., treasurer; and Mrs. Harris Smith, of Delta, Colo., parliamentarian.

Each of the four vice-presidents was assigned twelve states to organize during the next year.

As previously reported in these columns, Virginia was organized last Fall at the meeting of the State Society in Norfolk, with Mrs. R. Lloyd Williams, of Norfolk, as president, and since then several auxiliaries have been formed in different sections of the State. The Virginia Auxiliary was represented at the Convention in San Francisco by two delegates, Mrs. J. Shelton Horsley and Mrs. J. Allison Hodges, of Richmond, and Mrs. Southgate Leigh, from

Norfolk, as the first vice-president on the National Board.

It is regretted that more members could not have attended this meeting to gain inspiration for the work, and to have enjoyed the lavish hospitality extended by the ladies of San Francisco. California and the Golden Gate looked most beautiful that brilliant June day when the delegates arrived after their long trip, and the West more than ever sustained its reputation for "receiving strangers with open arms," for not only were the visitors handsomely entertained in the Convention City of San Francisco, but in several cities en route, and the doctors in Albuquerque, Los Angeles, and Portland, provided motor trips and delightful hospitality for the few hours the delegates stopped when passing through these cities.

The Convention, as an event, is over, but as a golden memory and inspiration, it will linger all through life.

M. G. II.

### The Medical Women's National Association

Held its ninth annual meeting in San Francisco, June 25 and 26, in conjunction with the American Medical Association meetings. Dr. Grace N. Kimball, President; Dr. Kate Campbell Mead, President-Elect. At the open session, Monday evening, Dr. Ray Lyman Wilbur, President-Elect of the A. M. A., delivered an eloquent and inspiring address on "The Power of the Minority."

At the open session, Tuesday morning, a Five Year Program was presented by the Executive Committee and Council, and was adopted. This Program is under Five Heads:

1. Continuation of the Work of the Committee on Medical Service, American Women's Hospitals; Dr. Esther P. Lovejoy, Chairman, 637 Madison Ave., New York.

2. Federation of American Women's Organizations with the Medical Women's National Association, under Organization Committee; Gertrude A. Walker, Chairman, Whitefield, N. H.

3. Public Health, Co-operating with A. M. A. Council on Health and Public Instruction, Hygiene, and Women's Foundation for Health, etc., Dr. Elizabeth B. Thelberg, Chairman, Vassar College, Poughkeepsie, N. Y.

4. Committee for Medical Opportunities for Women, Dr. Sue Radcliff, Chairman, 21 Morris St., Yonkers, N. Y. Internships for Young

Graduate-Members of the M. W. N. A. in Hospitals Conducted by the American Woman's Hospitals; in Missionary Hospitals and in Hospitals in U. S. A., as well as Opportunities for private practice, Service on Boards of Health, Government Appointments, etc.

5. Publicity for the Medical Women's National Association through the Bulletin and an Editorial Staff Consisting of the President and Executive Committee, President-Elect and an Editor-in-Chief. Dr. Grace N. Kimball, Poughkeepsie, N. Y., was appointed Editor-in-Chief.

The Bulletin, which was published quarterly last year, will be continued as the Official Organ of the Association and sent to all members of the M. W. N. A.

An amendment to the Constitution was passed, providing for Group Membership. This was in response to proposals for Federation made last year by certain State societies of Medical Women. Under the Group Membership Amendment, organizations of women whose basis of membership conforms to that of the M. W. N. A., viz., Membership in the A. M. A., may join the National as Group Members: Kansas State Medical Women's Society; New York State Medical Women's Society; Connecticut State Medical Women's Society; Portland, Ore. State Medical Women's Club affiliated through their representatives at the San Francisco meeting.

The Nebraska, Los Angeles and New England Medical Women's Societies signified their desire to take action regarding affiliation.

The M. W. N. A. had a most interesting scientific and educational exhibit, at San Francisco, showing the work of the American Women's Hospitals in Greece and Serbia. Twenty hospitals and a large number of dispensaries are being run by this committee of the M. W. N. A. in Greece alone, under the directorship of Dr. Mabel Elliott, New York Headquarters, 637 Madison Ave., New York; Dr. Esther P. Lovejoy, Executive Secretary.

Four periods on the A. M. A. Moving Picture Theater were assigned to the National—a film of work in Greece, Crete and the quarantine Work on Macronesi Islands, shown by Dr. Esther Lovejoy; and slides of Hospital and Surgical work in Serbia, under Dr. Etta Gray.

Dr. Kate Campbell Mead, of Middletown, Conn., was installed as President. Dr. Katherine C. Manion, of Port Huron, Mich., was

chosen President-Elect. Other officers are: vice-presidents, Dr. Martha Welpton, San Diego, Dr. Marjory J. Potter, San Diego, and Dr. Florence W. Duckering, Boston, Mass.; secretary, Dr. Jessie W. Fisher, Middletown, Conn.; treasurer, Dr. L. Rosa H. Gantt, Spartanburg, S. C.

The 1924 annual meeting of the Medical Women's National Association will be held in Chicago, Ill.

## The Truth About Medicine

In addition to the articles enumerated in our letter of May 29th, the following articles have been accepted:

Abbott Laboratories

Amidopyrine-Abbott.

Amidopyrine-Abbott Tablets, 5 Grains.

Epinephrin Chloride Solution-Abbott.

General Chemical Co.

Sofos.

Eli Lilly & Co.,

Iletin (Insulin-Lilly)

Iletin (Insulin-Lilly) H-10:5 Cc. Ampules.

Iletin (Insulin-Lilly) H-20:5 Cc. Ampules.

Powers-Weightman-Rosengarten Co.,

Sulpharsphenamine Billon

Sulpharsphenamine Billon, 0.1 Gm. Ampules.

Sulpharsphenamine Billon, 0.2 Gm. Ampules.

Sulpharsphenamine Billon, 0.3 Gm. Ampules.

Sulpharsphenamine Billon, 0.4 Gm. Ampules.

Sulpharsphenamine Billon, 0.5 Gm. Ampules.

Sulpharsphenamine Billon, 0.6 Gm. Ampules.

### NEW AND NONOFFICIAL REMEDIES.

**Insulin.**—An aqueous solution of an active principle from pancreas which effects sugar combustion. The strength of insulin is expressed in "units," one unit being one-third of the amount required to lower the blood sugar below 0.045 per cent. and cause convulsions in a rabbit weighing 2 kg., which has been previously starved for twenty-four hours. The administration of insulin to diabetic dogs and to man in severe cases of diabetes mellitus restores to the body the lost ability to oxidize carbohydrate, and glycogen is again stored in the liver. If insulin is administered at suitable intervals to a person suffering from diabetes mellitus, the blood sugar is maintained at a normal level and the urine remains free of sugar. Fat is also burned and, as a result, ketone bodies do not appear in the urine and diabetic acidosis and coma are prevented. The administration of insulin is indicated in cases of diabetes mellitus which cannot be controlled satisfactorily by dietetic treatment. Overdosage of insulin is followed by the development of serious symptoms which demand immediate treatment. Insulin is administered subcutaneously one, two or three times a day before meals. The dosage required to reduce the blood sugar to the normal level must be established for each patient by determination of the blood sugar before and after administration of insulin. In cases of coma or severe acidosis, an initial dose of 15 or 20 units of insulin may be given, followed at 3 to 4 hour intervals by smaller doses with simultaneous administration of glucose.

**Insulin-Toronto.**—A brand of insulin. It is marketed in 5 Cc. vials containing 10 units in each Cc., and in 5 Cc. vials containing 20 units in each Cc. Connaught Antitoxin Laboratories of the University of Toronto, Toronto, Ontario, Canada.

**Quinine Ethyl Carbonate.**—The quinine ester of ethyl carbonic acid. Quinine ethyl carbonate was first introduced as euquinine. It is used in place of quinine sulphate and similar soluble quinine salts when a practically tasteless quinine compound is preferred.

**Quinine Ethyl Carbonate—M. C. W.**—A brand of Quinine Ethyl Carbonate—N. N. R. Mallinckrodt Chemical Works, St. Louis, Mo. (Jour. A. M. A., June 2, 1923, p. 1617).

**Arsphenamine-Mallinckrodt.**—A brand of arsphenamine—N. N. R. (See New and Nonofficial Remedies, 1923, p. 46). It is marketed in ampules containing, respectively, 0.1 Gm., 0.2 Gm., 0.3 Gm., 0.4 Gm., 0.5 Gm., 0.6 Gm. and 1.0 Gm. Mallinckrodt Chemical Works, St. Louis, Mo.

**Barbital—M. C. W.**—A brand of barbital—N. N. R. (See New and Nonofficial Remedies, 1923, p. 62). Mallinckrodt Chemical Works, St. Louis, Mo.

**Cinchophen—M. C. W.**—A brand of cinchophen—N. N. R. (See New and Nonofficial Remedies, 1923, p. 90). Mallinckrodt Chemical Works, St. Louis, Mo.

**Mercuric Cyanide—M. C. W.**—A brand of mercuric cyanide—N. N. R. (See New and Nonofficial Remedies, 1923, p. 194). Mallinckrodt Chemical Works, St. Louis, Mo., (Jour. A. M. A., June 16, 1923, p. 1775).

**Insulin (Insulin-Lilly).**—A brand of insulin. (See Jour. A. M. A., June 2, 1923, p. 1617). It is marketed in 5 Cc. ampules containing 10 units in each Cc. and in 5 Cc. ampules containing 20 units in each Cc. Eli Lilly & Co., Indianapolis, Ind. (Jour. A. M. A., June 23, 1923, p. 1851).

**Amidopyrine-Abbott.**—A brand of amidopyrine—N. N. R. (See New and Nonofficial Remedies, 1923, p. 250). It is marketed in substance and in 5 grain tablets. Abbott Laboratories, Chicago, Ill.

**Epinephrin Chloride Solution—Abbott.**—A solution containing epinephrine chloride, equivalent to 1 part of epinephrine in 1,000 parts of physiological solution of sodium chloride, preserved by the addition of benzoic acid and saturation with carbon dioxide. For a discussion of the actions, uses and dosage of epinephrine, see New and Nonofficial Remedies, 1923, p. 112. Abbott Laboratories, Chicago, Ill. (Jour. A. M. A., June 30, 1923, p. 1910).

#### PROPAGANDA FOR REFORM

**Calcium Therapy in Tuberculosis.**—From a review of the literature, Maver and Wells concluded that there is no convincing clinical evidence of the value of calcium administration in tuberculosis. They believe that no deficiency in blood calcium exists in tuberculous patients. From carefully controlled animal experiments these investigators conclude that calcium administration does not affect the course of tuberculosis in animals. If the use of calcium compounds in the treatment of tuberculosis is to be continued, clinical experiments of a scientific character should be conducted. At the present time there appears to be no scientific basis for the use of calcium in tuberculosis. (Jour. A. M. A., June 2, 1923, p. 1619).

**Progress and Conservatism in Therapeutics.**—The Committee on Therapeutics of the Council on Pharmacy and Chemistry has published a communication calling attention to two books which physicians should have—New and Nonofficial Remedies and Use-

ful Drugs. It is explained by the Committee that for eighteen years the Council has done its utmost to bring before the medical profession the truth concerning the new proprietary medicinal preparations which are being offered to the profession. The work and functions of the Council are discussed, and it is explained that while the Council was organized primarily to put a stop to the exploitation of proprietary medicines under false claims and the use of secret preparations, its activities have broadened until its work may now be characterized as a "propaganda for the rational use of drugs." The communication concludes: "New and Nonofficial Remedies" and "Useful Drugs" together furnish information concerning all drugs, old and new, which are at present essential to, or give promise of value in, the practice of medicine. They have been compiled with a special object in view, namely, to meet the needs of the student and practitioner of today. The report is signed by C. W. Edmunds, M. D., Professor of Materia Medica and Therapeutics, University of Michigan, Ann Arbor, Mich.; John Howland, M. D., Professor of Pediatrics, Johns Hopkins University, Department of Medicine, Baltimore, Md.; Ernest E. Irons, M. D., Ph. D., Associate Professor of Medicine, Rush Medical College, Chicago, Ill.; W. T. Longcope, A. B., M. D., Professor of Medicine, Johns Hopkins University, Department of Medicine, Baltimore, Md.; G. W. McCoy, M. D., Director Hygienic Laboratory, U. S. Public Health Service, Washington, D. C.; W. W. Palmer, B. S., M. D., Bard Professor of Medicine, College of Physicians and Surgeons, Columbia University, New York City; Francis W. Peabody, M. D., Professor of Medicine, Medical School of Harvard University, Boston, Mass.; L. G. Rowntree, M. D., Sc. D., Professor of Medicine, Mayo Foundation, Rochester, Minn. (Jour. A. M. A., June 2, 1923, p. 1635).

## Book Announcements

**International Clinics.** A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles by Leading Members of the Medical Profession Throughout the World. Edited by HENRY W. CATTELL, A. M., M. D., Philadelphia, with the collaboration of others. Vol. II. Thirty-Third Series, 1923. Philadelphia and London. J. B. Lippincott Company. This volume contains papers on Insulin, on Medical Diagnosis and Treatment, and Surgery. Cloth. 304 pages.

**Recovery Record.** For use in Tuberculosis. By GERALD B. WEBB, M. D., Consulting Physician Cragmor, Glockner, and Sunnycrest Sanatoria; President Colorado School of Tuberculosis, Colorado Springs, Col., etc., and CHARLES T. RYDER, M. D. Colorado School of Tuberculosis, Colorado Springs, Col. New York. Paul B. Hoeber, Inc. 1923. 79 pages of text divided into four chapters, following which are 108 chart sheets. 12mo. Semi-flexible cloth. 195 pages (2 years' record), \$2.00 net. Postpaid on receipt of price.

**Physiotherapy Technic.** A Manual of Applied Physics. By C. M. SAMPSON, M. D., Formerly of the Physiotherapy Service, Walter Reed, U. S. A. General Hospital, Washington, D. C.; Formerly Chief of Physiotherapy Service and in Charge of Reconstruction Work at Several U. S. A. Hospitals. St. Louis. C. V. Mosby Company, 1923. 443 pages with eighty-five illustrations. 8vo. Cloth. Price \$6.50.

## Editorial

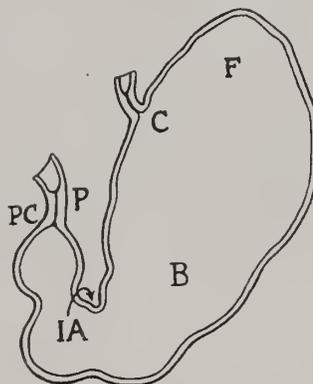

### The Slow Emptying Stomach.

The stomach is the repository, for a brief period, of the swallowed food taken daily into the body. Upon this organ devolves the duty of mixing and dissolving this food, and initiating the processes of digestion of it and, more or less promptly, discharging it into the intestines. While it is important that ingested food products taken in daily shall remain in the stomach and receive the treatment of mixing and partial digestion, so necessary for its physiological breaking-down into assimilable elements, it is equally important that ingested food products shall not remain in the stomach for "too long a time." The stomach may be injured functionally by such a misuse of it.

The mechanism of stomach function is better understood as one recalls the anatomical divisions of it. The stomach is divided into the cardiac and the pyloric portion by an indentation in lesser curvature known as incisura angularis. The cardiac end is subdivided into the (1) fundus (that portion lying "north" of a line horizontally through the cardiac orifice), and into the (2) "body of the stomach" (that portion between the fundus and the incisura angularis). The pyloric end of the stomach is divided into three parts: (1) the pyloric vestibule, (2) the antrum, (3) pyloric canal.

The steps in the mechanical unloading of the filled stomach may be stated in this way. Peristaltic waves originate about the middle of the body of the stomach and travel toward the

pylorus. The fundus region remains free of peristaltic wave-movement, but is the seat of a tonic contraction which maintains a constant pressure upon the food-content, delivering it to the pylorus with a steady force until the fundus is empty. This motor phenomenon of the

Schematic outline of the stomach. At C is the cardia; F, fundus; IA, incisura angularis; B, body; PC, pyloric canal; P, pylorus. The antrum is the portion from IA to PC inclusive. (From Cannon.) (See Physiology and Biochemistry in Modern Medicine, Macleod.)

stomach is an essential one in the emptying of food into the intestines. Without adequate motor power the stomach fails to empty itself and the partially digested food undergoes a fermentative and putrefactive change in spite of its pepsin-hydrochloric acid digestion.

In connection with this one may briefly consider the control of the pyloric sphincter. It seems necessary to modify views elaborated by Cannon that the pylorus is controlled by the acidity of chyme alone. Now, it seems that the control of the pylorus rests upon the "magnitude of the antral contractions." Chyme passes into the duodenum during gastric contraction and coincides with the peristaltic waves traveling over the stomach. The waves in their course over the stomach show varying degrees of contraction and relaxation. The time elapsed between phases of relaxation in the wave is spoken of as a gastric cycle. Stomachs vary in gastric cycles. Some waves are one, two, three or four cycle types of gastric cycles. The four cycle is the most common type of peristalsis. A gastric cycle requires two to three seconds and a four cycle peristalsis requires eight to twelve seconds. When the peristaltic wave, beginning in the body of the stomach and traveling toward the pylorus, reaches the antrum, the sphincter relaxes and the contents are propelled into the pyloric opening. The sphincter relaxes in response to every peristaltic wave

arriving at the antrum and apparently does so blindly, without regard to the reaction of the gastric or duodenal contents, says Macleod, although, no doubt, other factors than peristalsis enter into the emptying of stomach chyme into the pylorus.

Wheeler and Thomas' work in connection with observations made on the relationship between the activities of the duodenum below the "reservoir cap" and the movements of the antrum and pyloric sphincter is interesting. It was found that the duodenum enters upon its positive phase two and a half seconds after the commencement of the sphincter contraction and at the moment the antrum relaxes. It remains relaxed throughout the sphincter and duodenal contractions.\*

#### CONDITIONS INFLUENCING THE EMPTYING OF THE STOMACH.

It is known that the consistency of the foods does not have a very great effect upon the emptying of the stomach. Experiments upon the time required for certain foods to get out of the normal stomach show that there is considerable variation. For instance, the raw egg evacuates in a short time, in less than two hours, while the beef steak may be four hours in evacuating.

The presence of a considerable amount of gas, generated in stomachs as a result of dysfunction or indigestion of the food, and accumulating in cardia, markedly delays the emptying time of the stomach. This may result from the pneumatic pressure upon the stomach musculature which interrupts the peristalsis and eventuates in gastric atony, dilatation and ptosis.

The emptying time of the stomach is influenced by the secretory function indirectly but directly by the motor-function. The term atony applies to that want of power in the musculature to promptly and completely mix and evacuate food received in a normal meal. This condition is due, as above stated, to the failure of peristaltic waves arising in the body of the stomach and traveling to the pylorus, to generate enough force to empty the stomach of its contents. This is not ptosis. There may be and there usually is some dilatation of the organ, which results from the fatigue factor in muscle structure of the stomach wall. Hence,

we may have to deal with not only a slow emptying stomach (atonic) but also a dilated one. Such a stomach may, in addition to the factors of atony and dilatation, become displaced downward (ptosed). In such a fasting organ, the "succussion splash" is quite pathognomonic of ptosis without power to empty completely. The effort to make a line of delineation is of little practical importance, because in both instances the evacuating or emptying function is embarrassed and the organ is crippled.

The capacity of the stomach may be taxed by overloading. The meal may be a mixed one of meat, vegetables and sweets, with fluids. The stomach begins its peristaltic wave action in the body of the organ; the cardiac section fixes its muscular contractions upon its gas and fluid contents; slowly through the course of two to four hours, performing thousands of microscopic muscular contractions and four to five hundred expulsive wave contractions toward the pylorus, the mixed contents of meat, potato, salads, pies, sweets, coffee and what not, are gradually propelled toward and expelled through the pyloric outlet. So, continued and habitual overloading or dietary indiscretions begin to bring about a weary, atonic musculature. There may be and there usually is secretory disturbance also. Besides, there may be stomach atony with slow emptying function in patients suffering from general muscular weakness from long-standing general diseases, as anemia, syphilis, tuberculosis and diabetes mellitus; in persons who fail to take proper physical exercise or persons who lead sedentary lives.

Actual gastroptosis alone, without splanchnoptosis, is rare. But it does not matter whether or not the cardia actually leaves its upper attachments alone or in association with other viscera. The fact remains that the "deeps" of the stomach descend in such instances to the "pit" of the pelvis and the daily load placed in this reservoir is not evacuated or emptied, except tardily. This is the important desideratum. For it has been known that not all ptosed stomachs lack the power of evacuation. The position of the stomach is not the criterion for judgment of stomach function, but its power to evacuate its load is the real test of function. Physicians may look with keener interest upon the emptying function of the stomach as a measure for judging of its motor func-

\*Macleod, pages 484-495. *Physiology and Biochemistry in Modern Medicine.*

tion rather than upon the location of the loaded organ.

#### INDICATIONS OF SLOW EMPTYING STOMACHS.

Delayed evacuation is indicated by the usual signs of gastric indigestion. Not enough attention is given to the complaints of so-called "dyspepsia." "Dyspepsia" means stomach misfunction. One of the earliest of these dysfunctions is tardy gastric evacuation. A slowing of gastric emptying kicks up discomfort. The appearance of eructations after taking a meal is a symptom of it. The cardia, ballooned with gas, indicates impaired gastric motility as it may gastric secretory disturbance. The sense of fullness and dragging over the upper abdomen, heart-burn, and regurgitation of food, point to impairment of physiologic action in the stomach and may be positive evidence of the delayed evacuation, associated possibly with chronic gastritis, gastric dilatation and gastric ptosis.

In connection with these signs there are frequently signs of systemic disturbance, such as dizziness, morning headache, mental sluggishness (biliousness), melancholia, insomnia and physical weakness. Such patients are rarely free of other and associated morbid processes, which may enter more or less into the etiology of the gastric dysfunction under consideration. From the history of "stomach cases," one may sense often the associated pathology. Is it not singular how true to form the story of "gastric ulcer," "gastric cancer," "gastritis," "gall tract," and "the appendix" case comes out in the "bill of complaints?"

Every history that suggests the signs of gastric pain, nausea, heart-burn, belching, heaviness, oppression, and cardiac or respiratory disturbances following a meal, should receive a careful consideration from the point of view of gastric function and its associated early and late morbid pathology. Every "chronic stomach case," as every "chronic eye case," or other sort of chronic case, should be carefully studied as a whole. The patient should receive, if possible, a systematic general physical examination. This should be done with the patient in position for such complete general physical examination that is free of the encumbrance of clothing, with all due regard for the amenities of life, particularly modesty. Clothing, and the failure to use a good head mirror, or a good light, is often the cause of the errors of diagnosis. A body carefully inspected "from head

to foot," by an observing physician, is very much more liable to receive accurate judgment than one covered or only seen in sections. An examination in standing position is as important as one in the recumbent position.

Indications of a slow emptying stomach are readily confirmed by the stomach tube and X-ray examinations, as well as by inflation of the stomach with gas, with a Seidlitz powder, or by eliciting the succussion splash of a so-called "fasting stomach." If a stomach, for instance, six hours after an average meal, gives such evidence of immobility as the production of the splashing sound, referred to, one may conclude that there is evidence of improper function.

#### INTUBATION.

The introduction of a tube into the stomach is not difficult. It is not done often enough. The patient is often at fault, because few people there are who do not dislike the thought of "gagging" and nausea. Such an attitude subconsciously reacts upon the practitioner. The examination of the stomach contents, either after the so-called *test meal* has been given or the contents of a stomach that has been fasting for six hours, often may give evidence of the nature of the stomach complaint before gross morbid anatomy has been established. Were intubation done oftener in cases of "dyspepsia" or stomach cases, the probabilities are that the gross and terminal pathology with which we have to deal now would be prevented. The ideal method for the study of gastric function is by the fractional gastric method. This small tube tip can be "swallowed" easily. The patient, with a little instruction, can readily swallow the tube and "feed" it into the stomach. The material obtained should be examined as to (1) quantity; (2) length of time in the stomach; (3) degree of digestion, early and late; (4) the color, odor, general appearance of samples at various aspirations during the intubation; (5) total acidity, free acidity; (6) food retention; (7) microscopic examination; (8) blood; (9) pus; (10) mucus; (11) bile; (12) bacteria.

In the field of motor function of the stomach, one should remember that the Ewald test is evacuated, *in health*, in two to two and a half hours. In other words, an Ewald test meal should not get out of the stomach before two hours, or after two and a half hours after taking. If evacuated in an hour and a half,

there is hypermotility, and, if retained more than two and a half hours, there is hypomotility, or slow emptying power.

As one recalls the grouping of hypermotility cases into (1) achylia gastrica, (2) scirrhus carcinoma with patulous pylorus, (3) a small proportion of cases of duodenal ulcer, (4) those due to function (nervous) hyperperistalsis incident to examination, so one must classify the hypomotility cases in two general groups: (1) association with early digestive disturbances (dyspepsia and those with muscular atony, dilatation and ptosis), (2) true obstruction—blocking pathology.

## News Notes

### Virginia State Board of Medical Examiners.

At the June meeting of the Board, in Richmond, sixty-six doctors were licensed to practice in this State, fifty-seven by examination and nine by reciprocity. It is announced that this is the largest number to be licensed by the Board since 1914.

Those licensed by examination are:

Dr. Bolling Jones Atkinson, Johnston-Willis Sanatorium, Richmond.

Dr. Emerson M. Babb, Stuart Circle Hospital, Richmond.

Dr. W. H. Batte, Jr., Retreat for Sick, Richmond.

Dr. Benj. F. Bailey, Ft. Defiance, Va.

Dr. Wyatt S. Beazley, Jr., St. Francis Hospital, Jersey City, N. J.

Dr. John A. Blakeney, New York City.

Dr. Wm. P. Bittinger, Johnston-Willis Sanatorium, Richmond.

Dr. Jos. E. Burns, City Hospital, New York City.

Dr. E. P. Cardwell, Wilmington, N. C.

Dr. William E. Chapin, Richmond.

Dr. Fielding Combs, City Hospital, New York City.

Dr. John G. Davis, Jr., Roanoke, Va.

Dr. Saml. W. Eason, Jersey City Hospital, Jersey City, N. J.

Dr. Monroe Jacob Epting, Jr., St. Luke's Hospital, New York City.

Dr. Richard T. Ergenbright, City Hospital, Worcester, Mass.

Dr. Rowland H. Edwards, Memorial Hospital, Richmond.

Dr. Percy R. Fox, Retreat for Sick, Richmond.

Dr. Benjamin E. Glass, Muhlenberg Hospital, Plainfield, N. J.

Dr. Samuel J. Goldfain, Richmond.

Dr. Joseph T. Graham, St. Luke's Hospital, Richmond.

Dr. W. S. Grambling, Craig Healing Springs, Va.

Dr. Benjamin F. Haskell, Philadelphia.

Dr. Frank E. Handy, Toms Creek, Va.

Dr. Rogers N. Harris, St. Luke's Hospital, Richmond.

Dr. Robt. P. Hawkins, Jr., C. & O. Hospital, Clifton Forge, Va.

Dr. Frank Helvestine, Jr., Roanoke, Va.

Dr. Robt. Battaile Hiden, Pungoteague, Va.

Dr. Clack D. Hopkins, Flushing Hospital, New York City.

Dr. Humie Z. L. Horton, Apex, N. C.

Dr. Wm. B. Hubbard, Broadway, Va.

Dr. Robt. S. Kyle, Woodlawn, Va.

Dr. Estes Caskie Kidd, Nelson County, Va.

Dr. Robt. Bruce Lawrence, Richmond.

Dr. Lee S. Liggan, Memorial Hospital, Richmond.

Dr. Eugene L. Lowenberg, Lenox Hill Hospital, New York City.

Dr. Homer B. Luttrell, Amisville, Va.

Dr. Thomas Hodge McGavach, Waterford, Va.

Dr. John A. Mease, Jr., Memorial Hospital, Richmond.

Dr. John W. McNabb, Belleville, Pa.

Dr. Henry H. Menzies, Retreat for Sick, Richmond.

Dr. Edwin Raymond Mickle, Philadelphia General Hospital, Philadelphia.

Dr. Phil Hawkins Neal, Gouverneur Hospital, New York City.

Dr. Waverly R. Payne, Elizabeth Buxton Hospital, Newport News, Va.

Dr. Clarence E. Perkins, Northwestern General Hospital, Philadelphia.

Dr. Louis Perlin, Memorial Hospital, Richmond.

Dr. Fred F. Oast, Portsmouth, Va.

Dr. Miles P. Omohundro, Charlottesville, Va.

Dr. William I. Owens, Lenox Hill Hospital, New York City.

Dr. Russell W. Roberts, Faber, Va.

Dr. J. Churchill Robertsen, Long Island Hospital, Brooklyn, N. Y.

Dr. Harry T. Schiefelbein, New Libson, Wis.

Dr. David L. Strader, St. Charles, Va.

Dr. Leta J. White, Memorial Hospital, Richmond.

Dr. Ernest M. Wilkinson, Stuart Circle Hospital, Richmond.

Dr. John Powell Williams, St. Luke's Hospital, New York City.

Dr. Richard L. Willis, New York City.

Dr. Archer A. Wilson, Oxford, N. C.

Those licensed by reciprocity are:

Dr. Nat. H. Copenhaver, Rochester, Minn.

Dr. Francis A. Georger, Warrenton, Va.

Dr. Hannes Inberg, Warren, Ohio.

Dr. Kenneth E. Lowman, Norfolk, Va.

Dr. Seab A. Tuck, Eggleston, Va.

Dr. George Penn Dillard, Draper, N. C.

Dr. Walter L. Hogan, New York City.

Dr. George Richardson Joyner, Suffolk, Va.

Dr. Thos R. O'Rourke, Norfolk, Va.

**Ladies Especially Invited to Attend the Meeting of the State Medical Society Which Will be held in Roanoke, October 16th-19th.**

The Entertainment Committee wishes particularly to announce that an especial feature of the meeting of the State Medical Society this year will be plans for the entertainment of the ladies.

It will be recalled that a Ladies' Auxiliary was organized at the Norfolk meeting with Mrs. R. L. Williams of Norfolk as President and Mrs. Sparrell Gale of Roanoke as Vice-President. It is planned that as a preliminary to the future activities a meeting of the Auxiliary will take place at Hotel Roanoke on Wednesday morning, the second day of the meeting of the Society.

The Ladies' Entertainment Committee of Roanoke are at present busy with tentative plans which, among other things, include visits to points of interest in and around Roanoke, such as Hollins College, Virginia College, Roanoke College, a trip up the Mill Mountain Incline, and last but not least a trip to the Catawba Sanatorium, and a barbecue and entertainment at Lakeside.

The officers of the State Board of Health and of the Sanatorium have been good enough to include all members of the Society and visiting ladies in the invitation to visit Catawba. Likewise Dr. Everett Watson of Salem has kindly invited all to visit and inspect Mt. Regis Sanatorium.

It is now planned that early in the afternoon of Wednesday, following the Scientific program of the morning, automobiles will leave

Roanoke by the way of Salem, visiting Mt. Regis and going directly to Catawba. A splendid macadam road is now nearing completion the entire distance which, as those who have previously made the trip will attest, leads through beautiful and rugged mountain scenery which will be at its best in October.

If it be found agreeable to the Scientific Program Committee, it is planned to group such papers as may deal with Tuberculosis and kindred subjects and present them at the Sanatorium along with such demonstrations and other matters of interest as doubtless will be presented by the physicians of the Sanatorium.

Dinner will be served at the Sanatorium in ample time for the return trip to Roanoke and the resumption of the Scientific Program of the evening, following which a dance will be tendered.

While the complete plans for the barbecue and entertainment at Lakeside on Thursday have not been worked out, the Committee promises that it will not be lacking in features of interest. Following the barbecue the ladies will be entertained by a musical at the Country Club.

*Ladies make your plans to come to Roanoke and enjoy a splendid outing!*

**Open Letter to the Doctors of Virginia.**

1110 Capitol Street,

Richmond, Va.,

July 27, 1923.

There have been in Virginia a large number of cases of illness presenting the following characteristics:

Acute onset with severe epigastric pain which may extend later to one or both sides of the lower portion of the thorax. The pain is described as very severe, as cutting or as cramp-like. The pain is increased by deep breathing so respiration is shallow and rapid. A rate of 60 per minute has been noted. An expiratory grunt is frequently observed.

The temperature is usually 100 and 102, pulse 80 to 100. The patient looks very ill. The face is pinched or moderately cyanosed.

Constipation is the rule and abdominal distention is frequent.

The most severe symptoms are at the time of onset and last from four to twenty-four hours. The duration of acute illness is seldom more than five days but slight elevation of temperature may continue for three weeks.

The condition affects children and adults but is more common in the former. It spreads through families in the manner of a contact infection. There have been no deaths but a few cases have been followed by serious illness of some other type.

The condition is apparently an undescribed communicable disease now occurring as an epidemic. This description is issued so that you may be on the lookout for it in your practice. If it occurs or has occurred in your practice, please notify us of the number of cases and the date when your first case was seen.

ENNION G. WILLIAMS, M. D.

*State Health Commissioner and Collaborating Epidemiologist, U. S. P. H. S.*

### Attention, Doctors!

The above communication from the State Health Commissioner, Dr. Ennion G. Williams, explains itself. As a matter of interest to the profession, in addition to reporting your cases, as requested by Dr. Williams, it will be helpful to have an expression of opinion from our readers as to their treatment of these cases, with results obtained.

### Re-Organization of the Professional Activities of the Free Dispensary and the Hospital Division of the Medical College of Virginia.

The Medical Staff of the Hospital Division of the Medical College of Virginia was completely reorganized during September, 1922, and the professional activities in the Dooley Hospital for white children under ten years of age, the Memorial Hospital for the white patients over ten years of age, and the Saint Philip Hospital for negro patients, which hospitals are owned and controlled by the Medical College of Virginia, have been carried on by the reorganized Medical Staff, since that time. The Medical Staff is organized in the following manner:

The Administrative Committee of the Medical Staff comprises the Dean of the Faculty of the School of Medicine as Chairman, the Superintendent of the Hospital Division as Secretary, and the following professors of the School of Medicine of the College who, co-incident with their election, are appointed by the Executive Committee of the Board of Visitors as heads of the departments indicated: Professor of Medicine as Physician-in-Chief; Professor of Surgery as Surgeon-in-Chief; Pro-

fessor of Obstetrics as Obstetrician-in-Chief; Professor of Pathology as Pathologist; Professor of Roentgenology as Roentgenologist.

The Administrative Committee of the Medical Staff meets once each week at the Memorial Hospital, and thoroughly canvasses and discusses the various professional activities carried on in the Hospital Division. It is empowered to make, promulgate and enforce rules and regulations governing the professional and teaching work in the Hospitals, subject to the approval of the Medical Staff.

The Medical Staff is selected from the Faculty of the School of Medicine of the College, and is elected annually in June by the Executive Committee of the Board of Visitors. The personnel is nominated by the Chiefs of Departments represented on the Administrative Committee of the Medical Staff, upon the recommendation of the heads of the various divisions and services established in the Hospital Division, who are the heads of corresponding Divisions on the faculty of the School of Medicine of the College. They are known as Physicians and Surgeons, and Associate Physicians and Surgeons.

The Assistant Medical Staff is selected from the faculty of the School of Medicine of the College, and is elected annually in July by the Executive Committee of the Board of Visitors upon the recommendation of the Medical Staff. They are known as Junior Physicians and Surgeons.

The medical and surgical treatment of patients occupying beds in the wards of the hospitals, irrespective of whether their expenses are paid by the City, by the State, or by themselves, is directed and supervised by the group from the Medical Staff organized for that purpose. Physicians and surgeons are not permitted to charge or receive a fee or emolument for services rendered to Ward Patients, and arrangements have been made to accommodate in private rooms at a moderate charge patients debarred from the Wards on account of this ruling. Patients occupying beds in the Wards of the Hospitals, who are able to pay for the care and treatment rendered, are charged \$2.50 per day, which is in full for all examinations and treatment necessary, there being no extra charges whatever.

All reputable physicians and surgeons in Richmond have full privilege to treat patients occupying private rooms in any of the hos-

pitals, including the use of the operating rooms.

On July 1, 1923, the Free Dispensary, heretofore maintained by the Medical College of Virginia as a separate department, became the "Out-Patient Department" of the Hospital Division, and its affairs both administrative and professional will from that time on be directed and supervised by the officials of the Hospital Division. The Medical Staff of the Out-Patient Department will be selected from the personnel of the Medical Staff and Assistant Staff of the Hospital Division. Appointment on the Medical Staff and Assistant Staff of the Hospital Division carries with it an obligation to serve on the Medical Staff of the "Out-Patient Department" in the corresponding Division or Service. This will bring about a closer co-ordination of the work of caring for and treating patients in the various Departments, as physicians and surgeons treating patients in the Hospitals may, on the discharge of the patient from the Hospital, refer the patient to the Out-Patient Department for continued observation and minor treatment, under their direction and supervision. Likewise, patients applying to the Out-Patient Department for treatment, and requiring to be admitted to the Hospital, may be observed and in many instances treated by the physician or surgeon first seeing the patient in the Out-Patient Department.

Included in the program of enlargement of the Medical College of Virginia is a building seven floors in height, the first three floors to be used exclusively by the Out-Patient Department, and the other four floors to be used by the Pathological Laboratory and related activities.

#### Woman's Auxiliary.

Members of the Woman's Auxiliary of the Medical Society of Virginia will be much interested in the report given on page 335, this issue, by their delegate, Mrs. J. Allison Hodges, of Richmond. Only three of our Virginia members were represented at the San Francisco meeting of the National Woman's Medical Auxiliary, but we count on larger attendance next year, as the members of the Virginia Auxiliary become more interested in the work.

In San Francisco, entertainments were arranged for the ladies every day and these, with the many points of interest to be visited, added very greatly to the enjoyment of those

who attended. The crowning event, perhaps, was the visit to the beautiful Stanford University, including the organ recital and the reception at the home of President and Mrs. Ray Lyman Wilbur.

#### Report on Alcoholism in Virginia.

Dr. W. A. Plecker, Director of the Virginia Bureau of Vital Statistics, replying to an inquiry from the World League Against Alcoholism, London, as to the effect from a medical standpoint of prohibition in this country, states that much good has already been accomplished since the State prohibition law went into effect. Without reference to the improvement in the moral conditions among the working class, there has been a gradual but very decided decrease in deaths from cirrhosis of the liver, showing that chronic alcoholics are gradually decreasing. The chief reason for the present number of deaths attributed to alcohol "is that the stuff now being sold for whiskey is not whiskey, and would have by no means passed the test of former years." The number of deaths in Virginia from alcoholism in 1922 was forty-nine. The first year after the prohibition law went into effect in Virginia (1917), the number of deaths from alcoholism was only twenty, as compared with sixty the preceding year.

#### Dr. Irving S. Barksdale,

Son of Dr. George E. Barksdale, formerly of Richmond, but now connected with the U. S. Veterans' Hospital, at Oteen, N. C., has been elected professor of physiology in the Medical College of South Carolina, at Charleston. He will enter upon his duties the first of September. Dr. Barksdale graduated from Yale University School of Medicine this year, and his appointment is the indirect result of some research work he has done in the field of medicine. Dr. Barksdale has quite a war record, having seen service on the Mexican border and later in the World War.

