SEA FISHERIES.

Sea Fisheries: their Treasures and Toilers. By Prof. Marcel A. Hérubel. Translated by Bernard Miall. Pp. 366. (London: T. Fisher Unwin, 1912.) Price 10*s.* 6*d.* net.

"THE English have long understood that the men of the seaboard are not foreigners, but of the same nation as the men of the cities, the mines, and the fields." So writes Prof. Hérubel in the very complimentary preface to this English edition of his "Pêches Maritimes d'aujourd'hui et d'autrefois." He flatters us somewhat. The heroism, the picturesqueness, and the more striking hardships of fishing, these are pretty well known; but there is little enough knowledge of the working, as opposed to the spectacular, conditions of fishing, and of the fisheries as a trade and an employment. Fishing, to most people, is the special affair of someone else. Nor has the large amount of scientific research into fishery problems been adequately popularised. It has presented, as it were, no report to and for the general public. There is no good bridge between the highly technical Journal of the Marine Biological Association and learned monographs and trade periodicals on the one side, and unsystematic picture-books about fish and fishing on the other. Sharp controversies affecting the livelihood of more than a hundred thousand sea-going fishermen, who land yearly over ten millions' worth of fish, rouse next to no widespread interest, mainly for the reason that so few people know enough about fishing to hold an opinion.

The description given of a companion volume in the "Bibliothèque des Amis de la Marine" applies well to Prof. Hérubel's "Sea Fisheries": —"C'est une œuvre d'intelligente et agréable vulgarisation." It is a work, too, which was as needed in England as in France, and although the author wrote primarily of the French fisheries for his fellow-countrymen, he has so much to say about the English industry, and fishing in any case is so international, that he has produced what is certainly the best book up to the present for giving English readers some precise understanding of their own great fisheries. (But not their small fisheries; his remarks on the French small fishermen, merely transferred to England, are very misleading.) Without undue technicality —and it is so much easier to be technical on technical subjects—he is exceedingly systematic and comprehensive. Starting with the oceanography of the North Atlantic and with a brief survey of fish biology, he works out in some detail the cycle of oceanic life from non-living matter through plankton upwards to food-fishes, and arrives at the conclusion that "fishing-grounds are *regions in unstable equilibrium, when* [*where* in the French] *there is an encounter of two critical conditions,* one biological and the other oceanic"; or where, in other words, the oceanic conditions, such as meeting currents, with a consequent abundance of plankton, and contiguous breeding-grounds and nurseries, are favourable to fish-life, and where, in addition, the struggle to live amongst fish has a favourable issue for the edible species.

It so happens that these conditions are to be found together only where the sea is not too deep for fishing on the so-called continental plateaux. After considering the effect of fishing on the unstable equilibrium, Prof. Hérubel proceeds to lay down the law on fishery problems and regulations, and it may be said at once that his views on these subjects are far more questionable than the view which he presents of oceanic life and fishery operations.

In the second section of the book—and it is this which makes the work so unusually complete—he deals with the human side of the industry; with the fishermen as an integral part of it; with social life on the coast, the chief fishing ports, boats and gear, fishermen, profits, and distribution. Here his recommendations rest on a sounder basis. The scandalous toll taken by the middleman and the imperfections of transport cannot but strike any investigator in England no less than in France; nor can the fishing industry become really prosperous for the fishermen producers as well as for its horde of middlemen until its amazing abuses, its fluctuations and consequent gambling on the markets, are taken firmly in hand. All efforts to improve the fisheries must be more than futile so long as neither the fisherman nor the consumer stands to obtain any of the benefit.

It is a point insufficiently recognised by Prof. Hérubel. He has apparently been misled by the magnitude and the huge turnover, the confusing noise and hustle, of the English capitalistic steam fisheries; so much so, indeed, that he insists on his countrymen adopting their methods, though later on in the book he seems to admit that the more co-operative German and Danish methods are even better. "For one step taken by the French the English take fifty and the Germans a hundred." I do not observe (from his bibliography) that he has studied the 1904 report of the evidence given before the House of Lords Committee on the Sea Fisheries Bill. Had he done so, he could hardly have helped moderating his animus against small fishermen and his desire to suppress them altogether; for it was there conclusively shown that immature flat-fish do at certain ages and seasons congregate on the extra-territorial fishing grounds, and that the destruction of them inshore by all the small fishermen put together is an almost negligible factor compared with their wholesale destruction by the great steam fleets. It is impossible to avoid thinking that Prof. Hérubel's inordinate admiration for the steam fishing companies has led him to take sides with them, and to base his recommendations on the incomplete scientific hypotheses which happen to be favourable to their interests.

As soon, in fact, as incomplete scientific investigations are embodied in recommendations and regulations affecting the livelihoods of men, we meet with the question of fictitious accuracy in an acute form. An average, for instance, is not a substantive quantity, and is not used as such in scientific work; it is only valid for purposes of comparison with other averages similarly obtained. But when it is used in the framing of fishery regulations, its non-substantive character should be plainly realised, the more so since minor legislating bodies are always only too anxious to shelve their responsibilities on their scientific advisers.

Prof. Hérubel affirms that the flounder is adult (*i.e.* can reproduce itself) at $3\frac{1}{8}$ in., the sole at $5\frac{1}{10}$ in., the turbot at $5\frac{1}{2}$ in., &c. The average sole may be adult at $5\frac{1}{10}$ in.; but the average sole is a fiction; soles themselves are adult at somewhere about that size. Or to take a more striking example, Prof. Hérubel states that "400 Iceland herring will fill a barrel, while 800 Channel herring are required"; and that "the herring of one region never show themselves in another region—at all events, not in the form of shoals." Channel herrings do average somewhere between 700 and 800 to a barrel; but as a statement of fact, and not of average, Prof. Hérubel's figures are simply untrue; last winter I could scarcely pack $600\frac{1}{2}$ of Channel herrings into barrels which, this winter, were not properly filled with 900. (It may be worth while to state that a hundred of herrings in Channel ports is 120 fish, and on the barrels a hundred and a half is written $100\frac{1}{2}$.) Suppose, then, it were a question of forbidding fishermen to catch Channel herrings on account of their small average size. Obviously a regulation founded on the average figures would be as remote from actual fact as the much-advertised mean temperature of a certain seaside resort, where excessive heat in summer and withering east winds in the winter combine to produce an *average* temperature that would be delightful to live in if it ever existed there. In a like manner, by using averages and by exchanging terms which are not interchangeable, Prof. Hérubel arrives at the astonishing conclusion that the British fisherman "gains more than *twice as much* as the French fisherman." He does not, of course. He may catch more than twice the worth of fish, but very little of the excess is actually pocketed by himself.

Figures of fictitious accuracy, valid in scientific work, where they are compared one with the other, but not valid in their bearing on human life, are now so much in vogue—not only for framing fishery recommendations—that means should be taken more carefully to define what might be called their human validity. Had Prof. Hérubel done so, his "Sea Fisheries" would have been authoritative throughout instead of authoritative in its presentation, but extremely debatable in some of its recommendations, more especially as regards the small fisheries.

STEPHEN REYNOLDS.

DESIGN IN ILLUMINATION.

Principes de la Technique de l'Éclairage. By Dr. L. Bloch. Translated by G. Roy. Pp. 183. (Grenoble: Jules Rey; Paris: Gauthier-Villars, 1911.) Price 5 francs.

THIS book is a translation of Dr. L. Bloch's "Grundzüge der Beleuchtungstechnik," and although an interval of four years separates the original from the translation, the work was worth doing, as the admirable treatment accorded the subject by Dr. Bloch will secure a prominent place for his treatise in the literature of the subject for a long time to come.

The subject-matter is in strict accordance with the title, a condition not too closely observed in some text-books on illuminating engineering. The author has devoted his attention almost entirely to the development of methods of design of lighting installations from given data, whereby the results in illumination and costs can be predicted with a reasonable degree of certainty.

In the first chapter fundamental quantities and their relations are clearly and accurately dealt with, the idea of luminous flux in particular being elucidated by a material analogy, which will carry conviction to a far larger number of readers than will the hardly worked analogy with magnetic flux. The author uses throughout the photometric notation of the Geneva Congress of 1896.

Methods for the determination of mean spherical intensity from polar curves of intensity are briefly described in the second chapter, including the author's modification of Rousseau's construction, which adapts it for rapid calculation, but the equally convenient graphical method due to Kennelly is not mentioned.

Some general considerations with regard to exterior and interior lighting bring the third chapter to a conclusion, great stress being rightly laid on the importance of mean horizontal illumination as a factor in design.

The real business of the book begins in the fourth chapter. A method is here given by which the integral of the Rousseau curve for a given light source over the lower hemisphere is made to supply material for a table of total luminous flux emitted under any angle from the vertical to the horizontal.

A number of such curves are developed, each from the average polar curve of luminous intensity of a specified type of source, and all being reduced to the same value of mean spherical intensity. With the help of these tables, the cosine law, and some experimental data on reflection coefficients obtained by the author, a complete method of design is elaborated, applicable to most conditions in modern lighting. The author's justification for his broad generalisations and approximations appears from the comparatively close agreement existing between his observed and calculated values of illumination in examples taken from his practice in the street lighting of Berlin.

Photometry is dismissed at the beginning of the fifth chapter with little more than a description of the Brodhun illumination photometer as used by the author on the Berlin streets. This is followed by a description of a method for reducing to a minimum the number of street observations necessary for the determination of the value of the mean horizontal illumination.

The sixth and last chapter is devoted to indirect lighting, and, in spite of obvious difficulties, it is shown from actual examples that the formulæ and methods already devised are still able in certain cases to give fairly accurate results. It is not easy, however, to follow the author in his contention that the difference in cost between direct and indirect lighting for a given effect achieved may be in many cases of very small moment.

The book is a successful attempt to place the design of illuminating installations in a position comparable with that held by design in other branches of engineering.

THE FACE OF THE EARTH.

La Face de la Terre. By Prof. Ed. Suess. Vol. iii., pt. 2. Pp. xii + 531–956, 2 maps, 124 figs. (Translated under the direction of E. de Margerie.) (Paris: Armand Colin, 1911.) 12 frs.

THE present instalment of the French edition of Prof. Suess's great work includes only the first half of the final volume. It consists of translations of chapters x.–xvi., which deal with the western representatives of the Altaid mountain system of Prof. Suess, and with the Alps, Atlas, and various related mountains, which are all attributed to foldings within areas surrounded by an Altaid framework. The last chapter deals with the North Atlantic area, including Iceland and Greenland.

As the original has already been reviewed in Nature, it is unnecessary to reconsider the problems dealt with in the work. The chapters have been translated by MM. H. Baulig, Ch. Jacob, and P. Lemoine; the volume is edited by M. de Margerie, who is to be warmly congratulated on the great service he has made to students of Prof. Suess's work by this accurate and scholarly translation, and by the issue of this well-illustrated edition of the book.

The study of the work requires such frequent reference to geological maps, of which the original edition contains so few, that it is difficult to read except in a geological library. M. de Margerie's edition is, however, so richly illustrated by excellent maps and sections that the book is complete within itself. The German edition of the part here translated is illustrated by one plate and twenty-three figures. To these, M. de Margerie has added three plates and 101 figures, and, as many of them have been redrawn for this edition, they are often clearer than the originals. Moreover, many new additional references have been added and occasional explanatory notes, which are all enclosed within square brackets. Amongst these additions the bibliography of the Caucasus and the footnotes on Algeria are especially useful. Among the most important of the new illustrations is a valuable coloured geological map of the western Atlas. M. de Margerie's edition forms an atlas of diagrammatic sketch maps of the countries discussed. The maps are artistically excellent, but they sometimes follow the current, but inconvenient, practice of translating place names. It is no doubt difficult to decide when the translated form of a proper noun has become so widely used that it would be pedantic not to accept it. Nevertheless, it would be generally convenient if the number of such place-names were restricted as far as possible. Thus, such cases as the use of Terre de Grant for Grant Land render the index less useful to foreign students, and the adoption of François, instead of Franz, for a locality named after the Austrian Emperor tends to conceal the history of the name.

J. W. G.

DARWINISM IN THE LIGHT OF MODERN RESEARCH.

Die Abstammungslehre: Zwölf gemeinverständliche Vorträge über die Deszendenztheorie im Licht der neueren Forschung. By O. Abel, A. Brauer, and others. Pp. iv + 489. (Jena: Gustav Fischer, 1911.) Price 11 marks.

THE handsome volume issued by the Society for Natural Science in Munich (Münchener Verein für Naturkunde) is a striking proof of the breadth of Darwin's knowledge and of the many-sided character of his researches. The volume contains twelve papers relating to subjects dealt with by Darwin in establishing his theory of evolution; but while Darwin dealt with all of them single-handed, each of the contributions to this volume is the work of an expert. The first paper, an introduction to our present knowledge of evolution, is written by Prof. Richard Hertwig, of Munich, who gives a very clear account of the work and beliefs of Darwin's predecessors, especially of Cuvier's position as regard evolution. The second and third papers are written by Prof. Richard Goldschmidt, of Munich, and relate to the origin of species in the light of our present knowledge of heredity. In the fourth, by Prof. Richard Semon, the inheritance of acquired characters is discussed; the author thinks these may be inherited, but he employs the term inheritance in a limited sense. In the fifth, Dr. Paul Kammerer, of Vienna, recapitulates the chief facts in support of Darwin derived from experiments in breeding. The position of natural selection as a factor in evolution is the subject of the sixth paper, by Prof. Franz Doflein, of Munich.

Prof. August Brauer, in the seventh paper, gives the evidence arising from our modern knowledge of the geographical distribution of animals; while the additional evidence afforded by modern palæontology by Dr. Edgard Dacqué, of Munich, constitutes the eighth paper. Prof. Abel, of Vienna, writes the ninth paper, and describes the various fossil forms which have been discovered since Darwin's time, and their bearing on our knowledge of the evolution of the higher vertebrates. The bearing of recent discoveries in comparative anatomy on the theory of descent is related by Prof. Otto Maas, of Munich (tenth paper); while Prof. Karl Giesenhagen writes the eleventh, on the evolution of plant forms.

The last and twelfth paper occupies a third of the volume. It is written by Prof. Hermann Klaatsch, of Breslau, and is entitled by him "The Place of Man in Nature." Prof. Klaatsch, who deals with the descent of man, unlike the other contributors to this volume, is not content by a mere statement of the progress made since 1871; he brings forward a new genealogical tree for man and the anthropoid apes. Like Darwin, he regards man as derivative of the same stem as the anthropoid apes, but differs in supposing that man has retained the characters of the common stock to a greater degree than the anthropoids have.

Those who wish to examine a full statement of Prof. Klaatsch's theory of man's origin will find it here. In Prof. Klaatsch's opinion, the modern population of Europe is formed by the mixture of at least two stocks; one of these was evolved in common with the orang and entered Europe through Asia, while another human stock was evolved in common with the gorilla and entered Europe from Africa. In this way he accounts for the two prevailing types of nose among modern Europeans. The prominent or "Grecian" nose he supposes to be derived from the human "gorilloid" stock, while the australoid nose—of which he cites Darwin's nose as an example—came into Europe by the Eastern or "orangoid" stock. It is difficult to believe that Prof. Klaatsch is really quite serious in his contribution to "Die Abstammungslehre."

A. K.

OUR BOOKSHELF.

Jelinek's Psychrometer-Tafeln. Anhang: Hygrometer-Tafeln von J. M. Pernter. Herausgegeben von W. Trabert. Sechste Auflage. Pp. xii+129. (Leipzig: W. Engelmann, 1911.) Price 7 marks.

JELINEK's psychrometer tables are among the best known of the many humidity tables in use on the Continent. Originally prepared by Jelinek from the earlier tables of Regnault and Wild, the work has been successively re-edited by Hann and by Pernter, and now we have a further revision undertaken by Hofrat Trabert, the present director of the Austrian meteorological service.

The new edition differs from its predecessor mainly in the method of treatment of the wet-bulb readings at temperatures below the freezing-point. The values of the saturation pressure of water vapour used hitherto were those for vapour in equilibrium with supercooled water, although in practice the wet bulb is normally coated with ice. The present edition has been amplified by the addition of a table of saturation pressures of water vapour in equilibrium with ice, taken from the results of Scheel and Heuse, and on this table has been based a new set of tables for finding the vapour pressure and relative humidity from readings of dry and wet bulb thermometers at temperatures below the freezing-point when the wet bulb is covered with ice. The results for higher temperatures have been entirely recalculated, but their general arrangement remains unchanged.

The tables differ from most humidity tables in general use in that allowance is made in them for variations of wind velocity. The figures as printed are applicable to the readings of screened thermometers under conditions of light or moderate wind, but by the application of simple corrections to the wet bulb readings they can be rendered applicable on the one hand to readings in still air, and on the other to readings taken during gales or strong winds, or with an aspirated psychrometer such as the Assmann instrument.

Peeps at Industries: Sugar. By Edith A. Browne. Pp. vii+88. (London: A. and C. Black, 1911.) Price 1*s.* 6*d.* net.

THIS little book is the first volume of a series intended to deal with industries in the same way as "Peeps in Many Lands" has dealt with countries. The general get-up is attractive, the illustrations are good, and the reader is never fatigued by having too much serious matter presented to him on any one page. The whole ground is covered, both beet and cane sugar coming within the purview of the author, and the descriptions range from an account of a Demerara estate to a Belgian sugar factory and a London refinery. The style of the book may be judged by the following quotation:—"Sugar is hatched from germs which inhabit the sap of certain plants. In the birth stage it takes the form of tiny grains. I am going to tell you quite simply and briefly the way in which the germs become solid little grain bodies, and in the course of the story I shall answer many of the questions with which you are now bubbling over; sweep away, I hope, most of the difficulties that are now puzzling you."

We are not sure that the ordinary reader will quite catch the idea the author wishes to convey, but she becomes much more lucid in writing about the social aspects of the industries as distinguished from the more purely technical side. The descriptions of the sugar plantations, of the school for the negroes, and of Georgetown have an air of reality that cannot fail to appeal to the reader, whilst the accounts of the milling and extraction processes are equally attractive. Nor are economic questions left untouched, and although no actual tables of statistics are given—they would indeed have been out of place in a volume of this nature—the author succeeds in conveying the essential facts relating to the economic position. Altogether the little book is one that will give the intelligent child the sort of information he wants about the subject.

Photographic Lenses: A Simple Treatise by Conrad Beck and Herbert Andrews. Seventh edition, completely revised, with index. Pp. 324. (London: R. and J. Beck, Ltd., n.d.) Price 1*s.* net.

MANY thousands of this volume having been sold in the previous editions, there is but little need to describe its scope. It will be sufficient to say that the authors do not intend in it to give a full explanation of the laws that underlie the construction of photographic lenses, but rather to provide a practical guide for the user of lenses that he may be able to use them to the best advantage. The volume is excellently illustrated with diagrams that make clear the principles of elementary optics, the construction of various objectives, the comparative results of their tests, and also examples of the actual work that they enable the photographer to do. For those who wish to go a little further into the subject there is an appendix on "Equivalent Planes," and a second appendix in which a lens-testing optical bench is described, with the manner of using it. The lenses illustrated and referred to are all of Messrs. Beck's manufacture, but that fact does not, in a practical sense, limit the usefulness of the book. The present edition is brought up to date, especially with regard to recent anastigmats, and it is provided with a very good index.

Practical Botany. By Dr. F. Cavers. Pp. xvi+408. (Cambridge: University Tutorial Press, Ltd., 1911.) Price 4*s.* 6*d.*

TAKING a general view, there are four different sections recognisable in this students' practical botany: histology is placed first, then follow physiology of growth and nutrition, physiology of movement, and finally a sketch of practical work on selected cryptogamic types. There is, of course, no reason why teachers should begin with histology; on the contrary, experience points to a beginning with the seed and germination. Dr. Cavers lays some stress on the second chapter, which is intended to impress a more thorough knowledge of the organic products in plants. Seeing that the real aim of students' courses is rather to teach general methods and provide training than to implant facts, tests for proteins and other complex substances are much less valuable than the more tangible experiments of a physical nature.

Except in this matter, there is no hesitation in recognising that the author presents a remarkably clear and informative series of experiments. There is always satisfaction in experiments requiring simple and natural material, as in the test of a living turnip with beetroot juice, but Dr. Cavers on the whole favours the view that there is a necessity for specially designed apparatus capable of yielding exact measurements, in which connection he directs attention to several instruments designed by Prof. Ganong. An appreciable amount of generally unknown detail is supplied in the life-history of Pellia and Funaria, and otherwise this section is no mere repetition of available information. Teachers will be well advised to consult the book before drafting their physiological courses, as they are tolerably certain to discover suggestions or new experiments.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Heredity.

So long as naturalists persist in using ill-defined terms, the meaning of which they have not clearly thought out, the controversy about the inheritance of so-called "acquired characters" is bound to be sterile and interminable. If it be once granted that organisms are the product of the interaction of two sets of factors—the factors of the inheritance and the factors of the environment—it becomes obvious that not only every organism, but every "character" of an organism, must be the result of both sets of factors. And if by "character" we mean any such resulting structure or property as it appears to our senses, as we see it before us, then it becomes manifest that no character can be due wholly to inheritance or wholly to environment. The very words "acquired character" involve a fatal fallacy—suggesting as they do that one character may be more acquired than another. Since such wholly acquired characters do not exist, it is waste of time to discuss their possible inheritance.

Even Dr. Reid, in his letter in last week's NATURE, does not entirely escape from this logical error when he uses the word inheritance for the transmission of acquirements (characters) in unicellular organisms. It is a return to the vague, popular use of the term which would inevitably lead us back into the old tangle of inconsistencies. The biologist may define inheritance as the transmission of hereditary factors —it is not ready-made characters which are inherited, but the factors which help to produce them. The transmission in a protozoon of the characters of its parent is no more inheritance in the strict biological sense than is the transmission of the eggshell and albumen from the fowl to the chick, or of money from father to son.

Variation may be caused by changes in the environment giving rise to "modification," or by changes in the inheritance (the totality of the hereditary factors) giving rise to "mutation." Changes in the inheritance are due to the rearrangement of, addition to, or subtraction from the factors of inheritance. Ultimately these changes must be referred to the environment, and it is only when something from the environment thus alters or enters into the inheritance that mutation can occur.

It follows that if certain observations seem to show that "acquired characters" are transmitted by true inheritance, either they must be capable of some other interpretation, or our premise that every organism is the resultant of two sets of factors must be wrong. No escape from this alternative seems possible.

The dogmatic tone of this letter will, I hope, be forgiven me, as it has been assumed merely for the sake of brevity.

E. S. GOODRICH.

Merton College, Oxford, March 1.

Mars and a Lunar Atmosphere.

IN NATURE, February 22, p. 565, reference is made to an interesting observation by Prof. Luther, of the Düsseldorf Observatory. The note states that he saw the half of the disc of Mars nearest the moon become green just before occultation on December 4, 1911, and he suggests that this may have been due to a lunar atmosphere. The time was 16h. 40m. (Greenwich mean time), and I notice that the moon was full at 14h. 52m. on December 5, so that, at the time of the observation, the unilluminated crescent of the moon towards the planet must have been extremely narrow, so that the illuminated part of the lunar disc must have been quite close to the planet.

Now no refracting telescope is perfectly achromatic, and as one of the residual colours is green, it seems to me possible that this colour may have been due to moonlight imperfectly achromatised. It may also be suggested that the reddish colour of Mars might lead to the focus of the telescope being different for the planet and the moon. Another suggestion is that the colour of the planet might give rise to a complementary tint.

Turning to the date of Prof. Luther's previous observation, October 16, 1902, I find that the moon was full on that very day, and this seemed to link the two observations together, both being associated with a nearly full moon.

But, to my surprise, I found, on consulting the Nautical Almanac table of occultations, that no occultation of Mars, or of any planet, is set down for October 16, 1902, and, on looking up the positions of the moon and of Mars, it is obvious that none could have occurred, as they were distant in R.A. by some nine hours. It is evident then that there is some mistake in the earlier date, unless it is meant to apply to some small stars in Pisces.

I observed with a refractor the disappearance occultation of Mars at the dark limb of a moon rather more than half-full in the early morning of January 29 this year, but saw no trace of any green colour on the disc of the planet.

C. T. WHITMELL.

Hyde Park, Leeds, February 26.

The Teaching of Mathematics.

IN an article entitled "The Teaching of Mathematics" in NATURE of November 30, 1911, considerable space is devoted to a memorandum written by me for the Department of Public Instruction of New South Wales, to accompany and explain the programmes for the mathematical classes in the high schools recently established in this State. Regret is expressed by the writer of that article that New South Wales "has been frightened by difficulties which were bound to arise in a period of transition, into going back to the old methods instead of boldly remedying the evil by helping all teachers to get the spirit of the new methods."

The point at issue is the treatment of the fundamental theorems of congruence, parallels, and the angle-sum for a triangle, in the course of deductive geometry given to pupils in these high schools. In the programmes, as issued, the teachers are advised to follow Euclid's method (or something of the same nature) in these fundamental theorems. The Board of Education circular, from which we have ventured to differ in this particular alone, recommends that these results be obtained by induction and experiment.

It seems proper that your readers should be aware of the following facts:—

(i.) The course of geometry in question is not meant for children of twelve years of age and under, as the writer of your article seems to assume.

Pupils enter these schools after completing a full course of primary education. Their age at entrance varies from thirteen to thirteen and a half.

(ii.) Before entering the high schools they have had a full year's work at geometry. In this preliminary study the newer methods are fully employed; the results are obtained by induction and experiment, and a great part of what the Board of Education circular recommends is adopted. However, the box of mathematical instruments does not hold sway to the entire exclusion of theoretical work.

(iii.) Although it has been thought advisable to ask for some uniformity of treatment in these early theorems in the deductive course, when this stage is past the fullest amount of freedom is granted.

There is no doubt that experience will show that some modifications in the syllabus are necessary. Some of the points mentioned in your article had already been noted as requiring alteration, and the suggestions which it contains will certainly receive the careful attention of the proper authorities. But the decision with regard to the earlier stages of the geometry course was made only after the fullest consideration. For this reason it is to be regretted that it has been, to some extent at least, misunderstood by the writer of your article.

Sydney, January 10. H. S. CARSLAW.

IN spite of Prof. Carslaw's assurance that pupils on entering secondary schools have reached the age of thirteen or thirteen and a half and have had a full year's work at geometry, the writer of your article feels most strongly that it is extremely unwise to impose on them in their first year at the secondary school a logical treatment of the fundamental theorems of congruence and parallels. Anyone who has had much experience of teaching pupils of that age knows how difficult it is to teach this work and how little impression it makes except on a very small minority; on the other hand, if these theorems are frankly assumed (after the pupils thoroughly understand their meaning) the rest of the geometry usually done in secondary schools can be treated logically, and the vast majority of pupils will get a proper grasp of the ideas of logical geometry. In the latter case the foundations are broad and the structure is firm at every stage; if the fundamental theorems are treated logically, an attempt is made to build on a narrower base, but in the majority of cases the lower stories of the structure are insecure.

The writer of your article must still regret the attitude taken up by the New South Wales authorities on this point. R. Y. S.

The Isothermal Layer.

IN reading Dr. Evans's reply to my letter in NATURE of January 25 with regard to the isothermal layer, I was specially interested in his reference to radiation of heat from orbital interplanetary matter as a probable climatic factor, because in *Symon's Meteorological Magazine* of February, 1911, I suggested that the recurrence year after year of warm and cold periods, first directed attention to by the late Dr. Buchan, may be attributable to modifications in a screen of cosmic matter, such, for instance, as that from which the zodiacal light and the Gegenschein are reflected.

I mentioned in a later number of that magazine that my own observations of the light in tropical latitudes, extending over several years, conveyed to me the impression of a ring of cosmical bodies encircling the earth about the zodiac.

For evidence of the isothermal layer at the equator the report of Prof. Borson on the aërological expedition of the Royal Prussian Aëronautical Observatory to East Africa in 1908[1] may be quoted. In this report at least two instances are recorded of balloon ascents near the equator in which the isothermal was reached: on August 30, at a height of 17·3 km., when a temperature of −82·5° C. was registered, and slightly lower temperatures at higher elevations; and on September 5, at 15·4 km., temperature −70·3° C., slight inversions being registered at greater altitudes.

The greater height of the isothermal in equatorial regions may be due to strong convection currents, as Mr. W. H. Dines supposes,[2] even though the origin of the layer be attributable to reflected heat from interplanetary matter. CAMPBELL HEPWORTH.

2 Amherst Road, Ealing, W., February 18.

St. Elmo's Fire.

ON Thursday evening, February 22, about 9.20 p.m., whilst traversing a country road which crosses the head of Carr Wood, a well-wooded clough in the neighbourhood of Heywood, near Rochdale, I was fortunate enough to witness a most unique phenomenon. The road in question skirts a hill on the left-hand side, and the opposite side, at this particular place, overlooks a small plateau which runs along the edge of the clough.

During the day we had had much rain. The atmosphere was now very close and heavy, and everything was ominously silent, even the usual *breeze having disappeared*. Suddenly, without the slightest warning, there appeared an area of faint electric-blue light, almost circular in shape and about 70 yards in diameter, which covered the plateau. The edge of this area was not more than 10 yards from where the observations were made. The whole electric field seemed to be three or four feet above the ground-level, and was in a state of intense agitation. Within the general blue ground there appeared flashes of a more decided blue, very similar in character to forked lightning, but not nearly so distinct.

[1] "Results of Investigations of the Royal Prussian Aeronautical Observatory at Lindenburg." Edited by the Director, Doctor Richard Assman.

[2] "The Vertical Temperature Distribution in the Atmosphere over England, and some remarks on the General and Local Circulation." By W. H. Dines, F.R.S., Phil. Trans. Royal Soc., Series A, 211, page 269.

Sounds of two distinct types accompanied the agitation. The first consisted of whistling sounds, like that of numerous long-lashed whips swishing rapidly through the air, or perhaps that of the whistle of bullets. These sounds seemed to be associated with the general field of fainter blue.

The other sounds consisted of the characteristic crackle of electricity, and these became so numerous as they approached the climax that they resembled a magnified rustle. These cracklings seemed to be associated with forked discharges, and were probably due to the more distinct flashes coming into contact with the bushes which surround the plateau.

The phenomenon lasted about fifteen to twenty seconds, and disappeared as spontaneously as it had arisen. J. McV. M.

THE phenomenon described above appears to have been the luminous discharge known as St. Elmo's Fire. This takes place usually from pointed objects, and possibly the tree in your correspondent's sketch (not reproduced) played a part in the production of the phenomenon. The colour associated with St. Elmo's Fire depends upon the character of the discharge. It is blue when the earth is kathode and red when the earth is anode.

The discharge is not infrequent in mountainous countries. E. GOLD.

Hampstead Garden Suburb, N.W.

Earthworms and Sheep-rot.

EVERYONE who is interested in agriculture is aware that liver-fluke or sheep-rot is popularly associated with one or another of our common plants. Halliwell gives "sheep-killing" as a name for "the herb pennywort." In Britten and Holland ("English Plant Names") we find sheep-rot, sheep-bane, and other similar terms, and we are told that such plants as *Pinguicula vulgaris*, L., and *Hydrocotyle vulgaris*, L., are known by these popular names because of a supposition that these plants cause the liver-rot in sheep, which disease is often prevalent on wet land where the plants grow. The authors further inform us that "It is now ascertained that the liver-fluke, which always accompanies rot in sheep, exists in one of its stages as a parasite in the bodies of small water snails, which, in wet weather, creep upon the leaves of marsh plants, and are eaten by the sheep with the herbage. It is therefore with some reason that such names as 'Flowkwort,' 'Sheep-killing Penny-grass,' and 'Sheep-rot' have been given to these marsh plants."

Withering ("British Plants") has a similar note. Speaking of Pinguicula, he says, "The plant is generally supposed injurious to sheep, occasioning a disease which the farmers call 'rot.' But it may be questionable whether the rot in sheep is so much owing to the vegetables in marshy grounds, as to a flat insect called a fluke (*Fasciola hepatica*), which is found in these wet situations adhering to the stones and plants, and likewise in the livers and biliary ducts of sheep that are affected with the rot. From experiments conducted with accuracy, it appears that neither sheep, cows, horses, goats, nor swine feed upon this plant."

During a recent visit to Cumberland, however, the matter was presented to me in a new light. I was conversing with a farmer on the economy of the earthworm, when my friend protested that they were responsible for rot in sheep. His explanation was as follows. The worms make casts in spring, known in the north as worm-sprouts, just as in the eastern counties they are called worm-puts. On these fine young plants grow rapidly, proving very attractive to sheep. When the sheep feed on this tender grass they are liable to suffer from fluke, and it is therefore maintained that the fluke, or rot, is in some way due to the earthworm.

It would be interesting to know more about this popular fancy, and to learn whether anything is being done to help farmers to a more correct knowledge of the facts. HILDERIC FRIEND.

Swadlincote, Burton-on-Trent, February 17.

Meteor-showers.

I AM sure that a great many of your readers who are interested in the subject of meteors have noticed the letters of Mr. John R. Henry which have appeared from time to time in your columns, but I do not recollect having seen any letter from an observer stating either that Mr. Henry's prediction had been fulfilled or that it had failed. If a shower of the thirty-third magnitude is sufficiently marked to enable three secondary maxima to be fixed with accuracy, one of the third magnitude, such as we are promised at the end of this month (February) ought to be very perceptible indeed. But perhaps the word "magnitude" does not refer to the number of the meteors but to their average mass. If so, how is this mass to be ascertained? Mr. Henry gives us no information as to the part of the sky in which these meteors should on each occasion be looked for. F.R.A.S.

Dublin.

"F.R.A.S." is right in surmising that the magnitude of a shower does not depend upon the number of meteors that may be actually observed, but rather upon the general mass or quantity of matter imported into the atmosphere at the time. This may appear to be a distinction without a difference, but as the number of shooting stars counted by an observer will be influenced by the altitude of the radiant, the clearness of the sky, &c., it is evident that the intensity of the phenomenon cannot be fully measured by such results. It is assumed that the radiant is the same as that usually associated with the time of the year at which the shower occurs.

To determine the absolute mass of a meteor-shower is a somewhat intricate problem, but it is possible to obtain an approximate solution of it by assuming that the portion of the meteor-swarm which enters the atmosphere is moving nearly parallel to the earth's surface, and in being brought to rest puts the surrounding air in motion. There must thus result an atmospheric depression, and given the mean depth and extent of the latter, the mass of the shower may be calculated from purely dynamical principles.

The order of magnitude does not express, as may be supposed, the absolute but rather the relative intensity of a shower, with reference to some other shower which may be regarded as the standard-shower. Thus of the two showers referred to by "F.R.A.S.," one of the thirty-third, and the other at the end of February of the third order of magnitude, the former is of the weakest and the latter of the highest intensity in the whole month. The greater meteoric event, apart from its high intensity, happens to belong to an interesting type or group of meteor-showers, one of which of the tenth order of magnitude occurred in 1908 on September 28, and another of the eighteenth order in 1911, on April 8–9, both occasions being marked by a magnetic and the latter also by a moderate seismic disturbance.

JOHN R. HENRY.

THE AMERICAN LOBSTER.[1]

THE work referred to below is "in a measure both a revision and an extension" of Prof. Herrick's well-known memoir on "The American Lobster," published in 1896 in the Bulletin of the United States Fish Commission, from which several figures, including three fine coloured plates of larval stages, are reproduced. By far the larger part of the memoir, however, is concerned with the new knowledge of the natural history of the lobster that has been gained during the past fifteen years from the investigations of the author himself and of many other naturalists on both sides of the Atlantic. As Prof. Herrick remarks, "in all probability there is no marine invertebrate in the world which is now better known," and he has rendered a great service to zoology by bringing together a vast amount of information on the habits and mode of life, the reproduction, development, and growth of the lobster, and on the economic and legislative problems relating to its preservation and artificial propagation. Out of the many points of interest discussed only a few can be selected for comment here.

The European and American lobsters are commonly regarded as distinct species of the genus Homarus, but they are very closely related, and, as Prof. Herrick remarks, they "might at first sight be considered as geographical varieties" of a single species. The only structural character which is given as distinguishing the two is the form of the rostrum, which in European lobsters is smooth on the underside, while in American specimens it usually bears a pair of small spines. According to Prof. Herrick, "either one, two, or three spines of inconstant size may be present," and he implies that they may occasionally be absent altogether in American lobsters. Slight differences are said to exist in the larvæ of the two forms, although the author scarcely seems to be justified in stating that the European lobster is hatched "in a stage nearly comparable to the second larva of the American lobster." Even if this were so, however, it would be by no means conclusive as to their specific distinctness, since other cases are known among Crustacea of species (*e.g.* the prawn *Palaemonetes varians*) which differ in their mode of development in different parts of their geographical range. As a mere matter of nomenclature the question is, of course, only of interest to the systematist, but in view of the temptation to fill in gaps in our knowledge of the bionomics of either form by data drawn from the other, it may be of more than merely academic interest to determine as exactly as possible the degree of affinity between them.

Prof. Herrick states of the European lobster that its range in the Mediterranean is limited on the east by the Adriatic Sea, and this agrees with statements in other works of authority. If it be correct, however, it is curious that the species should have been so well known to Aristotle, whose natural history studies were mainly carried on, as Prof. D'Arcy Thompson has recently told us, on the island of Mitylene.

A detailed account is given of the structure and development of the great claws and of the process of autotomy and regeneration as affecting them. An interesting little piece of mechanism is described in the interlocking processes which strengthen the articulations between the basal segments of the limb. In the young lobster, in which the articulation between the second and third segments is movable, processes of this kind are developed on the adjacent margins of these segments. In later stages, however, the second and third segments become soldered together, the junction forming the "breaking plane" at which autotomy takes place, and a new process grows out from the third segment to interlock with one on the first. A full description is given of the torsion of the great claws by which the movable finger comes to lie on the inner side instead of on the upper and outer side as it does in the

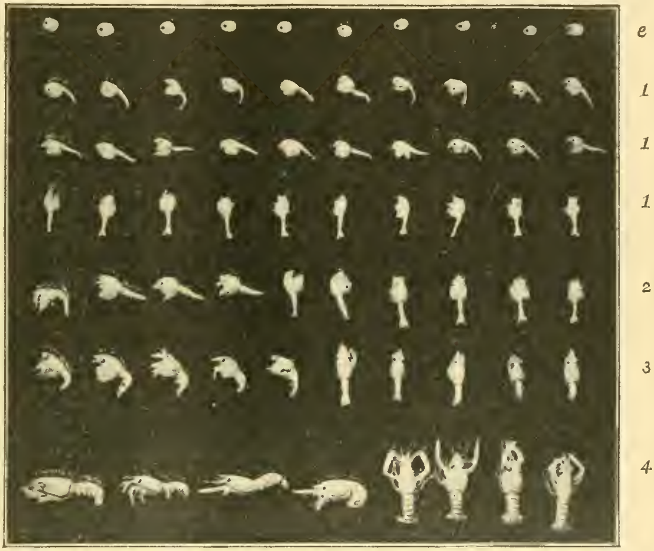

FIG. 1.—Growth stages of young lobsters: *e*, embryo at hatching (July); 1 (first line), first larva, not free from first moult; 1 (second and third line), first free larval stage; 2, second larva; 3, third larva; 4, fourth stage.

[1] "Natural History of the American Lobster." By F. H. Herrick. Bulletin of the Bureau of Fisheries, vol. xxix., pp. 149–408, pls. xxvii–xlvii (Washington, 1911.)

two following pairs of legs. The observation of this torsion, however, is not quite novel, for it was briefly but accurately described by Boas in his well-known (but apparently little read) "Studier over Decapodernes Slægtskabsforhold" (Vidensk. Selsk. Skrifter, Kjøbenhavn, 1880). The periodic arrangement of the teeth on the fingers of the great claws is described, and it is shown to arise in a very simple way by the successive appearance of new sets of teeth between those already existing. Reference is made to Stahr's fantastic opinion "that the æsthetic sense of this self-admiring crustacean is aroused as its eye wanders over the dentate margin of its 'hand.'"

The habits and reactions of the larvæ are dealt with at some length, and many interesting facts are recorded in connection with their swimming movements, food (and occasional cannibalism), colour, and power of colour-change. Even their psychology is not neglected, for it is stated that the "instinct of fear" becomes apparent only at

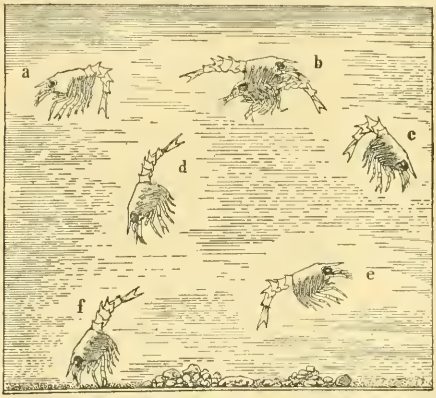

Fig. 2.—Swimming attitudes of young lobsters in the first free stages *a*, body bent in usual quadrant form; *b*, lobster swimming astride the carcase of another and devouring it; *c*, thoracic legs directed forward; *d*, rising position occasionally assumed; *e*, "floating" position; *f*, too weak to rise.

the fourth stage, when the little lobster prepares to give up its free-swimming life and to seek shelter on the bottom.

Prof. Herrick's remarks on the subjects of protective legislation and artificial hatching of lobsters are worthy of close attention. He strongly advocates the view that a minimum size-limit, such as most lobster-fishing countries have adopted, is ineffective on account of the fact that the smaller lobsters, which alone are protected, are vastly less fertile than the larger individuals. Some striking statistics are given to show the futility of artificial hatching unless the young lobsters are reared through the critical pelagic stages before they are set free.

As is usual with publications of the United States Government departments, the style of printing and illustration forms a pleasing contrast to that of most official publications in this country.

W. T. C.

SCIENTIFIC RESEARCH IN THE SUDAN.[1]

In reviewing the third report of the Wellcome Research Laboratories (Nature, June 24, 1909), we suggested that it would be advisable to separate the purely medical subjects from those dealing with agricultural or economic questions and matters of general scientific interest. This has been effected in the fourth report, and we now have two volumes, A, Medical, B, General Science, but the change is accompanied by at least one drawback, viz., that each of the separate volumes is now as large as its parent, and in addition we have a still bulkier review of the literature.

If we may unburden ourself at once of initial criticism, it is that these volumes are too bulky.

Copyright. From Fourth Report Wellcome Tropical Research Laboratories, Khartoum.

Fig. 1.—Sharpened teeth as practised by the Nyam-nyam.

This, we believe, is not entirely due to the number of subjects included, but in part to the diffuse style in which many of the articles are written, and the desire to impart elementary information—a praiseworthy desire, but one we think perhaps out of place in reports dealing with researches. The articles would, in our opinion, be improved by severe pruning. We suspect that there are certain considerations which prevent this, but for

[1] Fourth Report of the Wellcome Tropical Research Laboratories at the Gordon Memorial College, Khartoum, Dr. Andrew Balfour, Director. Vol. A, Medical, pp. 404+xxiii plates+118 figs. Price 21s. net Vol. B, General Science. pp. 353. Price 18s. net. Supplement to the Fourth Report, pp 448. Price 15s. net. (London: Published for the Department of Education, Sudan Government, Khartoum, by Baillière, Tindall and Cox, 1911.)

the scientific reader, not to mention the reviewer, the gain would be appreciable. The amount of literature put forth is so great that conciseness should be aimed at in the interests of all. Again, although we must express our admiration for the immense amount of labour involved in preparing the reviews of recent advances in tropical medicine, yet we feel certain that this is not the function of the overworked staff of the laboratory, and that they should spare themselves the drudgery and mental effort involved in producing such a work.

In Vol. A, Medical, the first article deals with a question of the first importance, viz., the extent to which sleeping-sickness prevails in the southern portions of the Bahr-el-Ghazal, and the measures taken to prevent its spread. So far cases have not been detected north of Wandi in the Lado, and in the coloured map this is represented as the distribution of *Glossina palpalis*, but this fly exists also on the bank of the Nile at Kajo-Kaje, south of Rejaf, as was shown later. Inspection posts have been established, clearing operations instituted, and the authorities are keenly on the alert. Whether *Gl. morsitans* in connection with sleeping-sickness is a negligible factor is open to considerable doubt: that it is not so in Rhodesia and Nyasaland, in parts of which we have cases of sleeping-sickness in absence of *Gl. palpalis*, is now established. In these places there appears to be a new species of human trypanosome; whether in the absence of this particular trypanosome, *Gl. morsitans* is free from danger to man remains yet to be definitely proved. In this article we do not see it expressly stated that the thick blood film method was employed for diagnosis, but its great utility and convenience can hardly be denied.

The second article likewise deals with trypanosomiasis, but in regard to animals. Four species occur in the country, viz. *T. brucei*, *T. evansi*, *T. nanum*, and *T. vivax*, but a consideration of the question as to whether these names represent the species present or not involves us in the very difficult problem of trypanosome identification. We cannot enter here into this question, but we would add a word of caution as to the measurement-curve method introduced by Sir David Bruce. The number of trypanosomes counted in one of the curves given is certainly too small, only 150, and as a matter of fact the chart (1910) given of *T. brucei*, though it resembles the earlier chart, bears not the slightest resemblance to the latest chart of this species published by Sir David Bruce.

C. G. SELIGMANN. From Fourth Report Wellcome Tropical Research Laboratories, Khartoum

FIG. 2.—Dwelling of Shilluk King, Fashoda.

The director contributes a lengthy paper on spirochætes in fowls, which is exceedingly prevalent, and marshals his evidence in favour of the view that the spirochæte breaks up into granules in the internal organs. His paper on fallacies and puzzles in blood examination will perhaps do some good in preventing the finding of any bits of stained matter in a blood film being recorded as new parasites by those desirous of fame; for in these days the editorial waste-paper basket is not as large as it used to be, and the publication of rubbishy papers is all too common. Yet, on the other hand, we fear the conscientious tyro will be overwhelmed with all the pitfalls recorded, and perhaps it is not enough emphasised that known parasites when present are easily recognised, and even each new parasite as it is discovered has such definite characters that, as a rule, the question of its parasitic nature is not a very difficult matter.

The existence of kala-azar in the eastern Sudan is a serious condition, for the disease may assume epidemic proportions. Unfortunately, at present little can be effectively done, as the mode of transmission is unknown, nor is treatment of much avail.

We have noted some of the longer and more important articles, but there is a medley of other matter. Worthy of note is the successful treatment by vaccines of two cases of "Veldt Sore." "Tropical Ulcer" seems to be rare, but the condition known as Oriental sore is not uncommon. There are in addition several articles on different aspects of tropical sanitation.

The amount of matter reviewed in the supplement is amazing, and the labour involved must have been very great. We gather from the introduction, however, that this will be its last appearance. While we shall regret its disappearance, yet we feel that the authors are quite right and absolutely justified in their decision.

Volume B, General Science, like Volume A, deals with a medley of subjects: water and soil analysis, research into gum and its relation to bacteria, entomology—it may be noted that a successful larvicidal fish has not yet been found—economic ornithology, poisonous snakes and scorpions, plant pests, municipal engineering, gold-mining in ancient times, and anthropology. The two papers on this last subject are perhaps of the most interest to the general reader, viz. that on tribal customs of the Nyam Nyam and Gour peoples, and that of the Divine Kings of the Shilluk. They are both extremely interesting, but may occasionally shock the hypersensitive. Our illustrations are taken from these two papers.

The volumes are, as usual, profusely illustrated with coloured plates, maps, and text figures, and there are complete indices.

We must express our astonishment at the amount of work done. We feel that the authors give too much of themselves, and that they are overtaxed. Undoubtedly the staff should be increased, and each member be allowed to devote himself to special subjects. It is quite impossible, if the best results are to be got, for a person to be a "factotum."

NOTES.

We are glad to learn that the preparation of a Life of Lord Lister is contemplated. We are asked to say that any letters of scientific interest forwarded to Mr. R. J. Godlee, 19 Wimpole Street, London, W., will be gratefully received for this purpose. If desired, the letters will be returned, after being copied.

It is announced in *The Times* that the Amsterdam General Radium Company has purchased the entire present stock of radium of the Austrian Government.

Lieut.-Colonel D. Prain, F.R.S., director of the Royal Botanic Gardens, Kew, has been elected a foreign member of the Royal Swedish Academy of Sciences, in succession to the late Sir Joseph Hooker.

An interesting collection of photographs by Mr. G. R. Ballance, of St. Moritz, Switzerland, illustrating the scenery on the frontier of Switzerland, France, and Italy, is on view at the Royal Photographic Society's house, 35 Russell Square, W.C. The exhibition is open free to the public, on presentation of visiting card, until April 20.

A series of seven lectures on "Modern Aspects of Helminthology" will be given at the Lister Institute by Dr. W. Nicoll on Tuesdays and Fridays, commencing March 19, at 5 p.m. These lectures will deal with the general outlines of helminthology and with the chief special problems relating to the parasitic worms of man. The course is open, without fee, to all medical men and to others interested in the subject.

On Tuesday next, March 12, Dr. T. Rice Holmes will begin a course of three lectures at the Royal Institution on "Ancient Britain," and on Thursday afternoon, March 21, Dr. F. A. Dixey will deliver the first of two lectures on "Dimorphism in Butterflies." The Friday evening discourse on March 15 will be delivered by Mr. Frederick Soddy, on "The Origin of Radium"; on March 22 by Prof. d'Arcy W. Thompson, on "The North Sea and its Fisheries"; and on March 29 by Sir J. J. Thomson, on "Results of the Application of Positive Rays to the Study of Chemical Problems."

An extra meeting of the Chemical Society was held on Thursday last, February 29, when Sir William Ramsay, K.C.B., F.R.S., delivered a memorial lecture in honour of Henri Moissan, who was born in 1852 and died in February, 1907. In introducing the lecturer, the president, Prof. Percy F. Frankland, F.R.S., stated it was fitting that the lecture held in honour of the discoverer of the most active element should be given by the discoverer of the most inert element. Sir William Ramsay referred to Moissan's early researches on the products of reduction of the oxides of the iron group and to his work on the oxides of manganese, nickel, and cobalt, and on the chromous salts. Moissan's numerous experiments on the compounds of fluorine, a series of researches which culminated in the discovery of elementary fluorine and, finally, of its isolation, and the apparatus used in this work, were described, and reference was made to the researches which led to the discovery of the method of preparing artificial diamonds.