#### Dr. R. M. Gilliam,

Formerly of Newport News, Va., and a graduate of the Medical Department of the University of Virginia in 1919, has been on a visit to Williamsburg, Va.

#### Dr. and Mrs. R. A. Vonderlehr

Have returned to their home in Richmond, after a visit to friends in Heathsville, Va.

**Dr. T. C. Harris,**

Recently of Kenbridge, Va., has located in Martinsville, Va., where he is associated with Dr. M. E. Hundley at the Lucy Lester General Hospital.

**Dr. Jury B. Loving,**

Upon completing his internship at St. Luke's Hospital, Richmond, the first of July, located at 636 North Main Street, Danville, Va.

**Dr. William H. Batte, Jr.,**

Jarratt, Va., is serving as one of the internes at Retreat for the Sick, Richmond. He is temporarily taking the place of Dr. Samuel P. Hileman, of Rockbridge Baths, who has been quite sick at his home, with meningitis. Both of these doctors graduated from the Medical College of Virginia this June.

**Dr. M. Grove-Hagen,**

Richmond, left the first of July for a visit to his former home in Norway. He expects to be back about the first of September.

**Dr. Ramon D. Garcin,**

Richmond, has been named one of the trustees of the Grand Chapter, Royal Arch Masons of Virginia.

Dr. Garcin has also been recently elected a member of the public library board of Richmond.

**Dr. and Mrs. A. T. Finch,**

Of Chase City, Va., recently attended the reunion of the Bacon family in North Carolina.

**Dr. Robert S. Spilman,**

Medical officer of the Virginia Military Institute at Lexington, has been the guest of his sisters at their home near Warrenton, Va.

**Dr. S. S. Northington**

And several friends of South Hill, Va., spent a week in July on a fishing trip at Ocean Park.

**Dr. and Mrs. R. L. Hudgins**

And little daughter of Farmville, Va., have been among the summer visitors at Virginia Beach.

**Dr. M. D. Arcy Magee,**

Washington, D. C., after spending several months abroad, will return home the latter part of September.

**Dr. E. L. Flanagan,**

Richmond, has returned from New York where he was engaged in post-graduate work in X-ray. He will shortly open offices in the Medical Arts Building.

**Dr. William A. McGowan,**

Richmond, has been elected a member of the board of directors of the Federal Trust Company, of this city.

**Former Virginian Awarded Croix De Guerre.**

Information has been received here stating that Dr. Lewis S. Herndon, formerly of Richmond, has been awarded the French Croix de Guerre, with a gilt star. The reward comes as the result of heroic care for the wounded near Soissons, in 1918.

Dr. Herndon graduated from the Medical College of Virginia in 1914 and, after a few months in North Carolina, located in Virginia until he entered the World War. He returned to this country after eighteen months' service, during which time he was wounded, and took post-graduate work at Manhattan and Lying-In Hospitals, New York City. He was for twelve months head of the house staff of the latter hospital. About a year ago he located in Newark, N. J., where he is now specializing in obstetrics.

**Dr. and Mrs. John D. Foltz**

And children have returned to their home in Richmond after a visit to Buckroe Beach and Ocean View, Va.

**Insulin Clinics.**

To meet the demand for the insulin treatment of diabetes, special clinics are being held in hospitals in a number of the larger cities in the United States and Canada, to teach physicians in general practice the proper methods of employing the treatment. This instruction is made possible by a large donation by Mr. John D. Rockefeller, Jr.

**Chiropractors Must Pass State Board Examination.**

We note from the *Journal of the A. M. A.* that chiropractors and other "drugless" practitioners, graduates of mechanotherapy schools, will be granted certificates to practice in the State of Alabama, provided they pass an examination given by the State Medical Examining Board. New regulations require that ap-

plicants be examined in certain branches, among which are anatomy, chemistry, physiologic chemistry, bacteriology and pathology.

#### **Dr. Samuel Newman**

Has returned to his home in Danville, Va., and opened offices in Arcade Building. He will limit his practice to diseases of infants and children. Dr. Newman served abroad for twenty months as a member of the Medical Commission of the American Joint Distribution Committee in Poland, Galicia and Ukraine, and for ten months as Volunteer Physician in the Children's Clinic of the University of Vienna.

#### **The American Association of Obstetricians, Gynecologists and Abdominal Surgeons**

Will hold its next annual meeting in Philadelphia, September 19, 20 and 21, 1923.

#### **Maj. Herbert C. Mallory, M. C.,**

Has been relieved from duty with the Eightieth Division, organized reserves, at Richmond, Va., and will sail from San Francisco, October 23, for the Hawaiian Islands, where he will report to the commanding general of that department for duty with the medical corps.

#### **Department Surgeons for Sons of Confederate Veterans, A. N. V.**

Drs. Benjamin L. Hume, Huntington, W. Va., E. Ackley Moore, Marshall, Va., and Lawrence T. Price, Richmond, are among those who have been appointed department surgeons in the Army of Northern Virginia, Sons of Confederate Veterans.

#### **Professor of Pediatrics, University of Virginia.**

Dr. Lawrence T. Royster, Norfolk, Va., was elected professor of pediatrics in the University of Virginia, Department of Medicine, at a special meeting of the university board of visitors, held July 13. Dr. Royster will assume his new duties about the first of January, 1924. This is the first time the University of Virginia has had a full time professor of pediatrics, this branch having been included in the course of medicine.

Dr. Royster is recognized as one of the prominent pediatricians of the South and is a member of the American Pediatric Society. He is an alumnus of the University of Vir-

ginia, having graduated from its Medical Department in 1897. He will be greatly missed in Norfolk, where he has done a great deal of work in the children's clinics in addition to his private work.

#### **Sanitary Inspectors Trained at the University of Virginia.**

The first ten weeks' intensive course for Sanitary Inspectors, held at the University of Virginia, was completed on May 1st. Those completing the course were Miss Mary Lee Helms, of Blacksburg, Va., John Walton Robertson, of Charlotte Courthouse, Va., and Philip Kime, of Salem, Va. All of these students have been appointed to positions as County Sanitary Inspectors, Miss Helms being located at Lebanon, Russell County, Mr. Robertson at Chincoteague Island, Accomac County, and later transferred to Loudoun County, and Mr. Kime having worked for some months in Albemarle County has been transferred to Greene County to control an epidemic of dysentery. All these workers are filling good positions, and their work has been highly commended.

The University of Virginia is offering twelve weeks' intensive course for the training of Health Officers and ten weeks' course for Sanitary Inspectors. These courses are almost entirely of a practical nature and are conducted in the field, the plan being to give as much practical training as possible in the time required so that those taking the courses can best serve the needs of the State.

#### **Dr. Walter E. Vest,**

Huntington, W. Va., in July visited Williamsburg, Va., where he attended a meeting of the board of managers of the William and Mary Alumni Association, of which he is a member.

#### **The Southwestern Virginia Medical Society**

Will hold its fall meeting in Abingdon, September 6 and 7. The president, Dr. R. H. Woolling, Pulaski, will deliver his annual address and a most interesting program on medical and surgical subjects has been prepared. A subscription banquet will be held on the evening of the 6th. Dr. E. G. Gill, Roanoke, is secretary-treasurer of this Society.

#### **Dr. Everett A. Lockett,**

Winston-Salem, N. C., has been appointed

county physician for Forsyth County, North Carolina.

**Dr. Joseph L. Spruill,**

Recently of the staff of the N. C. Sanatorium for the treatment of Tuberculosis, at Sanatorium, N. C., beginning September 1, will have charge of the Guilford County (N. C.) Hospital for the Tuberculous.

**Dr. and Mrs. C. V. Montgomery,**

Family and some friends, of South Hill, Va., have returned home after a motor trip through the Valley of Virginia.

**Dr. and Mrs. I. K. Briggs,**

South Boston, Va., are home again after a motor trip through New England.

**The Sixth (N. C.) District Medical Society,**

At its meeting in July, elected Dr. Eric A. Abernethy, Chapel Hill, president, and re-elected Dr. Burton W. Fassett, Durham, secretary.

**The American Therapeutic Society,**

At its annual meeting in San Francisco, the latter part of June, elected Dr. George H. Evans, San Francisco, president, Dr. Lewis H. Taylor, Washington, D. C., secretary, and Dr. Spencer L. Dawes, New York City, treasurer. Both of the latter were also elected to serve five-year terms on the council.

**Dr. and Mrs. Raymond C. Hooker,**

Richmond, have been enjoying a motor trip through several of the Southern states.

**The American Psychiatric Association,**

At its annual meeting in Detroit, the latter part of June, selected Atlantic City, N. J., as the 1924 place of meeting. Dr. Thomas W. Salmon, Larchmont, N. Y., professor of psychiatry at Columbia University, New York, was elected president; Dr. William A. White, Washington, D. C., vice-president; and Dr. Clarence Floyd Haviland, Albany, N. Y., secretary-treasurer.

**New State Health Commissioner of New York.**

Dr. Mathias Nicoll, of Albany, has been appointed New York State Commissioner of Health, to succeed Dr. Hermann N. Biggs, who died from broncho-pneumonia on June 28. Dr. Biggs was one of the pioneer health workers

of this country. Dr. Nicoll has been with the New York State Health Department for the past eight years and for the past four years has been Deputy Commissioner. Prior to that time he was secretary of the department and director of Public Health Education.

**Dr. James O. Mathews,**

Clinton, N. C., has returned home after several weeks in New York where he was doing post-graduate work. Dr. Mathews has many friends in this section, having graduated from the University College of Medicine, Richmond, 1897. He states that he lives on a farm and is doing a real country practice.

**Dr. O. O. Ashworth**

Has opened offices in Suite 701, Professional Building, Richmond, for the practice of general medicine. He will move to the Medical Arts Building when it is completed.

Dr. Ashworth was for two years an interne at St. Elizabeth's Hospital, Richmond, and for the past year has been assistant physician at Catawba Sanatorium, Va. He has recently been appointed assistant attending physician to St. Elizabeth's Hospital, Richmond, Dr. William H. Higgins being attending physician and head of the Medical Department there.

**Dr. and Mrs. Hugh McGuire,**

Alexandria, Va., left the latter part of July for a visit of some length in Nova Scotia.

**Dr. Hubert L. Wyatt,**

Petersburg, Va., has resigned as a member of the medical corps, Virginia National Guard, for business reasons.

**Dr. Hunter McGuire,**

Richmond, recently spent several weeks with a patient at Saranac, N. Y.

**Dr. and Mrs. Joseph Hume**

And daughter, of Norfolk, Va., motored to Old Sweet Springs, W. Va., early in August, to spend the remainder of the summer at that place.

**Dr. and Mrs. Thomas J. Kagey,**

Newport News, Va., are spending several weeks visiting Alaska.

**Dr. Sidney Trattner**

Has returned to his home in, Richmond after a visit to New York.

**Dr. and Mrs. E. H. Terrell**

And daughters, Richmond, are spending some time at Wrightsville Beach, N. C.

**Richmonders hurt in Motor Accident.**

Dr. Thomas E. Hughes, of Richmond, his brother, Dr. John M. Hughes, a dentist of this city, and their mother suffered a number of bruises and cuts in an automobile collision near Boonsboro, Md., early this month. In spite of their injuries, however, they were able to proceed with their trip.

**Dr. P. L. Hill, Jr.,**

Of the class of '17, Medical College of Virginia, who has been engaged in medical missionary work in Choonchun, Korea, for the past six years, is now on a furlough in this country. At present he is taking a special course in diseases of the spine at Battle Creek Sanitarium. Dr. Hill expects to return to Korea about the first of December.

**Aid to Authors.**

To those who are preparing or contemplating the preparation of manuscripts, the information given in the advertisement of the Corona Typewriter, in this issue of the Journal, may prove of interest and service.

By the way, why not look over our advertising pages every month? You will find many things of interest constantly.

**Dr. and Mrs. J. N. Elder,**

Hopewell, Va., have been on a visit to Mrs. Elder's relatives in Christiansburg, Va.

**Dr. Sam Wilson**

Returned to his home in Lynchburg, Va., the first of this month, after a visit to his mother in Petersburg, Va.

**Acting Health Officer in Petersburg.**

Dr. Mason Romaine has been acting as city health officer of Petersburg, Va., during the absence from the city of Dr. R. A. Martin, who has been undergoing treatment at a Richmond hospital.

**Dr. Powell Graham Fox,**

Who recently completed his term of service as an interne at the Retreat for the Sick, Richmond, has located at 310 Masonic Temple, Raleigh, N. C., where he is engaged in general practice.

**Dr. J. B. Dalton,**

Richmond, announces the removal of his of-

fices and residence to 1100 West Franklin Street, this city. He has just completed a very attractive building at this place.

**Southern Medical Association Meeting.**

Plans are being made for a "big" meeting of the Southern Medical Association in Washington, D. C., November 12-15, inclusive, under the presidency of Dr. W. S. Leathers, of University, Miss. The New Willard Hotel will be general hotel headquarters, though the various sections will hold their meetings in other hotels. Mr. C. P. Lorz, secretary-manager of the Association, Empire Building, Birmingham, Ala., will gladly furnish any information requested about this meeting.

**Dr. W. E. Dickerson,**

A graduate of the Medical College of Virginia in 1922, upon completing his internship at Retreat for the Sick, Richmond, in July, located in Danville, Va., with offices at 563 Main Street.

**Dr. George H. Snead,**

Of Fork Union, Va., leaves on the 20th of August for New York City, where he will take a post-graduate course in diseases of the eye, ear, nose and throat.

**Dr. F. J. Clements,**

Cartersville, Va., who graduated from the Medical College of Virginia this June, has located at Fork Union, Va., where he has taken over Dr. Snead's work.

**"Have a Health Examination on Your Birthday."**

With the above slogan the National Health Council is sponsoring a country-wide campaign for periodic health examinations. The movement has the endorsement of the American Medical Association. A committee of the A. M. A., has prepared forms which may be obtained at cost price from the Association headquarters, 535 N. Dearborn Street, Chicago.

The National Health Council, 370 Seventh Avenue, New York City, has prepared a pamphlet for distribution to the public, two excellent posters, a set of thirty lantern slides with lecture outline included, and a moving picture film. With the exception of the latter, which is available for free distribution, all of the other material is sold at cost price.

### The U. S. Civil Service Commission.

Washington, D. C., announces open competitive examination for medical assistant in pharmacology, receipt of applications to close September 11. The examination is to fill a vacancy in the Bureau of Chemistry, Department of Agriculture, and similar positions, at entrance salaries ranging from \$3,000 to \$3,600 a year.

Applications will be received by the Commission until December 28, for graduate nurse and graduate nurse follow up, to fill vacancies in the Veterans' Bureau and in the Indian and Public Health Services. Competitors will not be required to report for examination at any place, but will be rated on their education, training, and experience, on a scale of 100.

For detailed information apply to the above named Commission.

### For Sale.

West Virginia village and country practice and residence; prosperous churches, high school with normal training course, bank, three lodges, rich agricultural section, on class A road. Price \$5,000; residence alone worth the price. Address No. 264, care this journal. (Adv.)

## Obituary

---

### Dr. Arlington Cecil Jones,

A beloved and prominent physician of Covington, Va., died at his home in that place, July 15, after a lingering illness with Bright's disease. He was born at Doe Hill, Va., in 1871, and, after an academic course at Virginia Polytechnic Institute, studied medicine at the University of Virginia, from which he graduated in 1894. He then served for four years as demonstrator of anatomy at the University of Virginia. In 1899, he located in Covington. He had been a member of the Medical Society of Virginia since 1899. He is survived by his wife, two sons, his father, Dr. H. H. Jones, of Dunmore, W. Va., and a large family connection.

### Dr. William Alexander Wilson,

A prominent and beloved physician and citizen of Radford, Va., died June 22, after a long illness, and was buried in Christiansburg. He was born in Pulaski County, Virginia, 71 years ago and studied medicine at the University of Virginia, from which he graduated in 1874. While at the University, he was award-

ed the medal in chemistry. After this, he practiced for a while with his father, the late Dr. M. A. Wilson, in Puaski. He ministered to the sick in Radford for the past thirty-five years, and had always taken an active part in the civic affairs of the community. He had been a member of the Medical Society of Virginia for a number of years. Dr. Wilson is survived by his wife and one daughter, Mrs. J. L. Early, of Saltville, Va.

### Dr. George W. Richards,

Of Island Ford, Va., died August 4, at the age of ninety-six years. He was a graduate of the Medical College of Virginia in 1857, and served as a surgeon with the Confederate army throughout the war between the states. He practiced his profession in East Rockingham and Albemarle Counties for more than fifty years.

### Dr. James Reid Sterrett,

Durham, N. C., died June 10, following an operation for abscess of the lung. He was forty-two years of age and a graduate of the University College of Medicine, Richmond, in 1908, at which time he was appointed interne at Richmond City Hospital. He was at one time county physician for Durham County, North Carolina. Dr. Sterrett practiced for several years in Rockbridge County, Virginia and, during his residence in this State, was a member of the Medical Society of Virginia.

### Dr. Jacob Andrew Keck

Died at his home in Richmond, Va., July 26, after a long illness. He was forty-eight years of age and studied medicine at the Medical College of Virginia, from which he graduated in 1895. He was at one time a member of the Medical Society of Virginia.

### Dr. William B. Pryor Jones,

A well known homeopathic physician of Petersburg, Va., died July 15. He received his medical degree from Hahnemann Medical College and Hospital of Philadelphia in 1884.

### Irvine Cooper, Ph.G.,

Of Norfolk, Va., a member of this year's graduating class in pharmacy at the Medical College of Virginia, was fatally wounded on August 5, when a revolver which was being cleaned accidentally discharged. He died a few hours later, after absolving the man handling the revolver of all blame for the accident. The bullet penetrated his back and emerged through the abdomen.

# The Physician and S. M. A.

For Infants deprived  
of Breast Milk

To be used only under  
the direction of  
a physician

Sold by druggists on  
the order of  
physicians

S. M. A. was designed to simplify the physician's work of infant feeding, and to make it more effective. Thousands of physicians, scattered throughout the entire country, have accepted S. M. A. as embodying this spirit of helpfulness.

These physicians find that the simplicity of preparing feedings of S. M. A. adds to the effectiveness of their work because it makes it possible for parents to follow their directions accurately.

In the hands of these physicians S. M. A. is producing happy, healthy infants, who grow and develop normally, and are free from nutritional disturbances such as rickets and spasmophilia.

For samples and complete literature, please address The Laboratory Products Co., 1111 Sweetland Bldg., Cleveland, O.

# CALCREOSE

## Intestinal Antisepsis

THERE is good evidence that creosote acts as an intestinal antiseptic but patients object to its use because of its taste and the untoward effect on the stomach.

CALCREOSE (calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium, possessing the pharmacologic activity of creosote but free from its untoward effect on the stomach, therefore,

CALCREOSE lends itself admirably to the treatment of intestinal infections in which it is desired to administer creosote. Patients do not object to its use even when taken for comparatively long periods of time and in large doses.

### TREATMENT OF CERTAIN TYPES OF GOITRES.\*

By STUART McGUIRE, M. D., Richmond, Va.

The invitation to come to Baltimore and address such a distinguished group of men is an honor I sincerely appreciate.

I have been advised that in choosing my subject I should select one that would be of interest to both the physician and surgeon, and with this end in view I have decided to discuss the treatment of certain types of goitre.

I know that all of you are more or less familiar with diseases of the thyroid, but I trust I will not be tedious or wearisome in stating my personal views, and that, even if I do not advance anything new or original, I can at least refresh your minds or renew your interests in some of the questions as yet unsettled concerning the perversions of the functions of this organ.

The thyroid gland, to my mind, is in many respects the most wonderful organ in the body. Through its internal secretion it influences the physical development of the child and the mental activity of the adult. It regulates the growth of bone, the formation and distribution of fat and the nutrition of the skin, teeth, hair and nails. It plays an important part in menstruation and parturition and has much to do with sexual desire and power. It influences the rate of the heart beat and the character of the peripheral circulation. It presides over the nitrogenous metabolism of the body, and in other and perhaps unsuspected ways plays an important part in the human economy.

If thyroid secretion is excessive, there are symptoms or metabolic riot. Heat production and gaseous interchange are rapid. The body tissues are stimulated to a course of wasting dissipation. There are seen tremors, sweating,

tachycardia, muscular weakness, loss of weight and feverish mental activity. The evidence of thyroid excess suggests the entrance of tragedy into the life of its subject.

If thyroid secretion is deficient, the metabolism of the body is depressed and heat production and gaseous interchange are at a low ebb. In the young, growth is lessened and the skeletal system is dwarfed. Connective tissue cells remain myxomatous. The skin is dry and thick and the hair coarse and shows deficient nourishment. The nervous system halts in development and mentality does not rise above the level of the infant. Physically and intellectually, the victim of thyroid poverty is less a man, more a beast.

It is a temptation to speculate as to what the future may have to tell of the thyroid and other ductless glands. Who can say that the dullard, the drone and the vast army of inefficient and dependent may not be close cousins to the cretin? Who can deny that it is possible that thyroxin represents in some measures the baser ore, which worked in the fire of experience is seen and known in the gift of the gods which we call genius? What is there in the history of science to make us doubt that some day we may not find in the internal secretions a physiological explanation for the gall of Napoleon's ambition or the iron of Caesar's hand?

The essential cause of goitre is unknown, although it is thought that eventually it will be proved to be due either to the direct infection of the thyroid with bacteria, or the indirect action on the thyroid of toxins from infection in other regions such as the teeth or tonsils.

Goitre is much more common in women than in men, and this is believed to be due to the fact that the thyroid is a sex gland, and disturbances or diseases of the organs of reproduction are more frequent in the female than in the male.

Goitre is endemic in some sections of the

\*Read at meeting of the Medical and Chirurgical Faculty of the State of Maryland held in Baltimore, April 24-26, 1923.

country and this type is believed to be a geologic deficiency disease due to lack of iodine. By the proper administration of iodine to the pregnant woman and to the child during the period of adolescence endemic goitre may be prevented.

The frequency of goitre varies greatly in different sections of the country. The rigid inspection of a large number of men made during the recent war gave interesting and reliable statistics. Figures at the Surgeon-General's Office, based on the result of the examination of the first million men enlisted in the United States Army, showed that simple goitre was present in 14.79% of the recruits from the State of Washington and in only .75% from the State of Virginia.

From the standpoint of the clinician, goitres may be divided in four types, the adolescent, the simple, the toxic-adenoma and the exophthalmic.

Adolescent goitres are seen in young girls from the age of 14 to 20 years. The gland is symmetrically enlarged and increases in size with each menstrual period. The patient is usually nervous and often obsessed with morbid fears, but the symptoms attributed to the goitre are due to hysteria or other causes. Every surgeon has many cases of the adolescent type brought to his office. If he is competent and conscientious, he tells the patient that the condition is not a serious one and advises a life free from excitement or over exertion, an abundance of pure drinking water and perhaps the administration of iodine. Such cases usually get well with or without treatment.

Simple goitres are symmetrical in shape if due to a general parenchymatous hypertrophy, or asymmetrical if due to a cyst or adenoma. They do not produce constitutional disturbances, but simply give rise to deformity of the neck and mechanical symptoms due to pressure. Some of these cases may become toxic or in rare instances undergo malignant degeneration. Operations for simple goitres are indicated to correct deformity, to relieve pressure and to prevent the possibility of the development of toxic symptoms or malignant disease.

Toxic goitres or toxic adenoma develop in patients who usually have had a simple adenomatous goitre for years. These patients, in addition to the symmetrical enlargement of the

thyroid, have nervousness, tachycardia, coarse tremors of the fingers and marked loss of weight and strength. Their basal metabolism is perceptibly increased. Unlike the exophthalmic type, they have no marked changes in the eyes. Owing to the chronicity of the disease there is apt to develop secondary degenerative changes in certain vital organs such as the heart, liver and kidneys. Operations for toxic adenoma are urgently indicated. If done early, they are safe, as post-operative reaction is not usually severe and the general condition of the patient is good. If done late, operations are attended by great risk to life, and patients who recover are not usually restored to health, because it is impossible to cure the organic changes that have taken place in the heart, kidneys or other important viscera.

Exophthalmic goitres are due to a hyperplasia of the essential cells of the thyroid and are usually symmetrical in shape. The histological section of an exophthalmic goitre bears the same resemblance to the normal gland that a section of a lactating breast bears to the non-lactating organ. The symptoms of an exophthalmic goitre are not those of local pressure, but of constitutional intoxication from excessive thyroid secretion. The symptom-complex is a familiar one: nervousness, tremors, tachycardia, exophthalmos and feverish mental activity. The basal metabolic rate of these patients is markedly increased. The chief diagnostic differences between exophthalmic goitres and toxic goitres are that the exophthalmic type is usually seen in younger patients, that the symptoms develop more quickly and with greater intensity, and that there is the presence of the characteristic eye changes which are absent in the toxic variety.

There is no difference of opinion in the profession as to the treatment of the first three types of goitre. Adolescent goitres should be treated by medical and hygienic measures. Simple goitres should be operated on if they cause deformity or give rise to pressure symptoms, the patient often being the best judge as to when the disfigurement or discomfort they produce are sufficient to justify an operation. Toxic goitres or toxic adenoma should be removed as soon as discovered, as they do not tend to spontaneous cure or yield to non-operative treatment, and delay leads to incurable structural changes in the heart, kidneys and other vital organs.

When it comes to the treatment of the fourth type, or exophthalmic goitre, however, there is a sharp difference of opinion as to the proper procedure to be followed.

In reviewing the literature of the treatment of hyperthyroidism, one is struck by the fact that honest and experienced men hold divergent views, and that the same man often changes an apparently fixed opinion and attaches little importance to what he at one time considered an essential feature in the treatment of the disease. Until recently it has been impossible to analyze the results reported by different clinicians in series of cases treated by different methods, and to determine what influence was exercised by individual skill and what by the procedure employed. The recent introduction of the metabolic test, however, bids fair to settle many questions under discussion.

It has been demonstrated that the thyroid regulates the general metabolism of the body and that an increase or decrease of thyroid activity is accurately shown by corresponding changes in the patient's metabolic rate. Hence, by determining the degree of metabolism, we now have a scientific means by which we can estimate thyroid activity in an individual case and can tabulate mathematically the effect of the various forms of treatment that are advocated for its abnormalities.

There has not yet been sufficient experimentation or practical experience with basal metabolism to determine its exact clinical value. Like the thermometer it promises to be a most valuable agent, but also like the thermometer its record must be considered together with the patient's clinical symptoms. A patient with typhoid fever who has high temperature will not necessarily die, or one with a low temperature necessarily live. Likewise, a patient with hyperthyroidism may have a high metabolic rate and not be as seriously sick as another with a low rate who has structural changes in the heart, liver and kidneys.

I have found that the basal metabolic rate corresponds pretty closely with the patient's history and symptoms and with the pathological findings of the specimen removed, still I have not come to rely on it as a criterion of operability. This must be decided only after taking every factor into consideration. I have come to rely on basal metabolism, however,

first in making a diagnosis in early cases. The onset of hyperthyroidism is usually so gradual that it is difficult to recognize it in its incipency and here the metabolic rate will clearly differentiate it from hysteria, neurasthenia, tuberculosis and other conditions with which it may be confused. Second, in making a prognosis in late cases, the metabolic rate will determine whether the symptoms are due to the goitre or to degenerative changes in the vital organs and will indicate the danger of the operation and the results to be expected if the patient lives. Third, in assigning a relative value to the different forms of treatment advised for the relief or cure of hyperthyroidism, we are enabled to discard fuss, feathers and foolishness and to concentrate on measures of proved efficiency.

When I began the practice of medicine, it was in an era when electricity was employed in various forms for the treatment of diverse diseases. My father's office was equipped with faradic, galvanic and static machines, and under his supervision I applied the interrupted current to wasted and paralyzed muscles, employed electrolysis after the method of Apostole to absorb fibroid tumors, and sprayed and sparked the heads and backs of neurasthenic patients seated on glass stools. Among other cases was a group of goitre patients who were treated by cataphoresis, the negative pole saturated with tincture of iodine being placed on the enlarged thyroid and the positive pole at the back of the neck. Some of these patients were apparently markedly improved and as a result the number of goitre patients coming for treatment rapidly increased.

I soon grew tired of this routine and uninteresting office work and reading of the results being secured by Kocher of Switzerland, I began to importune my father to treat some of these cases surgically. He finally told me that he had once attempted the operation and that it was the most bloody and barbarous work he had ever done, and he concluded by saying "every man must learn by his own experience, but if there is one thing you may learn from me it is never to operate on a case of goitre." This advice was good for its day and generation. Kocher's mortality in his first seventy operations for simple goitre had been 40% and Chas. H. Mayo's mortality in his first sixteen cases of exophthalmic goitre had been 25%, and it is no wonder that the operation

was then regarded by the majority of surgeons as unwarranted.

Seventeen years ago I did my first thyroidectomy, and I have now operated on more than eight hundred patients for goitre.

In the first hundred operations I had no deaths. This was because I picked my cases. In my second hundred operations I had five deaths. This was because I had become bolder and accepted bad risks. I then became more conservative and adopted the position of Mayo, who at that time held that a thyroidectomy should not be considered a life saving measure and should not be performed on a bad risk, but that such cases should be treated by non-surgical measures and if they failed to improve should be allowed to die a medical death. Under this policy my mortality became satisfactory, but I was rendered unhappy by the necessity of refusing to intervene in certain cases where operation seemed to offer the only chance for life.

Finally, I adopted the teaching of Crile and now operate on every case of hyperthyroidism that is referred to me unless the patient is practically moribund. By adopting many of the measures Crile advises, I have had but three deaths in the last four hundred patients operated on for goitre. I have had my share of bad risks and I have not dodged any of them.

In what I have said I have been personal and reminiscent, but I have run the risk of criticism for a purpose. I wish to present certain views on the treatment of hyperthyroidism which differ from those held by other surgeons of greater reputation and larger experience, and I would not have the courage to do so unless I was able to justify my opinions by my results. It is true that my series of cases is small compared with those of certain large clinics, but it must be remembered that I have personally studied, operated on and cared for each patient, that I have rejoiced in their recoveries or grieved at their deaths, and that the experience gained has made a profound impression on me.

While we do not know much about the etiology of exophthalmic goitre, it is a fact that the condition frequently follows some acute disease and is maintained by a local focus of infection. Before beginning the treatment of any case, the tonsils and teeth should be examined and other possible sources of poison

should be determined and, if any diseased condition is discovered, it should be corrected. Recently an early but very acute case of exophthalmic goitre was brought to me. The patient had lost fifty pounds in weight, her pulse varied from 140 to 160, her metabolic rate was plus 87 per cent and she was delirious a greater part of the time. Examination showed abscesses at the roots of four teeth. The teeth were extracted and her symptoms immediately began to improve, without other treatment except rest and proper feeding; she made a rapid recovery, and is now apparently restored to health.

The first and most essential factor in the medical treatment of hyperthyroidism is rest. It should be absolute and complete and must be mental as well as physical. It is useless to try to secure it at home. Patients should be placed in a hospital where they can be under proper control.

Means and Aub studied the effect of rest on a group of cases. These patients had an average metabolism of plus 81 per cent and after from one to three weeks the same group had an average of plus 67 per cent. In a few of the more toxic cases the curve rose in spite of rest. There was no case in the series whose metabolism was brought to normal by rest alone. After about two weeks a level is reached and rest will not cause a further drop.

An ice bag over the heart seems to slow its rate and quiet its tumultuousness, and its application serves to keep patients more quiet in bed as they refrain from turning and twisting for fear of displacing it.

Water should be given in abundance in order to eliminate toxic products from the system by the way of emunctories. Distilled water, while not as palatable, will be found to be more efficient. This is partly due to its greater solvent qualities, but more largely due to the fact that patients think it has special merit and will drink it in larger quantities.

The diet of these patients is important. The machinery of their system is being driven under forced draft, and they need fuel to save the consumption of their own tissues. Food should be given every three hours and in as large quantities as possible without creating digestive disturbances.

The administration of various drugs with a view of lessening metabolism has been advocated. Of these hydrobromate of quinine with

ergotine, glycocholate of soda and pancreatic extract have the greatest number of advocates. Means and Aub have tested the action of hydrobromate of quinine on a group of patients and find that it had no apparent effect on the metabolic rate of the cases. While it is only of historic interest, it may be mentioned that the effect of Beebe's serum on metabolism was also tested and found negative. The administration of digitalis is recommended by Willius, not for its effect on metabolism, but because of its influence on the heart.

The use of X-ray has long been advocated in these cases and more recently the application of radium has been recommended, the theory being that a sclerosis is produced which lessens glandular activity. The relative merits of X-ray and radium have not been determined, but it seems that the choice is largely a question of the experience of the operator and the convenience of the patient. Means and Aub tested the effect of the X-ray on a group of cases. These patients had an average metabolic rate of plus 63 per cent. After one or two treatments at intervals of one month there was a reduction to plus 52 per cent. After four or five treatments there was a reduction to plus 40 per cent, and after two or three years' treatment there was a reduction to plus 13 per cent. The advantages claimed for the X-ray method of treatment are that it avoids an operation and is attended by less danger to life. The disadvantages are the increased length of invalidism, the greater difficulty of operating if surgery is ultimately necessary, the possibility of shrinkage of tissues of the neck, the danger of myxedema and of X-ray burns and the liability of treating colloid and cystic goitres which are not benefited.

The injection of boiling water or a solution of quinine and urea into the body of the thyroid has been advised. The theory on which this practice is based is that the destruction of the glandular cells and the obstruction of blood vessels will cut down the output of thyroid secretion. The method is not without immediate or remote disadvantages and dangers. Some patients are so sick that even this apparently simple procedure will cause an acute and perhaps fatal hyperthyroidism, others will not be benefited and a subsequent surgical operation will be made difficult by the adhesions it has caused, and

finally the irritation may result eventually in the development of cancer. Balfour reports 103 cases of malignant disease of the thyroid and it is a significant fact that seven gave history of having been treated by the injection method.

If a patient has time and money and is willing to make a pet of a diseased gland and try to humor it back to a normal condition, then palliative measures may be tried, but it is generally conceded at the present time that the safest, surest and quickest way to effect a cure is by surgery. The practice of destroying a portion of a gland in order to lessen its physiological activity is certainly illogical, but it is the best we can do until some chemical antidote for thyroxin is discovered.

The operations done for hyperthyroidism are ligations and partial thyroidectomies. The advocates of ligation state that while the benefits which follow the operation are marked, they are not permanent and that they should only be employed either as a test of a patient's reaction to trauma in cases where there is a doubt of the individual's ability to stand a thyroidectomy, or as a means to get a patient in condition for a more radical operation when it is obvious that at the time a thyroidectomy could not be done without great hazard. Observations in the various surgical clinics of the country show that the number of ligations being done is steadily diminishing and personally I have given them up altogether.

The favorable results attributed to ligations cannot be explained on an anatomical or physiological basis. The theory that ligations act by cutting down the blood supply is refuted by the experience of every operator who knows that tying one or more of the principal arteries does not materially diminish the vascularity of the gland. It is stated that all the blood in the body pass through the thyroid once every hour and ligations actually increase the blood supply by the formation of collateral branches. The theory that ligations interfere with trophic influence is an explanation that has no physiologic parallel in other parts of the body and is an argument about as mysterious and no more logical than those advanced to support Christian Science. The effects of ligations are in my opinion largely due to psychic influence and to the subsequent treatment of the patient and the same results can be secured by safer and less heroic means. In mild

cases ligations are unnecessary, and in severe cases they are more dangerous than a lobectomy or partial thyroidectomy. The greatest danger of an operation for exophthalmic goitre is acute post-operative hyperthyroidism and this is caused not by the amount of the gland taken out but by the amount of the gland left in, and can be best minimized by the removal of a large portion of the thyroid. In the early days of my work I had some bad results because I was timid and did not remove enough of the gland. With increasing confidence I have taken out more and more tissue and have secured better immediate results and have seen no remote bad consequences. I now do a double partial lobectomy, only leaving a small portion of the gland attached to the posterior capsule on either side. This leaves sufficient thyroid tissue to carry on the normal functions of the body, protects the recurrent laryngeal nerve and other important structures from injury, and gives good cosmetic results, as it does not destroy the symmetry of the neck.

The results of partial thyroidectomy are prompt and permanent. If the operation does not effect a satisfactory cure, it is because either not enough of the gland has been removed or that the operation has been delayed until the patient's symptoms are no longer due to hyperthyroidism, but to organic changes in the vital organs as well.

I do not wish it to be inferred that a radical operation should be done for a bad toxic or exophthalmic goitre without careful preliminary study and often prolonged treatment of each individual case. The patient should be put to bed, given absolute physical and mental rest, an ice-bag applied to the chest, and water and food properly regulated. The fluctuations of the disease should be carefully watched and the operation fixed for the most propitious time. Every effort should be made to inspire the patient with confidence and to relieve apprehension and fears.

A few patients will not bear transportation and should be operated on in their rooms without moving them from bed. Some do best under local anesthesia, others require light nitrous oxide oxygen in addition. Often after the removal of the desired amount of glandular tissue it is wise to pack the wound and delay closure for two or three days. It is always well to provide for liberal drainage. After the operation water should be given by

rectum or subcutaneously, morphia without atropia administered to relieve pain and quiet restlessness, and cold sponges or ice packs employed to combat fever if elevation of temperature occurs.

## THE TREATMENT OF LOBAR PNEUMONIA DUE TO PNEUMOCOCCUS INFECTION.\*

By LEWELLYS F. BARKER, M. D., Baltimore, Md.

Lobar pneumonia due to pneumococcus infection has well been designated the "captain of the men of death." The appalling mortality from this disease and the fact that the majority of the patients suffering from it are treated by general practitioners rather than in hospitals make a discussion of the treatment of the malady worth while in a meeting composed of men engaged in general practice.

The incidence of and mortality from pneumonia vary greatly at different periods of the year. As many people die of pneumonia during the first four months of each year as in the whole of the rest of the year. Indeed it is probable that the total mortality from January to April exceeds that from May to December.

A comparatively benign malady in early life, the mortality rate in lobar pneumonia increases with every decade, until between the ages of sixty and seventy probably three-quarters of all who are affected die of the disease, though the average mortality for all ages may not exceed perhaps twenty per cent.

### SYSTEMATIC METHODS OF TREATING LOBAR PNEUMONIA NOW LARGELY DISCARDED.

No chapter in the history of medicine is perhaps more interesting than that which deals with attempts at systematic treatment of lobar pneumonia. From the earliest times on, various remedial agents have been successively lauded for their curative power in this disease. But each of these methods of systematic therapy has in turn been abandoned. One master of medicine after another has prided himself in introducing a cure for lobar pneumonia. But despite every effort the average mortality has through the centuries remained nearly the same.

Let me remind you of some of these syste-

\*Read at the Seaboard Medical Society, Newbern, North Carolina, December 6, 1922.

matic methods of treating the disease and their failures; they will serve as notable examples of the excessive therapeutic credulity of many of the great leaders in our profession. Thus, Brown was a believer in the efficacy of "excitants" to increase the "sunken irritability" in lobar pneumonia. He gave wine, brandy and opium with this purpose in view, and a similar theory was responsible for the massive doses of alcohol prescribed by Todd in England and by Delhier in France. An opposite theory lay at the basis of the large doses of tartar emetic ("contra-stimulation" of Rasori), a therapy much employed by no less a man than Laënnec.