The biology class of the University of Colorado sent Dr. Alfred Russel Wallace, O.M., F.R.S., greetings on his birthday on January 8. The February 2 issue of *Silver and Gold*, a newspaper published three times a week by the associated students of the University, publishes the reply received from Dr. Wallace, in which he says: "From the day when I first saw a Bee-orchis (*Ophrys apifera*) in ignorant astonishment, to my first view of the great forests of the Amazon; thence to the Malay Archipelago, where every fresh island with its marvellous novelties and beauties was an additional delight, nature has afforded me an ever-increasing rapture, and the attempt to solve some of her myriad problems an ever-growing sense of mystery and awe. And now, in my wild garden and greenhouse, the endless diversities of plant life renew my enjoyments; and the ever-changing pageants of the seasons impress me more than ever in my earlier days. I sincerely wish you all some of the delight in the mere contemplation of nature's mysteries and beauties which I have enjoyed, and still enjoy."

The Academy of Natural Sciences of Philadelphia will celebrate the centenary of its foundation on March 19, 20, and 21. An important feature of the celebration will be the publication of three commemorative volumes: an index to the scientific contents of the entire series of Proceedings and Journal, now amounting to eighty-five volumes; a detailed history of the academy by the recording secretary, Dr. Edward J. Nolan, of which the Short History contributed by him to the "Philadelphia Founders' Week Memorial Volume" in 1909 may be regarded as a Prodromus; and a quarto volume of liberally illustrated memoirs by members and correspondents. A sufficient number of contributions have been received to guarantee the success of the latter publication, and the general committee has reason to believe that the entire celebration will be an adequate recognition of the honourable record of the society as one of the most efficient agencies in the cultivation of the natural sciences in America during the past hundred years.

A meeting was held at the Mansion House on February 28 in support of the London School of Tropical Medicine. Mr. Harcourt, Secretary of State for the Colonies, was the principal speaker. He said that in the last seven years the School has received from the Tropical Diseases Research Fund 13,000*l.* for special work in protozoology and entomology, for which separate laboratories in new buildings have recently been provided. The School has managed to save 5000*l.* as the nucleus of an endowment fund, but at least another 20,000*l.* is required to put it on a sound financial basis. It is also desired to raise 10,000*l.* for the provision of additional laboratories and residential quarters. Mr. Harcourt said it may, possibly, be asked why the Government does not itself find the necessary funds. The keepers of the national purse, he pointed out, have not been niggardly in their practical assistance to the work. The Treasury has contributed, and is contributing, for the last five years 1000*l.* per annum to the Sleeping Sickness Bureau; for five years, 1000*l.* per annum to the Entomological Research Fund; for three years, 5000*l.* per annum to Sir D. Bruce's expedition to Nyasaland to inquire into sleeping sickness; and from 1904–7, 500*l.* per annum; and from 1908 onwards, 1000*l.* per annum to the Tropical Diseases Research Fund; this amounts to 8000*l.* a year, in addition to capital donations. In addition, approximately 50,000*l.* has been spent during the last five years in investigation and suppression of sleeping sickness in Uganda.

The Committee on Science and the Arts of the Franklin Institute, Philadelphia, Pennsylvania, made the following awards of the Elliott Cresson medal on February 7: Dr. Alexander Graham Bell, Washington, D.C., in recognition of the value of his solution of the problem of the electrical transmission of articulate speech; Dr. S. W. Stratton, Washington, D.C., in recognition of his distinguished and directive work in physical science and metrology, and its application in the arts and industries; Dr. A. A. Michelson, Chicago, Ill., in recognition of his original and fruitful investigations in the field of physical optics; Dr. A. Noble, New York, in recognition of his distinguished achievements in the field of civil engineering; Dr. Elihu Thomson, Swampscott, Mass., in recognition of his leading and distinguished work in the industrial applications of electricity; Dr. E. W. Morley, West Hartford, Conn., in recognition of his important contributions to chemical science, and particularly of his accurate determinations of fundamental magnitudes; Dr. J. F. A. Von Baeyer, Munich, in recognition of the many important results of his extended research in organic chemistry and of his discovery of synthetic processes of great industrial value; Sir William Crookes, O.M., F.R.S., in recognition of his important discoveries in inorganic and analytical chemistry, and of his pioneer work on the discharge of electricity through gases; and Sir Henry E. Roscoe, F.R.S., in recognition of his extended and important researches in the domains of inorganic, physical, and industrial chemistry.

Dr. Knight Dunlap contributes to the current number of *The Psychological Review* an account of some interesting experiments upon the sensibility of the human subject to differences in the rate of succession of stimuli in two regular series of stimuli. One of these regular series is constant, the other is varied, and the two series are presented successively, the subject having to judge which has the faster rate. The rate-threshold thus reached is compared by Dr. Dunlap with the time-threshold, *i.e.* the subject's sensibility to differences in the length of a single interval of time. As might be expected, he finds that the sensibility for rate differences is considerably more acute than that for time differences, at least under the conditions of his experiments. The writer concludes that the rate judgment is not essentially based upon a judgment of individual time intervals. His paper is especially valuable as a record of experimental methods and for careful details of the instruments employed.

From Mr. W. Junk, of Berlin, we have received a "Bibliographica Coleopterologica," containing nearly 4000 entries of works and papers devoted solely or partially to beetles. The actual catalogue is preceded by a useful introduction on the faunistic literature of the subject.

CONSIDERABLE interest attaches to the description by Miss D. M. A. Bate in the January number of *The Geological Magazine* of the dentition and other remains of a large mouse (rat, we should have preferred to call it) discovered by herself in a cave on the west coast of Crete. The new species (*Mus catreus*) considerably exceeds the brown rat in size, and may be compared in this respect to the great Gambian rat (*Cricetomys gambianus*); it consequently forms a second instance of a relatively gigantic rodent in the Pleistocene of the Mediterranean islands.

THE fourth number of "Behaviour Monographs," published by Messrs. Holt and Co. at Cambridge, Boston, Mass., is devoted to an account of the ecology of the pond-snails of the genus Physa, by Miss Jean Dawson. From their omnivorous habits, these snails are valuable as purifiers of the ponds in which they dwell. Their own mucus serves to assist in procuring food, since it entraps microscopic organisms of all kinds, which are then devoured by the snails, together with the mucus itself. The rudimentary eyes apparently afford no assistance in procuring food, but the head and fore part of the foot are sensitive to food-stimulus.

A NEW Polypodium from the Panama regions, described by Mr. R. Mason in an extract from the Smithsonian Miscellaneous Collections (vol. lvi., No. 24), is remarkable, because the pinnæ of the sterile fronds are entire, while those of the fertile fronds are toothed or lobed and bear the sori apparently at the tips of the teeth. Another striking feature is the variation in the fronds, due to differences in the pinnæ, which in some cases are entire or once forked, in others much branched; it is suggested that the branching is correlated with injury to the apex of the fronds, which are normally of indeterminate growth.

IN connection with afforestation on the Thirlmere estate in the Lake district, Mr. A. B. Edwards contributes to the Transactions of the Royal Scottish Arboricultural Society (vol. xxvi., part i.) an article containing some useful hints on planting at high altitudes. Three-year-old seedlings were generally selected, and planted in prepared pits. Larch formed the main bulk of the plants, but where shelter was required a belt or intermixture of Scots, Austrian, and Corsican pines has been adopted. For higher elevations fir or spruce is recommended, notably the Menzies spruce. In support of a favourable anticipation of the financial success of operations, the author quotes figures from a plantation in the same district.

THE Upper Rhine, from Basle to Mainz, is one of the chief seismic districts of Central Europe, about 400 earthquakes being recorded there between 1800 and 1895. Of the latest earthquake, that of November 16, 1911, a popular account by W. Salomon is given in *Naturwissenschaftliche Wochenschrift* for February 11. Judging from the area of greatest intensity, there would appear to be two epicentres, one near Lake Constance, the other, from forty to fifty miles farther north, in the neighbourhood of Balingen, Ebingen, and Hechingen. From the frequency of after-shocks in the latter district, and from their absence from the former, however, there appears to be some doubt whether the shock belongs to the class of twin-earthquakes.

IN Heft 5 of the *Mitteilungen aus den Deutschen Schutzgebieten*, the region of the upper basin of the Mungo River, in the Cameroon protectorate, is fully described from the geographical viewpoint by Dr. F. Thorbecke. He deals specially with the higher country round the volcano of Manenguba, which rises to an altitude of more than 2000 metres, and considers it to consist essentially of a crystalline block overlaid by basaltic or trachytic sheets of lava. This seems to have been slowly raised, subsequent faulting and volcanic action having also played an important part in producing the present surface forms. Meteorological observations for 1910 from stations in the Cameroons, Togo, and New Guinea are also contained in this volume.

THE Canadian Naval Service Act having been passed in May, 1910, the Department of Naval Service was forthwith organised with branches dealing with naval matters, fishery protection, tidal and current surveys, hydrographic survey, and wireless telegraphy. Reports on all these for the fiscal year ending March 31, 1911, have been published, and contain many points of interest. The tidal work has been previously mentioned in noticing the tidal tables which have recently been published. Hydrographic surveys were carried out on the Great Lakes, on the Atlantic and Pacific coasts, and in Hudson Bay and elsewhere. Not many details are given of methods and results, but it is stated that the local attraction of compasses reputed to exist in Hudson Bay was not substantiated. Thirty-two radio-telegraphic stations exist, and a scheme has been prepared for the establishment of a system of such stations on the Great Lakes.

IN the November (1911) number of the *Geographische Zeitschrift* Prof. Penck gives a most instructive critical comparison of the three principal German atlases—these three, the hand-atlases of Stieler, Debes, and Andree, are generally considered to stand in the foremost rank of modern topography—and the discussion of the differences between them. He notes the increasing use of the most suitable projections in place of the very limited selection formerly employed, the careful choice of scale, and greatly improved character of the representation of relief. Contour lines or layers of colour might in some cases be utilised, and the great scarcity of physical maps in most atlases, which devote their pages primarily to the distribution of man and his works on the earth's surface, is a matter which calls for consideration. In spite of much recent progress, there is always room for improvement, and there is ample scope for the scientific study of cartography; the same may be said of cartography in this country, where, however, there is much more to be done before an ideal standard is reached.

A HEAVY gale was experienced in all parts of England on March 4 and the following night, when at

Dover the wind attained the velocity of 71 miles an hour. For a long time past cyclonic disturbances have arrived in proximity to our coasts from the Atlantic with considerable frequency, but, due to the persistent high barometer over western Europe, the incoming storm systems have followed a track to the northward, skirting our western and northern coasts. The storm area which arrived on March 4 completely traversed the British Isles, and probably subsequent disturbances arriving will for a time now follow a similar path. In connection with the disturbance, a severe squall, accompanied by thunder and lightning, passed over Kew at 4.30 p.m. on March 4, when the wind attained the velocity of 60 miles an hour, and a similar squall passed over South Kensington at 4.40 p.m., the wind velocity recording 42 miles an hour. At Dover a squall, with the wind blowing 68 miles an hour, was experienced at 4 p.m., and a corresponding disturbance passed over Valencia, in Ireland, at 7.40 a.m., which gives a rate of travel of rather less than 50 miles an hour.

THE past winter, comprised in the three months December, January, and February, proves to be one of the warmest experienced of recent years, notwithstanding the severe frost which occurred at the close of January and at the beginning of February. A summary of the weather for the thirteen weeks ended March 2, issued by the Meteorological Office, shows that the mean temperature for the winter was in excess of the average over the entire kingdom; the greatest excess occurred in the east and south-east of England and in the Midland counties. The aggregate rainfall for the winter was largely in excess of the average over the whole of the British Isles, except in the north of Scotland, where the deficiency amounted to 2·95 in. The greatest excess was 5·3 in., in the south-east and south-west of England. In the Midland counties the excess was 4·3 in., and in the south of Ireland 4·5 in. The rainy days were also in excess of the average everywhere, except in the north of Ireland. The duration of bright sunshine was deficient, except in the north of Scotland, but the difference from the normal was nowhere very large. At Greenwich the mean temperature was above the average in each of the three winter months, the excess being respectively 5°, 2°, and 4°; the mean for the whole period was 42·5°, which is 3° above the normal. There has only been one winter as warm in the last thirty-five years, the mean for the three months being 43·5° in the winter of 1898–9. The rainfall was also in excess of the average in each of the three months, the aggregate excess being 3·3 in. The duration of bright sunshine was in good agreement with the normal.

IN the December (1911) number of the Annals of Tropical Medicine and Parasitology, issued by the Liverpool School of Tropical Medicine, some novel "Tables of Statistical Error" are given by Sir Ronald Ross and Mr. Walter Stott. The tables show, for a given true percentage, how many observations must be made in order that the odds may be $m : 1$ that the observed percentage lies within given limits. The limits taken are ±1, ±2, ±3, ±4, ±5, or ±6 per cent., the odds 99999 : 1, 9999 : 1, 999 : 1, 99 : 1, 9 : 1, and 1 : 1, and the percentages are tabulated by steps of a unit. As the calculation appears to have been made, however, on the usual basis of a normal distribution, it is not clear what meaning can be attributed to the figures given for very low percentages, where the number of observations is not nearly sufficient to justify such an assumption. The tables, which are obtainable as a separate publication, should do much to lessen the publication of results based on quite inadequate statistical data, and thus serve a very useful purpose, but the point to which we have directed attention should have received more attention in the explanatory introduction.

MR. G. R. M. TEMPLE sends us from York a copy of a photograph, here reproduced, which illustrates very clearly the result of the expansion of water by freezing during the recent severe frost. The bottle was filled with clean water and tightly corked; when the water had frozen a stem of ice about 4½ in. in length was found to be projecting from the neck of the bottle, as shown in the illustration. This stem represented, of course, the increase of volume undergone by the water in passing from the liquid to the solid state. The bottle must have been cracked while solidification was going on, otherwise the water would have escaped.

Protruding stem of ice formed by the freezing of water in a bottle.

THE illustrated article by Prof. E. F. Northrup on a photographic study of vortex rings in liquids, published in our issue of February 1 last (vol. lxxxviii., p. 463), has prompted Mr. A. W. Ackermann to send a description of some experiments performed by him twenty years ago in the production of vortex rings in liquids. He took a cubical vaseline tin of 8·5 cm. edge, cut a hole in the lid 1 cm. in diameter, filled the tin with a solution of permanganate of potash, and placed the tin in a bath 6 ft. long. By means of a long stick impulses were given to the top or end of the tin, and the vortex rings were ejected at pleasure and studied. At Mr. Ackermann's suggestion, Prof. C. V. Boys, F.R.S., was asked if he had investigated the matter. He reminds us that the late Prof. Guthrie had a large glass trough made in the early eighties of the last century for experiments on liquid vortex rings. In the centre of one end there was a "gun" with a thick sheet india-rubber back. The gun was filled with a solution of rosaniline. Dr. Guthrie's trough was used later by Sir Arthur Rücker, F.R.S., while professor of physics at the Royal College of Science, London. Prof. Boys goes on to inform us that he would have expected that a trough wider than 12 cm., as described in Prof. Northrup's article, certainly not less than 30 cm. or a foot, would be greatly preferable, and equally that a gun with a larger muzzle than that employed would have been better.

THE annual general meeting of the Institute of Chemistry was held on March 1, Dr. George Beilby, F.R.S., the president, occupying the chair. During the course of his address the president said the fund for new buildings for the institute has reached 8500*l.*, but 15,000*l.* is considered necessary for erecting a building suitable for the work of the institute. Touching on the difficulties which confront public analysts and private practitioners, he referred to the attempts made on the part of certain local authorities to lower the status of the professional chemist by offering appointments at ridiculous remuneration. Enlightened municipal bodies realise that the proper administration of statutes, such as the Sale of Food and Drugs Act, cannot be expected unless they attract to their appointments men of competence and integrity, who can hold their own as responsible representative officers of their authorities. The Act is as much a statute against fraud as in the interests of public health, and it must be understood that the public analyst is in no way subject to the control of the medical officer of health. Prof. R. Meldola, F.R.S., was elected as president for the ensuing year, and the following as vice-presidents :—Dr. G. T. Beilby, F.R.S., Dr. F. Clowes, Dr. G. McGowan, Sir Alexander Pedler, F.R.S., Dr. J. M. Thomson, F.R.S., and Sir William Tilden, F.R.S.

THE Bulletin of the Bureau of Standards for December 15, 1911, contains an account of an investigation carried out by Mr. F. W. Grover on the effect of temperature and frequency on the capacity and phase difference of a number of commercial paraffined paper condensers. The alternating currents used were supplied by special generators designed for the Bureau. Bridge methods were used, balance being indicated by a vibration galvanometer. The phase differences found range from 6′ to 22° of arc. The change of capacity with frequency is large for low frequencies, and decreases as the frequency increases. The temperature coefficient of capacity is generally positive and of the order 1 per cent., but in some cases may be negative. The absorption appears to be represented with a fair degree of accuracy by Von Schweidler's extension of Pellat's theory that the dielectric displacement on the application of an electric field attains instantly a certain fraction of its final value, and then increases exponentially to its final value. Three exponential terms appear to be necessary to represent the observations. It follows from these results that paper condensers cannot serve as standards of capacity, and should not be used in any work in which a constant capacity is required.

COMMENTING on the fatal accident to Mr. Graham Gilmour, *Engineering* for March 1 considers that if the trussing of his machine was after the usual pattern in this type of machine, the provision for horizontal strength would not be very great, and failure would most likely be in this direction. The essential lesson in this and previous accidents appears to be that it is high time that the question of the strength of monoplane wings was gone into in a public manner, and that it is due to the public that the makers should demonstrate that they have a reasonable factor of safety, both vertically and horizontally, otherwise the monoplane in its present state will be put down as a machine in which safety has been so far sacrificed to the craze for "records" that it is not fit for practical flight.

THERE have been several proposals within the past few years to construct internal-combustion air-compressors on the free-piston system, and one which has been made and tested by Signor Giuseppe Matricardi, of Pallanza, Lago Maggiore, Italy, is described in *Engineering* for March 1. A heavy piston is propelled from one end of a cylinder to the other end by the explosion of a gaseous mixture behind it. During its motion it expels air in front of it through a port, and thence through a non-return valve into a reservoir. Near the end of its travel the piston overruns the port, and compresses into the end of the cylinder a fresh charge, which is exploded in its turn, shooting back the piston to the other end. In its passage the piston compresses and discharges into a reservoir the air in front of it, as before. It is said that a good efficiency and large output have been secured in the small machine already tested, but actual figures are reserved until a larger compressor, now under construction, is ready and tested by independent engineers.

WE are indebted to Messrs. Cassell for a copy of the first part of a new issue of Kearton's "British Birds' Nests." The fact that bitterns nested last year in Norfolk is recorded.

THE first part of "The Nature Book," which is described in a subtitle as a popular description by pen and camera of the delights and beauties of the open air, has been published by Messrs. Cassell and Co., Ltd. The work is to be completed in thirty-six fortnightly parts, at 7*d.* net each. It is profusely illustrated from photographs and a series of coloured plates.

THE report of the ninth meeting of the International Meteorological Committee, held at Berlin in September, 1910, and of the sixth meeting of the Commission for Terrestrial Magnetism and Atmospheric Electricity, which preceded it, has just been published as a Blue-book (Meteorological Office, No. 208, price 3*s.*).

THE "Classified List of Smithsonian Publications available for Distribution, January, 1912," has been received from Washington. Applicants for these publications are requested to state the grounds of their requests, as the Smithsonian Institution is able to supply papers only as an aid to the researches in which applicants are especially interested. The papers included in the list are distributed gratis, except in some cases, where a small charge is made.

OUR ASTRONOMICAL COLUMN.

BRILLIANT WHITE SPOTS ON MARS.—In No. 10, vol. xix., of *Popular Astronomy* Mr. L. J. Wilson, who observes Mars with an 11-inch reflector, cites several occasions during October and November, 1911, when his observations at Nashville, Tenn., revealed the presence of very conspicuous and brilliant white spots on the planet's disc; such spots were seen, on October 14, in the region following Hesperia. Comparing his recent observations with those made during 1909, Mr. Wilson concludes that the frequent formation of such spots is an unusual feature of the present apparition.

COMETARY PHENOMENA.—A discussion of cometary phenomena is published by Prof. Karl Bohlin in an abstract from the *Naturwissenschaftlichen Rundschau.* Prof. Bohlin deals with such matters as the orbits, the brightness and structure of the different parts of comets, the facts revealed by spectroscopic analysis, and the peculiar fluctuations of the form and brightness of the tails of various comets. Of general interest will be found the tables he gives showing the variation of all these features in a large number of well-known comets which have appeared since the seventeenth century.

THE ANTARCTIC CAMPAIGN.

AT the present time it is not unlikely that the south pole has been reached by both Captain Scott and Captain Amundsen, who are leading respectively British and Norwegian Antarctic expeditions. The accomplishment of this athletic feat is one that the public take an intense interest in, and not least of all at the present time because there are two competitors in the polar race, which adds zest from the sportsman's point of view. Any journey in Antarctic regions must also add something to our knowledge of the Antarctic regions, and any additional knowledge is of scientific value. But the two expeditions are of much greater interest to the scientific community from the point of view of the work they will do outside this journey to the pole, for, so far as the polar journey is concerned, Captain Scott intends to follow over his own track and Sir Ernest Shackleton's, except for the last hundred miles, and Captain Amundsen may, after tracking in a south-westerly direction across the surface of the Ross Barrier, also follow Sir Ernest Shackleton's track up the Beardmore Glacier, and thence to the pole, practically in the same line as Captain Scott. The only additional topographical information therefore gained by these journeys is in the possible track of Amundsen from the vicinity of Edward Land to the Beardmore Glacier, and the same track that both Scott and Amundsen are likely to take over the last hundred miles to the pole, which, we fairly well know from Shackleton's observations, must be situated at an altitude of something like 10,000 ft. on the inland ice of Antarctica. We hope that Scott and Amundsen will meet each other, and, mutually helping one another, reach the pole with honours divided.

Mr. Mossman reports that great reticence was shown by the members of the Norwegian expedition while in Buenos Aires with regard to Amundsen's southern journey, but that he was to leave for the south not later than September, and that he hoped to reach the plateau by another way than the Beardmore Glacier, and emerge somewhere in the neighbourhood of Alexander Land, a region already visited by Amundsen on board the *Belgica.* The accomplishment of a journey along this route would be not only a triumph of physical endurance, and good organisation of food supply and equipment, but would also add immensely to our knowledge of Antarctica.

If the pole is attained by either or both of these explorers, the thanks of the scientific world are due to them for having once and for all settled the matter, and thus helping the public to understand that serious south polar exploration is not to reach a certain mathematical point before somebody else, but rather to carry on systematic investigations within the greatest unknown area on the surface of our globe, an area that occupies about five and a half million square miles—*i.e.* almost as great as the area of Europe and Australia combined.

It was Scott's intention to land a party not only at McMurdo Sound, but also on Edward Land. After Scott and his party were landed at McMurdo Sound, Lieutenant Pennell received command of the ship, and took Lieutenant Campbell's party with him, consisting of six, all told. The party was, however, unable to land at Edward Land, "owing to the perpendicular ice cliffs." This being so, an attempt was made to land them "as far west of Robertson Bay as possible," and make discoveries in that direction, but "from Smith Inlet to Robertson Bay there was not a single spot where a party could land—all sheer ice cliffs." Campbell and his party therefore landed at Cape Adare. After landing the party Pennell cruised to the west of Cape North, and discovered new land westward in two places. In the meantime, Scott and his party had finished setting up their camp, and Scott had begun a journey to the south that was probably preliminary to his great effort to reach the pole. Beyond this we have very little information, but since the return of the *Terra Nova* to New Zealand we understand that the ship was chartered by the New Zealand Government in order to carry out some hydrographic operations in the vicinity of New Zealand during the winter months. These hydrographic observations, made under the auspices of the New Zealand Government, are sure to be of the greatest possible scientific value; and now the *Terra Nova* has sailed once more for the south, and no word will be heard of her for another month or so. It is understood, however, that Lieutenant Pennell takes news to Captain Scott that sufficient funds have been acquired to enable him to stay out for another season, so that if reaching the pole is disposed of, the expedition should have a most excellent opportunity of carrying out explorations and various observations which will be of the highest possible scientific value.

Amundsen's party has, according to information received, succeeded in landing on the Ross Barrier in longitude 162° W., about fifty miles west of Edward Land, at a place he has named Bay of Whales. The news of the discovery of the Norwegian expedition at this point by Lieutenant Pennell came as a great surprise to all in Britain, but from the scientific point of view it cannot but add to the value of Scott's observations as well as Amundsen's, and, as I have said, from the sportive point of view it adds zest. Moreover, every mile Amundsen and his party travel over to the east of Beardmore Glacier will be new, and any observations taken at the Norwegian base station will be entirely new and of great value.

The *Fram*, which has carried two successful expeditions to the Arctic regions, made a long voyage out to the Ross Barrier from Madeira without calling at any intermediate port, and again from the Ross Barrier she made a second extensive voyage without calling at any port until she reached Buenos Aires. During the past southern winter she has crossed the Atlantic twice from Buenos Aires to Africa, and has taken observations at sixty stations. In order to get a clear idea of the past work and future programme, I quote from information that Mr. Roald Amundsen has been good enough to send me which has been furnished to him by Captain Nilsen, the commander of the *Fram*:—

"We left Buenos Aires," says Captain Nilsen, "on June 8, 1911, exactly one year after our departure from Hörten (Norway), on our first oceanographic voyage to the northern part of the South Atlantic. The pilot accompanied us to Montevideo, where we stopped until Sunday morning, June 11, on account of a 'pamperos' (south-westerly wind very violent), when we continued our way in the Atlantic Ocean in good order. The weather hindered us from beginning the sounding before June 17, but from that day everything went on all right. We commenced first with sounding, taking also water samples and temperatures down to 2000 metres; but this took us eight hours, and as during this time we had to stop with fixed sails, one-third of the twenty-four hours passed. Time being short, as we would have to leave Buenos Aires about October 1, we could only get on a short distance in the Atlantic if we had to continue this work, and it was necessary, therefore, to abandon sounding altogether, and we took observations down to 1000 metres only. We sailed from the La Plata River in a line approximately straight towards 9° E. longitude and about 21° S. latitude; we arrived here on July 22, and sailed towards St. Helena, which we passed on the evening of July 29. We continued to South Trinidad, which we passed very close to on August 12. On August 25 we finished the oceanographic observations in about 25° S. latitude and 40° W. longitude. All in all, we have had sixty stations, and have collected 891 water samples, which will probably be sent home by the *Kronprinzessin Viktoria*. We have also about 200 bottles of plankton.

"We returned to Buenos Aires at midnight on September 1. During the whole time the weather has been fair, and our course was fixed according to the winds; we sailed eastward to Africa by almost steady northerly and north-westerly winds that lasted exactly four weeks, and during this time the motor was at a complete standstill. In order to cover as even distances as possible, we sailed at a rate of 4 to 5 knots. As we had to take in the sails at each station, they got so worn that they scarcely kept together at last; and I had no mind to use our second set of sails, that ought to be in tip-top order when we got into the 'roaring forties.'

"The voyage has in every respect been a good one for the *Fram*; her motor has been thoroughly examined and cleaned during the long rest, the rigging looked after, all iron has been cleaned for rust, and the vessel has been painted all over; the *Fram* looks finer now than she did when she was new. The stores have been arranged, registered, and cleaned, and the sailmaker, Rönne, has been sewing sails, &c., from 6 a.m. to 6 p.m., and several alterations and modifications have been made by the chief engineer, Lundbeck, who is a man and an engineer of the first order."

This is the chief information received from Captain Amundsen.

It seems almost a pity that a vessel so well fitted for oceanographical research as the *Fram* is, in higher latitudes, worked north instead of south of 40° S., for with the exception of the *Scotia's* hydrographical observations south of 40° S., little has been done in oceanographical research in high southern latitudes in the Atlantic Ocean, whereas north of that latitude the *Challenger* and subsequent expeditions have done much to add to our knowledge of those seas.

Some important observations have, however, been made south of 40° S. by the *Deutschland*.

The *Fram* is not expected to carry out any oceanographical research in her circumpolar voyage—she will only just have enough time to fetch the landing party, and again regret must be expressed that time has not been allowed to carry out such researches in those high southern latitudes by an ice-protected ship. Nothing is yet decided as to 1912, but Mr. Roald Amundsen does not think it likely that the *Fram* will proceed across the North Polar Basin before 1913, as that depends on the funds available.

Four other expeditions are also carrying on researches in the south polar regions, namely, an Australian one under Dr. Douglas Mawson, a German one under Lieutenant Dr. Filchner, a Japanese one under Lieutenant Shirasé, and last, but not least, the Argentine expedition, which sailed for the South Orkneys to continue the meteorological and magnetical work initiated by the Scottish expedition at Scotia Bay in 1903, and continued by the Oficina Meteorologica Argentina since 1904 at an annual cost of about 6000*l*. With regard to the Japanese expedition, practically no news has reached Europe, and, indeed, notice that the expedition left Sydney on November 19, 1911, came as rather a surprise, as it was thought that after being so hopelessly late in the previous season they would not for the present attempt further work. Whatever are the aims of the present Japanese expedition, the writer has reason to believe that we may expect Japan to take a very prominent part in Antarctic exploration of a purely scientific kind before many years are past. The work of the German expedition lies in the Weddell Sea in longitudes west of Coat's Land, Dr. Filchner having generally agreed with the writer that the region to the east of this should be left for the proposed Scottish expedition. If, however, the Germans fail on account of conditions of ice or other difficulties to carry on their work to the west of this longitude, it is quite understood that they are to be free to work to the eastward. So far as the writer is concerned, he is of opinion that it is not in the interests of science that an expedition actually in the field should be hampered in any way by reserving an area for another expedition which has not so far succeeded in raising all the necessary funds. The area of the unknown Antarctic regions is so vast that there is plenty of room for all-comers, and more especially so if there is a division of labour in the work.

There are two prominent theories of the structure of Antarctic lands. Filchner bases the plan of his expedition upon the theory held by himself, Dr. Penck, Dr. Otto Nordenskjöld, Sir George Darwin, and others, that there are two Antarctic land masses which are divided from each other by a channel possibly covered by a continuation of the Ross Barrier running across from the Ross Sea to the Weddell Sea, thus dividing Graham Land from the rest of the land. The other prominent theory, which has for long been held by Sir John Murray, and is supported by Sir Ernest Shackleton, Dr. Mawson, and myself, is that there is one great Antarctic continental land mass with no such division across it. A third theory, held by Dr. Nansen, is that the Antarctic land is composed of an archipelago of islands. In a paper [1] delivered to Der Schweizerischen Naturforschenden Gesellschaft at Basel in 1910, I summarised my reasons for holding the view that there was one great Antarctic continent.

Having a definite theory of the structure of the Antarctic continent, Filchner sets out to test the accuracy of it. His confidence augurs well for the success of the German expedition. "Morgen früh 10 Uhr (also am 10 December) gehen wir," says he, "in See nach dem Eis mit rein südlichem Kurs bis zum Auftreffen auf die Eisbarre und folgen ihrem nördlichen Rande, dann so lange östlich, bis wir sie durchqueren können." This confident assurance reaches us from South Georgia, from which place

[1] "Über die Fortsetzung des antarctischen Festlands zwischen Enderbyland, Coatsland und Grahamland, sowie das Vorhandensein im Morrellsland." Von Herrn Dr. William S. Bruce, Direktor der Scottish Oceanographical Laboratory.

I have had word from Lieutenant Dr. Filchner and Dr. Heim, geologist to the expedition. They inform me that they have so far had a successful voyage, having landed at St. Paul's Rocks, and having already taken as many as eighty soundings. Several of them appear to have been taken in the neighbourhood of South Georgia and the South Sandwich Group, and these will form a most important contribution to the study of former Antarctic continental connections with South America. "Storm and stress of weather hindered every attempt at landing on the South Sandwich Group," and in this connection it is interesting to note that this heavy weather was previously predicted by Mr. R. C. Mossman at Buenos Aires.

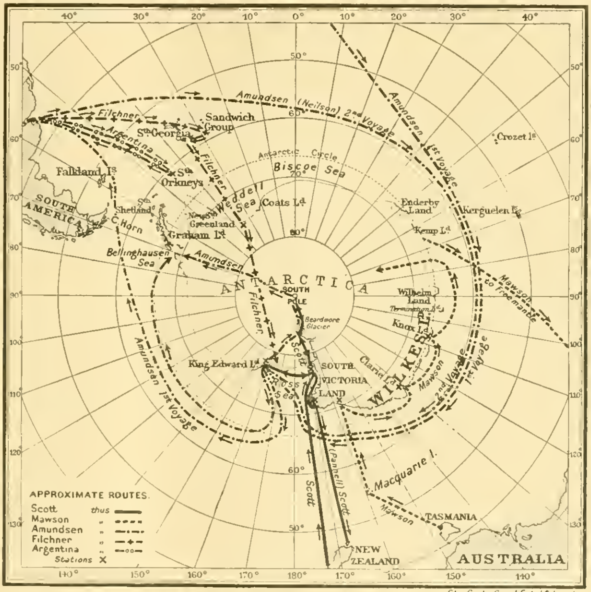
Prof. Penck, who has been good enough to furnish me with much useful information, says:—"Reaching the pole does not form a special feature of the programme." He also writes saying that Filchner will establish a station to the west of Coat's Land, and will not leave the Antarctic regions until the summer of 1913–14.

A most important line of sixteen soundings[3] has been taken from Monte Video to South Georgia and the South Sandwich Group which confirms the existence of deep water of 2500 fathoms which the writer supposed existed there[4] between 35° S., 52° S., and 21° and 55° W. Filchner extends this 3000-fathoms water to a point west of South Georgia, where he obtained a sounding of 3064 fathoms. This sounding, along with one of 2358 fathoms and a second of 2413 fathoms Filchner considers to the west of South Georgia, precludes the possibility of a "rise" (unterseeische Verbindung) between South Georgia and the South Sandwich Group, but another sounding of 1787 fathoms between Lieskow Island and South Georgia seems to confirm, to my mind, the existence of such a rise. Close to Candlemas Island 478 fathoms was obtained, and depths of 1144 and 1757 fathoms were obtained close to the group, just as the *Scotia* sounded in 1745 fathoms 15 miles off the South Orkneys.

Although the deeper water from the north dips rather further south than it was previously supposed to do, the suggestion that there is no "rise" is worth consideration as leading to the possibility of the Sandwich Group being cut off from the South American-Graham Land connection, and indicates the great importance of more soundings to the south of South Georgia. Quite extensive and interesting geological excursions were made in South Georgia, which were facilitated by Captain Larsen lending the German expedition his 500-ton yacht *Undine*. The Germans have found that South Georgia is a folded mountain range, probably part of the Faltengebirge of the South American Andes and Graham Land. The tuffs found by Gunnar Andersen in 1902 are found to be old Mesozoic and young Palæozoic tuffs. Dr. König found an ammonite in the state of Possessions Bay. Bad weather prevented pendulum observations, but earth magnetic elements were determined.

It took from November 1 to 14 to go from South Georgia to the South Sandwich Group. A course was first steered to Lieskow Island; the *Deutschland* then passed Candlemas Island, and left the group at Zavadowskij Island. Some of these islands are extinct, and others active, volcanoes. The rocks appeared to be basaltic. Volcanic sand containing basaltic fragments was secured by sounding.

Meteorological and other observations were made, and it is especially interesting to note that for the first time in Antarctic regions *ballons-sondes*, as used by the Prince of Monaco in Spitsbergen, were employed, since in South Georgia sixty-five of these balloons were released. These were traced to a height of 9 kilometres, or 29,528 ft., and should give



Stanfords Geog' Estab', London.

valuable information regarding the higher atmosphere in the south polar regions.

Whether Filchner succeeds in pushing far to the south to the west of Coat's Land, where he believes he will be able to land on a barrier similar to and continuous with the Ross Barrier, depends on the state of the ice in the Weddell Sea, and Mossman unfortunately predicts a series of bad ice years. If Filchner meets the pack as Ross met it in 1842–43, and as the Scottish expeditions met it in 1892–93 and in 1902–03, in which latter season also Nordenskjöld's ship, the *Antarctic*, was crushed and lost, he will not attain a high latitude to the west of Coat's Land, but if he has an open summer, as Morrell and Weddell had in 1822–23, he will get far south, and will fall in with land somewhere about 75° S., if the supposed rift valley from the Ross Sea does not exist. Filchner will also in all probability then be able to prove the

[3] *Zeitschrift der Gesell. f. Erdkunde zu Berlin*, 1912, No. 2.
[4] "Bathymetrical Survey of South Atlantic Ocean and Weddell Sea." By Wm. S. Bruce. With Map and Illustrations. *Scot. Geog. Mag.*, August, 1905.

existence or non-existence of New South Greenland, discovered by Captain Johnson in 1821–22, and revisited and described by Morrell in 1822–23—the summer Weddell attained the high latitude of 74° 15′ S. in those longitudes. If Filchner falls in with New South Greenland it will almost preclude the possibility of the existence of the suggested ice-covered strait cutting across Antarctica from the Ross to the Weddell Sea.

Altogether, the German expedition has most interesting and fascinating problems to solve, and with such a good ship—the *Deutschland*—with such excellent equipment and staff, and so competent a leader, should not fail to bring us back much valuable information.

The Australian expedition, under the able leadership of Dr. Douglas Mawson, is on quite a different plan from any of the others in the field, and in that it will do not only a considerable amount of hydrographical work, but will also make deep-sea biological research a special feature, it resembles more the general plan of the late Scottish expedition. In fact, the *Aurora's* trawling gear is much the same as that used by the *Scotia*, and she carries with her the *Scotia's* quick-working winch, which was used for hauling up the sounding apparatus, the deep-sea water-bottles and thermometers, and vertical plankton net. Mawson also emphasises meteorology, especially in relationship to Australia.

The *Aurora*, which was refitted in London under the guidance of Captain Davis—who is her master, and was previously master of the *Nimrod*—left Hobart on December 2, and pushed south-eastward, calling at the Macquarie Islands on December 21, after which Mawson intended to land a party west of Cape North, directly north of the magnetic pole. This party will hope to complete the magnetic data yet wanting in the vicinity of the south magnetic pole. Proceeding eastward, a second party will be landed at Clarie Land, and a third at Knox Land. These parties, by man, dog, and motor sledges, will seek to map out the coastline to the east and west of their respective stations. The voyage is then to be prolonged westward about the latitude of the Antarctic circle as far as Enderby Land, whence the *Aurora* will return to Fremantle.

The programme is a very ambitious one, and Mawson may rest well satisfied if he lands but one party and carries out a general investigation of this little-known and much disputed coast, including oceanographical and meteorological survey. In 70° E., viz., the longitude of Kerguelen Island, an attempt will be made to penetrate southward as well as in the longitude of the magnetic pole. Mawson regards this part of the Antarctic continent to which his efforts are to be directed as by far the most important portion of Antarctica yet to be explored. He points out that "along the whole 2000 miles of coast between Cape Adare and Gaussberg a landing has been made once only, and then but for a few hours, by d'Urville's expedition in 1840. Only a few vessels have ever come within sight of this coast, and practically none since the days of d'Urville and Wilkes."

Mr. Alfred Reid tells me that lack of coal may render it necessary for the *Aurora* to put into Kerguelen for ballast on her return to Fremantle under canvas. In April the *Aurora* will again go south with a number of Australian men of science in order to carry out dredging and sounding in seas between Australia and Antarctica, and in December the *Aurora* will proceed south once more to pick up Dr. Mawson and his colleagues at the three stations.

Mawson carries with him an aëroplane and certificated air pilot, and has, like Filchner, an installation of wireless telegraphy. The expedition, which carries a crew and staff of fifty persons, is well supported by the Australian and British Governments and by private enterprise.

Mawson is a geologist of the first order and a trained magnetic observer, and with Shackleton's expedition gained an intimate insight into the geology of Antarctica and its relationship to Australasian geology. He is an enthusiast, and his plans are original and well thought out. Mawson is well supported by Captain Davis and an excellent scientific staff, and thus the Australian expedition is sure of a scientific success, and more especially so since the expedition is not hampered by taking part in the race to the pole.

As I have already stated, little is known of the plans and prospects of the Japanese expedition, but it is to be hoped that they will be rewarded with a rich harvest of scientific results that will encourage future efforts on the part of Japan.

Finally, success is assured for the enterprising Republic of Argentina, with meteorological and magnetical work at the first-class station at Scotia Bay, which now commences work for the tenth consecutive year—a triumph without equal in the annals of polar exploration. Every year the Argentines send out a party of trained meteorologists and magneticians, who winter at Scotia Bay, frozen in and cut off completely from the rest of the world for twelve months, and it is interesting to note that the leaders of this work, under the able directorship of Mr. Walter J. Davis, of the Oficina Meteorologica Argentina, have been trained at Ben Nevis Observatory, which the British Government persistently refuses to support for no other reason apparently than that it happens to lie north of the Tweed.

WILLIAM S. BRUCE.

FISHERIES OF BENGAL.

THE Journal of the Royal Society of Arts of December 22, 1911, contains a full report of a paper on the fisheries of Bengal, by Dr. J. T. Jenkins, read before the society on November 14. In response to an invitation from the Indian Government, the author proceeded to India in October, 1908, for the purpose of undertaking, during a period of eighteen months, a practical investigation into the possibilities of the fisheries of the Bay of Bengal and the Sandarbans. He was provided with a trawling steamer, the *Golden Crown*, which was unfortunately not so efficient as she might have been; and with this vessel trawling was carried on for a considerable period in various parts of the bay, work being carried on night and day. As a rule, four hauls were made *per diem*, and it was found, despite the monsoon, that trawling can be carried on at all seasons of the year. The results fully confirmed the anticipations which had previously been made by Lieut.-Col. Alcock and others as to the richness of the fishery, large supplies of the food-fishes most esteemed in the Calcutta market, as well as others, being obtained.

Even the coarser kinds would find a ready sale among the poorer classes of Bengalis, while in the case of uneatable species like sharks and swordfishes the liver and fins could be utilised.

As to the practicability of bringing the catches in good condition to market, it was found that, if stored in ice, the fish would keep perfectly well for a certain time. In the event of the fishery being worked commercially, it is recommended that Diamond Harbour, which is much lower down the Hughli than Calcutta, with which it is connected by railway, should be selected as a base for trawling.

The collections included a large series of fishes and invertebrates, which have been handed over to the Indian Museum to be worked out.

Only a short time could be devoted to the fisheries of the Sandarbans, that vast area in the Ganges delta which includes large rivers and pestiferous creeks where fish-life is impossible, but such observations as could be made indicate that here too profitable fisheries could be established, for it is to the Sandarbans that the hilsa (Indian shad), one of the most esteemed of Calcutta food-fishes, resorts for the purpose of spawning.

As a preliminary to the development of the rich fisheries of Bengal, it is recommended that a Fisheries Department should be established by the Indian Government without delay. R. L.

DISINTEGRATING BACTERIA AND OTHER ORGANIC CELLS.

BACTERIAL toxins may be broadly divided into two varieties. In one of these the toxin is excreted into the medium on which the organisms are cultivated, and in the other type the toxin is retained within and forms an integral part of the living bacterial cell.

It is now generally recognised that the disease-producing effects of pathogenic micro-organisms are almost entirely due to the toxins, whether intracellular or extracellular, which they secrete. For immunising purposes or for the preparation of anti-sera, the toxin which is excreted may be obtained from the culture medium by filtration through a porous porcelain filter, such as the Pasteur-Chamberland, the organisms being retained by the filter and the toxin passing through. The diphtheria and tetanus bacillus are examples of this type.

The majority of micro-organisms, however, do not excrete their toxin, at least to any extent, and among those that retain it within the cell are typhoid, cholera, plague, glanders, *B. coli*, *B. streptococci*, *B. staphylococci*, &c. In these cases some method of rupturing the cell-wall, so that the contents may escape, has been found to be desirable. This allows of not only the use of the toxin as such, but also renders it possible to investigate the chemical composition and properties of the bacterial proteins and other cell constituents.

The apparatus to be described fulfils the required conditions, and causes the cell-wall to be ruptured so that the contents are obtained unaltered. It is necessary that there should be no appreciable rise of temperature during the operation, apart even from any extraneous cooling arrangement, or else chemical change would occur; the apparatus therefore must be so far as possible frictionless. Every organism must come under the grinding action, so that either no whole cells remain or their number is reduced to a minimum. The containing vessel in which the grinding action takes place must be so effectually sealed that, during the process of disintegration, no cells have any opportunity of escaping. This applies particularly when pathogenic organisms are being dealt with. The apparatus as designed is made in two forms; in one (Fig. 1) it is mounted between horizontal centres, and in the other (Fig. 2) between vertical centres. In the former the grinding action is controlled by gravity, and in the latter by electromagnetic means.

The appliance consists essentially of a phosphor bronze or steel pot or vessel, A, in which a number of steel balls, B, are allowed to revolve. The steel balls accurately fit the inside of the containing vessel, so that as the machine rotates they are in contact over nearly one-half of their circumference with the inside of the vessel. A metal cage, C, is made of such a shape that its prongs lie between the balls, so that the latter cannot collide one with another when the machine is rotating. Mounted at the centre of the metal vessel is a steel cone, D, which is of such a size that it keeps the balls in their proper position in close contact with the periphery of the containing vessel. This cone is an important part of the apparatus as upon it depends the pressure that may be exerted on the balls; and, further, as the result of its use the balls themselves have freedom to slip

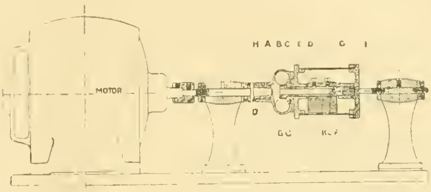


Fig. 1

if any additional strain is thrown on them, or if any undue amount of material comes under their action. The containing vessel is closed by a metal cap, E, which screws down, hermetically sealing the vessel. A groove is made in the top of the containing vessel into which a lip on this screw cap loosely fits. Sufficient space remains between the two, as shown in the figure, to allow of some bacterial agent being placed therein, thus effectually preventing the escape of whole bacteria or ground material from the containing vessel. Over the whole of this a cylindrical cap, F, is placed, and in the top of this cap a metal cone, G,

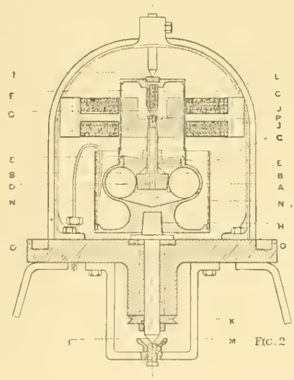

Fig. 2

is fitted, which presses by means of a spring on to the top of the steel cone, D. The steel cone is itself hollow, and is closed by a small metal cap, L. A lead or steel weight, K, is fitted on to the steel spindle, D, and is clamped on any desired position along it.

The apparatus is mounted on a cone, H, and runs between this cone and the centre, I. It may be conveniently connected directly up to a motor, as shown in the illustration, or may be driven by a belt from any suitable source of power by putting a grooved pulley on to the left-hand end of the spindle.

The grinding action takes place between the steel balls contained in the metal vessel and the interior surface of the same. It is evident that if the weight, K, were not on the central cone, as shown, or unless some similar method were adopted to control the cone to prevent it from rotating, no grinding action would result; the central cone, in fact, must either remain still or be allowed to rotate at a slower speed than the containing vessel. The metal weight, K, is of such size that on the whole machine being driven at a suitable speed the action of gravity results in the steel cone remaining still, and so a grinding action takes place between the steel balls and the inside surface of the containing vessel. To bring the bacterial or other cells under the grinding action of the balls, the speed of rotation should be from 1000 to 1500 revolutions per minute; centrifugal action is then sufficient to ensure that the whole of the material does actually come between the balls and the metal vessel.

The method of using the machine is briefly as follows:—The bacteria, after being removed from the culture tubes or plates on which they are grown, are centrifugalised; the semi-fluid mass is then emulsified with saline solution, so that it is of a creamy consistence. This material is then introduced into the container by means of a pipette through the hollow centre of the steel cone. This ensures that no parts of the machine are disturbed more than is absolutely necessary either before or after grinding. The machine is then run for a longer or shorter period, depending on the amount of material to be dealt with, and the ground material is then pipetted off through the central steel cone. As the balls are themselves free to rotate, the amount of friction is negligible, but any rise of temperature may be prevented by allowing a small stream of carbonic acid gas from a cylinder of liquid carbonic acid to impinge on to the side of the vessel; alternatively an ether spray, such as is used for section-cutting purposes, may be used, and will be found quite efficient.

The vertical type of machine (Fig. 2) is exactly similar in all essential details, except that the central steel cone is controlled by means of electromagnets. On the top of the cone a mass of soft iron is fixed, and this is kept from rotating by means of the electromagnets, J. The only constructional difference is that the containing cylinder, F, is made of vulcanite, so that it is perfectly diamagnetic. The chief advantage of this design over the one previously described is that it can be completely covered by a glass bell-jar while in action. A bactericidal agent may be placed in the groove O, and the bottom edge of a bell-jar allowed to dip into it.

The effect of disintegrating yeast cells for ten and fifteen minutes is seen in Figs. 4 and 5 respectively, Fig. 3 showing the cells before the commencement of the process. It is interesting to note that in Fig. 5 the cell contents have taken up the stain which was used in making the microscopical preparation, whereas the cell envelopes remain unstained and show as clear areas, thus demonstrating that the cell contents have been completely expressed.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. E. A. Newell Arber, of Trinity College, has been approved by the general board of studies for the degree of doctor of science.

The general board of studies has issued an important report on advanced students, of which there are at present two classes: (1) those who qualify for a degree by submitting a dissertation approved by a degree committee of a special board, and (2) those who qualify for a degree by reaching a certain specified standard in a tripos examination. The board points out that there is considerable variation in the standard required of advanced students in the various tripos examinations.

The number of advanced students of the latter class admitted to courses of study in the fourteen years from 1896 to 1909 inclusive was 101. In the same period eight applications were refused. Of the 101 admitted, 35 reached the standard required in their respective tripos examinations; 18 were rejected; 48 did not present themselves for examination. These statistics point to the conclusion that a good many students are admitted to the status of advanced students who have no real claim to the distinction which such admission may be held to confer.

After full consideration of the working of the present regulations, the general board has come to the conclusion that it is desirable that advanced students should no longer be admitted to courses of advanced study, but that they should be admitted to courses of research only.

With this end in view, the board proposes that the class of affiliated students should be enlarged, and that affiliated students should not only be permitted to proceed to a degree after residing in the University for six terms, but in the case of certain tripos examinations should be also admitted to the second part without necessarily having fulfilled the ordinary condition of having previously passed in the first part of the tripos or in some other tripos.

OXFORD.—On Wednesday, February 28, Mr. W. Bateson, F.R.S., honorary fellow of St. John's College, Cambridge, and director of the John Innes Horticultural Institution, delivered the annual Herbert Spencer lecture at Oxford, the subject being "Biological Fact and the Structure of Society." Man, he said, is an animal guided by natural laws. It is only lately that accurate inquiry has been started into the actual meaning of heredity, but it is now becoming recognised that parents cannot pass on factors that they do not themselves possess, and that the conditions of life are less important than genetic qualities. Still, even now our knowledge is not sufficient to warrant public interference with the ordinary practices of society. "We should probably be no better off if marriages were made at Westminster instead of in heaven." In one respect, however, the course is clear—segregation of the feeble-minded and hopelessly unfit is absolutely necessary. On the other hand, the existence of a physical defect such as cataract is not incompatible with a useful life and profitable work. There are many kinds of men, but the conditions are so complex that complete classification is impracticable. Two classes, however, may be distinguished—those who can take an interest in science and those who cannot; public men belong, as a rule, to the latter class. In law all men are equal, but science is juster than the law. A high birth-rate is not an unmixed blessing; it produced, for example, the misery of the "forties." It is incumbent on the State to see that no one goes without food, but a motive must be kept for individual effort. Classes are essential, and a necessary condition of progress is that every individual should be got into his right class. Present social conditions are too unstable to last, and Mr. Bateson doubts whether many wish that they should. It is to be hoped that the new order, whatever shape it may take, will grow up not in subservience to nostrums, but under the guidance of scientific fact.

WE learn from *Science* that the plans of Mr. George M. Pullman for the establishment of a manual training school at Pullman, Ill., are assuming definite form. Prof. L. G. Weld, formerly professor of mathematics and Dean of the University of Iowa, has been despatched on a tour of America and Europe to collect data to guide the board of trustees in the construction of the buildings and the arrangement of the curriculum. Building operations, it is expected, will be commenced next year. A site of forty acres has been purchased at a cost of 20,000*l*. A fund of 200,000*l*. was bequeathed by Mr. Pullman at his death in 1897 for founding the institution. This fund was invested in securities, which have increased in value until now there is about 500,000*l*. at the disposal of the governors for the school.

THE general and departmental reports for the session 1910–11 of the Bradford Technical College show a steady increase in the number of students in attendance. In view of the advanced nature of much of the work in the day courses, the committee has decided to follow the practice usual in connection with university colleges, and appoint external examiners, who will be associated with the college staff in the final diploma examination and the examinations for the technological scholarships. An extensive research has been carried out in the chemistry department, with the help of students, on the production of some new sulphur bases and their utilisation as sources of colouring matters. The work in the evening classes, it is satisfactory to note, is organised mainly in systematic courses of instruction, in which the technical subject is associated with the underlying sciences. Laboratory work, wherever possible, supplements class work. The courses occupy three evenings per week, and extend over three, four, or five years. The various laboratories of the engineering department continue to carry out tests and investigations for local firms and for trade purposes. The value of the experience gained in this way and the opportunity afforded of bringing the department into constant touch with the trade are greatly appreciated.

THE first issue of the Johns Hopkins University Circular for the present year is devoted to the report of the president of the University for the year 1910–11. President Ira Remsen says that the principal event of the year was the work that culminated in the raising of the sum required to secure the contribution of 50,000*l*. by the General Education Board towards the endowment of the University. In the offer of the General Education Board it was stipulated that "a supplementary sum of not less than 150,000*l*. shall be contributed to the University on or before December 31, 1910." The work of collecting this money was actively undertaken in October, 1910, and was so successful that on December 31 the desired amount had been contributed in cash or promised. Indeed, the amount contributed was greater than that stipulated by the General Education Board. Up to the present, including the amount contributed by the General Education Board, the University has available, in consequence of this effort, about 240,000*l*. Of this sum, 100,000*l*., according to the conditions of the gift, must be reserved as endowment. It is hoped that additional contributions will be made so that the sum of 400,000*l*. may be available for several pressing needs. The greater part of the volume, which runs to 109 pages, is made up of reports on the instruction in the chief branches of study and reports by various administrative officers of the University.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 15.—Sir Archibald Geikie, K.C.B., president, in the chair.—Dr. T. Graham **Brown**: An alleged specific instance of the transmission of acquired characters—investigation and criticism. An examination of the "Brown-Séquard phenomenon" in guinea-pigs—usually considered to be a classical instance of the alleged transmission of an acquired character—throws much doubt upon its value in this controversy. The phenomenon is not an acquired peculiarity produced *de novo* on division of a great sciatic nerve. It is due to the raised excitability of a mechanism—that of the scratch-reflex—already present; and this raised excitability is probably due to the removal of an inhibiting influence by section of the nerve. The phenomenon, therefore, cannot be considered as transmissible as an acquirement *per se*. If anything is transmitted as an acquired character, it must be the state of raised excitability of the scratch-reflex. The presence of the phenomenon in the offspring observed by Brown-Séquard may be admitted, but this may be explained otherwise than by assuming a transmission of acquired characteristics. That the alternative explanation—the presence in the offspring is due to a production of the state by injury to the toes and feet inflicted by the parent—is true is rendered possible, and indeed highly probable, by certain parallel evidence submitted in this paper.—W. B. **Alexander**: Further experiments on the cross-breeding of two races of the moth, *Acidalia virgularia*. This paper deals with the descendants of some of the moths of this species reared by Messrs. Prout and Bacot, who read a paper on their results to the Royal Society on February 25, 1909. They did not arrive at any definite conclusions in regard to the process of heredity followed. The author agrees with them in finding that *Acidalia virgularia* and its variety *canteneraria* are not two Mendelian forms of the species, though he finds that one of the differences between the two forms, namely, the presence of black speckling on the wings of *A. virgularia*, is inherited according to Mendel's law.—F. H. A. **Marshall**: The effects of castration and ovariotomy upon sheep. (1) The development of horns in the males of a breed of sheep in which well-marked secondary sexual differentiation occurs (as manifested especially by presence or absence of horns) depends upon a stimulus arising in the testes, and this stimulus is essential not merely for the initiation of the horn-growth, but for its continuance, the horns ceasing to grow whenever the testes are removed. (2) The removal of the ovaries from young ewes belonging to such a breed does not lead to the development of horns or definitely male characters, except possibly in a very minor degree.—Dr. T. L. **Lewellyn**: The causes and prevention of miners' nystagmus. Miners' nystagmus is an occupational neurosis confined to coal miners. It is characterised by a rotatory oscillation of the eyes, and produces a disability which is marked and prolonged in severe cases. One thousand six hundred and eighteen cases received compensation in the United Kingdom in 1911. Pathologically the complaint appears to be a condition of imperfect centripetal impulses (imperfect fixation, disturbance of equilibrium, &c.), the intimate connection between the centres governing the associated movements of the eyes being lost, and incoordinate movements ensuing. The principal preventive measures indicated are improvement of illumination, elimination of unfit workers by medical examination, and employment of coal-cutters in thin seams.—W. Lawrence **Balls**: The stomatograph. The stomatograph is a self-recording instrument adapted from Mr. Francis Darwin's porometer (see NATURE, August 10, 1911). A five days' record of the opening and closing of the stomata of the cotton plant in Egypt is given, showing the stomata wide open during bright sunshine. The author has elsewhere shown that during this part of the day *no* growth occurs, and there is evidence that the apparent waste of water then occurring is of importance as keeping the leaves cool, since when transpiration is artificially checked the leaves are rapidly injured or even killed by the high temperature.—G. A. **Buckmaster** and J. A. **Gardner**: The composition of the blood gases during the respiration of oxygen. A number of analyses were made of the blood of cats respiring (1) air, (2) oxygen for periods of one to two hours. The average composition in c.c. per 100 c.c. of arterial blood for cats breathing air was as follows (mean of thirteen experiments):—Total gas, 53·76; CO_2, 38·43; O_2, 14·22; N_2 1·12. The percentage saturation of hæmoglobin with oxygen was 83. For cats breathing oxygen the mean values by thirteen experiments were as follows:—Total gas, 53·79; CO_2, 38·65; O_2, 14·93; N_2 0·16. The average percentage saturation of hæmoglobin with oxygen was 89·6. From their experiments the authors conclude that the inhalation of oxygen does not materially augment either the quantity of this gas or the quantity of carbon-dioxide in the blood.

February 22.—Sir Archibald Geikie, K.C.B., president, in the chair.—Prof. H. L. **Callendar**: Bakerian lecture on the variation of the specific heat of water, investigated by the continuous mixture method. A single formula has been found to represent the variation of the specific heat s according to the continuous electric and mixture methods over the range 0° to 100° C. The formula is as follows:—

$$s = 0{\cdot}98536 + 0{\cdot}504/(t+20) + 0{\cdot}0084(t/100) + 0{\cdot}0090(t/100)^2,$$

in terms of the specific heat at 20° C. taken as unity, and in terms of the scale of the temperature t deduced from the platinum scale pt by means of the standard difference-formula,

$$t - pt = 1{\cdot}50t(t-100) \times 10^{-4}.$$

The same formula for the specific heat also represents the most probable reduction of Regnault's experiments over the range 110° to 190° C.—Dr. C. **Chree**: Short index to reports of physical observations—electric, magnetic, meteorological, seismological—made at Kew Observatory.—R. T. **Lattey** and H. T. **Tizard**: The velocities of ions in dried gases. The authors have determined the velocities of positive and negative ions in dried hydrogen and carbon dioxide.—Prof. T. H. **Laby** and P. W. **Burbidge**: The observation by means of a string electrometer of fluctuations in the ionisation produced by γ-rays.—F. B. **Pidduck**: The wave-problem of Cauchy and Poisson for finite depth and slightly compressible fluid. The paper is in some respects a completion of a former one on the propagation of a disturbance in a fluid under gravity. The solution of the two-dimensional Cauchy-Poisson problem for finite depth is worked out numerically, the effect of limiting the depth being very considerable.

Royal Meteorological Society, February 21.—Dr. H. N. Dickson, president, in the chair.—J. **Fairgrieve**: The thunderstorms of May 31, 1911. The author dealt with the thunderstorm which visited the London district on Derby Day, and especially with the movement of the rain which accompanied the storm. Having obtained information from nearly 700 observers as to the time of rainfall or absence of rain, he has been able to prepare an interesting series of maps for each quarter of an hour from 12.30 to 8.45 p.m., showing the areas over which rain was actually falling.—R. G. K. **Lempfert**: The thunderstorm of July 29, 1911. This storm was of the line-squall type. The author has been able to trace the spread of the phenomenon across the British Isles, and he showed by a map of isochronous lines that it first struck the extreme end of Cornwall about 2 p.m. on July 29, and passed across Shetland at 3 p.m. next day. He pointed out that the disturbance may be regarded as the displacement of an easterly by a southerly current, but the process of displacement was an unusually complicated one. The general sequence of events seems to have been somewhat as follows: a moderate east wind is interrupted suddenly by a squall from the south. After the squall has passed the wind returns temporarily to an easterly direction, to be again interrupted by another squall from the south. This process may repeat itself several times. A period of several hours of light and variable wind, during which easterly directions predominate, supervenes, and finally the wind settles down to a steady southerly or south-westerly wind of moderate force. In many cases the squalls were not accompanied by rainfall. What appears to have struck observers most forcibly was the way in which huge quantities of dust were whirled up by the wind. Accounts from Cardiff state that dust was brought from the south side of the Bristol Channel by the squall winds, which did much structural damage.—S. **Skinner**: The "Drosometer," an instrument for measuring the amount of dew.

PARIS.

Academy of Sciences, February 19.—M. Lippmann in the chair.—L. **Guignard**: Notice on the life and work of Edouard Bornet.—A. **Lacroix**: The volcanoes of Central Madagascar. The Ankaratra *massif*. The products of the Ankaratra volcanoes cover an area of not less than 4000 square kilometres. The petrographical constitution has been investigated, and is found to be much more complex than that sketched by Baron.—A. **Müntz** and E. **Lainé**: The quantity of water and frequence of watering as depending on the physical properties of soils. It is very essential that any irrigation scheme should be preceded by a careful study of the soils on which the water is to be placed. Cases are cited in which, owing to the lack of permeability of the soil, irrigation has been actually harmful to the land.—M. du **Ligondès**: The condensation of the solar nebula in the Laplace hypothesis. The enormous condensation necessary, according to the Laplace hypothesis, to the formation of Neptune has been pointed out by Fouché; the author shows that there is also a discontinuity in the condensation between Jupiter and Mars.—**Billon-Daguerre**: The fusion of pure quartz. A description of the electric furnace used for fusing quartz, and obtaining a clear, transparent product.—P. Th. **Muller** and Mlle. V. **Guerdjikoff**: Refraction and magnetic rotation of mixtures. H. Becquerel has shown that for pure substances there is a connection between the refractive index and the magnetic rotation; for solutions, however, there would appear to be no general relation between these two magnitudes.—Paul **Joye** and Charles **Garnier**: Contribution to the study of neodymium compounds. The different spectra given by neodymium hydroxide heated to temperatures between 300° and 700° C. are shown to correspond to the formation of definite hydrates.—A. **Portevin** and G. **Arnou**: The effects of reheating aluminium bronzes. Measurements are given of the alteration of hardness produced, and photographs reproduced showing the change in the structure of the alloys.—Daniel **Berthelot** and Henry **Gaudechon**: The photolytic decomposition of smokeless powder, of picric acid, and of ammonium picrate by the ultra-violet rays. The gas in which the smokeless powder is exposed to the rays is shown to have an influence on the nature and amount of the gaseous decomposition products.—H. **Masson**: The principal constituents of essence of labdanum. Two ketones were isolated from this oil, 1 : 5 : 5-trimethyl-6-hexanone and acetophenone; the latter substance has not been previously noticed as a constituent of an essential oil.—A. **Prunet**: The Japanese chestnut at the experimental station at Lindois (Clarente). Experiments have been carried out on the disease-resisting properties of various chestnuts, and the Japanese chestnut (*Castinea japonica*) has been found to be the most suitable tree to replace the chestnuts destroyed by the *maladie de l'encre*.—A. **Demolon**: The fertilising action of sulphur. Sulphur has been shown by direct experiment to be beneficial to plant growth, especially Cruciferæ. It appears to exert a favourable action upon the development of chlorophyll, since during drought the plants on the plots treated with sulphur did not turn as yellow as the untreated control plots.—Em. **Bourquelot** and Mlle. A. **Fichtenholz**: The identification of the glucoside from the leaves of *Kalmia latifolia* with asebotine. Eykman in 1883 gave the name asebotine to a glucoside extracted from the leaves of *Andromeda japonica*; the glucoside extracted from the leaves of *Kalmia latifolia* is shown to be identical with asebotine.—**Michel-Cohendy**: Experiments on life without micro-organisms. Although normally provided with a rich microbial flora, the chicken can live absolutely without micro-organisms, and this aseptic life does not prejudice growth or development in any way. According to these experiments, the theory of the necessary connection between the animal and its bacteria, a principle which has been given as a well-established biological law, is not in accord with facts.—P. **Armand-Delille**, A. **Mayer**, G. **Schaeffer**, and E. **Terroine**: The culture of the Koch bacillus in a definite chemical medium. A formula is given for a culture medium containing definite chemical compounds only. On such a medium it is found that the tubercle bacillus develops perfectly, rapidly, and abundantly, retaining all its morphological and biological characters.—A. **Moutier**: The measurement of the arterial elasticity in clinical practice. The measurement of arterial elasticity cannot be carried out with an apparatus using circular compression, only those using localised compression giving correct results. Bloch's sphygmometer is the best instrument at present available.

HEAT ENGINE LABORATORY PRACTICE.

The Testing of Motive-Power Engines, including Steam Engines and Turbines, Locomotives, Boilers, Condensers, Internal Combustion Engines, Gas Producers, Refrigerators, Air Compressors, Fans, Pumps, &c. By R. Royds. Pp. xii+396. (London: Longmans, Green, and Co., 1911.) Price 9s. net.

DURING the last decade the training of engineering students has undergone a great change. Our colleges have recognised that the engineering laboratory is not only a place where the student may see various principles previously expounded in the lecture-room put into practice and experimentally proved, but that it is a place where tests and trials are carried out upon a commercial basis and in an up-to-date manner by the student himself. If the student be put in direct charge of such tests, he will most assuredly develop that faculty of self-reliance which is one of the characteristics of a successful engineer. Side by side with this internal development there has been a vast change in the design and nature of motive-power engines, so that the modern laboratory has developed into an assembly of many varied types of prime movers. In acquiring information which will enable him successfully to cope with the different practical difficulties met with amongst so many types, the student had to refer to many sources, the chief being the recent publications of the technical societies and Press. This book does that for them, and does it very thoroughly. It meets a distinct want, and at such a reasonable price it should be recommended to all college students.

After giving it a welcome, we hope the author will not take it amiss if we indulge in complaint. Chapter i. treats of general principles of thermodynamics, units, and cycles of operation. On p. 6 the author states that the centigrade scale of temperature measurement is used by some engineers, but more often by physicists and chemists. We believe we should be correct in saying all men of science save some, mostly engineers, use the centigrade scale. Why do not engineers come into line? If the author would have bravely adopted Cent. instead of Fahrenheit, he would have aided in bringing about a change which is slowly coming to pass. This leads us to suggest he might have included the pound-calorie in his enumeration of units of heat, a unit recognised by the University of London in their engineering examinations. Surely also it is more reasonable to expect the conversion of Fah. to Cent. readings to be made by subtracting 32, then multiply by $\frac{5}{9}$, than to remember the suggestion on p. 6, for which no reason is given. At the end of the book there is a series of tables, including conversion constants, properties of various vapours, and steam tables. We note that the latter are from "Marks and Davis." We were hoping that when the last edition of Prof. Ewing's book, "The Steam Engine," was produced, the researches of Prof. Callendar were going to be recognised by English engineers. In an appendix to his book Prof. Ewing gives some properties of steam, and tables, which are certainly more rational in form than any others compiled from data outside Prof. Callendar's papers. We hope that in his next edition the author will introduce the pound-calorie unit and a short explanation of Callendar's work in his chapter i., together with steam tables compiled therefrom, and thus associate himself with Prof. Ewing and Dr. Mollier in bringing about a desirable change. The explanations of the various cycles of operations of the working fluid are well given, and in conjunction with lectures will make an excellent combination for the earnest student.

The testing for accuracy of instruments such as gauges, indicators, &c., makes a long chapter for No. ii. This is good, as many are unduly predisposed to accept such as correct instead of always regarding them with suspicion. We should like to see a device for testing indicator springs hot, the methods shown being all under conditions dissimilar to their actual working state. Does the author use an indicator cock and connect an indicator to a dead-weight gauge tester, as shown in Fig 34? The fluid pressure will more nearly reproduce actual working conditions. Carefully and well written as chapter ii. is, the author is best in chapter iii., on measurement of brake horsepower. We are glad to see a description of a band brake which will give torque without causing a bending action due to large brake loads on one side.

Chapter iv. is outside the scope of English laboratory work. The testing of locomotives is in the hands of a few, and those highly skilled, and therefore needs not a general treatment as is here given, but a special treatise. Is it too much to hope that soon we may have in such a city as London an experimental plant for locomotive testing? It would surely prove of great use even if only for training up stokers at short notice. Chapters v., vi., and vii. are concerned with the testing of steam engines, turbines, and boilers. We are glad to see so much of the report of the Institution of Civil Engineers, vol. cl., embodied in these chapters. The author deals carefully with the "missing quantity" of steam as passed by the engine, and the pages dealing with leakage to exhaust are very good.

The testing of internal combustion engines is an up-to-date review of work which is being done by the British Association Committee, and also includes gas producers, the Diesel type, &c. The chapter on refrigeration tests is helpful, but, as the author would probably admit, it is very difficult to get all the conditions steady enough to make the tests as satisfactory as could be wished. The testing of water-turbines and pumps complete the book, which is the more valuable for a carefully compiled index at the end. As we stated above, it is a book which is needed, and we can heartily recommend every student to place it on his work-desk. It is comprehensive, but it deals very thoroughly with the most general types of engines and boilers. The illustrations are good and plentiful, and we conclude by congratulating the author on producing such a practical treatise.

A. J. M.

GROWING OUR OWN SUGAR.

Sugar Beet: Some Facts and Some Illusions. A Study in Rural Therapeutics. By "Home Counties" (J. W. Robertson-Scott). Pp. xx. + 424. (London: Horace Cox, "Field" Office, 1911.) 6*s.* net.

THIS work is based largely upon articles published in *The Field* and *The Times* during the years 1910–11, and is essentially an examination of the arguments for and against the proposals to establish a beet sugar industry in this country. "There are those," the author remarks, "who hail sugar beet as the saviour of the countryside; and there are those who are sure that the notion of growing our own sugar at a profit is preposterous." For each of these classes he has collected a large number of "facts," and to some of the former he indicates what in his judgment are "illusions."

That sugar beets can be grown here, and of as good quality as on the Continent, hardly needed demonstration. What did require investigation was whether, in all the circumstances, it was worth our while to do it.

The author examines this question step by step. He describes the chief experiments that have been made in this country, from the Lavenham venture some forty years ago to the East Anglian trials made under Dutch auspices in 1910. In these trials, it may be mentioned, more than three hundred acres were planted with beet intended for exportation to Holland, and the quantity registered as actually exported was 3909 tons. This weight, however, is untrustworthy, as it includes a large proportion of adherent soil. The factory purchasing the roots pays upon the weight of the cleaned beets only; and heavy deductions had to be made from what the farmers supposed to be the weight of their crops. Probably one of the "illusions" indicated in the title arose from calculations based upon a crop yield which, for the reason mentioned, might be over-estimated as much as 10 to 50 per cent. Whilst average crops of more than 20 tons per acre have been talked about in this country, the cold fact remains that on the Continent in 1910 the average yield ranged from 9·3 tons in France to 13·3 tons in Germany.

For various reasons the East Anglian experiments were only moderately successful. The causes of this are indicated; and the author compares the results of these and other English efforts with the teachings of practical experience abroad. He quotes numerous reports, and generally gives chapter and verse for his carefully guarded conclusions. These are, briefly, that a cooperative factory, growing its own beets, or a large proportion of them, would have the best chance of success; but that an ordinary factory, established after careful investigation, under good management, and with proper support from farmers in the vicinity, would have fair prospects; also that the introduction of the beet sugar industry would help in bringing about in rural England changes of some value agriculturally and sociologically, and is deserving therefore of sympathetic study. Owing, however, to the developed condition of our agriculture, and also to the increasing competition of cane sugar, the benefit in England would not be likely to equal that obtained on the Continent.

Of purely scientific interest there is very little in this "study in rural therapeutics"; but from the agricultural point of view it ought to do a good deal towards clearing away misconceptions.

C. S.

COLLOIDS IN INDUSTRY.

Die Bedeutung der Kolloide für die Technik. Allgemein verständlich dargestellt von Prof. Kurt Arndt. Zweite Auflage. Pp. 46. (Dresden: Theodor Steinkopff, 1911.) Price mk. 1.50.

ALTHOUGH it is fifty years since the distinction between colloids and crystalloids was first drawn by Thomas Graham, it is only quite recently that the conception of colloid substances has been extended beyond the ranks of a few specialists to possess some meaning for the public at large. Almost as recent and remarkable in its suddenness has been the feverish eagerness with which the properties and behaviour of colloids have been investigated. In Germany, there are several journals devoted entirely to colloid chemistry, as well as text-books of every variety.

Unfortunately, there is a tendency to adopt an exaggerated terminology, and to obscure the problems by complicated methods of treatment instead of striving after the simplest possible language. In consequence, the subject is invested with a mysticism which is quite unnecessary.

For this reason a book of the type written by Dr. Arndt is to be welcomed, and the fact that an edition has been exhausted already shows that the work has met a demand.

Following a brief introduction, which, although necessarily condensed, is written in relatively simple style, attention is directed in turn to a number of industries in which the materials handled are colloids. It is the aim of these sections to emphasise the fact that the substances concerned are colloids rather than to explain their behaviour in practice. The list is a very extensive one, ranging from such inorganic materials as glass, tungsten lamp filaments, pottery, and cements to organic industries, including dyeing, tanning, soap-boiling, brewing. Finally, reference is made to the part played by colloids in sewage disposal and in agriculture. The examples are very comprehensive, and serve to show how generally colloids enter into industrial operations.

The discovery by Siedentopf and Zsigmondy of the ultra-microscope, an instrument whereby the single particles in colloid solutions are made visible, has facilitated greatly the investigation of colloidal solutions of metals. In the manufacture of ruby glass, for example, gold chloride is added to the molten glass; when quickly cooled this is colourless, but on subsequent heating up to the point of softening, it suddenly becomes ruby red. The ultramicroscope shows the presence in the coloured glass of colloidal gold particles; in the colourless glass none are to be seen. The explanation is that at first the gold particles are too small to colour the glass; on heating, they increase in size and give rise to the colour.

E. F. A.

PRACTICAL PYROMETRY.

Pyrometry: a Practical Treatise on the Measurement of High Temperatures. By Chas. R. Darling. Pp. xii+200. (London: E. and F. N. Spon, Ltd.; New York: Spon and Chamberlain, 1911.) Price 5*s.* net.

WITHIN recent years pyrometry has become an essential factor in a large number of industrial operations where high temperatures are involved; particularly is this the case in the metallurgy of steel, where success or failure often entirely depends on correct adjustment of the temperature within narrow limits. Mr. Darling's excellent series of Cantor lectures were therefore very welcome, and no less welcome and of wider service will this small volume, the outcome of these lectures, prove.

The "practical man" has a love for the "practical" test in the furnace or kiln, and for many operations, such as those in pottery and china production, an actual firing test is to be commended, but generally manufacturers are devoting more attention to actual temperature measurements. Great advances have been made in recent years in perfecting forms of pyrometers suitable for works practice, amongst which mention may be made of temperature recorders continuous in action, and pyrometers of the radiation type, first introduced by Féry in 1902. The later form of these instruments, with fixed focus, enables excellent measurements of furnace, molten metal, and other high temperatures to be taken by the simple process of directing the pyrometer at the object and reading the deflection on a suitable portable galvanometer.

The author deals in a comprehensive manner with the various types of instruments, and gives valuable advice as to the suitability of those of different classes for special purposes, and emphasises the fact that choice of an unsuitable pattern has often led to considerable monetary loss and the condemnation of an instrument which, in its proper sphere, would have proved satisfactory.

After mentioning that for practical purposes the gas scale is in agreement with the thermodynamical scale of temperature, and serves as a standard of comparison for other instruments of practical form, the author points out that comparison is only possible to the present limit of the gas scale (1550° C.), and that beyond this the results can only be arrived at by extrapolation, which in some cases has led to grave errors. With instruments of the radiation type, however, assumption that the laws applicable for the lower ranges will hold for the higher ones appears to be justified.

Mr. Darling is a clear and concise writer on a scientific subject which has wide commercial application, and his treatment of the subject of practical high temperature measurement in this volume will commend itself to the practical man, who, whilst requiring sufficient of the scientific side to understand the principles involved, does not require abstruse science in his handbooks. This volume, like the author's well known "Heat for Engineers," admirably fulfils these requirements.

J. S. S. B.

POPULAR BOTANY.

British Trees, including the Finer Shrubs for Garden and Woodland. By the late Rev. C. A. Johns. Edited by E. T. Cook. Pp. xvi + 285 + 56 plate (24 coloured).

British Fungi: with a Chapter on Lichens. By George Massee. Pp. x + 551 + 40 plates (coloured).

(London: G. Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., n.d.) Price 7*s.* 6*d.* net each.

ONE of these two books, which are uniform in external appearance only, represents, we presume, the demand which has affected publications of all kinds for books with coloured illustrations. The result has been an output of a large number of bad books, and to this class we unhesitatingly relegate the new edition of Johns's Trees and Shrubs. The coloured plates of the trees and shrubs are so poor—they appear to be photographs daubed with colour—that in most cases it is only from the label at the foot that one can discover what the picture is meant to represent. The value of coloured plates is, on the other hand, well shown by Mr. Massee's book on fungi, since in the bold and well-executed plates by Miss Ivy Massee the distinguishing characters of many of the species described can be seen at a glance and in a manner which would be otherwise impossible.

Mr. Massee's book is mainly intended to enable the naturalist to determine the names of our British fungi; but it should do more than this, and should help to create a real and intelligent interest in the subject.

The somewhat unorthodox statements met with here and there are decidedly refreshing, and should act as a stimulus to those who might otherwise be mere collectors of fungi. The first part of the book, consisting of 63 pages, serves as a general introduction to the systematic section of the book. In this earlier portion an adequate account of the structure and of the relationships of the various groups of fungi is given, which will enable the user of the book to understand the essential details of fungal morphology. The chapters on methods of collection and modes of preservation are equally valuable. On the recognition of edible and poisonous species the coloured plates play a most important part, and the dictum of Dr. M. C. Cooke, "Eat them; if you live they are edible; if you die they are poisonous," reminds us of the similar advice given by Mr. Belloc about the viper:

> "Yet another great truth I record in my verse,
> That some vipers are venomous, some the reverse;
> A fact you may prove if you try
> By procuring two vipers and letting them bite;
> With the first you are only the worse for the fight,
> But after the second you die."

A few words of criticism must be added, since owing to some carelessness the enumeration of the figures on Plate ii. is incorrect, and the uninitiated person may not be able to recognise which is the poisonous fly agaric. It is also somewhat unreasonable suddenly to come across the explanation of Plate i. facing p. 83.

In the second part it is difficult to find one's way about, as no reference to pages is given from the generic keys, and this entails a good deal of tiresome hunting which might easily have been avoided. Apart from these slight blemishes, however, the book is deserving of all praise. The short concluding chapter on lichens is quite useful, but we hope, with the author, that before long we may have a good book on these plants, and that it will be written and illustrated in as able a manner as the volume under review.

To turn to the work on trees and shrubs is not a pleasant task. Had the truth of the saying about new wine and old bottles been appreciated, this new edition might not have been produced; and when the new wine proves to be bad, the disaster is all the more conspicuous. It is a book without order or definite plan of arrangement. Much useful and interesting information is given under the different trees and shrubs described, but turning over the pages is somewhat like fishing in a bran pie, as one never knows what the next article will be. The plates also afford no clue, as for the most part they are distributed haphazard through the text without any reference to their proper positions. There are a large number of reproductions from photographs, and these are in striking contrast to those in colour. Most of them and several of the coloured illustrations also have obviously been taken in the Royal Botanic Gardens, Kew, and there seems to be no reason why this fact should not be stated. The plate of *Salix fragilis* in colour is identical with a photograph published in the Kew Bulletin in 1907.

A curious case is afforded under Robinia, where without any word of explanation an illustration of the curious and uncommon fastigiate variety at Kew is given, which would lead the ordinary reader to believe that this is the normal appearance of the tree. Then, again, the statement at the foot of a plate of a remarkably fine and healthy specimen of the monkey puzzle (*Araucaria imbricata*) that it "is not suitable for Britain, as it soon dies off," is, of course, a glaring error. The book is unworthy of further notice, for even the text figures are of no value.

OUR BOOKSHELF.

Das Pflanzenreich. Herausgegeben von A. Engler. Heft 48 (iv., 23C), Araceæ-Lasioideæ. By A. Engler. Pp. 130. Price 6.60 marks. Heft 49 (iv., 101, Nachträge), Monimiaceæ (Nachträge). By J. Perkins. Pp. 67. Price 3.60 marks. Heft 50 (iv., 50, ii. B. 21), Orchidaceæ-Monandræ-Dendrobiinæ. Pars ii. Genera n. 278–279, and (iv., 50, ii. B. 23) Orchidaceæ-Monandræ—Thelasinæ. Genera 280 and 280A. By Fr. Kränzlin. Pp. 182+46. Price 11.60 marks. (Leipzig: W. Engelmann, 1911.)

THE subfamily Lasioideæ includes Amorphophallus, Rhektophyllum, a West African climber, Montrichardia, an arborescent form, and many tuberous-stemmed plants such as *Thomsonia nepalensis*; vegetative shoots or bulbils are normally developed from such tubers, being produced in great profusion by *Dracontium asperum*. Entire sagittate leaves are not uncommon, but a much divided leaf with sagittate outline is more typical. The spadix is exceedingly variable in form; in the case of *Amorphophallus rex* it bears a peculiar appendage and a singular spathe. The various phylogenetic relationships of the various genera are discussed at length. Cytospermum is regarded as the most primitive on account of its perigoniate hermaphrodite flower, the presence of endosperm in the seed and its pantropic distribution; the genera Nephthylis and Montrichardia are placed at the other end of the scale by reason of their naked unisexual flowers and poral dehiscence of the anthers.

The supplement to the early volume on the Monimiaceæ contains the additions that have accumulated in ten years. A compliment is paid to a well-known benefactor by the establishment of a new genus Carnegiea, although the association with a type specimen from New Caledonia is not immediately obvious. Two new myrmecophilous plants are noted in *Steganthera insignis* and *S. torricelliensis*.

The fiftieth part is principally a monograph of the genus Eria, in which the author follows Lindley except in the separation of the subgenus Trichotosia; with these two, Porpax is closely associated, but Phreatia is removed from the Dendrobiinæ to a new combination with Thelasis.

Primitive Animals. By Geoffrey Smith. Pp. x+156. (Cambridge: University Press, 1911.) Price 1s. net.

IN this book the author gives a concise account of the principal characters of a number of primitive animals, and of the arguments based upon their study. He first shows the great antiquity of the chief phyla by instancing the fact that in the oldest fossil-bearing rocks (Cambrian) there are representatives of certain families of Crustacea (Nebaliidæ, Cypridæ) which exist at the present day. In considering the lowest forms of life, the author points out that animals depend ultimately for their food upon plants, and suggests that "the presence of chlorophyll was the necessary precursor of life," but concludes that the problem of the origin of life is not within range of solution. Special attention is devoted to the Appendiculata, and particularly to Peripatus as a connecting link between Annelids and Arthropods. The structure of Nebalia and Anaspides is discussed in reference to the light it throws on the course of crustacean evolution. The chief characters of several invertebrate larval forms are considered in regard to their bearing on the relationships of certain phyla to one another; in this connection Mr. Smith maintains that, although certain larval forms, *e.g.* the trochosphere and the nauplius, may be ancient, they are not to be regarded as representing the ancestral form of the phyla to which they belong.

The annelid theory of vertebrate descent is discussed, and the difficulty of reconciling this view with the conditions present in Balanoglossus is pointed out, the origin of vertebrates being relegated by the author to the category of unsolved problems. Among other subjects treated in an interesting manner are the derivation of lungs from the air-bladder of Dipnoi, the rise of the mammals, and the degeneracy of marsupials. The volume brings into prominence the special features which have been found to throw light on phylogenetic problems, and is a good introduction to the mode of application of the comparative method in morphology, and to some of the principal results obtained.

Micropetrology for Beginners. An Introduction to the Use of the Microscope in the Examination of Thin Sections of Igneous Rocks. By J. E. Wynfield Rhodes. With a preface by C. H. Sidebotham. Pp. xv+126. (London: Longmans, Green and Co., 1912.) Price 2*s.* 6*d.* net.

THE object of this work, as stated by its author, is to supply teachers in evening technical schools, and others, with practical information on the use of the petrological microscope—so far at least as is necessary in the instruction of students in geology for the Intermediate B.Sc. of the London University. It is disappointing to find that a work of this kind is considered to be necessary, for it might fairly be hoped that teachers, undertaking the preparation of candidates for university degrees, would themselves have the necessary practical knowledge for the guidance of their students in manipulation—seeing that an ounce of *showing* is worth a pound of *telling*.

So far as is possible in work of this kind, the practical directions given in the book are clear, and anticipate many of the difficulties that may arise. The weakest portion of the book is the second chapter, in which an attempt is made, in a few pages, to deal with the question of the optical properties of minerals. In the aim at condensation many unexplained terms are employed, and not a few statements are made which are open to serious criticism. Much more successful is the latter portion of the book, in which a number of rock-sections are described and illustrated; but as the selection of rocks is confined to those of igneous origin, many important rock-forming minerals, like the garnets, are not among those figured. The preface of the book suggests that it is not intended to take the place of an ordinary text-book, but to supply the information which is not given in such works, being left for the laboratory-demonstrator to supply and this would seem to be the limit of the book's usefulness.

Famous Chemists. By E. Roberts. Pp. 247. (London: G. Allen and Co., Ltd., 1911.) Price 2s. 6d.

IT seems a little difficult to understand the object of writing a series of disconnected short biographies of distinguished chemists now that we have several readable histories of chemistry of moderate compass in which biography is woven into connected narrative. At the same time it must be stated, after conscientiously reading the book from cover to cover, that these biographical epitomes are well done. The chief contributions of each master are clearly indicated, and the human touches on the whole artistically added. Boyle hardly has his due proportion, and Berthelot and van't Hoff are not included at all.

Perhaps the chief thing to be said for this compact gallery of chemists is that it may help to stimulate an interest in history, and lead the reader to a more thorough study of the life-work of the great men who have made chemistry what it is. This is an educational and liberalising side of chemical study which in the past has been much neglected. It is a pure convention, and a mischievous one, that isolates the study of natural philosophy itself from the study of its history.

A. S.

Earth and her Children. By Herbert M. Livens. Pp. 248. (London: T. Fisher Unwin, 1912.) Price 5s. net.

MR. LIVENS practises the art of teaching nature study by means of pleasant little stories in which plants and animals speak autobiographically. The nature knowledge imparted in the twenty-four chapters into which the book is divided is much diluted by the conversational matter introduced, but the stories will please many children, and may lead a few to observe nature for themselves.

LETTERS TO THE EDITOR.

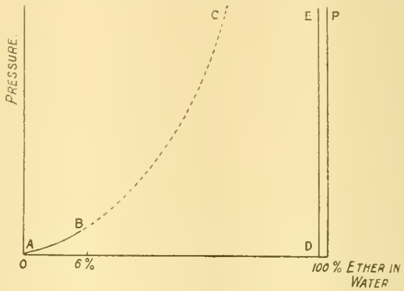
Osmotic and Liquid Membranes.

IN an interesting letter in NATURE of February 22 Lord Berkeley has considered the question of a possible osmotic cycle in which a liquid such as ether is placed at the same time in connection through membranes with an aqueous solution of sugar and with water, while the latter is also in similar connection with the solution.

The water is kept at zero pressure, while the ether and the solution are at the osmotic pressure of the latter.

As a consequence of a view of osmotic membranes which I have lately ventured to put forward in a paper in the Proc. Roy. Soc., he quite correctly deduces that equilibrium should exist for different strengths of the sugar solution provided the pressure is its osmotic pressure, and in addition that the ether should hold the same amount of water in solution at the different pressures. Or, to quote his words, "the same solution of water in ether has two different osmotic pressures." This he regards as impossible.

Perhaps the best way to consider this question is to examine first the simple case of water placed on either side of a membrane permeable to water, but not to ether, and to suppose ether gradually added to one side. The osmotic pressure will rise, as shown by AB, to a maximum value at about 6 per cent. of ether. No solution of greater strength than this is possible until we reach 98·95 per cent. The osmotic pressure is now again zero, but rapidly rises, as shown



along DE, approaching the pressure axis P asymptotically; so that practically without any concentration change we can have any osmotic pressure we please.

The dotted curve has been added to show the normal character of the curve for substances which dissolve in all proportions, and probably if the pressure on both sides of our membrane were raised to a sufficiently high value the two portions of the ether curve would unite somewhat after the fashion of the Van der Waals's isothermals, and ultimately form the normal case, because experiments (not yet published) show that the portion DE moves to the left under pressure.

If the above experiment be supposed repeated, but with sugar in solution on the other side of the membrane to that to which the ether is added, the first possible *strong* solution of ether is greater than 98·95 per cent., or DE is moved to the right. As in the case of water, so in the case of sugar solution, DE can be moved to the left by raising the pressure on both sides of the membrane. For a 60 per cent. solution of sugar the pressure to bring it back to its old position is 80 atmospheres.

Returning now to Lord Berkeley's cycle, we are in a position to see how equilibrium can exist without an appreciable change in strength of the ether solution when different strengths of the sugar solution are used. Referring to his figure, equilibrium exists across membrane *bd* at the osmotic pressure of the solution when the concentration of the ether is 98·95 per cent., and practically the same concentration is required for equilibrium at the membrane *bc*, no matter what the pressure may be.

Perhaps I may add that the view of osmotic membranes which I wished in my paper to emphasise is that a substance which acts as ether does in the condition at DE can, so long as the mechanical strength is somehow supplied, cause water to pass into a solution; for on the side of the solution it holds less water than on the side of the water unless the solution is raised in pressure so as to bring the concentration of water in the ether to be the same throughout.

University College, London.

The Weather of 1911.

It is probably no exaggeration to say that all students of meteorology who have been fortunate enough to read Sir Edward Fry's letter in NATURE of November 16 have been greatly impressed by it, and have awaited with eagerness the discussion to which it must inevitably lead. Already, at this early stage, they must feel a sense of gratitude to the writer of the letter for having enriched the science by calling forth the excellent reply from Dr. Shaw in the number of November 30.

Now, as was to be expected, that ultra-violet solar radiation has come up for consideration, and Dr. Carl Ramsauer, in the issue of December 14, has entered a strong plea for recognition of the part it did not play in producing rain, in Europe, during the summer and fall of 1911, the time seems ripe for "the other side of the world" to enter the discussion, so that European men of science may take a glance "out and beyond their latticed home," and realise that sunshine and meteorological changes are phenomena quite commonly witnessed in other regions of the earth.

It is to be understood that nothing in this letter is to be considered as the result of a careful study of observational data, and, furthermore, that the ideas here expressed have been inspired solely by articles in NATURE, by my personal experience, and by a cursory knowledge of meteorological changes gained from the weather chart of the Argentine Meteorological Office, which shows the daily changes over the southern half of South America, a region quite as extensive as, if not much greater than, all Europe.

In his interesting article, Dr. Ramsauer says, amongst other things, that he and Prof. Lenard have distinguished three actions of ultra-violet light on dust-free gases, and that one of these actions is the "formation of condensation nuclei." This, he says, gives us the *chief* source of nuclei in the earth's atmosphere, which are meteorologically so important; and his final conclusion is:—"Thus the lack of nuclei, and the consequent fine weather of the year, can be attributed to a *much diminished ultra-violet radiation of the sun*." (The italics are mine.) He makes no mention as to variable efficiency in different parts of a bundle of solar rays, and so his conclusion must be taken as uniformly applicable to the entire bundle of rays impinging upon the earth. As the difference of longitude between the two continents is only a few hours, it may be assumed that the solar rays falling upon Europe and South America constitute separate parts of a single uniform bundle of rays; also, as ultra-violet rays are to be considered as the controlling agency in the production of condensation nuclei, they must be assumed to be most active, and rainfall therefore most copious, over the continent with the midsummer sun. Let us see how far his conclusions are justified by facts.

During the mid-year and later months of 1911 Europe experienced an unprecedented season of heat and drought, beneath the unobstructed rays of a high sun; Dr. Shaw states that apparently all requisites for dense clouds and heavy rains were frequently satisfied, and Dr. Ramsauer suggests that the poverty of the intense solar rays in ultra-violet waves was responsible for the fact that no precipitation occurred. During the same period, July to November, a portion of South America equal in extent to Europe, under the relatively feeble radiation of a low sun, was treated to a superabundance of condensation nuclei, and probably to the most excessive drenching ever noted in this part of the world. The current conditions, with reversed seasons, are really just as interesting. The rains continued here during the summer solstice and ended suddenly on January 1; so that, on passing through perihelion, although the sun was not far from the zenith, and was about five million miles nearer than when Europe experienced its extraordinary weather, sending out proportionately more intense ultra-violet and all other kinds of solar rays, the sky was clear, and has remained practically so during the past two weeks of our midsummer, notwithstanding that this is normally the rainy season of the year, and conditions are favourable for the development of showers and even general rains; meanwhile in Europe, *mirabile dictu*, the advent of the new year has been marked by disastrous floods in many parts.

Do not these facts constitute another exemplification of the saying that "one-half of the world does not know (usually realise) how the other half lives," and of the further thought that it is extremely difficult completely to interpret cosmical processes by means of laboratory experiments?

In the present state of the sciences of meteorology and solar physics it is impossible to look upon these perfect and abnormal contrasts of the past year in the conditions in Europe and South America as merely fortuitous occurrences. In seeking for their explanation we must inevitably follow Dr. Shaw in ascribing the important terrestrial activities to the dynamics of the upper air, and amplify his proposition slightly by naming the sun as the prime source of all the trouble. Is it not possible that with the already long period—nearly two years—of almost complete quiet on the solar disc, the conditions on the earth are approximating to what they would be if the sun were not a variable star? With a constant output of solar energy would not the atmospheric layer contained between the isothermal region and the earth's surface act more uniformly, like an engine—the part over the summer hemisphere, being heated by the most intense radiation during long days, acting as steam chest; the part over the winter hemisphere, cooling through long nights and feeble solar radiation, acting as condenser, while the convective processes of the equatorial region serve as the safety-valve through which would be brought about an orderly alternation of hot and relatively dry summers, and wet but not extremely cold winters in both hemispheres?

It is probable that a complete answer to Sir Edward Fry's question will have to come from some such world-wide conception as this rather than from a study of meteorological conditions on a particular continent. Possibly the pronounced conditions during the past year may point out a way for alleviating to some extent the disappointment of those investigators who seek to establish a well-defined periodicity in temperature and rainfall variations based upon the variability of the sun, as they apparently emphasise the necessity of determining exactly the epochs of maxima and minima in the sun's own period, and taking account of his position in the ecliptic at such times. If a minimum, for instance, coincide with a solstice, then an abnormally hot and dry summer in one hemisphere, with an abnormally wet and probably warm winter in the opposite one, should be considered as confirming the sun-spot theory, and not as contradicting it, and so the effect may be graduated around the ecliptic, being least pronounced probably when a minimum falls in an equinoctial month. A hasty comparison of Dr. Wolfer's relative sun-spot numbers with the rainfall data of a few widely separated stations appears to hold out some encouragement for treating the data in this way.

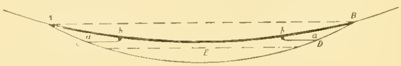
Concentric Joints in Ice.

In Nature for January 25 a correspondent directed attention to concentric joints and bulbs which he noticed in the thin ice-sheets which covered several small partially dried-up pools, and stated that he would like to have an explanation of their cause.

I have seen circular ribs on the underside of ice-sheets on small pools which would appear to have been formed as shown by the accompanying diagram.

When the pool was full of water, a thin sheet of ice formed between A and B. As the water sank into the ground an air space *aa* formed near the margins, the ice at the same time sagging. During the frost the further inward spread of the air space was arrested for a time by the freezing of the ring *bb*. Soon, however, in spite of the growth of the ring, the fall of the water-level allowed the air space



aa suddenly to increase in size, and another ring was then formed inside the first, the process being repeated several times, until the water-level fell to E clear of the ice. From the water surface evaporation took place, and the vapour condensed on the underside of the ice-sheet, thickened it and made the ridges more pronounced and bulb-like.

The number of rings and the thickness of the ice depend upon the keenness of the frost and the rate at which the water-level falls.

A similar structure can be produced by perforations in thin ice-sheets partially supported by vegetation. The innermost ring is then the one first formed.

The fact that lines of weakness are produced above each rib is interesting, but has escaped my notice.

Remuneration of Public Analysts.

On behalf of the Association of Chemical Technologists, I beg to enter a strong protest against the course of action that is being followed by the Lambeth and Wandsworth Borough Councils in regard to the filling of the appointments of public analyst for those boroughs which have become vacant by the death of Dr. John Muter.

The terms of remuneration offered by both these borough councils are far below the lowest of the very inadequate rates of payment made to public analysts in London and throughout the country, and the acceptance of such appointments by a qualified scientific chemist on such terms would be degrading to the chemical profession and detrimental in the highest degree to the interests of the public. On the terms offered, it is absolutely impossible that the responsible duties attaching to such appointments can be efficiently performed. A public analyst has great personal responsibility, his position is one of considerable anxiety, the value of his work is not generally understood, and the office he holds is widely disliked, for he is appointed under the provisions of Acts of Parliament which are extremely unpopular among certain sections of the community. It is therefore essential that he should be in a position of such independence that he may not be liable to influence or pressure from any persons whose interest it may be to prevent, so far as possible, the effective administration of the Acts. It must be remembered, too, that with the enormous increase in scientific adulteration, the work of a public analyst is to-day very different from the work required even ten years ago, and it is therefore all the more necessary that the general public for whose protection the Acts were passed should appreciate the advisability of preventing the ever-increasing attempts of local authorities of a certain type to reduce the remuneration of the scientific officers concerned to a level rendering the satisfactory discharge of their duties impossible.

J. Wilberforce Green (*Secretary*).

30 Victoria Street, Westminster, London, S.W., March 6.

The Storm of March 4.

In Nature of March 7 reference is made to the storm of March 4, and figures are quoted giving the velocity of the wind recorded at several stations. It would appear that the storm attained a greater velocity here than at either of the stations named, and a few particulars of the record made by the Dines pressure-tube anemometer erected at Pendennis Castle, Falmouth, by the Meteorological Office, may be of interest.

On the morning of March 4 a progressive mean velocity of from 20 to 50 miles an hour was recorded; at 6 p.m. it had increased to 65 miles per hour, and this velocity was maintained to midnight. The squalls were very violent; between 2 p.m. and midnight a maximum velocity of 80 miles or more was registered more than twenty times, whilst the greatest squall attained a velocity of 98 miles at 6 p.m. This has been but once exceeded (or reached) since the anemometer was erected in 1902, viz. 103 miles at 11.30 p.m. of March 14, 1905.

Edward Kitto (*Superintendent*).

The Observatory, Falmouth, March 11.

Observed Fall of an Aërolite near St. Albans.

During a heavy thunderstorm which ensued on Monday, March 4, between 2.30 p.m. and 4.15 p.m., an aërolite was observed to fall at Colney Heath, near St. Albans. The observer, who has placed the specimen in my hands for examination, stated that the stone fell within a few feet from where he was standing, and that it entered the ground for a distance of about 3 ft. Its fall was accompanied by an unusually heavy clap of thunder. The example weighs 5 lb. $14\frac{1}{2}$ oz., and measures $6\frac{3}{4}$ in. $\times 5\frac{5}{8}$ in. at its greatest length and breadth respectively. The mass is irregularly ovate on the one side, and broken in outline on the other. The actual surface throughout is fairly deeply pitted, and under magnification exhibits the usual chondritic structure of the crystalline matter, with interspersed particles of what appears to be nickeliferous iron.

Hertfordshire Museum, St. Albans.