Local and general bleeding also had great vogue for a long period for the combating of the inflammation of the lungs, a therapy strongly advocated by Broussais and later by Bouillaud, both French clinicians of eminence in their time. It is recorded that Broussais in his own last illness ordered six venesections and the application of over sixty leeches to himself. In the year 1819, in his division of the Val de Grace Hospital, more than one hundred thousand leeches were used. So popular became this method of treatment that in France in the year 1824 as many as three hundred thousand leeches were applied, and in the year 1827 some thirty-three million leeches were made use of. Bouillaud pushed bleeding to an extreme, in many cases causing syncope. His idea was to bleed the patient until he was white (*saigner a blanc*)! So universal had the custom of bleeding in pneumonia become that in 1849 a physician was put under arrest for not bleeding a patient who suffered from the disease.

A little later, the treatment of pneumonia by means of large doses of digitalis was recommended by Hirtz of Nancy and by Petrescu of Bucarest. Even Traube had confidence in the combination of bleeding and digitalis therapy.

Still another method of systematic therapy was campher in large doses recommended by Seiffert of New York and by Oppenheim and Loeper in Europe.

Notwithstanding the advocacy of each of these methods by men of real eminence they have all fallen into disfavor, and the remedies that were vaunted for universal application are now restricted to employment only on special indication.

#### THE ERA OF THERAPEUTIC NILHILISM.

It is but little wonder that therapeutic scepticism greatly increased as clinicians gradually became aware of these successive failures in those systematic methods of treatment of lobar pneumonia to which I have referred. It was Skoda, especially, who emphasized the fact that patients suffering from lobar pneumonia recover just as often when nothing is done except to keep the patient comfortable in bed on a simple diet as when heroic methods of therapy are employed. It was only through experience that physicians learned how well patients suffering from pneumonia can do when left to nature's method of cure. During the years 1842 to 1846 in the Weiden District Hospital in Vienna, three hundred and eighty persons were treated for primary pneumonia, eighty-five of them by venesection, one hundred and six by large doses of tartar emetic, and one hundred and eighty-nine simply by dietetic measures. The results reported were as follows:

CURED:	
With venesection -----	68
With tartar emetic -----	84
With dietetic methods -----	175
DIED:	
With venesection -----	17
With tartar emetic -----	22
With dietetic methods -----	14
MORTALITY RATE:	
With venesection -----	20.4%
With tartar emetic -----	20.7%
With simple dietetic methods -----	7.4%

This was a remarkable showing and led many conservative clinicians to follow Skoda's example of utilizing only expectant and symptomatic methods of treatment. His maxim was, "Observe the course of a disease when it is left to itself, uninfluenced by drugs."

#### CRITERIA FOR JUDGING OF THE EFFICACY OF THERAPY IN LOBAR PNEUMONIA.

We have seen how, systematic therapy proving a failure, clinicians came gradually to rely upon expectant and symptomatic treatment only. They were content to relieve symptoms as they appeared and to use special methods of treatment only when they seemed to be indicated by the appearance of special symptoms or signs.

In recent years attempts at specific therapy (as contrasted with expectant symptomatic therapy) have been revived, particularly since our knowledge of the infectious processes has

grown, and methods of vaccine therapy, immunotherapy and chemotherapy have developed. In order, however, to judge of the efficacy of any specific method of therapy, careful clinicians are no longer content with the mere impression that a given therapy exerts a favorable effect. They demand the application of objective methods of measurement before passing judgment upon efficacy on the one hand or of worthlessness on the other.

In general, it is now recognized that the course of a lobar pneumonia depends partly upon the number and virulence of the invading microorganisms (pneumococci) and partly upon the powers of resistance and the mode of reaction of the sick person. As every general practitioner is aware, pneumonia is a more fatal disease in some epidemics than in others, and even in one and the same epidemic the virulence of the micrococcus lanceolatus may vary considerably. Attention must be paid, therefore, to both epidemiological and individual factors when judging of the efficacy of any form of specific therapy. Accordingly, the statistical results must include (1) a large number of cases (on account of individual differences) and (2) cases from more than one period of prevalence (on account of differences in epidemiological factors). It is desirable also that the statistics include (3) cases occurring in different localities. Finally, it is desirable (4) to group the cases according to the type of *pneumococcus* that is causal.

One of the best methods of judging the efficacy of a therapy is to compare in the same epidemic the results obtained in patients under treatment with those obtained in control cases not subjected to the treatment. The epidemiological factor is then the same in the treated and in the untreated cases. As Cahn-Bronner has emphasized, statistics that deal with contemporaneous cases where there are both control cases and treated cases of a similar sort, and where the material is abundant and is distributed over several years, afford the requirements for an objective judgment of the influence of a given therapy. In other words, the most careful clinical observation of single cases thus studied will yield information not derivable from the haphazard study of statistics that have not been similarly controlled.

When the treatment of the disease is begun late, the most important criterion of its efficacy is the mortality rate. When the treat-

ment on the other hand has been begun early, one can use as a criterion not only the mortality rate but also the duration of the fever after the initial chill or, in its absence, after the first rise in temperature.

#### DISCUSSION OF CURRENT CONCEPTIONS OF PNEUMONIA THERAPY.

In our time, following the lead of clinicians like Billings, Fitz, Janeway, Osler, and Shattuck in this country, most practitioners in the treatment of lobar pneumonia have been content with the institution of a simple dietetic-hygienic regime, with expectant-symptomatic therapy, and with the treatment of complications. They soon became aware that patients suffering from milder forms of lobar pneumonia get well spontaneously, and that no violent therapy of any sort is needed, or is beneficial if applied. In the severer forms of pneumonia they have learned that great care in the general management of the case (especially good nursing, close attention to the relief of troublesome symptoms, and support of a failing circulation) will often turn the balance in favor of the patient and save his life. In the worst forms of pneumonia, especially the asthenic types of the aged, the therapist has been practically helpless and has been compelled virtually to throw up his hands!

Recently, in addition to the simpler forms of therapy just mentioned, new hope for specific forms of therapy has been aroused. Before discussing the newer causal therapy, however, it will be convenient to refer in more detail to the main points of practical importance in functional, regulatory and symptomatic therapy.

#### FUNCTIONAL REGULATORY AND SYMPTOMATIC TREATMENT OF PNEUMONIA.

*Symptomatic therapy* neither attempts to intervene in the disease process as such nor to attack its cause, but does make the effort to relieve single troublesome symptoms. *Functional therapy* tries to restore some normal function that through the disease has become disturbed or abolished. And *regulatory therapy* attempts to aid the body in reacting against the disease process or the disease cause. These forms of therapy, symptomatic, functional and regulatory, are the forms that we have relied upon most since the abandonment of the old systematic methods of treating

pneumonia and before the advent, very recently, of new forms of etiotropic therapy.

Lobar pneumonia usually begins abruptly with a chill, a stitch in the side, and a rapid rise of temperature; these are the symptoms that bring the practitioner to the patient's bedside. It is only rarely that these symptoms are preceded by prodromata such as headache, pains in the limbs, anorexia, or signs of bronchitis. The actual onset is usually so characteristic that the experienced practitioner, when he hears the history of chill, of pain in the side, and of fever, when he observes an increased respiratory rate, an accelerated pulse rate, and delayed expansion on one side of the chest with perhaps a little suppression of the breath sounds there or a few fine crepitant rales, knows that he is dealing with the onset of a lobar pneumonia. He will, if there be an excruciating pain in the side, relieve it promptly by a small dose of morphine and will then immediately set about the organization of the sick room, and the nursing, and will arrange for the general management of the case.

#### GENERAL HYGIENIC AND DIETETIC REGIME.

The patient will be kept quietly in *bed*, a place in most cases already sought before the advent of the physician. He should be dressed in a light night-gown, which opens at the back rather than in front, or which opens both in front and behind. The bed and mattress should be comfortable and the covering warm but light. A blanket and a rubber sheet should be placed under the bottom white sheet to ensure warmth and dryness. A hot-water bag should be placed at the patient's feet, the hot water being renewed at frequent intervals.

The *room* should be large, exposed to sunlight and well ventilated. Most rooms can be sufficiently well ventilated by means of windows. If a sleeping porch be available, it may be employed. For a period, at the Johns Hopkins Hospital, we placed all pneumonia patients out-of-doors, even in the winter time, and I must admit that they did very well. I see no reason, however, for insistence upon out-of-door treatment provided an in-door room is well ventilated. Nursing and medical attention can in-doors be given so much more easily than outside that the advantages seem to me to be on the side of in-door rather than of out-door treatment.

The *surroundings* of the patient should be

quiet; he should be left very largely to the ministrations of the nurses and the physicians. He should lie in an atmosphere of reassurance. Members of the family or friends who would disturb such an atmosphere should not be admitted. Family visits should be limited to one or two persons at a time and the stay of each should be brief.

In the treatment of pneumonia, *good nursing* is one of the most important features. The chances of the patient for recovery are distinctly increased if it is possible for him to have two well trained nurses in attendance, one for the night and one for the day. Such ideal nursing care is, however, possible only for the well-to-do, and circumstances must determine what approximation to this ideal is feasible in a given case. The nurses will keep the patient comfortable in bed, and will prevent unnecessary exertion. They will control the ventilation of the room and the number and character of visitors admitted. They will keep the clinical charts for the physicians, on which the temperature, pulse, respiration, fluid intake, fluid output, bowel movements, and prominent symptoms are registered. They will see to it that food and water are administered at regular intervals, and they will be always at hand to facilitate the physical examinations that are made by the physician and to carry out faithfully the therapeutic regimen he prescribes. Members of the family or friends, with the best will in the world, cannot do for a patient what a trained nurse can do, and the wise physician will see to it that, whenever practicable, the patient's chances for recovery are favored by the institution of skilful nursing from the very start.

The *diet* should consist of liquid food, chiefly of milk, or of milk with a little cereal added to it, though at intervals chicken broth or meat or vegetable broths may be added for variety. In the milder cases eggs, either soft boiled or raw, or in the form of egg albumin, may be administered. In addition, the patient should drink freely of water or of lemonade, and if desired some cane sugar may be added to the lemonade and some milk sugar to the milk. In severe cases with delirium, insufficient food and liquid may be taken by the mouth, in which case it may be necessary to administer it per rectum or even subcutaneously. Vomiting also may interfere with oral administration of food and liquid, in which event sub-

cutaneous infusions of salt solution containing glucose may be administered, or one may give a 0.047% solution of glucose per rectum by the Murphy-drip (fluid warmed to body temperature; one liter introduced by the drop method twice a day).

That due attention to *evacuation of the bowels* should be given goes without saying. If the patient is seen at the start he may be given two grains of calomel at night followed by a saline the next morning. A daily movement of the bowels should be secured by means of salines, of enemata, or by the use of a little castor oil. Drastic purgatives should be avoided. In toxic cases diarrhœa is sometimes a troublesome symptom and may require checking by means of a little Dover's powder or a little paregoric after each movement.

*Hydrotherapy*, internal and external, is an important item in the general regime, since it goes far toward combating the effects of the toxemia and in preventing circulatory failure. In mild cases a tepid sponge once or twice daily, disturbing the patient as little as possible, contributes to the patient's well being and somewhat lessens the fever. If the temperature be very high, a cold sponge may be given every three hours or the patient may be wrapped in wet cold compresses (wring out of water at a temperature of 78° to 60° Fahrenheit) every hour. Some physicians immerse patients showing hyperpyrexia in a cold tub just as in the treatment of typhoid fever by the Brand method. In my experience, however, cold sponging or the application of wet compresses yields fully as satisfactory results and is less disturbing to the patient and makes smaller demands upon the nursing force and attendants; moreover the psyche of the patient is less agitated. In applying cold compresses it is best to wring the compresses out of cold normal salt solution rather than out of plain water, to avoid maceration of the skin with predisposition to local skin infections.

The *mouth* should be kept clean and moist by the nurse. In mild cases the patient may rinse it at frequent intervals with a suitable mouth wash and may even use the tooth-brush morning and evening. In severe cases the care of the mouth must be left entirely to the nurse who will clean it with a swab soaked in mouth-wash.

The *nose*, too, should be kept clean and if possible open. If there be swelling of the tur-

binates and obstructed nasal breathing temporary relief may be given from time to time by snuffing up a menthol-eucalyptol ointment.

Many physicians feel that from the beginning it is desirable to administer regularly some form of drug, partly in order that the patient and his friends may feel that something in a pharmacotherapeutic way is being done, partly because they believe that the administration of a mild diuretic like potassium citrate (one gram four times a day) or a mild diffusible stimulant like ammonium acetate (one gram three or four times per day) will contribute something to the welfare of the patient. I can see no especial objection to the administration of either of the remedies mentioned though I am doubtful whether they are of any real value aside from the psychotherapeutic effect that they may produce. I should warn, however, against the routine administration of any drug that can be disturbing to the digestion of the patient or that causes discomfort in any form. The expectorant mixtures are particularly to be condemned; they do no good, most of them are disagreeable to take, and many of them disturb digestion by exciting nausea or causing meteorism.

#### THE RELIEF OF SINGLE SYMPTOMS.

The more experience one has in the treatment of pneumonia the greater his recognition of the salutary effects on the patient of relief of disturbing symptoms, especially pain, cough, dyspnoea, insomnia, and abdominal distention.

*Cough*.—It is especially the dry cough at the onset of the disease and during the period of consolidation that demands symptomatic relief. It is very fatiguing to the patient; it increases the pain in the side during the day and, if left uncontrolled at night, keeps the patient awake. This dry and, for the most part, non-productive, cough can be sufficiently controlled during the day by a twelfth of a grain of heroin and a quarter of a grain of codein given in tablet form every two, three or four hours as required. At night it is well to administer, hypodermically, a small dose of morphine at 9:00 P. M. and to leave an order for its repetition during the night if the cough is disturbing. It is surprising what small amounts of morphine will suffice; for some patients 1/16, 1/12 or 1/8 of a grain are adequate. It does not seem to me right to permit patients to be harassed by racking cough

during an acute pneumonia when this cough can be fairly well controlled by the methods described and without harm to the patients.

*Pain.*—The pain in pneumonia, usually described as a "stitch in the side," is due to a dry pleurisy where the lobar pneumonic process reaches the pleural surface. It is often so violent at onset as to require a small hypodermic of morphine for its relief. When less severe, the application of a flat ice-bag or of salt solution compresses may sufficiently ameliorate. The older clinicians were wont to apply wet or dry cups, mustard plasters, blisters or poultices for the relief of this pain. Though these measures in many instances ease the pain, they are objectionable since they irritate or macerate the skin, favor local skin infections and interfere seriously with physical examinations of the chest. Instead of applying poultices of flaxseed or of kaolin one does better to be content with a flat ice-bag or with salt solution compresses at the beginning and to follow these later with a simple "pneumonia jacket" (to open both in front and behind) made of cotton batting stitched between layers of cheese-cloth.

*Dyspnoea.*—The shortness of breath and the accelerated respiratory rate at onset are usually relieved when the pain of the stitch in the side is assuaged and after mild hydrotherapeutic measures have been instituted. If, however, great oppression be felt owing to massive pulmonary involvement and especially if the patient be full blooded, a venesection or the withdrawal of from 300 to 500 cc. of blood by means of a syringe from a vein at the bend of the elbow will often give marked relief. In the dyspnoea of the later stages, especially when associated with anoxemia, inhalations of oxygen may be really valuable. The ordinary methods of administering oxygen are, however, very faulty. When oxygen is needed, it is best to administer it by the Haldane method, which permits a certain intake of 2.5 litres of oxygen per minute (Meakins), or by means of Meltzer's hollow tongue depressor. In hospital practice where a respiratory cabinet is available, the patient may be placed in the cabinet filled with oxygen (Means).

*Insomnia.*—This is often a distressing symptom and is associated with restlessness that adds greatly to the fatigue of the patient. As has been pointed out it often depends upon the dry racking cough and small doses of morphine, which lessen the cough and relieve the

pain, also give sleep. In the absence of cough and pain an adalin-luminal tablet, a small dose of barbital or of one of the barbital derivatives, or a dram of the *mistura chloralis et potasii bromidi composita* (N. F.) may contribute to a restful night.

*Abdominal Distention.*—Distention of the abdomen is a common symptom in lobar pneumonia and is often an evidence of a severe toxemia causing atony or paralysis of the wall of the intestines. Much can be done to prevent its development by keeping the mouth clean, by careful attention to the diet, by regular evacuation of the bowels, by forcing water, and by external hydrotherapy. Tympanites often develops, however, despite these measures and demands symptomatic treatment. Turpentine stupes to the abdomen, turpentine enemata, or the occasional passage of a rectal tube, permitting the gas to escape, may do much to relieve it. In severe meteorism I have several times seen much benefit follow the hypodermic administration of pituitrin in full doses (1 cc. ampoule). Occasionally 1 cc. of pituitrin will cause cramping of the intestine and pain in which event  $\frac{1}{2}$  cc. may be given and repeated after a few hours. Tympanites should not be neglected for, pressing the diaphragm up, it further interferes with a respiration that is already impaired, increases the dyspnoea and anoxemia, and throws a greater burden upon the right heart.

#### TREATMENT OF THE COMPLICATIONS OF LOBAR PNEUMONIA.

Space will not permit of a full discussion of all of the possible complications of lobar pneumonia and I shall refer only to those that are more common; especially to toxæmia, circulatory failure, and empyema.

*Severe Toxæmia.*—As I have said, the physician does much to combat the toxemia by instituting a careful general dietetic-hygienic regime, and, especially, by internal and external hydrotherapy (which promotes elimination through the skin and kidneys) and by saline laxatives or enemata.

Severe toxic symptoms can sometimes be ameliorated by venesection. When patients do not swallow sufficient fluid, the toxæmia is likely to be more marked; salt solution should then be injected subcutaneously (300 cc. to 500 cc.) and salt and glucose solutions may be given per rectum by the Murphy-drip method.

*Circulatory Failure.*—The most dreaded

complication of pneumonia and that responsible for death in perhaps the majority of cases is circulatory failure, dependent either upon weakness of the myocardium or, more often perhaps, upon loss of tone of the peripheral arterioles (vasomotor paralysis). It is for this reason that cardiotoxic therapy and measures designed to maintain the tone of the peripheral arterioles have long been popular in the therapy of pneumonia. Many clinicians use digitalis from the beginning, in the hope of maintaining the tonicity and contractility of the cardiac muscle, especially that of the right ventricle. There would seem to be no objection to this in patients who before their attack of pneumonia have suffered from cardiac or renal disease, though in my opinion it is not desirable as a routine measure in all cases. The closest watch should be kept, however, upon the behavior of the heart, and when signs indicating overstrain of the right heart develop, therapy should be prompt and vigorous. Digitalin or strophanthin may be given by intramuscular injection and, if there be marked cyanosis or signs of a developing pulmonary oedema, venesection should not be delayed. In incipient pulmonary oedema, in addition to the measures mentioned, a subcutaneous injection of morphine with atropin, or of atropin alone, may be helpful.

A change in the quality of the pulse may be an important indication for therapy. As soon as the pulse tends to become faster, to be smaller in volume, and softer, the administration of caffeine or of camphor should be begun. One may give 0.1 of caffeine sodium benzoate from three to five times per day by mouth, or powdered camphor (0.2) with benzoic acid (0.2) and a little milk-sugar three times per day by mouth. If the pulse failure develop more rapidly, caffeine sodium benzoate may be given subcutaneously (in 15% aqueous solution), or camphor may be given subcutaneously in doses of 2 to 5 cc. of camphorated oil (20% solution.) Strong black coffee is an excellent stimulant for the heart, given as hot as the patient can drink it. Alcohol is indicated if the patient has been accustomed to taking alcohol regularly. Pneumonia in alcoholics is particularly fatal and delirium tremens (an abstinence phenomenon) is likely to develop when an old toper is suddenly deprived of his regular alcoholic intake.

In vasomotor paralysis, in addition to the cardiotoxic therapy just mentioned, an effort

may be made to restore the peripheral arterial tone by the administration of pituitrin, of epinephrin, or of ergotol subcutaneously, and possibly something may be done to stimulate the vaso-constrictor center in the medulla by the hypodermic administration of strychnine, (1/20 grain) every two or three hours. The latter drug will also be indicated if there should be a tendency to respiratory failure.

*Empyema.*—Every lobar pneumonia is complicated by a dry pleurisy, which is responsible for the stitch in the side at the onset. Pleurisy with serous effusion and pleurisy with purulent effusion (empyema) are more important complications. They are most often met with toward the end of the pneumonic process, or after the crisis has occurred. Regular physical examinations should be made, especially in cases in which the fever continues or in which there is a recrudescence of the fever after the crisis. An exploratory needle should be introduced when the physical signs are at all suspicious. If pus be found, the pleural cavity should be freely drained.

*Jaundice.*—In severe pneumonias, jaundice may appear as a complication, due either to a catarrhal cholangitis or to toxic injury to the liver itself. The complication is best ignored unless the jaundice persists after the pneumonia has run its course.

*Meningitis.*—Suppurative meningitis due to the pneumococcus, occurring as a complication of pneumonia, is likely to be fatal, though spinal drainage, and possibly the introduction of anti-pneumococcus serum into the subarachnoid space may occasionally be life-saving. Symptoms of meningitis, however, do not necessarily indicate a suppurative process. Meningitis serosa, or meningismus, is not uncommon as a complication of pneumonia, and the symptoms are often relieved by lumbar puncture. Many cases presenting meningismus at one time or another during the course of a pneumonia recover.

*Collapse at the Crisis.*—If, at the crisis, symptoms of collapse appear, with rapid feeble pulse, falling blood pressure and profuse perspiration, the treatment is the same as that suggested for circulatory failure due to vasomotor paralysis (see above). In addition, a hypodermic of atropin may be administered.

*Profound Asthenia.*—Asthenic pneumonia is common in the aged, and in other persons in whom resistance to infections is lowered.

The reactive powers of the organism seem to be in abeyance, for the patients may show little or no fever, only a slight cough, a little dyspnoea, few physical signs in the lungs, though they have a rapid feeble pulse, and manifest profound general weakness. Sometimes cases of asthenic pneumonia occur in small epidemics, probably owing to a peculiar virulence of the invading microöganism. The different forms of asthenic pneumonia are exceedingly dangerous; when they are met with, the prognosis should be very guarded. Cardiotonic and vasotonic therapy should be begun early. Despite every effort to increase the reactive powers of the organism, the disease is only too prone, in such cases, to terminate fatally.

#### MANAGEMENT OF CONVALESCENCE FROM LOBAR PNEUMONIA.

After the crisis, convalescence is, in favorable cases, rapid, and patients if not closely watched may increase their diet too rapidly or attempt to return to exertion too early. They should be kept in bed for at least a week after the temperature is normal, the diet should be only gradually increased, and careful attention should be paid to all the details of hygiene until strength has been fully restored. When allowed to leave the bed, a patient should sit up only one hour or less the first day, two hours the second day, and three hours the third day, after which, if he has grown stronger, he may be allowed to walk about a little. Should the appetite be poor some bitter tonic (nux vomica and gentian) may be given. The patient should be urged to protect himself carefully for at least a month after the illness. When possible he should have a change of air (at the sea or in the hills) until recovery has become complete. Such measures are especially important in patients who have had complications like empyema. Convalescents should be warned that those who have had lobar pneumonia once are more prone than other people to pneumonic infections; every precaution should therefore be taken to build up the general health and to avoid undue exposure to cold or excessive fatigue, especially during the winter months.

#### MODERN ATTEMPTS AT ETIOTROPIC THERAPY.

The mortality of lobar pneumonia, even under the most appropriate functional, regulatory and symptomatic therapy, is still very

large, and physicians are, therefore, naturally anxious for the discovery of some form of therapy that will lessen this mortality. Especially since such brilliant results in the treatment of certain infections by vaccine therapy, by serotherapy and by chemotherapy have been achieved, there has been much experimentation in the direction of the discovery of a specific therapy for lobar pneumonia due to the pneumococcus. To the present status of this phase of our subject, we may now conveniently turn.

*Vaccine Therapy.*—Rosenow (1918) of the Mayo Clinic has recommended the use of partially autolysed pneumococci in the treatment of lobar pneumonia, advising the administration of 1.0 cc. daily until the temperature reaches normal. He reports a mortality of only 7% in 200 cases treated. It is too soon as yet to pass judgment upon this form of therapy but it is perhaps worthy of a thorough trial in some of our organized clinics. I doubt if it is desirable for the general practitioner to resort to it until larger experience has been gained.

There is some evidence that the injection of pneumococcus vaccine (polyvalent) may be useful as a prophylactic measure at times when pneumonia is prevalent, though it is not certain as yet that such vaccination is as efficacious as the vaccination against typhoid. The report of Cecil and Austin (1918) in 12,519 instances is encouraging, as are the reports of Burnside (at Camp Dix) and of Duckwall (at Camp Taylor). It seems probable, however, that any immunity derivable from the injection of pneumococcus vaccine is of relatively brief duration.

*Serotherapy.*—Thanks to the researches of Rufus Cole and his associates at the Hospital of the Rockefeller Institute in New York, and to those of investigators at the Pasteur Institute in Paris, we have been given new hope for an efficacious treatment of pneumonia at least in one or two of its forms. The studies of Dochez and Gillespie (1913) and those of Lister in South Africa in the same year proved the existence of different types of pneumococci. These investigators isolated three different types (type I, type II and type III), each of which on animal inoculation gives rise to specific agglutinins and to specific precipitins. Beside these three groups, there are other forms of pneumococci (not all alike), which differ from the first three types in their morphology, in their solubility in bile, and in

the immune bodies to which they give rise. Cole at once undertook the experimental production of anti-sera for the different types of pneumococci. Thus far a specific serum of high titer has been successfully produced for type I; another serum, less efficacious, has been made for type II; attempts to produce a serum beneficial in infections from type III have been wholly unsuccessful. Infections due to pneumococci not belonging to types I, II and III, are usually benign infections ending in recovery without specific treatment.

Obviously, if sera antagonistic to the single types are to be employed therapeutically, it is desirable to determine as soon as possible after infection the particular type of pneumococcus that is its cause. Various methods of determining the type have been worked out, among them a method of mouse inoculation by Blake (1917), a method by means of a special culture medium by Avery (1918), and a coagulation method by Krumwiede and Valentine, (1918). Arrangements are now made in private bacteriological laboratories and in public health laboratories for typing pneumococci speedily, so that it is possible in most cases to receive a report within twenty-four hours after the collection of the sputum or of material obtained by lung puncture.

On account of the dangers of anaphylaxis, certain precautions should be observed before the administration of a specific serum. A history of hay fever, of bronchial asthma or of the previous use of anti-sera should make one particularly cautious. Even though the history be unsuspecting, it is probably wise to give first an intracutaneous injection of 0.02 cc. of horse serum diluted with ten times its volume of normal salt solution, and to compare the effect of this injection with that of the same amount of normal salt solution used as a control. If the patient be sensitized, a definite wheal will develop at the site of the injection within an hour. Whether the patient is thus found to be sensitive or not, if one desires to be entirely safe he may give a desensitizing dose of 0.5 to 1.0 cc. horse serum subcutaneously an hour or two before injecting the antipneumococcus serum intravenously.

The dosage of Cole's serum for type I is 100 cc. diluted with an equal volume, or more, of normal salt solution prepared from freshly distilled water. It is injected intravenously and at the body temperature very slowly over twenty to thirty minutes. The injection is

stopped immediately if cyanosis, dyspnoea or marked pallor should appear. Any evidence of anaphylaxis is an indication for the prompt injection of 10 minims of a 1 to 1,000 solution of epinephrin and 1/100 or 1/120 of a grain of atropin sulphate. Indeed, these remedies should be made ready for injection (in a syringe) before the intravenous therapy is undertaken.

The intravenous injection of the antipneumococcus serum is often followed by a rather pronounced reaction (fever, chill, cyanosis) in the course of from thirty to sixty minutes, but this reaction is usually followed within a couple of hours by a marked fall in the temperature and by sweating. Should the fever return within four to eight hours, a second intravenous injection of 100 cc. is given, and this dose may be repeated every eight hours until the temperature remains normal (Cole). In most cases three doses of the serum have been found sufficient.

In about half the cases that recover, the symptoms of a mild serum sickness appear in a week or ten days after injection, manifested by hives, itching, and joint pains. In a few cases the serum sickness is severe and requires epinephrin injections and local soothing applications for its control.

That the serum prepared to combat infections with type I has some efficacy seems to me to be clearly shown by the statistical results, though experience is as yet too limited to permit us to gauge very accurately the reduction in mortality that can be gained. Dr. E. A. Locke of Boston tells me that in a series observed by him the mortality was not less than that of controls that did not receive the serum. It goes without saying that the serum should be administered as early as possible after the initial chill and as soon as the typing has been completed.

What has been said above refers particularly to experiences with a high titer serum against type I pneumococcus. Favorable results have been reported by Cecil, (1918) from the use of a specific serum against type II, and Spooner, (1920), corroborates Cecil's view. Workers at the Rockefeller Institute are, however, doubtful of the possession, as yet, of a serum against type II of sufficient potency, and all agree that sera effective against type III still remain to be produced.

Truche, of the Pasteur Institute, (1919), has made four different sera corresponding to

the four different races of pneumococci. He recommends subcutaneous injections in doses of 80 to 100 cc. the first day and in doses of 20 to 40 cc. on following days, or better still intravenous injections (diluting 20 cc. of serum in 180 cc. of normal salt solution at the body temperature). Truche also uses the sera against pneumococcus infections of the pleura, of the meninges and of the endocardium. He advises intrapleural injection in doses of 60 cc. the first day and of 20 cc. on each following day after evacuation of an effusion. In meningitis he gives 40 cc. into the subarachnoid space as well as 20 cc. intravenously. In endocarditis he gives 20 cc. intravenously.

In 1921, Stengel of Philadelphia made a report on the use of serum and blood of convalescent patients in the treatment of lobar pneumonia. He advises collecting the serum from patients shortly after the crisis, keeping it on ice in a sterile container, and using it not later than from ten to fourteen days after collection. He gives from 30 to 70 cc. of this convalescent serum at a dose.

Polyvalent sera against pneumococcus infections have been prepared by Kyes and others. In one of the army hospitals, therapeutic experiments were made with Kyes' serum, and it appeared to exert at least some favorable effect.

The use of the Huntoon preparations has been advocated by some clinicians. The reactions after injection are often violent, sometimes dangerous, as in other forms of "foreign protein therapy." At present the consensus of opinion seems to be that the high titer serum produced against type I pneumococcus at the Rockefeller Institute is definitely of some value in the treatment of lobar pneumonia, due to infection with this type. Farther than this no definite statement dare yet be made.

*Chemotherapy of Lobar Pneumonia.*—For more than fifty years quinine has been used in one way or another in the treatment of lobar pneumonia, first as a tonic, later as an antipyretic, and still later as a specific remedial agent. Some very distinguished clinicians have been convinced of the advantages of quinine therapy. DaCosta around 1880 is said to have strongly advocated full doses of quinine shortly after the chill (S. Solis Cohen). He asserted that it will often arrest the development of an acute lobar pneumonia:—"It is difficult to prove this fact because one has no means of knowing that what is absent

was on the way. Yet it is true. The fact that pneumonia sometimes aborts spontaneously or runs a very short course does not negative this view. The real difficulty is that one rarely sees his patients soon enough." Since 1904 Solis Cohen has systematically used large doses of the double hydrochlorid of quinine and urea subcutaneously, intramuscularly and intravenously, in the treatment of lobar pneumonia (see his report, 1913).

A distinguished Edinburgh physician, the late Dr. George A. Gibson, believed that he had saved lives, even after patients had entered coma, by injections of quinine.

Aufrecht introduced the parenteral method of administering quinine in pneumonia and has systematically used it subcutaneously in the treatment of the disease since 1895. His advice was to give quinine subcutaneously when the disease is at its height, is taking a severe course and is becoming threatening, especially when the pulse is small, soft and frequent, or when slight deliria become noticeable. He thought that the beneficial results are less in its effects upon the temperature than in the specific influence that it exerts upon the causal microorganism or its products. It was rare to see a lessening of the fever; much oftener he saw a "favorable influence upon the total course of the disease." This method of Aufrecht's has been designated the "specific late treatment of pneumonia with subcutaneous injections of quinine." The "early treatment of pneumonia with intramuscular injections of quinine" was begun by A. Cahn and has recently been given a very careful trial by C. E. Cahn-Bronner, who believes that the course of pneumonia can be definitely shortened by early intramuscular injections of quinine.

Meanwhile, on account of the earlier clinical studies with quinine and on account of the influence of quinine and quinine derivatives on trypanosomes, Morgenroth and Levy, (1911) undertook the chemotherapy of bacterial infections and recommended the use of an especial quinine derivative, namely ethyl-hydrokyprein, or optochin, as a most suitable chemical for the treatment of pneumococcus inflammations in man. Since 1911 many studies have been made both of the optochin treatment of pneumonia and of the quinine treatment of pneumonia.

Optochin kills pneumococci in vitro. If it be injected into the peritoneal cavity of mice

thirty minutes before inoculation with what is ordinarily a fatal dose it will save the lives of a large percentage of them. Morgenroth and Levy undertook experiments to see whether or not optochin is useful in human pneumococcus infections and whether doses sufficient to be effective against the infection can be used without injury to the organism. Their results have been controlled by a number of clinicians in Europe and in America. Most of the clinical reports are against the use of optochin because of the danger to the eyes. Its use was forbidden in military service in Germany during the great war.

In this country a critical study of the matter was made by Moore and Chesney, (1918); they too felt that they dare not recommend the use of optochin for the routine treatment of lobar pneumonia. The whole matter has recently been reviewed by Cahn-Bronner in the *Ergebnisse der innere Medizin*. (1922).

It would appear to be true that, in a certain proportion of cases, lobar pneumonia may be shortened or even aborted by the use of optochin, that the general state of the patient can often be improved and that the mortality rate can be somewhat diminished. Though the results have been, on the whole, disappointing, they are still noteworthy. The best method of administering optochin is that of Mendel who gives optochin base in five doses of 0.3 grams or in six doses of 0.25 grams per day; the total daily dose not exceeding 1.5 grams. Mendel thinks it important also that optochin be given along with a pure milk diet, which is continued through both the day and the night. If optochin be given in this way there seems to be very little danger; a fairly steady absorption is arranged for. It is interesting that optochin has a specific effect upon pneumococci but no effect upon streptococci, whereas the reverse is true of eukupin.

The best way of administering quinine is, according to Cahn-Bronner, to give 0.5 grams in 5 cc. of a solution made up with urethane. The formula of the fluid is as follows: quinine muriate 2.0; urethane 1.0; distilled water ad. 20.0. Of this solution, 5 cc. contain 0.5 gram of muriate of quinine. Quinine thus injected is not too concentrated, an objection that has been raised against the use of Merck's ampoules of chininum dihydrochloricum carbamidatum (0.3 and 0.1 gram) though these ampoules are very convenient for carriage by the general practitioner. The preparation,

however, sometimes produces painful infiltrations at the site of injection, and so the more dilute solutions of quinine urethane are to be preferred.

Cahn-Bronner recommends injection of the quinine-urethane solution into the muscles of the thigh. It is important (1) to use a sterile quinine solution that contains no acid, (2) to use a glass syringe freshly boiled (without addition of soda), (3) to disinfect the skin and (4) to avoid moistening the injection needle on the outside with the quinine solution. If these precautions are taken there will seldom, it is claimed, be necrosis or abscess formation.

The adult single dose is 0.5 gram of muriate of quinine. Larger doses are, it is asserted, no more efficacious. The first injection is made as early as possible after the chill, and, if the fever does not fall within twenty-four hours, the injection is repeated. One then waits forty-eight hours and, if the crisis has not occurred, then gives a third injection of 0.5 gram, so that a total amount of 1.5 grams is injected within four days.

Though a careful study of statistics indicates that only about 3.7% of control cases show a cessation of the fever within four times twenty-four hours after the initial chill, on quinine therapy (in 188 cases) no less than 55.5% became fever-free before the end of the fourth day and 25% had aborted within 12 hours after the first injection. The mortality rate reported by Cahn-Bronner was only 6.4% for the cases treated with quinine, whereas in contemporaneous control cases, even after removing from the statistics patients who had entered the hospital moribund, the mortality was 20%. Among the patients that received their quinine injections within the first three days of the disease the mortality was only 5.7%. There was noticed also a marked improvement in the general state of the patient (circulation and respiration). In pneumonias, other than those of pneumococcus origin, it is said that quinine therapy produced no favorable effects.

A comparison of the effects of quinine with those of optochin in lobar pneumonia of pneumococcus origin showed the following results:

*Early defervescence* with parenteral quinine therapy 55%; with optochin therapy 33.6%.

*Mortality*, when treatment was given during the first three days, with quinine 5.7%, with optochin 9.5%; in all cases, early and

late, with quinine 6.3%, with optochin 13.4%.

The conclusion reached, therefore, was that quinine therapy was just as efficacious, indeed, somewhat more so than optochin therapy and, moreover, quinine therapy is free from danger to the eyes.

The way in which quinine acts is not, it is admitted by Cahn-Bronner, understood. It certainly has no direct pneumococcidal effect, but its action is believed none the less to be specific.

Though even with the use of quinine and optochin the mortality rate in lobar pneumonia is still high, nevertheless the reduction indicated by the statistics given would make it seem worth while to make a trial of the quinine therapy, at any rate until sufficiently large numbers of cases have been treated in different epidemics and in different places (with adequate control) to establish the value or the worthlessness of the remedy. It is conceivable, too, that further experimental work may yield a quinine derivative that is even more efficacious than any thus far tried. Results of quinidin in the treatment of auricular fibrillation indicate how important it is to find the exact chemical constitution that is best suited for a specific therapeutic purpose. Until the proof has been brought, however, that quinine or some quinine derivative has, in reality, a specific effect in lobar pneumonia, let us remain sceptical, bearing in mind the fate of the long series of attempts at systematic therapy of this disease in the past.

1035 North Calvert Street.

### INTRADURAL SURGERY IN ITS RELATION TO ABSCESS OF THE BRAIN.\*

By WELLS P. EAGLETON, M. D., Newark, N. J.

Operations for brain abscess originating from the ear and the nose give much better results than operations for brain tumors, as far as the actual curing of the patient and his restoration to usefulness is concerned.

If we drain an abscess, experience has shown that the patient is apt to be almost, if not completely, restored to health; but in the nature of the disease, being a suppurative process, the operative mortality must be higher than that of tumors; that is, not immediate death, but death within a period that is in direct relationship with the operation itself, be it one week or three months. As long as the sup-

uration is not controlled, the disease for which we operated has not been eliminated.

When a brain abscess originates from the ear, the suppuration enters either from direct extension of the infection passing through the dura or from a retrograde thrombophlebitis of a cerebral vein. In the first instance, the abscess is always situated contiguous to the area of bony caries; in the second, the abscess, while within the cerebral substance, is adjacent to the area of the primary bony involvement; the internal surface of the dura not being affected, there is no adhesion between it and the cortex. In the former case, as the dura is involved from direct extension of the suppurative process, there are adhesions between the brain and the dura.

CLASSIFICATION: *Adjacent (Secondary).*\* These two types of abscess, because of their location, I have designated as Adjacent (Secondary); adjacent because the abscess is invariably situated adjacent to the primary focus, and secondary because the intradural pathological process is secondary to primary infected process in the bone.

If the process is from direct extension, there may be a tract leading directly through the dura, into the abscess itself. This is an abscess with a stalk. When, however, it originates from a thrombophlebitis, there is no stalk in the earlier stages of the disease, but later there may be, as a stalk may develop from the growth of the abscess outward.

*Intercurrent (Tertiary)* abscess of the brain, either of the temporosphenoidal lobe or cerebellum, may originate from a previous thrombophlebitis of one of the large venous sinuses, the infection having involved first the sinus (as an infective thrombosis of the lateral sinus) and from this extended out into the brain substance by way of one of the veins entering the sinus.

This type of abscess may be situated in any part of the brain, at a considerable distance from the primary focus of infection of the bone. I have designated this type Intercurrent (Tertiary);\* intercurrent because the pathological process is carried by blood vessels, and tertiary, because the abscess really follows a secondary suppurative process of one of the large sinuses, which latter was the result of the primary otitis or nasal sinusitis.

*Metastatic.* In addition, we have metasta-

\*Read by title before the Virginia Society of Oto-Laryngology and Ophthalmology at Richmond, April 18th, 1923.

\*Eagleton, W. P., Brain Abscess. Its Surgical Pathology and Operative Technic, 1922, Macmillan Co.

tic abscess, in which the abscess originates from the bloodstream itself, being caused by nidus, liberated from an infected area, passing into the circulation and being deposited in one of the small cerebral veins. Metastatic abscesses originate not from arterial emboli, but from venous emboli—that is the nidus is deposited in a small vein where the ebb and flow of the blood and the low pressure of the blood is favorable to the development of a vascular occlusion followed by an infective thrombophlebitis and abscess.

This classification is of importance because it is clinical, it can be helpful in deciding the position of the abscess giving rise, as adjacent, intercurrent and metastatic abscesses do, to absolutely different symptoms during invasion.

**OPERATIVE APPROACH:** Although an adjacent abscess of the temporosphenoidal lobe is generally easily located surgically and evacuated, at least partially, the operation itself is only part of our surgical problem.

In intercurrent abscess, on the other hand, with our present methods of localization, both clinical and surgical, the position at operation generally cannot be accurately determined. This is especially true in cerebellar abscess as, in an analysis of a large number of cases of post-mortems of abscess of the cerebellum, we have found that the position of the abscesses varies greatly.

However, cerebellar abscess can generally be located by multiple brain punctures. If the only thing necessary were to find the abscess, undoubtedly this could be accomplished in the majority of cases through a small dura exposure.

In cases of abscess of the temporosphenoidal lobe this is especially true, because all of the adjacent abscesses are situated directly over the tentorium, while those of the frontal lobe present even less difficulty, as they almost invariably lie directly behind the frontal sinus. The surgeon is usually able to puncture the abscess after taking away the posterior wall of the frontal sinus.

**FACTORS TO BE PROVIDED FOR BEFORE ENTERING THE DURA; COMPRESSION AND CEREBRAL DISPLACEMENT:** But the location of the abscess is only the beginning of the surgical problem. The number of abscesses that have been evacuated at operation is very large, but the number that have recovered after location is comparatively small.

An important factor in the surgical treatment of brain abscess that must be planned for before opening the dura is subsequent cerebral compression. Secondary cerebral compression enters only to a limited degree into the post-operative treatment of brain tumors. In brain tumors, edema from the trauma may be met by lumbar puncture, intravenous administration of hypertonic salt solution, or magnesium sulphate by the stomach; and, while the edema may recur once or twice, it will ultimately subside as the compression itself has no influence on the subsequent condition of the brain if its immediate effect can be tided over.

Compression in suppurative diseases of the brain is a different process. If we examine the post-mortem records of brain abscess that have died after being evacuated through a small dural opening, we find that the abscess (or the area of suppurative edema) has extended, and that the cortex over the abscess, between it and the dura, is discolored. In other words, the areas of the brain adjacent to the abscess have begun to be gangrenous; the abscess has extended. This is a pathological fact, the importance of which is not as generally recognized as it should be.

We must prevent, if we can, this lighting up, by the operation, of an encephalitis in a region that is not already infected. To meet this condition before exploration, we should plan a bony flap large enough to be able to see a large area of the cortex and to explore it with the least amount of damage, thus preventing as far as possible a subsequent increase of the intracranial contents by a secondary edema.

These factors can only be met by large bone flaps and large dural openings. Whenever I have deviated from this principle I have invariably regretted it; and although with it many of my cases have died, I still feel the principle is right and that it should be adopted in every case. Without it I have lost several cases which, from the pathological condition and the position of the abscess as found at post-mortem, would have recovered.

In cerebellar abscess, to be able to see every part of the cerebellum, the incision must extend from one mastoid to the other and down the median line of the back of the neck; both flaps turned back, the whole cerebellar region explored, the bone removed and the sinus of the affected side obliterated; after which the dural incision extends from one mastoid to the other. Before opening the dura, a ventricular

puncture must be performed; the whole cerebellar fossa can then be explored and the abscess located with the least amount of trauma to the brain tissue.

Here I want to say a word about the dishonesty of the reports that occur in cerebral surgery. The books are full of statements of which the authors have little knowledge whatever and no experience. This was demonstrated not long ago in looking over a book on surgery in which I found a plate of an osteoplastic flap of the cerebellum that was devised years ago by a European surgeon, on anatomical grounds; he published it. Few cases could possibly recover from the operation for such a flap in the presence of increased intracranial pressure; the patient would die from hemorrhage during its performance. Yet, this description has been repeated in many books. It seems to me it is time that this copying without verification were stopped, for the good of medicine.

In temporosphenoidal lobe abscess an osteoplastic flap must be made, also in frontal lobe abscess. This exposes the dura completely. During this exposure there is apt to be some hemorrhage because the increased intracranial pressure causes the blood to leave the head by the diploic vessels instead of through the normal return venous channels.

The excessive increased intracranial pressure, so frequently encountered in brain tumors is never present in brain abscess, because of the nature of the lesion, yet we have increased intracranial pressure. A tumor is a slow growing process and by the slowness of its growth it gives the brain tissue opportunity to readjust itself. An abscess grows more rapidly and, because of its acute growth and its suppurative nature, can never reach the size often attained by tumors, without killing the patient.

An abscess destroys a part of the brain tissue by suppuration and does not add as greatly to the total bulk of the contents of the dura as brain tumors. Consequently we do not have the excessive bleeding from the skull in brain abscess operations that occurs in cerebellar tumor operations. The dread that I have always had of the profuse bleeding, so frequently seen in cerebellar tumor, has not been warranted during exposure of the dura in brain abscess.

It is after exposure of the dura that the chief surgical problems are presented, for we must prepare for the subsequent compression from

increased intracranial pressure that is apt to follow the operation.

It may be asked "if a lumbar puncture relieves the increased intracranial pressure, why is not this a simple way in brain abscess?"

LUMBAR PUNCTURE, ITS DANGERS: We are so in the habit of performing lumbar punctures and they are apparently so free from accident that we have become careless. A lumbar puncture on a normal individual, or an individual suffering from a degenerative disease, syphilis, meningitis, or a lateral sinus thrombosis (any condition in which the pressure, even though increased, is evenly distributed over the whole of the cerebrospinal fluid circulatory system), does not give bad results, although now and then a prolonged reaction occurs for which we cannot account. But in any condition of increased intracranial pressure from an *increase in the brain bulk* itself, a lumbar puncture is dangerous, and in my experience has actually caused a number of avoidable deaths.

It has long been known that abscess of the brain, even without lumbar puncture, is not infrequently followed by a sudden fatal termination. The same thing happens in brain tumor. The explanation usually offered has been that the respiratory centre has been herniated through the foramen magnum, causing paralysis of respiration. An intracranial death is always a blue death.

CEREBRAL DISPLACEMENT: I accepted this theory until my attention was called to the frontal lobe abscess as well as the occipital lobe abscess that dies suddenly, neither of which can cause medullary herniation. Post-mortem examinations demonstrated to me that the cause of death is frequently not from prolapse of the medulla alone. The explanation is that increased intracranial pressure from abscess or tumor is associated with displacement of brain substance itself which, if further altered, causes hemorrhage into the vital centres. The death may not be sudden.

Normally the brain is held together by the piaarachnoid as in a bag. Its shape is preserved by the vessels running through it; they are very elastic and firm. In a case of gangrenous cerebral herniation, after some of the disorganized brain tissue has been removed by irrigation, I have seen the free vessels remain, some over an inch in length, still very elastic. They could be stretched an appreciable distance.

In increased intracranial pressure from a *localized lesion* such as abscess or tumor (especially in cerebellar abscess), the vital centres are displaced away from the median line,—away from their normal position. In this displacement the blood vessels are also displaced. On account of their elasticity they stretch. This is possible without hemorrhage, because it occurs gradually, hour by hour, day by day, the process being a slow one. To this alteration in the position of the intracranial contents they adjust themselves. Nevertheless, they are abnormally placed, they are under stress; if now a surgeon does an operation and suddenly opens the dura, if extreme cerebral herniation occurs, the delicate vessels may rupture. For some reason the vessels of the pons apparently are the ones that most frequently rupture, and from the branches of the basilar artery hemorrhage also occurs. If the hemorrhage is extensive, there is immediate death; if not, a long period of Cheyne-Stokes respiration with semi-cama and then death.

I believe that nobody has called attention to this condition prior to a communication which I presented before the International Otological Congress last summer.\*

If the surgeon performs a lumbar puncture in the presence of cerebral displacement with increased intracranial pressure from an abscess or tumor, he causes exactly the same thing. There is now a combination of suddenly lowered pressure from below, allowing the brain to be herniated through the foramen magnum. At the same time he has altered the already abnormal position of the cerebellar contents, which may cause pontine hemorrhage.

Lumbar punctures in brain tumors or brain abscess have been in my experience attended by several unpleasant surprises. But we should attempt to lower the intracranial pressure before we open the dura, because we may have uncontrollable cerebral herniation. To accomplish this a ventricular puncture may be performed.

**VENTRICULAR PUNCTURE:** Judging by my experience, ventricular puncture sometimes is different. In supratentorial lesions it is often impossible to locate the ventricle on the side of the lesion, as it may not exist, being obliterated. The opposite ventricle may be either large or small.

When the lesion is below the cerebellum, the ventricles are generally more or less distended and can easily be located.

I have encountered other technical difficulties in ventricular puncture. Once on making a little opening in the dura through a trephine opening there occurred a gush of blood. I plugged it with wax, and it stopped. Whether or not in making the little nick through the dura I cut into a small pial vessel that was immediately crowded into the hole, I cannot say. In another case of increased intracranial pressure I had a loop of pial vessel protrude from the small opening. I "clipped" and replaced it without difficulty.

To reduce the increased intracranial pressure, it is desirable before opening, to give the patient magnesium sulphate by mouth; or an intravenous injection of hypertonic salt solution during the operation.

The combination of ventricular puncture and intravenous injection of salt should allow the dura to be opened with safety, the brain examined, the tract, if there is such, found, and the abscess evacuated through this tract. It may be necessary to perform a lumbar puncture, but we must realize the danger we are running.

**DRAINAGE:** The question of drainage, to my mind, is one of the most important, next to the exploration itself. All text-books recognize this, but few state that the drainage of abscess, of otitic or nasal origin, must vary according to whether the abscess is chronic with a capsule or acute without a capsule. It is not so much a question of the kind of drainage, as it is of the type of abscess in the given case.

If we have an acute intracerebral abscess without a capsule, we should be decided before we start that we probably will not drain. Our chief object should be to evacuate the abscess; to liberate the pus that is in the cavity of the abscess. There is nothing more to be done. This will horrify many but it is according to surgical principles, for, after the infection has been eliminated as far as possible, to put drainage material into an acute intracerebral abscess without a capsule is simply to place an irritant to the brain which will favor a continuation of the suppuration. Later if the abscess refills, a capsule having been formed, drainage material will have to be introduced.

If you have a chronic abscess with a capsule, it is a different matter. Here an effort should be made not to simply drain, but to eradicate

\*Eagleton: "Technical Considerations in the Treatment of Cerebellar Abscess." Trans. 10th International Otological Congress, Paris, 1922.

the suppuration. The whole of the interior of the abscess being cut off, as it were, from the normal brain tissue, it should be cleansed and, as it is obliterated by the pressure of the surrounding tissue, we place drainage material in it. A piece of greased rubber tissue will allow drainage with the least amount of irritation. I have tried fascia lata but, as dead fibrous tissue favors suppuration, I had to remove it on the second day. I believe the carotid artery of a dog would be a good material as it resists suppuration, and would furnish a channel through which to irrigate, if necessary. I have not tried it.

**CLOSURE:** If we leave the dura widely open, we will lose the case because the piaarachnoid must be protected from injury; so it must be closed tightly, except for the smallest possible opening through which the brain protrudes.

**AFTER TREATMENT:** I think that the most important thing I have learned during the past year about abscess of the brain is that, if we are to give the patient even a fair chance to recover, the care after operation demands the same forethought and attention to details with which the operation was prepared and performed.

How can secondary compression be foreseen and recognized? Ophthalmoscopic examination should be made at frequent intervals. In but a few cases has the fundus picture been of assistance to me, but in these few cases it has been of the greatest assistance. I do not believe that papilloedema is caused by compression alone, but I do believe that it may be the earliest sign of compression. If a papilloedema appears *after operation* we should be on the lookout; something is wrong. The blood pressure should be taken every fifteen minutes. A rising systolic pressure demands attention. A rising pulse pressure is of grave significance.

If coma deepens, we are justified in performing a ventricular or a lumbar puncture. Meanwhile an intravenous injection of salt or the administration of a solution of magnesium sulphate by mouth may keep the edema down.

**TRAINED TEAM WORK NECESSARY:** Brain abscess should be handled only by a team who are trained to do this work. In every hospital in which there are a large number of cases of traumatic cerebral injury, there should be a special service.\* To them should be turned over all head cases on every service. Today I

have two assistants, who always help me, an expert anaesthetist who has had experience in head cases, and one trained nurse,—that is a team of five trained people. We are still short one person, as there is frequent need of an assistant to cut a piece of fascia lata or to perform a blood transfusion.

When we think of the many difficulties that may be encountered, it is readily seen that only by team work can we possibly give the patient the best chance. For myself, I will not perform an intracranial operation outside the hospital in which I routinely do this work. I feel that to operate on intradural cases elsewhere is taking an unnecessary chance that may be disastrous to the patient. I am perfectly willing to operate on a patient in deep coma from a brain abscess or trauma in other hospitals. They have at best a poor prospect of recovery, and to remove them might invalidate this. But in cases in which the patient is not in coma, I insist that they be brought to the place where the team works.

**RESULTS:** From the text books one would think that from fifty to seventy per cent. of brain abscess recover. But all large compilations of cases show that less than fifteen per cent. of all the cerebellar, and less than forty per cent. of all the temporosphenoidal lobe abscesses have recovered. Even this, in my opinion, is too high, because it takes a great deal of courage to report successive failures, while every successful case is so brilliant that it is sure to be reported.

**PROGNOSTIC SIGNIFICANCE OF MULTIPLE LESIONS:** It is a clinical fact that the greater the number of lesions present at the time of operation, the less the hope of recovery. A sinus thrombosis prior to the formation of brain abscess is a predisposing cause of death, although the mortality from it alone is not high. An associated meningitis almost invariably terminates fatally, although a few cases have recovered, but the association of sinus thrombosis, brain abscess and infective meningitis offers little hope of the patient's recovery, even though the abscess is evacuated. Deep location of the suppuration, or acute abscess, and encephalitis, all are unfavorable conditions. We know that even if the abscess has been properly evacuated, the patient is apt to die. In any case the patient has but one real chance; we cannot afford to lose a single technical trick during or after the operation.

## RECENT ADVANCES IN THE DIAGNOSIS AND TREATMENT OF SYPHILIS.\*

By WARREN T. VAUGHAN, M. D., Richmond, Va.

The serologic study of syphilis has become so extensive that in large medical hospitals and clinics the Wassermann reaction has been made practically routine. Coincident with the development of routine tests for syphilis, clinicians have come to rely more and more upon the laboratory for their diagnosis and have neglected the methods of physical examination and analytic diagnosis. In the past when syphilis was suspected, a thorough search was immediately instituted for any and all signs or stigmata suggesting this disease. How much easier it is to await the laboratory report and thereupon establish or eliminate syphilitic infection!

Not only is routine laboratory technic not infallible, but furthermore, there are without doubt not a few cases with truly negative Wassermann reactions. These cases will be misdiagnosed if too great reliance is placed upon the laboratory examination. Pride in one's ability to recognize disease should impel one to make a thorough examination and to establish the tentative diagnosis, even before receipt of the laboratory report. If the report is then found to be at variance, it is still possible that the laboratory is in error. It is then that judgment, that rare virtue so necessary to the diagnostician, becomes of paramount importance.

Perhaps the condition most frequently met with, in which the patient although actively syphilitic shows a negative blood Wassermann, is chronic advanced syphilis of the central nervous system. Here the spinal fluid will usually show a positive reaction.

Marcel Pinard describes a case with multiple, painful exostoses without signs of syphilis and with a negative Wassermann and Hecht reaction, but which subsequent events showed to be a case of heredosyphilitic infection. The initial symptoms appeared at the age of 22, following trauma. As the exostoses became more numerous, syphilis was suspected and the blood was tested and found to be negative. The spinal fluid Wassermann was also negative. Under antisyphilitic treatment the symptoms rapidly disappeared.

The same author has recently reported an even more interesting case. A pregnant

woman of 35, with headaches, facial paralysis and albuminuria, presented herself for diagnosis. Syphilis was suspected and a Wassermann was done on three occasions, and by three different serologists, each time with negative results. The woman at term gave birth to an infant showing all of the classical signs of congenital syphilis, with skin eruption, snuffles, etc.

Two children from a previous marriage were examined and in both were found the characteristic signs of heredosyphilis.

This woman had suspected syphilis before her second marriage and had consulted a physician who made blood tests and then informed her that she was "une malade imaginaire." The patient remarried, therefore, with medical sanction, and continued to produce hereditarily syphilitic children.

Pinard draws attention to the unfortunate circumstances resulting from a medical attitude of mind which depends entirely upon the result of the Wassermann reaction for guidance, and emphasizes the importance of searching for evidences of syphilis among other members of the family, a search which often furnishes information which the serologic reaction withholds.

The value of the Wassermann reaction in serologic diagnosis is unquestioned, but the method is not without its real disadvantages. The various ingredients entering into the complement fixation reaction must be titrated with the utmost precision. Antigens are known to be variable. Complement tends to deteriorate with relative rapidity and since the interpretation of the test depends upon the disappearance of complement activity, its deterioration may be mistaken for fixation. Again, serum is occasionally either wholly or partially anticomplementary. Furthermore, many sera contain a natural hemolysin, the presence of which leads to erroneous negative conclusions. These and many other technical difficulties undoubtedly explain why, in spite of the fact that the Wassermann reaction has now been in use more than fifteen years, it is not, as yet, wholly dependable.

The fact that alcoholic extracts of non-syphilitic organs may be used in the test has discredited the specific antibody conception of the reaction. It is chiefly this fact that has inspired recent attempts to simplify the technic. The earlier interpretation of the Wassermann reaction as an antigen-antibody re-

\*Read before the South Piedmont Medical Society, Danville, Va., April 18, 1923.

action has been questioned and it has been suggested that the phenomena observed are based on colloidal reactions. In 1907 several investigators suggested that a precipitate is formed in the positive Wassermann test and Jacobstahl showed with the ultramicroscope that such a precipitate actually is present when a mixture of Wassermann antigen and syphilitic serum is incubated for one and one-half hours. Attempts to produce a visible precipitation as indicative of syphilitic infection were first successfully carried out by Lange who developed the colloidal gold reaction. Of the ten or more precipitation or flocculation reactions that have been more recently described, the Meinicke, the Sachs-Georgi and the Kahn reactions have, because of their relative simplicity and because of their high correlation with the Wassermann test, received especial attention and study.

It has been shown that the globulins in syphilitic serums and spinal fluids are increased above the normal, and the precipitation occurring in the various tests is supposed to be a reaction between seroglobulins and lipid extract such that the resulting flocculate is a lipoglobulin aggregate. The Sachs-Georgi reaction is one of the simplest so far proposed. The technic consists in the incubation for from eighteen to twenty-four hours of a mixture of inactivated serum, sodium chlorid and cholesterinized heart extract. A positive reaction usually occurs at the end of that time although the tubes are customarily allowed to remain at room temperature overnight, when a second reading is taken. The test has been compared with the Wassermann reaction in over thirty-one thousand cases and in the aggregate there was an agreement of 86.9% in all tests performed by various workers.

The main difficulty with both the Meinicke and Sachs-Georgi reactions lies in the fact that the end results are read after forty-eight hours incubation, at which time the serums frequently show sufficient contamination to lead to false interpretations. The Kahn reaction is read after a much shorter interval and is even further simplified. In it the final precipitate is easily seen with the naked eye and in strongly positive serums spontaneous flocculation occurs, enabling interpretation as soon as the reagents are thoroughly mixed. Serums are mixed with small amounts of diluted cholesterinized antigen and with non-

cholesterinized antigen and the mixture is then vigorously shaken for three minutes. Sometimes at the end of this period a positive reading may be had, although as a rule readings are made after incubation overnight. The possibility of standardizing this type of reaction is increased by the fact that only one reagent is added to the serum. Young, in reporting a comparison between the Kahn and Wassermann reactions in five thousand and eighty serums, found an agreement of 93.03 per cent. between the two reactions.

Serologic examination for the presence of syphilis has become so generally relied upon that any method which will increase the accuracy of the test should be utilized. Standardization of the original test is of the utmost importance. Other simpler reactions such as the Kahn and Sachs-Georgi test may be used for confirmatory evidence. It may be that ultimately some simpler flocculation reactions will entirely supplant the Wassermann test. In the meantime, it must be borne in mind that the mechanism of none of the reactions is accurately known. We cannot explain why in syphilis and in practically no other disease some change has been produced in the blood serum by which the precipitation reactions will become positive.

When salvarsan was introduced into the medical world, the details of its administration had been already worked out. Ehrlich, after having chemically perfected the spirocheticide, had had its action tested on thousands of individuals in several of the best German clinics, so that when the treatment came into general use the experimental phase had been passed, and the dosage and manner of administration had already been worked out in detail. In this way unfortunate accidents in the hands of inexperienced physicians were to a great extent avoided.

Nevertheless, there have been several important and valuable changes in the method of arsphenamine therapy during the last ten years. In the treatment of syphilis, it was soon discovered that the "therapia sterilisans magna," which had been satisfactorily employed in animals, could not be reproduced in man. Our inability to destroy all of the spirochetes in the body with one massive intravenous medication has rendered it necessary to administer repeated doses. The question of dosage in the treatment of syphilis has therefore become extremely important.

Ehrlich, in his original work on trypanosomes, recognized that in those cases not entirely cured by the first treatment, relapses were even more difficult to cure. Treatment which had been unsuccessful in a first attempt was usually unsuccessful on repetition. Repeated treatments, none of which cured entirely, were often found to have progressively less influence on the activity of the infecting parasite. A condition of "Festigkeit," increased tolerance or resistance to the action of the drug, had been produced.

The possible development of "drug-fastness" by the infecting agent, in individuals undergoing antisyphilitic treatment, is now recognized as an important feature and a phenomenon to be avoided if possible.

A contribution of considerable significance has been made recently by Bronfenbrenner and Schlesinger, who found that minute doses of arsphenamine, instead of inhibiting the progress of the spirochetal infection, actually caused the disease to progress more rapidly and more extensively in the animals so treated than in other animals similarly infected but not treated at all. Bronfenbrenner and Noguchi found some time ago that minute amounts of arsenic present in culture media stimulated the growth of spirochetes. Very minute quantities of arsphenamine appear therefore to be of less value than no treatment at all. The phenomenon appears analogous to that found in the treatment of cancer by the roentgen ray, where small doses stimulate the cells to proliferation while larger doses destroy. Bronfenbrenner and Schlesinger point out that this stimulative action of minute doses of arsenical compounds is not to be confused with the development of increased tolerance, but is characterized by an actual increase in the rapidity of multiplication of the parasites.

The dosage used by these investigators is, of course, extremely small and it does not follow from their report that the occasional small doses used therapeutically in the treatment of syphilis have a stimulating action. It is quite probable that even these small doses are sufficiently large that they inhibit multiplication. This is indicated by the customary diminution in the intensity of the positive Wassermann reaction and clinical improvement.

Brown and Pearce have shown in a recent article that insufficient treatment with

arsphenamine or neoarsphenamine may alter the immunologic status in experimental animals to such an extent as to favor the development of a second or superimposed infection without a cure having been accomplished for the first. They inoculated the rabbits and, after the development of the primary lesion, treated the animals with single massive doses of arsphenamine or neoarsphenamine. The primary lesions as a rule retrogressed and in some instances disappeared. Reinoculation, at a time when the drug was no longer present in the body in sufficient amounts to produce an effect, and when the original primary lesion had practically disappeared, produced in most of the rabbits a second primary lesion at the site of reinoculation. In the majority of the animals the original infection had not been entirely destroyed and, as the original parasites once again commenced to multiply, chancres developed both at the site of the original inoculation and the site of reinoculation.

It has long been held that individuals once infected with the spirochete of syphilis are immune to reinfection as long as the germ remains active in the body. Reinfection usually is assumed to be evidence that the patient had been cured of the former infection. The work of Brown and Pearce shows quite conclusively that experimentally, at least, an individual may become reinfected with syphilis even though the original invaders are still living in his tissues. Similar phenomena have occasionally been reported in man.

How frequently the factors discussed above will become of importance in the treatment of syphilis is uncertain. Certainly the standard doses in use in the large clinics have proved their worth. But that they are the ideal dosage does not follow. There is a tendency with many to give relatively smaller doses of arsphenamine or neoarsphenamine than formerly. Past experience and recent laboratory observations appear to be of accord in indicating that the dosage in antisyphilitic treatment should be as high as safety permits.

The standard intravenous dose of arsphenamine is 0.6 gm., that of neoarsphenamine 0.9 gm. These quantities appear to be sufficiently large for satisfactory therapeutic results and yet are not so large that they cause untoward results. They contain about equal amounts of arsenic and are supposed to have equal therapeutic value. The majority of critical

observers have found, however, that there is a difference in the effectiveness of the two drugs when given in these doses. Most syphilologists have concluded that arsphenamine produces prompt results and is less liable to be followed by relapse. The popularity of the second preparation is due to the greater ease of administration, a factor which should play a less important role than it actually does. In nearly all of the armies, during the war, syphilis was treated with nearsphenamine. This was undoubtedly due to the greater ease, and shorter time required for administration, thereby facilitating the treatment of larger numbers of individuals, and to the fact that considerably less apparatus was required. Rightly or wrongly this has given an official sanction to the use of nearsphenamine.

Considerable experimental work has been done within recent years to determine if possible the comparative value of the two drugs. Schamberg, Kolmer and Raiziss, working with trypanosomes, found that the trypanocidal activity of arsphenamine was 1.74 times that of nearsphenamine. Castelli and others, working on trypanosomiasis, spirillosis, and rabbit syphilis reached similar conclusions, finding that the activity of the former was between 1.5 and 1.78 times that of the latter. If we are to accept these results we should conclude that: therapeutically 0.6 gm. of arsphenamine is not equivalent to 0.9 gm. of nearsphenamine, but rather to 1.05 gm. The therapeutic activity of 1.05 gm. of nearsphenamine is equivalent to that of 0.6 gm. of arsphenamine.

The trypanocidal dose of arsphenamine (*dosis therapeutica*) is 4.564 times less than the highest tolerated dose, (*dosis tolerata*). On the other hand, the therapeutic dose of nearsphenamine is 6.35 times smaller than the highest tolerated dose. The latter is, therefore, a safer drug, the margin of safety between the two doses being distinctly greater. This is true even if 1.05 gm. instead of 0.9 gm. of nearsphenamine should be used.

The average *minimum effective dose* for arsphenamine is 3.1 gm. per kilo body weight; for nearsphenamine, 3.4. These two doses are approximately the same. *The minimum lethal dose* on the contrary is 53.2 for arsphenamine and 96.5 for nearsphenamine. Once again we see a wider margin of safety in the latter drug. Voegtlin and Smith desig-

nate as the "therapeutic ratio," the ratio  $\frac{M. L. D.}{M. E. D.}$ . For arsphenamine this is 17.2, and for nearsphenamine 28.4. The higher the ratio, the less danger is there in administering the drug in amounts greater than the M. E. D.

These experimental observations coincide with clinical knowledge that toxic reactions occur less frequently after large doses of nearsphenamine than after corresponding doses of arsphenamine.

Schamberg, Kolmer and Raiziss have made a study of the relative toxicity of the two drugs. They found that for rats and mice nearsphenamine is about 2.4 times less toxic than is arsphenamine. They conclude that, as far as is indicated by intravenous experiments on rats, the usual dose of 0.6 gm. of arsphenamine is about 12 times less than the highest tolerated dose, while 0.9 gm. of nearsphenamine is 19 times less than the highest tolerated dose for the latter drug. Here again the conclusion is that larger amounts of nearsphenamine are of less danger than are proportionate amounts of arsphenamine.

It is well known that nearsphenamine may be given with safety at shorter intervals than arsphenamine. Will it not be true then, that if the former drug is administered in slightly larger doses and somewhat more frequently, say 0.9 gm. thrice weekly, equally good therapeutic results will be obtained? This raises a question as to whether the difference in therapeutic results is due merely to a difference in dosage or whether it depends on a chemical difference between the two drugs.

Schamberg concluded from comparative studies that the addition of the formaldehyde sulphoxylate group found in the nearsphenamine may lessen the affinity of this drug for the protoplasm of the parasite, but at the same time lessening the affinity for the body proteins to an even greater extent. This hypothesis would explain both the diminished therapeutic effect and also the decidedly lessened toxicity. Another phenomenon bearing on relative toxicity is the observation by Schamberg that arsphenamine in practically all concentrations hemolyzes red blood cells *in vitro*, while nearsphenamine does not do so in any concentration clinically employed. Schamberg has concluded that arsphenamine is more active therapeutically but that this advantage is balanced by the much higher toler-

ated dosage of nearsphenamine and by the fact that the latter is less likely to cause biochemical disturbance in the blood and the tissues.

The preceding review indicates fairly clearly the unsettled status of arsphenamine and nearsphenamine dosage. At present there is sufficient evidence to justify those who prefer to use the simpler technic of nearsphenamine therapy, but only on the condition that sufficiently large and frequent doses be administered.

There is some diversity of opinion as to what therapeutic procedure may best be followed in obvious nervous system infection. In general, three views are held. First, that intravenous medication alone produces satisfactory results; second, that intravenous medication should be combined with spinal drainage; and third, that the administration of salvarsanized serum intraspinally produces the greatest benefit.

The performance of spinal fluid drainage after intravenous treatment was originally based on the assumption that with reduced intraspinal pressure the arsphenamine circulating in the blood will diffuse more readily into the subarachnoid space. Dercum claims better results than by the Swift-Ellis method, due he thinks, to the more thorough drainage. Every possible drop of fluid is removed each time. Theoretically, the rapid removal of fluid will produce a relative hyperemia of the cord and brain with resulting improved nutrition to the parts. Dercum draws an analogy to the Bier method of hyperemia as used in surgery. If his theory is true, drainage alone, irrespective of intravenous treatment, might improve the nutrition of the central nervous system with resultant spontaneous improvement.

The presence of arsphenamine in the spinal fluid, according to Dercum, is of no significance and probably plays no part in the good results obtained. The difficulty in syphilitic medication lies not in the failure of passage of the spirocheticide through the choroid plexus into the subarachnoid space, but in its failure to pass through the walls of the capillaries situated in the nervous tissue, into the parenchymal cells where the chief damage takes place. The hyperemia resulting from spinal drainage would increase any such tendency to pass through the capillary walls.

Fordyce, who is an ardent advocate of the

Swift-Ellis method of treatment, takes vigorous exception to Dercum's conclusions. He points out that Swift and Ellis did not develop their method under the mistaken idea that the nervous system received its nutrition from the spinal fluid, but rather because intraspinal therapy had been successfully employed in the treatment of cerebrospinal meningitis. Many forms of neurosyphilis have their site in the meninges and are limited to these structures. Meningovascularitis cannot always be differentiated clinically from paresis and in most cases of true paresis there exists at the same time a meningitis. Positive spinal fluid findings in central nervous system syphilis are due usually to meningeal involvement and this can best be treated by the direct application of a spirocheticide. The more pronounced the luetic meningitis, the more marked will be the benefit derived from intraspinal medication. Fordyce states that numerous cases have been entirely cured and many greatly benefited by Swift-Ellis treatment after the failure of those methods so strongly advocated by Dercum and others. Numerous cases of progressing optic atrophy have been permanently arrested by intraspinal medication after the failure of prolonged intravenous treatment.

The prevention of late neurologic accidents in syphilis does not depend solely upon a recognition of early invasion. The theory that inadequate treatment predisposes to late nervous involvement has been discussed in some detail by Keidel. Little is known with regard to immunity in syphilis but we have considerable indirect evidence that the human body does develop some degree of immunity against the *treponema pallida*. The observation of Colles regarding the apparent immunity of the pregnant mother and that of Profeta, that a "non-syphilitic" child born of syphilitic parents appears immune, were the first observations based on such a conception. As a rule a syphilitic cannot be superinfected. Pearce and Brown have shown experimentally that insufficient treatment will destroy this immune mechanism and that a second chancre may then be produced even while pathogenic microorganisms persist in the first. They have proposed two "laws," both of which aid in an understanding of late neurosyphilis following inefficient treatment. According to the "law of progression," various tissues of the body are not equally susceptible and reactive to

syphilitic infection. Some groups are more susceptible than others, and with a progressing infection there is an orderly sequence from one group to the next. Interference with the course of the infection, as by treatment, may protect some tissues, but unless persisted in may fail to protect tissues higher in the scale. Reidel observes that certain tissues with relatively high resistance to invasion show little defensive reaction after finally becoming involved. If these observations are applied to the central nervous system, the latter tissue may be considered relatively insusceptible to invasion with the spirochete, and at the same time unable to satisfactorily develop an immunity reaction when it does become so invaded. Thus the nervous system must depend for its protection upon the presence of immune bodies derived from other tissues. With destruction of the treponema, the general immunity reaction becomes less vigorous and the nervous tissues more easily fall prey to the invading parasite.

The second law formulated by Brown and Pearce, "the law of inverse proportions," assumes an inverse quantitative relationship in the intensity of consecutive reactions in syphilitic infection. Thus in the primary sore, a defense reaction is set up. If this is vigorous and the chancre is extensive, the later manifestations are likely to be milder if they appear at all. Conversely, with a small, non-reactive chancre, the secondary and tertiary phenomena are usually more extensive. It has long been observed that in secondary syphilis with extensive cutaneous manifestations, central nervous infection is less apt to occur, whereas with but slight cutaneous involvement, later neurosyphilis is more frequent. Treatment which mitigates the severity of the primary and secondary reactions without completely eliminating the infection may predispose to involvement of those more highly resistant tissues such as the central nervous system.

Thus we may use the term accurately when we speak of prophylactic treatment of neurosyphilis. The efficiency and completeness of treatment of the primary and secondary lesions appears to be of considerable importance in determining later neural infection.

The weight of evidence indicates that intraspinal administration of salvarsanized serum has a distinct field and should be employed in all cases in which intravenous treat-

ment has not satisfactorily cleared up the central condition. For satisfactory results intraspinal treatment must be begun early. Tabes and taboparesis when usually recognized are past cure and usually past improvement. The future hope of therapeutic advancement in this field consists in early recognition of neural involvement and intensive treatment before the appearance of localizing signs or symptoms. The routine which I have followed consists in the giving of an initial course of intravenous therapy, followed by re-examination of the spinal fluid. If improvement is noted, the method of treatment is not changed. If no improvement in the spinal fluid findings has occurred, intravenous treatment is reinforced by intraspinal therapy, using the Swift-Ellis technic. In cases of early secondary syphilis it is safer to give three or four intravenous treatments before performing the initial lumbar puncture, so as to lessen the hazard of meningeal invasion subsequent to the puncture itself.

A negative blood Wassermann does not rule out central nervous system syphilis, even in those cases who have had no anti-luetic treatment. In case of doubt, a diagnostic lumbar puncture will give valuable information. The intrathecal pressure should be roughly estimated, cell count and globulin content should be recorded, and Wassermann reaction should be determined. I have also been employing the colloidal gold reaction as a control for the Wassermann. It is important to use amounts of fluid up to 2 c.c., in the Wassermann test, so that a weak positive will not be overlooked.

No case of syphilis can be said to be successfully protected against late neurosyphilis until the spinal fluid has been studied and found to be normal.

Early treatment of neurosyphilitic lesions, before the development of localizing signs, offers the only promise, at present, of satisfactory therapy. Spinal fluid examination affords the only means of recognizing this early involvement.

Every syphilitic should have at least one lumbar puncture performed, early in the course of his disease.

The use of bismuth in the treatment of syphilis was developed in France chiefly through the efforts of Sazerac and Levaditi, who recognized the value of the earlier uncompleted work of Sautou and Robert of the

Pasteur Institute. The preliminary observations made by Sauton and Robert were published in *Annales de L'Institut Pasteur* in 1912. No further experimental work was performed until after the war when, in 1921, Sazerac and Levaditi published their preliminary observations. In January, 1922 a symposium on the use of bismuth in the treatment of syphilis appeared in the *Annales de L'Institut Pasteur*. Between January and December, 1922, twenty-seven articles on the use of bismuth in syphilis have been recorded in the *Quarterly Cumulative Index*, coming from the following seven countries: Argentina, Denmark, Italy, Brazil, Uruguay, Germany and Switzerland. During the same period the treatment was not discussed in the American medical press.

Fournier and Guenot have collaborated with Sazerac and Levaditi in the clinical use of sodium-potassium-tartrobismuthate. They give the drug intramuscularly in a 10 per cent. suspension in olive oil and emphasize the importance of depositing it into the muscles rather than subcutaneously. The latter method is decidedly more painful while the inconvenience from intramuscular injection is no greater than that observed after intramuscular mercury. A total of two or three grams of bismuth should be given during the first month of treatment. Two or three injections of 0.2 grams are given daily, after which the patient receives 0.3 grams twice weekly throughout the month. After this period, treatment may be continued with weekly injections of 0.2 to 0.3 grams or the patient may be allowed one month rest, after which the regular course is repeated. The only necessary precaution for the patient to observe is a careful hygiene of the mouth.