TRAVEL, SPORT, AND ADMINISTRATION.[1]

IN a handsome volume Mr. Hesketh Prichard tells the story of a short journey made by Mr. G. M. Gathorne-Hardy and himself in Labrador in 1910. The coast settlement of Nairn, from which the journey started up the Fraser River, lies somewhat north of the centre of the Labrador coast. In this latitude there is little enough to tempt men up to the interior plateau, and the explorers broke new ground in striking out of the Fraser Valley, climbing a tributary valley on its south flank, and striking southward and westward to the George River. They returned on their tracks, so were able to travel light when on the plateau by leaving caches of food at different points against their return. They depended largely on game and fish, and were fortunate in obtaining a sufficiency of both, though more than once they went hungry. The writer points out, and it is easy to realise, how near to the margin of safety an expedition travels thus lightly equipped and in so desolate a country. Adverse circumstances carried Leonidas Hubbard across that margin and drove him to starvation; Mr. Prichard pays a moving tribute to his efforts. It does not appear that the present expedition attempted more than to see "what the country looks like"; scientific observation was not systematically attempted in any direction. But valuable details as to the physical geography of the country traversed are to be gathered from the narrative, and among several photographs of interest in this connection, that of a raised beach in the George Valley may be selected for mention. And the travellers can speak with authority on sub-Arctic insect pests.

FIG. 1.—A "raised beach" in the George Valley. From "Through Trackless Labrador."

The Rocky Mountains and Selkirks in Canada have been visited by more than one scientific mountaineer, and Prof. Coleman's name stands very high among the number. In the present volume the scientific side of his work gives place for the most part to the interests of the mountaineer and the simple love of the mountains which is shared by all who visit them. Sometimes, however, occasion is found for an easy lesson on mountain-building and like topics; on page 357 and following pages there is an admirable explanation of the raising and shaping of Mount Robson, the summit of which the author was not destined to reach, in spite of more than one attempt. The accounts of the author's journeys range back over a number of years. His first visit to the Rockies was made in 1884. In 1885 he was in the Selkirks, and in 1888 he made a venturesome journey by canoe on the Columbia River. The latest journey described in the book is that above referred to, when Mount Robson was visited in 1908. It is not always easy to say exactly where a traveller has broken new ground in these mountains; hunters, prospectors, and railway reconnaissance surveyors have covered much of the ground. Moreover, instances have often been mentioned (and Prof. Coleman mentions some) of existing maps being found so untrustworthy as to be unrecognisable on the spot. In localities where he was not actually treading a new trail Prof. Coleman was sometimes the first scientific traveller to tread an old one, and mountaineers and tourists who may in the future follow him in increasing numbers as the country is opened up will find many occasions to thank him for what is obviously to him a labour of love.

The area dealt with in "Abdullah Mansûr's" book is, broadly speaking, south-western Arabia, and more particularly the Aden protectorate and its hinterland. The writer brings to his task the experience of ten years' service in the protectorate and a keen sense of humour, which together make his book no less entertaining than instructive. He points out, on the opening page of a very able introduction, how on leaving the sphere of imme-

diate British influence the traveller feels the impression of "having stepped back in the pages of history to mediæval times. This illusion is further enhanced by ancestral castles and a working feudal system." This being so, the author might perhaps be criticised on the score of anachronism when he tells his story in good colloquial language of the most modern kind, and even makes the native characters on his stage converse in it—were it not that the change from the conventional biblical style in rendering native speech is frankly refreshing. The Aden hinterland merges into a region which is one of the least known in the world the seat of an early civilisation which must either have existed under more favourable climatic conditions than now obtain there, or must have learned means of contending against conditions now forbidding settlement, if not mere passage. Mr. Bury clearly feels regret at having stood on the threshold of the unknown without entering it. Nevertheless, he adds much to the knowledge of the parts which he visited—their geography, their inhabitants, and their fauna. History is dealt with in an appendix, as well as in a preface by Major-General Maitland, an ex-political resident at Aden. A compliment is due to the few lines which close the book, entitled "A Desert Vesper."

FIG. 2.—The Selkirks from Asulkan Pass. From "The Canadian Rockies."

Sir Edward Durand's book is the record of a mighty hunter, though it makes "no pretence of posing as a sporting classic." In its pages will be found stories of practically every form of sport in India from tiger-shooting to mahseer-fishing. The writer had exceptional opportunities of enjoying the best sport that the country could furnish. His experiences, therefore, should serve as a guide to others, and his stories are often made to point a moral. He writes, perhaps, on no subject with more authority than on horses in his third chapter, at the opening of which he says, "I have had a large number pass through my hands, from racers and hunters to polo ponies." He greatly favours the Arab, with its "cannon-bone of the consistence of ivory"—in respect of this particular feature there is an interesting comparison between various breeds. This chapter is full of sound advice. There are very effective illustrations in half-tone from drawings portraying the chase of the tiger, wild pig, and other animals.

It is difficult to realise that the bulk of the matter which makes up Capt. Orr's history of Northern Nigeria deals with events confined within the last decade. It was in 1900 that the British Government assumed direct control in this territory. This form of administration had been preceded by chartered company administration, but Sir George Goldie had shown that "the absorption of the company in the Imperial Government" was a process contemplated when the company first applied for its charter. The company had deserved well of the Empire as an administrative organisation; it had to contend not only with internal native opposition, but with external complications, until the Anglo-French Convention of 1898 settled the frontier question. Having had assistance from Sir George Goldie himself and the Earl of Scarborough, Capt. Orr is able to tell the story of the company with no less authority than that of the ten years of Imperial government, in which he himself took part, being attached to the political department of the colony. He treats in full detail of the events of the early years of the century, the occupations of Bauchi, Bornu, Kano, and Sokoto, which were carried out in 1902–1903, followed by the organisation of provinces. The difficulties of establishing a general and equitable system of taxation in place of a local and inequitable native system are fully brought out, and the genius of Sir F. Lugard in attacking this and other problems is clearly seen and acknowledged. Each other important department of administration has its chapter. Introductory to the whole is the survey of the history, such as it is, of the country from the earliest known times, and a chapter descriptive of the country and its people enables the reader to appreciate the problems faced by the administration, especially in respect of dealings with the native peoples. The Hausas and the Fulanis or Fulahs, and particularly the latter, are of especial interest. From this descriptive chapter it appears, as is probably not generally realised, that the Northern Nigerian Government has had to deal, not with uncivilised natives alone, but with peoples who possess or at least claim a certain degree of civilisation and systems of government which already, in some cases, recognise the principles of vassalage and slavery, and are not easily tolerant of a suzerain power. Capt. Orr's volume is illustrated by simple but sufficient maps, save that no attempt is made towards the portrayal of relief or other physical characteristics. There is ground for regret here, especially when it is remembered what admirable geographical work so many Nigerian Government officials have found time to accomplish amid all their strenuous duties.

"The Story of the Zulus" is a rather sombre story, though even by strict historical methods it is not shorn of all the romance attached to it through the medium of fiction. Mr. Gibson has been a magistrate in Zululand, and was brought up in Natal at a time when Zulu opposition to white settlement was active. In this new edition he has been able to make use of new material discovered since the first issue, and the matter of the book has in consequence been not only revised but extended. Its claim to recognition as an authoritative work is thus strengthened.

O. J. R. H.

THE HUMAN FORM.[1]

MANKIND in general is imbued with a deep-rooted instinct of interest in the human form, the reality of which is substantiated by the contrast between the uncouthness of the ape and the gracefulness of man, which this interest, working through sexual selection, has brought about.

[1] "Die äusseren Formen des menschlichen Körpers in ihrem allgemeinen Zustandekommen. By Prof. E. Gaupp. Pp. 57. Thirteenth part of the "Sammlung anatomischer und physiologischer Vorträge und Aufsätze." (Jena: Gustav Fischer, 1911.) Price 1·50 marks.

But while it is thus ingrained in the nature of all human beings, not excepting even Schopenhauer, to find some fascination in the contemplation of the forms of the rest of our species, there are two classes of students whose business it is, during the course of the technical training for their professional work, to familiarise themselves with the exact topography of the surface of the human body and to inquire into the nature of the factors which determine its form. The artist, be he sculptor or painter, studies the body for the purpose of reproducing its features in the creation of statues or pictures; the medical man because the visible parts of the body afford the landmarks to guide him in the perilous undertakings incidental to his professional labours in the hidden depths of the body.

Although these two classes of students work in the same field of investigation they are seeking different kinds of knowledge, for much of the information that is of vital importance to the surgeon is of no interest to the sculptor. Teachers of anatomy have recently begun to realise that the usefulness of teaching in surface anatomy can be enhanced by taking a wider view of the subject in imparting knowledge to either class of students by borrowing judiciously, both in methods and knowledge, from the other class.

It is now widely acknowledged among teachers of anatomy in medical schools that the use of living models, after the manner of the art-teacher, is essential as a corrective to the mistaken ideas of the surface form of the body acquired from the cadaver in the dissecting-room; and the professional teacher of art-anatomy, if he is in the habit of dissecting, is able to impart to the medical student a great deal of useful information which he acquires when looking at the body from his own viewpoint. The time has come when the real teacher of anatomy for artists has begun to realise that it is not enough to show his students the human skeleton and demonstrate its muscles. He must give him facilities for examining and handling the muscles, and for investigating the nature and arrangement of tendons, aponeuroses, and intermuscular septa, and for studying the varieties of fatty tissues, and the factors (sex, age, and the individual and racial characters) that modify these packing tissues.

But, most important of all, he must be taught the difference between a dead and a live muscle, and between a living muscle that is in active contraction and one that, though "resting," is in a state of tonicity, which is a condition vastly different from the flaccidity of a dead or paralysed muscle.

Such studies are essential if the artist is to portray living men in action, and not merely models in the attitude of performing the given act. By this it is not meant that the student of art should attempt to fathom the mysteries of the "Integrative Action of the Central Nervous System," but he should learn the general principles of reciprocal action of muscles and the meaning of tonus.

As a concise and well-balanced introduction to these wider aspects of surface anatomy, Prof. Gaupp's most admirable little brochure deserves to be read by every student of art and medicine; and it is to be hoped that the kind of teaching his book supplies will soon become available in all schools of true art.

In Manchester during the last four years we have had an excellent demonstration of the strikingly beneficial results that can accrue to the student of art when anatomy is taught by an adequately trained teacher with the facilities which a dissecting-room affords.

At a moment when the constitution of the provincial schools of art in this country is in the melting-pot, and new alliances are being discussed with local universities, it is important to emphasise the benefits of such a working association between a school of art and a school of medicine, which will be useful to both.

G. Elliot Smith.

NOTES.

Dr. H. Brereton Baker, F.R.S., has been appointed to succeed Sir Edward Thorpe, F.R.S., as professor of chemistry in the Imperial College of Science and Technology, South Kensington, at the end of the present session.

Mlle. E. Chandon has been appointed assistant astronomer at Paris Observatory.

The widow of the late Prof. Hitzig has given 84,000 marks to the Prussian Academy of Sciences for the encouragement of researches on the brain.

In reply to a question relating to the protection of ancient buildings and other historic monuments, asked in the House of Commons on March 6, the Prime Minister announced that the First Commissioner of his Majesty's Office of Works proposes to introduce at an early date a Bill dealing with the question of the preservation of ancient monuments and buildings.

The death is reported, in his fifty-second year, of Dr. Charles Robert Sanger, assistant professor of chemistry at Harvard University from 1899 to 1903, and full professor since the latter date. Before his call to Harvard he occupied the chair of chemistry at the United States Naval Academy and at Washington University, St. Louis, successively. He was a member of the American Chemical Society and of the Deutsche Chemische Gesellschaft.

Prof. Henry Williamson Haynes, says *Science*, has bequeathed to the Peabody Museum of Harvard University 200*l.* for the library and all his prehistoric and archæological objects, and his books and pamphlets relating to such subjects. To the Boston Society of Natural History is given his fossils, minerals, and other objects of natural history. To Harvard College is given Mr. Haynes's Etruscan, Greek, and Roman vases, and his ancient coins and medals. The Boston Museum of Fine Arts is to receive his Egyptian antiquities.

At the meeting of the Royal Geographical Society on Monday last, Dr. J. Mackintosh Bell described some New Zealand volcanoes, and treated of recent volcanic activity in the central and northern parts of the North Island, and among the islands in the Bay of Plenty. The great eruption of Mount Tarawera in 1886 was treated exhaustively, and the present topography of the mountain as the result of twenty-five years' erosion on the material piled up in the course of the eruption was shown. The other volcanic regions were similarly dealt with.

The Biological Survey of the U.S. Agricultural Department has secured the cooperation of the National Zoological Park in experiments in breeding mink for the purpose of ascertaining the possibilities of rearing them in captivity for commercial purposes. This has never been attempted by the Government heretofore, but it is hoped that by the combined efforts of the two organisations something of practical importance can be accomplished. The main object in view is to secure data relative to the best methods of rearing mink for their fur, especially as to details of housing, feeding, mating, and caring for them.

A Reuter message from Calcutta reports that in the Legislative Council on March 8 Sir S. Harcourt Butler opposed a motion (which was afterwards withdrawn) to abolish the office of Director-General of Archæology, and said that the Government is determined to carry forward Lord Curzon's archæological work. The Government of India, he stated, contemplates increased expenditure, an increased establishment, an improvement in the production and circulation of publications, and especially the training of Indians for research and other work. Part of the scheme is the absorption of the Director-General in the Research Institute.

As statements have been published from time to time relating to the transmission of tuberculosis through the use of telephones, and especially of those in public call offices, the Postmaster-General has had the matter thoroughly investigated by Dr. Spitta, of St. George's Hospital. He has just issued a statement, in the course of which it is remarked that the final report which has now been received from Dr. Spitta shows that the results have been entirely negative. Dr. Spitta is of opinion, in view of the whole course of the experimental work, "that the transmission of tuberculosis through the medium of the telephone mouthpiece is practically impossible." These results are supported by an independent inquiry initiated some time ago by the American Government as to the condition of public telephones in the United States. They fully confirm the results of work carried out by Dr. Klein, of St. Bartholomew's Hospital, in 1905, at the instance of Dr. Collingridge, the City Medical Officer of Health, who caused a number of telephones in use at call offices of the National Telephone Company to be removed for bacteriological examination.

A provisional programme of the first International Eugenics Congress, to be held at the University of London on July 24–30, has been issued. The general heads under which the subjects to be discussed at the

Congress will be grouped are:—the bearing upon eugenics of (*a*) biological research, (*b*) sociological and historical research, (*c*) legislation and social customs; and the consideration of the practical applications of eugenic principles. An exhibition is being arranged which will include charts, pedigrees, photographs, and specimens illustrative of heredity, especially in man; relics of Charles Darwin, Francis Galton, and Gregor Mendel; and portraits of notable workers. Major Leonard Darwin is to be the president of the Congress. Particulars may be obtained from the honorary secretary, Mrs. Gotto, 6 York Buildings, Adelphi, W.C.

A small committee has recently been formed in Manchester, with Mr. R. H. Clayton as chairman and Mr. W. F. A. Ermen as secretary, the object of which is to further the movement for the purification of the atmosphere from coal smoke. The committee has sent circulars to scientific and other societies in Manchester asking them to appoint delegates to a meeting, at which arrangements are to be made for a deputation to go before the City Council. This deputation will urge the council to inaugurate a separate and independent department with a committee formed from the various existing departments of the Corporation which are affected directly or indirectly by smoke, with co-opted representatives of various societies. The duty of this department would be to study the various sources of pollution, and to investigate the possible applications of existing or new methods which might be adopted for the prevention of the present pollution.

From the *Rendiconti del R. Istituto Lombardo* we learn that a prize offered by the late Dr. Cagnola for "a well-proved discovery on the directing of flying balloons" has been unawarded. A reference to the issues of previous years shows that the same result has occurred practically without exception during the whole period in which aërial navigation has made the greatest progress. There have been recently numerous discoveries on the directing of flying balloons, which have been well proved by the performance of long-distance flights, and this prize has played no part in their successful development. In view of the fact that it was founded long before the days when aërial navigation became an accomplished fact, it should be evident that the title of the prize is sufficiently elastic to cover such developments as improvements in motors and propellers, even when tested by such methods as are employed successfully in our own National Physical Laboratory.

It is with sincere regret that we learn of the death of Mr. A. E. Hodgson, senior assistant at the Natal Observatory, which took place at Durban on February 11. Born at Leeds in 1880, Mr. Hodgson was trained at the Royal College of Science, London, where he afterwards became a demonstrator in astrophysics, and later joined the staff of the Solar Physics Observatory under Sir Norman Lockyer. In 1903 he accepted a post as assistant under Mr. Nevill at the Natal Observatory, subsequently becoming senior assistant. Here he performed the routine duties of the time service, &c., and also made observations of comets, putting into all his work a whole-hearted enthusiasm which was ever characteristic of him. According to an appreciation appearing in *The Natal Mercury*, Mr. Hodgson, had he lived, would probably have been placed in sole charge of the observatory on the retirement of Mr. Nevill. He was a fellow of the Royal Astronomical and Physical Societies, and his early death will be a great loss to those who enjoyed his friendship, both in Natal and in this country. The funeral took place at Durban on February 12.

The arrangements in connection with the Optical Convention which is to be held during six days in the last fortnight of June this year are making satisfactory progress. The Board of Education has consented to provide space for the exhibition forming part of the Convention in the Science Museum at South Kensington. The guarantee fund has reached 1055*l*., and active steps are being taken to ensure the success of the Convention. An exhibition and catalogue committee has been constituted, and is subdivided into twenty-four sections. A committee upon papers has been appointed, and it is expected that the result of their labours will be the publication after the meetings of a valuable volume of Proceedings. Prof. S. P. Thompson, F.R.S., is the president of the Convention, and the list of vice-presidents includes the names of many distinguished physicists and astronomers. Dr. R. Mullineux Walmsley, principal of the Northampton Polytechnic Institute, Clerkenwell, is the chairman of the executive committee, and Mr. J. W. Gordon, 113 Broadhurst Gardens, Hampstead, N.W., is honorary secretary.

On Thursday last, March 7, *The Times* recorded the discovery of an oak-tree trunk during the excavations for the extension of the Hampstead and Highgate Railway at the shaft near the Charing Cross District Railway Station. The tree was found at a depth of 40 ft. beneath the present surface in a bed of sand forming part of the younger gravels of the Thames. It was quite black, but perfectly sound. The roots and a portion of the trunk some 2 ft. in diameter were exposed in a prone position, as if the tree had been transported during flood time and then stranded. A stag's horn has been found in the same formation. No special importance attaches to these particular finds; the really significant circumstance is that their existence does not appear to have been made known to interested parties until a paragraph was written for the daily papers by a passing observer. The tree had been found long before, and lay in the wooden enclosure which surrounds the shaft, and it was not until it was turned out to be carted away that attention was directed to it. The geology of the shallow deposits underlying London is full of interest to all and is of considerable importance, and it can only be elucidated, now that so large an area is completely built over, by careful observation and correlation of the numerous deep foundation excavations and tunnels that are constantly being made and rapidly obscured. It is much to be regretted that no official exists to attend to the scientific aspects of these excavations in a systematic manner.

THE September (1911) number of *The Museum Journal*, issued by the University of Pennsylvania, is largely devoted to a description of the Polynesian department of the splendid collection made by Mr. E. W. Clark. This includes remarkable exhibits of finely carved ceremonial axes from Mangaia, clubs from Marquesas and Samoa, paddles from the Austral Islands, and a magnificent series of state clubs from Tonga, which exhibit in the most perfect way the artistic capacity of the Polynesian races.

IN a paper entitled "The Distribution of Early Bronze Settlements in Britain," read by Mr. O. G. S. Crawford before the Royal Geographical Society on February 14, an attempt is made to determine the geographical and racial elements in the type of culture represented by the class of pottery designated "beakers" by Mr. Abercromby, and one of the earliest forms of metal implements known, the flat celts or axes of copper or bronze. The British areas in which these articles are found together fall into several groups:—first, the east coast of North Britain extending from Cromarty Firth to the River Tees; second, the Yorkshire Wolds south of the Vale of Pickering and east of the Vale of York; third, the Peak District of Derbyshire; fourth, the Fen country between Stoke Ferry and Newmarket; fifth, between the Thames at Oxford and the chalk hills of South Dorset. It is pointed out that the incidence of the discoveries of these articles in juxtaposition is connected with the movement of the short-headed groups of peoples from various parts of Europe and the northern Mediterranean areas.

THE March issue of *Pearson's Magazine* contains an article by Mr. C. G. Crosley on the problem of the feeble-minded. More than 150,000 feeble-minded persons form part of the present population of this country. The majority of them, says Mr. Crosley, drift continually in and out of our workhouses and prisons, unable to support themselves or to lead a decent life; worst of all, they are free, by marrying and having children, to pass on the taint of degeneracy to the next generation. Of the 150,000 feeble-minded, nearly 70,000 are urgently in need at the moment of special provision for their care and control. Feeble-minded people are wonderfully prolific. The average birth-rate per marriage among the feeble-minded is seven, as against the four of normal persons. It is urged by Mr. Crosley that an essential preliminary to reform is that we should realise that feeble-mindedness is incurable. The State, he says, must have powers to care for and control, for so long a time as is thought expedient, all feeble-minded persons not properly provided for who are a danger to themselves or to society. Accommodation must be provided, in the shape of colonies, which could be cheaply built and would be practically self-supporting, where the inmates could be happily and usefully employed in agricultural or industrial work.

DR. CRESSWELL SHEARER contributes a remarkable memoir to *The Quarterly Journal of Microscopical Science* (February) on the problem of sex determination in *Dinophilus gyrociliatus*. This minute annelid worm lays its eggs in capsules, several together. Some of the eggs in each capsule develop into males and others into females, and the young females are actually fertilised by the males before they leave the egg-capsule, and while they are still in the larval condition. Their ova are, however, not yet formed, and the spermatozoa actually conjugate with the so-called oogonia. Henceforth the oogonium has a double nucleus, half derived from the male and half from the female parent. During subsequent divisions of the oogonium each half of the nucleus divides independently. Dr. Shearer calls the two halves "male and female pronuclei," but they are clearly not male and female pronuclei in the ordinary sense. The greater part of the process of oogenesis, then, appears to take place after the nucleus of the spermatozoon has entered the oogonium and the sperm nucleus continues dividing with the nucleus of the oogonium. Towards the close of oogenesis the final products of the division of the so-called pronuclei appear to conjugate. In some cases, however, division takes place in such a way that one of the daughter cells contains no representative of the male "pronucleus," and thus two kinds of mature eggs arise, those which contain chromatin substance derived from both male and female parents, and those which contain chromatin substance from the female parent only. The former are believed to give rise to female and the latter to male individuals.

THE recently published report of the advisory committee for the Tropical Diseases Research Fund for 1911 (Cd. 6024) testifies by its bulk to the numerous investigations on tropical sanitation and the etiology of disease that are being carried on throughout the Empire, since it is nearly double the size of the report for the previous year. The actual report of the committee occupies three pages; against an income of 3345*l.*, the committee has incurred an expenditure of 3795*l.* 6*s.* 8*d.*, and attention is directed to the urgent need of further sums being placed at its disposal. The remainder of the volume consists of appendices containing reports on anti-malarial measures in the colonies and protectorates, and on the work done in the laboratories or schools of tropical medicine in this country and in the colonies. Many of these reports contain detailed accounts of researches as yet unpublished; for example, the account given on pp. 71–76 of the investigations of Prof. Minchin and Dr. J. D. Thomson on the transmission of the rat-trypanosome by the rat-flea and the development of the parasite in the insect host. Many interesting and novel observations are contained also in the reports of Dr. Castellani for Ceylon, of the bacteriologist for British East Africa, and especially in the three reports of Dr. L. Nicholls for St. Lucia, which are very full and are accompanied by numerous illustrations. It is to be hoped that these investigations are not destined to remain buried in a Blue-book.

THE biology of the delta and the inundation-area of the Danube, with a short notice of the fisheries, formed the subject of an address by Dr. G. Antipa, director of the Bucharest Museum, delivered at the eighth International Congress held at Gratz in August, 1910. The paper has lately been published at Jena in pamphlet form by Mr. Gustav Fischer. The subject is divided into two sections, one dealing with the physical conditions of the inundation-area and its relations to the periodical oscillations in the water-level of the Danube generally, and the other with the life of different portions of this area and its variation according to the different water-levels of the river. Of particular interest is the author's description of the various means by which the fauna and flora accommodate themselves to the varying levels of the water, but, for reasons of space, these cannot receive detailed notice. A high water-level in the inundation-area is the delight of the fishermen, as will be evident from the statement that whereas in 1904, when the water-level only reached the 3·50 m. mark, and there was no overflowing of the banks, the catch of fish was 920,000 kg., in 1907, when the water rose to 5·40 m., and the banks were overflowed for 128 days, the product was no less than 6,447,000 kg. This abundance of fish during big inundations is, however, only a part of a general phenomenon, the water-organisms at such seasons attaining a preponderating development at the expense of the land fauna and flora.

PART IV. of the "Selected Reports from the Scientific and Technical Department of the Imperial Institute" (Cd. 6022, 1912) is devoted to rubber and gutta-percha. It relates chiefly to the composition and quality of rubbers prepared in different ways, and obtained from trees and plants grown under various climatic conditions in a number of British colonies. The trees and plants in question include not only well-known kinds such as Hevea, Funtumia, and Castilloa, but others less well known which may prove to be of value where the cultivation of the more important rubber-producers is not possible. The reports show the chemical composition of the samples submitted, and in many cases indicate the technical valuation also. In several instances the differences produced in the quality of the rubber by different methods of coagulating the latex are pointed out. Much work has been done by the department in studying the problems of coagulation, "curing," and "tackiness" in rubber, but the conclusions are withheld for the present, pending confirmation by further experiments now in progress. A few specimens of gutta-percha from the Straits Settlements and other districts, and of balata from British Guiana and Venezuela, are described. Attention is directed to the question of utilising Para rubber seed, enormous quantities of which are now becoming available through the maturing of large plantations. The seed yields about 20 per cent. of oil, which is of commercial value as a substitute for linseed oil, and the residual cake may be of use for feeding cattle; some preliminary trials of it have given promising results, but require to be supplemented by experiments on a larger scale.

AT the meeting of the Mathematical Section of the Vienna Academy on February 8, Prof. J. Hann submitted an important work entitled "The Diurnal Variations of Wind-force on the Summit of Ben Nevis." The wind-force observations had not been discussed before; to a great extent only estimates of the hourly values could be given in the valuable published tables, as rime and snow-drift frequently interrupted the record of the anemometer. Dr. Hann carefully investigated the relations between the estimated and registered values during fifteen summer months, and found corrections applicable to the values at different parts of the day; afterwards he subjected the estimated monthly means to harmonic analysis. The maximum wind-force at Ben Nevis occurs with extraordinary regularity between 1h. and 2h. a.m. in all months. The minimum occurs at 4h. p.m. from November to March; at 5h. p.m. from April to June; at 3h. p.m. from July to October. The diurnal variation, even in winter, is well marked, with a large amplitude; at this season the difference of the daily extremes amounts to 1·05 m.p.s., and in summer to 1·55. The smallest values occur in spring and autumn. Storm frequency shows a regular daily variation in both half-years, with two maxima and two minima; in winter the maxima occur at 2h. and 9h. a.m., and the minima at 6h. a.m. and 3h. p.m. In summer the daily period agrees completely with that of air-pressure: maxima, 9h. a.m. and 10h. p.m.; minima, 4h. a.m. and 3h. p.m. In the yearly mean this agreement still holds, with the trifling exception that the second maximum occurs at midnight. This double daily period of storm frequency is a very singular phenomenon; it is also shown at Vienna and other places.

THE photometric equipment of the laboratory of the Holophane Company of Newark, Ohio, is described and illustrated in the February number of *The Illuminating Engineer* of New York. The photometer is of the Dibdin radial type, the standard lamp moving on horizontal rails, while the lamp to be tested moves up and down a vertical shaft extending through three stories of the building. The photometer screen is maintained by two rods at a fixed distance from the lamp under test, and bisects the angle between the rays coming from the two sources. Arrangements are provided which allow the lamp under test and its reflector to be rotated either together or independently of each other. The Lummer-Brodhun contrast photometer screen is used, and in addition rotating sectors are provided which cut down the light on either side to a known fraction of its original amount. For direct-current tests the current is supplied by storage cells, and for alternating currents a small motor generator is run from the cells.

COMMUNICATION No. 124 from the Physical Laboratory of the University of Leyden contains a short paper on the magnetic properties of solid oxygen, glass, and anhydrous ferrous sulphate at low temperatures down to 14° on the absolute scale, by Prof. Onnes and Dr. Perrier. In each case the susceptibility increases rapidly as the temperature falls, but appears in the case of oxygen and ferrous sulphate to reach a maximum at about 20° absolute. In the case of oxygen, the susceptibility increases fourfold on liquefaction. The deviations from Curie's law are considerable throughout. A second paper in the same communication is by Prof. Onnes, and deals with the electrical resistance of mercury at these low temperatures. The resistivity of mercury in the solid state at the melting point is about 50 ohms per centimetre cube. As the temperature decreases it falls regularly to 0·12 ohm at 4·3° absolute. In the interval between 4·23° and 4·18° absolute it falls to a value of the order 10^{-5} ohms per centimetre cube, that is, it practically disappears.

Two of the late Prof. Van't Hoff's former students, Dr. W. P. Jorissen, of Leyden, and Dr. L. Th. Reicher, of Amsterdam, have recently published a very interesting volume entitled "J. H. Van't Hoff's Amsterdamer Periode, 1877–1895" (Helder: C. de Boer, jun., 1912, pp. 106). Dealing principally with Van't Hoff's work as a university professor in Amsterdam, the book contains also an account of the teaching of chemistry in Amsterdam before Van't Hoff's arrival, a short account of his life, and a detailed bibliography of his published books and papers, and of the biographical and other notices which have been written concerning the great Dutch chemist. The illustrations form a very interesting feature of the volume, consisting of portraits of Van't Hoff at different periods of his life, portraits of his predecessors at Amsterdam, and pictures of the Amsterdam Chemical Laboratory in the various stages of its history. The book forms an important contribution to the history of Van't Hoff's life and work, and the authors are to be warmly congratulated, not only on the affectionate piety which has inspired their work, but also on the care and labour that they have bestowed upon it.

Engineering for March 8 gives some additional particulars of the oil-engined ship *Selandia*, the first passenger sea-going vessel fitted with Diesel engines. There are two main engines, driving twin screws, each engine consisting of a set of eight single-acting cylinders 20⅞ in. in diameter by 28·75 in. stroke, working on the four-stroke cycle. It is evident from the successful running that no pains and no expense have been spared in rendering the auxiliary machinery as immune from breakdown as is possible. During the voyage from London to Antwerp, the indicated-horse-power developed in eight cylinders was 1190, or 1000 brake-horse-power, assuming 84 per cent. efficiency as obtained on the test bed at the maker's works. The fuel-oil consumption is about 0·45 lb. per brake-horse-power hour. The indicator diagram shows a mean pressure of about 91 lb. per square inch at 129 revolutions per minute. It is claimed that this type of engine has increased the cargo-carrying capacity by 1000 tons.

IN the article upon "Soot" which appeared in NATURE of February 29, reference was made to an article upon "The Sootfall of London" which appeared in *The Lancet* of January 6. Mr. S. Archibald Vasey writes to point out that the experimental portion of the inquiry was done entirely in *The Lancet* laboratory under his personal supervision. Messrs. des Vœux and Owens took no part in the laboratory work, which included some 400 analyses, though their names were associated with it in our article.

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A NOVA.—A telegram received from Kiel yesterday states that a new star, of the fourth magnitude, has been discovered in the neighbourhood of η Geminorum by Herr Enebo, of Domaas, Norway. η Geminorum transits about 6.30 p.m., and sets near the north-west at about 2 a.m.

EPHEMERIDES OF COMETS.—A continuation of the ephemeris of Brooks's comet (1911*c*) is published by Prof. Millosevich in No. 4558 of the *Astronomische Nachrichten*, and shows that the comet is in the southern extremity of Circinus, and is very faint.

Schaumasse's comet (1911*h*), according to the ephemeris published by the discoverer in the same journal, is almost stationary about half-way between β and ζ Ophiuchi, and is about eight times less bright than when discovered. An observation on February 16 showed the comet to be excessively feeble.

In No. 4559 of the journal Dr. Ebell publishes new elements for Quénisset's comet (1911*f*), and gives an ephemeris covering the period April 5 to May 15. The comet is now in Carina, and is of about the tenth magnitude.

OBSERVATIONS OF BIELIDS IN NOVEMBER, 1911.—Assisted by four students, Prof. Pokrowski kept watch for the Bielid shower of meteors on November 17 and the succeeding nights. On the first night twenty-six meteors were seen between 8h. and 12h. (Dorpat M.T.), and of twelve seen between 8h. and 10h. nine appeared to come from a radiant at 24°, +42°. Four meteors from 25°, +42° were seen on November 24, and on several nights other radiants given in Denning's catalogue were seen to be active.

THE SMITHSONIAN ASTROPHYSICAL OBSERVATORY.—Mr. Abbot's report for the year ended June 30, 1911, contains some most interesting results, chiefly concerning the sun's radiation.

He emphasises the fact that simultaneous observations have now been made at Washington (sea-level), Mount Wilson (altitude, more than a mile), and Mount Whitney (altitude, nearly three miles), and that the close agreement of the results indicates that the effects of the earth's atmospheric absorption are practically eliminated. From the observations made during 1902–10, the general mean for the solar constant is found to be 1·922 calories (15° C.) per sq. cm. per minute. The solar radiation appears relatively greater in the infra-red than in the ultra-violet, possibly because the shorter radiation from the deeper layers of the solar atmosphere are selectively absorbed during their passage through the upper layers; but, taking all things into consideration, it is probable that we receive solar radiations from sources having temperatures between 5000° and 7000° abs. C., and mostly between 6000° and 7000°. The observations tend to confirm the existence of an irregular variation in the solar radiation from day to day; its amplitude is from 3 per cent. to 10 per cent., and its period ranges between five and ten days.

Observations from the summit of Mount Whitney show that one square degree of polar sky, at night, gives 0·0746 the light given by a first-magnitude star, and that the observed increased brightness of the night sky near the horizon must be ascribed to some terrestrial agent, such as a continuous faint aurora.

OBSERVATIONS OF SUN-SPOTS AND FACULÆ IN 1911.—Prof. Riccò's annual summary of the solar observations made at Catania during 1911 appears in No. 1, vol. i. (second series), of the *Memorie della Società* *degli Spettroscopisti Italiani*, and indicates a general decrease of the solar activity, not only as compared with the preceding year, but also during 1911. The daily frequency of spots was 0·5, and of faculæ 0·8, while on 196, or 64 per cent., of the days of observation no spots were recorded.

THE NORWEGIAN SOUTH POLAR EXPEDITION.

LAST Thursday we published an article by Dr. William S. Bruce on the Antarctic campaign, in which the plans of the several expeditions were described. The same day Captain Amundsen arrived at Hobart, Tasmania, and it became known in London late in the evening that he had reached the South Pole, and was returning.

The news was made public by *The Daily Chronicle*, which also published the full narrative of Captain Amundsen's journey. We congratulate our contemporary upon its enterprise in this respect, and upon the excellent accounts it has given of polar exploration. The following facts are taken from the narrative published in *The Daily Chronicle*.

The Attainment of the South Pole.

Amundsen began his journey south on February 10, 1911, and from this date to April 11 he established three depôts. The winter was spent in changing the entire outfit. The lowest temperature recorded during the expedition was −59° C. The mean temperature for the year 1911 was −26° C. Amundsen set out on the second journey on September 8, but had to return to await the arrival of spring. It was in the middle of October that the spring came in earnest. On October 31 the depôt in lat. 81° S. was reached, that in 82° on November 5. On November 9, 83° was attained, and depôt number four established. On November 13 and 14, 84° S. and 85° S. were reached, and other depôts established. On November 17 the barrier was reached, and climbing began, and many distressing experiences, of which Amundsen's narrative tells. The concluding steps of the arduous enterprise may thus be summarised.

On December 6, 1911, Amundsen attained his greatest height, 10,750 ft., as measured by the hypsometer and aneroid. This was at latitude 87° 14′ south. On December 9, 88° 39′ was reached, and on some following days the latitudes attained were as follows:—December 10, 88° 56′; December 11, 89° 15′; December 12, 89° 30′; and December 13, 89° 45′.

On December 14 the Pole itself was reached, and the temperature recorded was −23° C. The plateau on which the Pole was located is a vast plain, alike in all directions, mile after mile.

The following day, December 15, in fine weather, a series of observations, which lasted from 6 a.m. to 7 p.m., were taken, the result giving 89° 55′. In order to observe the position of the Pole as closely as possible, Amundsen and his men travelled as near true south as they could for the remaining 9 kilometres.

On December 16 four members of the expedition took observations every hour of the day's twenty-four. The exact result will be a matter for expert examination.

Amundsen states he observed the position of the Pole as closely as it is in human power to do with the instruments he had—sextant and artificial horizon.

The distance from the winter quarters to the Pole was about 1400 kilometres, so that on an average Amundsen's party marched 25 kilometres a day.

No news has yet been received from Captain Scott, whose base was 400 miles from Captain Amundsen's, but it is possible that he has also reached the South Pole by another route.

CONSIDERATION OF RESULTS.

Captain Amundsen's brilliant expedition has not only reached the South Pole, but appears to have settled the question of the possible connection between Ross Sea and Weddell Sea by a sea-filled rift valley passing to the east of the Pole. This hypothesis was maintained by Lieut. Filchner, and his plans for the present German Antarctic Expedition are based upon it.

The general evidence seemed to be opposed to this theory, as was remarked in NATURE (vol. lxxxiii., p. 318). Subsequently Sir George Darwin announced that the tidal evidence appeared to indicate a direct sea way from the Ross Sea to the South Atlantic, and the great weight of this evidence in favour of Lieut. Filchner's view was referred to in NATURE of December 29, 1910.

Captain Amundsen has now discovered that the barrier ice ends to the south in a "bight" in lat. 86° and long. 163° W.; there may perhaps be some cable error in the latitude, as the discovery was made on November 11, when the explorers were at about 83½° S., and statements elsewhere in the report suggest that the end of the barrier may be at about 85° S.

The bight which forms the southern shore of the barrier appears to be formed by the union of the mountains that continue southward from South Victoria Land with a chain which trends southwestward, and which Captain Amundsen describes as probably the continuation of King Edward VII. Land. He does not, however, mention having seen any mountains on the eastern side of the barrier during the first part of the journey southward.

Captain Amundsen climbed to the South Polar plateau further south than the Beardmore Glacier, by which Sir Ernest Shackleton reached it. The new route seems to have given an easier ascent; but after reaching the plateau its level was more undulating, as he crossed a series of glaciers which apparently flow eastward, and therefore may indicate that the Ross Sea is continued southward by a depression. Hence the hypothetical Transantarctic rift valley may possibly exist, but with its floor above sea-level. The strongest argument for it has, however, been disproved.

Speculation on this question may, however, await the publication of the more detailed evidence as to the nature and trend of the new mountains discovered to the east and north-east of the Pole.

The meteorological results also promise to be of special interest, for Captain Amundsen experienced fine weather and light breezes when on the South Polar plateau. The fierce southern gales that hindered Sir Ernest Shackleton were perhaps exceptional, for Captain Amundsen describes the ice on the plateau as level, and "only here and there marked with a tiny sastrugi." Captain Amundsen's general results fully confirm the descriptions of Sir Ernest Shackleton.

The outward journey, including the ascent to the height of 10,500 ft., was made at the rate of 25 kilometres a day, and the return at 36 kilometres. This high speed was probably due to the use of dogs, which have again shown their value in polar work.

A party under Lieut. Prestud reached King Edward VII. Land, to the east of the Great Ice Barrier, and the geological collections made there may throw much light on the relations of that land to South Victoria Land.

Reaching the South Pole, discovering the end of Ross's Great Ice Barrier, and making the first landing on King Edward VII. Land is a remarkable triple achievement, and the Norwegian expedition has certainly gained results of first-rate geographical value. Dr. Nansen is to be congratulated on the latest success of his school of polar heroes.

THE TEACHING OF MATHEMATICS.[1]

THE papers before us on "The Teaching of Mathematics in the United Kingdom" are published by the Board of Education as special reports on educational subjects. Each paper of the series (eleven papers are now before us) is written by an expert on the particular subject he treats, and their substantial agreement on educational principles shows the revolution which has taken place in the last decade, and is still taking place in mathematical education.

Last century the subject was taught on the most conventional lines. Few thought of comparing the values, for either mental discipline or knowledge, of different portions of the subject or of different methods of teaching. Such books as the "Inventional Geometry" of Herbert Spencer's father proves the existence of occasional thoughtful men; but in the deadness of the time such books were lost sight of until rediscovered to-day.

The reformers of the later nineteenth century dealt with rigour of proof and completeness of logical development. They aimed at doing for other branches of mathematics what Euclid had done for geometry. A system of mathematics in which the whole subject develops by irrefragable reasoning from a small number of assumptions is a lofty ideal and is an entrancing occupation for certain mature minds; but the school is no place for it. The examination in recent years of attempts at such a system, Euclid's included, leads to the view that no system can do more than approximate roughly to the ideal; the statement of the preliminary assumptions cannot be made complete or the logical development rigorous. This conclusion has added strength to the arm of the band of reformers who hold that this ideal, even if attainable, is out of place in the school.

These reformers recognise that the boy's mind is not the adult mind writ small, that reasoning power develops from an approximate zero in the infant to something far short of perfection in the adult; perfection of reasoning not being attained even in the greatest mathematicians. Consequently they replace this ideal of logical perfection by the ideal of a course suited at every age to the mental development of that age, both in matter and in method of presentation. The matter must in the earliest years be entirely concrete, and must gradually become more abstract with the increasing age and power of the pupil. It should never become entirely abstract, to the exclusion of the concrete, for even in its highest developments mathematics is merely a tool for ultimate application to concrete problems. It is true that it is an economy of labour to have a few mathematicians who work chiefly in the abstract and improve the tool for others to use; but even for these few some knowledge of concrete problems has value for the proper direction of their efforts.

The method of presentation must likewise have regard to the age of the learner. At first there is little reasoning, the teacher's object being to provide in connection with concrete material the abstract ideas for later reasoning, as well as to give precision to such abstract ideas as the pupil already possesses. In the earlier stages evidence is chiefly experimental and intuitional. By appropriate training and increase of years the mind develops and demands more logical evidence. The evidence, suited always to the needs of the pupil, and restricted to the kind which he asks and can grasp, gradually approaches that Euclidean form at which the nineteenth century aimed.

The choice of material out of the various branches of mathematics is important in two ways. The first and obvious criterion is that, other things being equal, the branch which has a direct use in after life, a "bread-and-butter" value, is to be preferred to the branch which has not. The other is that the branch which is the better mental gymnastic is to be chosen. Fortunately these two criteria generally indicate the same branches, the bread-and-butter subject by its relation to life exciting an interest which goes far to give it the preference as mental gymnastic.

The above views run through most of the eleven papers now under review. The battle was first fought in the secondary school, and has been won there as far as the principles are concerned, the questions now at issue being the working out of courses founded on them. The principles are being brought to bear even on the classical boy, naturally enough the last to be affected by a reform in mathematics. In the first paper of the series, "Higher Mathematics for the Classical Sixth Form," Mr. Newbold shows how, in place of the dull committing to memory of Euclid's propositions, such a Form has, by a discussion of problems of everyday life, been given a real and useful grasp of the ideas of the infinitesimal calculus.

In the universities the battle for the new principles is beginning, and Dr. Filon, in his paper on "The Relations of Mathematics and Physics," does yeoman service. As evils requiring regulation he names "(1) mutual misunderstanding due to over-specialisation; (2) the accumulation of uninterpreted material in physics and of abstract concepts in mathematics; (3) the neglect of applied mathematics."

It is unfortunate for the mathematical students at Cambridge that in the rearrangement which admitted physics to a position of consequence, that subject was placed in a tripos distinct from mathematics. Since this estrangement between the two subjects, Cambridge has produced no mathematicians to compare with giants like Kelvin, Stokes, Clerk Maxwell, and Sir J. J. Thomson. Recently a move in the right direction has been made in the attempt to combine the early training of mathematicians, physicists, and engineers; but the success of such a scheme requires more than the revision of regulations.

The third and fourth papers are on "The Teaching of Mathematics in Public Elementary Schools." In these schools the position is somewhat disappointing. The teachers are slow to avail themselves of the free-

dom now allowed to them, partly no doubt because of their long discipline under fixed syllabuses, probably partly also because in their work (chiefly arithmetic) there exists no association like the public-spirited Mathematical Association, which has contributed so greatly to the solution of the problem of courses of mathematics in secondary schools.

However, there is progress. Ten years ago, in answer to the simplest question not introduced by one of the mystic words, "multiply," "add," &c., pupils would reply, "I don't know what rule it belongs to." Or they would determine how long Mr. Gladstone lived by multiplying together the years of his birth and death. The two papers now under review show a great advance on that time. And if stocks and shares are still too much in evidence, and the portions of geometry and algebra selected for addition to the curriculum leave something to be desired, there is yet evidence of a great ferment, from which sooner or later good must come. In particular the new Central Schools are full of promise.

The fifth pamphlet of the series, "The Algebra Syllabus in the Secondary School," is a statesmanlike discussion by Mr. Godfrey of the reforms which are at present most urgent in school mathematics. The present ferment in education is acting not only on mathematical masters, but on all other masters, headmasters included. The number of subjects claiming recognition in the school is so great that all cannot be successful in their claims. The inquiry is made with regard to every subject, whether, by reason of its value for knowledge, training, or discipline, it deserves a place in the curriculum or no. Difficult as it is for the mathematician to believe, it is the fact that, so far as concerns non-mathematical boys, the verdict is in danger of going against algebra as at present taught. Many public schools would like to curtail seriously the time given to mathematics.

Something is wrong when headmasters of position and judgment look back on their mathematical training as the "transient but blighting shadow of $x+y$." And those who believe in the value of a mathematical training for all boys must give earnest consideration to the remedy advocated by Mr. Godfrey, a remedy which is already applied in some schools.

Algebra as at present taught is so abstract as to be incomprehensible to the majority of boys. It includes also many portions which lead nowhere in particular, and have no exceptional value as mental discipline. Mr. Godfrey reviews the customary algebra course, and shows severe pruning to be possible and desirable. The time saved by this pruning it is proposed to utilise in giving a useful and educational acquaintance with numerical trigonometry, mechanics on an experimental basis, and the ideas of the infinitesimal calculus. On the calculus Mr. Godfrey's proposals may be usefully studied along with the first pamphlet of this series.

A paper on "The Correlation of Elementary Practical Geometry and Geography" (6) is appropriately included in the series. Geography supplies many illustrations and problems for the use of the mathematical master. In return, when the geography master discusses maps and plans and their making, he finds as a result of the work of his mathematical colleague a readier comprehension on the part of his pupils.

Mr. Eggar's views on "The Teaching of Elementary Mechanics" (7) are shared by the best masters. That they are not more generally put into practice is mainly due to the backwardness of most examining bodies to recognise their merit. It is also partly due to the want of faith of the teacher, for a preliminary or concurrent practical course undoubtedly gives a better grasp, and fits a boy better than the old plan, even for the oldest-fashioned theoretical examination in mechanics. The value of a practical course is placed beyond doubt when the two associations, which represent science and mathematical masters respectively, unite in so strong a recommendation as is contained in the report quoted by Mr. Eggar.

Many words of wisdom are scattered through the paper. One valuable aspiration is that in the future mathematics and physics will be in the hands of one master. For the teaching of mechanics this has the merit of more complete correlation between the practical and theoretical courses. For the mathematical master a knowledge of physics will give a breadth of understanding which is not always found at the present day.

For details of the course Mr. Eggar's paper must be consulted. We will only say here that he wisely follows the historical order in beginning with statics.

(8) "Geometry for Engineers" is less pleasing than the preceding ones. The elaboration of the proposed treatment of conic sections, and (to a less extent) the time it is proposed to devote to synthetic geometry, would appear to necessitate the postponement to a very late stage of subjects so essential to an engineer as mechanics and the infinitesimal calculus. On the other hand, one sympathises with the author's view of the importance of descriptive geometry, both on account of its direct usefulness and on account of the mental training involved in thinking in three dimensions.

(9) "Mathematics in Secondary Schools for Girls." Miss Story's pupils are fortunate in having a mistress so well able to distinguish the gold from the dross. While selection of material is very desirable for boys, it is all-essential for girls. After half a century of attempts to fashion girls' education on the lines fixed by tradition for boys, the country is now realising that it wants to have its girls made into good women and not into inferior men.

(10) "Examinations from the School Point of View" opens with the sound doctrine that qualifying and competitive examinations should be kept distinct, the former being intended to determine which pupils have attained a certain standard, the latter to pick out a certain number of the best. The union of the two tests in a single examination makes the questions too difficult to be a fair test of a moderate general education. On a given range of work fairly complete answers to easy questions are better evidence of ability and knowledge than fragmentary answers to difficult questions.

The author's next proposition is more difficult of acceptance: that in a matriculation examination 70 or 80 per cent. of the candidates should be passed. The object of such an examination being to test fitness to study at a university, the examiners are surely already generous in deciding that 50 per cent. possess that fitness.

Objection to the technical bent of the Army Entrance Examination is possible only in a country which plays at keeping an army. In France and Germany the army is a highly technical profession, and the school education carefully arranged on that understanding. With the author's statement that better ability cannot be secured by stiffening the examination we entirely agree; the remedy lies elsewhere.

In (11) Miss Stephens describes an interesting experiment on the "Teaching of Mathematics to Young Children." The excellent method of the ten-bundle and the hundred-bundle will no doubt lead up to the 100-times table, the 1000-times table, &c., which are more valuable than the 11- and 12-times tables.

David Beveridge Mair.

THE EXTENSION OF THE PHYSICAL AND ELECTROTECHNICAL LABORATORIES OF THE UNIVERSITY OF MANCHESTER.

THE new extension of the physical and electrotechnical laboratories of the University of Manchester was formally opened on Friday evening, March 1, by Prof. Schuster, F.R.S. A well-attended reception and conversazione was held on Friday evening in the old and new laboratories. Many interesting experiments and exhibits of apparatus were on view during the conversazione and on Saturday morning. In the course of the evening a meeting was held in the large lecture theatre. The Vice-Chancellor, Sir Alfred Hopkinson, referred to the growth of the work in the physical laboratory and the necessity of providing more space for research. Mr. S. Z. de Ferranti, president of the Institution of Electrical Engineers, was awarded the honorary degree of doctor of science. Prof. Lamb, in presenting Mr. Ferranti to the Vice-Chancellor, said that more than a quarter of a century ago he attacked the problem of the transmission of electrical energy in its most concentrated form, and, undaunted by discouragements and prophecies of disaster, he solved it in practice on a commercial scale with complete success. It was largely to his initiative and his labours that we owed the plentiful use of the light which supplemented and often, alas! superseded and surpassed the sunshine of Manchester.