Under this treatment spirochetes disappear from the primary sore after the first to the third injection. The chancre becomes completely healed within five to twenty-five days, usually within two weeks. The Wassermann reaction, if negative at the initiation of treatment, usually remains so. If positive, the strength of the reaction falls as satisfactorily, or perhaps more so, than after the use of arsphenamine.

Bismuth is particularly useful in the contagious stages and, according to the authors, causes more rapid and complete disappearance of the contagious lesions, than does arsphenamine. In secondary syphilis the cutaneous

lesions disappear as a rule within a week. The strength of the Wassermann reaction is very favorably influenced, becoming practically negative within two or three months as a rule, but varying considerably as with other forms of treatment. Tertiary lesions improve with almost equal rapidity. This is particularly true of gummata and tertiary skin and mucous membrane manifestations. The authors report no conclusive observations on visceral or nervous syphilis.

No untoward effects from the use of bismuth have been reported other than a tendency toward stomatitis similar to but usually not as severe as that following the use of mercury. A marginal pigmentation usually appears in the gums, analogous to the familiar lead line. The stomatitis is usually a fusospirillary infection similar to that of Vincent's angina. It is satisfactorily treated by the methods customarily employed in Vincent's angina and may even be rapidly cured by the local application of the tartrobismuthate in powder form. Bismuth appears in the saliva but in an altered form, probably combined with sulphur, in which it has lost its spirillicidal properties.

The immediate results from the injection of bismuth compounds in syphilis appear from the published reports to be as good as or better than those obtained with mercury and arsenic compounds. In any case, the drug will be valuable for alternate use with the latter, in those cases where the infecting parasite has apparently acquired a degree of tolerance to the drug. It will be several years before the end results from bismuth treatment can be comprehensively tabulated. In fact it has not been until recently that we have come to realize the significance of the late unsatisfactory accidents from standard treatment with mercury and arsphenamine.

The discovery of the *treponema pallida* by Schaudinn and Hoffmann, the cultivation of the spirocheta by Noguchi, the application of the Bordet-Gengou phenomenon to the serologic diagnosis of syphilis by Wassermann and the preparation of salvarsan by Ehrlich have concentrated our attention on attempts to rid the body of the spirochete and to obtain a serologic cure, and have diverted our thoughts from the patient as an individual, so that in many instances we have lost sight of the importance of clinical cure. This is

often not obtained until long after the Wassermann reaction has become negative.

To summarize the treatment of syphilis in a few words, I would emphasize two general facts which may appear mutually antagonistic. The eradication of syphilis in the individual case is not always indicated by the obtaining of a negative Wassermann reaction. Sometimes, particularly in nervous system involvement, the patient is still actively syphilitic and suffers from a progressive disease even though the blood reaction is negative. In these cases treatment which is discontinued on a negative laboratory report is incomplete. It is the disease and not the laboratory reaction that should be treated.

On the other hand, there is a disposition on the part of many to treat the patient too vigorously in their effort to obtain a serologic cure, so that the general condition suffers from the poisoning of medication. Here it is often better not to attempt to obtain a negative Wassermann reaction. In individuals who are Wassermann fast, the treatment is sometimes more disastrous than the disease. This is often also true in elderly individuals or patients with advanced myocardial degeneration, aortitis, etc.

Here we are faced with a dilemma. Some patients with negative Wassermanns are not cured and need more treatment. Others, whose Wassermanns are still positive, should receive no further treatment. How may we determine whether to go farther or to stop short? The answer to both phases is summed up in the dictum, treat the patient rather than the disease. The laboratory tests are of inestimable value but of greater value still is attention to the clinical course of the patient's illness.

### SOME RESULTS OF PROTEIN SENSITIZATION WORK IN BRONCHIAL ASTHMA, HAY-FEVER AND ALLIED CONDITIONS. REPORT OF CASES.\*

By GRAFTON TYLER BROWN, M. D., Washington, D. C.

A year ago I read a paper<sup>1</sup> before this Society, reviewing in a brief way protein sensitization work and reporting my own case. I

\*Read before the Medical Society of the District of Columbia, March 21, 1923.

1. Brown, G. T.: Protein Sensitization in Bronchial Asthma, Hay-Fever and Allied Conditions. With Report of Writer's Own Case, Va. Med. Mo., 49:188 (July) 1922.

feel that it might be of interest and possibly of some benefit to relate to you some of my own results.

#### BRONCHIAL ASTHMA.

By means of a careful history and cutaneous tests, bronchial asthmatics may be roughly classified into the following groups: food, animal epidermal, bacterial, pollen, miscellaneous inhalants (orris root, etc.), and non-sensitive. In the limited time at my disposal it will only be possible for me to report one case as illustrative of each of these groups.

#### FOOD ASTHMA.

*Case 1.* Mr. J. T. M. Age 62 years. Referred by Dr. Welburn. Had severe asthma for about twenty years, accompanied by a very productive and troublesome cough. Attacks came on suddenly. Worse in summer. Also had symptoms of hay-fever. Whenever he went in a field where they were cutting wheat or to a mill where they were threshing it, he would be unable to sleep all night because of asthma and hay-fever. He gave large reactions to the proteins of wheat flour and tomatoes, and lesser reactions to the pollens of wheat and rye. I advised him to completely eliminate wheat and tomatoes from his diet and gave him a sputum bottle, feeling that an auto-genous vaccine was indicated because of the severe bronchitis. A week later he brought back the empty sputum bottle and reported that he was entirely free of all asthma, cough and expectoration. He has remained free to date, a period of eight months, with the exception of a few isolated attacks following exposure to wheat, *i. e.*, one attack followed going through a wheat field, another followed repairing a flour sifter. In this case wheat flour undoubtedly acted both by inhalation and ingestion to produce symptoms.

#### ANIMAL EPIDERMAL ASTHMA.

*Case 2.* Mr. D. W. L. Age 32 years. Referred by Drs. Hazen and Eichenlaub. Asthma, perennial hay-fever, and eczema. Asthma started at about 9 years of age. Hay-fever and eczema started at about 12 or 13 years of age. Family history negative as regards sensitization. Patient stated that if he went to the theater where they had an animal act with horses, or to a parade where there were horses, or if he rode behind a horse he would have severe asthma and hay-fever. His occupation as foreman of a coal company, with

teams passing in and out of the yard almost continuously, brought him more or less intimately in contact with horses. On his vacations, when he would visit his mother and father in the mountains, where there were no horses, he would be entirely free of asthma, hay-fever and eczema. On his last visit, however, they had gotten a horse, and he had asthma, hay-fever and eczema the entire time he was there. Whenever his asthma and hay-fever were worse, his eczema would also be worse. Patient was so miserable most of the time, that he had contemplated suicide. Has taken about eighteen X-ray treatments for eczema and has had two negative Wassermans. A few tests for protein sensitization were performed in October, 1920, by Dr. Ketron, of Baltimore, who found him very sensitive to horse dander. On thoroughly testing him, I obtained a four plus reaction to horse dander and lesser reactions to a number of other substances. Treatment with horse dander protein extract has completely relieved him of asthma and hay-fever, but has had little effect on the eczema, and elimination of the various other substances to which he reacted apparently had no effect. In spite of a large number of treatments with horse dander protein he still gives quite a marked cutaneous reaction to the same. I believe this incomplete desensitization accounts for the persistence of the eczema.

#### BACTERIAL ASTHMA.

By bacterial asthma, I mean asthma due to sensitization to protein contained in the bodies of bacteria.

*Case 3.* Mrs. G. C. Age 33 years. Referred by Dr. Le Comte. Patient had influenza in 1917, which left her with a very severe cough and hemoptysis. Was told by a physician that she had pulmonary tuberculosis and was sent to Asheville, N. C. This diagnosis was unconfirmed by specialists there and she returned home. Then asthma set in, which she has had steadily ever since, a period of about five years, accompanied by a very troublesome bronchial cough. Asthma always worse at night, in fact she had not had a whole night's sleep in five years. Very susceptible to colds, which always aggravated the asthma and were accompanied by ulceration of her throat and enlargement of the cervical lymph glands. Treated by competent nose and throat specialists the latter part of 1919. X-ray of teeth,

negative. Took osteopathic treatments from February, 1920, until October, 1921. About March 1, 1922, she developed what appeared to be angioneurotic edema, affecting her ankles, hands, lips and eyelids. Her skin had become very rough, split around finger nails, and cracked and bleeding between toes. Urine negative. Blood and spinal fluid Wassermann negative. On testing her I obtained a very marked reaction to the protein of streptococcus hemolyticus, and lesser, though quite definite, reactions to wheat flour, tomatoes, peas, turkey and a few other foods. An interesting feature of her food reactions was that they were all delayed, *i. e.*, did not appear until several hours after the tests were made (food reactions almost always appear within five to thirty minutes). Her reaction to streptococcus hemolyticus did not appear until the next day and was of the inflammatory type with no wheal formation, but I have found this to be the rule with bacterial reactions. She was advised to completely eliminate from her diet all foods to which she had reacted. Examination of two separate specimens of her sputum showed it to contain a weakly hemolytic streptococcus in practically pure culture, from which a vaccine was prepared, and she was treated with the same. Under this treatment her asthma cleared up very promptly and she remained entirely free for a period of four months. The edematous swellings disappeared following the second or third treatment. Her skin resumed its normal texture, with a disappearance of the splits and cracks about the fingers and toes. Then she went in swimming one day, got her hair soaking wet, and rode around in an open machine. As a result she had an acute attack of pleurisy and congestion of the lungs, followed by a return of her asthma, though in a much milder form. I retested her with bacterial proteins and she gave only a doubtful reaction to streptococcus hemolyticus, but quite a marked reaction to staphylococcus aureus.

Examination of her sputum at this time revealed staphylococcus aureus and streptococcus hemolyticus in the proportion of about 4 to 1, and a vaccine was prepared containing these organisms in the same proportion. Since the first treatment with this vaccine she has been free of asthma, with the exception of a few isolated attacks following the ingestion of some offending food, such as wheat flour or

tomatoes. Has gained about 23 pounds and other than being a little wheezy, at times, when she has a cold, looks and feels wonderfully well. On a very recent test she gave only a slight reaction to staphylococcus aureus, and streptococcus hemolyticus was absolutely negative.

#### POLLEN ASTHMA.

Seasonal pollen asthma, especially as an accompaniment of seasonal hay-fever, is so commonly met with that I will report instead under this head a case of non-seasonal pollen asthma.

*Case 4.* Mr. E. S. Age 30 years. Referred by Dr. Cissel of Highland, Md. Asthma. First attack started in fall about three years ago and lasted until the following March. Was living in White Plains, N. Y., at the time. Second severe attack started in March, 1922, left him some time in April, then returned the latter part of May or first of June and had been very bad ever since up to September 1922, when I started to treat him. Spent two weeks in hospital because of asthma. In between these very severe attacks he would be wheezy. Asthma worse at night. No difference between warm and cold, or dry and damp weather. During severe attacks took from 10 to 15 minims of adrenalin chloride hypodermically every three hours. This nearly always relieved him, but only for about three hours. No relief from inhalation of fumes from asthma powders. No symptoms of hay-fever, *i. e.*, no itching of eyes and only an occasional sneeze. Very susceptible to colds, which aggravated asthma, in fact seemed to have a cold nearly all the time. Wheezed a good deal and was scarcely able to move during bad attacks. Weight 117 pounds. On testing, found him sensitive to sweet vernal grass, red top, orchard grass, chicken feathers, cat and dog hair. Had cats and dogs about the house at this time, but was not exposed to cats or dogs when he had his first severe attack in White Plains, N. Y. Floss pillows were substituted for feather ones, and we felt that some improvement followed this change. Treatment was started September 28, 1922, with the three grass pollens to which he had reacted and his asthma cleared up almost immediately, and he has remained free ever since, with the exception of being a little wheezy when he has a cold. Is now doing the hardest kind of work with no shortness of breath on exertion, and

states that he feels better than he has for over 3 years. Present weight 142 pounds, a gain of 25 pounds.

*Comment:* I know there are a number who will deny that grasses, ragweed, etc., can cause asthma at other times than during their period of pollination, but the fact remains that I have seen a number of these non-seasonal cases who give definite reactions to pollens, and treatment with the pollen or pollens involved relieves them of asthma; again, too large a treatment aggravates the asthma. A possible explanation of this would be that there is sufficient pollen lying around in dust to cause symptoms on inhalation at any time of year. However, it would seem that if this were so, the seasonal hay-fever sufferer, who is often exquisitely sensitive to pollen, should also have symptoms at other times of the year. What seems to me to be a more probable explanation for these non-seasonal pollen asthma cases is that they are so poisoned during pollen season that their resistance is lowered for the remainder of the year; possibly during pollen season a disturbance of the colloidal balance of the blood occurs, which persists more or less throughout the year, unless corrected by specific pollen therapy.

#### ASTHMA DUE TO MISCELLANEOUS INHALANTS.

Under the head of miscellaneous inhalants, orris root easily stands first, because of its extensive use in face powders, sachets, tooth powders and hair shampoos.

*Case 5.* Miss E. H. Age 35 years. Perennial hay-fever and asthma of eight years' duration. Itching and redness of eyes, for which she used boric acid and argyrol. I might state that itching of the eyes is very significant of sensitization. Had never had a very severe attack without what appeared to be a cold, but was wheezy practically all of the time. Had noticed that face powder caused sneezing. Skin tests were made, and she gave a larger reaction to orris root than I have ever seen to any test. The flexor surface of her forearm was red, hot and swollen, extending nearly from the wrist to the elbow. She also gave a positive reaction to her own face powder. On substituting a powder which did not contain orris root all of her symptoms cleared up almost immediately. Had some slight trouble later, which she found to be due to a powder used by her room-mate. This was ten months ago, and she has had no recurrence.

## NON-SENSITIVE ASTHMA.

Under non-sensitive asthma, are grouped all those patients who fail to react to any form of protein. It is my opinion that a considerable proportion of these so-called non-sensitive cases are also due to sensitization, and that we have merely failed to detect the offending substance. In justification, however, of the assumption that we have made a diagnosis by elimination, in these patients, of bacteria as the cause of their trouble, I might say that the majority of them can be relieved of asthma by proper autogenous vaccine therapy.

*Case 6.* Mrs. M. O. H. Age 43 years. First seen August 1, 1922. Severe asthma and bronchitis. Bronchial trouble started September, 1921, followed in February, 1922, by violent asthma. Believes she had several mild attacks of asthma preceding this date, unrecognized by her physician. Had never been susceptible to colds, and never troubled with a cough previous to September, 1921. Worse in cold weather, and on damp days. Sudden changes in temperature aggravated her trouble. Worse at night. During bad attacks could hear her wheeze all over house. Coughing preceded asthmatic attacks. Cough was very productive and sputum blood streaked at times. No itching of eyes. Her history, therefore, pointed very strongly towards germs as the cause of her asthma. On testing, found her negative to all proteins. An autogenous vaccine was prepared from her sputum containing streptococcus hemolyticus and viridans in the proportion of about 4 to 1, and she was given 100 million organisms as the first dose. Prostration set in shortly after this treatment, followed by a marked improvement in the asthma and bronchitis. I repeated the same dose, following which she was free of all symptoms of asthma and bronchitis. I then gave her 200 million, which dose was followed by petechiae on limbs, but no asthma or cough. This dose was repeated, with no reaction other than temporary prostration. Then 300 million was tried, and resulted in an extreme aggravation of her asthma and bronchitis. I saw her three times in one day and was forced to resort to hypodermics of adrenalin, morphine and atropine, and heroin for relief. Her family became alarmed at her condition and Dr. Sterling Ruffin was called in consultation. Because of her unpleasant reactions to vaccine treatment, a von Pirquet test was performed,

which gave a positive twenty-four hour reaction. She told me at this time that quinine had always disagreed with her. A skin test with quinine sulphate gave a positive reaction, demonstrating the fact that sensitization may exist to non-protein substances. It was discovered that she had been taking a tonic containing quinine, which was of course discontinued. A couple of very small tuberculin treatments were then tried but with absolutely no effect on the asthma. In this connection, I might state that I have been unable to get the favorable results reported by Van Leeuwen and Varekamp in the tuberculin treatment of asthmatics giving a positive von Pirquet. Then treatment with the autogenous vaccine was tried again, starting with a smaller dose, *i. e.*, 50 million, and increasing it more cautiously than before. Ten treatments were given, the maximum being 300 million. Following the first of these treatments her cough and asthma disappeared and she has had no further trouble.

Have reported this case in considerable detail to meet the objection so frequently raised, that results in the vaccine treatment of asthma are always due to non-specific protein therapy. If this were true, it would seem that large doses would be more effective than small ones, but I have repeatedly found the reverse to be the case.

## HAY-FEVER.

Hay-fever may be perennial or seasonal in type. Perennial hay-fever has already been mentioned (cases 2 and 5). Seasonal hay-fever may be classified into early spring, late spring or summer, and fall types.

## EARLY SPRING HAY-FEVER.

Early spring hay-fever is not very commonly met with, and is usually due to sensitization to tree pollens.

*Case 7.* Mrs. J. M. B. Age 48 years. Referred by Dr. Louis Greene. Early and late spring or summer hay-fever for past three years. Has been susceptible to roses all her life. Attacks started the last of April or first of May, reached their height about the middle of May, became milder in June and were usually over by July 4th. Attacks began with sneezing, which lasted one-half to three-quarters of an hour, then eyes would itch and water. Nose would stop up at night and she would wake in morning with headache and

sense of fullness in head. Eyes bothered her more than anything else, for which she had been taking local treatment. I first saw her May 18, 1922, at the height of her attack. On testing her I obtained a very marked reaction to hickory tree pollen and also quite a large reaction to rose pollen. Tests with grass pollens were all negative. She stated that she had a number of hickory trees on the place, one of which was right outside her bedroom window; and also that she spent considerable time in her rose garden. She was advised to sleep on the opposite side of the house away from the hickory tree and to stay out of the rose garden. I had a report a week later that she had no further trouble.

Roses are insect pollinated and do not cause symptoms except on intimate exposure even in sensitive patients.

#### LATE SPRING OR SUMMER HAY-FEVER.

Late spring or summer hay-fever is commonly spoken of as "rose cold," which is a misnomer, as most of these cases are due to sensitization to one or more of the grass pollens.

*Case 8.* Mrs. D. B. H. Age 29 years. Referred by Dr. Arthur Zinkhan. Had hay-fever almost as long as she could remember. Affected in April, May, June and first part of July. She reacted to all the grass pollens, her dominant reaction being to timothy. Believing that sufficient treatment with timothy alone would desensitize her against the entire grass group, she was given pre-seasonal treatment with timothy pollen extract. As a result, she went through the entire season without the slightest symptom of hay-fever.

Pre-seasonal treatment, started far enough in advance of season to get the patient as completely desensitized as possible just before pollination of the particular offending plant or plants, is undoubtedly the ideal method of treating seasonal hay-fever. In those cases in which pre-seasonal treatment is incomplete, or in which there has been no pre-seasonal treatment, co-seasonal treatment is well worthy of trial, as illustrated by the following case.

*Case 9.* Mr. M. L. Age 34 years. Late spring or summer hay-fever for past six years. Attacks started about May 10th, and lasted until middle of July. Perfectly well all the remainder of year. First seen May 12, 1922. His hay-fever had started the day before, and

appeared to be a very severe attack. He reacted to all the grass pollens, his dominant reaction being to timothy. Rose was absolutely negative. Co-seasonal treatment with timothy pollen extract was started May 13th. After one week, during which three treatments were given, there was a marked improvement, and after three weeks' treatment his hay-fever disappeared and he remained entirely free for the remainder of the season.

Pre-seasonal treatment is given at weekly intervals unless the time is limited, in which case the interval between treatments may be lessened, especially on the smaller doses. Co-seasonal treatment, on the other hand, is preferably given at irregular intervals, depending upon the duration of relief following the individual treatment.

#### FALL HAY-FEVER.

The typical fall hay-fever season is from about the middle of August until the first frost, which coincides with the period of pollination of ragweed, to which pollen practically all of these cases are dominantly sensitive.

*Case 10.* Mrs. J. V. Age 32 years. Fall hay-fever and asthma since 4 months of age. Attacks started between 15th and 20th of August and lasted until first frost. Free remainder of year. Asthma, which fortunately only occurred during hay-fever season, was so severe that she was unable to move, and was kept under morphine with a trained nurse in attendance. Had spent previous five seasons in Michigan and was practically, though not entirely, free there. Tonsillectomy, removal of nasal polypi, and cauterization of nasal mucous membrane had been tried, but with no relief. Had sinus trouble for past two winters. Patient stated that contact with daisies would cause hay-fever and peaches on the table made her feel uncomfortable. Cantaloupe or watermelon caused itching of throat. Unable to eat grapefruit as it caused severe urticaria. She reacted to short ragweed, giant ragweed, daisy and a few other members of the compositae; also to grapefruit, cantaloupe, watermelon and peaches. Her dominant reaction being to short ragweed, this was selected for pre-seasonal treatment. As a result of this treatment, which she put to a very severe test by driving around the country in an automobile, she went through the entire season, for the first time in her life, without a sneeze or a wheeze. She had one

day of slight prostration during season following the eating of peaches. This illustrates the advisability of making tests in these seasonal hay-fever patients with other than pollens, which are of course necessary, in order to detect any possible contributing factors.

What has been said under late spring or summer hay-fever in regard to pre-seasonal and co-seasonal treatment applies also to fall hay-fever.

*Case 11.* Mr. E. G. M. Age 39 years. Referred by Dr. Horrigan. Fall hay-fever of about five years' duration. Attacks started about August 20th, and lasted until frost. Well all the rest of year. I first saw him September 7, 1922, in the midst of his hay-fever, and a pitiful sight he was. His eyes were very much inflamed and itched intensely. There was profuse lachrimation; also sneezing and rhinorrhea. Some nights unable to sleep at all. Worse on dry days.

This attack had started August 17th, a little earlier than usual. He reacted to a number of fall pollens. His dominant reaction being to short ragweed, this was selected for co-seasonal treatment. The first treatment was given September 8th, and as a result he reported five days later that he was 90 per cent relieved. Two more treatments were given with equally gratifying results.

#### ECZEMA.

Eczema due to sensitization to one or more food proteins is very commonly met with, especially in infants and young children. Eczema or dermatitis, however, may also be due to contact of a sensitized skin with most any type of substance.

*Case 12.* J. J. R. Male. Age 47 years. Referred by Dr. H. H. Hazen. Eczema of thirteen weeks' duration. Started on front of neck. Patient thought it was due to shaving too close. Then spread to forehead and around mouth. Next it spread to arms, then legs, and finally body affected, especially around waist and back of shoulders. Had grown progressively worse in spite of various local applications, and X-ray treatments. Itching severe at times. Neck raw and bleeding. Legs swollen. Considerable pus formation. Food tests all negative. Tests were performed with great difficulty because of the condition of his skin. He had been wearing a long fur coat ever since the beginning of the skin trouble,

so crude alcoholic extracts were prepared from fur clipped from the collar and lining of this coat, to which he reacted. On discarding the fur coat his skin cleared up.

Unfortunately he has since developed an erythema, which we feel is quite different from his former trouble. I might say that this erythema is clearing up very nicely following one X-ray treatment.

In closing, I would state that in reporting these cases selected from many other similar ones to illustrate some of the important phases of protein sensitization work, it is not meant to infer that all of the results are as satisfactory as these.

1726 M Street, Northwest.

#### FEVER.\*

By WYNDHAM B. BLANTON, M. D., Richmond, Virginia.

There remain enough puzzling questions concerning temperature in health and disease, I believe, to make it still a subject of interest to us all. For instance, there is a well recognized diurnal fluctuation of temperature in man, which averages about one degree and is maximum in the afternoon. Nocturnal birds exhibit a similar fluctuation, but on the contrary their maximum rise is in the early morning. Why is it then that if man reverses his habits and works at night, he continues to have his maximum rise in the afternoon even though he be asleep? And what after all is the cause of the afternoon rise of temperature?

*Heat Production and Heat Loss:* The satisfactory understanding of fever or pyrexia implies the proper evaluation of the balance between these two factors. The creation of heat in the body arises chiefly from oxidation processes going on in the muscles, though other subsidiary oxidations add slightly to the heat produced. These oxidations include chemical changes in the glands during function, and the specific dynamic action of protein and carbohydrate digestion. In health, need for increased heat production is responded to by additional muscle work, such as shivering, increased muscle tone, or voluntary exercise.

In, disease, increased heat production or fever is explained by Macleod<sup>1</sup> as the resultant of the effect of toxins on tissue increasing the osmotic pressure of their protoplasm. In consequence there is a flow of fluid from blood vessels to tissue followed by concentration of

\*Read before Richmond Academy of Medicine and Surgery, April 24th, 1923.

the blood. (Such concentration can easily be demonstrated in fevers). Now with concentration of the blood there naturally follows a reduction of the blood upon the surface of the body. Contraction of surface vessels is the expected reaction to diminished blood flow or concentration. The conditions of a cold skin therefore obtain. The normal afferent impulses from an area of contracted vessels, or a cold skin, stimulate the heat center, which may in turn respond in one of two ways, either by increasing heat production or by diminishing heat loss. In either event a rise of the average body temperature is the result. Two other less inviting theories of heat production in fever find their adherents. One is the so-called neurogenic theory, which implies the integrity of nervous connections to and from the essential heat center; the other places the responsibility of febrile acceleration entirely on the liver and is based on comparative measurements of heat in the liver and muscles during pyrexia. In any explanation of heat production in the body, it seems to me highly improbable that there should be a different mechanism in health and disease. The heat of pyrexia must be produced in general as the normal body heat is, that is, in muscle oxidation. The stimulus may arise centrally, as in heat center punctures, or locally, as when increased heat production follows infections in cold blooded animals, or in warm blooded animals with high severed cords.

On the whole, heat loss is better understood than heat production. The elimination of heat in the body follows the well known laws of conduction, radiation and evaporation. The first two factors account for three times the loss due to evaporation. On the surface of the body almost the entire elimination of heat occurs. The cutaneous circulation under vasomotor control is a most important link in the mechanism for heat loss, as in this way the surface mobilization of heat bearing blood is effected, and it is at the surface of course that cooling occurs. The mechanism which controls this loss of heat is probably dependent upon the so-called heat center of the corpus striatum, which, in response to various afferent stimuli, increases heat elimination by the stimulation of sweat glands and vasodilators, and decreases heat elimination by the stimulation of vasoconstrictors. Thus the cutaneous circulation of an extremity may be doubled by

applying heat. The normal and natural stimulant, aside from afferent cutaneous impulses registering surface temperature is increased body temperature, as for example during exercise or in the pyrexia of disease. It has been shown that the simple flowing of the pyrexial blood through the cerebral circulation is sufficient to stimulate the heat center.

When all the factors are considered, heat storage seems to be the essential element of pyrexia. In other words the thermo-regulator has been turned up a notch or two. This is effected chiefly through conservation of heat. It is remarkable how little additional heat is produced in pyrexia, (20%), as compared to that formed during eating or exercise, (300%).

*The Calorimeter* has played an important role in the elucidation of the factors entering into the mechanism of heat production and heat elimination in the rise and fall of temperature. The most elaborate studies concerning this phase of fever have been carried on under the direction of Dr. DuBois, using the Russell Sage respiratory calorimeter. Typhoid fever, malaria, and tuberculosis have been the febrile diseases chiefly investigated. In all of them it has been shown that normal respiratory quotients obtain. It has likewise been shown that heat production during the febrile period is relatively small, being increased but forty per cent in typhoid and thirty per cent in tuberculosis. In the malarial chill the increase is from one hundred to two hundred per cent, due probably to shivering, with the accompanying muscular contractions. The exact mechanism has been most elaborately worked out during the several phases of this chill<sup>2</sup>. Here it has been shown that the skin temperature lags strikingly behind the rectal temperature until a considerable while after the chill. It has also been shown that heat production is but slightly increased prior to the chill. During the chill there is a marked increase. Subsequent to the chill, for a few minutes the increase continues to range between twenty and thirty-eight per cent. It then slowly decreases to normal. Heat loss remains normal throughout the period of the chill, is slightly increased immediately afterwards, but rises sharply during the period of the continuous high temperature and increases still further during the falling temperature. In typhoid fever, "a rising temperature was accompanied by an increasing heat production

which outweighed the increasing heat elimination. . . . . With a falling temperature the heat production remained fairly level while the elimination was increased."<sup>3</sup> In tuberculosis a rising temperature was characterized by increased heat production, a falling temperature by increased heat loss. The toxic destruction of protein with a negative nitrogen balance in typhoid fever may be counteracted by feeding fifty to one hundred per cent more than the normal protein requirement. In the case of tuberculosis this toxic destruction of protein has been shown to be smaller than in typhoid and the habit of overfeeding, especially of protein, has been remarked upon as possibly dangerous in that the accompanying elevation of metabolism throws more work upon pulmonary function.

*Clinical Thermometry:* Astonishing is the regularity with which physicians employ thermometers and the ubiquitousness of the hospital temperature chart argues for widespread faith in such data. The use of any exact instrument, such as the mercury thermometer, often leads us astray into believing that we thereby gain exact information. And so we lay great stress upon temperature variations, reading and charting tenths of degrees. As a matter of fact clinical thermometry as ordinarily practiced, be the thermometer ever so exact, is often very misleading. This is simply because we assume that the thermometer reading represents the body temperature when as a matter of fact it registers only local temperature. The temperature of the mouth is different from the temperature of the axilla and the temperature of the rectum, and no one of these represents the temperature of the body. In estimating the heating efficiency of a house furnace, to test only the temperature of one room affords no information at all concerning the other rooms. Now not only does the temperature of the mouth, axilla and rectum vary under normal conditions, but the temperature of the mouth itself varies in health in response to a number of factors. The circulation and vasomotor control are extremely important in determining these local variations, which as we have said, in no way affect the temperature elsewhere in the body. Cold hands and cold feet may accompany a rising temperature. Heat elimination may be the same over a warm skin as over a cold skin, depending entirely upon the level of blood

cooling. If there is vasomotor dilatation and surface cooling there is warmth of the skin. If the blood is cooled in the deeper layers of the skin, the skin is cool.

Strictly speaking we are seeking for the average body temperature in practicing clinical thermometry. As a matter of fact what we obtain is only local body temperature. The average body temperature represents a calculation based upon the height and weight of the individual and the difference between heat production and heat loss over a definite length of time. This is of course too difficult a procedure for routine use and is unnecessary except in careful investigations. As a usual thing the clinical thermometer affords useful and approximate information. It does not give us average body temperature, and if the factors of local variation are carefully considered and eliminated, mouth temperature, for example, should in general parallel, though not exactly equal, the average body temperature. I do not wish to disparage the use of the clinical thermometer, but to emphasize care and conservatism in the interpretation of slight temperature variations from the normal.

*Fever in Diagnosis:* Armed with all the available knowledge concerning the physiology and pathology of pyrexia, we are often at a loss in the interpretation of temperature elevations. We may actually fail to recognize the presence of pyrexia, as for example when a patient is repeatedly examined in the morning and shows a temperature rise only in the afternoon; or when a subject of intermittent temperature is seen on the afebrile days. Or on the other hand, we may be puzzled by elevated temperature in the apparently healthy, discovered in examinations for military service or insurance. This type of temperature rise is familiar to hospitals under the name of "Sunday temperature." It is probably purely a nervous phenomenon exhibited by patients entering a hospital, coming to a doctor's office, or seeing visitors. In the nervously unstable one occasionally encounters temperatures of 100° to 102° accompanied by corresponding accelerations of the pulse. That these rises are nervous in origin is evident from the fact that if such persons are made to recline from ten to fifteen minutes in a quiet room the temperature quickly returns to normal with the slowing of the pulse. So common in this elevation of temperature in nervous young women

observed to follow the excitement of physical examination that the practice should be followed of securing all constitutional signs before the history or examination is undertaken. The physiological explanation of these cases probably lies in the instability of a center which allows of vasomotor constriction with diminished heat loss. There must then arise afferent stimuli from a cold skin accelerating heat production. The effect of psychic influences in these persons is obvious also from their cold clammy skin.

Martinet,<sup>4</sup> for clinical consideration, divides pyrexias into those of short and long duration, and the intermittent fevers. The real cause of the majority of fevers of short duration is probably never discovered, even taking into consideration the exanthemata, respiratory and gastro-intestinal infections. In children, for example, the two or three day temperature flare-ups accompanied by no very definite concomitant findings, with all due respect to the pediatrician, make his diagnosis little better than guess work. Probably in the summer time he brands most of his cases gastro-intestinal and in the winter respiratory, but the febrile child in summer will often tax the imagination to find anything wrong with his stools, and the febrile child in winter may have neither red throat nor cough. Similarly with adults. An honest analysis of our short febrile cases will show us at best to be flounders in the dark, willing to catch at any straw. Thus every winter temperature of short duration practically becomes a case of that awful disease known to the public as "Flu." I do not think there is any doubt of the fact that we know little of the causation of many of the short lived pyrexias, by whatever name we choose to brand them, and fortunately, the storm has come and gone while we are still choosing among our brands.

When we approach the fevers of long duration there should be and probably is more accuracy in diagnosis, because we have more time to make observations, and the chances of more striking physical findings are greater. Cabot<sup>5</sup> from hospital statistics states that typhoid fever, sepsis and tuberculosis embrace 90 per cent of long continued fevers. Martinet<sup>4</sup> puts tuberculosis at the head of the list, emphasizing the importance of latent tubercle infection of the lungs and kidneys, and maintaining that ninety-eight per cent of long continued

fevers fall into a category headed by tuberculosis and including sepsis, (that is, endocarditis and pus anywhere, obvious or occult, such as the appendix, gall bladder, genito-urinary, gastro-intestinal tracts, pleura, lungs or lymph glands,) influenza, rheumatism, typhoid and paratyphoid infections. The remaining two per cent include occasional causes such as meningitis, malaria, leukemia, neoplasms, Hodgkin's disease, atropine poisoning, and thyrotoxicosis.

I believe that the average case of obscure pyrexia of long standing will be elucidated by following the usual leads of a careful history and the physical findings, but this is not always the case, and the advantage of having in mind such a classification as that of Martinet<sup>4</sup> is frequently illustrated, as for example in a case of carcinoma of the stomach. The patient, a middle aged man, presented himself with an afternoon temperature of 100 to 101 degrees, complaining of weakness, and with the associated findings of leucocytosis, and anemia, and the signs of myocardial disease. Attention was focused on his temperature, the cause of which baffled investigation for more than two months. Then the search was enlarged to include all possible causes of pyrexia. There were no leads pointing to the stomach until the sudden onset of vomiting. Gastric analysis, stool analysis, and X-ray of the stomach were now done, and immediately established the diagnosis of carcinoma of the stomach. On the other hand, a well nourished woman of thirty-three complained of headache and fleeting pains throughout the body. She had a moderate leucocytosis. Her temperature ranged however from 103 to 100 degrees for more than two months without revealing a satisfactory cause. The history, physical and laboratory findings, including urine, blood, Widal, stool and X-ray of head and chest, were disappointingly negative. The usual string of specialists explored their respective fields. An exploratory laparotomy was likewise barren of results, and the elevated temperature continued. She returned home, dismissed her doctors and in a few weeks was temperature free. Nor did she nor anyone else know how it happened.

*The Purposefulness of Pyrexia:* Both experimental and clinical experience point I believe to the usefulness of pyrexia especially in infections. Pyrexia itself, except in heat stroke, where there is probably some other ad-

ditional factor operative, is rarely injurious to the individual. Nannyn, as pointed out by Ringer<sup>6</sup>, demonstrated that animals could be maintained for long periods of time at febrile temperatures without showing any injurious effects. Rolly and Meltzer<sup>7</sup> years ago showed the actual beneficial effect of hyperthermia upon animals in resisting infections. Animals which were kept at a temperature of about 40 degrees Centigrade, when injected with cultures of pyogenic organisms, showed a fifty per cent mortality, whereas all control animals, whose temperature was not raised, uniformly died after similar injections. It seems fairly certain that fever serves the useful function of assisting in the body's reaction to infection. In spite of the fact that bacteria in the test tube show fairly definite optimum temperatures for growth, in the body the temperature never rises sufficiently to inhibit seriously their growth *per se*. The effect of pyrexia seems to be entirely in favor of raising immunity. Ringer cites a table showing the very definite effect of elevations of temperature upon the phagocytic function of the leucocytes. Rolly and Meltzer also showed that bacteriolytic substances as well as agglutinins were elaborated in far greater quantities and much more rapidly in pyrexial animals than in controls. In this connection MacCallum<sup>8</sup> says that fever is in a way analogous to the vascular reaction in inflammation in that it is the process which facilitates the more essential activities of the phagocytes and the production of defensive chemical substances in the body.

*The Treatment of Pyrexia:* The proof seems fairly certain that pyrexia is purposeful, that the processes of resistance to infection go on more vigorously and effectively in the human body in the presence of an elevation of its temperature. In view of the fact that during exercise heat production may exceed by ten times the heat production of fever, which probably averages about twenty-five per cent plus, there is little harm to be expected from the actual excessive heat production. Heat storage, however, due to failure in heat elimination, may or may not be injurious. Meara<sup>9</sup> believes that temperatures that do not exceed 104 degrees do not need treatment *per se*. Hyperpyrexia which may be taken to represent temperatures above this figure demand the usual treatment exemplified in the cold bath for sunstroke. Meara<sup>9</sup> goes on to point

out that hydrotherapy in febrile conditions, such as typhoid fever, is not directed primarily at hyperthermia, but is useful for its influence in increasing elimination through the skin and for its reflex influence upon blood pressure and its steadying effect upon the heart and respiratory centers. On the same score the use of drugs, particularly the coal tar products, should be condemned. Whether they reduce temperature by increasing heat loss (as the coal tars), or by sweating (as aconite), or by vasodilation (as whiskey), or by lessening heat production (as quinine), we are in the end interfering with a purposeful reaction and our therapy is meddling.

The protein shock gotten by intravenous injection of dead bacteria, advocated by Snyder<sup>10</sup> and others in the treatment of chronic arthritis, is thought to depend for its effect upon the chill and accompanying high fever.

The hyperpyrexia of thermic fever or heat stroke is no doubt injurious. Temperatures of 104° to 114° accompanied by coma and convulsions are certainly associated with cerebral and visceral injury.<sup>11</sup> This is borne out at autopsy in such findings as cerebral edema and hemorrhage with cloudy swelling of the liver, heart and kidneys. The fact that it appears that the fatal cases show high urea and creatinin retention in the blood bespeaks some other antecedent factor in those who die, especially when the age incidence and alcoholic history are taken into consideration.<sup>12</sup>

Aside from hyperpyrexia there appear to be two possible sources of harm from elevations of body temperature. The negative nitrogen balance which often accompanies pyrexia is taken to indicate a specific destruction of protein. Sufficient feeding, especially of carbohydrates, as has been shown, will spare the body protein. Acidosis may also follow fever, due likewise to deficient carbohydrate intake and the consequent hurried and incomplete combustion of fat. Sufficient allowance of starches and sugars in the diet will ward off this complication. That leaders in the profession have appreciated the dietetic demands of pyrexia is shown in the request of Robert Graves nearly a century ago that his tombstone bear only the inscription, "He Fed Fevers."

## A DISCUSSION OF SOME PHASES OF MENTAL DISEASES.\*

By JESSE A. STRICKLAND, M. D., Norfolk, Va.

In discussing the subject of mental disturbances, I realize that I have nothing new to bring forth. My object is simply to freshen your memory with some phases of the general subject, and try to show that because an individual is insane, it does not necessarily follow that he should be given over to the care of an attendant, and lost sight of by the medical man. The insane are no longer looked upon as the inspired instruments of the Deity. Insanity implies disease, either of the whole organism or of some special part. There are usually no demonstrable changes in the brain or its appendages and the mental symptoms may be due to exhaustion from some visceral disease, or from poisons circulating in the blood stream. That the brain can be influenced by poisons without any microscopic changes is definitely proven by the action of certain drugs, such as alcohol, hyoscine preparations, patent medicines, paraldehyde, and so on.

In this connection it is well to recall that alcohol depresses the motor activity of the brain and, in the acute stages of alcoholism, sets up an ataxia, or may produce a complete toxemia, which manifests itself in delirium, tremors, hallucinations and delusions, both auditory and visual. Pathological studies have shown that prolonged use of alcohol may

result in degenerative changes in the cortical cells, bringing about a mental state known as alcoholic dementia. Of the other drugs that play a part in mental upsets, hyoscine is depressive, causing delirium and disturbance of all the coordinated movements, delusions and hallucinatory experiences; patent medicines act usually by absorption of poison; while paraldehyde results in a temporary upset.

From the mental disturbances which can be traced from such obvious causes, we come to the limitless line of investigation that bears in its train the manifold phenomena that produce the psychoneuroses. In following it, we often touch upon the field of the unknown.

Just how far actual foci of infection enter into the etiology of the psychoneuroses, we are not able to say, but I am of the opinion that a focus of infection in one whose nervous system is already unstable may play a major part in their development. While searching for such a cause, we should not omit a careful examination of the prostate, as this organ may frequently be the seat of a specific or non-specific infection. I recently saw a case of psychoneurosis in a man with infected tonsils, who showed some improvement following tonsillectomy, but whose condition did not finally clear up until a urologist discovered and treated a chronically infected prostate. I might say here that proctitis, or an ulcerated rectum, although rare, may be a source of infection, causing rheumatism and also a mental or nervous state as mentioned above.

Of the infectious diseases, epidemic influenza is probably most prone to be complicated by psychic disturbances. The mental upsets are more frequently seen in persons over twenty years of age, affecting women more often than men. There seems to be a neuropathic or psychopathic predisposition in all forms of psychosis encountered here; most frequently noted in those cases where the psychosis did not become apparent until after the febrile stage of the disease. As a rule, the more serious the influenza, the more severe the psychosis. It is generally agreed that there is no specific influenza psychosis but an unstable mentality may be aggravated by the disease. Menninger<sup>1</sup> has said that the significance of the influenzal psychoses is in their relationship to dementia praecox. Post-febrile delirium and dementia praecox were by far the most numerous sequelae of influenza.

In like manner we find that we do not

\*Read before the Seaboard Medical Association, at Newbern, N. C., December 7, 1922.

definitely know just what the pathology of the brain in pellagra has to do with the mental state, which is evidenced by hallucinations and delusions. Here there is very probably permanent destruction of the brain cells. Many patients apparently recover from the initial attack, only to have a recurrence the following year, but some, after one attack, recover completely and never have another.

Advancing from the field of mental disturbances coincident with non-specific infection, we reach those conditions which may be termed functional diseases of the brain, such as epilepsy, dementia praecox and manic depressive psychosis.

The mental condition of an epileptic depends upon the type of continual attacks of the disease, whether petit mal, or grand mal. In many cases of attacks of petit mal occurring in children, the patients have been of low mentality previous to the attacks or even from birth. Just recently I saw a child nine years old, who demonstrated the disease by three or four sharp snaps or jerks of the head. This child did not progress in school, even in the simplest forms of kindergarten work. The Binet-Simon test showed her to be an imbecile. X-ray findings demonstrated a pathological sella turcica. Adults with epilepsy are suspicious, irritable and forgetful, repeating their acts without reason, and forgetting to perform the daily task set for them. Just how much degeneration we have of the cortical cells, or what brings it about, we cannot say. We do know that the attack causes a swelling of the brain tissue and an increase of fluid in the ventricles. I have a young woman under my care who was very bright as a girl, and whether a head injury following a fall from her horse was the cause of her initial convulsion, or whether she had a convulsion and fell from her horse in consequence, I cannot say. I do believe, however, that in many cases the attack is the cause of the accident, rather than the accident being the cause of the disease.

Manic depressive psychosis, as its name implies, consists of two separate conditions: an acute maniacal stage and a depressed phase. According to Kreplin's classification, manic depressive psychosis includes mania, melancholia, circular insanity, and recurrent insanity. There is another type which has been described, in which the patients are mildly depressed. I refer to cyclothymia. These are the cases that are first seen by the general

practitioner, and many are handled very successfully by him. I am convinced that in some way the glands of internal secretion are associated with many types of manic depressive psychosis. Tucker, several years ago, reported a number of cases of pituitary psychosis, which did not differ materially from the manic depressive form. A thyrotoxicosis, or hyperthyroidism, may in like manner be the cause of definite maniacal or depressive attacks. A manic depressive tendency can often be traced from youth in members of psychopathic families. The young man or woman who frequently has the blues over trivial situations, and who is just as easily elevated, is a potential case of manic depressive psychosis.

I have a case of a young woman, twenty-six years of age, a tailoress by trade, who in 1918, after periods of severe headache, for which she sometimes took as many as 20-30 grains of aspirin a day, became very much concerned about a friend who was on the Cyclops, the collier that was lost at sea. His fate preyed on her mind to such an extent that she resorted to the Ouija board for help. Her translations from the board proving unsatisfactory, she passed from this state into that of a raving maniac, talking to the Kaiser, blaming him for the destruction of the ship and the loss of her friend, and claiming that the Kaiser held him in captivity in Germany. Her emotions were demonstrated by violent temper, cursing, and various forms of auditory hallucinations, such as conversing with the Deity and He with her, in regard to the boy's release. This condition persisted for days, the girl being kept quiet only by sedatives, hot packs and the continuous bath. After a period of a few weeks she cleared up well enough to leave the institution, and has had no apparent trouble since; although in talking to her, one notices that she is somewhat elevated.

In contrast to this case, is the following: Mrs. B., age 42, supposedly at the climacteric period, the wife of a coast guard, saw a ship explode and burn near shore, and feared for the safety of her husband, who among others, went to the rescue of the crew. She became greatly depressed after this experience. The depression increased, she became suicidal, and finally refused to take food, which necessitated tube feeding. Her mental and physical inertia was so marked, and her resistance so lowered,

that she developed pneumonia and died within a few weeks after the time of her upset.

In speaking of mental diseases that may be traced from childhood, one naturally thinks first of dementia praecox, since, as its name implies, it is a dementia of the young, occurring about the adolescent period, relatively earlier in girls than in boys. I am not going into its various classifications, except to say that the catatonic type, in my experience, seems more apt to clear up. That is to say, it seems to pass from an acute to a chronic stage. There are cases, however, where a boy or girl has seemed to be bright or even precocious up to the age of puberty, and then, like lightning from a clear sky, develops a sudden upset which we diagnose as dementia praecox. What causes dementia praecox, we are unable to say. Mott,<sup>2</sup> in his investigations, claims that in a large proportion of dementia praecox, there is complete arrest of spermatogenesis and a more or less regressive atrophy is shown, the degree of changes depending upon the age at which the mental symptoms were first manifested, and the time elapsing between the onset and death. In some cases, spermatogenesis may never have occurred. Mott points out that "Active nuclear proliferation is going on, necessitating an abundant nucleic acid formation, which acid is the main constituent of the heads of the spermatozoa. The failure of nuclear activity in the testicle in dementia praecox is very important in view of Nissl's and Alzheimer's demonstration that the essential histologic change in the nerve cells in this disease is one of nuclear decay. "The critical dementia praecox period of life is adolescence, when the sexual function matures. This affords evidence of the important relation between the sexual function and disease of the mind." The question then arises, is a regressive atrophy of the reproductive organs the cause of mental changes, first by its disturbing influence on the whole endocrine system; second, by the suppression of normal sexual impulse; or third, is it evidence of an inherent lack of vital energy, germinal in origin? At what period this nuclear decay begins, it is difficult to say. It may start before puberty, or later in life. So long as the boy does the work of a boy, he is all right, but when confronted with life's more serious side, with its many ups and downs, he develops a complex and reacts by a mental upset.

People suffering from this type of mental disturbance constitute a large proportion of the patients in insane asylums today. Such individuals, as a rule, go from bad to worse. We may have a patient who gives the history as a school-boy of being "queer" and apathetic, and who may or may not do well in his studies, depending upon the amount of work he is asked to do. This boy suddenly decides that he wants to stop school and go into business for himself, but, in trying to concentrate on any one line, he finds it impossible to focus his attention, and vacillates back and forth through half a dozen forms of industry, usually complaining that his associates "have it in for him" and are not "giving him a square deal," either from a social or financial standpoint. I recently had a young man under my care who presented the above picture. He went into the brokerage business with his brother-in-law, suddenly made up his mind that his partner was cheating him, and proposed to sell out. The boy went to South Carolina, wishing to get away from destructive outside interest and strike out for himself. At this time his mental upset had developed to such an extent that he claimed people were following him, watching and criticizing his every movement. He said that the police of Charleston had been notified of his arrival and, although he did go into the cigar business, he lasted only a very few days, because "they watched him so closely they ruined his business." As a matter of fact he was in the throes of a complete upset, and fell into a state of amnesia of about two weeks' duration, during which time he was brought to Norfolk. After a few weeks of institutional treatment he cleared up sufficiently to go home under family care, where he spent his time trying to write poetry and songs. He has had remissions, one after another up to the present time. This boy had been in the Army and was sent overseas, but was never able to go to the front or take part in the war activities. Just how far the army life furthered his wretched condition, I am unable to say.

When we consider the types of disease that are conducive to mental unbalance, we first recognize the necessity of proving or disproving the presence of brain syphilis, especially paresis. There is a difference of opinion as to how soon after infection, mental disturbances arise from paresis. Some writers claim that

they may appear as early as the second or third month after the appearance of the initial lesion. Naunyn, in a study of 335 cases, reported forty-eight per cent. developed signs of cerebral syphilis within three years after infection. On the other hand, forty years have been known to elapse before cerebral symptoms manifest themselves. In the two cases I have to report, there were intervals of eleven and twenty years respectively between infection and manifestations of mental disturbance, but in this regard, it must be remembered that these statistics are not necessarily authentic, depending as they do on the word of a parietic after his condition began to improve.

The mental state of a parietic, while apt to be despondent, may, on the other hand, show marked excitement, as in the two cases I have to report. The first case was that of a white man of 46, a dairyman by trade, who came to me in January, 1921. He was a poorly nourished, greatly emaciated individual, weighing only 94 pounds. His family history gave no evidence of tuberculosis nor any serious mental disturbance. There had been one child who was a moron. Neurological examination of this man disclosed the following symptoms. All deep reflexes exaggerated, pupils fixed; no Babinski; no clonus; slight Romberg. Mentally, he was confused, talking constantly but disoriented as to time, place and persons, had delusions of grandeur and was under the impression that he was actively engaged in trading horses and cattle. His mental trouble was said to have started three weeks before I saw him. He later admitted an initial lesion 20 years earlier. Laboratory findings showed a four plus Wassermann of both blood and spinal fluid, and 20 cells in the fluid. Treatment, which was instituted at once, consisted of six intravenous injections of neo-salvarsan with complete drainage of the canal, coupled with mercury inunctions, and mixed treatment by mouth. His mental state became clearer and his physical condition improved so much that in March he weighed 115 lbs. I did not see him again until July, when he returned for another series of neo-salvarsan injections, with drainage, and two Swift-Ellis treatments with mercury and iodide as above. At this time his spinal fluid Wassermann was four plus and that of his blood two plus. He then weighed 139 pounds, and his whole condition showed marked improvement. The

point in this case, however, which I wish to emphasize, is this: Although the man received repeated intensive treatments, and noted marked improvement, physically and mentally, his Wassermann reaction never fell below four plus in the fluid and two plus in the blood, as long as I had him under observation.

The second case was a white man, formerly night clerk and cashier of a hotel, who came to me in November, 1921, complaining of headache, forgetfulness and cough. He had formerly consulted an internist on the suspicion that he had tuberculosis. This man admitted having had a sore mouth sometime between 1908 and 1910, and one dose of 606 at that time. Examination showed fixed pupils, absent deep reflexes, positive Romberg, 40 cells in his spinal fluid, and four plus Wassermann of both blood and fluid. Mentally he was disoriented, had delusions of grandeur, thought the house was burning up, and was generally excited. A diagnosis of tabo-paresis was made.

This man received six intravenous injections of neo-salvarsan with drainage, mercury inunctions and mixed treatment by mouth. Two months later he was greatly improved, even to his reflexes. He refused to submit to further Wassermann tests but, after three more months, with no other treatment, he returned to his work at the hotel.

There is a difference of opinion as to the efficacy of anti-syphilitic treatment in paresis. One view holds that a meningitic or perivascular infiltration can be reduced, and the spirochete killed, with cessation of toxin formation and inhibition of degenerative changes. (Solomon,<sup>3</sup> etc.) Noguchi and Moore,<sup>4</sup> on the other hand, claim that the spirochetes probably linger in the deep tissue of the cortex, and that anti-syphilitic drugs are prevented by a filtering process from reaching the central nervous system, thus failing to accomplish any therapeutic effect.

On such evidence as we have, some men refuse to treat general paralysis of the insane. But in this, as in any case of human disability, I take the stand that we have nothing to lose and all to gain, as in the cases just discussed, in which I feel that while they may and doubtless will have remissions, I have

been, from a humanitarian standpoint, amply repaid.

### PHYSICAL EXAMINATION OF THE LUNGS IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.\*

By DEAN B. COLE, M. D., Richmond, Virginia.

The patient should be made to feel at ease as far as possible, stripped to the waist and allowed to sit on stool (or straight chair if stool is not available), facing window so light will fall over examiner's shoulders. The physician should also be seated on a stool (if another is available), otherwise on straight chair and should make himself as comfortable as possible. Comfort for both patient and physician is essential. For this reason the examining room should be comfortably warm or cool as the case may be, and as free from noise as possible. Now have patient drop shoulders slightly forward with good muscular relaxation and you are ready to proceed with the examination.

The four means of physical examination of the lungs are inspection; palpation; percussion; and auscultation. These will be considered in the order named.

INSPECTION comes next to auscultation in importance and not infrequently is inspection the most important factor in making a correct diagnosis. Almost at a glance the following facts may be noted: whether patient looks well or ill; is he nervous and excited; is face flushed or does he look pale and anemic; is he well nourished or is he emaciated; is muscular development good or poor—do not confuse muscular development with whether or not a patient is well or poorly nourished for he may have both good muscular development and good nutrition, or either or neither.

\*One of a series of lectures and demonstrations to a class of physicians in the diagnosis of tuberculosis, held under auspices of the Health Bureau, Department of Public Welfare, Richmond, Va., February 15 to April 15, 1923.

Notice patient's build, whether robust or not; type of chest, whether broad, flat, funnel, chicken, long and narrow, barrel, or any combination of these; also type of breathing, whether thoracic, abdominal, or mixed.

After having made a mental or physical note of the above, note patient's chest expansion, whether or not expansion is diminished; if so this would suggest an old tuberculous lesion, or pleural adhesion, or some other mechanical restriction. It may be a relative thing, as in an acute pleurisy or pleurisy with effusion, where the opposite lung is compensating.

Note any lagging, always remembering that this is suggestive of a more acute condition than fibrosis or pleural adhesions. It is frequently advisable to stand up and look down on the patient, using a blue pencil for marking symmetrical points for comparison. At any rate never forget that patient has both a front and back. The scapulae are excellent landmarks for comparison. Make note of any prominences, depressions, retractions, or scoliosis. Also any pulsations, whether normal or abnormal. It is well to always look for apex beat of the heart, for I have known more than one physician to treat a patient for months without discovering that the heart was to the right of the sternum. Observe the condition of the skin, whether moist or dry, profuse sweating, etc. Examine fingers for clubbing, remembering clubbed fingers are suggestive of some chest condition but not necessarily tuberculosis.

PALPATION is used primarily to confirm inspection as to lagging and diminished expansion. This is best done by placing patient against wall, using rather firm pressure with both hands palpating homologous areas. Palpation is also of use in differential diagnosis. In the presence of consolidation, fibrosis, or cavity, one would expect to find vocal fremitus increased. Pleural effusion, thickened pleura, or pneumothorax usually cause a diminution of vocal fremitus. Remember to palpate homologous areas, using light touch, and have patient to say "nine, nine" aloud. Pottenger lays especial emphasis on palpation in determining muscular rigidity or spasm, muscular atrophy, skin tension, and presence or absence of subcutaneous fat. This is of unquestionable value.

PERCUSSION. I will not go into the physics of percussion more than to say its value is

based on the fact that sound is produced when an elastic body is made to vibrate by striking. This sound varies from tympany (best gotten over stomach or intestines partially filled with gas) to flatness which is heard when arm or leg is percussed. Between the two extremes of tympany and flatness we have hyper-resonance, resonance, and dulness. Tympany may be gotten over a pneumothorax, a large cavity, or even over deep consolidation, if sufficient normal or partially collapsed lung overlies it.

*Hyper-resonance.* Compensating lungs and emphysematous lungs frequently give a hyper-resonant note.

*Resonance* is best elicited high in axillary spaces.

*Dulness, decreased resonance, etc.,* may be produced by anything impairing the lung elasticity, from pneumonic consolidation to slight tuberculous infiltration.

*Flatness* is most often encountered in pleural effusions.

Remember in percussing chest to have only one finger in apposition to chest wall, use fairly firm pressure, a light stroke delivered from wrist, and compare homologous areas. I prefer to percuss from base upward, but that is a matter largely of preference.

AUSCULTATION is the most important method we have at our disposal for physical diagnosis of lung disease. Not infrequently does our stethoscope show us how little we gain from inspection, palpation, and percussion. As to stethoscope, I think the Ford is the usual preference. At any rate, ear pieces should fit the ears with comfort, and at the same time exclude outside noise; the tubes should be heavy enough and short enough to avoid kinking, and the bell should fit firmly so as not to make any noise in moving. As a general statement, I would say the simpler the stethoscope, the better.

In auscultating the chest, have patient breathe quietly with mouth open and a little more rapidly than normal. Now listen in both axillary spaces to get the normal vesicular breathing for this particular patient, but be sure patient is breathing properly. Now listen over anterior surface of chest (I prefer to begin at base and go up) for any breath changes, remembering that broncho-vesicular breathing occurs normally above and inside a circular line from middle of clavicles through second chondrosternal junction, more marked

on right than on left side. Turn patient around and examine back in same way. Broncho-vesicular breathing is normal at extreme apices and between scapulae near spine, also at left base below angle of the scapula. Remember that broncho-vesicular breathing is characterized by prolonged high pitched expiration and is not normally found outside of areas just mentioned. Abnormal broncho-vesicular breathing leads one to suspect pathology and to think of fibrosis due to tuberculosis as the cause, as this is the most frequent cause.

Be on the alert for suppressed breathing as this is frequently one of the first signs of a developing tuberculosis. After studying the breath sounds, have patient to whisper "one, two," gently during expiratory phase of breathing. Normally the whisper can be heard over about the same areas as normal broncho-vesicular breathing but not elsewhere, except on spine which we will not consider here. This should confirm findings as to the presence or absence of breath changes and frequently is a more delicate means of determining slight variations from the normal.

Now examine for rales in same way but have patient to breathe out gently and cough. He will naturally breathe in if you will make him breathe out and cough at rate of thirty times a minute. Forget everything but rales and listen for them. If present, try to determine their comparative size and their wetness; whether or not they occur in showers; and if more than one kind of rale is present. Also determine if they are superficial or deep, or both, and in just what phase of respiration do they occur, remembering that they may occur at beginning of inspiration, or throughout inspiration; or with or just after cough; or they may occur at any time, apparently at their convenience. One's understanding of rales and accompanying breath changes determines to a great extent his ability to diagnose and prognose tuberculosis. By a careful study of the physical signs can be determined to a great extent the age and extent of the lesion, whether or not it is spreading or has recently spread, and in general, the outlook for the patient. The physical findings, history, symptoms, laboratory findings, and X-ray must all be considered together and correlated finally, but each should be studied individually as if

there were no other evidence.

Before taking up rales I want to mention some of the adventitious sounds that the examiner must be on the lookout for:

- (1) Muscle crackles;
- (2) Sternal crepitations;
- (3) Sterno-costal crepitations;
- (4) Skin crackles;
- (5) Atelectatic rales.

These are all heard at apex of lung.

The first four can be differentiated by having patient hold breath, and moving part in question. *Atelectatic* rales will disappear after three or four deep breaths. *Marginal* rales are heard at base, near margin of lungs, and they are, as a rule, coarse and dry and disappear after patient breathes deeply a few times. They are of no importance. Pleural sounds, rales, or rubs may vary from inspiratory rales to a to-and-fro breathing rub. Unless a pleurisy is well defined it may be difficult to diagnose. Clicks cannot be described better than the term itself. They may occur in any part of the chest at any time and are generally of no significance.

#### RALES

There are many classifications of rales. Personally, I prefer the one used by Colonel Bushnell, which is about as follows:

*Crepitant and subcrepitant*: Occur in showers in inspiration, and inspiration only. Found in acute inflammations as pneumonia, or a recent extension of a tuberculous process, which pathologically is a pneumonic process. (The atelectatic rale, and rale of an almost healed lesion, is a fine rale, and frequently has many of the characteristics of crepitant and subcrepitant rales.)

*Indeterminate Rales*: The indeterminate rale occurs at any phase of respiration or may occur throughout respiration and cough; may sound superficial, or deep, or both. It has no regard for time or place.

Small and medium moist. Most often heard in tuberculosis. Always denote chronicity.

Large moist. Frequently heard in last stages of tuberculosis or beginning cavity formation. Also heard in edema of lungs and sometimes in bronchitis.

*Bubbling or Gurgling Rales*: Usually heard in cavity formation. May be produced in large bronchi. If caused by tuberculosis, never found in earlier stages of the disease.

*Sibilant and Sonorous Rales*: Rales of bron-

chitis. These rales may be musical or noisy and usually it is impossible to diagnose or rule out tuberculosis when these rales are present.

Metallic tinkle, succussion splash, etc., do not occur in uncomplicated pulmonary tuberculosis, so will not be considered here.

For diagnosis of pulmonary tuberculosis on physical findings *alone* the signs *must* be in the upper half of the chest. Tuberculosis *usually* invades the upper portion of the lungs and not the lower. However, if the lesion is basal, tuberculosis should be ruled out or diagnosed by means of history and symptoms or by the X-ray or the microscope.

For a *definite* diagnosis of tuberculosis one or more of the following should be present:

- (1) Tubercle bacilli in sputum.
- (2) Small or medium moist rales (called by many moderately coarse) in upper half of chest. Diagnosis may be made on finding subcrepitant or sometimes other rales with breath changes, but here history, symptoms, etc., must be considered.
- (3) Parenchymatous X-ray lesion.
- (4) History of hemoptysis of a dram or more.
- (5) Pleurisy with effusion.

Positive diagnosis may be made on presence of either 1, 2 or 3, or both 4 and 5. If either 4 or 5 be present, tuberculosis is nearly always the cause.

One positive sputum, if reliable, makes the diagnosis of tuberculosis unquestionable. One negative sputum is of little value, so, where in doubt, continue to have sputum examined until some definite diagnosis can be made.

2609 Hanover Avenue.

#### PROPHYLAXIS OF TUBERCULOSIS.\*

By H. R. EDWARDS, M. D., Richmond, Virginia.  
Clinician, Bureau of Tuberculosis Education, State Board of Health.

As is natural, a physician engaged in public health work must place in the forefront prophylaxis rather than cure; and I venture to say that, so far as tuberculosis may be concerned, it would be difficult to find any authority who might feel inclined to accept the other order of importance.

Under the heading, "Prophylaxis," we will have to include precautions; and if we are able

\*One of a series of lectures and demonstrations to a class of physicians in tuberculosis, held under auspices of the Health Bureau, Department of Public Welfare, Richmond, Va., February 15 to April 15, 1923.

to utilize our knowledge in this respect, not specifically but generally, it is safe to say that tuberculosis would become increasingly rare among human beings and that finally it would disappear.

I shall not here discuss publicity or propaganda. It is too complicated and varied to be condensed within the scope of a single paper. It is one of the most important single agencies in the battle with tuberculosis. In all branches of public health work, the people have to be prepared for efforts in their behalf, feeling naturally antagonistic to things that are beyond their knowledge; and in no branch of the work is education more essential than in tuberculosis. Hence we have the importance of "Propaganda."

There are two governmental functions that might be called essential to the control of tuberculosis. There should be adequate and general inspection of dairies and slaughter houses. No milk should be sold unless the producing cow has been tuberculin tested. Protection in these lines is partial; but it should be general. There should be actually compulsory registration of cases of tuberculosis. We have a Virginia law requiring this registration but it has never been enforced. We are now endeavoring to effect compliance with the law and are meeting with a fairly favorable response; but our efforts must not stop with persuasion if we should find persuasion to be ineffective.

The need for registration cannot be over-emphasized. Health officers are powerless to follow up cases when they are ignorant of the existence of the trouble; but when cases are reported, personal and written or printed advice can be given, so the patient may have a better chance of recovery and those near him have a better chance of escaping infection.

As to specific methods for application to individual cases, there should be special efforts made to reduce or remove predispositions to tuberculosis where there has been definite exposure to the disease. Children in families which have tuberculous histories or in which there is a present case of tuberculosis should be carefully examined and regularly weighed. Their dietetic conditions should be safeguarded; needed corrections, such as the removal of diseased tonsils or surplus adenoids, should be made; and the teeth of such children should receive particular attention.

From the viewpoint of either prevention or cure, treatment under ideal conditions is necessarily an expensive procedure, generally beyond the limits of the public purse and frequently too much for private means. Change of climate and surroundings, and the many conveniences that a sick person might reasonably wish, are not within the reach of the average case and are beyond the sphere of public health endeavor; but this handicap to the realization of an ideal should not discourage us.

For, indeed, it is a reassuring fact that our knowledge of tuberculosis and its treatment has in recent years broadened so that now we find ourselves able to cure the trouble anywhere if we find a co-operative patient, eager to be cured and willing to utilize all the aids we give him. This is a very fortunate condition; because the majority of the cases must depend upon home treatment; and it is not likely that ultimately home treatment will supersede sanatorial care.

This feature is here introduced because open-air sleeping is one of the principal features of sanatorial care. Sleeping porches as a preventive aid are eminently desirable; but if it is impracticable to provide a sleeping porch for the child who is to be protected, it is rarely, if ever, impossible to secure for him a room with adequate ventilation and abundance of fresh air. In a well ventilated room into which a constant supply of fresh air is coming, a child should sleep at least ten hours each night. Less than that period is not enough.

Cleanliness is a large factor in prophylaxis, and poverty is no excuse for filth. The house should be clean and the child should be clean. We should bathe frequently and be particularly careful about cleaning the teeth.

Regular living is necessary. Meals should be given at regular hours and the diet should receive particular attention. Milk, and plenty of it should be given; eggs, cereals, vegetables, and meat in moderation should be included in the fare. Abstention from tea or coffee will help to make the child strong and increase its resistance.

Children who are receiving this prophylactic attention should be carefully watched during and following any of the acute fevers, such as measles, scarlet fever, or pertussis; and particular attention should be given them if they

develop any condition that tends to weaken the lungs.

With minor variations, on the whole very similar treatment can be given to the adult as to the child. Whenever a case of tuberculosis has been located it is advisable for the rest of the family to use the same precautions that are recommended for the patient. It is practically certain that all of them have received the infection, and it is virtually sure that some of them may be developing active disease, which, if taken in time, will probably heal and give no further trouble.

Dissipation in any form should be avoided by those who are trying to avert tuberculosis. Regularity of living habits is a prime necessity for keeping fit.

Cold bathing is a great aid to the hardening process and is very necessary in the cure of tuberculosis. If a man accustoms himself to the cold bath by gradually reducing the temperature, he will suffer little discomfort and his body will become inured to changes of temperature, his pores will be toned and elimination increased. All these are factors that lessen susceptibility to tuberculosis.

Fresh air is a necessity not only at night but at all times. Those who work in unsanitary buildings that are poorly ventilated should, if possible, change to better quarters; but, if that is impracticable, they should at least be certain of proper ventilation and of clean surroundings.

Where there is a definite case of tuberculosis, certain precautions should be observed, if the others in the family are to be protected. The sputum of the patient must be burned. Sputum cups are so cheap that almost anybody can afford to buy them; but inability to buy need not prevent their use. There are a number of philanthropic organizations that will gladly give the cups to the men or women who cannot buy them. If the patient does not get the cups or does not have one available when he feels the need of expectoration, he should spit into a paper napkin or a newspaper. Whatever he uses for a receptacle should later be burned. The only exception to this rule that should be tolerated is the use of a glass vessel containing a strong liquid disinfectant and having a tight cover which should not be removed except when the container is being used or cleaned. If any sputum from a tuberculous patient should be spilled, it must be

wiped up while moist, with a rag or paper soaked in lysol or mercury bichloride solution.

The patient should keep in his pocket pieces of gauze so folded that after they have been used to cover a cough or a sneeze, they will not allow the moistened part to come into contact with the hands of the patient. It is inexcusable for a tuberculous patient to cough or sneeze without covering his mouth and nose.

These pieces of gauze, just like the sputum cups, should be burned daily. The patient should have with him a container or envelop of some sort for the used gauze. They should never be folded and stuck into his pockets. Used pieces should never be placed with the unused ones.

All dishes used by the patient should be used only by him. They should be washed separately from the dishes used by the rest of the household. Hot soap suds and water should be used for cleaning them, and subsequently they should be rinsed in boiling water. If these precautions are taken a tuberculous patient is not likely to be a source of danger to those near him.

In fact, it may be said that, if any one suffering from tuberculosis is careful in his personal habits and so places his sputum that it cannot get to another person, and if his attendant is careful to see that his table utensils are properly sterilized and kept away from others, people in a home where there is a tuberculous patient are as safe as they would be in an average home, and far safer than they would be where there are careless coughers and sneezers.

---

## THE DIFFERENTIAL DIAGNOSIS OF PULMONARY TUBERCULOSIS.\*

By W. NELSON MERCER, M. D., Richmond, Va.  
Director, Tuberculosis Division, Health Bureau.

First we will consider the physical signs elicited in diagnosing the various lesions in pulmonary tuberculosis, and then the differential diagnosis of this disease.

The important question is to determine whether the signs present indicate a healed or an active lesion. Persistent moist rales, heard after expiration and cough, are the only reli-

---

\*One of a series of lectures and demonstrations to a class of physicians in tuberculosis, held under auspices of the Health Bureau, Department of Public Welfare, Richmond, Va., February 15 to April 15, 1923.

able signs of activity in pulmonary tuberculosis. The common physical signs are harshness of respiratory sounds, prolongation of expiration, increased conduction of voice, and more or less dullness on percussion, all of which are usually caused by an advanced process, and very rarely by acute inflammation. When these signs occur in an early case, the patient is usually febrile and evidently ill. In cases of ambulant subjects in apparently good health, the presumption is that the above signs indicate an old, not an early lesion.

#### THE ACUTE LESION.

If small, this lesion is manifested by rales with or without changes in breath sounds, percussion note, and voice transmission. The more acute the lesion, the greater probability that its presence will be indicated only by rales. If of large extent, the lesion is distinctly a broncho-pneumonia, characterized at first by the usual signs of pneumonia, crepitant and subcrepitant rales; when caseated, by absence of rales, except coarse and distant rales from the larger bronchi, also by impairment of expansion of the lung, and more or less dullness or tympanitic resonance; when breaking down, the lesion shows signs of a cavity and the presence of gurgling rales of varying size.

#### THE ACTIVE CHRONIC LOCALIZED LESION.

Activity is denoted by the presence of rales, together with the other signs described under the arrested lesion, but the rales do not of necessity show that the lesion is extending, nor that the activity is of much clinical importance. The more active and recent the chronic lesion, the less marked the breath changes and the more conspicuous the rales.

#### THE ARRESTED CHRONIC LESION.

The arrest of a lesion is characterized by the absence of rales. The signs elicited are harshness of breath sounds, prolongation of expiration, increased vocal fremitus and resonance, and by varying degrees of dullness on percussion.

#### DISSEMINATED TUBERCULOSIS.

The peribronchial type is common and frequently not recognized. It may be manifested only by distant rales with or without slight changes in breath sounds, usually bronchovesicular. If well marked, there will be lagging on the affected side and increased vocal resonance. Less pronounced cases are dis-

tinguished from chronic bronchitis by the character of the rales (coarser in bronchitis) and by their distribution. More frequently the peribronchial type is found with a superficial focus, in which case bronchovesicular breathing with or without rales may extend some distance below the limits of the focus. Extension to the formerly sound lung is the most important point of diagnosis in the peribronchial type. There may be a small apparently arrested lesion on one side, usually the right, with signs of extension involving the whole or greater part of the other lung manifested only by rales after expiration and cough. In ambulant afebrile patients, harshness of breath sounds and prolongation of expiration indicate an old lesion, while the more acute the lesion the greater significance have the rales and less marked are the breath changes. The possible signs elicited in the disseminated type of pulmonary tuberculosis are: diminished expansion at the base, increased tactile fremitus, shorter high-pitched note with heavy percussion, slightly prolonged expiration, rales (often indeterminate) heard near the margin of the sternum in the second, third, or fourth interspaces, and between the scapulae behind (heard after expiration and cough), and sometimes an area of pectoriloquy.

#### THE DIFFERENTIAL DIAGNOSIS OF PULMONARY TUBERCULOSIS.

It has been shown by various workers in tuberculosis sanatoria that a number of patients admitted as having active tuberculous lesions in the lungs have been proven non-tuberculous, or no active lesions could be found. Among 198 autopsies at the Boston Consumptives' Hospital, 23 cases or 11.5% proved to be non-tuberculous or had no active lesion. In other sanatoria 353 necropsies revealed 38, or 10.8% non-tuberculous. Many hospitals have a large number of "negative sputum" cases, some as high as 50%, which would indicate that mistakes in differential diagnosis are sometimes made, and, therefore, it behooves us to devote sufficient time and care in utilizing all the means at our disposal in the city to reach a correct diagnosis in justice to our patients and to the welfare organizations concerned in their aid and treatment.

For convenience, we will divide the conditions to be considered into two main groups, as follows:

1. Those in which suspicious symptoms predominate.

2. Those presenting definite physical signs in the lungs.

#### 1. CASES IN WHICH SUSPICIOUS SYMPTOMS PREDOMINATE.

*General Asthenia.*—These patients are usually women or children who are constitutionally frail, below average weight, have little endurance, and may present symptoms of nervousness, irritability, indigestion, headache, etc., without definite cause. They may have frequent colds and other infections and simulate tuberculosis closely. They should be kept under prolonged observation, and repeated examinations are indicated to make a definite diagnosis. Careful supervision of their daily life will probably restore them to good health, and watchful oversight by the physician will generally produce most favorable results.

*Neurasthenia.*—This group is similar to the last, but having more pronounced nervous symptoms. The nervous symptoms may be due to tuberculous toxemia, but more often they are not. Prolonged observation with supervision of the patient's mode of life not only makes the correct diagnosis but also is the treatment indicated whether the patient is tuberculous or not.

*Hyperthyroidism and Other Endocrine Disturbances.*—Malaise, loss of weight, nervousness, digestive disorders, and sometimes a chronic cough, when the thyroid is enlarged, are the usual symptoms. Upon examination, these patients are found to be poorly nourished, have a rapid pulse, are easily fatigued, and may have a slight afternoon rise of temperature increased by exertion or excitement. General examination shows the fine tremor in the fingers, tachycardia, slight enlargement of the thyroid gland, exaggerated tendon reflexes, and possibly exophthalmos—typical signs of hyperthyroidism. The Goetsch adrenalin test and the basal metabolism rate may be of use in borderline cases. Where disturbed balance of the various internal secretions is present, nervousness and malnutrition associated with ovarian or adrenal symptoms may occur. Observation and regulation of the life of the patient over a prolonged period, and probably the use of extracts of animal ductless glands, or in some cases of hyperthyroidism, surgical intervention, result satisfactorily and make the diagnosis.

*Fever of Obscure Origin.*—(a) Typhoid and Paratyphoid Fevers: Frontal headache, epistaxis, enlargement of the spleen, continued fever without marked morning remissions, and later, tympanites, rose spots, positive Widal and blood culture, make the diagnosis of typhoid. But no other signs than fever often appear for a week or ten days before the above definite signs are evident. If bronchitis complicates typhoid, the differential diagnosis is more difficult. The signs in the chest are not localized, are bilateral at the bases, and vary in location and extent. The early active febrile stage of pulmonary tuberculosis will probably subside in two or three weeks if the patient be put to bed. Repeated examinations of the chest and sputum, and X-ray study will make the correct diagnosis.

(b) Malaria: The symptoms of pulmonary tuberculosis are often mistaken for malaria, but if proper care is taken in getting the history, examining the chest, daily temperature record, blood examination for the malaria plasmodium, sputum examination for tubercle bacilli, and rest in bed, the diagnosis will be made without delay.

(c) Influenza: The diagnosis of "grippe" is often made when other conditions exist, and early localized tuberculosis is most frequently overlooked by physicians, when careful search for signs in the chest combined with sputum and X-ray examination would clear up the diagnosis. Whenever cough and fever continue after the acute stage, tuberculosis should always be suspected.

(d) Focal Infection: In this group of conditions with some constitutional reaction, chest pains, and probably cough, the differential diagnosis from obscure tuberculous lesions is rather difficult. The teeth, tonsils, sinuses, intestines, and genito-urinary tract are usually the seat of such foci, and in doubtful cases should be investigated as the source of infection, after careful examination of the lungs fails to reveal evidence of pulmonary tuberculosis. Irregular fevers will often cease when the focus of infection is removed.

In the above group of conditions with indefinite constitutional symptoms, pulmonary tuberculosis should always be suspected because of its frequency, and with patience and care in the search for direct evidence the correct diagnosis can usually be made.

## 2. CASES PRESENTING PHYSICAL SIGNS IN THE LUNGS.

*Tuberculous Infection and Tuberculous Disease.*—Thus far we have considered the interpretation of general symptoms akin to those associated with pulmonary tuberculosis, and we have found that suitable regulation of the daily life of the patient while he is under observation is of marked value both for diagnosis and treatment of the condition whatever it may be. More difficult are the cases which present slight variations upon physical examination of the lungs. Tuberculous infection is denoted by the signs of slight impairment of resonance, slight alteration in the breath sounds, or fine crackling rales in an apex. When such signs are found, the lesion is of the inactive fibroid type unless accompanied by constitutional evidence of active disease, and it is best determined by repeated examination of the chest and careful observation of the temperature, pulse, fatigue, nutrition, digestion, etc., but without these symptoms the diagnosis of active clinical tuberculosis is not justified upon these physical signs alone.