Prof. Schuster, before declaring the new buildings opened, addressed the meeting, and described the development of the physical department of the University. In a subsequent portion of his address he spoke of the great field for the student of physics in India and the colonies.

When the main physical laboratories were built in 1900, a large part of one floor was set aside for the department of electrical engineering, while a special laboratory, known as the John Hopkinson Dynamo Laboratory, was built. The steady growth of the department and the increase of the number of those engaged in original investigation have, in recent years, placed great pressure on the space of the laboratory. This was emphasised by the nature of many of the researches in radio-activity, in which large quantities of radium are employed. The effect of the γ rays, which are able to traverse the walls and floors of the laboratory, disturbed the measurements of the workers not only in the immediate vicinity, but also in the neighbouring rooms. In order to provide additional space, the Council of the University decided to remove the department of electrical engineering from the physical laboratory proper and to locate it in a new building. In these new engineering laboratories, part of the first floor, containing six research rooms, has been set aside for physics, while a small electrochemical laboratory has been erected outside for work on radio-active substances. The physics department has thus the use of the space formerly occupied by electrical engineering. The addition of a number of new research rooms for physics, removed some distance from the main physical laboratory, will prove of great advantage for the purpose of original investigation, especially for radio-activity and allied subjects. It is intended to keep the new laboratories uncontaminated by radio-active matter, and they will be employed mainly for the more delicate measurements.

The new buildings were designed by Mr. J. W. Beaumont, the architect of the main physical laboratories. They form a simple but substantial structure faced externally in red Ruabon brick with stone dressings so as to harmonise with the main physics buildings.

A noteworthy feature of the new buildings is the system of bare wires run on insulators, which has been adopted throughout for the experimental circuits. This system has proved so satisfactory in the main laboratory that it has been employed wherever possible in the present extension. From the battery, which is of 600 ampere-hour capacity, with a maximum discharge rate of 300 amperes, heavy bare copper conductors run along a subway beneath the main corridor to the switchboard room in the north wing. From this, by means of plug boards, current can be distributed over the whole building.

CALENDAR REFORM.

AN article by Mr. Victor Anestin, of Bukarest, on calendar reform in the States of the Greek Church, extracted from A. Richter's "Kalender" (Riga, 1912), has been received. The author gives an interesting account of the efforts which have been made in the Balkan States and in Greece towards the adoption of the Gregorian calendar, and describes the state of public opinion on the question at the present time. It is a pathetic story of ecclesiastical prejudice and jealousy on one side and political irresolution and instability on the other. The chief obstacle to following the practice of western Europe lies in the fear entertained by each national church of being denounced as schismatic by the other adherents of the Greek faith, and this prevents any one of the churches, though nominally independent, from taking the lead and sanctioning the reform. Hence the outlook at present is not promising. Mr. Anestin expresses the opinion that the fate of the reform in these States depends on the action of Russia, since the other Greek churches would not be likely to impugn the Russian church, but would probably follow its initiative. In the meantime, the matter does not advance. Roumania seems to have gone further than the other States, and though a Bill enacting the change which was presented to the Chamber came to nothing owing to the political circumstances of the time, the postal and telegraph services and the railways use the Western calendar, and all the almanacs show both styles side by side.

A certain value in the existence of two calendars is suggested by the following quite charming story which happens to appear in close juxtaposition to Mr. Anestin's article, and, if not bearing seriously on the question, may be reproduced as an interesting piece of folklore. It appears that the gipsies of Servia and Montenegro go in fear of the evil spirits which are abroad at Christmas. Therefore an old gipsy living on the Hungarian-Servian border has devised this subtle means of protecting himself. On Christmas Day (N.S.) he hangs up in his hut a Servian (O.S.) calendar; thus any prowling demons will see at once that he is a Serb, and as such observes the Julian Christmas. Thirteen days later he hangs up a Hungarian (Western) calendar; and then, of course, the evil spirits will recognise their powerlessness over him since, so far as he is concerned, Christmas is already a thing of the past.

Ticehurst, and H. F. Witherby; The Birds of Australia, G. M. Mathews, vol. ii., Part i., illustrated; Flight of Birds, F. W. Headley.

Chemistry.

Edward Arnold.—The Chemistry of Bread-making, J. Grant; Smoke: a Study of Town Air, Prof. J. B. Cohen, F.R.S., and A. G. Ruston, illustrated. *Cambridge University Press.*—Brewing, A. C. Chapman; The Story of a Loaf of Bread, Prof. T. B. Wood. *Constable and Co., Ltd.*—An Introduction to the Study of Fuel, Dr. F. J. Brislee; The Chemistry of the Rubber Industry, H. E. Potts; The Chemistry of Dyeing and Bleaching of Vegetable Fibrous Materials, J. Hubner, each illustrated. *Gurney and Jackson.*—The Manufacture of Sulphuric Acid and Alkali, Prof. G. Lunge, vol. i., Sulphuric Acid, new edition, vol. iv., Preparation of Alkali, &c., by Electrolysis; Technical Methods of Chemical Analysis, Prof. G. Lunge and Dr. C. A. Keane, vol. iii. *W. Heinemann.*—Experimental Domestic Science, R. H. Jones. *T. C. and E. C. Jack.*—Chemistry of Non-living Things, Prof. E. C. C. Baly, F.R.S. *Longmans and Co.*—A Dictionary of Applied Chemistry, Prof. Sir Edward Thorpe, C.B., F.R.S., assisted by eminent contributors, revised and enlarged edition, vol. ii., illustrated. *Methuen and Co., Ltd.*—Modern Research in Organic Chemistry, F. G. Pope, illustrated; Qualitative Organic Analysis, F. B. Thole, illustrated; A Practical Chemistry for Technical Institutes, Dr. A. E. Dunstan and F. B. Thole, illustrated; Second Year Organic Chemistry for Schools and Technical Institutes, F. B. Thole, illustrated. *Mills and Boon, Ltd.*—Problems in Practical Chemistry for Advanced Students, G. F. Hood, illustrated. *J. Wiley and Sons (New York).*—A Summary of Methods in Chemical Analysis, Prof. F. A. Gooch.

Engineering.

Edward Arnold.—The Theory and Design of Reinforced Concrete, O. Faber and P. G. Bowie, illustrated. *Constable and Co., Ltd.*—American Electric Central Station Distribution Systems, H. Barnes Gear and P. F. Williams, illustrated; The Energy Diagram for Gas, Prof. F. W. Burstall; Railway Signalling Engineering, L. P. Lewis, illustrated; Modern Sanitary Engineering, G. Thomson, illustrated; a new edition of Irrigation, Sir H. Brown. *Gauthier-Villars (Paris).*—La formation des Ingénieurs électriciens, Prof. A. Blondel; Les nomogrammes de l'Ingénieur, R. Seco de la Garza. *Longmans and Co.*—Elementary Internal Combustion Engines, J. W. Kershaw, illustrated; The Mechanics of the Aëroplane: a Text-book, Capt. Duchene, translated from the French by J. H. Ledeboer and T. O'B. Hubbard, illustrated. *G. Routledge and Sons, Ltd.*—The Control of Water for Power, Irrigation, and Town Water-supply Purposes, P. à M. Parker, illustrated. *J. Wiley and Sons (New York).*—Subways and Tunnels of New York: Methods and Cost, with an Appendix on Tunnelling Machinery and Methods and Tables of Engineering, G. H. Gilbert, L. I. Wightman, and W. L. Saunders, illustrated; Practical Methods of Sewage Disposal for Residences, Hotels, and Institutions, Prof. H. N. Ogden and H. B. Cleveland; Design of Electrical Machinery, Prof. W. T. Ryan, in three volumes, illustrated; The Design and Construction of Roofs, Prof. N. C. Ricker; Cost of Concrete, Dr. F. W. Taylor and S. E. Thompson; Laboratory Manual for the Use of Students in Testing Materials of Construction, Prof. L. A. Waterbury, illustrated.

Geography and Travel.

A. and C. Black.—The World (Regional Geography), J. B. Reynolds, illustrated; Man and his Conquest of Nature, Dr. M. I. Newbigin, illustrated; Geographical Pictures: Land Forms and how They are Made, Series iii., The Sculpture of the Surface, edited by S. M. Nicholls, in two packets; Historical Geography of the British Isles, M. S. Elliott, illustrated; Elementary Picture Geography Series: How Other People Live, H. C. Barnard, illustrated; The Children's World, S. Shenessey, illustrated. *W. Blackwood and Sons.*—Chiefs and Cities of Central Africa: Across Lake Chad by Way of British, French, and German Territories, O. Macleod, illustrated. *Cambridge University Press.*—Physical Geography for South African Schools, A. L. du Toit; Cambridge Geographical Text-books—Junior, A. J. Dicks; Cambridge County Geographies: Oxfordshire, P. H. Ditchfield; West London, G. F. Bosworth; Breconshire, C. J. Evans; North Lancashire, Dr. J. E. Marr, F.R.S.; Radnorshire, L. Davies; Dumfriesshire, Rev. Dr. J. K. Hewison; Perthshire, P. Macnair; Renfrewshire, F. Mort. *Gauthier-Villars (Paris).*—Guide scientifique du géographe explorateur, C. de Beauregard. *W. Heinemann.*—Animal Life in Africa, Major J. Stevenson-Hamilton. *H. Holt and Co. (New York).*—Elements of Geography, R. D. Salisbury, H. H. Barrows, and W. S. Tower. *Macmillan and Co., Ltd.*—Across Australia, Prof. B. Spencer, C.M.G., F.R.S., and F. J. Gillen, illustrated. *A. Melrose.*—Big Game Hunting in Central Africa, Dr. J. D. Brunton, illustrated. *Kegan Paul and Co., Ltd.*—A Voyage to the Arctic in the Whaler *Aurora*, D. M. Lindsay, illustrated. *G. P. Putnam's Sons.* In the Amazon Jungle: Adventures in a Remote Part of the Upper Amazon River, including a Sojourn among the Cannibal Indians, A. Lange, illustrated.

Geology.

A. and C. Black.—Romance of the Rocks, Rev. C. A. Hall, illustrated. *Gebrüder Borntraeger (Berlin).*—Geologischer Führer durch die nördliche Adria, Dr. R. Schubert, illustrated; Petrographisches Praktikum, Prof. R. Reinisch, Zweiter Teil: Gesteine, new edition, illustrated; Geologische Charakterbilder, edited by Prof. H. Stille, Heft 9 and 10, illustrated; Geologie der Steinkohlenlager, Prof. H. Dannenberg, Zweiter Teil, illustrated. *Cambridge University Press.*—The Work of Rain and Rivers, Prof. T. G. Bonney, F.R.S.; Rocks and their Origin, Prof. G. A. J. Cole; The Origin of Earthquakes, Dr. C. Davison; Glaciers and Ice Sheets, Prof. Garwood; The Earth, Prof. Poynting, F.R.S.; Natural Caves and Fissures, Dr. A. Rule; Submerged Forests, C. Reid, F.R.S. *W. Heinemann.*—A History of Scenery: a Geological Reader, R. G. A. Bullerwell. *T. C. and E. C. Jack.*—Geology, Prof. T. G. Bonney, F.R.S. *T. Fisher Unwin.*—The Building of the Alps, Prof. T. G. Bonney, F.R.S., illustrated. *J. Wiley and Sons (New York).*—Building Stones and Clays, E. C. Eckel, illustrated.

Mathematical and Physical Science.

D. Appleton and Co.—The Sun, C. G. Abbot, illustrated. *Cambridge University Press.*—Clouds, C. T. R. Wilson, F.R.S.; The Physical Basis of Music, A. Wood; The Meteorology of the Globe, Dr. W. N. Shaw, F.R.S.; Beyond the Atom, Prof. J.

Cox; The Measurement of Time, the Astronomer Royal; Principia Mathematica, A. N. Whitehead, F.R.S., and B. Russell, vol. ii.; Differential Geometry, Dr. A. R. Forsyth, F.R.S.; Statics, Prof. S. L. Loney; Structure of the Atmosphere, C. J. P. Cave. *Gauthier-Villars (Paris)*.—L'Electricité et l'Optique, A. Potier, illustrated; Leçons sur les principes de l'Analyse, R. Adhémar, Tome i., illustrated; Grandeur et Figure de la Terre, J. B. J. Heinemann.*—Introductory Electricity and Magnetism, C. W. Hansel; Experimental Mensuration: an Elementary Text-book of Inductive Geometry, H. S. Redgrove. *Hodder and Stoughton.*—The Electrical Properties of Flames and of Incandescent Solids, H. A. Wilson. *H. Holt and Co. (New York).*—Elements of Physics, E. H. Hall. *T. C. and E. C. Jack.*—Radiation, Dr. P. Phillips; Light, according to Modern Science, Dr. P. Phillips; Weather-science, G. F. K. Lempfert; Lord Kelvin, Dr. A. E. Russell; Sir W. Huggins and Spectroscopic Astronomy, E. W. Maunder. *Longmans and Co.* A Treatise on the Analytic Geometry of Three Dimensions, Dr. G. Salmon, F.R.S., new edition, revised by R. A. P. Rogers, 2 vols., vol. ii. *Macmillan and Co., Ltd.*—Studies in Terrestrial Magnetism, Dr. C. Chree, F.R.S (Science Monographs); Studies in Radioactivity, Prof. W. H. Bragg, F.R.S. (Science Monographs). *Mills and Boon, Ltd.*—Graphs in Arithmetic, Algebra and Trigonometry, W. J. Stainer, illustrated. *John Murray.*—A New Geometry, A. E. Layng. *R. Oldenbourg (Munich and Berlin).*—Einführung in die Mathematische Behandlung der Naturwissenschaften, Kurz gefasztes Lehrbuch der Differential- und Integralrechnung mit besonderer Berücksichtigung der Chemie, Profs. W. Nernst and A. Schönflies, new edition, illustrated. *G. P. Putnam's Sons.*—Astronomy in a Nutshell, G. P. Serviss, illustrated; A Beginner's Star Book, K. McKready, illustrated. *W. Rider and Son, Ltd.*—Mathematical Theory of Spirit, H. S. Redgrove. *The University Tutorial Press, Ltd.*—Mathematical Physics, vol. i., Magnetism and Electricity: a Mathematical Treatment for Students of Physics, C. W. C. Barlow; Qualitative Determination of Organic Compounds: a Systematic Treatment of Advanced Practical Organic Chemistry, J. W. Shepherd; Junior Heat: for the Cambridge Junior Local Examination, Dr. J. Satterly. *J. Wiley and Sons (New York).*—Practical Mathematics for Second Year Students in Applied Electricity Courses, E. H. Koch, jun.; An Introduction to General Thermodynamics, Prof. H. A. Perkins.

MEDICAL SCIENCE.

F. Alcan (Paris).—Bréviaire de l'Arthritique, Dr. M. de Fleury; Les Opiomanes: Mangeurs, Buveurs et Fumeurs d'Opium, Dr. R. Dupouy; La Fatigue et le Repos: la Fatigue, la Conservation des Forces, la Médication par le Repos, Dr. F. Lagrange; Les Sporotrichoses, Drs. de Beurmann and Gougerot; Traitement des Neurasthéniques, Dr. P. Hartenberg; Manuel de Kinesithérapie, Drs. Wetterwald and others, 2 vols. *Edward Arnold.*—Practical Anatomy, F. G. Parsons and Dr. W. Wright, 2 vols., illustrated; Caisson Disease and Diver's Palsy, Dr. L. Hill, F.R.S.; Lead Poisoning and Lead Absorption: the Symptoms, Pathology, and Prevention, with Special Reference to their Industrial Origin and an Account of the Principal Processes involving Risk, Dr. T. M. Legge and K. W. Goadby; The Protein Element in Nutrition, Major D. McCay; Shock: the Pathological Physiology of some Modes of Dying, Prof. Y. Henderson; The Carrier Problem in Infectious Disease, with Particular Reference to Enteric Fever, Diphtheria, Cerebro-spinal Meningitis, Bacillary Dysentery, and Cholera, Drs. J. C. G. Ledingham and G. F. Petrie. *Baillière, Tindall and Cox.*—Veterinary Toxicology, G. D. Lander; Foods: their Origin, Manufacture, and Composition, W. Tibbles. *John Bale, Sons and Danielsson, Ltd.*—Translations of Prof. Hermann Sahli's Tuberculin and Innere Sekretion: Ihre Physiologischen Grundlagen und ihre Bedeutung für die Pathologie, Prof. A. Biedl. *Cassell and Co., Ltd.*—British Red Cross Society Training Manual, J. Cantlie; Health Culture for Busy Men, illustrated; Health Habits and How to Train Them, illustrated; Healthy Brain and Healthy Body, illustrated; A System of Surgery, edited by Drs. C. C. Choyce and J. M. Beattie, 3 vols., illustrated. *Gustav Fischer (Jena).*—Hermiszbildungen: ein Atlas von Querschnitten angeborener Herzfehler mit besonderer Berücksichtigung des Verhaltens des Atrioventrikularsystems, Prof. J. G. Mönckberg, illustrated; Die Ursachen des chronischen Magengeschwürs, J. W. T. Lichtenbelt, illustrated; Das Bakterien-Anaphylatoxin und seine Bedeutung für die Infektion, Dr. H. Dold; Ueber die Regenerationsvorgänge in den Nieren des Menschen, Dr. A. Tilp, illustrated; Die Blutbildung und seine klinische Verwertung, Dr. V. Schilling, illustrated; Intoxications-Psychosen, Dr. F. Kanngiesser. *Hodder and Stoughton.*—Infectious Diseases and their Preventive Treatment, E. C. Seaton. *T. C. and E. C. Jack.*—Hypnotism, Dr. A. Hutchison. *H. Kimpton.* A Text-book of Dental Histology and Embryology, including Laboratory Directions, Prof. F. B. Noyes, illustrated. *Longmans and Co.*—A Manual of Surgical Treatment, Sir W. Watson Cheyne, Bart., F.R.S., and F. F. Burghard, with the assistance of T. P. Legg and A. Edmunds, new edition, in five volumes, vol. ii. *Macmillan and Co., Ltd.*—Anæsthetics and their Administration: a Text-book for Medical and Dental Practitioners and Students, Sir F. W. Hewitt, M.V.O., new edition, illustrated. *Methuen and Co., Ltd.*—The Science of Hygiene: a Text-book of Laboratory Practice, Dr. W. C. C. Pakes, edited and revised by Dr. A. T. Nankivell, illustrated. *G. Routledge and Sons, Ltd.*—Return to Nature, authorised Translation of "Kehrt zur Natur Zurück," A. Just, by H. A. Nesbitt, illustrated. *The University Tutorial Press, Ltd.*—Text-book of Hygiene for Teachers: an Account of School Hygiene based on Elementary Physiology, Dr. R. A. Lyster.

TECHNOLOGY.

A. and C. Black.—Tea, E. A. Browne (Peeps at Great Industries), illustrated. *Gebrüder Borntraeger (Berlin).*—Metallographie, Dr. W. Guertler, Erster Band, Heft 10. *Cassell and Co., Ltd.*—Wool Carding and Combing, Prof. A. F. Barker and E. Priestley, illustrated; The Steel Square Simply Explained, illustrated; Bevels and Cuts: Easy Methods of Marking Them, E. Hardy; Incubators and Chicken-rearers. *Constable and Co., Ltd.*—Commercial Paints and Painting, A. S. Jennings; Brewing and Distilling, J. Grant. *John Lane.*—Bricks and Mortar, F. I. Thomas. *Crosby Lockwood and Son.*—Crushing and Grinding Machinery Practice: a Handbook on the Machinery used in Crushing and Grinding Operations on all Classes of Materials, T. G. Marlow, illustrated. *Methuen and Co., Ltd.*—Gem-stones, and their Distinctive Characters, Dr. G. F. H. Smith, illustrated. *John Murray.*—Cocoa: its Cultivation and Preparation, W. H. Johnson, illustrated. *Sir Isaac Pitman and Sons, Ltd.*—Tobacco: from Grower to Consumer, A. E. Tanner; Wool: from the Raw Material to the Finished Product, J. A.

Hunter; Coal: its Origin, Method of Working, and Preparation for the Market, F. H. Wilson. *T. Fisher Unwin.*—Unwin's Technological Dictionary, three parts, in French, German, and English, edited by Dr. A. Tolhausen, revised by L. Tolhausen, with a supplement, including all modern terms and expressions in electricity, telegraphy, and telephony. *Whittaker and Co.*—Manufacture of Nitro-lignin and Sporting Powder, E. H. Durnford, illustrated; The Radio-telegraphists' Guide and Log-book: a Manual of Wireless Telegraphy for the Use of Operators, W. H. Marchant, illustrated. *J. Wiley and Sons (New York).*—Handbook of Sugar Analysis, C. A. Browne, jun.; German and American Varnish-making, Prof. Max Bottler, translated, with notes on American varnish and paint manufacture, by A. H. Sabin, illustrated; Analysis of Paint and Varnish Products, Dr. C. D. Holley.

MISCELLANEOUS.

Baillière, Tindall and Cox.—The Economics of Feeding Horses, Prof. H. A. Woodruff. *Cambridge University Press.*—The Psychology of Insanity, Dr. B. Hart; Metals, F. E. C. Lamplough; Prehistoric Britain, L. McL. Mann. *Chatto and Windus.*—A History of Babylonia and Assyria from Prehistoric Times to the Persian Conquest, L. W. King, vol. ii., illustrated. *W. Heinemann.*—Introductory Science, W. Tunna Walker. *T. C. and E. C. Jack.*—Introduction to Science, W. C. D. Whetham, F.R.S.; The Meaning of Philosophy, Prof. A. E. Taylor; Psychology, Dr. H. J. Watt. *Macmillan and Co., Ltd.*—Manual of Statistics, the late Sir R. Giffen, F.R.S. *Milner and Co.*—Dactylography: or Finger Prints in Relation to Evidence of Man's Genetic Descent, &c., H. Faulds, illustrated. *John Murray.*—Science of the Sea: an Elementary Handbook of Practical Oceanography for Travellers, Sailors, and Yachtsmen, prepared by the Challenger Society for the Promotion of the Study of Oceanography, and edited by Dr. G. Herbert Fowler, illustrated. *G. P. Putnam's Sons.*—Nature's Harmonic Unity: a Treatise on its Relation to Proportional Form, S. Colman. *J. Wiley and Sons (New York).*—Fire Prevention and Fire Protection, J. K. Freitag; Applied Methods of Scientific Management, F. A. Parkhurst, illustrated.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—In a letter to the Vice-Chancellor, dated March 7, Viscount Esher states that a generous benefactor, who stipulates that his name shall not be mentioned, has placed in his hands a sum of 20,000*l.* for the purpose of endowing a professorship at Cambridge in connection with the experimental study of heredity and of development by descent. It is stipulated also that the new chair shall be called the Balfour Professorship of Genetics. The same benefactor "is willing to furnish such funds as may be necessary to provide and equip a small station at Cambridge for the use of the professor should such a course be considered desirable after careful examination of the methods likely to be most satisfactory for the purposes of research in the domain of genetics."

Lord Rayleigh, Chancellor of the University, has been nominated to represent the University on the occasion of the celebration in July next of the two hundred and fiftieth anniversary of the foundation of the Royal Society; Sir T. Clifford Allbutt, K.C.B., and Dr. Macalister, professor of anatomy, to represent the University at the bicentenary festival of the Medical School of Trinity College, Dublin, in July next; and Dr. E. W. Brown to represent the University at the centenary anniversary of the Academy of Natural Sciences of Philadelphia in the present month.

Syndicates have been appointed to obtain plans for the extension of the School of Agriculture on the Downing site, and for the erection of the building for the Forestry Department at the south-east corner of the same area, and the Vice-Chancellor has been authorised to obtain tenders for the extension of the engineering laboratory.

The next combined examination for fifty-seven entrance scholarships and a large number of exhibitions, at Pembroke, Gonville and Caius, Jesus, Christ's, St. John's, and Emmanuel Colleges, will be held on Tuesday, December 3, and following days. Mathematics, classics, natural sciences, and history will be the subjects of examination at all the above-mentioned colleges.

THE new hygiene and physiology laboratories of the Battersea Polytechnic will be opened on Monday, April 22, by the Master of the Worshipful Company of Drapers, his honour Judge Benson, who will deliver an address and distribute prizes and certificates.

PROF. A. WILLEY, F.R.S., and Dr. W. F. N. Woodland have been elected fellows of University College, London. Dr. Woodland, who is assistant professor of zoology at the college, has been appointed to the chair of zoology at the Muir Central College, Allahabad, India.

THE London County Council has arranged for maintenance grants of 5500*l.*, 11,460*l.*, and 11,610*l.*, respectively, to be paid to the University of London for the years 1911–12, 1912–13, and 1913–14. In each year 1000*l.* is intended for home science at King's College for Women, 1500*l.* for libraries, 500*l.* for the physiological laboratory, and 500*l.* for advanced lectures; 2000*l.* each year is intended for general university purposes. In each of the years 1912–13 and 1913–14 5400*l.* is intended for the university professoriate and for the encouragement of French and other Romance languages.

IN the *Popular Science Monthly* for February, Prof. A. F. Chamberlain directs attention to some interesting characteristics of the modern English language, which he considers may conduce towards English becoming the universal language of the future. These characteristics include the power of importing and assimilating foreign words when required for the exigencies of intercommunication without subordination to grammatical categories and merely formal canons; the formation of hybrid words, the use of prefixes and suffixes, and the reduction of long words by abbreviated forms. The author quotes the word "remacadamising" as an instance built up from five different languages—Latin, Gaelic, Hebrew, Greek, and English. He considers that no other language in the world possesses the same qualities, which, by the way, somewhat reflect England's qualities as a free-trade colonising nation, and may be intimately connected with our national characteristics.

IN the House of Commons on March 6 Sir Philip Magnus asked the Prime Minister whether the Government has made itself responsible for the housing of the University of London throughout its history; whether he was aware that in the Treasury minute of February 16, 1899, the liability to provide a suitable home for the University is acknowledged;

and what steps the Government proposes to take in the matter, in view of the unsatisfactory accommodation for the University disclosed in the report of the Royal Commission on University Education in London? In reply, Mr. Asquith said the Government has provided accommodation for the London University throughout its history. The minute cited was written before the removal of the old University to South Kensington, and refers to the possibility of an arrangement between the authorities of the Imperial Institute and the Treasury. It must not be construed as admitting liability on the part of the Government to provide for all possible requirements of the University in the future. The report of the Royal Commission points out that the University must depend to a large extent upon private endowments for its full development. The Government does not think that it would be opportune to take any steps in connection with the matter before the final report of the Commission is published.

SOCIETIES AND ACADEMIES.

London.

Royal Society, February 29.—Sir Archibald Geikie, K.C.B., president, in the chair.—Dr. A. **Harden** and Dorothy **Norris**: The bacterial production of acetylmethylcarbinol and 2 : 3-butylene glycol.—H. Péré considered that glyceraldehyde was produced during the bacterial fermentation of sugars, and advanced the hypothesis that all sugars undergoing such decomposition were primarily broken down to glycerose. The authors have repeated his experiments, and find that the volatile, reducing, and lævorotatory substance which he considered to be glyceraldehyde is in reality acetylmethylcarbinol. Hence the above hypothesis cannot be considered as proved. A quantitative examination has been made of the products formed by the action of *B. lactis aërogenes* (Escherich) on glycerol under anaërobic conditions. These consist of ethyl alcohol and formic acid, comprising 60 per cent. of the whole, together with smaller quantities of acetic, lactic and succinic acids and 2 : 3-butylene glycol, carbon dioxide, and hydrogen.—H. S. **Ryland** and B. T. **Lang**: An instrument for measuring the distance between the centres of rotation of the two eyes. The apparent position of a pin fixed at a known distance in front of a scale is taken with each eye singly. The operation is repeated with the pin at a different distance, the other conditions remaining unaltered. From the data thus obtained the distance between the centres of rotation of the two eyes can be calculated. The result is independent of variations in the distance between the pupils, and the process can be applied in cases of squint. In an alternative method three pins in a row parallel to the scale are used.—J. F. **Gemmill**: The locomotor function of the lantern in Echinus, with remarks on other allied lantern activities. (1) *Locomotion out of water* (reference is made to previous accounts by Romanes and Ewart).—The urchin raises itself from time to time on the tips of its teeth in preparation for a forward "step" or lurch. The "step" is then brought about (*a*) by strong pushing or poling on the part of the lantern, (*b*) by similar but weaker action on the part of the spines, (*c*) by the influence of gravity acting at a certain stage. Active progression by lantern alone is possible in small and medium-sized urchins. Progression by spines alone is very limited indeed. An urchin can travel with the help of its lantern even when loaded to the extent of half a pound or more. There is usually some rotation as well as progression, but the two are not associated as cause and effect. The causes of rotation are discussed, and an analysis is given of the lines or curves of progression in relation to rotation. Other points to which attention is directed are:—muscles involved; strength of effort; change of direction; inversion; equatorial section; recording surfaces of plasticene and other substances; the inertia and momentum of the rhythmic action. (2) *Locomotion under water.*—Here the lantern is not needed for ordinary locomotion, particularly over more or less horizontal surfaces. There are, however, various circumstances, normal and experimental, in which it is employed with effect—for example, when the urchins are loaded or travelling up a slope on certain surfaces, or only partially immersed, or mounting rapidly up a vertical surface. (3) The locomotor action of the lantern is a particular manifestation of a rhythmic functional activity which can also subserve feeding (no doubt the most important function), boring, and "forced respiration."—Captain A. D. **Fraser** and Dr. H. L. **Duke**: The relation of wild animals to trypanosomiasis. (1) *Trypanosoma uniforme* was the only species of trypanosome obtained as the result of examination of wild animals, including thirty-two Lake-shore antelopes. (2) The available evidence points to bush-pig, crocodile, monitor, frog, and fowls being refractory to *T. gambiense*. (3) The edible rat, which is susceptible to *T. gambiense*, can, by virtue of its habits, be of little importance in considering the question of a reservoir.—Dr. H. L. **Duke**: The transmission of *Trypanosoma nanum* (Laveran). This trypanosome can be transmitted by *Glossina palpalis*, the proportion of positive flies obtained being relatively large, and indicating that this fly may play an important part in the spread of the disease in Uganda.—E. H. **Ross**: The development of a leucocytozoon of guinea-pigs. The paper describes an investigation of some remarkable structures found in the mononuclear leucocytes (lymphocytes) of the blood of guinea-pigs; they are known as "Kurloff's bodies." There has been considerable controversy regarding the nature of these bodies, some authorities describing them as vacuoles containing secretion products, some as symbiotic structures, as chlamydozoa, as cytoryctes, as parasites, and as spurious parasites. By a new technique for *in vitro* staining, known as the jelly method, the minute structure of these bodies can be seen, while the lymphocytes which contain them are stained alive. The method shows conclusively that Kurloff's bodies are living parasites. The method also shows how the bodies develop within the lymphocyte host, for the chromatin within them stains in the various phases, and the whole development can be followed from the earliest Leishmania-like inclusion in the leucocytes until ultimately the leucocytozoon is seen to contain a mass of spirochæte-like bodies which have been likened to *gametes*. The blood of such guinea-pigs shows, when examined with the dark-ground illumination, free-swimming spirochætes, and these have been fixed and stained. The details of the jelly method are described.

March 7.—Sir Archibald Geikie, K.C.B., president, in the chair.—Sir William **Crookes**: The devitrification of silica glass. A clear and transparent tube of silica glass with a bulb blown at one end was exhausted to a high vacuum. It was heated in an electric resistance furnace in such a manner that the bulb was exposed to the greatest heat while the lower part of the tube was comparatively cool. After being kept at a temperature of 1300° C. for twenty hours the bulb and upper part of the tube had devitrified, becoming white and translucent like frosted glass. The tube was resealed, exhausted, and exposed to 1300° for eleven hours. On cooling, the point of the tube was broken under mercury, and from the amount that entered it was ascertained that 7·79 per cent. of the tube's capacity had leaked through the devitrified silica.—Sir William **Crookes**: The volatility of metals of the platinum group.—Prof. W. M. **Hicks**: A critical study of spectral series. Part ii.—The principal and sharp sequences and the atomic volume term. This is a sequel to a paper on the same subject published in the Philosophical Transactions, vol. ccx. (1910). The sequences which give the principal and the sharp series are discussed as they occur in the second and third groups of the periodic table of the elements, and it is found that, in opposition to the rule in the alkalies, the P-series is based on the *s*-sequence and the S-series on the *p*-sequence. Additional evidence is afforded to show that these sequences depend on atomic volumes of elements in quite definite way.—Prof. W. E. **Dalby**: An optical load-extension indicator, together with some diagrams obtained therewith. The paper describes a new instrument by means of which automatic records of load-extension diagrams can be obtained with precision, the records being free from errors due to inertia, pencil-friction, and to any strains caused by the yielding of the testing machine in which the specimen is being tested.—R. **Whiddington**: The transmission of kathode rays through matter. It has been found experimentally that a kathode ray moving with velocity v_0 can possess, after traversing a thickness x of material, a velocity v_r given by the relation $v_0^4 - v_r^4 = ax$, where a is a constant depending on the nature of the material.—R. **Whiddington**: The velocity of the secondary kathode particles ejected by the characteristic Röntgen rays. Application of the results of the preceding paper to the experimental investigations of Beatty into the absorption of kathode particles in air leads to the conclusion that the fastest of the secondary kathode particles ejected from a plate by Röntgen rays characteristic of the element of atomic weight w possess a speed equal to $k'w$, where k' is a constant nearly equal to 10^8.—E. E. Fournier **d'Albe**: The potential effect in selenium. A new type of selenium bridge (or "selenium cell") was constructed by coating a plate of unglazed porcelain of high insulating power with graphite and dividing the surface into two conducting portions by cutting, with a diamond, a to-and-fro line through the graphite. The plate was then coated with selenium and sensitised. The bridges so constructed showed no polarisation, and were well adapted to the study of the "potential effect," or the change of resistance with the voltage applied.

Institution of Mining and Metallurgy, February 15.—Mr. H. Livingstone Sulman, president, in the chair.—C. O. **Bannister**: On the theory of blast-roasting of galena. This is an exhaustive record of researches made by the author, with the view of determining the nature of the reactions that take place during the blast-roasting of galena when present alone and when in admixture with lime, limestone, gypsum, etc. The introduction of the paper deals with the previous researches of Huntington and Heberlein, Carmichael and Bradford, Savelsburg, Austin, Dwight and Lloyd, and others, and the theories to which the published results of those authorities gave rise, and the author then goes on to describe his own recent series of experiments, with diagrams and tables showing the observed conditions in temperature at different periods of time during the course of roasting galena mixed with lime, silica, litharge and lime, limestone, calcium sulphate, magnesium oxide, ferric oxide, slaked lime, etc. As a result of his carefully conducted experiments the author has arrived at the conclusion that the older theories as to the formation and subsequent reaction of peroxides, plumbites, and plumbates are wrong, as also those depending on definite reactions between calcium sulphate and lead sulphide; that later theories depending on the diluent effect of various agents are only partially true; that the oxidation of lead sulphide takes place in three stages; that in the presence of lime, limestone, and magnesia, the sulphates of calcium or magnesium are formed in preference to sulphate of lead; that silica and calcium act merely as diluents, without chemical action until a temperature of over 1000° is reached; that ferric oxide in certain physical states acts as a catalysing agent; and that silica acts at high temperature in decomposing lead sulphate and calcium sulphate.—H. K. **Picard**: A graphic method of illustrating the results of extraction tests. The author has devised for his own use a system of placing in graphic form the results of extraction or concentration tests on ore samples, which is illustrated and described. It consists in the employment of "squared" paper, on which areas are marked out for the various weight units of the tests carried out, and the percentages of ore content are indicated by covering so many squares of these areas with a wash of solid colour. The result, as shown in an example submitted by the author, is at once apparent, and from the graphic indications it can be ascertained whether certain products should be rejected, re-treated, or mixed with other products.—A. T. **French**: Quick combination methods in smelter assays. This paper, which is practically a collection of laboratory notes presenting together a scheme for the combination of various approved methods of smelter analysis, was not discussed at the meeting owing to the lateness of the hour.

Geological Society, February 28.—Dr. Aubrey Strahan, F.R.S., president, in the chair.—L. J. **Wills**: Late Glacial and post-Glacial changes in the Lower Dee Valley.—E. B. **Bailey** and M. **Macgregor**: The Glen Orchy anticline (Argyllshire). The district described stretches from the head of Loch Awe to Beinn Achallader, and is the south-eastern continuation of the Fort William, Ballachulish, and Appin country dealt with by one of the authors two years ago. The subject is the tectonics of the schists.

Cambridge.

Philosophical Society, February 26.—Dr. A. E. Shipley, F.R.S., in the chair.—L. **Doncaster**: The chromosomes in oogenesis and spermatogenesis of *Pieris brassicae*.—R. P. **Gregory**: The chromosomes of a giant form of *Primula sinensis*. Dr. **Cobbett**: Preliminary note on the occurrence of living bacteria in the organs and blood of normal animals.—S. R. **Price**: Some observations with dark-ground illumination on plant cells.—R. C. **McLean**: Rhizopods from the Carboniferous period.

Edinburgh.

Royal Society, February 5.—Sir T. R. Fraser, F.R.S., vice-president, in the chair.—Dr. R. Stewart **MacDougall**: The bionomics of *Nematus ericksoni* (Hartig), the large larch-sawfly. The larvæ of this sawfly, which was first noticed in numbers some years ago in the Lake district, have also been found at work in Wales, and more recently in Perthshire and Forfarshire. In breeding out adults from cocoons collected in spring, Dr. MacDougall obtained 165 females to one male. Hewitt had previously recorded two males to 298 females. To test this suggested parthenogenesis, seven newly issued virgin females were placed on May 26, 1910, on a young larch, which was potted and so confined that no other insect had access to it. By June 12 three were dead, and in a few days the remaining four had died. Although there was no reasonable doubt as to the sex, the dead insects were dissected, and proved all to be females. Eggs had been freely laid, and through June the caterpillars which hatched from them fed greedily. Examination on July 3 showed two caterpillars on the soil of the pot, and these had spun their cocoons by July 7. On July 17, the soil was sifted from the pot, and altogether 47 cocoons and five dead caterpillars were found. The cocoons were kept over the winter in suitable conditions indoors. On April 21 three females issued, and by May 8 fourteen other adults—all female. In five other similar experiments with virgin females, eggs were freely laid and caterpillars hatched. One experiment gave no result. Dissection of the female adults showed ovaries with eighteen tubes to each, and at the moment of dissection 180 eggs. From cocoons collected in the open many parasites were also bred, *Mesoleius aulicus* being abundant. Dissection of *M. aulicus* females showed twenty tubes to each ovary, and at the moment of dissection 160 eggs. Out of 249 cocoons 171 of *Nematus ericksoni* issued, 62 Ichneumonid parasites, and 16 Tachinids of the species *Exorista*.—Prof. W. **Peddie**: The molecular theory of magnetism in solids. The theory was developed so as to apply to a single homogeneous arrangement of molecular magnets in any crystalline grouping. The results in the special cases of cubic and hexagonal arrangements were applied to the magnetic crystals magnetite and pyrrhotine. A possible application to the case of the earth's magnetism was also discussed.—G. P. **Seamon**: Note on torsional oscillations of magnesium wire. These experiments were a continuation of Peddie's own experiments on torsional oscillations, and gave similar results to those obtained with other kinds of metals.

PARIS.

Academy of Sciences, February 26.—M. Lippmann in the chair.—Maurice **Hamy**: The determination of the astronomical flexion of meridian circles.—A. **Hallrer**: The preparation of 1 : 5-diphenyl-2 : 2 :4 : 4-tetramethyl-3-pentanone and 1-phenyl-2 : 2 : 4 : 4-tetramethyl-3-pentanone. The method of alkylating with sodium amide and methyl iodide has been applied to symmetrical dibenzylacetone and 1-phenyl-3-pentanone. The successive methylation of these two ketones has given the desired tetramethyl derivatives as the final products.—A. **Laveran**: Generalised infection of mice by *Leishmania donovani*. It has been shown experimentally that generalised infections can be caused in mice by *L. donovani*, and it is probably the same for the rat. It still remains to be proved if the small rodents can contribute to the propagation of the disease.—Paul **Sabatier** and A. **Mailhe**: A new method of catalytic preparation of the aldehydes, starting from the acids.—Pierre Puiseux was elected a member of the section of astronomy in the place of the late M. Radau.—Milan **Stefanik**: Observation of the total eclipse of the sun (April 28, 1911) at the island of Vavau.—Ch. **Maurain** and A. **Toussaint**: Study of the surfaces of aëroplanes with an electric carriage. The only accurate measurements made up to the present on the action of air on aëroplane surfaces have been carried out on small-scale models exposed to currents of air. The present experiments were carried out on full-sized planes, carried on an electrically driven carriage with a range of velocities up to 23 metres per second. A set of experimental results for two surfaces of different shapes is given.—M. **Guéritot**: An attempt at a method permitting the deduction of the ratio of the two specific heats of gases from a volume measurement.—G. **Charpy** and S. **Bonnerot**: The permeability of iron for hydrogen. That iron is permeable to hydrogen has been known since the researches of Saint Claire Deville and Troost, but no quantitative measurements have been made. The authors have measured the rate of passage of hydrogen through iron at temperatures ranging between 350° C. and 850° C.—P. **Langevin**: The comparison of gaseous and dissolved molecules. A reply to the criticism of M. Colson on the laws of dissociation of nitrogen peroxide in the gaseous state and in chloroform solution. It is shown that in concentrations sufficiently dilute, that is, in concentrations directly comparable with those in the gaseous conditions, the dissociation constant of nitrogen peroxide in chloroform solution is in good agreement with the law of mass action, allowance being made for the known difficulty in the colorimetric measurements.—Georges **Dupont**: The oxyhydrofuranes. The ketohydrofuranes give the oxyhydrofuranes by reduction with sodium and alcohol, although the reaction fails in some cases. The reduction could not be effected with zinc and potash or ammonia, with sodium amalgam or with hydrogen and platinum black.—C. **Picado**: The nutrition of the epiphytic Bromeliaceæ. These plants absorb not only mineral salts, but also proteid substances arising from the digestion of the vegetable and animal detritus retained in their leaves. They are the only plants which feed regularly on such detritus.—E. **Pinoy**: The preservation of wood. The wood is covered with a solution containing 5 per cent. of gelatin, 2 per cent. of potassium bichromate, and 0·5 per cent. of sodium fluoride, and exposed to light. Wood treated in this fashion is rendered completely indestructible by moulds.—Gabriel **Bertrand**: The extraordinary sensibility of *Aspergillus niger* towards manganese.—F. **d'Herelle**: The propagation in the Argentine Republic of the Mexican locust disease. Cultures of *Cocobacillus acridiorum* were used with great success to destroy the plague of locusts in the province of Santa-Fé, and the Argentine Government has decided to make use of this in all places attacked by these insects.

BOOKS RECEIVED.

Bad Reichenhall als klimatischer Kurort. By Drs. B. Alexander and E. Alt. Pp. 64+iv tables. (München: Otto Gmelin.)

Grundlinien der Pflanzen-morphologie im Lichte der Palaeontologie. By Prof. H. Potonié. Zweite Auflage. Pp. vii+259. (Jena: G. Fischer.) 7 marks.

Markose. By Prof. Max Verworn. Pp. iii+37. (Jena: G. Fischer.) 1 mark.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 2212, Vol. 89] THURSDAY, MARCH 21, 1912 [PRICE SIXPENCE

Registered as a Newspaper at the General Post Office.]

THURSDAY, MARCH 21, 1912.

AN ENGLISH PHYSIOLOGIST.

Sir John Burdon-Sanderson: a Memoir by the late Lady Burdon-Sanderson. Completed and edited by his Nephew and Niece. With a selection from his papers and addresses. Pp. 315. (Oxford: Clarendon Press, 1911.) Price 10s. 6d. net.

SIR JOHN BURDON-SANDERSON belonged to that golden age of natural science, the second half of the nineteenth century. Born at the close of the year 1828 he was privileged to share in, and gifted to profit by, the wealth of discovery and conception which enriched biological knowledge from 1850 to 1880. There are many notable names in this period, Bernard, Helmholtz, Ludwig, du Bois-Reymond, Darwin, Huxley, Hooker, Pasteur, and Lister; and among these Burdon-Sanderson takes an honoured place; it is therefore fitting that some record should exist of his life and work. In his speech at Edinburgh Pasteur, in 1884, recalled with enthusiasm Robert Flint's exhortation to "remember the past and look to the future," and impressed on the students whom he was addressing the advice to "associate the cult for great men and great things with every thought." The present memoir, begun by the late Lady Burdon-Sanderson, and completed by Dr. J. S. Haldane and Miss Haldane, is a laudable effort towards the fostering of this cult. It deals with one who was intimately associated with the rise of modern English physiology, and is justly regarded as the founder of scientific pathology in this country.

In physiology Sanderson was not only an exact investigator, but the upholder of sound experimental methods; indeed, he extended these to the teaching of the subject, thus changing the character of such teaching from the didactic to the experimental type. In pathology his influence was still more potent, as he was the first to undertake for sanitary purposes the carrying out of pathological investigations along strictly scientific lines and by rigorously exact methods; it is not too much to say that the great developments of pathological and sanitary science which have taken place in England were started by his investigations and his influence.

All this is set forth in the memoir, which must therefore be of special interest to the scientific reader. In the early chapters a pleasant and graphic account is given of Sanderson's youth, education, and early scientific training. This part was written by Lady Burdon-Sanderson, and is full of interest; it is simply set forth, but as it was evidently a labour of love it gains in force by its very simplicity, particularly when, as frequently happens, vivid touches reveal some striking traits of Sanderson's personality. If the test of effective biography be its power to create in the mind of the reader a picture of the kind of man who forms the subject of the biographer, then, as far as they go, these early chapters will endure this test. Nor is such presentation unimportant, for, like many notable men, Sanderson was pre-eminently a personality It was his impressive character which gave him such influence over others, and which, when taken in connection with his gifts and scientific achievements, became almost overwhelming. He was one of the world's gifted sons, but in addition he was essentially a sympathetic intellectual. This was realised not only from his speech and manner, but from his face and form, so that the value of his approval or criticism was greatly enhanced through his personality and bearing.

The chapters which, as mentioned above, describe his family circle and his development bring before the reader this personality, and the necessity for a rational basis of conception, combined with the display of sympathetic toleration and interest, is here displayed as the keystone of his temperament.

The later chapters which describe his scientific career in London, and later in Oxford, are not so happy as regards their setting. The narrative is somewhat broken up through the introduction of written statements and extracts from obituary notices, so that the effect of the whole is impaired. The quotations from the numerous documents sent to Lady Burdon-Sanderson for the purpose of the memoir, deal in some cases with similar aspects of Sanderson's life and work, and in this way there is considerable overlapping, with its resulting diminution of interest. No doubt it was a task of some difficulty to piece together the fragments left by Lady Burdon-Sanderson and, in doing so, to mould the whole into a continuous and effective narrative. It is to be feared, therefore, that Sanderson's scientific achievements, extending as they do over a rather large biological field, will be scarcely appreciated by many readers. The importance of his discoveries in electrobiology, of his modifications in physiological teaching, of his epoch-making reports to the Privy Council on tuberculosis and allied subjects, and of his work at Oxford as the real founder of her medical school, is not so manifest as it might have been owing to the arrangement of this part of the memoir. But the account is in itself fairly complete, and it is emphasised by appending to the memoir a selected number of addresses given by Sanderson on various occasions. These add to the value of the whole book, since they afford a ready means of appreciating Burdon-Sanderson's intellectual point of view in relation to biological problems.

The last chapter of the memoir gains in interest because it is devoted to the consideration of his personal characteristics and opinions. Such consideration is the salt of most biographical writings, and derives the chief part of its piquancy from the necessary introduction of the biographer's own view as to the nature of the opinions held by the subject of his account. It need scarcely be said that the essence of the piquant interest is the circumstance that the biographer now treads on ground which is open to criticism.

The present memoir offers, in its last chapter, a fair mark for comment when it implies that Burdon-Sanderson came to regard biological phenomena from what in these days would be called the "neo-vitalistic" point of view. The writings of a sympathetic intellectual, like Burdon-Sanderson, must of necessity contain statements which might give some colour for this implication, but the memoir brings forward as pertinent to the matter a letter written by Sanderson a year before his death. In this he expresses the view that a biological excitatory process (*i.e.* the condition of tissue activity) is something "organismal," by which he means "involved in organism." It is by no means clear what this connotes, but at least it is clear what in his opinion it does not connote, for he goes on to say that organismal changes, as such, are not measurable, that is, cannot be stated in terms of physics and chemistry. The writers of the memoir infer from this that Sanderson

"had come to the conclusion that physiological processes involve something which is neither physical nor chemical in nature, and which is not a mere mysterious accompaniment of these processes, but which is their essential part" (p. 169).

But in the letter already referred to Sanderson explicitly states that in science "nothing that is not measurable is known"; and it may be confidently asserted that he would never have allowed the scientifically unknowable to be incorporated in the sum of what constitutes physiological or pathological science. An organismal or vitalistic essence may find a place in other realms of knowledge, but not in one which claims to be a branch of science.

Burdon-Sanderson does not appear, therefore, to have departed fundamentally from the view which he expressed so often and so emphatically during his active scientific career and which is acknowledged in the memoir (p. 170). This view bases modern physiology on the introduction of physical and chemical methods of experiment and explanation. Some notes made by him as late as 1903 upon "The Pathway to Reality" (the Gifford lectures of his nephew, the present Viscount Haldane) show that he then still entertained the same opinion, since he wrote that "all discovery in biology is the discovery of the operation, where before concealed, of mechanical and chemical principles" (memoir, p. 168).

Whatever may be the issue as regards the adoption of more vitalistic conceptions in the future, it seems clear that a rational point of view, such as was the mainstay of biological progress in the latter half of the nineteenth century, was one which Burdon-Sanderson deliberately adopted; and it appears that he adhered to it throughout his life.

The memoir contains a curious oversight on the first page as to the year of Sanderson's birth, this being given as 1829 instead of 1828. It is embellished by at least one admirable and hitherto unknown likeness (p. 148), this being printed from a photograph taken by Miss Acland during Sanderson's later life in Oxford.