*Conditions Presenting Marked Physical Signs.*—Mistakes in diagnosis by the general practitioner in this group of cases are more frequent, due to the need of consultation with those who specialize in pulmonary diseases.

The physical signs are generally marked and extensive, with cough and expectoration. Repeated examination of the sputum for tubercle bacilli, and X-ray study will often clear up the diagnosis. Negative sputum in extensive tuberculosis is extremely rare.

(a) Emphysema and Chronic Bronchitis: This condition is often confused with pulmonary tuberculosis, but the diagnosis can be made by a history of chronic cough worse in winter months, asthma with dyspnea and signs of emphysema, negative sputum for tuberculosis, and coarse rales which are bilateral and inconstant. This condition usually occurs in older people and may be accompanied by chronic tuberculous lesions in the apices with or without tubercle bacilli in the sputum. "Tuberculosis carriers" are often met with in this group which may have been unrecognized as such for years, and they are a constant source of infection to others. Repeated examinations of the sputum and X-ray plates should be made in difficult cases of this group.

(b) Peribronchitis or Chronic Bronchopneu-

monia: This group is very common, usually following influenza, and may be caused by the pneumococcus, influenza bacillus, or the streptococcus. Symptoms are mild, fever a few days, cough and expectoration, and possibly some hemoptysis. Following influenza the upper air passages and sinuses are often involved. The physical signs are those of infiltration which occur in the lower lobes. The diagnosis is made on the absence of constitutional symptoms with extensive physical signs throughout the chest, negative sputum for tubercle bacilli, but showing the above microorganisms of acute respiratory infection, X-ray picture of linear peribronchial markings slightly increased, and the clearing up of symptoms and signs in a shorter time than similar tuberculous lesions usually require.

(c) Bronchiectasis: Chronic cough, expectoration of large quantities of purulent and foul sputum at intervals, loss of weight, fatigue, dyspnea, cyanosis, fever 99.5 to 101 at times, and possibly hemoptysis, continue for years. The physical signs are indefinite, due to the lesions being either single or multiple and bilateral and they are located usually in the lower lobes of the lungs but may extend upward. If single, signs of consolidation, pleuritic adhesions, or a cavity will be found in the lower part of the chest posteriorly, but when multiple and bilateral the signs are those of a chronic bronchitis with emphysema. Cavities usually form in the lower lobes, rarely in the upper.

The X-ray picture, the characteristic foul sputum which separates into three layers—greenish-yellow, straw, and frothy yellow—negative for tubercle bacilli, the history of the case, and the physical findings will make the diagnosis.

(d) Abscess of the lung usually follows operations on the tonsils or jaws and is preceded by aspiration pneumonia or septic pulmonary embolism. High fever, sweating, emaciation, cough with expectoration of large quantities of brownish, foul, sputum without tubercle bacilli, and probably hemoptysis or hemorrhage form the clinical picture. The physical signs are usually in a lower lobe, the apex remaining clear.

(e) Gangrene of the lung may follow aspiration pneumonia, pulmonary embolism, or the presence of foreign bodies in the bronchi. The symptoms of gangrene of the lung are irregu-

lar high fever, prostration, cough, and large quantities of fluid, fetid, and frothy sputum with particles of lung tissue in the lower layer. X-ray study and sputum examinations aid in the diagnosis.

(f) Cancer of the Lung: Sarcoma and carcinoma of the bronchi, lungs, and pleura may present symptoms similar to pulmonary tuberculosis in the early stage—low grade temperature, cough, hemoptysis, loss of weight. Pressure of the tumor may cause enlarged veins on the chest wall and shoulder or neck and possibly dilatation of the pupil on the affected side with dyspnea as the tumor enlarges. Cachexia, with a waxy-yellow color and blanching of the face, appears in contrast to the feverish appearance seen in tuberculosis. Emaciation is evident much earlier in tuberculosis than in malignant disease of the lung. The physical signs over the tumor are flatness, feeble or absent breath sounds without any rales in the circumscribed area, and above the area of flatness there is an area of resonance, which does not occur in tuberculosis.

When fluid complicates cancer of the lung or pleura the pressure signs given above are more apt to occur than in other conditions, and upon aspiration of the chest, if blood be found, it is strongly indicative of malignancy. The presence of coarsely granular eosinophile cells in the fluid would point to cancer of the lung. The sputum is negative for tubercle bacilli and small in quantity. The diagnosis is made by the symptoms, physical signs, and the X-ray.

(g) Actinomycosis: In the early stages the symptoms resemble tuberculosis—loss of weight, cough, fever, etc., later a fluctuating swelling in the chest wall with signs of pleural effusion appears. The sputum and pus from the swelling show the streaks of actinomycotic growth.

(h) Streptotrichosis of the Lung: The diagnosis can only be made by microscopic examination of the sputum for the streptothrix, as the symptoms resemble tuberculosis closely.

(i) Spirochetosis—Hemorrhagic Bronchitis: The symptoms are cough, copious expectoration, but no fever in most cases, while the general condition of the patient remains excellent. The character of the sputum makes the diagnosis alone as it is viscous and thick throughout, is much like the juice of gooseberries, and contains the spirocheta bronchialis.

(j) Cardiac Diseases: Organic heart disease, notably mitral stenosis, often causes cough, expectoration, hemoptysis, mild fever, and emaciation which would lead to a diagnosis of tuberculosis, but upon careful examination the cardiac lesion will be heard as a presystolic murmur within the apex of the heart. The area of cardiac dullness is usually enlarged in these cases, and the first sound of the heart has a slapping quality. Dyspnea is more marked in cardiac cases than in the tuberculous, and rest for a few days will relieve it in cases of heart disease. In all cases with lesions of the mitral valve and dilatation of the heart showing inconstant rales in the lower part of both lungs, it is safer not to diagnose pulmonary tuberculosis unless tubercle bacilli are found in the sputum.

(k) Syphilis of the Lung: This is very rare and difficult to diagnose when present. There are cough, expectoration, slight fever, loss of weight, and sometimes blood spitting. The lesions are usually in the lower lobes and accompanied by other signs of syphilis in the bones, skin, larynx, etc. X-ray pictures and repeated negative sputum examinations will aid in the diagnosis, but a positive Wassermann reaction will frequently be found in patients who have both syphilis and tuberculosis and is therefore not absolutely reliable in differentiating these diseases. The therapeutic test of salvarsan and mercury in positive Wassermann cases with other suggestive signs of syphilis will often clear up the pathology which is the result of luetic infection.

Osler found only twelve cases of pulmonary syphilis in 2,500 autopsies at Johns Hopkins; and only two cases in 6,000 at the Copenhagen Hospital were proven to be such post-mortem.

### GRANULOMA INGUINALE.\*

By CLYDE F. ROSS, M. D., Richmond, Va.  
Associate in Genito-Urinary Surgery, Medical College of Virginia.

Granuloma Inguinale is also known as "Ulcerating Granuloma of the Pudenda," "Granuloma Venereum," "Serpiginous Ulceration of the Genitals," "Groin Ulceration," etc., but none of these names seems to describe the condition in its various manifestations. They all imply it is a disease of the genital regions when

\*From the Urologic Service of the Medical College of Virginia. Read before the Medical Society of Virginia at its fifty-third annual meeting in Norfolk, October 31-November 3, 1922.

such is not always the case, so in reality we have no exact terminology for the condition.

Granuloma, for as such will it be spoken of in this article, was originally thought to have been solely a tropical disease having been first reported by Conyers and Daniels<sup>1</sup> in 1896 as occurring in the British tropical possessions, but now the disease has been recognized in the United States and we realize it has been present for years but diagnosed under other names. Randall<sup>2</sup> states it has been present in Philadelphia for fifty years and has been recognized but wrongly diagnosed for twenty-five years. In 1920 Symmers<sup>3</sup> reported two cases from the Bellevue Hospital, having been assisted in arriving at a correct diagnosis by a South American surgeon who was visiting the hospital at that time. This condition first came under my observation during the summer of 1918 at the Base Hospital, Camp Greene, N. C. There were mobilized drafted colored troops from North Carolina, South Carolina and Tennessee. I remember several cases diagnosed as syphilis, for want of a more correct diagnosis, which I now know were in reality granuloma. Some of these patients may have had positive Wassermanns but anti-syphilitic treatment had no effect upon the lesions and the patients were given surgeons' certificates of disability and discharged. Upon coming to Richmond I was again confronted with this condition, but not until Symmers published his article did we know its true nature and its cure.

Up to the time we reported seven cases before the Medical Society of Virginia in Lynchburg<sup>4</sup> in 1921, there had been only twenty-seven cases reported in the United States by five different writers, but since that time there have been a number of cases reported from those sections of the States particularly where the negro resides. In this report we wish to add ten more cases to our previously reported seven.

Granuloma may be defined as a chronic infectious ulcerating granulating disease, occurring in any part of the body but mostly on or around the genital organs, with no tendency to glandular involvement or serious impairment of health.

The causative organism has not been definitely placed although the consensus of opinion is that it is due to an intracellular encapsulated organism found in large mononuclear cells and known as Donovan's body after Donovan<sup>5</sup> who first found it in 1905. Others, notably

Driscoll<sup>6</sup>, believe it is due to a symbiosis of the spirillum and the fusiform bacillus, the same organisms causing Vincent's angina and erosive or gangrenous balanitis (fourth venereal disease). Randall has done a great deal of work in trying to prove Donovan's body the true cause but has never been able to reproduce the disease. In three of his sixteen cases an organism was cultured which resembled the organism seen in the mononuclear cells. He as well as Symmers, Campbell<sup>7</sup>, Lynch<sup>8</sup>, and others have found the Donovan's body almost universally present in their reported cases, while Aragao<sup>9</sup> claims the organism is pathognomonic of the disease. We have been very unfortunate in our attempts to locate the organism. Seven patients were examined with positive findings of the Donovan body in only one case and the spirillum in two. In the one case in which the Donovan body was located we also found the spirillum. Two patients are now undergoing examinations and in eight no attempt was made to locate organisms.

Its mode of transmission is also as yet undetermined. We do not believe it is venereal in origin for in all of our cases, with possibly one exception, we have never known of one patient conveying it to another, yet there are histories of men and women living together with no transmission of the disease. It may prove to be an insect borne disease as by the pediculosis pubis.

Conyers and Daniels<sup>1</sup> give the following description of the microscopic picture with which we agree and upon which we have depended along with clinical findings for a diagnosis:

"The mass of nodules are composed of round cells, with a large (but usually badly staining) nucleus, contained in a delicate reticulum of fibrous tissue. This mass is covered by epithelium in its greater extent and in the older and larger nodules merges gradually into a subadjacent dense fibrous stroma in which small masses of similar rounded cells are embedded. The growths are very vascular and the capillaries are much dilated, but there are no hemorrhages. There is no sign of suppuration or caseation, and no giant cells are found in any of the sections. The overlying epithelium has undergone certain modifications; it is usually intact; or cracked and occasionally over small areas absent or ill formed, and the cells of the rete malpighii are ill defined and swollen. None of the pigment so characteristic of the colored race is found in

the deeper layers. In many specimens there is a proliferation of the interpapillary epithelium, in some, sufficient for columns of epithelial cells to appear to descend into the round celled growth. In some, on the other hand, the papillae have almost disappeared from a more widespread proliferation of the epithelium. The hair follicles in many cases share the epidemic thickening, and the hairs grow strongly and are not changed in color. In a section of a small nodule the round cell mass will be found to be roughly wedge-shaped, the base of the wedge being towards the skin, the growth ascending with the vessels into the papillae."

The lesions seem to be both primary and secondary in origin. When beginning primarily, it may start as a papule, pustule, or nodule which ulcerates, and upon the base of this ulcer granulations appear and spread by contiguity or usually by continuity of tissue. If it is secondary in origin, the infection seems to be engrafted upon some prior lesion as an inguinal bubo. Fourteen of our cases were primary and three secondary. The three latter were secondary infections of buboes.

The lesion presents itself as a light red mass of granulation tissue which in the older cases ulcerates in the center and heals, leaving a firm raised cicatricial area covered by very thin epithelium. The granulating areas vary in the amount of elevation but are usually more raised at their margins and depressed in the center. They are covered by a thin, pearly grey scab and, except in moist regions, have very little secretion. This secretion may be fetid or not.

At times, instead of there being tissue proliferation, there is ulceration with great destruction of tissue, particularly so if the lesions affect the glans penis, prepuce, or vulvae. When healed, the scar tissue often contracts and produces deformities, especially so if it involves the urethra, vagina, or anus. Instead of the disease being at all times of long continued duration, there seems to be an acute form of very rapid destruction.

In our male patients the lesions were confined to the glans penis and prepuce in four cases, and in the other nine there was an involvement of the inguinal region in every case, with extension to other parts in some cases. In one of the latter there was an involvement of the mouth, nose and throat. The typical inguinal granuloma begins in the inguinal

region, either on one or both sides, extends upward towards the anterior superior spine and downwards into the inguinal folds. If untreated, it will spread over the perineum, around the folds of the nates and up over the sacral region. None of our recent cases have been so extensive, as the diagnosis has been made during the early stages.

In our female patients the vulvae seem to be the site of predilection as in all four the vulvae were involved, with involvement of the inguinal region in two cases. In two cases there were extragenital lesions, one involving the neck and another involving the mouth, showing a high percentage of lesions out of their normal location.

The lymph nodes are not involved and the subjective symptoms are slight. All of our patients have been in the colored race, although Randall and Lynch both report one case each in the white race. By men doing work among both sexes, it is reported as freely in one sex as the other. The female cases reported by us have been only those seen in consultation.

In the past these lesions have been variously diagnosed chancroidal ulcers, syphilis, condylomata acuminata, tuberculosis cutis, and epithelioma. Except when secondarily infected, it does not resemble the chancroidal ulcer in that it has not the ulcerated undermined edges nor the foul purulent discharge of the chancroidal lesion.

Since the advent of the Wassermann and arsenic therapy, it is not so often confused with syphilitic lesions. Although a number of these patients showed a positive Wassermann, yet anti-syphilitic treatment had no effect upon the lesions. In fact nearly all of our patients had had arsphenamine with no improvement, whether they had positive Wassermanns or not. The absence of the tubercular bacilli, the clinical and the pathological findings should serve to distinguish granuloma from tuberculosis cutis. The presence of glandular enlargement, metastasis, and the pathological picture should differentiate malignant disease from granuloma.

Until the organism causing the disease can be positively identified, the diagnosis will rest upon clinical findings, pathological examination of sections, and the results of antimonial therapy. Any granulating or ulcerating lesion around the genitals or located elsewhere, resistant to ordinary surgical treatment, unimproved by anti-syphilitic remedies, of long

duration, devoid of pain, should be given the advantage of tartar emetic therapy.

In antimony and potassium tartrate we have added one more drug to our list of specifics and most likely opened up a new field in drug therapy. Recent literature refers to its beneficial action in bilharziasis, filariasis, gangosa, cachar sore, malaria, leishmaniasis, and trypanosomiasis. We have yet to see a case of granuloma which could not be cured by its use and in our experience with drugs none has shown the marvelous healing powers as tartar emetic in this disease.

Antimony and potassium tartrate were first used in the treatment of granuloma by Aragao and Vianna in 1912, but the success attained was not so great until its was used intravenously. Hoffman<sup>10</sup> first reported its use intravenously in 1920. In our seventeen cases, thirteen were healed, two discontinued treatment, and two are now undergoing treatment with great improvement.

The U. S. P. Tartar Emetic (Antimony and Potassium Tartrate) in sterile distilled water is used intravenously in one per cent solution. The initial dose is 5 c.c. and is increased one c.c. each dose until 10 to 12 c.c. are given at a dose. This amount was diluted up to 25 c.c. by sterile distilled water and injected three times a week. Improvement is usually noticed after three or four injections. The drug in some patients causes immediate vomiting which lasts only a short time. To prevent this all patients are instructed to return for treatment with empty stomachs. We have never experienced any severe untoward symptoms. The oral administration of tartar emetic has not been attended with visible improvement. Caution should be observed not to spill any of the solution into the tissues as the results are very distressing. After lesions have healed, treatment should be continued weekly for three months to prevent recurrence. This after-treatment is very essential and should not be neglected. In two cases where it was neglected, there were recurrences which responded readily to more treatment.

Owing to the fact we have as yet no complement fixation test for granuloma, as we have in syphilis, it is impossible to say if these patients are cured or just temporarily relieved. It may be found necessary to repeat courses of treatment in this disease every year as we do in syphilis.

In our seventeen cases, ages ranged from

seventeen to fifty years. Thirteen were males and four females. Fourteen were primary and three secondary. Duration of the disease was from one month to eleven years, as follows: one, eleven years; three, ten years; one, eight years; one, seven years; two, two years; five, one year; and four, less than one year. The amount of tartar emetic given was from six to forty grains and the period of treatment extended from two to six weeks.

#### EMPYEMA.\*

By J. K. GRAY, M. D., Marion, Va.

During the past five years there has been a greater incidence of empyema among both the civil and military population than has ever been noted previously, and special advantages for the study of this disease have been afforded by the comparison of the various methods of treatment as carried out upon large groups of cases. Much has been learned during this time and the mortality has been markedly lowered by a clearer understanding of the physiologic and pathologic processes involved and the formulation of better and more individualized methods of treatment. It seems opportune at this time to present for your consideration a review of the established principles in the diagnosis and treatment of this condition and in addition such data as will modify or change them.

**ETIOLOGY:** At one time regarded as a disease which occurred only rarely, except as a sequel or late complication of lobar pneumonia, we have now to recognize empyema as occurring very often as an early complication and especially so with the streptococcus bronchopneumonia and that following measles. The hemolytic streptococcus has been found to be responsible for most of the epidemic cases, especially where complicating bronchopneu-

\*Read before the Southwestern Virginia Medical Society in Christiansburg, May 17, 1923.

monia, while the pneumococcus has been found to be the causative factor in the sporadic cases.

**PATHOLOGY:** The amount and character of the exudate, as well as the time of occurrence, has been found to vary with the type of organism present. The streptococcus is apt to produce a large fluid exudate in a short time, later tending to become purulent. The influenza type tends to produce only a small amount of fluid and this is purulent from the beginning. On account of the small amount present, it has been found that occasionally it will be absorbed spontaneously, but this of course is the exception rather than the rule. The pneumococcus exudate is purulent at all stages of its development, and large in amount. All of these types of exudate may contain large flakes of fibrin and especially if allowed to remain undrained for any length of time. The pleura having reacted gradually to the infection is in the usual case thickened and resistant; however a serious pathological condition is sometimes found in the presence of an encysted empyema. The rupture of such into an uninfected pleural cavity is a serious accident, it appearing that the sudden contact of so much septic material with the undiseased pleura has much the same effect as it would on the peritoneum. The gross findings in chronic cases have been more clearly outlined by the use of the X-ray, especially in determining the position and extent of cavities and sinuses when injected with some opaque material.

**DIAGNOSIS:** There has been nothing of great importance added to the knowledge concerning the general principles of diagnosis of empyema as carried out by careful history and observation of symptoms and a thorough physical examination. The laboratory methods of diagnosis however have been more fully developed and under the heading two main features are to be considered.

*First:* Bacteriologic examination of the discharges should be carried out both in diagnosis and treatment, this being important in that it helps not only in the planning of how and when to operate, but also as a control during the treatment with antiseptic solution and as a guide toward when closure should be permitted to take place or plastic operation attempted.

*Second:* An X-ray plate and fluoroscopic examination, while not absolutely necessary, is a valuable aid in diagnosis. However, after the cavity is drained, and especially if air is

allowed to enter, it is difficult to interpret the findings, because of the great variations in density of the chest contents. In the investigation of chronic cavities in order to determine position and extent, the best method of outlining the cavity has been found to be by injecting with 20% bismuth and 3% acacia in cottonseed oil. This procedure was also successfully employed by Stevens as a guide in determining the extent of expansion of the lung in empyema cavities of long duration.

**TREATMENT:** Up to the period of the outbreak of the war, the established method of treating empyema as soon as discovered was immediate thoracotomy, with or without rib resection, and usually no irrigation was instituted for several days, if at all, later on exercises to encourage lung expansion were instituted and suction apparatus was used by some, but the results were not generally satisfactory. The tremendous mortality of empyema among the soldiers at Camp Lee at the outbreak of the war was investigated by a specially appointed commission who found the streptococcus to be the etiologic factor, complicating streptococcus pneumonia. They found that early operation had been performed in most cases, and with fatal results in many; so that a policy of deferred operation was adopted whereby repeated aspiration was performed on the acutely ill cases in order to relieve the pressure symptoms until the pneumonic process had subsided. At this time the usual thoracotomy was performed and Dakin's fluid irrigations established. The preliminary treatment by aspiration has even resulted in a recovery without operation in several cases. However, in none of these has there been formation of real pus. The adoption of this policy and method resulted in very gratifying results.

The Thiersh method of treatment has been revived with modifications. This method was devised to prevent collapse of the lung by pneumothorax and consisted in passing a large caliber rubber catheter into the pus cavity by means of a trocar and attaching a flexible rubber tube to the end of the catheter so that the walls of the tube would collapse on inspiration and prevent the entrance of air, at the same time allowing free drainage. A modification of this method is the closed method of Mozingo, whereby Dakin's fluid is instilled and withdrawn through the tube at such intervals as are deemed necessary to sterilize the cavity and

remove the pus. This method is applicable in many cases and has several advantages, such as simplicity, avoidance of shock and prevention of sacrifice of tissue. It is agreed by a great many that Dakin's fluid irrigations are practical and safe, provided first an injection of physiologic saline is used in order to determine the presence of an opening into a bronchus in which case the injection of Dakin's fluid would be followed by unpleasant results due to irritation. The method is naturally adapted to cases in which the pus is in a fluid state and the presence of fibrinous masses would be a serious objection to its use and indication for a wide opening in order to permit their escape. With the antiseptic irrigation treatment properly carried out, it is probable that the formaldehyde and glycerine injections would not be necessary and, in addition, there is a tendency toward pleural thickening with such treatment. The technical nature of this procedure might prove to be a drawback in some cases where the operator was not practiced in the technique. As an emergency procedure, therefore, simple aspiration with a large caliber needle would be sufficient to relieve the condition until a better method of treatment could be carried out. There has been some criticism of the use of Dakin's fluid on the ground that it is too irritating to be used in the pleural cavity. Notwithstanding the fact that Dakin's fluid is not absolutely essential in the treatment, it appears that it has shortened convalescence in many cases.

This method while apparently mechanically perfect is not without the disadvantage that after four or five days there is a tendency toward retraction of the skin around the tube and consequent leakage of pus. If this did occur however, one would still have the choice of a resection and drainage, and probably by that time the patient would have passed over the critical period and other changes have taken place within the pleural cavity which would render thoracotomy a safer procedure than if it had been undertaken in the first place. A modification whereby the entrance of the tube could be made air-tight has been devised, and is made effective by means of circular cap of rubber made air-tight around the tube and to the skin by means of Sinclair's glue. In cases where there is no tendency for the lung to expand under the closed method of treatment, it is an indication that a dense fibrous layer is

forming upon the surface of the lung with resulting compression. In such a condition, provided the acute stage of the disease has passed, prompt operation is indicated with the freest possible drainage and irrigation in addition. The choice of operative procedure, whether by the conservative method in which drainage and irrigation are carried out through a tube passed through an air-tight opening in the chest wall, or the more established method of rib resection, must be governed by individual needs of the case. An aid in the formation of this decision is character of the organism. It has been observed that streptococcus empyema occurs early with pneumonia, while the pneumococcus follows the lung process later. The character of the pus in the streptococcus type is usually thin enough to be aspirated or withdrawn through a tube, while in the pneumococcus type it is usually thick, contains fibrous masses and can only be effectually evacuated through a large opening. There have been great advances in the treatment of chronic empyema and in the hands of Keller of the Army Medical Corps a new method of procedure has been adopted whereby with the use of Dakin's fluid for obtaining asepsis, and a policy of dividing the operative procedure into a number of brief stages, he has been able to obtain remarkable results in a great number of apparently hopeless cases.

As regards treatment, in conclusion let it be said that, as far as the anaesthetic is concerned, the use of a general anaesthetic has been found not necessary with properly induced local anesthesia and some have gone so far as to say that it is criminal to employ general anesthesia.

PROGNOSIS: Expansile power of the lung and especially activity and tone of the diaphragm are rapidly restored following removal of septic material and irrigation with Dakin's fluid or salt solution. Failure of expansion of the lung has been found more often to be due to the surface being covered with septic material due to which the physiologic activity of both the lung and the diaphragm are retarded, and in the presence of this failure to expand, caution should be exercised in the closure of the external wound lest pus pockets, sinuses, and cavities be found later to exist. The outlook for recovery has been improved and the number of chronic cases lessened as methods have been adopted more to suit the needs of the in-

dividual case. A certain number of cases have resulted fatally, but only in the face of overwhelming complications, where the treatment has been carried out properly. The causes of chronicity have been made more plain by recent methods of study, rendering direct attack upon the underlying causes more effectual.

#### CONCLUSION

*First:* Extensive operation, as by rib resection, should not be performed as long as there is a pneumonic process in existence.

*Second:* Remove pus during the acute stage duly by aspiration or air-tight tube drainage, especially if respiration is mechanically embarrassed by the accumulation of a large amount of fluid.

*Third:* Operate as soon as the pneumonic process or acute stage has subsided, by rib resection and wide drainage or tube drainage with free irrigation.

*Fourth:* The early and continued use of irrigating solution, both normal saline, and Dakin's fluid, for both their mechanical and bactericidal actions is indicated.

*Fifth:* Chronic empyema is more rare than formerly and the outlook when it does occur has been made more favorable by the use of Dakin's fluid and a specially developed operative procedure.

### RENAL TUBERCULOSIS.\*

By W. O. POINDEXTER, M. D., Newport News, Va.  
Urologist to Elizabeth Buxton Hospital.

Tuberculosis of the kidney constitutes one of the important chapters of surgery and certainly one of extreme importance to the urologist, since 25% or 30% of all the surgical lesions of the kidney are tuberculous. The statistics of Kronlein and Israel bear this out. Caulk of St. Louis found fifty-five tuberculous kidneys in two hundred and fifty surgical operations upon this organ.

By the introduction, retention and colonization of tubercle bacilli in the kidney many types of morbid processes may develop. The French school classifies miliary tuberculosis, nodular tuberculosis and tuberculous nephritis. It seems satisfactory to classify two main types, (1) acute miliary and (2) chronic or surgical tuberculosis, and in addition we may have (3) a toxic tuberculous nephritis.

Authorities are now pretty generally agreed

that the vast majority of cases of renal tuberculosis represent blood borne infection from some other source in the body, such as lung, bone, gland, bowel, or joints, which first attacks the kidney and then the ureter or bladder secondarily. Primary infection of the urinary bladder through the urethra is an exceedingly rare occurrence. Kuster states that 10% of patients dying of tuberculosis have renal involvement.

The question of ascending renal infection along the ureter from a bladder focus has long been a favorite topic of energetic controversy between both clinical and experimental observers of large experience. Most observers, however, hold that while this is a theoretical possibility which now and then may materialize, it is certainly exceptional and most of the reported cases admit of more rational interpretation on the assumption of independent and repeated haematogenous infection. The masterful work of George Walker showed that ascending infection up the unobstructed ureter did not occur. Bauerism states that with the flow of urine unobstructed, tubercle bacilli cannot reach the kidney intra-ureterally. Infection along the ureteral lymphatics, both in tuberculosis and non-tuberculosis, has certain advocates. Most authors concur in the belief that the usual path of infection is through the blood stream, and there is abundant evidence to warrant the conclusion that this is the most universal manner of renal infection. With a small tuberculous involvement within the body, there are frequently temporary bacillemias. It is therefore easy to appreciate how a kidney, constantly filtering organisms, could under certain conditions become infected.

As to the exact location of the initial lesion within the kidney, there is dispute. Cabot and Crabtree, in their work, seem to believe that experimentally the earlier lesion is at the base of the pyramid between the cortex and is more common in the tubular region. In the massive or ulcerative type the organ becomes converted into multiple cavities, which may communicate with the pelvis, are separated from one another by septa of disintegrating renal or fibrous tissue and filled with necrotic material. This may go on to complete destruction of the parenchyma. If the ureter becomes permanently obstructed before the secretory portions of the kidney have been fully destroyed, tuberculous pyonephrosis results.

Then the organ again may be studded with

\*Read at the meeting of the Walter Reed Medical Society at Smithfield, Va., in the fall of 1922.

numerous firm grayish-white nodules varying in size from one to three or four millimeters in diameter which show little or no tendency to ulcerate.

Total obliteration of the ureter is produced by superficial ulcers which destroy the mucosa and submucosa, leaving intact the muscle wall, the occlusion being affected through regenerative changes with scar tissue formation.

Now, then, what should lead us to suspect the existence of this disease and how are we to establish the diagnosis? Fortunately, there is rarely any great difficulty if we are careful to obtain a complete, accurate history, and then resort to the various methods of examination now at our command.

The disease is preeminently one of young adult life and is by far the most frequent of all purulent renal affections of this period. Not only is it unilateral at the outset in over 90% of cases, but the relative infrequent and extraordinary late involvement of the second kidney is a striking characteristic which has a most important bearing upon the treatment. The disease may long remain symptomless and be first observed through a mixed infection. On the other hand, while still confined to one kidney and in the early stages, it may give rise to any one or all of a characteristic group of symptoms which should lead to its prompt detection.

These may be conveniently divided into (a) local and (b) constitutional symptoms. CONSTITUTIONAL SYMPTOMS may be summed up as follows: Irregular fever, night sweats and lastly emaciation.

#### LOCAL SYMPTOMS:

*Frequent and painful urination*, present both night and day. The pain is referred along the course of the ureter and to the neck of the bladder, coming, as a rule, at the end of urination.

*Haematuria*. Intermittent haematuria without obvious cause should always be suggestive of renal tuberculosis, as this may be the first symptom. The bleeding is continuous for days or weeks at a time, differing from haematuria associated with calculus, and total instead of terminal which usually signifies some bladder lesion.

*Pyuria*. Pus is present at some time in all cases, the urine is pale, low specific gravity and usually acid, but may become alkaline through a mixed infection. The pain in renal tuberculosis is dull and aching in character and may radiate along the course of the ureter. It

may be colicky in type and very severe when the ureter may become blocked by a blood clot or caseous material thrown off from a disintegrating kidney.

Tubercle bacilli can usually be demonstrated in the urine if persistent and repeated search is made from the twenty-four hour specimens. Crabtree claims they can be found in practically all cases if the urine is allowed to stand for a while and, after pouring off the supernatant fluid, the sediment be centrifuged by high power for one to two hours. But we must not forget that it is possible for tubercule bacilli to be excreted in the urine by a healthy kidney which is not tubercular. If we fail to find the bacilli in the urine we must then resort to animal inoculation; the disadvantage of this test is the time required.

When the disease invades the bladder, we have the symptoms of cystitis. There is frequent, urgent urination night and day, associated with great pain both during and at the end of urination. The viscus becomes extremely intolerant and irritable and robs the patient of all restful sleep. Emptying the bladder affords little or no relief and, as the disease advances, marked strangury and tenesmus dominate the symptom-complex.

Cystoscopy is an invaluable aid in enabling us to determine accurately certain points: first, to make a positive diagnosis; second, to determine the location, extent of renal involvement, and third, to investigate the functional activity of one or both kidneys.

In advanced cases the bladder is so intolerant of instrumentation that an anesthetic may have to be given; spinal or sacral usually suffices. In the early stage we usually find the ulcerations of the bladder, which are either discrete or grouped around the ureteral orifice or trigone as minute, slightly elevated, greyish-yellow nodules, surrounded by a zone of hyperemia. This tendency to localize around the ureteral orifice or trigone is of diagnostic value.

If the case is examined when the disease is still confined to the region of one ureteral orifice, pictures are seen which may be considered practically diagnostic. Thus ulceration confined to this region indicates that the kidney of that side is almost surely diseased. A puffy red ureteral orifice in an otherwise healthy looking bladder is very suggestive. So also is the retracted crater-like ostium. Then again the orifice may be enclosed in a circle of little vesicles or the so-called bullous-edema, which

is almost pathognomonic of descending renal tuberculosis. Catheterization of the ureter with a comparative study of the urine collected from both sides, by volumetric, bacteriologic, chemical and microscopic methods, is of the greatest help in establishing the diagnosis, revealing the extent of the disease and the competency of the non-infected kidney. So, too, we can observe directly the exact time of appearance in the urine of indigo-carmin or phthalein that has been given hypodermically. We may also by injecting some opaque substance into the kidney pelvis, such as 25% sodium bromide (which is the least irritating of all), determine the amount of dilatation, and the outline of the calyces.

TO SUMMARIZE: We should take a careful history; make a general physical examination to disclose a primary focus elsewhere in the body; measure the bladder capacity which is greatly reduced; note a contracted, irritable viscus intolerant of instrumentation, a cystitis resisting or even aggravated by treatment especially the silver salts, and the persistent acid pyuria from which no organisms grow on ordinary media, associated with the other urinary findings already given. We should also note the cystoscopic findings, and the impaired kidney function with the radiographic disclosures, and finally the use of tuberculin in proper selected cases. If after exhausting all these measures the surgeon is still uncertain, it is a perfectly legitimate procedure to investigate it directly through an exploratory lumbar incision.

TREATMENT: The most important feature in the surgical outlook of the tuberculous subject is the finding of a unilateral tuberculous kidney and finding it early before the late results have become manifest. Some authors advise the removal of the most diseased organ in bilateral tuberculosis but others believe this to have very little effect on the other organ. In bilateral tuberculosis surgical efforts do little, except for renal drainage, to protect a seriously bothered bladder.

The length of operation is very important, especially in regard to the anesthetic. Careful dealing with the perirenal fat is very important, since it has been definitely shown that many of the persistent tuberculous sinuses are due to infection in the remaining fat. As far as possible the fat should be removed. Treatment of the ureter varies with the different cases. Many amputate low down as possible

and do not drain. It is useless to try to remove the entire ureter as the most important part has to be left, that is the intramural part, and most authors feel that such removal is unnecessary. The bladder lesions usually heal after the removal of the tuberculous kidney, the time being in proportion to the severity of the infection.

Tuberculin after operation is claimed by some to be of much benefit, as it seems to hasten the healing of the wound and the amelioration of the bladder symptom. For the painful bladder, I know of nothing better than mercurochrome. Such patients are all put in the sunlight and under the usual tuberculous hygiene.

### BACILLUS ACIDOPHILUS AS A THERAPEUTIC AGENT.\*

By GEORGE F. REDDISH, Ph. D., Richmond Va.  
Associate Professor of Bacteriology, Medical College of Virginia.

At the last annual meeting of the American Association for the Advancement of Science (December, 1922), Dr. A. B. Macallum, of McGill University, chairman of the section of Physiology and Experimental Medicine, took as subject for his address "The Urgency of Research on the Great Portal to Disease in the Body, the Intestinal Mucosa."<sup>1</sup> This is by no means a new idea to most physicians and bacteriologists alike, but Dr. Macallum is so positive in his claims that this channel is of first importance in the introduction of many diseases, that it seems worthy of serious consideration. He first calls attention to the fact that the intestinal mucosa when functioning properly is capable of warding off the poisons elaborated in the intestines as a result of putrefaction caused by certain of the intestinal bacteria; because of this selective action, it is capable of protecting the body from these harmful products. After being continually subjected to the action of such poisons, however, these cells gradually lose the property of functioning in this way, and then some or all of these products pass into circulation, giving rise to many and varied complications. Dr. Macallum<sup>1</sup> states further:

"It is not too much to say that in this failure on the part of the epithelial cells an explanation may be found of the origin of a large number of diseases of the body. It is my firm conviction that arteriosclerosis, hepatic cir-

\*Read before the Richmond Academy of Medicine and Surgery, February 23, 1923.

rhosis, acute yellow atrophy of the liver, nephritis in some of its forms, angina pectoris, senile dementia and dementia precox are all due to failure, more or less pronounced, on the part of the intestinal epithelial cell to play its normal part. In some cases this failure may develop suddenly as in acute yellow atrophy, in other cases it may involve a gradually lessened capacity of the epithelial cell to reject or neutralize the products of putrefactive action. That dementia precox has this origin is indicated by the facts that it is frequently associated with intestinal stasis more or less pronounced and that not infrequently in this disease there may be atrophy of the testes or ovaries, facts that can only be explained by supposing that not only this atrophy but the degeneration of the cortex are due to the action of toxins of intestinal origin. Senile dementia, when not of arteriosclerotic origin primarily, is probably due to a gradually lessened capacity of the intestinal cells to reject the toxic products of putrefactive fermentation."

"The intestinal mucosa must then be regarded as the great portal to disease of the body. This portal may be completely closed as it is in the normal healthy condition of the mucosa or it may be gradually or suddenly pushed open and disease, chronic or acute, may result. If this portal could be kept closed always old age might be indefinitely postponed and bodily vigor maintained for a much longer period than it is now. There is no reason to suppose that the heart, the skeletal muscles, the liver, the kidneys, the nervous system and the endocrinous organs cannot function indefinitely if they are not subject to toxic action and in their normal condition they must be much less subject, through any other portal, to bacterial infections than they are when their condition is altered by the access of toxic material absorbed from the intestinal cavity. The complete closure of the great portal permanently maintained would greatly lessen the incidence of disease and increase the average length of life."

"It is probable that excess in diet, especially in its protein constituents, may task the capacities of the epithelial cells and diminish their power to react normally, with the result that they allow to pass through them, and to the underlying tissues and the circulation, the products of intestinal putrefaction which in

their healthy vigorous condition they do not permit to enter them. This would explain some of the pathological results of a high protein diet. It is also very probable that the primary and most important action of vitamins in diet is on the epithelial cells which, with the glandular structures below them, as McCarrison has found in his observations on animals fed on autoclaved food, undergo marked atrophic and necrotic changes, followed by an extensive invasion of the mucosa by bacteria. The changes which other organs show in avitaminosis have yet to be shown due directly and not indirectly to their deprivation of the vitamins. Once the Great Portal is thrown wide open, neuritis, degenerative changes in the pancreas, thyroid and spleen, atrophy of the testes and ovary, and hypertrophy of the pituitary and adrenals may be of toxaemic origin. Constipation also seems to be one of the earliest results of avitaminosis and its causation may be similarly explained."

That toxins of intestinal origin are a factor in many of the diseases mentioned above, as well as other less definite complications, is well-known to the medical profession. As a factor in promoting health and in prolonging life, the condition of the intestinal canal must be given primary consideration. Just what condition in the intestines is most favorable for normal life, for good health and for a possible long life? The tendency at the present time among bacteriologists and physicians is to consider a simple bacterial flora in the intestines as one of the most important factors to be included. Granting that there may be other factors of equal importance which may be developed later on, some recognition must be given to the very conclusive data already at hand to support the claims for a simplified flora as an aid to this end.