GEOLOGY OF THE PARIS BASIN.

Géologie du Bassin de Paris. By M. Paul Lemoine. Pp. vi+408. (Paris: A. Hermann et Fils, 1911.) Price 15 francs.

THE author of this work is already known to us as one of the compilers of the geological map of France, as also for his valuable researches on the geology of Madagascar and Morocco. The present volume treats of an area which geologically has, perhaps, been more completely studied than any other part of the world by such eminent authorities as Lamarck, Cuvier, Brongniart, Orbigny, Deshayes, Hébert, Barrois, de Lapparent, G. F. Dollfus, Cossmann, H. Douvillé, and a host of others. Some eight hundred titles of books and papers arranged alphabetically under authors' names form the bibliography, although, we are informed, this is by no means to be regarded as a complete list of the literature.

Preliminary remarks are made on the subjects of stratigraphy, petrography, palæontology, and tectonics. These are followed by a full account of the various deposits extending from Triassic to Quaternary times, due recognition being given to all zonal subdivisions of the rocks, with their index and characteristic fossils, a matter of so much importance especially in the true history of the Mesozoic formations. All such details are well arranged under the numerous localities represented in the Paris Basin.

In the order of description the stratigraphical deposits may be scheduled as follows:—

	Trias	Eocene	Thanétien
	Rhétien		Sparnacien
Jurassic	Hettangien		Yprésien
	Sinemurien		Lutétien
	Charmonthien		Bartonien
	Toarcien		Ludien
	Bajocien	Oligocene	Sannoisien
	Bathonien		Stampien
	Callovien		Chattien
	Oxfordien	Miocene	Aquitanien
	Rauracien-Séquanien		Burdigalien
	Kimeridgien		Helvétien
	Portlandien		Tortonien
Cretaceous	Neocomien		Sarmatien-Pontien
	Valanginien	Pliocene	Plaisancien
	Hauterivien		Astien
	Barrêmien		Sicilien
	Aptien		Quaternaire
	Albien		
	Cenomanien		
	Turonien		
	Sénonien		
	Emschérien		
	Aturien		
	Danien		
	Montien		

The geological nomenclature employed is mostly in accordance with that adopted in the late Prof. A. de Lapparent's last edition of the "Traité de Géologie," although among the Tertiary subdivisions we note the introduction of the new term "Chattien" for the inclusion of the *Calcaire d'Étampes* and the *Meulières de Montmorency*, beds which are regarded as forming the youngest of the Oligocene series and which were previously recognised by authors as belonging to the lowest Aquitanian rocks of the Miocene period. This is an adaptation of Fuchs' "Chattischen-Stufe," established for the Oligocene Sands of Cassel in North Germany, in which also was comprised the Ormoy beds of the Paris Basin. Subsequently M. G. F. Dollfus founded the name "Casselien" for the same horizon, but afterwards altered it to "Kasselien." On account of priority, therefore, we gladly support M. Lemoine in his recognition of "Chattien."

Students will appreciate the nine well-executed coloured geological maps that accompany this volume, as well as the numerous smaller maps and sections, showing considerable detail, which are inserted as text figures. The first of the coloured maps gives a general idea of the limits of the formations; a second is illustrative of the tectonic lines of the region; another depicts the areas where the lower Jurassic rocks are developed; a further map shows the marginal lines of the Sequanian, Portlandian, and Neocomian beds; in a fifth we have displayed the depth and altitudes of the Albian deposits; the next three explain the position of the Thanetian, Sparnacian, and Lutetian rocks, the remaining map exhibiting the regions of the Sannoisian and Aquitanian beds. We think that the introduction of some illustrations of characteristic fossils would have been an advantage, and we are likewise of opinion that one analytical index, to include localities, genera, as well as species, names of deposits, and every other item of importance, would have been preferable to the two indices given, which only affect specific names and localities. A properly prepared index is known to be an expensive matter in the publication of a reference work, but its existence is of supreme moment to the student and professor alike, who, without wading through an extensive "Table des Matières," frequently require to make rapid reference into the geology of a district, the distribution of a fossil, particulars of a rock structure, or to some problem of tectonic interest.

The book, however, contains a mine of information; it is excellently printed, the black-typed headings to the paragraphs giving a great clearness to the text, and we strongly commend it to all geologists interested in the structure of this region of France. R. B. N.

WIND CHARTS OF THE ATMOSPHERE.

Charts of the Atmosphere for Aeronauts and Aviators. By A. Lawrence Rotch and A. H. Palmer. Pp. 96+24 charts. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1911.) 8*s.* 6*d.* net.

THIS volume contains twenty-four charts, with accompanying text, dealing mainly with average wind conditions from ground level up to 30,000 feet, at the observatory at Blue Hill, Mass., of which Prof. Rotch is the founder and director, and at St. Louis. The book is intended for the use of airmen, and its aim is "to extend the work on surface winds and ocean currents done by Maury to the regions with which the navigator of an air-craft is concerned." The arrangement of the work, whereby all the charts appear on the right-hand page of an opening, and the corresponding descriptions on the page immediately opposite, is very convenient, and the clearness of the diagrams is enhanced by the absence of printing on their reverse sides, although this involves alternate blank openings like an atlas.

Chart 1 shows heights of clouds, and maximum heights attained by different species of air-craft. In Chart 2 is shown, *inter alia*, the average relation between wind velocity and height up to 30,000 feet at Blue Hill. The velocities in the lower layers were determined by means of kites; in the upper layers by means of theodolite observations of clouds, which took place "almost daily during two years." The curve exhibits an almost constant rate of increase of velocity of about nine miles per hour per 5000 feet, except in the first few thousand feet, where the rate of increase is slightly higher. Chart 3 shows that the maximum velocity in winter is greater than that in summer, the difference increasing considerably with height. In charts 6 to 9 effective use is made of isopleths, or lines that show the variations of a quantity which is dependent upon two others. The simplest example of a diagram of isopleths is probably afforded by an ordinary contour map, showing the dependence of height upon position. In these charts, however, the three quantities represented are all of different dimensions; thus, charts 7 and 8 show how velocity varies with height and season, and with height and time of day, respectively.

In charts 10 to 19 are represented by means of wind-roses the percentage frequency and velocity of winds of all directions at heights ranging from 650 feet (ground level) to 10,000 feet at Blue Hill. The results for 650 feet are deduced from hourly observations made at the observatory; those for greater heights are obtained from 230 kite ascents made during fifteen years, on occasions when the velocity was more than ten and less than seventy miles per hour, this being the condition necessary for kite-flying. The results are similar to those obtained at Lindenberg, near Berlin, by Prof. Assmann, the main features being the ultimate decided preponderance of westerly and north-westerly winds in summer and winter respectively, and the gradual increase of velocity with height for all directions.

Chart 21 correlates the preceding ten charts by indicating how to pass from those drawn for one level to those for the next higher level; it shows how to forecast the average upper winds from a knowledge of the surface wind and the prevailing atmospheric circulation, taken to be either cyclonic or anticyclonic. To the aeronaut and aviator this problem must ever be of great importance.

The next charts give wind-roses for the region of the north-east trade wind, and indicate clearly the existence of the south-west anti-trade. These results are derived from 715 observations of direction and velocity in sixty-seven balloon ascents made during four expeditions by M. Teisserenc de Bort and Prof. Rotch on board the *Otaria*.

The volume concludes with a chart giving two summer airship tracks across the Atlantic; one from Boston to London in the region of prevailing westerly winds, the other from Lisbon to the West Indies through the trade wind area. This chart will be of much interest to aeronauts who wish to emulate the example of Messrs. Wellman and Vaniman.

The facts set out should become familiar to the meteorologist as well as to the airman. To the latter, the charts represent, so to speak, the wind-climate of the region in which his craft move, and they are consequently of importance to him. They will not assist him to forecast the likelihood of dangerous phenomena like line-squalls—for that information he must look elsewhere—but as these exceptional occurrences are comparatively infrequent, the average state of the atmosphere as represented on the charts is also usually a reasonable guide to the conditions to be expected on a particular occasion.

Prof. Rotch was a pioneer in the development of modern methods of upper-air research, and this work will be welcomed by all who are interested in the practical and theoretical problems of the atmosphere.

FIRST AID ON THE FARM.

Veterinary Studies for Agricultural Students. By Prof. M. H. Reynolds. Pp. xix + 290. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1910.) 7*s*. 6*d*. net.

IT is no easy task to write a useful work on elementary veterinary science for laymen, for we venture to say that in no other science does the old proverb apply so obviously, viz., "A little knowledge is dangerous." We must candidly admit, however, that the task has been admirably accomplished by the author of the work under review. That the work should have run into seven editions in seven years speaks for itself.

Roughly speaking, the book is divided into six sections, viz.: Anatomy and Physiology, Pathology, Causes and Prevention of Disease, Infectious Diseases, Non-infectious Diseases, and Obstetrics. The bearing of the earlier sections on the later ones is obvious, for one must of necessity be able to recognise the normal conditions before being able to detect departures from the normal. The author rightly sounds a note of warning against "the blind home-dosing of stock to which farmers and stockmen are very much inclined," and frequently in the course of the book he warns the owners for their own sakes not to attempt treatment of any other than the simpler ailments. On the other hand, where skilled veterinary assistance is not available, the information given in this book may be of very great service. The chapters on disinfection and ventilation are especially good.

It would be a very remarkable book indeed in which no faults could be found, and the criticisms we offer are in the hope that they may be borne in mind when another edition is called for. On page 12 the sesamoid bones are described as being "triangular." Their shape is more correctly "pyramidal." In connection with the description of the stomach of the ruminant, it would be an advantage if it were dealt with a little more fully. At present the description is far too meagre to be of any service. On p. 92 a list of hereditary diseases is given as scheduled by the Minnesota Stallion Law. Navicular disease is not included, although there is ample evidence of its hereditary nature. Laminitis is probably debatable as a hereditary disease, but it might be included in such a list of undesirable points with advantage, for the conformation so commonly associated with it is undoubtedly hereditary. The make-up of chapter xx. seems to us to have got rather mixed, for the two first paragraphs of p. 92 referring to heredity would be more appropriately placed to follow the paragraph on in-and-in breeding on p. 90, instead of being sandwiched between paragraphs referring to air.

The chapter on Actinomycosis is very good indeed, although we should be very sorry to see anybody, farmer or veterinary surgeon, resort to the caustic line of treatment as outlined on p. 149, especially as better results can be obtained by internal medication without producing the same amount of pain and suffering.

The illustrations throughout the book are excellent on the whole, though we fail to see any point in the inclusion of Figs. 74 and 75. In neither case is there anything shown at all diagnostic of milk fever.

We have no hesitation in recommending this book to agricultural students, for it should be of great service to them in the pursuit of their veterinary studies.

THE NATURE OF BONE.

Der Aufbau der Skeletteile in den freien Gliedmassen der Wirbeltiere. Untersuchungen in urodelen Amphibien. Von Prof. H. von Eggeling. Pp. vi+324+4 plates. (Jena: Gustav Fischer, 1911.) Mk. 16.

AT the present time the problems relating to the precise nature and mode of development of osseous tissue are being submitted to a searching scrutiny, and many of the most cherished beliefs of the majority of anatomists concerning the process of evolution and the real structure of bone are being threatened. Great activity is being displayed in investigating such problems as the mode of deposition of the calcium salts in the scleroblastema; the precise relationship of this process of calcification to the cells which in a sense determine it; whether there is any fundamental distinction between enchondral and intramembranous ossification; and whether bone is really the inert, unchanging tissue one is apt to think essential in a skeletal support.

These problems and others of a similar nature are forcing themselves upon the attention of workers in widely separated fields of biological inquiry. Surgeons like Sir William Macewen, as the result of clinical experience, have been led to question the current accounts of the development of bone; radiographers have been amazed to find how rapidly an acutely-inflamed bone reacts to the inflammatory process and becomes transparent to the X-rays; palæontologists have been puzzled to explain why obviously homologous bones in two amniotes may ossify in different ways, being enchondrous in one and intramembranous in another; anatomists find a difficulty in drawing a sharp line of distinction between enchondrous and intramembranous bone in certain parts of the skeleton; and embryologists and bio-chemists meet with many difficulties when they attempt to explain the precise mode of deposition of the calcium salts and the nature of the tissues in which they are laid down in the process of bone-formation.

Most of the work which hitherto has been done with the object of elucidating these and allied problems has been based mainly upon the investigation of the more highly organised and specialised Amniota. But Prof. von Eggeling has wisely selected for his research the simplest and least modified material he could obtain: he has devoted his whole attention to the investigation of certain specific features of the process of ossification in the limb-bones of the Urodele Amphibia, the most primitive vertebrates possessing limb-bones precisely comparable to those of the Amniota.

His results are presented in the form of this large monograph, packed with a mass of detailed information relating to the ossification of the limb-bones in twenty-four species, representing every family of the Urodela.

He gives a long and minute analysis of the voluminous literature relating to the structure and histogenesis of so-called coarse-fibred and fine-fibred bone; and then sets forth his own observations.

The most primitive osseous tissue is a product of the periosteum, but the dental cement and part of the placoid-organs of Selachians are of the same nature. It assumes its distinctive form by reason of the fact that the scleroblasts develop first amidst a coarse-fibred matrix of connective tissue.

At a later stage, both in phylogeny and ontogeny, buds of vascularised tissue eat their way through the sheath of coarse-fibred bone into the cartilaginous core; and in this loose delicate tissue fine-fibred bone becomes laid down in concentric layers, lining the canals which lodge the vascular material. This "marrow-bone" (*Markknochen*) represents the superstructure laid down upon the more ancient coarse-fibred bony foundation, perfecting its structure, and rendering it more efficient as a weight-bearer. The medullary cavity is formed by the anastomosis of the intrusive canals filled with highly vascular tissue, which forms the rudiment of the marrow.

A great deal of precise and suggestive information is given in regard to these and other matters, such as the phylogeny of the Haversian canals and the nature of epiphyseal centres of ossification.

The chief interest of the book lies in the support it gives to the growing conviction of the essential uniformity of the processes of ossification, although perhaps its author might not go so far as to admit this. G. Elliot Smith.

OUR BOOKSHELF.

The Story of the Five Elements. By E. W. Edmunds and J. B. Hoblyn. (The Library of Modern Knowledge.) Pp. viii + 264. (London: Cassell and Co., Ltd., 1911.) Price 2*s.* 6*d.* net.

This book is of a type now becoming more common, an elementary account of science intended for "the intelligent general reader who, having a genuine interest in science, is nevertheless unable to follow up any one branch of it in close detail." To write such a book successfully a sound knowledge of the subject, a gift of attractive exposition, and a good literary style are necessary. These are evinced in a very satisfactory measure by the authors of the work before us. No serious misstatement has been noticed during perusal—nothing more important than the use of "dephlogisticated" for "phlogisticated" on pp. 70 and 89. The exposition is clear, and a fresh turn is given to the story of elementary chemistry by following the track of the ancient "elements." The language is not hackneyed, nor yet aggressively unconventional. A perusal of the book will not make a chemist, but it will give a just idea of chemistry to an intelligent reader; and to an elementary student, in the shackles of a traditional text-book, it will afford a salutary relief, a breath of fresher air. A. S.

An Introduction to Therapeutic Inoculation. By Dr. D. W. Carmalt Jones. Pp. xiv + 171. (London: Macmillan and Co., Ltd., 1911.) Price 3*s.* 6*d.* net.

This book, by one who is a pupil of Sir Almroth Wright and the director of the department of bacterio-therapeutics of a London hospital, may be taken as an authoritative guide to the inoculation method for the treatment of infective diseases. It is divided into two parts, the first dealing with the principles underlying the method, the second with its practical application. Stress is rightly laid on the importance of the exact diagnosis of the nature of an infection by bacteriological methods, and it can scarcely be doubted that in the future exact diagnosis of the condition and the treatment of the infection itself will become more and more laboratory procedures, the function of the clinician being to decide if the disease is an infective one, to aid the recognition of the disease by the use of physical methods of diagnosis, to invoke laboratory methods to assist in the diagnosis, to exercise a general control over the patient, and to treat the general condition of the patient and any complications that may arise.

Full directions are given for the estimation of the opsonic index, which, in spite of adverse criticism, is considered by the author to possess considerable value for diagnosis and treatment, and for the preparation of the vaccines necessary for the inoculation treatment. Finally, the practice of inoculation in the treatment of various infections is fully considered.

R. T. H.

The Babylonian Expedition of the University of Pennsylvania. Series A: Cuneiform Texts. Edited by H. V. Hilprecht. Volume xxix., Part i.: Sumerian Hymns and Prayers to God (*sic!*) Nin-ib from the Temple Library of Nippur. By H. Radau. Pp. x + 88 + 21 plates. (Philadelphia: Department of Archæology, University of Pennsylvania, 1911.)

One of the most interesting peoples of the ancient world was the Sumerian race, which founded the great civilisation of Babylonia. The cuneiform writing of western Asia was their invention, and the religious system of Babylon, which had so great an influence upon the Hebrew cult from which Christianity sprang, was originally theirs. Among the spoils of the American expedition to Nippur, in southern Babylonia, which are now being published under the editorship of Prof. Hilprecht, were a large number of the usual clay tablets inscribed with Sumerian hymns to the god Ninib. These are now translated and described by Herr Hugo Radau. That he has done his work well there can be no question, though we may not agree with all the conclusions he draws from his material. The non-Semitic Sumerian language, entirely different from the tongue of the Semitic Babylonians who borrowed the culture, including the script and religion, of the Sumerians, offers peculiar difficulties to the translator, and others may not always agree with the interpretation which Herr Radau gives to individual words and phrases of his texts; but the general sense of the originals is clear enough. Of the religious tone of these hymns, the best idea is to be derived from a perusal of them. We scarcely agree with the exaggerated estimates which their translator, perhaps pardonably, is often led into with regard to them, and his "macrocosmology" and "microcosmology" seem far-fetched. But of the main facts as expounded by him there is no doubt.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Acquired Characters and Stimuli.

Dr. Archdall Reid is usually so luminous in his statements concerning heredity that I hesitate to express my disagreement with what he has written in Nature of February 29, and elsewhere previously, as to the use of the term "acquired characters." It is, of course, true with regard to this term, as with regard to a great many others, that it can be interpreted to mean what its original user, namely, Lamarck, did *not* mean. But I cannot see that anything is gained by so doing. On the contrary, in such cases it seems to me best to endeavour to keep the term for what its introducer meant by it. I also fail to see any advantage in grouping together the various necessary chemical and physical environments of a living thing under the word "stimuli." They do not become changed in nature by the application to them of that term, which is customarily used with more limited application.

It is, of course, true (and I should suppose thoroughly familiar to every biologist) that the reproductive germ of an organism unfolds or "develops" in response to the action upon it of certain surrounding conditions—its environment. When those conditions are "normal," a normal germ develops in response to them—the normal characters of the species. When the conditions to which the young organism is exposed are in some limited degree and in regard to certain ascertainable factors abnormal, the organism develops (in some cases) one or more abnormal characters differing from those developed by an otherwise equivalent specimen retained in the normal environment. The new character or characters developed in response to the abnormal environment (which we assume to be allowed to act on the growing young organism only, and *not* on its parents) are called by Lamarck—and by those who wish to discuss Lamarck's theory—"acquired characters" (*changements acquis*). The word "acquire" is used to mean "something added to" or "changed in" the normal form of the species.

It is not, I think, permissible to say that the normal characters which arise in response to normal conditions are with equal fitness to be described as "acquired." Of course, *all* the characters successively developed by a growing reproductive germ or young organism *may* be spoken of as "acquired" by the organism during its growth from extreme youth to age. But to do so when discussing Lamarck's theory is deliberately to create confusion. The thing in addition to and upon which "acquirements" are made is, in Lamarck's use of the word "acquire," not the growing individual, but the normal specific form as exhibited in normal individuals. That, I take it, is Lamarck's meaning, and it is that which I and others have for more than twenty-five years accepted. I am sorry to say that to use the word "acquired" at this period of a historical discussion, in another sense, is what an unfriendly critic (which I am not) would call "quibbling," and, moreover, quibbling without any discernible object or purpose.

I should like once more to point out (as I did many years ago in a similar correspondence in these pages) that the measurable factors of the normal environment of a species of plant or animal often exhibit within that normal limit a great range in quantity and intensity. This range differs in different species and groups of organisms, but, as a rule, the normal specific form is developed under conditions which are not very closely limited. A species is usually so "wound up" (to use a metaphor) as to be stable under a wide range of conditions. Outside that range we find first a zone or area of excess or decrease of one or more factors of environment, such as heat, light, moisture, mechanical pressure, chemical character of food, &c., within which the organism still flourishes whilst giving *new* or *abnormal* responses to the *new* and *abnormal* quantities of the environmental factors. These responses are Lamarck's *changements acquis*—our "acquired characters"—characters which are not those of the species when existing in the by no means narrowly limited range of factors which are its normal environment.

Beyond this zone or area of *potential* (or tolerable) environment with its corresponding *potential* development of acquired characters not normal to the species in normal environment, we come to a further zone of larger increase or decrease of environmental factors. Here the organism does not respond as a living thing; it has no reserved potentialities which are called into activity by this further increase or decrease of one or more of the factors of the environment; the environment has become impossible or destructive, and the organism ceases to live.

It is important to distinguish these three zones of limitation in increase or decrease of factors of the environment for every species, the normal, the potential, and the destructive. It is a necessary part of bionomic inquiry to determine the range *plus* and *minus* of the several factors of each quality of environment—normal, potential, and destructive—in regard to whole series of species of both plants and animals.

E. Ray Lankester.

Bournemouth, March 9.

Coordinated Purchase of Periodicals in two Newcastle Libraries.

In 1905 Dr. Thomas Muir read a paper before the Royal Society of Edinburgh entitled "Library Aids to Mathematical Research," in which he urged that unnecessary duplication in the purchase of periodicals should be avoided by adjacent libraries. The matter has been taken up in Nature, *e.g.* in vol. lxxxvii., p. 222. The following brief account of what is being done in this regard in Newcastle-upon-Tyne may therefore be of interest.

In 1908 representatives of several Newcastle institutions met in the Public Library, at the invitation of the public librarian (Mr. Basil Anderton), to consider whether any coordination could be effected as regards the purchase of certain learned societies' journals and some of the more expensive and less used periodicals. Armstrong College was represented by Profs. Bedson and Jessop. Prof. Duff, who had for a considerable time manifested cordial sympathy with the project, was unavoidably absent from the meeting. In the course of discussion various journals were named in regard to which concerted action seemed desirable, but for one reason or another, while the principle was commended, only the representatives of the Public Library and Armstrong College were at the time ready to take practical steps in the matter.

Prof. Jessop moved that a beginning be made with certain mathematical journals, and that of those that were being bought in duplicate (one by each institution) some be discontinued, and that the money so set free be applied to the covering of fresh ground. The suggestion, as modified by discussion and finally moved by Prof. Jessop, was approved, and the public librarian embodied it in a recommendation which he laid before the Public Libraries Committee, which resolved that the Public Library should stop taking in the following:—London Mathematical Society Proceedings; *Journal de Mathématiques*; *Quarterly Journal of Mathematics*; *Fortschritte der Mathematik*; *Mathematische Annalen*; and should take instead: *Annali di Matematica: Tortolini*; *Bulletin de la Société Mathématique de France*; *Atti dei Lincei*; *Zeitschrift für Mathematik: Schlömilch*; *Giornale di Matematiche: Battaglini.*

The Public Library periodicals were to be stored so as to be accessible to Armstrong College readers, duly accredited, for consultation in the library and for use at home. For future volumes of the first set of periodicals, properly accredited Public Library readers were to have similar access to Armstrong College volumes.

A copy of the resolution was sent to the Library Committee of Armstrong College, which likewise adopted it. The curators of Armstrong College Library (Profs. Bedson and Duff) and the public librarian were then in a position to carry the scheme into practical working. They decided the appropriate dates for discontinuing old periodicals and for starting new ones; they arranged that the students of each library should be admitted to corresponding privileges in the other library; and they drafted and printed the necessary regulations and forms.

As the scheme was found to work satisfactorily for the mathematical section, the committees concerned authorised extension of the idea. The officers accordingly made further revisions in other subjects, at meetings which they held from time to time. The classical section was first dealt with, and the responsibility of providing the leading periodicals was allocated to one institution or the other. Other sections were dealt with in due course. In this way all the more important journals taken by the two institutions (scientific, historical, philosophical) have been assigned to one or other of the libraries, with the result that unnecessary duplication of expenditure is now avoided. Naturally, a certain amount of duplication is still necessary, since a single copy will not always answer the needs of students. But the general result is that a good deal of money has been set free, and has been used for covering fresh ground.

The same principle has also, to some extent, been adopted as regards buying expensive books, of which one copy in the town is sufficient. It may be added that, as a side issue of this cooperation, there will shortly appear, in a catalogue which the Public Library is issuing, the titles of a number of interesting books on classical subjects which the library of Armstrong College possesses, but which are not duplicated in the Public Library.

Basil Anderton.

Public Library, Newcastle-upon-Tyne.

Mars and a Lunar Atmosphere.

In his interesting letter on the above subject in Nature of March 7, Mr. Whitmell is quite correct where he mentions that the moon was at full on October 16, 1902, when, according to my note, Prof. Luther observed an occultation of Mars. In fact, there was a total eclipse that night, and that was the phenomenon which Prof. Luther actually observed.

The abridgment of a previously condensed translation led to the substitution of the misleading "similar," and I must apologise to Mr. Whitmell for the trouble this may have caused him in looking the matter up. Prof. Luther on that occasion observed a section of a dark concentric ring bordering the small crescent of the nearly totally eclipsed moon, and this he suggested might be caused by the absorption of a fairly extensive atmosphere.

The Writer of the Note.

Observed Fall of an Aërolite near St. Albans.

Under the above heading in the issue of Nature for last week I reported upon the circumstances and other details of a supposed fall of a meteorite during the storm of March 4, as described to me by an observer, Mr. H. L. G. Andrews, at Colney Heath, near St. Albans. I have now submitted the stone for examination to Dr. George T. Prior, of the British Museum (Natural History), who informs me that it is not of meteoric origin.

G. E. Bullen.

Hertfordshire Museum, St. Albans, March 16.

THE INFLUENCE OF WEATHER ON BEES.

Although all who are interested in bees, either from the scientific or the commercial and practical sides, are agreed that the weather plays a most important part in their lives, very little appears to have been done to ascertain the exact effects which different kinds of weather have upon them. The reason may well be that those who are interested in bees from a practical point of view would not be able to devote the time necessary to the making of elaborate observations of the weather and the weighing of colonies daily, to say nothing of the laborious calculation necessary to ascertain the results of the observations.

In the autumn of 1910, the so-called Isle of Wight disease was raging very fiercely in the southern counties, and to account for the widespread character of the scourge, many beekeepers advanced the idea that a succession of bad seasons was responsible to a great extent, if not entirely, for the trouble.

It seemed to me that the proper course to pursue was to make a long series of observations in order to find out what particular kinds of weather were most conducive to the well-being of bees or the reverse. I therefore commenced, in April of 1911, a series of experiments. Commencing with a strong colony, which weighed with its hive 39 lb. on April 20, I began to weigh it every evening, and on May 5, for the sake of comparison, I also weighed a weak colony. This only weighed with its hive 36½ lb., the other being on that date 8 lb. heavier. The bees were hybrids, an excellent and good-tempered variety, eminently suitable for experiments, though not the best of honey gatherers.

The queens of both colonies were sisters, that of the strong one having been raised in 1909, and that of the weak one in 1910. It is pretty universally agreed among beekeepers that a queen in her second year is at her best, and according to this idea, which is quite sound, the weaker colony should have done better than the other, but there is a factor in the situation which is really more important than the age of the queen. This is the amount of stores possessed by the colony at the commencement of the season. Should there be a shortage of stores, breeding is much slower;

and although, by artificially feeding the weaker colony for the first week or so, I might have made good the deficiency, I wished the experiments to represent as far as possible the natural increase of the bees. To this may be attributed the comparatively poor results achieved in a good season.

My apiary is situated about 300 ft. above sea-level, and stands in a sheltered, sunny position. The main honey-producing plants are, in April, the sallows and the bush fruits, currants and gooseberries. Then follow, in this case during the first ten days in May, pears, plums, cherries. After this the apples (both cultivated and wild) produced a plentiful supply of nectar, and these, accompanied by the holly, sycamore, and horse chestnut, lasted till nearly the end of the month. The maple, which in some districts is a valuable aid to brood rearing, is scarce near me.

Down to May 20 the weather had been of a somewhat varied character, the sky being frequently overcast and seldom clear, the winds mainly from the south-west, and light to fresh in force. The temperature, however, was above the mean, the minima being exceptionally high for the period. On the evening of the 21st the strong colony was 17 lb. heavier, and the weak one only 4 lb.

On the 22nd the temperature rose considerably and the sky was clearer; in the ten days ending May 31 the strong colony gained 16 lb., and the weak one 4 lb. The hawthorn came into bloom soon after the middle of the month, and provided a very heavy crop of pure honey of delicious flavour and density. This hawthorn honey-flow continued during the first ten days of June, and during that period there was a gain of 8 lb. in the strong hive and 3 lb. in the weak one.

By this time the strawberries were in bloom, and the main honey flow seemed to be close at hand. The blackberries, which are a great honey source in this neighbourhood, began about the 5th of the month, and the white clover, from which the main crop is usually gathered, on the 8th. Notwithstanding this, the remainder of the month was of an exceedingly disappointing character, owing to the prevalence of high winds, low temperatures, and largely overcast skies. On June 30 the colonies weighed 82 lb. and 47 lb. respectively, being a gain during the twenty days of 2 lb. and $\frac{1}{2}$ lb. only.

No sooner did July open, however, than the weather improved, the wind blowing lightly from the north-east, the sky clear, and high temperatures prevailing. Honey came in at a great rate down to the 22nd of the month, when the flowers dried up completely on account of the drought. During this period nearly all the surplus was procured from the white clover; the limes, which were certainly blooming freely, seeming to have little attraction for the bees, and the blackberries producing only a small portion of the surplus.

In the twenty-two days the strong colony gained 32 lb. and the weak one 25 lb.

Before passing on to state the conclusions I arrived at after tabulating all the results, I may point out how marked is the difference between the colony having large stores to commence the season with and one that is deficient in that respect. As will be seen, the weak colony did practically nothing during the May honey flow, owing to its being so much behind in breeding; but when the queen, having plenty of supplies, began to push the breeding, the colony pulled up nearly level, and had there been any heather here it is most probable she would have outstripped her older sister. This is a lesson the practical beekeeper may well take to heart. A few pence spent on sugar in the autumn will be amply repaid by an early crop of honey the following season.

The next striking thing is the suddenness with which a flow of honey commences and leaves off. In the May flow, for instance, after three days when there was an actual loss of weight, and one where there was only a gain of $\frac{1}{2}$ lb., the next day showed a gain of 3 lb., which continued more or less for several days. Again, on July 2, the gain was $\frac{1}{4}$ lb., but on the 3rd $2\frac{1}{4}$ lb., followed by $3\frac{1}{4}$ lb., $4\frac{1}{2}$ lb., $2\frac{1}{2}$ lb., $3\frac{1}{2}$ lb., $3\frac{1}{2}$ lb., 2 lb., 2 lb. This offers another useful lesson to the beekeeper. A day's delay in putting on surplus chambers may result in the bees swarming; for once they commence preparations, which they do as soon as they find their quarters getting cramped, no device will stop them, and they will refuse to enter the supers. If the extra room is provided in good time, they take to it readily and work steadily on.

It is impossible in the space of this short article to give the details of the observations made. All that can be done is to state as briefly as possible what conclusions are to be drawn from an analysis of them.

The total gain of the strong colony, which I will call No. 1, was 76 lb., which is an average of 0·791 lb. per day. The weak stock (No. 2) gained $36\frac{1}{4}$ lb., or an average of 0·447 lb. per day.

The range of pressure over the whole period was very small, the barometer being universally high, but I have divided the readings into three equal parts, high, medium, and low. On the twenty-eight days when the mercury was high the gains averaged for No. 1, 1·402 lb.; No. 2, 0·936 lb. On the thirty-one medium days, No. 1 averaged 0·710 lb., and No. 2 0·218 lb. On the days of comparatively low pressure, No. 1 averaged 0·203 lb., and No. 2 0·125 lb.

Here we have conclusive evidence that a high barometer is favourable. Especially is this the case with the weak stock, for it does very badly under any except the best conditions.

With regard to temperature, I have divided the maxima also into three sections, those under 65° F., those between 66° and 75°, and those above 75°. As may be expected, with the high readings come good results, the average being 1·182 lb. for No. 1, and 0·743 lb. for No. 2. With a medium day temperature, No. 1 averaged 0·723 lb., and No. 2 0·213 lb. Under low temperature I find the results extremely poor, the average of twenty-three days being 0·108 lb. for No. 1, and an actual loss of 0·068 lb. for No. 2.

No doubt the extremely bad effect of low day temperature on a weak colony is occasioned by the necessity on such days for the bulk of the population to stay at home and keep up the temperature, or, alternatively, the loss of brood by chilling.

Of course, the influence of the weather is felt in two distinct ways. There is the effect on the bees themselves, regulating the numbers that are able to leave the hive, and also the influence on the flowers, occasioning a variation in the amount of nectar secreted.

It is generally held that warm, moist nights are favourable to the secretion of nectar, but although my results show that more honey was secured when the previous night's temperature was high, yet when we remember that the extremely low temperatures occurred when there were few flowers in bloom, the evidence is not sufficient to enable us definitely to state that warm nights induce a flow of nectar.

There is much less disparity in the results under this head than with any other elements, the results being for temperatures under 50°, 0·542 lb. and 0·147 lb.; for those from 50° to 57°, 0·716 lb. and 0·343 lb.; and for those above 57°, 1·150 lb. and 0·775 lb.

Some time ago an undoubted authority on beekeeping gave it as his opinion that there was very rarely a flow of honey during the prevalence of an east wind. In order to gain some evidence on this head, I divided the tables of the direction of the wind into two parts, the first showing easterly winds, including all winds blowing from the north to south-south-east, the other including all winds blowing from the south to north-north-west. The result shows a decided advantage in favour of the easterly winds, the returns being 50 per cent. more in the case of the strong stock, and 25 per cent. in that of the weak one. It is not difficult to find the reason for this, for when the wind is in the west or south-west, other conditions are unfavourable, they being generally accompanied by cloudy skies and showery weather. On the other hand, the highest average of gains occurs when the wind is due north-east, such winds bringing dry, cloudless weather in most cases.

Of more importance is the strength of the wind. The average results when the wind was light or moderate in force were in both cases more than four times better than when the wind was blowing freshly.

In this case the strong stock suffered more than the weak one, the only instance where the weak stock proved superior. From this I conclude that the strong stock, being able to send out a larger proportion of foragers, suffered proportionately heavier losses of bees. The slightest difference in the time taken by an individual bee to return to its hive must have a great effect when we consider the thousands of journeys made in a day. Moreover, the more slowly the insects fly, the more liable are they to fall a prey to predatory birds. Many are no doubt blown to the ground by gusts of wind and become chilled before they have recovered strength to rise again. It is also certain that some, foraging on the extreme edge of the usual mile radius, are blown out of their course into regions unknown to them, and are unable to find their way back again. I am of opinion that on days when the wind blows strongly the hive entrances should be shaded, so as to tempt the bees out as little as possible, unless the hives are so situated that the bees have their foraging ground immediately around them, such as on a moor or in a clover field. If they have to fly high or travel far for their supplies, the gain of honey, if any, will be more than counterbalanced by a great loss of bees.

By far the most important element in the weather is the degree of sunshine. Warmth, dryness, stillness are all favourable to the increase of the colonies, but without bright sunshine the best results cannot be secured.

During the whole period there were fourteen days on which the sky was completely overcast, and the average for those days showed a net loss of 0·053 lb. in the strong colony, and 0·146 lb. in the weak one; whereas the average gain when at least a part of the day was quite clear was more than $1\frac{1}{4}$ lb. in No. 1, and a trifle under 1 lb. in No. 2. There were twenty-four days when the sky was intermittently overcast, and in both cases the average is below the mean of the whole period. The reason for this is that bees in the open fields when the sun is shining hurry home as soon as a cloud comes up. Sometimes, in the height of the honey flow, a cloud passing over the sun will bring them home at such a rate that on one or two such occasions I have gone out, thinking they were swarming.

I am a great advocate of placing hives where they will get the maximum sunshine, and I never allow any permanent shade near them, believing that every gleam of sunshine is gain to the hives. If it happens that the weather is cold in the early spring, or a strong wind blowing, it is easy to prop a board over the entrance to keep them in, but it is not so easy to take away a permanent sun-excluder on favourable days.

The tables showing the gains under varying degrees of humidity do not reveal any preponderance in favour of either a high or low rate of moisture. As I mentioned before, some believe that warm, moist nights are favourable to the secretion of nectar, and I hope in the course of the experiments I make in the coming season to be able to gain some definite knowledge regarding this.

The rainfall over the whole period was so small that it gives but little information, but in every case where rain fell during the previous night or on the day in question, there was either a loss or at best a very small gain.

To sum up, the facts which I consider established are:—

First, that sunshine is of the utmost importance, and every beekeeper should see that his hives get the maximum of it. This is obtained by placing the hives quite in the open, with the entrances facing south-east. They thus secure the earliest rays of light, and the bees are tempted to start work early.

Secondly, high winds cause great loss among the colonies, and it would be advisable when such prevail to keep the bees confined to the hives, unless there are sources for honey-gathering in the immediate vicinity. Unless the supers are on, the bees should on such occasions be fed artificially, so that the work of brood-rearing may not be hindered.

Thirdly, during a honey flow in the early part of the season weak colonies must have all the heat possible conserved by contraction of the brood-chamber and heavy top coverings, so that the largest number of foragers may be released.

Fourthly, as soon as the brood combs are well covered with bees, and the weather fine, the supers should be put on and covered up warmly. A day's delay at the crucial moment may ruin the prospects of a colony for the season, causing swarming and waste of time during the honey flow.

And, finally, the difference between the results secured by these two colonies shows that it is of very great importance that stocks go into winter quarters with abundance of stores, so that the earliest spell of fine weather may be utilised by the queen for pushing the breeding. The honey flow from the fruit and forest trees may be made a considerable source of revenue if colonies are got into strong condition in time to take full advantage of it.

Herbert Mace.

THE VIVISECTION REPORT.

The Royal Commission on Vivisection published, on February 12, its long-delayed report. Four years have elapsed since the Commissioners ceased to hear evidence: and we are left to guess at the causes of this delay. The report is already out of date: it says not a word about the work of Flexner, the work of Ehrlich, the work of Bruce, since 1908; it says nothing of the latest results of the preventive treatment against rabies and typhoid fever, nor of the latest diphtheria statistics from the hospitals of the Metropolitan Asylums Board.

Still, we can afford to forgive these defects: for the report, happily, is unanimous. There is no minority report. Two of the Commissioners died in the course of the inquiry; the remaining eight all sign the report. Three of them sign it subject to certain reservations, contained in memoranda; but these reservations leave untouched the main outlines of the report. The changes recommended by the Commission are of no profound importance to science, and are all of them within the province of the Home Office. There is none of them that requires the intervention of Parliament; and it is certain that Parliament has graver matters to think of than the exact estimate of experimental physiology and pathology.

The report is rather colourless: that is the price of unanimity. It deals with certain anti-vivisection statements politely, but there is a politeness which is not to be mistaken for approval. It reviews, quietly, what we all know already—the mighty deeds of the last thirty years, the development of Pasteur's principles, the work of Lister, the magnificent warfare against tropical diseases, and so forth. It devotes attention to the benefits gained by animals from experiments on animals; and to the public recognition of the value of such experiments. It recommends a slight increase of the Inspectorate, a further restriction of experiments under Certificate B, a special restriction of experiments involving the use of curare, that drug so much talked of and so seldom seen, and so forth. It contains some good passages: for instance:—

"We desire to state that the harrowing descriptions and illustrations of operations inflicted on animals, which are fully circulated by post, advertisement, or otherwise, are in many cases calculated to mislead the public, so far as they suggest that the animals in question were not under an anæsthetic. To represent that animals subjected to experiments in this country are wantonly tortured would, in our opinion, be absolutely false."

And again, of certain anti-vivisection witnesses:—

"After careful consideration of the above cases, we have come to the conclusion that the witnesses have either misapprehended or inaccurately described the facts of the experiments."

Thus, in spite of its colourless, dull style, the report is fairly satisfactory to men of science, and to the public. It comes at a time when the public is concerned with heavy national trouble and peril; and we believe that the public will be glad to leave the whole subject to the experts and to the Home Office.

NOTES.

It is officially announced that the King has appointed Sir J. J. Thomson to the Order of Merit. Other men of science who are members of the Order are Lord Rayleigh, Dr. Alfred Russel Wallace, and Sir William Crookes.

We understand that a portrait bust of the late Sir Joseph Hooker, from a sitting taken just before his death, has now been completed by Mr. Pennachine, the sculptor. A few visitors at Mr. Pennachine's studio, 68 Western Road, Ealing, W., consider it an excellent piece of work.

Dr. Charcot has been awarded the gold medal of the Paris Geographical Society, in recognition of his work of exploration in south polar regions.

At the anniversary meeting of the Royal Irish Academy on March 16, Prof. Jean Gaston Darboux and Prof. Elias Metchnikoff were elected honorary members of the academy in the section of science.

It is announced that the twentieth "James Forrest" lecture will be delivered at the Institution of Civil Engineers on Friday, April 19, by Mr. H. R.

Arnulph Mallock, F.R.S., his subject being "Aërial Flight."

Dr. Ales Hrdlicka, curator of physical anthropology, United States National Museum, has been appointed as the representative of the Smithsonian Institution at the eighteenth International Congress of Americanists, which will meet in London on May 27 to June 1. He has also been designated by the State Department as a representative of the United States on this occasion.

The eleventh general meeting of the Association of Economic Biologists will be held at Dublin on March 28–29, under the presidency of Prof. G. H. Carpenter. Among the subjects of papers to be read and discussed are:—biological training for agricultural students; parthenogenesis; methods of testing grass seeds; the culture of *Phytophthora infestans* (the potato-blight fungus); the food of birds; the pollination of hardy plants; and cereal breeding.

We are informed that the collection obtained by Mr. Edmund Heller, who represented the Smithsonian Institution on Mr. Paul J. Rainey's African expedition, will rival that made by the Smithsonian African expedition in 1909 and 1910. In all there are about 700 large mammal skins in salt, 4000 small mammal skins, and a large number of birds and reptiles, most of them coming from regions not visited by the previous expedition, while some are from remote localities never before visited by naturalists.

From a report in *The Times* we learn that at a meeting of the Council of the Royal College of Surgeons on March 14, Sir Henry Morris, in the course of an eloquent tribute to Lord Lister, said:—"His gentle nature, his deep compassion, his courteous and dignified bearing, his imperturbable temper, his resolute will, his indifference to ridicule, his tolerance of hostile criticism combined to make him one of the noblest of men. His work will last for all time; its good results will continue throughout all ages; humanity will bless him for evermore; his fame will be immortal." The council unanimously decided that this tribute should be inscribed upon a tablet and placed in a suitable position within the walls of the college, "to serve as evidence to future generations of the honour, respect, and reverence in which the great founder of aseptic surgery was held by his contemporaries and immediate successors."

The experiments about to be undertaken by the Board of Agriculture and Fisheries in the breeding of horses on Mendelian lines will be watched with great interest. Impressed with the results of breeding on such lines in the case of the smaller domesticated animals, Captain Dealtry C. Part has given to the Board a large sum of money for carrying on similar experiments with horses. The direction of these experiments has been entrusted to Major C. C. Hurst, director of the Burbage Experiment Station, who will have the advice and assistance of Mr. F. W. Carter, superintending inspector of the Board of Agriculture. It has been decided that the best type of light horse for general purposes is the weight-carrying hunter, while the best foundation stock for crossing is the thoroughbred, and it is proposed to try to produce from the latter a distinct breed possessing the qualities of the former. The foundations for such a type already exist in weight-carrying steeplechasers, which have been found to breed true. Mares suitable for the purpose of the experiment have been selected, but there is some difficulty in regard to stallions; with those at present available, about one-half of the progeny is expected to be of the stamp required.

Reference has already been made in the public Press to the publication in the Government *Gazette* of a Bill by the Minister of Commerce of the Union of South Africa for the reform of the weights and measures of that Union. The Decimal Association has now received a copy of the Bill, and states that it represents a great advance towards the complete introduction of the metric system. The standard units of each table of weight and measure as shown in the second schedule of the Bill are those of the metric system alone, but the use of the imperial measures, with certain modifications, is permitted. The only Cape measures allowed are the rood of 12 Cape feet, their squares, and the morgen. The hundredweight is eliminated, and the cental of 100 lb. substituted; the ton is to be 2000 lb., and the carat is fixed at 205·304 mg. Section 12, subsection 3, provides that no person shall sell drugs and medicines retail by weight or measure except by measures of the metric system. It is not yet known whether the Bill has been introduced, but little, if any, opposition is expected to it, as the reform has been well discussed in the Union and the chambers of commerce have been consulted.

The following are among the subjects of lectures to be given at the Royal Institution after Easter:—Mr. F. Balfour Browne, "Insect Distribution, with Special Reference to the British Islands"; Prof. W. Bateson, "The Study of Genetics"; Prof. W. M. Flinders Petrie, "The Formation of the Alphabet"; Prof. A. W. Crossley, "Synthetic Ammonia and Nitric Acid from the Atmosphere"; Prof. J. Norman Collie, "Recent Explorations in the Canadian Rocky Mountains"; Prof. H. T. Barnes, "The Physical and Economic Aspects of Ice Formation in Canada" (the Tyndall lectures); Prof. J. H. Poynting, "The Pressure of Waves"; Mr. Willis L. Moore, chief of the U.S. Weather Bureau, "The Development and Utilities of Meteorological Science." The Friday evening meetings will be resumed on April 19, when Mr. Alan A. Campbell-Swinton will deliver a discourse on "Electricity Supply: Past, Present, and Future." Succeeding discourses will probably be given by Sir George H. Darwin, Mr. W. C. Dampier Whetham, Prof. W. Stirling, Mr. W. Duddell, Prof. Howard T. Barnes, Sir William Macewen, and other gentlemen.

We are glad to notice that efforts are being made to form an Indian Association for the Advancement of Science, the primary object of which is to afford a medium of communication between workers in different parts of India. It is proposed to hold an annual meeting (sectional or otherwise) in the more populous Indian towns where papers may be read and discussed, the proceedings to be published in the form of an annual report. Details are to be arranged at an early meeting in Calcutta. In a circular asking for cooperation and support for the proposal, Profs. P. S. MacMahon (Lucknow) and J. L. Simonsen (Madras) remark: "We realise that the future of science in India depends upon the adequacy of the practical training which students receive in college laboratories, and, furthermore, that nothing is better calculated to increase its efficiency than the inculcation of research as the ultimate purpose of all scientific knowledge. It is unnecessary to point out how many and varied are the problems awaiting solution and how intimately the social and economic future of India is bound up with the successful application of scientific methods to all the activities, whether agrarian or industrial, of the community. We cordially invite the participation of Indian men of science, convinced in the belief that in such measure as it is accorded the objects of the society shall more nearly approach fulfilment and its usefulness and permanence be assured."

To *The Museums Journal* for March, Dr. Ernst Hartert communicates an illustrated account of the additions and alterations to Mr. Rothschild's museum at Tring.

Witherby's *British Birds* for March contains an account of the life and writings of Thomas Muffett, an English physician and ornithologist, who died in 1604, by Mr. W. H. Mullens, who originally contributed it to the publications of the Hastings and St. Leonards Natural History Society. Muffett's chief ornithological work, "Health's Improvement," which treats primarily of food, is ascribed to the year 1595, but is known by a posthumous edition published in 1655. The author was acquainted with more than one hundred kinds of British birds.

In his report for 1911, Captain Stanley Flower states that in October of that year the menagerie at Giza and the aquarium at Gezira contained 1761 specimens, representing 401 different forms of animals, this being the largest stock hitherto maintained at any one time. It is stated that the widely distributed tropical aquatic aroid plant, *Pistia stratiotes*, which had disappeared from Egypt for more than a century, has been rediscovered in the Delta by Prof. G. Schweinfurth. Specimens have been introduced into the Giza Gardens.

When the South American marsupial genus Cænolestes was established in 1895 by Mr. O. Thomas it was referred to the diprotodont section of the order. In 1909 Miss P. H. Dederer pointed out that it showed so many polyprotodont resemblances as to preclude its reference to the former group, and it was accordingly made the type of a new suborder, Paucituberculata. Dr. R. Broom (Proc. Linn. Soc. N.S. Wales, vol. xxxvi., p. 315) disputes this view, and regards the diprotodont lower dentition (like the front teeth of the aye-aye) as of no taxonomic importance, and consequently includes the genus in the Polyprotodontia, regarding it as a specialised relative of the American opossums.

In the Transactions of the Bristol and Gloucestershire Archæological Society, vol. xxxiv., part i., for 1911, Mr. J. E. Pritchard announces the discovery in a Bristol excavation of the skull of an ancient type of horse. Prof. J. Cossar Ewart, on examination of the specimen, reports that it belongs to a small, slender-limbed horse or pony of the "plateau" type. Slender-limbed horses of an apparently similar class occurred as a wild species during Pliocene times in Italy and France, and others lived in Europe during the Neolithic, Bronze, and La Tene periods. Remains of similar horses have been found in Kent's Cavern, Torquay, and a nearly complete skeleton of this "plateau" type was found in the Roman fort of Newstead, near Melrose. An example of the same kind, unearthed by the Rev. Dr. Irving at Bishop's Stortford, was described by him at the last meeting of the British Association held at Portsmouth.

The Quarterly Journal of Microscopical Science for February (vol. lvii., part iii.) contains a useful account by Miss Freda Bage of the histological structure of the retina in the lateral eyes of Sphenodon (Hatteria). She finds that the retina agrees closely in structure with that of other reptiles, and that the sense cells consist of cones only, which may be either single cones or double cones. The structure of these cones is very complex, and is described in detail.

Three years ago considerable interest was aroused among students of reproduction problems by Dr. Guthrie's announcement that he had succeeded in transplanting ovaries from black to white hens, and *vice versâ*, with certain interesting effects on the offspring. The experiments have been repeated by C. B. Davenport, of the Carnegie Institution at Washington's station for experimental evolution, and published in *The Journal of Morphology* (vol. xxii., No. 1), but no evidence could be obtained that the engrafted ovary ever became functional. It was concluded that regeneration of the extirpated ovary took place, followed by the production of abundance of eggs.

From an announcement in *The Journal of the Board of Agriculture* (vol. xviii., No. 8) we learn that the Board has arranged for the continuation of the experiments carried on privately for many years by Mr. Elliot at Clifton-on-Bowmont. The soil is poor, very stony, and liable to deteriorate unless skilfully managed. Owing to its dryness, it suffers severely from drought; it can, in fact, by no ordinary system of farming be made profitable. Mr. Elliot's method was to plough up the herbage and to sow a new lot of plants capable of resisting drought; after many trials a mixture was devised suited to the conditions, and also bringing in profit. It contains cocksfoot, fescue, tall oat grass, and such drought-resisting plants as yarrow, kidney vetch, chicory, and burnet. After four or five years this mixture can be followed by arable crops. If the scheme proves profitable on further investigation, it will be of great value in agriculture.

An interesting paper in *The Agricultural Journal of India* (part vi., vol. iv.) deals with the manufacture of palm sugar in Upper Burma. Both the male and the female trees are tapped for their juice from the time the first flowers appear until late in the year, *i.e.* about eight months. The juice is boiled down to a syrupy state, is then allowed to cool, and rolled into balls, which are exposed to the sun to dry. The methods, needless to say, are very wasteful, and necessitate a large consumption of wood for fuel, which for centuries has led to indiscriminate forest cutting. There is evidence to show that dense virgin forests stood in the past where only sun-burned arid areas now are, and unless the timber wasting is stopped serious results are bound to follow.

We are in receipt of part ii. of Mr. J. H. Holland's "Useful Plants of Nigeria." Part i. was noticed in Nature for December 30, 1909, where the scope of the work was described in detail, and the importance of the natural resources of that country was alluded to. The present part covers the natural orders from Connaraceæ to Araliaceæ, and includes, therefore, the order Leguminosæ. For variety of economic products this order can hardly be surpassed. Foodstuffs, timbers, dyes, drugs, gums, and resins are those which are of most importance to Nigeria. The work, which is published as "Additional Series IX." to *The Kew Bulletin*, is not only invaluable to those interested in Nigeria, but contains a wealth of information for all engaged in the study of economic products of this nature.

Dr. G. Platania contributes an interesting paper on the oscillations of the sea on the coasts of Sicily to the last number of the *Bollettino* of the Italian Seismological Society (vol. xv., pp. 223–72). These oscillations, which are known by the name of *marrobbio* in the district referred to, were made the subject of simultaneous observations at various places in Sicily during the months of April and May, 1905, and more recently at several stations, and especially at Mazzara on the western coast. The oscillations vary greatly in amplitude, sometimes exceeding the total range of the semi-diurnal tide. The periods are also very variable, those at Mazzara ranging about the values 10–18 and 21–26 minutes, the smaller average agreeing fairly with the period of oscillation in the open bay. The occurrence of the *marrobbio* seems to depend on the existence of a cyclonic distribution of atmospheric pressure in the neighbourhood of the Sicilian coasts.

In *The Geographical Journal* for March, Prof. H. Bingham, the director of the Yale Peruvian Expedition, describes the results obtained. Careful topographical work was done in surveying a series of areas on large scales from 1 : 4500 to 1 : 3600, with the necessary contour lines. Lake Parinacochas was also surveyed, and the altitude of Mount Coropuna determined by triangulation. A considerable amount of geological and physiographical work was accomplished, furnishing evidence of past climatic changes and of a complex history for the coastal terraces, showing that a submergence took place in Tertiary times and that a later erosion is still in progress. Human bones were found near Cuzco buried under 75 ft. of gravel, and the conclusion was arrived at that they were interstratified with this deposit. The object of the expedition was primarily to reconnoitre the region, and other expeditions to follow up the more important discoveries are contemplated.

The summary of the weather issued by the Meteorological Office for the week ending March 16 shows that for the fifth week in succession the mean temperature was in excess of the average over the entire area of the United Kingdom. The excess was decidedly less than in some of the preceding weeks, although it amounted to 4° in the east of England, and was nowhere less than 2°. The excess of temperature, as almost continuously throughout the past winter, was due to a persistent southerly wind from off the Atlantic. The rains last week were generally less heavy than of late, although the amount was in excess of the average over nearly the entire kingdom. At Greenwich the thermometer in the shade registered 61° on March 14, which is 12° above the average for the season, and is as high as in any previous year on the corresponding day since 1841.

To the Journal of the Meteorological Society of Japan for November last, Prof. T. Okada contributes an article entitled "Geometrical Constructions for Finding the Motion of a Cyclone by Observing the Shift of Wind," in which the law of wind gyration during the passage of a storm is rendered in a more definite form, based upon the following two assumptions, neither of which may be strictly true:—(1) that the angle between the direction of the wind and the gradient is constant in the cyclonic region under consideration; (2) that the cyclonic centre is making a uniform rectilinear motion during the interval of time under consideration. The solutions of the problems which are given for cases when a ship has come to a standstill or is moving are useful and interesting; at the same time, we think that captains of vessels would prefer to adhere strictly to the ordinary rules laid down in their handbooks, which have been carefully drawn up by the Admiralty and others for dealing with storms in all circumstances.

Attention has been directed to a somewhat unfortunate omission in the review by Prof. Bryan of the Bulletin of the Calcutta Mathematical Society (Nature, February 29, p. 583) which appears to overlook the valuable collections of abstracts published in Europe in the *Jahrbuch über die Fortschritte der Mathematik*, the *Revue semestrielle*, and, we may add, the International Catalogue of Scientific Literature. While regretting this oversight, the reviewer still thinks that an opening exists for a journal published regularly, and at frequent intervals, giving an up-to-date summary of what is happening in the mathematical world in the smallest possible compass, and modelled largely on the journal described. Annuals like the *Jahrbuch* in no way meet this want.

A new determination of the atomic weight of radium has been made recently by Dr. O. Hönigschmid, of Vienna, who had at his disposal 1·5 grams of radium chloride, that is, about four times the amount which has previously been available. He purified his salt by fractional crystallisation from dilute nitric acid, the method worked out by Mme. Curie. He took, however, certain precautions not taken by Mme. Curie, both in the purification and in the subsequent analysis by precipitation with silver nitrate. On the basis of 107·88 for silver, he arrives at the result 225·95, with a possible error of 0·02. Dr. Hönigschmid's paper forms No. 7 of the *Mitteilungen aus dem Institut für Radiumforschung*, of Vienna.

We have received a pamphlet containing an account of a new laboratory for experiments on radio-active substances which has been opened at Gif, Seine-et-Oise, under the direction of M. Jacques Danne, editor of *Le Radium*. The laboratory, which is private in character, has been arranged to provide facilities for commercial and scientific work on radio-active minerals and products, and to provide the necessary apparatus and instruction for those who wish to acquire a practical knowledge of radio-active methods and their application. In addition, it will be available for investigation both in the theoretical and commercial side of radio-activity. The laboratory is conveniently situated in a retired spot about 206 kilometres from Paris, and consists of a number of detached buildings, including a laboratory for chemical and physical work on radio-active substances, another for research and practical instruction, and also a library and administrative offices. Photographs are given of the various buildings and the interior of some of the laboratories, which appear to be well equipped for the work proposed. The laboratory has been designed to supplement the work of university laboratories and radium institutes, and no doubt will prove of value especially in connection with the commercial side of radio-activity. The creation of this laboratory illustrates the increasing technical as well as scientific importance of the rapidly growing subject of radio-activity. All communications are to be addressed to the director of the laboratory at Gif, or at his office, 91 Rue Denfert-Rochereau, Paris.

As the result of their measurement of the expansion of mercury, Prof. Callendar and Mr. Moss in their recent paper before the Royal Society gave the value of the mean coefficient of dilatation between 0° and 100° C. as $182 \cdot 05 \times 10^{-6}$. As this result differs from the value $182 \cdot 54 \times 10^{-6}$ obtained by Dr. Chappuis at the Bureau international des Poids et Mésures, they express the opinion that it is not safe to take the coefficient of cubical expansion of the material of a containing vessel as three times the linear coefficient, which Chappuis had done. In the *Verhandlungen der Deutschen Physikalischen Gesellschaft* for February 15 Drs. Scheel and Heuse, of the Reichsanstalt, show that the results of Chappuis for both water and mercury agree with those obtained at the Reichsanstalt, and they are disposed to think that some error has crept into the measurements of Callendar and Moss. They support this view by reference to Harlow's measurements of the expansion of fused silica. When these are based on the results of Callendar and Moss they differ from, and when based on the older results they agree with, those of other observers.

The Bausch and Lomb Optical Company has forwarded to us specimens of their new and improved models of microscopes produced at the beginning of the present year. This American firm is well known for first-class work, and its association with the Carl Zeiss optical works at Jena, with which it exchanges ideas and experiments, gives it great opportunities and standing; the various improvements it has effected, together with reduction in prices, will therefore be of interest to all users of the microscope. The type of instrument is Continental rather than British; there is no centring of the substage for bright field illumination, although the dark field is provided for in this respect. We note the presence of provision for oblique illumination, the absence of which generally in our English stands is regretted by some. Messrs. Bausch and Lomb do not catalogue apochromatic objectives, but, as was to be expected, their association with the Jena glass works enables them to produce achromatics of excellent quality, penetration and minimum of colour being their characteristics. It is worthy of note that they obtain these results without using fluorite. Some of the smaller instruments are marvels of cheapness, and great choice of fittings is given. We direct special attention to the mechanical stage provided for fixing to a square stage; it is one of the cheapest and most convenient we have seen, the screws being in close juxtaposition. The pamphlet on the use and care of the microscope issued with each instrument is admirably written and is full of suggestions of value to the beginner.

In continuation of their well-known experiments on photochemical action, Profs. Ciamician and Silber describe in the *Atti dei Lincei* (vol. xx., p. 673) a number of striking cases of oxidation of aromatic hydrocarbons brought about by sunlight and gaseous oxygen in presence of water. Toluene, the three xylenes, and cymene, when mixed with water and exposed in large flasks or bottles to the action of the gas in bright sunlight during several months, give rise to the corresponding carboxylic acids, toluene forming benzoic acid and the xylenes the corresponding toluic acids; the yield in some cases was as high as 30–40 per cent. of the theoretical quantity. Small quantities of the dicarboxylic acids are also formed in the case of the xylenes, metaxylene, for instance, yielding isophthalic acid. *p*-Cymene gave rise principally to paracumic acid, $C_3H_7.C_6H_4.CO_2H$, but the interesting compound $(CH_3)_2C.(OH).C_6H_4.CO_2H$ was also formed, together with its product of dehydration, $C_3H_5.C_6H_4.CO_2H$. It is noteworthy that *ortho-* and *para*-nitrotoluenes remain unchanged when exposed to the action of moist oxygen under similar conditions, without giving rise to more than traces of acid.

A useful addition is made to our knowledge of the strength of reinforced concrete piles in an article in *Engineering* for March 15. The author, Mr. F. H.

Jeffree, considers the strength of the pile to resist the various handling processes it has to undergo before being finally driven. From the diagrams given, the pile is subjected to a maximum bending moment of $W(L-8)^2/8$ in.-lb., where W is the weight of the pile in lb. per inch run, and L is its length in inches. Expressions are given for the moment of resistance for the pile lying on the flat and also for one diagonal of the section vertical. As reliance is placed on the continuity of the concrete to protect the steel from corrosion, the author proposes to limit the stress on the steel to 20,000 lb. per square inch before driving the pile. Hair cracks in the concrete will thus be avoided. The article closes with a useful table giving the section moduli and limits of safe length for piles from 10 to 16 in. square with various amounts of reinforcement in which the above-mentioned conditions are fulfilled.

The interest taken in the development of the Diesel engine was evidenced by the very large attendance at the Institution of Mechanical Engineers on Friday, March 15, when a paper was read by Dr. Rudolph Diesel. The author considers that England has the greatest interest in replacing the coal-wasting steam engine by the Diesel engine, as enormous savings can be thus effected in her most valuable treasure—coal. As tar and tar oils are from three to five times better utilised in the Diesel engine than coal in the steam engine, a more economical way of using coal is obtained if, instead of being burnt in boiler furnaces, it is first converted into coke and tar by distillation. Coke is useful for metallurgical and other general heating purposes; from a part of the tar the valuable by-products are first extracted, and undergo further processes in the chemical industry, whilst the tar-oils and combustible by-products, together with a great part of the tar itself, are burned in the Diesel engine under extraordinarily favourable conditions. For river vessels in the colonies, the Diesel engine is very suitable. Questions regarding the limiting dimensions of cylinders, influenced by the strength of the metal and by the heat produced, were raised in the discussion.

A list of the publications of the Carnegie Institution of Washington has been received. Copies of each publication, except the "Index Medicus," are sent gratuitously to a limited list of the greater libraries of the world, while the remainder of the edition is on sale at a price sufficient only to cover the cost of publication and carriage to purchasers. Brief descriptions of the contents of the more important volumes add greatly to the value of the catalogue.

OUR ASTRONOMICAL COLUMN.

Nova Geminorum No. 2.—A second telegram, which arrived from Kiel too late for us to publish the correction last week, announces that Herr Enebo's new star is near θ, not η, Geminorum. The new position, being at a greater altitude, is better for observation than the earlier one, and on March 15 the nova was quite easily found a little to the south and east of θ Geminorum; the accompanying chart shows, approximately, the position, and also that of Nova Geminorum No. 1, discovered photographically by Prof. Turner in 1903.

Greenwich measures made on March 15 give the position as 6h. 49m. 14s., $+32°$ 15′. Photographs of the spectrum show the hydrogen lines, both dark and bright, with other bright lines, and the magnitude was estimated as about 4·0; observations made independently at Chichester and Birmingham show that the star, later on March 15, was fainter than the fourth magnitude. Later observations, by several

observers, show that by Monday night the star was certainly fainter than magnitude 5.

We learn from Prof. Fowler that a spectrum secured during a short, clear interval on Friday night, at the Imperial College of Science, shows the spectrum to be similar to those of Novæ Persei and Aurigæ in the earlier stages. Although the dispersion is small, the bright and dark hydrogen series are easily seen.

Observations of Mars.—With the 10-in. refractor of the Urania Observatory, Herren Janssen and Andersen made a number of observations of Mars during the months September to December, 1911. An eosin-red glass was at times employed to accentuate the contrast between the different parts of the planet's surface. While the "coastlines" generally were very well defined, the islands in the "Südmeere" were very pale; the details of the observations are shown on a chart accompanying the paper in No. 4561 of the *Astronomische Nachrichten*. Twenty-nine "canals" were seen, but none was seen doubled.

The Constitution of the Ring Nebula in Lyra.—In a paper recently communicated to the Heidelberg Academy, Prof. Max Wolf finds that certain radiations are emitted only by well-defined portions of the Ring Nebula, the line λ 4686 arising solely from the central dark space, while the line λ 3729 occurs chiefly towards the outer edge of the bright ring; this differentiates these two radiations from the others in the nebular spectrum, and, according to Prof. Wolf, probably denotes different substances with widely differing atomic weights. Dr. Nicholson's failure to account for these two lines in his recent theoretical discussions of the spectrum of the hypothetical substance "nebulium" consequently affords no indication that his theory is untenable.

THE NATIONAL PHYSICAL LABORATORY DURING 1911.

THE annual meeting of the General Board of the National Physical Laboratory was held at Teddington on Friday last, March 15. As usual, a large number of visitors were invited to view the Laboratory, and were received by Sir Archibald Geikie, president of the Royal Society and chairman of the general board, and by Lord Rayleigh, the chairman of the executive committee. The visitors were glad to see that the director, Dr. Glazebrook, was sufficiently recovered, after his recent illness, to be able to take part in the proceedings.

The continued development of the work of the laboratory has been well maintained during the past year. The William Froude National Tank was formally opened in July last. The Wernher building, erected, as its commemorative tablet states, by Sir Julius Wernher to advance the science of metallurgy, was completed in the autumn. A new laboratory has been provided, under a scheme approved by H.M. Treasury, to carry out tests for the Road Board on road materials and on experimental road-tracks. Other new buildings are now in course of erection.

It was explained in the report of the Laboratory for the year 1910 that the control of the meteorological work carried out at the Kew Observatory had been transferred to the Meteorological Office. The testing of thermometers, telescopes, watches, and other instruments previously carried on at Kew—the observatory department of the Laboratory—was to be continued there until the necessary accommodation could be provided for the removal of the work to Teddington. The further buildings now under construction will enable this transference to be made. They include an optics section, which will provide space for all the optical work now carried out at Kew and Teddington, leaving room in Bushy House for other portions of the Kew work; and an administration building, with offices, library, &c., and a section for the receipt and despatch of instruments. The need for such a building had become imperative, owing to the great increase in the activities of the Laboratory.

Towards the cost of these new buildings the Treasury will contribute the sum of 15,000*l.* The committee in its report explains that an additional sum of about 10,000*l.* will be necessary for the satisfactory equipment of the buildings, and expresses confidence that the appreciation shown in the past of the national work done by the Laboratory will be continued, and that the help needed will be readily forthcoming.

The most interesting addition to the equipment completed during the past year, and shown in operation on Friday last, is the Lorenz apparatus for the determination of the ohm in absolute measure. Some particulars of this have been given previously. Much attention has been devoted recently to the elimination of the thermal electromotive force at the brush contacts, and with the form of brush finally adopted—annealed phosphor-bronze wires stretched as a bowstring and pressed on the circumferences of the discs—it is found that the desired result has been obtained. A further difficulty, the determination, with the high accuracy necessary, of the distance between the equatorial planes of the coils, has been met by a special device. A light tubular magnet is suspended from an agate knife edge resting in an agate **V**, and swings like a pendulum; its rest-point can be determined as for a weighing balance. This magnetic pendulum is placed inside a coil, and the position for which there is no axial displacement when a current is passed through the coil can be observed within about three thousandths of a millimetre. This method promises to be very accurate, and will appreciably lighten the work of obtaining the measurements. The first determinations of the ohm with the apparatus will, it is hoped, be made very shortly.

An entirely independent method of evaluation of the ohm in absolute measure has been applied by Mr. Campbell. This is one of several methods he has suggested for the comparison of resistance with mutual inductance. An auxiliary condenser is tested against a resistance by Maxwell's commutator method and against a standard mutual inductance and two resistances by Carey Foster's method, the results giving the ohm in terms of the mutual inductance, the value of which is calculated from its dimensions. Though not aiming at so high an accuracy as it is hoped may be attained with the Lorenz apparatus, the method appears to yield very good results.

The photometry division has completed an interesting research on the visibility of point sources of light. The investigation was undertaken, at the request of the Board of Trade, in connection with the certification of ships' lights, which at a distance of two miles are seen simply as bright points of no perceptible angular magnitude. The unit of visible intensity adopted for comparison purposes is that of a point source of one-millionth of a candle-power one metre distant from the eye; this unit approaches the limit of visibility. An important point investigated was an apparently anomalous dimming of lights observed in the case of some persons using spectacles, which was found to be due to the chromatic aberration of the eye.

In the course of the research on the fundamental high-temperature scale in the thermometry division some interesting ionisation phenomena have been met with, recently described before the Royal Society by Dr. Harker and Dr. Kaye. The division has also taken up the determination of the thermal conductivities of heat insulators as used for cold-storage purposes, a subject of much practical importance.

The metrology division has been largely occupied with the necessary work involved in the maintenance of standards, and with test work. The behaviour of the new silica standard metre is being very carefully followed. As in previous years, a number of investigations have been carried out for the Engineering Standards Committee.

In the engineering department a large number of interesting investigations have been completed. Dr. Stanton's research on the effect of wind pressure on structures has been proceeding continuously almost since the date of the opening of the laboratory. The object of the work has been to enable a trustworthy prediction of the wind pressure on a large engineering structure to be made from laboratory experiments on a small model of the structure. The earlier parts of the work were concerned with experiments on small models in an air channel, which were compared later with the results of observations on larger structures in the natural wind. Following this, an attempt has been made to ascertain whether a trustworthy estimate of the total wind pressure over a large structure can be obtained from observations at one point. This work has recently been completed, and it is considered that sufficient data have been obtained to enable a prediction of the wind pressure over an area of several thousand square feet to be made from observations at a single point in the area. There remains the investigation of the more or less exposed nature of the site on the lateral variation of wind-force. For this purpose, permission has been received to make the observations on the Tower Bridge, and this work will be commenced shortly.

The work of the aëronautics division has made good progress; in particular the study of the best forms of aëroplane surfaces, and of the distribution of flow round such surfaces, has been greatly advanced. An opportunity of describing this work will arise later, on the issue of the annual report of the Advisory Committee for Aëronautics.

The metallurgy department was occupied for some considerable time during the autumn with the transference to the new Wernher building. The principal item of research work has been the investigation of the aluminium-zinc alloys, carried out for the Alloys Research Committee of the Institution of Mechanical Engineers.

Mr. Baker, the superintendent of the William Froude National Tank, has carried out a number of investigations, some of which have been already described in these pages. Careful comparisons have been made with Mr. Froude's results at Haslar by tests on models to lines supplied by him, and experiments have also been carried out with a model similar to others tested at Clydebank and Washington. These tests have shown satisfactory agreement, and the national tank is now ready to go forward with general experimental investigations of ship resistances.

In this short summary it is impossible to do more than touch on the many points of interest presented by the work of the laboratory. Enough, however, has been said to show that the laboratory continues fully to justify the appreciation which the great manufacturing firms of the country have displayed of its value to industry.

OZONE AND VENTILATION.

THE Journal of the Society of Arts of February 9 contains a paper by Messrs. Leonard Hill and Martin Flack on "The Influence of Ozone in Ventilation." The authors point out that whilst it is not legally permissible for the carbonic anhydride in the air of a factory to exceed a few parts per 1,000, no harm whatever is caused by breathing air containing up to 4 per cent. of this gas. A similar statement applies to deficiency of oxygen, which does not become important until the proportion falls to 14 or 15 per cent. These conclusions are quite in accord with the fact that, on account of the dead-space separating the lungs themselves from the open air about one-third of the air drawn into the lungs is re-breathed; it is thus quite impossible that a few parts per thousand of carbonic anhydride in the outside air should affect the lungs, in which the percentage is normally about 5 per cent.

Another theory of the ill-effects of bad ventilation is the supposed liberation of organic poisons. This also is probably fictitious, as animals will live and thrive when supplied exclusively with air already breathed by other animals, and containing 3½ per cent. of carbonic anhydride; they are liable to die of suffocation if the air supply is interrupted, or if the percentage of carbonic anhydride rises to 10 to 12 per cent. As an explanation of the discomfort arising from lack of ventilation the authors suggest: (1) the stagnation of the air, resulting in diminished evaporation from the skin, and a consequent sensation of lassitude; (2) the nausea caused by the odour emitted from an imperfectly washed crowd. The value of ozone in ventilation depends largely upon its power of removing this odour; sterilisation is perhaps less important as expired air is practically sterile; infection is conveyed by droplets of saliva, which cannot be removed by ventilation, but soon settle, and may be removed when the room is dusted.

LA HOUILLE BLANCHE.[1]

THE work of the French "Direction de l'Hydraulique" has already been the subject of two articles in these columns (May 7, 1908, and November 25, 1909). On both occasions a tribute was paid to the very effective and thorough manner in which the department was carrying out its systematic investigation into the hydraulic reserves of the mountain ranges of France. The volume now under review is the fourth of the series, and it sustains the favourable impression created by its predecessors. It brings the record of observations down to the end of 1910, completing a period of very nearly eight years since the inception of the department. The service, in so far as it relates to the region of the Alps (which is the only range at present under observation, though the extension of the work to the Pyrenees is impending), is now concentrated under the direction of M. R. de la Brosse, whose former coadjutor, M. R. Tavernier, has become Inspecteur général de l'Hydraulique agricole.

The area of country comprised within the purview of the inquiry amounts to 22,000 square miles, and lies immediately to the south of the Lake of Geneva, extending to the shores of the Mediterranean, and being bounded on the east and west, respectively, by the Italian frontier and the river Rhone. The principal basins are those formed by the tributaries of the Rhone on its left bank between Geneva and the sea, the most noteworthy being the Isère, the Durance, the Var, the Arve, and the Dranse. Gauging stations to the number of 180 have been established in suitable localities, and the total number of gaugings carried out to December 31, 1910, was 3116, of which 726 represent the work of the last twelve months. The greatest number of records taken at any one station amounted to fifty-nine, and the mean for the whole was seventeen.

From the observations two factors, or coefficients, have been deduced. First the mean characteristic discharge, which represents the minimum guaranteed for half the year; and, secondly, the modulus, or arithmetical mean of the discharges corresponding to the daily level. The former of these factors is valuable in computing the industrial trustworthiness of a stream, and the second is an important element in connection with regularisation works. As an instance may be taken the case of the Durance at Rousset, where, during the five years 1905–9, the records show a variation in discharge between 18 and 440 cubic metres per second, giving as mean figures for the whole period a low-water discharge of 20 cubic metres per second, a modulus of 68, and a total annual volume of 2,138,000,000 cubic metres. The mean characteristic discharge, *i.e.*, the minimum on which it is possible to reckon during half the time, is about 46 cubic metres per second.

The motive power in the French alpine region actually harnessed at the present time amounts to 473,000 h.p., dvided approximately as follows:—Metallurgy, 210,000; power and light distribution, 155,000; chemical products, 60,000; paper, cardboard, &c., factories, 30,000; electric traction, 10,000; miscellaneous, 8,000. Other schemes are now projected which will shortly raise the total to something in the neighbourhood of 2,000,000 h.p.

The volume contains one or two useful essays by individual contributors on technical matters connected with the taking of observations, and there are several interesting photographs. Then follows part ii., which

[1] Service des Grandes Forces Hydrauliques (Région des Alpes). Compte Rendu et Résultats des Études et Travaux au 31 Décembre, 1910. Tome iv., pp. 556. Annexe i., Cartes, pp. 14+8 cartes; Annexe ii., Nivellements, 33 planches. (Ministère de l'Agriculture, Direction de l'Hydraulique et des Améliorations Agricoles, 1911.)

constitutes by far the bulk of the work, being a tabulation of the numerical readings taken at successive dates throughout the year at the different stations.

There are two "Annexes." The first is a series of charts showing the disposition and extent of the various factories and works where hydraulic power is turned to account, and the second is a series of longitudinal sections, or profiles, of the watercourses of the Isère and the Arc.

All are admirably prepared, and give rise to the reflection that some things are done much better abroad than they are at home. Our own country stands out in "splendid isolation" in possessing no hydrological service and in making no official attempt whatever to catalogue, define, and conserve her natural resources of water power and supply, now running to waste or liable to misappropriation. In this attitude she finds no sympathy or support from her neighbour across the Channel, nor from the United States, nor Italy, nor Switzerland. Each of these countries has realised the advantages accruing to trade, agriculture, and the public welfare generally from a systematic development and control of La Houille Blanche.

POETRY AND SCIENCE.

THE Professor of Poetry at the University of Oxford, Dr. T. Herbert Warren, President of Magdalen College, gave a public lecture on March 2 on the subject of "Poetry and Science." He began by quoting his predecessor Matthew Arnold, who wrote on New Year's Day, 1882: "If I live to be eighty, I shall probably be the only person left in England who reads anything but newspapers and scientific publications."

Has Matthew Arnold's gloomy prophecy been fulfilled? Have newspapers and science killed real literature? In particular, are the interests of science hostile to the interests of literature?

Where science has dominated, has poetry languished? This is a very burning question, for science has certainly made great advances. It impresses the man in the street, chiefly by its usefulness. It is the poet and the poetic person who are impressed by the marvel, the magic, and the mystery of science. Matthew Arnold inherited the tradition of Wordsworth, who was a great poet of Nature, but not a poet of Natural Science. He strove hard to do justice to it, both in his prose prefaces and in his poetry, but with imperfect success. Wordsworth's poem "The Poet's Epitaph" contains a most beautiful and memorable description of the poet, but is scarcely fair to the man of science, who is generally a man also of natural affections. The man of science may be as fond of his mother as the poet, who is often one of the most selfish of beings, and if he would not "botanise upon his mother's grave" because he knows no botany might be quite capable of turning her into copy.

Further, the poet is not "contented to enjoy the things that others understand." He must synthesise in his own way. Wordsworth himself was for ever philosophising and moralising.

Keats, again, is often cited as complaining that Newton had destroyed the beauty of the rainbow by reducing it to prismatic colours, but Keats was perhaps not serious in this charge.

Goethe, on the other hand, did not object to Newton for reducing the rainbow to prismatic colours, but only for doing so wrongly.

Matthew Arnold "poked fun" at science as he did at religion, and was even less willing to treat it seriously than religion. He was often exceedingly amusing, and his famous description of a scientific education in "Friendship's Garland" was highly so.

Darwin, who began by being a great lover of poetry, thought that in later days he had lost the power through atrophy, but in point of fact the atrophy was by no means complete. He remained a most poetical writer. The closing paragraphs of the "Origin of Species" were worthy of Lucretius, which they strongly resembled.

History shows that poetry, philosophy, and science had all begun life together as children of one family. The early Greek poets, like the authors of the Books of Genesis and Job, dealt with the origin of things and the Story of Creation. The early thinkers who succeeded them expressed their thoughts in verse, and were often highly poetical. What could be more poetical than the "dark" science of Heraclitus? The same relation was maintained through Greek literature. The greatest astronomer of antiquity, the inventor of the Ptolemaic system, was the author of a beautiful epigram which was truly poetic. From Greece and Alexandria, science and poetry passed together to Rome, and might be found combined in Lucretius and Virgil. The greatest singers of antiquity were the most alive to science. Modern literature shows the same phenomenon in Dante and in Milton and in Tennyson. This is specially well brought out in a book by a living man of science, Sir Norman Lockyer's "Tennyson as a Student of Nature." On the last of the three poets Sir Oliver Lodge has also written briefly, but with rare force, in the recent volume "Tennyson and his Friends."

As time has gone on, the scientific spirit has increasingly made itself felt in poetry, and may be seen in the works of F. W. H. Myers and his brother, in the late Duke of Argyll, in George Romanes, in Richard Watson Dixon, and still better in his friend and editor, Mr. Robert Bridges. And others of the earlier poets had also been acquainted with science, notably Gray and Shelley.

With regard to the greatest of all, if Bacon wrote Shakespeare it is odd that Bacon's science does not appear more often in the plays, but in any case it may be remembered that Bacon wrote poetry of his own and had a place in the "Golden Treasury."

Other lands and literatures too have had their scientific poets, the most famous being Goethe, of whom the best account is to be found in the popular lectures of a most poetical man of science, Helmholtz. I can speak at length only of one, the French poet of the last century, Sully Prudhomme, who combined science, philosophy, and poetry. The best account of him is to be found in the study by M. Zyromski. "Poetry," said Sully Prudhomme, "is not only the lyrical outburst of our sentiments. The great poetry has noble destinies, and will sing the conquests of science and the synthesis of thought."

The average man does not care for "great poetry," or only for that part of it which appeals directly to his own feelings. Just now, what Sully Prudhomme calls *lyrisme*, that is, personal poetry, holds the field, but that has not always been so, and will not always be so. Science has not destroyed poetry. Cambridge, the University of Science, has been the University of Poetry, and with the revival of Science at Oxford in the last century, beginning in Shelley's time, poetry revived too. The really great poet must respond to the main and moving interests and influences of his day. The old facts and factors, the old *motifs*, do not change. Rebekah at the Well, David's lament over Saul and Jonathan, Hector and Andromache, Catullus at his brother's grave, still move us. But while these remain, our outlook on the world does gradually change, as Sully Prudhomme foretold in his fine sonnet to "The Poets of the Future.' Science will certainly go on, and scholarship and poetry will go on at its side and beneath its ægis. The "scientific use of the imagination" on which Tyndall, that most poetic man of science, discoursed so finely forty years ago will be balanced more and more by the imaginative use of science..

The famous epigram by Ptolemy, the author of the Ptolemaic system, with the Professor's version of it, may conclude the address:—

ΠΤΟΛΕΜΑΙΟΥ.

Οἶδ' ὅτι θνατὸς ἐγὼ καὶ ἐφάμερος· ἀλλ' ὅταν ἄστρων
μαστευω πυκινὰς ἀμφιδρόμους ἕλικας
αὐκέτ' ἐπιψαύω γαίης ποσίν, ἀλλὰ παρ' αὐτῷ
Ζανὶ θεατρεφέος πίμπλαμαι ἀμβροσίης.

I know that I am mortal, and doomed to fleeting days,
But when I track the circling stars in myriad-orbèd maze,
I tread the earth no more, but sit beside the Lord of Heaven,
And taste the ambrosial food whereby the life of Gods is given.

CIVIL SERVICE ESTIMATES FOR SCIENCE AND EDUCATION.

THE Estimates for Civil Services for the year ending March 31, 1913, are being issued as a series of Parliamentary Papers. The following particulars referring to the money under this vote to be devoted to scientific work and to higher education are taken from the paper entitled "Class IV. Education, Science, and Art."

Under the heading "Scientific Investigation, &c.," we find that the amount of the grants in aid for 1912–13 is 125,523*l.*, which represents a net increase over the total for 1911–12 of 61,920*l.* This considerable advance is explained largely by the increase of 29,500*l.* in the grant to the National Library of Wales and of 31,000*l.* to the National Museum of Wales.

The grants in aid enumerated under the heading of the Royal Society, and voted for scientific investigations and scientific publications, for the expenses of the Magnetic Observatory at Eskdalemuir, and for salaries and other general expenses of the National Physical Laboratory, remain as in 1911–12; the grant in aid of the expenses of the aëronautical section of the National Physical Laboratory, however, has been increased from 4885*l.* to 5775*l.* The total grants in aid under all these headings reach 23,775*l.*

The grant to the Meteorological Office has been increased from 16,850*l.* to 17,000*l.*, and that of the Royal Geographical Society from 500*l.* to 1250*l.* The Edinburgh University will receive 1728*l.*, as compared with 1508*l.* in 1911–12, and the International Seismic Association 370*l.*, as compared with 210*l.*

The Estimate for Universities and Colleges, Great Britain, and Intermediate Education, Wales, amounts to 314,200*l.*, an increase of 10,400*l.* over that for 1911–12. The total for universities and colleges is 287,000*l.*, an increase of 10,500*l.*, which all goes to Scottish universities.

The vote for Science and Art in Ireland reaches 138,591*l.*, as compared with 117,883*l.* in 1911–12, 30,600*l.* of the increase being accounted for by larger annual grants to schools and classes of science, art, and technical instruction. The estimate of the amount required for grants under the Irish Universities Act, 1908, is 130,000*l.*, or a decrease of 56,256*l.* on 1911–12.

The estimate of the amount required to pay the salaries and expenses of the Board of Education and of the establishments connected therewith is 14,504,765*l.*, allocated, so far as the chief items are concerned, as follows:—administration, 202,333*l.*; inspection and examination, 249,633*l.*; elementary schools, 11,832,235*l.*; training of teachers, 603,000*l.*; secondary education, 756,000*l.*; technical institutions, evening schools, &c., 621,800*l.*; universities in respect of technological work, 42,000*l.*; Imperial College of Science and Technology, 20,000*l.*; Science Museum, 18,018*l.*; Geological Museum, 3694*l.*; Geological Survey of Great Britain, 17,644*l.*; and Committee on Solar Physics, 2171*l.*

THE GYROSTATIC COMPASS AND PRACTICAL APPLICATIONS OF GYROSTATS.[1]

THE problem of a *practical* gyrostatic compass has attracted the attention of many, but the credit of being the *first* to produce a practical working instrument belongs to Dr. Anschütz, who, with those associated with him, has devoted some twelve years of patient work and no inconsiderable sum of money in experiments. Since then some important work has been done by Hartmann and Braun in Germany, and Mr. Sperry in America, details of which are not available.

Few people have any idea of the difficulties attending the installation and correct adjustment of a magnetic compass on board a large steel ship, and more particularly on a battleship or cruiser, so as to work surrounded by huge masses of steel, and in order to withstand the terrific shocks caused by the firing of heavy guns, and the problem would to-day be impossible had it not been for the theoretical work of Sir George Airy, the applied genius of Lord Kelvin, and the present practical improvements introduced by the superintendent of compasses at the Admiralty.

A magnetic needle can only point in the direction of the lines of magnetic force at the place where it is set up, and it is well known that there are very few places on the globe where the magnetic needle points true north and south.

Dr. Anschütz attacked the problem of a gyrostatic compass with enthusiasm, and has continued to work at it in the face of many and great disappointments with a thoroughness and patience which is characteristic of his nationality. The construction of the compass meant new designs for everything in connection with its motors, &c. His first experiments were with gyrostats suspended with the gyro free to move about its three principal axes, or, as it is termed, having three degrees of freedom; but it is easy to show how impossible it is to construct such a gyro so as to be sensitive to small movements, and yet really accurate in practice.

To make use of the gravity effect of the earth, Dr. Anschütz mounts his gyrostat in the form of a pendulum; as the earth rotates the gyrostat tends to maintain its plane of rotation parallel to its original plane in space. The earth's gravity acts against this tendency, and a precession results, the only position of equilibrium occurring when the gyro axis has set itself parallel with the axis of rotation of the earth.

In the actual compass the friction of the universal joint carrying the pendulum arrangement must be very small for the gyro to take an ultimate position with accuracy—the length of the pendulum, and hence the effect of gravity, must be small, so as to keep the compass free from disturbances—and therefore the precession is very slow, and the compass would swing to and fro on either side of the meridian indefinitely; its mean position would, it is true, be the true north and south line, but valueless for practical use.

[1] From a Discourse delivered at the Royal Institution on Friday, February 23, 1912, by Mr. G. K. B. Elphinstone.

The sizes, weights, and speeds chosen are such as to result in a compass having many times the directive force of a magnetic compass, and therefore responding to much smaller alterations of direction than can readily be observed with a magnetic compass. The compass itself being quite non-magnetic, can be put down under armour—in a position where a magnetic compass could work only with very special precautions and under grave difficulties. The action of the contact is to control a small electric motor, which moves a plate away from the contact on the card as soon as it touches it, and then the motor stops; the motor drives a transmitting device which controls as many receivers as are wanted in the ship.

The receivers are merely electrical counters, and can be put in any position; the small dials make one complete revolution for only 10° change of course, and these are geared after the manner of clock-hands to the outer dial, one turn of which corresponds to a turn of thirty-two points, or 360°; they are arranged to turn at a quicker rate than any large ship can turn in the water. The movement which the inner card makes, for a very small alteration of course, is considerable, and takes place instantly; and, owing to this fact, enormous improvement is possible in the steering of a large ship when the helmsmen have become used to the appearance of the dials.

Attention must be paid to the necessity of corrections which have to be applied to the readings of the compass.

The first correction is an interesting one, as it is not apparent at first sight; it is common to every form of gyrostatic device which takes the earth's rotation into consideration. If a ship with a gyro compass is steaming due east or due west, the ship's speed is added to the speed of rotation of the earth in space, or deducted from it. Suppose the ship steams due north, then the resultant travel of the ship in space is along the diagonal line, as it is moving from west to east by the earth's rotation, and south to north by its own steam. Therefore it is travelling in space about some axis which it sets its own axle and its N. and S. line on the compass card, parallel to which is not the north and south axis of the earth.

The speed of the ship, the course and the latitude, come into this correction, for which tables are made out, the maximum correction which has to be considered being some 3°; for all manœuvring this correction can be neglected.

The second correction which has to be taken into account is due to the existence of the air blast used in damping, the damping checking the precession whenever this takes place. The precession varies with the cosine of the angle latitude; the air blast is constant in its effects in all latitudes, depending only on the speed of rotation of the gyro—therefore there is a varying cause and a constant retarding force, and in consequence a varying result. The effect is that for every 10° of latitude a correction of about $\frac{1}{2}$° has to be applied—$\frac{1}{2}$° in a distance of 600 miles.

The gyro compasses in use in the British navy are adjusted to be correct at 50° north latitude, so that for all cruising in the Channel and say up to the Firth of Forth, this correction does not require consideration.

Both these corrections can be treated arithmetically by adding to or deducting from the reading on the card the same quantity *all the way round*; it does not vary in different parts of the card, as is the case when applying a deviation correction to a magnetic compass reading.

The worst difficulty which the gyro compass is faced with is the effect produced by violent rolling or great vibration in a ship. This has been receiving a great amount of attention from the inventors during the last eighteen months, since practical experience at sea showed the necessity of some improvements in this respect. Fortunately the results of the investigations have led to considerable improvement, and to a complete cure of the trouble experienced in this way, so that it will shortly be possible for gyro compasses to be installed in ships which are quite independent of the rolling motion or vibration of the vessel.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LONDON.—Two important benefactions were announced last week. The first is an offer of 100,000*l.* from an anonymous friend of the University, made through Lord Haldane as chairman of the Royal Commission on University Education in London, as a contribution towards the cost of acquiring the vacant site north of the British Museum for new University headquarters. This munificent offer, announced last Friday, was followed next day by an offer from the Drapers' Company to erect a Senate House and administrative offices at an approximate cost of 60,000*l.* The offer is not explicitly associated with the site mentioned above, but it is based on the report of the Royal Commission, which suggested a building such as is indicated, together with other buildings appropriate to the site, which is divided into four plots. The Drapers' Company stipulate that the other buildings are to be provided within a reasonable time. In connection with the gift of 100,000*l.*, a board of trustees has been formed, composed of Lord Haldane, representing the Government; Lord Milner, representing the Royal Commission; Lord Rosebery, representing the University; and Sir Francis Trippel. It is stated that the donor has already done a great deal for university education, and holds that the University of London ought to be the chief educational institution of the Empire.

GLASGOW.—The Vice-Chancellor, Sir Donald MacAlister, K.C.B., has been appointed by the University to represent it at the fifth jubilee festival of the Royal Society.

The centenary of the launch of the *Comet* as a passenger steamer on the Clyde is to be celebrated during the summer. Prof. Barr, of the chair of engineering, and Prof. Biles, of the Elder chair of naval architecture, are the University representatives on the centenary committee.

Mr. J. M. F. Drummond, appointed lecturer in botany, is to have special charge of plant physiology.

The fine collection of prehistoric antiquities recently displayed in the Glasgow National Exhibition has been deposited by Mr. Ludovic Mann in the Hunterian Museum.

Proposals are under consideration for the erection within the University of a monument of the famous Glasgow brothers, John and William Hunter, the latter of whom was the founder of the Hunterian Museum.

IT is announced in *Science* that gifts of more than 100,000*l.* to the University of California have just been secured through the will of the late Mrs. Jane K. Sather, of Oakland. Plans have been begun for the Sather Campanile, a lofty bell-tower, for which Mrs. Sather provided some 40,000*l.* Two professorships are endowed, and endowment is provided for three book funds.

DR. H. L. SMITH has accepted a call to the presidency of Washington and Lee University, Lexington, Virginia, and will probably enter upon the duties of that office in July next. Since 1901 he has been president of Davidson College, N. Carolina, where he previously held the chair of physics. He is well known in the Southern States as a lecturer on scientific and educational topics at summer schools, "Chautauquas," &c.

The annual gathering of the South-Western Polytechnic Institute was held on Friday, March 15. The Right Hon. W. Hayes Fisher, M.P., chairman of the governing body, presided, and a report on the work of the session 1910–11 was read by the principal. The report showed that 988 students joined for work in the day and 1575 in the evening during the session, that nearly 600*l.* was gained in outside scholarships by the students, and that a large number of university and other successes had been gained. After distributing the certificates and prizes, Sir David Gill, K.C.B., F.R.S., addressed the students. He impressed on them that knowledge was the latent power of doing things, that what they gained in their classes constituted their mental tools, and that they should learn something of everything, and, above all, they should learn everything of something. He advocated the formation of a department of astronomy to include, what he considered most important, instruction in the practice of finding one's position in an unmapped country. He had met with many young engineers who were quite at a loss when they were asked to lay down a railway track in an unmapped country. The vote of thanks was proposed by Sir William White, who referred to Sir David's work on the sun's distance, and seconded by the Mayor of Chelsea. About 2400 guests attended the conversazione afterwards.

A Royal Commission to inquire into the methods of appointment to and promotion in the Civil Service and other cognate matters has been appointed. The terms of reference are:—To inquire into and report on the methods of making appointments to and promotions in the Civil Service, including the Diplomatic and Consular Services, and the legal departments; to investigate the working and efficiency of the system of competitive examination for such appointments, and to make recommendations for any alterations or improvements in that system which may appear to be advisable; to consider whether the existing scheme of organisation meets the requirements of the Public Service, and to suggest any modifications which may be needed therein. The commission is constituted as follows:—the Lord MacDonnell, G.C.S.I., K.C.V.O. (chairman), the Duke of Devonshire, the Bishop of Southwark, Sir Henry Primrose, K.C.B., Sir Kenneth Muir-Mackenzie, G.C.B., K.C., Sir Donald Macalister, K.C.B., Sir Guy Granet, H. Baker, M.P., J. R. Clynes, M.P., S. J. G. Hoare, M.P., R. D. Holt, M.P., P. Snowden, M.P., A. A. Booth, A. Boutwood, P. E. Matheson, A. E. Shipley, Graham Wallas, Miss Haldane, and Mrs. Dean Streatfeild. The secretary to the commission is S. Armitage-Smith, of the Treasury, to whom correspondence may be addressed at Treasury Chambers, Whitehall, S.W.

SOCIETIES AND ACADEMIES.

London.

Royal Society, March 14.—Sir Archibald Geikie, K.C.B., president, in the chair.—Prof. E. **Goldmann**: A new method of examining normal and diseased tissues by means of *intra-vitam* staining. The author's original method of *intra-vitam* staining by injection of trypan and isamin blue has been greatly advanced in several points described.—Dr. E. K. **Martin**: The effects of ultra-violet rays on the eye. Three lines of investigation have been taken and carried out, in each case on rabbits:—(1) *Absorption.*—Using an iron arc as the source of light and a quartz spectrograph, the absorption of the media of the eye was found to be as follows:—Cornea.—All rays of wave-lengths less than 295 $\mu\mu$ are cut off completely. Lens.—Absorption commences at 400 $\mu\mu$ and is complete beyond 350 $\mu\mu$. Vitreous.—Shows a broad absorption band with ill-defined margins extending from 280–250 $\mu\mu$. All the media were found to be uniformly permeable to rays between the wave-lengths 660–400 $\mu\mu$. (2) Results of repeated exposure of eye to light containing a high proportion of ultra-violet rays. A series of animals were exposed at repeated intervals for from three to twelve months. They showed marked inflammatory reaction in the cornea and conjunctiva, and in one case a proliferation of the cells of the anterior lens capsule. (3) Transmission of hæmolysins to aqueous humour after exposure of eye to short wave-length rays. The aqueous of animals which have been sensitised to the blood of another species has no power of hæmolysing red blood-corpuscles of that species. After exposure of the eye of such an animal to the quartz mercury vapour lamp, the aqueous becomes actively hæmolytic, and remains so for a period not as yet determined, but in any event longer than the duration of the resulting inflammatory changes.—Dr. W. S. **Lazarus-Barlow**: The presence of radium in some carcinomatous tumours. Elsewhere the author published evidence that acceleration of electroscopic leak may be produced by the residue of carcinomatous tissue after its extraction with ether and subsequently with water, or after extraction with acetone. The results were criticised as being small, and as possibly explicable by alteration in capacity of the electroscope occasioned by introduction of the substances within it. The subject was therefore reinvestigated with an electroscope of constant capacity in which a fixed wire grating separated the portion containing the gold-leaf from the portion into which the substances were introduced. Twenty-seven samples of primary carcinoma, eight of secondary carcinoma, two sarcomata, and five normal livers and lungs were examined under these conditions, and the original conclusion was confirmed.—C. **Russ**: An improved method for opsonic index estimations involving the separation of red and white human blood corpuscles. The observed errors by the improved method were one quarter the magnitude of those by the old process, the conditions of experiment being almost completely comparable.—Prof. W. M. **Thornton**: The electrical conductivity of bacteria, and the rate of inhibition of bacteria by electric currents. Tap water containing *B. coli communis* can be completely sterilised by direct currents in several hours at 0·2 ampere sq. cm. Alternating currents sterilise water nearly, if not quite, as well as direct currents having the same current-density. Milk is curdled by direct current at the positive pole and thinned at the negative pole. Milk can be sterilised without curdling by passing alternating current, this being largely thermal. The cause of the marked bactericidal action of light is suggested to be syntony between it and the frequency of electronic rotation in the atoms of protoplasm.—E. C. **Hort** and W. J. **Penfold**: A clinical study of experimental fever. *Conclusions:* (1) That the establishment as separate entities of these various types of fever no longer rests on secure ground; (2) that future advance in the experimental study of fever is not possible unless precaution be taken to ensure that the water or saline used for injection is free from the fever-producing body described.—S. G. **Shattock** and L. S. **Dudgeon**: Certain results of drying non-sporing bacteria in a charcoal liquid air vacuum. The bacteria used comprised *B. coli*, *B. typhosus*, *Staphylococcus pyogenes aureus*, *B. pyocyaneus*. The action of light was excluded during the experiments. *B. typhosus* and *B. coli* died both *in vacuo* and in air-dried slips within five days. *S. pyogenes aureus* persists considerably longer under both conditions. The interest centres around *B. pyocyaneus*. Air-dried films did not survive beyond nine days. The slips kept *in vacuo* were alive at seven months. *B. pyocyaneus* was submitted *in vacuo* to the action of heat, and also to the sun's rays (the sealed vacuum tubes being submerged in water). Its resistance to these agencies, in the dried state, *in vacuo*, was not materially, if at all, increased. The bacillus was killed, moreover, by the action of ultra-violet rays on being removed from the vacuum and treated in an atmosphere of nitrogen. So far as the possibility of interplanetary bacterial life is concerned, it is evident that bacteria in the fully dried state, if free in the interplanetary vacuum, would be killed by the solar light. As Sir James Dewar's experiments have demonstrated that the ultra-violet rays will kill undried bacteria whilst in the frozen condition at the temperature of liquid air, there is little to support the hypothesis that the living protoplasm on the earth originally immigrated from interplanetary space in a free or unincluded condition—that free, particulate life has entered the earth's atmosphere, as a result of light propulsion, from extramundane space.