As already indicated, the intestinal bacteria which cause putrefaction are the real cause of the above diseases which result from absorption of toxins through the intestinal mucosa. The first object, therefore, would be to eliminate the cause of the poisons which were being elaborated. The use of intestinal antiseptics is not recognized as efficient for this purpose, and the value of their use has even been definitely discounted through careful experimental work. Fantus<sup>2</sup> has shown that calomel does not exert a germicidal effect on the intestinal bacteria when administered in the usually

prescribed dosage. It was also found by Dragstedt, Dragstedt and Nisbet<sup>3</sup> that the usual antiseptics employed for hand sterilization would not destroy bacteria when placed directly within a section of the intestines of dogs. It was found that dogs died from toxemia of bacterial origin from closed segments even when these strong antiseptics were added and held for certain lengths of time. It seems, then, that other agents besides intestinal antiseptics should be resorted to in checking the activities of these harmful bacteria.

Within recent years, results of research on changes in intestinal flora due to diet have shown that the flora can be materially changed if the proper diet be consumed. It has been shown by Rettger<sup>4</sup> and his colleagues, at Yale, Torrey<sup>5</sup> and others, that a high carbohydrate diet will yield a change in bacterial flora from one consisting largely of putrefiers and gas formers, to one composed almost entirely of aciduric types. Such a change can be brought about readily by the administration of large amounts of milk sugar. Rettger has shown that a similar result can be secured by the ingestion of young milk culture of *B. acidophilus* even more readily than by means of high carbohydrate diet. At present, the latter method is decidedly more popular than the former, not only because of the better results obtained, but also because of the more palatable taste of the latter and more agreeable effects. Broth culture has been used by Gompertz and Vorhaus<sup>6</sup> with very good results. So far, experience has shown that *B. acidophilus* is more viable and lives longer in milk than in broth culture, and decidedly better than in such commercial products as are being put upon the market in various forms. The activity in the commercial field is indicative of recognized merits of the principle, but unfortunately most of the products are of questionable value. Those commercial products which have lactose or dextrin as their principal constituent are of value, but the price charged is somewhat out of proportion to the cost of the constituents. The number of reliable concerns which are interested in this matter is indicative of a deep interest in this therapeutic agent.

Admitting that it is usually not advisable to go against the laws of nature, and that constipation and a putrefactive flora are normal to

adults, it still is not illogical to attempt to prevent premature old age, and such conditions as arteriosclerosis by producing an infantile condition in the intestines. In fact, this would seem entirely logical, and certainly has been of definite benefit clinically in a large number of cases. At the present time, this measure seems to approximate the ideal suggested by Macallum as a means of preventing degeneration of the intestinal mucosa more nearly than any other at hand. Therefore, it seems that this agent should receive a thorough trial clinically in the hands of the practicing physician and, should it prove to supply the necessary means to bring about the desired result, be accepted into his general practice as a permanent treatment for such types of disorders for which it is suited.

#### THE CONTUSED ABDOMEN.

By E. B. CLAYBROOK, M. D., F. A. C. S., Cumberland, Md.

In March 1913, I read a paper before the Eastern Panhandle Medical Society, at Martinsburg, W. Va., the title of which, was "Injuries of the Abdominal Viscera, Without External Evidence of Injury." At that time, I reported eight cases and referred to two others previously reported that had occurred in my practice.

In a paper read before the Southern Medical Association in Asheville, on injuries of the

spleen, I reported four cases of this type. In looking over my records, I find that since these reports I have operated on seventeen other cases of visceral injury without external evidence. These injuries varied from small tears in the mesentery, to large tears in the bowel and liver. There was one case of severe laceration of the kidney.

Therefore, it seems that such injuries are quite common in occurrence and, if I may judge from the few referred cases I have seen, they are very often overlooked. One young man that I saw after three days, had been tussling with a fellow workman, when he was struck in the abdomen by the knee of the other man. He went to a doctor's office and after casual examination was sent home without a diagnosis. One day later he was quite ill and sent for another doctor who treated him two days before calling consultation. The consultant ordered him to the hospital at once, and when he arrived he was operated on immediately. The abdomen was full of fluid and coarse undigested food, from a tear in the jejunum about one inch long. This man died of peritonitis which could and should have been prevented.

The chief thing for us to consider, as industrial surgeons, is that such cases are not rare, and we can not too strongly urge a careful watching, and frequent examinations of any patient that has suffered an injury to the abdomen. The diagnosis in these cases must be made on the history and *early* clinical signs, if the patient is to have a fair show for his life.

The literature gives symptoms that, if waited for, will be followed by death, even if operation is done. Hence, we must re-model our ideas of the clinical picture which presents. Most writers stress rapid pulse, temperature, abdominal facies, absent liver dulness and severe shock among the symptoms. These are symptoms of severe hemorrhage or peritonitis. The patient should be operated on before getting into this condition. The history usually shows that the man has had a blow on the abdomen, has been squeezed through the body, has been run over by a vehicle, or has had a fall upon the abdomen.

I saw two cases, in which the patient fell, striking on the abdomen. One fell off a car, and the other fell over a fence. Both suffered large tears in the bowel. Another man merely

slipped while standing up in a horse cart, striking the front of his abdomen against the front of the body of the cart. He had a tear in the ileum two inches long. The violence is often seemingly slight and hardly worth considering.

The SYMPTOMS must be considered from the standpoint of those that may be observed early, because here is a condition in which the diagnosis must be made early in justice to the patient. Consequently, to my mind there are only five symptoms of first importance that should be looked for in these patients. There are a few others which have bearing on the case, and may aid in its interpretation. I will take these up in the order of their importance.

(1) *Transmission of heart and respiratory sounds*, so that they may be heard all over the abdomen. This sign may be absent in severe injury and may be present with a fairly slight amount of trauma in the abdomen, with a small hemorrhage. If it is present and well marked, there is always accompanying injury: and it of itself is a strong indication for exploring the abdomen.

(2) *The Silent Abdomen*. The entire absence of peristaltic sounds always means trouble, but we may have very active sounds with severe injury, at times. If the patient has had morphine, this may lessen peristalsis, but will never obliterate all sounds.

(3) *Tenderness*. This of course, may come from muscular contusion but, if marked, localized and elicited by firm rather than light pressure, the inner organs are probably its source; and its location is a fair indication of the point of injury, as a rule.

(4) *Rigidity*. This may be present or absent. If present, it may mean contusion of the abdominal wall, but in that case it is not marked and is not accompanied by the transmission sign, or the silent abdomen. The history will help in the decision.

(5) *Vomiting*. This usually occurs until the stomach is emptied. It is then absent, until peritonitis induces late vomiting. The vomited material is usually ordinary stomach contents, though in some cases, when the contusion is high up and severe, it may contain blood. Usually, when blood is vomited, if a careful examination is made, a concomitant injury of the mouth or pharynx will be demonstrated, the blood having been swallowed.

These five symptoms, to my mind, are the

most important, in arriving at a diagnosis. While pain may be a help, it is rather unreliable, except as taken in consideration with the foregoing.

Dr. S. S. Gale, of Roanoke, Va., suggested that a blood count is of great value. In cases where there is severe internal hemorrhage, we would get a high white, and a low red count. This may at times be of great assistance, but many of the cases of bowel rupture show practically no hemorrhage at all. It is possible to have quite a dangerous injury with no blood reaction, until some hours allowed the development of peritonitis, followed by leucocytosis.

The bladder in all cases should be catheterized to exclude rupture or a tear in the urethra.

**THE DIAGNOSIS.** This must be made early and we must arrive at our decision through a consideration of those symptoms that arise early. We must remember that the early symptoms, whatever the injury, are due solely to the irritation of the peritoneum by fluid contents of a hollow organ, or the outpouring of blood into the free cavity.

First the history. Did he get a fall? Was he squeezed in a close place? Did he have a blow on the abdomen, or was he run over by a vehicle? Did he vomit; if so, how often and how soon after the injury? What was the nature of the vomitus?

This, followed by a careful auscultation and palpation of the abdomen, will give us as good an insight into the case as we can get.

If he has either the silent abdomen, or the transmission sign with rigidity, or tenderness, and the history is such, as to lead to a strong suspicion of visceral injury, then I feel that it is right to make a tentative diagnosis of visceral injury: and exploration should be done.

If there is strong doubt as to visceral injury, then the man should be placed in a hospital under careful watching. He should be seen by the doctor hourly, until he feels assured that there is no injury to the organs.

I do not mean to advocate promiscuous opening of the abdomen; but I do feel that too many men are allowed to die annually, while the attendant is waiting the development of symptoms which will assure the diagnosis. When conditions justify an assured diagnosis, it is often too late to operate, and the dire

prediction so often seen in the newspapers, "Mr. Jones, injured internally, will die," is promptly fulfilled.

I have opened two men that showed no special injury (except small bleeding) that would have caused any serious trouble if left alone. I feel that no injustice was done these men. They had other injuries that complicated the findings.

In operating on these patients, one must be prepared to do anything, from plain packing, or ligation of a bleeding point, to a re-section of the bowel, or nephrectomy. I feel that we can never be more explicit in our diagnosis, than that some internal organ is injured.

### TRACHEOTOMY; IMPROVED TECHNIQUE.

By ELBYRNE G. GILL, M. D., Roanoke, Virginia.

There are times when all laryngologists are called upon to perform a tracheotomy in cases when intubation will not answer:

(1) When intubation tubes are not available or their use is not understood.  
(2) In excessive edema of the larynx when the intubation tube does not relieve.

(3) When the membrane is in the lower tracheal track.

The accidents which may be incident to this operation are:

(a) Failure to open the trachea, especially in very fat children.

(b) Severe hemorrhage when the incision is carried too far to either side.

(c) Irregular incision making it difficult to introduce cannula.

(d) Asphyxiation from blood escaping into the trachea.

(e) Asphyxiation from collapse of the trachea.

(f) Septic pneumonia or lung abscess caused by the escape of blood and infected material into the trachea and bronchi.

The above complications can be avoided, also the haste in performing the operation can be obviated, by employing the following technique:

1st. Before performing the operation, introduce the bronchoscope and allow it to remain in the trachea and bronchus until the operation has been completed.

All that is necessary in employing this technique is to be equipped with one broncho-

scope, one laryngoscope and a pocket battery, with its connections. A competent laryngologist should be able to expose the larynx and introduce the bronchoscope in one minute's time.

When the bronchoscope is once introduced, there will be no need for undue haste in performing the tracheotomy as the patient will have been provided ample breathing space and the operator will have a firm land mark to follow in cutting down on the tracheal rings. After the incision has been made through the tracheal rings and all bleeding controlled, the operator can then remove the bronchoscope to the point of the incision and then introduce the tracheal cannula and this completes the operation.

The incision should be made low, following the method described by Jackson. If this is done, a tracheotomy will be performed and not a laryngotomy.

As far as the writer has been able to learn this technique is not being employed and has not been mentioned in any recent text book on laryngology.

### THE IMPORTANCE OF THE GLANDULAR SYSTEM AND A PLEA FOR THE PRESERVATION OF THE TONSILS.\*

By J. E. COPELAND, M. D., Round Hill, Va.

The glands of the human body perform an important part in its economy, but the functions of the great majority of its six hundred glands is shrouded in mystery and a knowledge of their physiological actions is often discovered only by the effect of some pathological condition of their structure. The functions of the glands afford a wide field for the physiologist and clinician and the most imaginative theorist has scarcely dreamed of their agencies in the development of the human body and the importance of their maintenance of it in health. While glandular therapy has received considerable attention, many discoveries have, unfortunately, been utilized by drug mongers who exploit their products for profit. Nevertheless, there is efficacy in a number of glandular preparations, if properly administered.

Recently we read that an eminent investigator claims that a criminal tendency is

caused by diseased glands. We are all familiar with the fact that, in certain diseased conditions of the glands, other remote glands of the body with which no anatomical connection can be, or at least, never has been demonstrated, are seriously affected. For instance, parotitis when confined to its original habitat, the parotid gland, is more or less mild and, so far as is known, a harmless disease, but when in its course a metastasis supervenes, which is not an infrequent occurrence, grave and irreparable injury to the procreative organs of the male results and in this event the testes become involved, epididimitis occurs, the spermatic cord is obliterated, or at least its function is impaired, and sterility results. In females a metastasis affects the mammary glands and, if the subject be a nursing woman, the milk dries up and the glands cease to function. Normally, the thymus gland atrophies at puberty, but if from faulty metabolism it retains its original size or increase in bulk, we find enlarged bones, muscles of the face, hands and other parts of the body, which condition is known as acromegalia. Just here we can not refrain from a digression to remark that the phrase "faulty metabolism" is a very valuable acquisition to the vocabulary of the physician and that we should thank the inventor for its coinage and that he claims no patent right on its use, as it serves to conceal our ignorance and often satisfies our patient's curiosity. If the thyroid gland atrophy, myxœdema with its attendant tremors, œdema, leucosis and, in the female, suppression of the menses, results. On the contrary, if the thyroid gland enlarge, we have exophthalmic goitre, protrusion of the eye balls and tachycardia with all their attendant evils. In Hodgkin's disease, we have hypertrophy of the lymphatic glands of the body due to the growth in them of adenoid tissue, which, if the patient survive a sufficient time, extends to other glands, notably the liver, spleen and kidneys, accompanied by anaemia, emaciation and death. If the suprarenal glands atrophy, we have Addison's disease with its bronzed skin, weakness and death. The eminent physiologist, Brown-Sequard, who was a Professor in the Medical College of Virginia, first demonstrated that by irritating the diminutive pituitary gland with "a bare bodkin," produced polyuria. In addition to the above, we might adduce more examples, but these should suffice to invite attention to the im-

\*Read before The Loudoun County, Virginia, Medical Society, November 7, 1922.

portant and, in many cases, the indispensable part that the glands exercise in the growth and health of human beings and also of the lower animals.

In February and March 1880, an endemic of follicular pharyngitis in many cases of which the tonsils were involved prevailed over a radius of five or six or more miles that included Rectortown (at which place I was at that time located) and Delaplaine and a portion of the Cobbler Mountain in Fauquier County, Virginia. The following summer a young doctor located at Delaplaine and, like most young doctors, he had a poorly equipped armamentarium, but was the proud possessor of a tonsillotome which he used indiscriminately on numbers of persons whose tonsils were enlarged from the endemic of the previous winter. I advised my patients against the operation. Previous to the endemic I read in *The Hospital Gazette* a lecture by an eminent professor in New York, on follicular pharyngitis and tonsillitis, in which he condemned tonsillotomy as rendering the patient sterile. I have ever since that time (nigh unto one-half of a century) watched the effects of tonsillotomy and can give many instances that have come within my cognizance, of this result of the operation. I need not particularize but will mention one instance that will serve as an example. Several men were present in a store at Oak Hill within the bounds of this endemic. One of them remarked that a son of a neighbor had tonsillitis. Another remarked that he should have his tonsils cut out and asked my opinion of the operation. I hesitated but finally replied in plain language that it would render him incompetent to fulfil the Scriptural injunction to "Be fruitful and multiply and replenish the earth." My assertion caused some confusion which I ascertained was occasioned by the fact that three of the men who were present had had their tonsils removed, had subsequently married and, after a lapse of several years, their wives had not become pregnant. Similar cases were mentioned by others who were present. Of course, as in the case of the ovaries, if a portion of the tonsil be left intact it may continue to function. The fact that after the menopause is established the tonsils atrophy and no remains of the tonsil can be recognized proves that there exists some connection between the function of menstruation and the tonsils.

Tonsillitis is evidently connected with a rheumatic diathesis which develops during the gormandizing period of childhood and youth and later, from similar or other causes, manifests itself in rheumatism or gout. The treatment of the one is applicable to the other. Give salicylate of sodium and colchicum. In young girls tonsillitis is often complicated with some menstrual disturbance. In these cases give guaiacum.

On October 6, 1922, Charles E. Page, M. D., Boston, Mass., writes that "Dr. John N. Mackenzie, a distinguished physician, a throat specialist and professor in Johns Hopkins University, in an address declared that the operation on the tonsils is 'a surgical insanity' and gave his reasons in detail, the chief point being that the tonsils are very important and useful organs and that there is no more occasion for the removal of an inflamed tonsil than an inflamed eye."

Tonsillitis is an affection peculiar to childhood and adolescence and frequently to newly married people and generally in time vanishes, as it were, of its own volition. If, however, pus supervene and enlargement persist, lance and drain it as you would an abscess of any other part of the body, but leave intact as much as possible of the stroma on which depends the secretion and function of the glands and which is undoubtedly connected with the procreation of the species. I am aware that this assertion is contrary to the opinion and practice of physicians generally, but let them watch the effects of tonsillotomy and they will or should cease to emasculate the innocent, helpless and confiding children and will teach parents the steriizing result of this deleterious practice.

**Railroads grant reduced rates to our meeting in Roanoke. It is necessary that each member secure from the office of the State Society a certificate establishing his membership. This privilege will not be granted again unless our members generally use it.**

## Proceedings of Societies

### The Nelson County Medical Society,

At its regular meeting in July, elected Dr. H. G. Dickie, Massies Mill, president for the ensuing year, and re-elected Dr. J. F. Thaxton, Tye River, secretary-treasurer. Dr. J. B. Woodson, Lowesville, was elected delegate to the Roanoke meeting of the Medical Society of Virginia, and Dr. D. C. Wills, Arrington, was elected alternate.

The Society held a special meeting August 13th. for the discussion of the Schick test and the administration of toxin-antitoxin in the prevention of diphtheria. Dr. George Payne, of the State Board of Health, was present at this meeting and gave a demonstration of the test and also administered the toxin-antitoxin to several of the Lovingson school children. Dr. Payne was also present at another meeting August 20th, at which time the results of the Schick test were observed.

The Society will meet again the fourth Monday in September.

J. F. THAXTON, *Secretary.*

## Secretary's Announcement.

### Reduced Railroad Rates to the Meeting in Roanoke.

As a result of much hard work on the part of Dr. J. Beverly DeShazo, of Ridgeway, Virginia, the railroads have granted reduced rates on the certificate plan for our meeting in Roanoke. Members may secure from the office of the Society a certificate which on presentation to ticket agents will enable them to purchase round trip tickets for themselves and dependent members of their families at one and one-half regular fares. Last year we did not comply with the requirements of the companies as to the number using the certificates. *It is essential that every member who attends get one of the certificates. A postal request is all that is necessary. We are so anxious to get them to the members that we pay the postage and provide the envelopes. If you find later that you are not going, possession of the certificate will do you no harm. If we do not get 250 members to use the certificates this year the*

*privilege will be withdrawn and in the future our members will invariably pay full fare. One certificate is all that is necessary for a member and any number of dependents who may accompany him.*

### The U. S. Civil Service Commission,

Washington, D. C., announces that applications will be received until December 28 for Junior Medical Officer, to fill vacancies in the Indian Service. Competitors will not be required to report for examination, but will be rated on their education, training, and experience. Full information and application blanks may be secured from the above named Commission.

## Editorial

### Insulin in Juvenile Diabetes.

A sick child appeals to every one. the world over. The scientific development of pediatrics within the last score of years has done much to lessen illness and death among the children of civilized countries. Infants now receive a more balanced ration. The infant's food, whether breast-fed or non-breast-fed, is more carefully managed and administered. The protection of milk from bacterial changes, the proper modification and balancing of infant feeding, the hygienic and physical control of the environment and bodies of infants has done a large part in reducing the high incidence of acute illness and mortality among children. Besides, from infancy through juvenile years, greater scientific care is now exercised in feeding, in weighing and measuring, in eliminating sources of infection such as infected tonsils and teeth, in searching for and correcting constitutional diseases such as tuberculosis, and in righting and adjusting physical deformities in the years of growth and development.

All of these accomplishments have heartened and brightened every one as these vast improvements in child growth and child physical culture have been observed during the past decade. But in the midst of the optimistic view of the great advances in this field, one dark spot, juvenile diabetes, has persistently remained. While the progress in and success of the fight against the diseases of infancy and childhood has been won in many diseases, the

ominous disease of diabetes, yet casts its long shadow across the path of childhood, for juvenile diabetes has usually been fatal.

Is insulin to change this? One may read Geyelin's\* paper and take hope. The paper is based on the observations made of nine children from two to sixteen years of age. The type of diabetes in each one of his cases was severe. The inherent progress of these cases seemed to be in keeping with the type, being progressively worse. In the nine, and in thirty odd additional cases, there have been no therapeutic failures. In the group of cases forming the basis of the report under review, there was

Fig. 1.  
Geyelin's case before insulin.

a definite and continuous gain of weight. The gain in weight in his cases varied, but it was present. The gain was, of course, influenced by (1) length of time patient was under treatment and control, (2) age and original weight and condition of the child, (3) the amount of insulin and amount of food given. The gain of weight in the group ranged from two pounds in three months to twenty-two pounds in seven months. In this connection there was observed a commensurate increase in muscular strength and physical vigor, and also in mental well being. In addition to this, there was

\*"The Use of Insulin in Juvenile Diabetes." The Jour. of Metabolic Research. Nov.-Dec. 1922, p. 767.

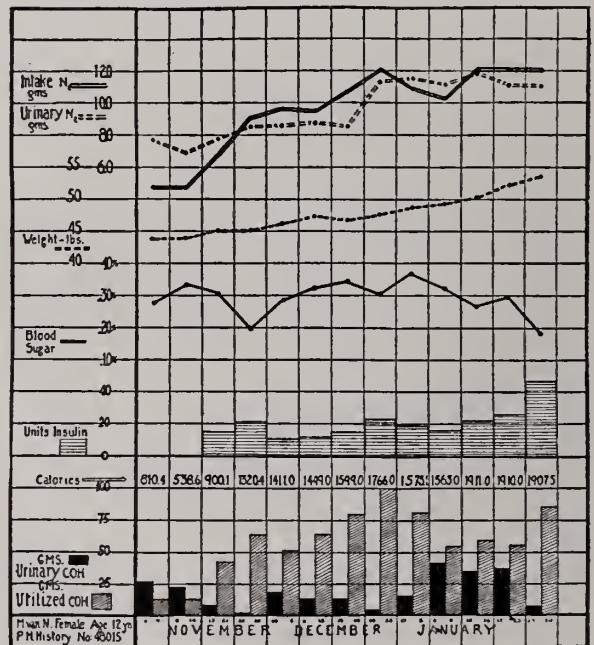

noted a definite increase in the carbohydrate tolerance, varying with severity of the case and amount of insulin given. Insulin treatment and diet adjustment seemed to arrest the downward course of the disease. Let us quote Geyelin, Case VI, for it has an effective lesson to teach:

"Case VI. M. V. N. Age 12 years. Presbyterian Hospital History No. 48015. Date of onset: (1) By symptoms—October 24, 1920. (2) By urine analysis—November 5, 1920. Followed since November 8, 1920.

*History and Summary of Pre-Insulin Course:* Grandmother a diabetic. Patient was a normal, healthy child, whose best weight at 12 years was 57½ pounds. Onset of diabetes was sudden, two weeks before her admission to the hospital. Polyuria was first noted, two days later polydipsia and polyphagia began. She lost four pounds in two weeks. Glycosuria was discovered, three days before admission, by a local doctor, who put her on a diet high in fat and low in carbohydrate. On the second day of this diet she became drowsy, was nauseated, and vomited. On admission she was drowsy, but could be roused. Cheeks were flushed, lips very red, tongue dry, eyeballs soft, heart rapid, breathing very deep with acetone odor to breath. Examination was otherwise negative. She weighed 53.5 pounds. Her fluids were forced to 3,000 cc. per day. She was given sodium bicarbonate, 26 gm., and put on a diet of carbohydrate, 70 gm., protein, 30 gm., fat, 0 gm. for 3 days. Blood CO<sub>2</sub> rose from 10.9 volumes per cent to 57.6 volumes per cent. Blood sugar remained at 0.380 per cent. There was great clinical improvement. Urinary sugar disappeared after a day on carbohydrate, 30 gm., protein, 10 gm., fat, 0 gm. and one day on carbohydrate, 10 gm., protein, 10 gm., fat 0 gm. After one complete fast day, the diet was gradually raised to carbohydrate 80 gm., protein, 24 gm., fat, 10 gm., before sugar reappeared. She was discharged after one month, sugar-free on carbohydrate, 30 gm., protein, 50 gm., fat, 60 gm.

She was treated in the out-patient department, and was sugar-free for the next eight months, on a diet which was gradually raised to carbohydrate, 50 gm., protein, 65 gm., fat, 110 gm. Her weight rose to 56.5 pounds. Two blood sugars during this period were normal. Toward the end of this time (August 1921), her tolerance began to fall, until, one year af-

ter onset (November 1921), she showed sugar on carbohydrate, 20 gm., protein, 35 gm., fat, 35 gm., and was sugar-free on carbohydrate 10 gm., protein, 25 gm., fat, 25 gm. Acetone was always present in the urine from about this time on. In November 1921, she had a tooth extracted, which proved to have a pus sac at the root, and during the next few months she suffered from frequent colds. In the first six months of her second year she was kept on a gradually decreasing diet with frequent fast days, and was admitted to the hospital in May 1922, showing sugar on carbohydrate, 20 gm., protein, 20 gm., fat, 50 gm. Physical examination was negative, weight 46 pounds, blood

Case VI

sugar 0.298 per cent. On a diet of carbohydrate, 14 gm., protein, 20 gm., fat, 90 gm., her daily urinary glucose averaged 28 gm. Her carbohydrate was cut to 7 gm. with no effect on the glycosuria. She was then put on carbohydrate 0 gm., protein, 20 gm., fat, 20 gm., on which she became practically sugar-free after six days. She was kept on this for 14 days in all, and then remained sugar-free for 5 days on carbohydrate, 5 gm., protein, 20 gm., fat, 30 gm., but began to show sugar on carbohydrate, 5 gm., protein, 30 gm., fat, 35 gm., and continued to show a daily output of 20 to 30 gm. of sugar on carbohydrate, 6 gm., protein, 25 gm., fat, 50 gm. She was discharged on carbohydrate 5 gm., protein, 25 gm., fat, 60

gm., weighing 51.75 pounds, and in the next two months showed only a trace of sugar most of the time though her diet was raised to carbohydrate, 7 gm., protein, 30 gm., fat, 65 gm. It should be noted that her urinary volume during this time was very large.

Third admission October 31, 1922, for insulin therapy. During a control period of two weeks before insulin was started, daily urinary sugar averaged 25.6 gm. on a diet affording 39.15 gm. available carbohydrate, with average daily nitrogen loss of 2.6 gm. This made the utilized carbohydrate 13.6 gm. Blood sugar averaged 0.297 per cent and blood  $\text{CO}_2$  48.7 volumes per cent. Weight was constant at 44 pounds. Basal metabolism—38 per cent.

Fig 2  
Same case four months after insulin.

Average urinary volume was 5,000 cc. with consequent great loss of heat. Clinical condition was characterized by extreme weakness and lethargy.

*Course under Insulin Therapy:* Chart shows increase in weight and carbohydrate utilization coincident with insulin therapy. Positive nitrogen balance is attained. The maximum insulin effect is seen at the end of the second month, and is followed by three weeks of relatively delayed progress, with return to negative nitrogen balance. The gain in weight was

uninterrupted and was not accounted for by fluid retention. During this period, on account of shortages in supply, insulin therapy was several times interrupted for a day or two at a time. Over the period covered by the chart gain in height was about 3 cm. Distribution in diet of carbohydrate, protein, and fat in last three weeks of chart was, carbohydrate, 50 gm., protein, 75 gm., fat, 150 gm.

*Abscesses at site of injection:* None.

*Independent infections:* January 22, acute pharyngitis and cervical adenitis. January 25, maxillary sinusitis; antrum opened, found to contain pus, and irrigated daily from January 25 to February 9.

*Serum sickness:* None.

*Insulin shock:* None."

Allen and Sherrill's\* summary and conclusions on Insulin are:

"1. All of the 79 cases of uncomplicated diabetes in this series have responded favorably to treatment with insulin. There has been only one death, due to flagrant disregard of diet. The increases of diet, weight and strength made possible by the new treatment even in the severest cases are beyond comparison with anything possible under any other known method.

2. Of 9 coma patients treated with insulin, 5 died and 4 recovered. All or nearly all of these cases were evidently hopeless with ordinary treatment, and the saving of lives can be directly credited to the insulin. In most of the unsuccessful cases insulin reduced or abolished glycosuria and ketosis, and the reasons for death under these circumstances are still hypothetical. The necessary dosage in coma cases may run into hundreds of units in 24 hours, the possible limits of safety or usefulness being as yet undetermined. All the measures formerly in use, together with somewhat more glucose or carbohydrate than formerly customary, should be used as adjuncts to insulin.

3. Among 14 cases complicated by local or general infections, there have been 5 deaths and 9 survivals. The higher nutritive level made possible by insulin promises to be especially important for cases of diabetes with tuberculosis. For other medical and surgical infections, notably gangrene, insulin is extremely helpful for bringing glycosuria and other symptoms under control more rapidly and thoroughly than otherwise possible while

obviating the necessity of extreme undernutrition. The limited experience seems to indicate that moderate undernutrition is still beneficial to such cases in conjunction with insulin, at least during the period of chief danger. Emphasis should be placed upon thorough control of the diabetes rather than upon high nutrition. The general resistance and the healing of wounds are no better under insulin than they have been under efficient dietary control heretofore. The incidence of respiratory and other minor infections is perhaps slightly higher than under the former strict undernutrition treatment. The lowering of tolerance which has long been familiar under diet treatment is now represented by an increase of the insulin requirement during infections.

4. We have followed the general principle that treatment should keep the urine normal and the blood as nearly normal as possible. It is seldom feasible with the present methods of using insulin to keep the blood sugar as rigidly normal as with diet alone, especially in severe cases, because of the danger of hypoglycemia, but with care this ideal can be rather closely approximated. All our attempts with lax or inaccurate diets in conjunction with insulin treatment have led to disastrous results. Thorough training regarding the use of both diet and insulin should be given, preferably in an institution, to all patients before they attempt the management of their condition away from direct supervision. After such training patients have proved able to continue the treatment successfully at home, and the average standard of fidelity has been higher than before. *Insulin has tremendously improved diabetic treatment, but has not simplified it.*

5. The occurrence, symptoms and treatment of hypoglycemia, as described by the Toronto investigators, have been confirmed. The avoidance of danger from this cause is ordinarily a simple matter both in an institution and for well trained patients in their homes.

6. Our general standards of nutrition have been, for growing children ample diets for their development, and for adults enough to keep them a few pounds below their original or normal weight and to make them comfortable and fit to work. While gross excesses of carbohydrate are avoided, the diets are nevertheless of agreeable mixed character, and

are planned not in conformity with any fixed rule but rather to suit the empirical needs of each individual case in respect to both composition and total caloric value.

7. The insulin dosage necessary for control of symptoms under the above conditions has ranged between the extremes of 4 units and 70 units per day in different cases. The requirements vary with the severity, the total diet, the body weight, and other known and unknown factors. Our dosage also has been individualized to suit each case, as we believe that all rules based on the glucose value of the diet or any other principle yet known are widely fallacious.

8. Exercise seemed to accomplish an increased utilization of sugar in three cases under insulin treatment, as formerly known under diet treatment. The influence in this direction is only slight, and the chief practical importance of the observations lies in the warning that heavy exertion may increase the danger of hypoglycemia in certain cases.

9. Insulin showed no perceptible influence upon non-diabetic conditions such as kidney disease, cirrhosis of the liver, or neurasthenia.

10. In 3 cases, diabetics seemed to lose tolerance demonstrably when glycosuria was permitted with insulin treatment. Several other patients have shown gain of assimilative power with insulin beyond anything that could be expected with diet alone. There seems to be no chance of real cure unless possibly in certain mild or incipient cases, with which the trials are still in progress. On the whole, when allowance is made for accidental or modifying factors, the insulin requirement of most cases remains fairly constant and the patients return to their former condition if insulin is withdrawn. These observations at least encourage the hope that downward progress can be arrested by suitable use of insulin, and they therefore add support to the theory that functional over-strain is the essential cause of the progressiveness of diabetes.

From a practical standpoint, three points seem worthy of emphasis by repetition. *It is feasible for patients at their homes to remain free from glycosuria and nearly free from hyperglycemia under combined treatment by diet and insulin. Over-nutrition makes freedom from glycosuria difficult, and exposes to acidosis, infection and other dangers. Insulin is a literally epoch-making discovery, which revolu-*

*tionizes the results of diabetic treatment when properly employed, but it cannot atone for lax or inaccurate dietary methods."*

Williams\* Conclusions are:

"1. In the study of any remedy for the treatment of diabetes, the significance of dietary control must be thoroughly evaluated, because with proper regulation diabetics may gain and maintain to a very considerable degree the ability to utilize glucose.

2. It requires from 2 to 4 weeks of careful observation and dieting to determine approximately the maximum diet which will enable a diabetic to maintain a normal blood sugar level and urine free from glucose.

3. If proper dietary control be continued, the diabetic may gain slightly in food tolerance over a period of a year or more or he may decline with more or less rapidity in that time.

4. Because of the foregoing facts, it is difficult to measure with precision the value of insulin in diabetes.

5. A series of 44 cases were studied over periods of time varying from 20 to 250 days. Of these 37 were unusually severe, nine cases being in coma when treatment was begun. The food tolerance of 34 cases had been carefully determined by previous study.

6. Four deaths have occurred. Two of these can be directly attributed to insufficient insulin, and two were from causes unrelated to the diabetes.

7. The 40 living cases have gotten along with far greater comfort and strength than was experienced before the institution of the insulin treatment.

8. The feeding of high diets and attempting to make their utilization possible by large doses of insulin has not been satisfactory.

9. The best treatment, apparently, is a diet which will enable the patient to meet the energy requirements of light work with sufficient insulin to insure the metabolism of the food.

10. Time and frequency of dosage are important. Apparently the action of extract lasts only for a few hours. In severe cases it should be administered at least twice and better three times a day in properly spaced doses.

11. To prevent reactions a higher blood sugar level should be permitted than is customary when extract treatment is not employed.

12. The first effect of insulin apparently is to cause the storage of glucose. Later it may in part be burned. During the night glucose appears to be released from the tissues, leading to a high morning blood sugar and often urinary sugar.

13. Diabetic patients receiving insulin treatment experience a noteworthy gain in strength and well-being which suggests that the body is served in other ways than in the improvement in carbohydrate metabolism.

14. Experience to date does not warrant the conclusion that the natural function of the pancreas in cases of severe diabetes is either increased, regenerated or diminished because of the use of the extract."

Write to office of Medical Society of Virginia, Richmond, for your certificate entitling you to reduced railroad fare to the Roanoke meeting. A postal card request is all that is necessary.

## News Notes

### Roanoke Meeting, Medical Society of Virginia.

Supplementing a former announcement relative to the golf tournament, it is now definitely planned to play a handicap of thirty-six holes. The tournament will begin at 10 A. M. Tuesday, the opening day of the meeting, and an exciting contest is anticipated. Up to the present twenty-three members have signified their intentions of taking part in the handicap, and it is planned that cars will leave Hotel Roanoke about nine-thirty for the Country Club, and that eighteen holes will be played in the forenoon, after which luncheon will be served at the Club, and the remaining eighteen holes will be played in the afternoon. The awarding of the cup will take place at one of the social functions later on during the meeting. It should be borne in mind that since the tournament will take place in the forenoon and early afternoon, the regular program will not in any way be encroached upon.

By the way of a reminder, stickers for use upon mailing matter have been arranged for by the Committee in charge, and a supply will be gladly furnished to those who wish to ex-

hibit and to all others interested in developing a good attendance at the meeting.

The Chairman of the Exhibit Committee announces that the demand for space has been very active and that the exhibits promise to be unusually attractive from every standpoint. The exhibit room is conveniently located, well lighted, and an inspection of the list of exhibitors shows them to be such as will guarantee that the latest and best will be shown in drugs, books, instruments and appliances.

The scientific program promises papers on many interesting subjects, in addition to those in the general symposium on "The Pancreas." Dr. Seale Harris, Birmingham, Ala., and Dr. E. P. Joslin, Boston, have accepted invitations from the president, Dr. J. S. Davis, to attend and present papers. Other visitors may be named at a later date.

In addition to the golf tournament, automobile rides and other entertainments have been arranged for members and the ladies accompanying them.

Be sure to write this office to secure your certificate to enable you to have reduced railroad fare.

#### **Ladies—Attention!**

The ladies of the Auxiliary to the Medical Society of Virginia are invited to attend the State Convention which meets in Roanoke, October 16-19. A large attendance is earnestly requested as a great many matters of importance are to be decided at this meeting. Roanoke is putting forward every effort to give us a royal welcome. It is necessary to have a "get together" for exchange of ideas, to enable us to have a successful organization and vie with our sister states. A great pleasure is in store, as the new president-elect of the National organization, Mrs. J. Allison Hodges, of Richmond, will attend.

In March, notices were sent to the different counties to organize and to notify the State Secretary, Mrs. Burnley Lankford, that they had received the notices and had organized. Very few have given the desired information. At your earliest convenience, please send the names of your organizations, officers, and also delegates who will attend the Roanoke meeting to the State Secretary, Mrs. Burnley Lankford, 530 Shirley Avenue, Norfolk, Va.

It is very important to have this information at an early date in order to form plans for the convention and to give the Roanoke

ladies an idea of the number who expect to attend.

MRS. R. LLOYD WILLIAMS, *State President.*

#### **Woman's Auxiliary, Medical Society of Virginia.**

The above notice to doctors' wives and daughters is self explanatory. At the meeting in Norfolk, last year, the Woman's Auxiliary to the Medical Society of Virginia was formed. The aim of the Auxiliary is to co-operate with the doctors of the State in their efforts "to educate the public in matters of sanitation and health; to assist in entertainment at State, district and county society meetings; to promote acquaintance among doctors' families, that local unity and harmony may be increased." These matters should be of interest to all ladies in members' families.

Won't you attend the Roanoke meeting and learn more of the Auxiliary's work?

#### **Maternal Welfare Work in Virginia.**

In a report recently issued by Dr. W. A. Plecker, State Registrar of Vital Statistics, it was stated that the largest number of sepsis deaths in Virginia during the past ten years was 191 in 1917. Since the placing of midwives of the State under the supervision of the State Registrar, there has been noted a saving of 40 to 50 mothers a year, though this may not be wholly the result of this legislation.

The work begun by the Bureau of Vital Statistics has been taken up by the Bureau of Child Welfare of the State Board of Health under the Sheppard-Towner Act of Congress, the expense being borne by that fund. Mrs. Emily Bennett, a Johns Hopkins nurse, has been placed in charge of this work and is developing it in a splendid manner, building upon the foundation laid by the Bureau of Vital Statistics and working in connection with it. She has been systematically carrying out the Bureau's system of midwife instruction, by courses of lectures given by herself, by county nurses, and by lectures and other forms of instructing mothers and prospective mothers.

The Bureau is anxious to help mothers by sending to all who will request it printed prenatal instructions and booklets. All women are urged to have good medical care.

#### **The Gorgas Memorial.**

The House of Delegates of the American Medical Association, at its San Francisco

meeting, by a standing vote endorsed the plan for the establishment of a memorial to General Gorgas, whose genius stamped out yellow fever in Cuba and Panama, and taught the control of these diseases. The memorial will take the form of a research laboratory and a teaching institute for tropical and preventive medicine, and will be located in Panama on a beautiful site on the Pacific shore, donated by the Republic, President Porras, and the citizens of Panama, who have guaranteed the initial building. This is to be known as the Gorgas Memorial Institute of Tropical and Preventive Medicine.