Zoological Society, February 20.—Dr. A. Smith Woodward, F.R.S., vice-president, in the chair.—Dr. A. T. **Masterman**: Recent investigations on age-determination in the scales of salmonoids, with special reference to Wye salmon.—Dr. H. Lyster **Jameson**: The structure of the shell and pearls of the Ceylon pearl-oyster (*Margaritifera vulgaris*, Schum.); with an examination of the cestode theory of pearl production. The author began by reviewing the work on the subject of pearl production carried out in Ceylon by Prof. Herdman, F.R.S., and his successors. He examined the theory, enunciated by Prof. Herdman, that most Ceylon "fine" pearls had for their nuclei the remains of cestode larvæ, and that these larvæ, which are abundant in the liver and connective tissues of the pearl-oyster in Ceylon, were the "cause" of the most valuable pearls. Dr. Jameson maintained that the evidence adduced in support of this theory by Prof. Herdman and Mr. Hornell was insufficient. The second part of the paper dealt with the structure and formation of the shell and of pearls. The various repair-substances, which replace the ordinary shell substances under abnormal or pathological conditions, were described, their relations to the normal substances of the shell were discussed, and their occurrence in the pseudo-nuclei of pearls dealt with. The "calcospherules" which Herdman regarded as free concretions, and as the cause of "muscle pearls," were considered to be in fact minute pearls, composed of the hypostracum, or special shell-substance to which the muscles are attached. The author maintained that, as he had already laid down in his 1902 paper, the real cause of pearl production would have to be sought, not in the nuclei or pseudo-nuclei of pearls, but rather in the pathological conditions under which the tissues of the mollusc gave rise to the pearl-sac.—R. **Shelford**: Mimicry amongst the Blattidæ; with a revision of the genus Prosoplecta, Sauss. The author dealt with a number of exceptions to this usually cryptically coloured type of cockroach, and in greater detail with the Prosoplecta, nearly all the members of which presented a remarkably close and detailed resemblance to other insects.—Rev. O. **Pickard-Cambridge**: A contribution to the knowledge of the spiders and other arachnids of Switzerland. The paper was based on a number of specimens collected for the author by various persons, at different times, and contained the description of one new species.

March 5.—Sir J. Rose Bradford, F.R.S., vice-president, in the chair.—H. L. **Hawkins**: The classification, morphology, and evolution of the Echinoidea Holectypoida.—H. G. **Plimmer**: The blood-parasites found in the Zoological Gardens during the four years 1908–11. The paper contained the results of examination of the blood of 6430 animals, in about 7 per cent. of which parasites were found. Many of these parasites were described for the first time, and in other cases the hosts were newly recorded.—Prof. G. O. **Sars**: Zoological results of the third Tanganyika expedition, conducted by Dr. W. A. Cunnington, 1904–6. Report on some larval and young stages of prawns from Lake Tanganyika.—Dr. R. **Broom**: The structure of the internal ear, and the relation of the basi-cranial nerves in Dicynodon, and on the homology of the mammalian auditory ossicles.

Royal Microscopical Society, February 21.—Mr. H. G. Plimmer, F.R.S., president, in the chair.—Mr. **Rousselet**: Fourth list of new Rotifera since 1889. The year 1889 was when Hudson and Gosse's monograph of the Rotifera was completed by the issue of the supplement, recording altogether 400 species at that time. The author explained that his three preceding lists, published in 1893, 1897, and 1902, contained 393 new species, and the fourth list now submitted 214 names, a total of 607 new species since 1889. Mr. Rousselet estimated the present Rotiferous population of the world comprised 857 species. The greatest number of new species in the present list appeared amongst the Bdelloid Rotifers; 101 species, mostly described by James Murray, were obtained from moss collected by him from all parts of the world, from Scotland to the Antarctic regions. Of the other orders represented there were Rhizota, 8; Ploima-Illoricata, 30; Ploima-Loricata, 74; and Scirtopoda, two new species.

Linnean Society, March 7.—Dr. D. H. Scott, F.R.S., president, in the chair.—Prof. Percy **Groom**: Note on the internodes of Calamites. The author contended that the nodes corresponded to a cycle of growth during the vegetative season, and supported his views by measurements supplied by Dr. F. J. Lewis.—Rev. T. R. R. **Stebbing**: Historic doubts about Vaunthompsonia. The author pointed out that the number of the *Natural History Review* for July, 1858, was received by the British Museum at the date stamped as "16 JY 58," thereby proving its priority over Vaunthompsonia.

Mathematical Society, March 14.—Mr. J. E. Campbell, vice-president, in the chair.—G. T. **Bennett**: The cubic surface as a degenerate quartic.—E. B. **Elliott**: Differential operators which generate all seminvariants and all ternary covariant sources.—W. H. **Young**: Goursat's form of Cauchy's theorem (informal).

Mineralogical Society, March 12.—Prof. W. J. Lewis, F.R.S., president, in the chair.—Dr. G. F. Herbert **Smith** and F. N. A. **Fleischmann**: The zeolites from Killyflugh and White Head, Co. Antrim. Chabazite occurs in three different kinds of crystals and gmelinite in two, and the former is found pseudomorphous after calcite. Analcite occurs in clear trapezohedra, and natrolite in fine needles. The character of the occurrences was described.—Dr. J. **Drugman**: Quartz twins. Further specimens of bipyramids, twinned on the primary rhombohedron, from the Esterel, France, were shown, thus establishing this mode of twinning, which was first described by Q.

Sella in 1858. From the same locality were shown also bipyramids twinned on $\xi(11\bar{2}2)$, in which, too, the prism is absent, and there is no flattening perpendicular to the twinning plane, as in the Dauphiné and Japanese specimens.—T. V. **Barker**: Note on the optical properties of mercuric iodide. Preliminary determinations by means of two 30° prisms gave 2·746 and 2·447 as the values of the ordinary and extraordinary refractive indices for sodium, and 2·566 and 2·357 for lithium light, respectively, the degree of accuracy being about 0·002. More accurate values are anticipated when better prisms have been prepared, but the results so far obtained suffice to show that the double refraction and colour dispersion are remarkably large in amount.—Arthur **Russell**: Notes on the minerals and mineral-localities of Shropshire. The occurrences of thirty-two species, excluding rock-forming minerals, were described. Calcite was obtained at Snailbeach Mine, Minsterley, in splendid crystals of varied habit, among others being large, pale mauve rhombohedra twinned on $c(111)$, and opaque, white, prismatic crystals twinned on $r(100)$. Very large crystals of barytes and fine crystals of calcite came from Wotherton Mine, Chirbury. The occurrence of pyromorphite and witherite at several localities was noted.—Dr. Emil **Hatschek**: A series of specimens and lantern-slides illustrative of some reactions in gels. An inorganic gel (silicic acid) was used, and the compounds resulting from the diffusion in it of several solutions were shown; there was a tendency to banding in the upper part of the precipitate, while spherulitic growths appeared in nearly every case.—W. Campbell **Smith**: A spherulitic dolerite from Vryheid, Natal. The rock was interesting on account of the size and beauty of the spherulites, which are revealed on the weathered surfaces.

Royal Anthropological Institute, March 19.—Mr. Alfred P. Maudslay, president, in the chair.—Dr. C. S. **Myers**: Primitive music. The chief objects and methods of studying the music of primitive peoples were described, illustrated by examples from Borneo (Sarawak), Torres Straits (Murray Islanders), and Ceylon (Veddas). The music of the Murray Islanders and of the Todas was analysed to show (1) the wide difference even between such very simple forms of music belonging to two distant peoples; (2) the different lines of musical development traceable within different communities; (3) the great importance, alike for ethnology and for musical history, of studying the process of diffusion of the various styles of music and also of musical instruments, in regard to their form, their intervals, and their absolute pitch.

Edinburgh.

Royal Society, February 19.—Prof. Ewart, F.R.S., vice-president, in the chair.—Dr. Thomas **Scott**: The Entomostraca of the Scottish National Antarctic Expedition. The collection consisted chiefly of Copepoda, of which there were 145 species, three parasitic, the rest free-living. Sixty-two species, including one new variety, belonged to the suborder Calanoida. The Harpacticoida were represented by forty-one species, twenty-eight being new, with two new genera, almost all taken in or near Scotia Bay, South Orkneys. There were twenty-seven species (three new and one new variety) of Cyclopoida, and one species of Caligoida. The Cladocera in the collection were represented by two species of Evadne. There were twenty-two species of Ostracoda, of which fourteen (ten new) were collected in Scotia Bay.—Dr. W. E. **Hoyle**: The Cephalopoda of the Scottish National Antarctic Expedition. Six species were taken off South Africa, four (one new) off South America, and four were Antarctic, being obtained near Scotia Bay. The new species of Polypus, *P. Brucei*, was represented by a single male specimen from the Burdwood Bank, off Tierra del Fuego. Male and female specimens of *Moschites charcoti*, examples of which have been only once previously recorded, were taken in Scotia Bay.—Prof. W. A. **Herdman**: The Tunicata of the Scottish National Antarctic Expedition. The collection was a large one, characterised by the abundance and large size of individuals, by the excellent preservation of the specimens, and by morphological variations. Of the Ascidiaceæ (simple and compound), there were sixteen different species (one new) in six families of six genera, mostly obtained from the Falkland and South Orkney Islands. The new species, *Fungulus antarcticus*, was a deep-sea form obtained in lat. 64° S. at a depth of 2485 fathoms. The rare genus Fungulus is represented by only another solitary specimen, *F. cinereus*, Herdman, got by the *Challenger* at 1600 fathoms' depth in lat. 46° S. between the Cape of Good Hope and Kerguelen Island, at least 3000 miles distant from where the new species was found.—Prof. Andrew **Gray**: General dynamics. Note I.: Hamilton's partial differential equations and the determination of their complete integrals. The partial differential equations were deduced directly from the canonical equations, and important use was made of the second partial differential equation which is satisfied by the function S', a function which has been comparatively little used. Some interesting relations between the functions S and S' were established, and were utilised in applications.—Prof. Sutherland **Simpson**: An investigation into the effects of seasonal changes on body temperature. The experiments were made with 114 domestic fowls, six different breeds being represented. In a general way the body temperature followed that of the external air, being lowest in the winter months and highest in the summer months. The barometric pressure had no influence. The curve of egg-production reached its highest level in April and May; and in general it was found that cyclical body changes had little or no effect on body temperature as compared with outside influences.

Manchester.

Literary and Philosophical Society, February 20.—Prof. F. E. Weiss, president, in the chair.—Prof. W. H. **Lang**, F.R.S.: Branching in the Ophioglossaceæ. The branching in Helminthostachys was shown to be related to the vestigial buds discovered by Gwynne-Vaughan. The vascular supply to the branch was connected with the stele of the rhizome, and not with the subtending leaf-trace. Vestigial buds are also constantly present in the axils of the leaves of *Botrychium lunaria*, and may have a vestigial vascular supply derived from the margins of the subtending leaf-trace. When a branch develops, its vascular supply is from the leaf-trace, and not from the stele of the stem. The branches that occur occasionally in Helminthostachys and Botrychium are not "adventitious," but originate from these dormant axillary buds. They are comparable with the branches of the Hymenophyllaceæ and Zygopterideæ, and their structure strengthens the probability of a relationship between the Ophioglossaceæ and the latter group.—T. G. B. **Osborn**: Recent investigations into the nature of the moulds which attack exported cotton goods. Several common fungi and bacteria were found infecting the goods.

March 5.—Prof. F. E. Weiss, president, in the chair.—R. L. **Taylor** and Clifford **Bostock**: The action of dilute acids on bleaching powder. In these investigations a method originally described by Taylor was used for distinguishing between free chlorine and hypochlorous acid, and, in a mixture of the two, determining their relative amounts. Bleaching powder was distilled with varying amounts of different acids, together with a considerable amount of water. Hydrochloric, sulphuric, and nitric acids act pretty much alike, giving off, with comparatively small amounts of acid, almost pure hypochlorous acid, but, with larger amounts of acid, mixtures of hypochlorous acid and chlorine, and finally nothing but chlorine. Acetic and phosphoric acids act in the same way with small amounts of acid, but the hypochlorous acid never entirely disappears, even with large quantities of acid. When bleaching powder is distilled with boric acid (and a sufficient amount of water), practically pure hypochlorous acid is produced, even when the boric acid is used in comparatively large quantities. Although at the ordinary temperature carbon dioxide liberates nothing but chlorine from bleaching powder, as the temperature is raised hypochlorous acid begins to be evolved, mixed with chlorine, and when the liquid is actively boiling practically pure hypochlorous acid is produced.—Dr. A. **Holt**, Dr. **Edgar**, and Mr. **Firth**: Sorption of hydrogen by pallidium. Experiments lead to the following conclusions: (1) Pallidium is not always in a condition in which it will absorb hydrogen, but it can be made to do so by heating to about 400° C. in either air or *in vacuo*. The power of picking up gas dies away with time, and cannot be restored unless the metal is reheated. (2) Hydrogen is first condensed on the surface of the metal (*ad*sorbed layer), and then gradually diffuses inwards (*ab*sorption). It is possible to get the metal either saturated outside and with no gas in the interior, or saturated in the interior and not on the surface. (3) Diffusion of hydrogen through the metal begins at about 120° C., and increases in rate with rise of temperature. The same temperature does not, however, always produce the same rate, as it depends somewhat on the state of the metal. The rate does not obey any simple law of diffusion or effusion.

PARIS.

Academy of Sciences, March 4.—M. Lippmann in the chair.—A. **Lacroix**: The granular rocks intrusive in the basaltic breccias of Reunion. Their importance in the interpretation of the origin of the homogeneous enclosures of the volcanic rocks. The author has been led by a study of the *massif* of the Piton des Neiges at Reunion to modify his views on the formation of the enclosures, and considers that they must be regarded as having been formed in the volcano itself and not consolidated at great depths. MM. **Leclainche** and **Vallée**: The specific treatment of wounds. Details of the preparation of a polyvalent serum for the treatment of wounds, and a preliminary account of the results obtained by its use.—Emile **Belot**: The formation of the lunar craters with experimental reproduction. Frédéric **Riesz**: Some points in the theory of summable functions. MM. **Papin** and **Rouilly**: The gyropter. A description of a helix for use in aërostats, driven by reaction and having no mechanical connection with the motor.—A. **Grumbach**: The detection of very small quantities of material by the direct electrometric method.—Pierre **Achalme**: The function of interatomic electrons in electrolysis.—Georges **Baume** and Néoptolème **Georgitses**: The fusibility curves of some volatile binary systems at very low temperatures. The binary systems investigated were hydrogen chloride-hydrogen sulphide, hydrogen chloride-ethane, and hydrogen chloride-propionic acid. The melting points of these mixtures were studied down to -170° C., and the results given as curves.—A. **Faucon**: The rotatory power of camphor dissolved in carbon tetrachloride as a function of the concentration. An expression has been deduced from the experiments giving the rotatory power of solutions of camphor in carbon tetrachloride. The influence of temperature on the rotation has also been studied.—A. **Recoura**: The complex ferric compounds. Ferric fluoride.—A. **Magnan**: The weight of the stomach in mammals.—Mieczyslaw **Oxner**: Experiments on memory and its duration in marine fishes. The experiments were carried out with freshly caught specimens of *Coris julis* and *Serranus scriba*; these fishes were able to remember colour, and the memory lasted not less than twenty-five days.—O. **Dubosq** and Ch. **Lebailly**: The spirochæta of fishes.—M. **Sollaud**: The metamorphoses of *Leander serratus*.—Raphael **Dubois**: Clasmatosis of the shell and pearl: its function in the formation of the mollusc shell and of pearls. The formation of pearls cannot be traced to a single cause, and the author concludes that the mechanism of the formation of the shell and the pearl is the same. The mechanism consists fundamentally in the formation of two secretions. It results from these researches that there are two modes of pearl formation, one parasitic and the other non-parasitic.—Michel **Cohendy**: Experiments on life with pure cultures following on aseptic life. In a previous paper the author has described the growth of fowls raised under absolutely aseptic conditions. In some cases the bird was accidentally contaminated with micro-organisms, and these cases have been kept under observation in order to see how they affected the development. The result showed that the sterile chicken is not abnormally sensitive to microbial action. It would appear, however, that a bacterium innocuous to the non-aseptic bird may become pathogenic to the aseptic bird.—Alfred **Carpentier**: The discovery of a Psaronius with a well-preserved structure in the lower Westphalian in the north of France.—P. E. **Dubaleu**: The warm springs of the department of the Landes.

BOOKS RECEIVED.

Über die Luftsäcke der Vogel. By F. E. Schulze. Pp. 36+plate. (Jena: G. Fischer.) 1.60 marks.

Experimentelle Studien zur Soma- und Geschlechtsdifferenzieurung. By Prof. J. Meisenheimer. Pp. 28. (Jena: G. Fischer.) 1 mark.

Handwörterbuch der Naturwissenschaften. Edited by E. Korschelt and others. Zweite und Dritte Lieferung. Pp. each 160. (Jena: G. Fischer.) 2.50 marks each.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 2213, Vol. 89] THURSDAY, MARCH 28, 1912 [Price Sixpence

Registered as a Newspaper at the General Post Office.]

ROYAL INSTITUTION OF GREAT BRITAIN.

ALBEMARLE STREET, PICCADILLY, W.

LECTURES ARRANGEMENTS AFTER EASTER, 1912.

Tuesdays.

Edmund Gosse, Esq., LL.D.—Two Lectures on "Algernon Charles Swinburne: His Early Life and Work." On Tuesdays, April 16, 23, at Three o'clock.

Frank Balfour Browne, Esq., M.A.—Two Lectures on "Insect Distribution, with Special Reference to the British Islands." On Tuesdays, April 30, May 7, at Three o'clock.

Professor William Bateson, M.A., F.R.S., Fullerian Professor of Physiology, *R.I.*—Two Lectures on "The Study of Genetics." On Tuesdays, May 14, 21, at Three o'clock.

Professor W. M. Flinders Petrie, D.C.L., F.R.S.—Two Lectures on "The Formation of the Alphabet." On Tuesdays, May 28, June 4, at Three o'clock.

Thursdays.

Professor Arthur W. Crossley, D.Sc., F.R.S.—Two Lectures on "Synthetic Ammonia and Nitric Acid from the Atmosphere." On Thursdays, April 18, 25, at Three o'clock.

Professor J. Norman Collie, LL.D., F.R.S.—Two Lectures on "Recent Explorations in the Canadian Rocky Mountains." On Thursdays, May 2, 9, at Three o'clock.

Professor Howard T. Barnes, D.Sc., F.R.S.—Two Lectures on "Ice Formation in Canada: (1) The Physical Aspect; (2) The Economic Aspect." (The Tyndall Lectures.) On Thursdays, May 16, 23, at Three o'clock.

Professor J. H. Poynting, Sc.D., F.R.S.—Two Lectures on "The Pressure of Waves" (Experimentally Illustrated). On Thursdays, May 30, June 6, at Three o'clock.

Saturdays.

Reginald Blomfield, Esq., A.R.A., M.A.—Three Lectures on "The Architecture of the Renaissance in France, 1494–1661." On Saturdays, April 20, 27, May 4, at Three o'clock.

H. Plunket Greene, Esq.—Three Lectures on "Interpretation in Song" (with Vocal Illustrations; Accompanist, Mr. S. Liddle). On Saturdays, May 11, 18, 25, at Three o'clock.

Willis L. Moore, Esq.—Two Lectures on (1) "The Development of Meteorological Science"; (2) "The Utilities of Meteorological Science." On Saturdays, June 1, 8, at Three o'clock.

Subscription (to Non-Members) to all Courses of Lectures (extending from Christmas to Midsummer). Two Guineas. Subscription to a Single Course of Lectures, One Guinea, or Half-a-Guinea, according to the length of the Course. Tickets issued daily at the Institution, or sent by post on receipt of Cheque or Post-Office Order.

Members may purchase not less than Three Single Lecture Tickets, available for any Afternoon Lecture, for Half-a-Guinea.

The Friday Evening Meetings will be resumed on April 19, at 9 p.m., when Mr. Alan A. Campbell Swinton will give a Discourse on "Electricity Supply: Past, Present and Future." Succeeding Discourses will probably be given by Sir George H. Darwin, Mr. W. C. Dampier Whetham, Professor W. Stirling, Mr. W. Duddell, Professor Howard T. Barnes, Sir William MacEwen, and other gentlemen. To these Meetings Members and their Friends only are admitted.

Members are entitled to attend all Lectures delivered in the Institution, the Libraries, and the Friday Evening Meetings, and their Families are admitted to the Lectures at a reduced charge. Payment: First Year, Ten Guineas; afterwards, Five Guineas a Year; or a composition of Sixty Guineas.

Persons desirous of becoming Members are requested to apply to the Secretary.

THE SIR JOHN CASS TECHNICAL INSTITUTE,

JEWRY STREET, ALDGATE, E.C.

Principal - - Charles A. Keane, D.Sc., Ph.D., F.I.C.

The following Special Courses of Instruction will be given during the Summer Term 1912:—

BIOLOGICAL CHEMISTRY.

By ARTHUR R. SMITH, M.Sc., F.I.C.

A Course of Practical Instruction suited to the requirements of Candidates for the Final Examination of the Institute of Chemistry in Biological Chemistry (Branch F), and of those engaged in work connected with the manufacture and control of foodstuffs.

The class will meet on Mondays from 7 to 10 p.m., and also on Tuesdays and Wednesdays from 7 to 10 p.m., so as to allow a choice of evening for the second attendance, commencing on Monday, April 15, 1912.

GENERAL PHYSICAL CHEMISTRY.

By G. SENTER, D.Sc., Ph.D.

A Course of Lectures followed by practical work arranged to meet the requirements of those engaged in Chemical and Electrical Industries who desire to obtain a knowledge of the methods of modern Physical Chemistry and its applications.

Wednesday evenings, 7 to 10 p.m., commencing Wednesday, April 17, 1912.

Detailed Syllabus of the Courses may be had upon application at the office of the Institute, or by letter to the Principal.

SOUTH-WESTERN POLYTECHNIC INSTITUTE,

MANRESA ROAD, CHELSEA, S.W.

Day Courses in preparation for London University degrees in Mechanical and Electrical Engineering, in Chemistry, Physics and Natural Science.

Session Fee, £15. Similar *Evening Courses*, Session Fee, £3 10s.

Technical Day Courses arranged to extend over 3 years and prepare for Engineering, Electrical, Chemical and Metallurgical professions.

Mathematics	*W. H. Eccles, D.Sc.; *J. Lister, A.R.C.S.
Physics	*S. Skinner, M.A.; *L. Lownds, B.Sc., Ph.D., *F. W. Jordan, B.Sc., and C. F. Hogley, B.Sc.
Chemistry	*J. B. Coleman, A.R.C.S.; *J. C. Crocker, M.A. D.Sc., and *F. H. Lowe, M.Sc.

* Recognised Teacher of the University of London

Prospectus from the Secretary, post free, 4*d.*; at the Office, 1

Telephone: 899 Western. SIDNEY SKINNER, M.A., Principal.

UNIVERSITY OF MANCHESTER.

FACULTY OF MEDICINE.

(Including the Dental, Pharmaceutical and Public Health Departments.)

The SUMMER SESSION will commence on TUESDAY, APRIL 23 when the Registration of Students will begin at 9.30 a.m.

Lectures and Practical work will begin on Wednesday the 24th.

The Courses of Instruction, which are open to Men and Women Students also meet the requirements of other Universities and Examining Bodies.

Clinical Instruction.—In association with the University there are Hospitals containing over 1000 beds. The New Royal Infirmary, which stands in close vicinity to the University, and which contains 492 beds, offers unrivalled opportunities for Clinical Study. The New Dental Hospital, which is also adjacent to the University, provides every modern requirement for the teaching of Dentistry.

There are Halls of Residence both for Men and Women Students.

Prospectuses as to Courses of Study and Examinations will be forwarded on application to the Registrar.

THURSDAY, MARCH 28, 1912.

GABRIEL LIPPMANN.

Savants du Jour: Gabriel Lippmann. Biographie, Bibliographie Analytique des Écrits. By Ernest Lebon. Pp. viii+70. (Paris: Gauthier-Villars, 1911.) Price 7 francs.

UNDER the able editorship of M. Lebon, who enjoys a considerable reputation in his own country as a mathematician and mathematical astronomer, the enterprising firm of Gauthier-Villars is engaged in bringing out a series of monographs on the lives and achievements of the contemporary men of science of France. Up to the present the numbers published deal with the scientific careers of MM. Poincaré, Darboux, Picard, and Appell. Each memoir occupies from 70 to 80 large 8vo pages, printed on thick hand-made paper with ample margins, and containing a photogravure portrait of its subject, the whole constituting a remarkably handsome work well worthy of the reputation of the eminent publishing house concerned in its production.

The number before us treats of the life-work of Prof. Lippmann, the distinguished professor of physics of the faculty of science in Paris, member and vice-president of the Academy of Sciences, commander of the Légion d'Honneur, Nobel Laureate, and a foreign member of the Royal Society. M. Lippmann is known to all physicists more especially by his work on electro-capillarity, by his enunciation of the law of the conservation of electricity, and his notable contributions to the science and practice of colour photography. He is, however, the author of numerous memoirs in all branches of physics pure and applied. He has occupied himself in turn with the study of the phenomena of capillarity, Carnot's functions, the application of Coulomb's law to electrolytes, electrical measurements, the determination of the ohm, and the theory and mode of use of seismographic apparatus—a range of subjects which well serves to illustrate the many-sidedness of the man and the catholicity of his studies.

M. Lippmann, although born of French parents—his father was of Lorraine and his mother from Alsace—owes much of his inspiration to German influence. On the conclusion of the war of 1870 M. Lippmann had the courage to repair to Heidelberg, where he was welcomed by Kühne, Kirchhoff, Koenigsberger, and Lossen. In the first instance he was attracted by the problems of physiological chemistry, and worked with Kühne on the albuminous phosphates. But he soon abandoned chemistry for physics, and, entering Kirchhoff's laboratory, took up the study of electro-capillarity, which eventually culminated in his well-known memoir of 1875. He graduated at Heidelberg, and after a year at Berlin, under Helmholtz, he returned to Paris and became attached to the physical laboratory at the Sorbonne, then under the direction of Jamin, whom he eventually succeeded. The physical laboratory of the Sorbonne in those days was a wretched affair, consisting of some sheds and two or three rooms on the ground floor of a house in the Rue Saint-Jacques. M. Lippmann is far better housed to-day, but he has still a tender regard for the old shed in which he had worked with such signal success for upwards of twenty years.

M. Lebon's biographical notice is executed with taste and discrimination. Much of M. Lippmann's work has dealt with problems of the hour, and it has occasionally happened that he has been assailed by questions of priority, especially by certain English authorities. But M. Lebon deals with these matters impartially, and with an obvious desire to mete out strict justice to all concerned.

The analytical bibliography which necessarily constitutes a large part of M. Lebon's memoir has been carefully edited, and will be of great use to those to whom M. Lippmann's many publications are not readily accessible. M. Lebon's work is in every way a worthy contribution to contemporary scientific biography and a record of brilliant achievement, and as such we heartily congratulate both him and its subject on its appearance.

JOTTINGS OF A SPORTSMAN-NATURALIST.

Stalks in the Himalaya. Jottings of a Sportsman-Naturalist. By E. P. Stebbing. Pp. xxviii+321. (London: John Lane; New York: John Lane Company, 1912.) Price 12*s.* 6*d.* net.

IN a book with a title and sub-title of such import, there are certain things that one expects to find.

The naturalist—or even the plain unlabelled son of Adam—who has lifted up his eyes to the hills, and has considered the manifold works of the Lord therein revealed, looks for some brief account of their physical features, and of the ways in which these are being changed or confirmed by sun and frost and rain; for some brief account of their fauna, if not also of their flora, and of any adaptations or variations, or seasonal changes that can be discerned or suspected; for some occasional observations and well-founded reflections upon the general facies of the fauna of a tract where two great zoogeographical regions meet and overlap. If he be a naturalist of the old-fashioned kind, he will hope, when he eagerly opens a book dealing with the Himalayas, to catch some echo of the music of their melting snows and of their "wood-notes wild"—the scream of the marmot, or the joyful noise of the Dipper (Cinclus) heard above the turmoil of its native waters. He will hope for a few glimpses of their forest-clad buttresses, here aflame with rhododendron or with wild-rose, there dripping with orchid and lichen and moss; now standing out sharp as a two-edged sword, now engulfed in rolling billows of mist. He will hope to catch some reflection of the magic light of their blue and purple valleys.

The sportsman, on the other hand, will expect a good contour map of the country, some remarks on ways and means, on times and seasons, on weapons and kit, on shikaris and guides, and on a multitude of little things, like the effects of a rarefied atmosphere upon wind, eye, and judgment.

But in these Jottings of a Sportsman-Naturalist what the naturalist will find are some very ordinary descriptions of some of the larger mammals that live on the Himalayan slopes, served up along with accounts of certain open-air manœuvres by the author. Each animal is brought upon the stage, usually with some stereotyped introduction, such as "Have you ever had a chance of critically examining a large male serow upon the mountain side?" or "What a fine beast is a noble old ram"; and all the labours of the chase are duly emphasised.

The author describes well-known animals, such as the goral, the serow, the tahr, the markhor, the bharal, the urial, and the black bear, which he (like scores and scores of other men) has seen and followed and shot; the Kashmir stag and the brown bear, which he saw at a distance; and the snow-leopard, the ibex, and the so-called Sikkim stag, which he did not see. All these animals (except the Sikkim stag unseen of the author) have been fully described, again and again, though the author does not mention the fact, by Hodgson, and Blyth, and Jerdon, and Blanford—to name only a few of his many illustrious predecessors. Beyond mammals, he makes some remarks on the jungle-crow, and describes the colouring of three species of pheasants. He also gives several pages to "the lizard of the Himalaya," which he characterises as "an impudent and corpulent little beggar," and caricatures as a "paterfamilias" living with a "spouse," and chastising "a young hopeful."

Nor will the sportsman find much to please him. British officers, of course, have sometimes to be angry and sin, but one does not like to read of a sportsman constantly "turning angrily" upon his shikari, and being followed by grumbling orderlies, and congratulating himself that the rifle (luckily loaded) is in his own hands instead of in those of the enraged guide, and complaining because a rest-house is pre-occupied by people who appear to be extremely civil and considerate. And to all who know Indian servants, how staunchly they stand by their master in times of discomfort, it is positively painful to read of a sportsman whose servant reports unpleasant news "with a note of evil joy in his voice," and tells his weary and hungry master that there is no dinner because no specific order for that meal has been given. This is not the native servant that we all know. Most old Indians can tell of servants who would give and lose all rather than be untrue to their salt.

There are also little things in which the author is perfunctory. That famous old Himalayan shikari General A. A. Kinloch is always referred to as "Kinlock"; that Nestor of Indian naturalists the late W. T. Blanford is referred to once by his proper name, once as "Blandford"; and Dr. Syntax is several times outraged—as in the sentence, "Two essentials are absolutely necessary for he who," etc.

A book professing to deal, however informally, with natural history and wild sport must, quite apart from any literary standard, be also measured by other standards—educational, scientific, philosophical, or technical. By any of these standards this book cannot be classed. About the best thing in it is a plate of a range of snows, facing p. 30, and this is spoilt by a fancy label that leaves the locality unmentioned.

HYDRAULICS.

A Treatise on Hydraulics. By Prof. H. J. Hughes and A. T. Safford. Pp. xiv+505. (New York: The Macmillan Co. London: Macmillan and Co., Ltd., 1911.) Price 16s. net.

In a country so favourably situated for the utilisation of hydraulic power as is the United States, the growing interest in the study of the science of hydraulics, as marked by the rapidly increasing number of text-books on the subject, is not to be wondered at. The book under review is the joint production of the assistant professor of civil engineering and of the lecturer in hydraulic engineering at Harvard University, and is written as a text-book for university students.

An introductory chapter, dealing with the various units involved, is followed by three chapters devoted to hydrostatical problems. In this section, which occupies a somewhat large proportion—some seventy pages—of the book, the questions of the pressures on plane and curved surfaces, sluice gates and masonry dams, the thickness of pipe walls, and the equilibrium of floating bodies are adequately discussed, while a brief mention is made of piezometers and differential gauges.

Chapter v., which introduces the subject of fluids in motion, is very short and rather disappointing, Bernoulli's theorem, on which practically the whole science of hydraulics is founded, being introduced without any attempt at even an elementary and approximate proof of its truth.

Chapter vi. discusses briefly the flow of water, touching on the questions of hydraulic gradient, critical velocity, methods of measurement, and resistance to flow. In this connection the bald statement that in channels the resistance decreases with a rise in temperature certainly requires modification. In chapters vii. and viii. the Pitot tube and the Venturi meter are very adequately treated.

In chapter ix., dealing with orifices, the theoretical treatment is anything but scientific. The method adopted, common in the older text-books, consists in assuming that at all points at the same depth in the plane of an orifice, the velocity of efflux is the same, being that corresponding to the head of water above the point, and that the direction of flow at each point is perpendicular to the plane of the orifice. The discharge so obtained is then multiplied by an empirical constant to give the true discharge. Both assumptions are fundamentally unsound, and although the method leads to the usually adopted formulæ, its limitations should certainly be pointed out in any book intended for students. The chapter concludes with a good collection of experimental data, and is followed by a chapter on mouthpieces, including converging and diverging tubes, the experimental data in which are not quite so up to date. Chapter xi. is devoted to a discussion, extending over twenty pages, of Freeman's experiments on fire nozzles.

In chapter xii. the theoretical treatment of weir flow follows on similar lines to that of flow from orifices, but this is followed by a well-written discussion of the experiments and empirical formulæ of Francis, Bazin, Fteley and Stearns, and Smith, and of the United States Deep Waterways experiments on rectangular weirs. Triangular weirs and the trapezoidal weir are then considered, but broad-crested weirs are very briefly dismissed to a table in the appendix. Chapters xiii. and xiv., dealing with float and current-meter work, are good.

In chapter xv., the resistances to pipe flow and the losses at bends and valves are considered. The various exponential formulæ for pipe flow are practically ignored, the Chezy formula being the only one to receive detailed attention.

A good list of experimental data concludes a somewhat disappointing chapter. The flow in open channels is treated in the next chapter, the formulæ of Chezy, Kutter, and Bazin being well discussed. The forms of channel giving best results are given, without, however, any proof that these really are the best forms.

Chapter xvii. is devoted to the impact of water on fixed and moving vanes, and to water hammer. In the latter connection, no attempt is made to develop the simple formula for the rise of pressure following sudden stoppage of motion in a rigid pipe line, while the statement that the intensity of hammer pressures depends primarily on the volume of water in the pipe certainly needs amplification.

The final chapter deals with turbines and centrifugal pumps. The main outlines of the theories of the impulse wheel and of the reaction turbine are stated lucidly, and are illustrated with reference to actual examples. It was surely, however, a mistake to chose the 1895 Fourneyron turbines at Niagara for special mention as modern machines. The chapter is concluded by a very brief discussion, extending over three pages, of the centrifugal pump.

The impression left on the reviewer's mind is one of unevenness. The treatment of the fundamental theorems, on which, as a foundation, the science is built up, leaves a great deal to be desired, and as the book is intended primarily for students this is a matter of great importance. Those parts of the book which deal with experimental data are in general good, and in the hands of an instructor who would elaborate the foundation work it should give good results. The book is clearly printed and well illustrated.

A. H. G.

A HUNTER IN THE UPPER YUKON RANGES.

The Wilderness of the Upper Yukon: a Hunter's Explorations for Wild Sheep in Sub-Arctic Mountains. By Charles Sheldon. Pp. xxi+354. (London: T. Fisher Unwin, 1911.) Price 12*s.* 6*d.* net.

THE volume before us is essentially a hunter's book, and will be most appreciated by those to whom all incidents of the chase are gratifying. Nevertheless, in Mr. Sheldon the crude hunter is blended and tempered with the field-naturalist, so that his range of observation often goes beyond the requirements of sport. Also, as a hunter, on this occasion he took up the *rôle* of specialist, and set out to kill selectively and not indiscriminately. His quarry was the mountain sheep of the Upper Yukon basin; for it was incidentally his object to clear up the relationship of the local varieties or subspecies of this animal. In the event he is able to show that the three forms *Ovis dalli, O. fannini, and O. stonei* merge imperceptibly into each other.

The main hunting-grounds described in the book lie in three separate parts of the little known mountainous country forming the eastern side of the Upper Yukon basin, and in each case the author believes that he broke new ground. His descriptions of the wild life of the region are touched in graphically, yet with due restraint; while the physical features of the land are readily deducible from the narrative and from the accompanying illustrations.

It is inevitable in a book of this type that there will be passages likely to give pain to a reader to whom the slaughter of wild animals is repellent. For instance, anyone but a toughened hunter may wince, after reading of the killing of a she-bear, to find mention of "the wailing of the cub pealing wildly through the mists above" among the author's night-impressions that brought to him "the wild enchantment of the wilderness" (p. 30). In recording another and still more painful incident of the chase, the author himself is moved to consider the singular psychology of the hunter-sportsman in whom "an intense fondness for the wild animals" is combined with "his paradoxical love of hunting and killing them" (p. 46). Is it not, indeed, just one among the many of men's doings in which there is a present-day clash between old-rooted instincts and new-born sympathy, with instinct proving in most of us, as yet, the stronger?

One of the author's journeys was made in companionship with another mighty hunter, Mr. F. C. Selous, who has already published an account of the trip. Thus, in a few instances, the sportsman-reader can refer to two separate and independent narratives of the same chase.

The author's sincere eulogium on the ably-recorded exploratory work of the late Dr. G. M. Dawson, of the Geological Survey of Canada, on the head-waters of the Yukon (pp. 185–7), will be read with pleasure by all who cherish the memory of that most capable and indomitable man.

Besides its numerous photographic illustrations of the usual type, the book is embellished with some spirited coloured pictures of animal life, by C. Rungius. The appendices include a short bibliography; a list of animals; a reprint of the original descriptions of northern sheep; and a table of horn-measurements.

HANDBOOKS ON ANALYTICAL CHEMISTRY.

(1) *Huiles Minérales: Pétroles, Benzols, Brais, Paraffines, Vaselines, Ozokérite.* By Henri Delahaye. Pp. 215. (Paris and Liège: Ch Béranger, 1911.) Price 4 francs.

(2) *Matières Tannantes Cuirs: Gélatines, Colles, Noirs, Cirages.* By L. Jacomet. Pp. 249. (Paris and Liège: Ch. Béranger, 1911.) Price 5 francs.

(3) *Soude-Potasse-Sels: Dénaturation des Sels.* By P. Méker. Pp. ii+245. Paris and Liège: Ch. Béranger, 1911.) Price 5 francs.

(4) *Alcools: Alcool, Alcool Dénaturé, Dénaturants.* By M. Louis Calvet. Pp. viii+376. (Paris and Liège: Ch. Béranger, 1911.) Price 6 francs.

(5) *Les Matières Cellulosiques: Textiles Naturels et Artificiels Pâtes à Papier et Papiers.* By Prof. F. J.-G. Beltzer and J. Persoz. Pp. xv+454. (Paris and Liège: Ch. Béranger, 1911.) Price 7.50 francs.

(Manuels Pratiques d'Analyses Chimiques. Publiés sous la direction de M. F. Bordas et M. E. Roux.)

THESE five volumes belong to a collection of practical manuals of analytical chemistry produced under the direction of MM. Bordas and Roux; they are intended for the use of French official laboratories, and of technical chemists generally. They give an outline of the chemistry of the products in question, with concise directions for the analytical examinations required. In the case of the first four volumes, the purely chemical matter is supplemented by copies of the official stipulations or fiscal regulations bearing on the use of the various commodities in France, and, in the case of alcohol, in other countries also.

(1) In this work the opening chapter deals with the definition and classification of petroleum products, leading up to the detailed instructions for their analysis and discrimination. The usual physical and chemical operations required in the technical examination of these products are described, including the determination of the density, viscosity, flashing-point, behaviour on burning, and examination by fractional distillation. Following this comes a section upon the interpretation of the results obtained; this includes a number of examples *in extenso*, illustrating the methods of distinguishing between Russian, American, and Roumanian types of petroleum products. Shale oils, paraffins, mineral waxes, bitumens, and benzols are each accorded a short section; whilst an appendix includes descriptions of certain special methods devised to discriminate Russian from American petroleum, and also to solve the problem—not always a simple one—of

analysing mixtures containing members of both the paraffin and the benzene series of hydrocarbons. Within its somewhat limited scope, the volume is a useful laboratory handbook.

(2) The last remark applies also to M. Jacomet's little work on the chemistry of tanning materials and leather. The recognised methods of examining these products are given, including Proctor's well-known tables for the identification of natural tannins, and those of Andreasch for the recognition of the particular tannin which has been employed in producing a given specimen of leather. In addition, sections are devoted to other substances connected with the leather industry, such as glue, gelatine, gum, and other adhesives, varnish, and polish; these sections are by no means the least valuable. The work is packed with the kind of information which the leather chemist wants in his everyday tasks, and it deserves a cordial word of praise.

(3) More than a third of this volume is taken up by copies of the French fiscal regulations relative to soda and salt. Of the remainder, a substantial proportion has reference to the analytical examination of denatured salt—that is, salt which, to exempt it from taxation, has been rendered unfit for table use by an admixture of various substances, ranging from wallflower essence to sulphate of mercury. For a free trade country this has only a remote interest. The rest of the book contains concise directions for the analysis of sodium and potassium hydroxides, and of such of the salts of these elements as have pharmaceutical or industrial importance.

(4) The "alcohols" which form the subject of this volume are the various forms of ethyl alcohol used in manufactures. Spirituous liquors employed as beverages are excluded. In addition to details of the methods for estimating secondary products (fusel oil, aldehydes, esters, acids) required in the ordinary analysis of commercial alcohol, the chemical matter comprises descriptions of the official methods used in France and other countries for the detection and determination of various denaturing substances. These include methyl alcohol, acetone, "benzine," ether, turpentine, mercuric chloride, pyridine, and so forth. A few unofficial processes are also given, but the author disclaims any attempt at bringing together all the known analytical methods which have been devised for examining alcohol. A chapter which will occasionally be useful to the specialist gives a *resumé* of the legislative enactments concerning industrial alcohol in European countries and in the United States. It has not been brought up to date, however, so far as the United Kingdom is concerned; the "ordinary" methylated alcohol described on p. 63 was abolished more than five years ago, and its place taken by "industrial" alcohol, denatured with five (not ten) per cent. of wood naphtha.

The work includes a number of tables for use in alcoholometry. It is a serviceable volume, but is written, of course, especially from the French point of view.

(5) Considering the small size of this volume, and its other contents, the authors have managed to give in it a very full account of the chemistry of cellulose, so far as we at present know it. The constitution of the cellulose molecule is still a matter of debate, though something substantial has been done towards the elucidation of the problem. In the celluloses and their compounds it has been shown that alcoholic, aldehydic, and ketonic properties exist, and theories of constitution based on these and other facts have been proposed. Useful in a provisional and suggestive sense these theories certainly are, but none are regarded as definitely established, and until the question is settled the chemistry of cellulose must remain a more empirical matter than that of benzene and its derivatives, for example.

The present position can be gathered from the volume under notice, and the authors express the hope that their work will facilitate research by guiding the reader through the maze of published investigations. This it is well calculated to do. It does not, however, deal only, or mainly, with the pure chemistry of the subject. It is essentially a practical treatise, and gives working details of the examinations required in the various branches of the industry. The theoretical side is nevertheless kept in view, and copious references are supplied. In the sections devoted to lignocelluloses and paper there are numerous illustrations of fibres and apparatus.

Judging by the five examples now published, this series of handbooks promises to be a useful and trustworthy one.

C. S.

OUR BOOKSHELF.

An Australian Bird Book: a Pocket-book for Field Use. By J. A. Leach. With introduction by Frank Tate. Pp. 200. (Melbourne: Whitcombe and Tombs, Ltd., 1911.) Price 3s. 6d.

This useful book is intended as a pocket-book for field use to enable teachers and observers generally to name the birds they meet with. It deals with 395 species—a considerable proportion of the Australian avifauna, the balance being made up mainly of birds closely related to those of which illustrations are given, or of very rare birds restricted to a small area. The plan of the book is to indicate by numbers the strength and distribution of the various families of birds over the world in general, and especially in Australia, and to give a concise description of each species. This includes the local name or names (if any); its distribution in Australia; its status—whether stationary or migratory, comparative abundance, &c.; the kind of country it frequents; a short description of its size and plumage, and a few words as to its song or other notes, and its food. All the species are illustrated, and in the majority of cases are figured in colours as well as in black and white. The illustrations are, with few exceptions, from specimens in the National Museum.

In addition to this useful and necessary, but somewhat dry, portion of the handbook, about a third of the little volume is occupied by a most interesting lecture on the Australian avifauna. Thus the book appeals to a much wider class of naturalists than that for which it has been mainly written. For the ornithologists of other countries will find in it an excellent introduction to, and a valuable account of, the birds of a very interesting part of the world. Mr. Tate in his introduction alludes to the growth of a generation trained to look upon the characteristic beauties of Australia with an appreciation almost unknown to their pioneering fathers and mothers, and he combats the popular belief that their birds are songless. An index to the coloured plates and a general index make reference to any particular bird easy.

Unity in Nature: an Analogy between Music and Life. By C. E. Stromeyer. Pp. x+589. (London and Manchester: Sherratt and Hughes, 1911.) Price 12*s.* 6*d.* net.

This is a readable discourse on things in general, from physics and astronomy to ethics and politics. As the title indicates, the author expounds certain musical analogies, such as the relation between intervals in the octave and distances in the solar system; but, after the first few sections, the matter of the book becomes more general. There is a good deal of amusingly-put speculation about the kind of world that a "flatland" of two dimensions would be (as sketched by Mr. Hinton), and this, of course, leads to fourth-dimensional space and what might happen there. Then, after a chapter on sexual ethics in which a more or less Schopenhauerian doctrine is taught—with much apt illustration, historical and geographical—we come to the female suffrage question, on which the author has vigorous opinions. If women get the vote, "there is every probability that female Members of Parliament would soon be elected; these would decide to elect female Prime Ministers, and as Parliament claims to be omnipotent, there is the prospect of having autocratic female rulers" (p. 507). Also on the disproportionate number of lawyers in Parliament Mr. Stromeyer has some cutting and probably justified remarks; and on education he enters a wise protest against too much classicism. The punctuation of the book leaves something to be desired, and on p. 104 "bromide" appears several times when "bromine" is meant; but these are small details. The author shows wide culture and has a pleasant style.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Prof. Bergson and the Eye of Pecten.

I find that Prof. Bergson in his Philosophies has been making use of a comparison between the eye of Pecten, the scallop, and the vertebrate eye. This comparison is used as the basis of some far-reaching conclusions, and therefore it becomes important to direct the attention of readers of Nature to the fact that the example taken is an extremely bad one. Prof. Bergson states that the eye of Pecten agrees in the most minute details with the vertebrate eye. Now there is no resemblance whatever either in structure or development between the two. The only feature possessed in common by both eyes is an inverted retina, and this is by no means unique in the animal kingdom.

W. J. Dakin.

University of Liverpool, March 19.

Mersenne's Numbers.

At various times Nature has inserted notices of the successive discoveries in relation to Mersenne's Numbers. In the issue of August 12, 1909, Colonel Cunningham's discovery that 228479 was a factor of 2^p-1 when $p=71$ was announced: the other factor was 10334355636337793, but whether this was a prime or not was left undetermined. The same result was discovered last January by Mr. Ramesam, of Mylapore, Madras, and he subsequently resolved the larger factor into the product of 48544121 and 212885833. I think these results may be of interest to some of your readers.

W. W. Rouse Ball.

Trinity College, Cambridge, March 23.

The Electrolytic Transportation of the Active Deposit of Actinium through Pure Water.

In the course of some detailed investigations on the conditions of the electrolysis of some radio-active products, I have encountered in the case of actinium the following phenomenon. The products of the active deposit of actinium, though apparently not soluble in water under ordinary conditions, under the action of electric force could be driven from the anode in the state of ions into the water, and eventually transported to the kathode. The experiments were as follows.

The active deposit of actinium was collected on the surface of a platinum plate exposed during some hours as a negative electrode in the emanation of actinium. Immediately after the removal of the plate from the emanation, its activity was measured by means of an electrometer, and the beginning of the curve of its decay was determined. The plate was then immersed in pure, several times distilled water, and formed the anode during the electrolysis of the water. The kathode was also a platinum plate. The activity of the anode was again measured after the electrolysis. It could be seen that the plate was in certain conditions deprived by the electrolysis of a great part of its activity, especially in the case when a very great electromotive force (220 or 440 volts) was applied. If the current passed through the water during a longer time (2 or 3 min.), and the distance between the electrodes was not too great (1 or 2 cm.), a great part and often the total activity lost on the anode could be detected on the kathode. The activity of the kathode proceeded not only from actinium C and probably actinium D, but also the product actinium B was undoubtedly present. (New nomenclature after Rutherford and Geiger, *Phil. Mag.*, 22, p. 621, is used throughout this communication.)

Closer investigations of the conditions of this phenomenon established the fact that this removal of the active products from the anode took place only in the case when the activated plate serving as anode was used during a preceding electrolysis of water as kathode, or, in other words, was previously electrolytically saturated with hydrogen. This saturation of the plate with hydrogen was found as the necessary condition for making possible the removal of the radio-active products from the anode. The atoms of the active deposit were driven under the action of the great applied electromotive force as ions into the pure water. If the plate had been previously sufficiently saturated with hydrogen, and used then as anode, it was possible by applying a great P.D. to drive from it into the water in a few seconds a great part, viz. up to two-thirds, of the active products deposited on it. On the other hand, it was not possible to deprive the plate of its total activity even by applying a P.D. of 840 volts, nor by electrolysis during half an hour. The more detailed results of these investigations will be given elsewhere. TADEUSZ GODLEWSKI.

Lemberg, Physical Laboratory of the Technical High School, March 18.

Autophanous Eyes.

I HAVE been greatly interested by the correspondence lately appearing in NATURE on the subject of eyes gleaming in the dark, and there are one or two points about which I should much like to hear a little more.

With regard to human eyes never glowing, I knew one case some years ago of a young Scotch girl whose eyes glowed with a distinct deep-red light. She was a fair-complexioned girl with auburn hair and the peculiar red-brown eyes which go with that colouring.

On the subject of cats' eyes, can anyone tell me why the glow is invariably red in blue-eyed cats and green with yellow or green eyes, *as the glow is not from the iris, but from the tapetum*? I had a half-Persian cat for years with one blue and one yellow eye, and in the dark they were perfect little "port" and "starboard" lights. The red glow of the blue-eyed cat, whether Persian or Siamese, is a deep ruby (not spinel like a mouse's eyes), and is noticeable even with tiny kittens before the colour of the iris is developed at all.

With Persian kittens it is possible to tell as soon as their eyes are open whether they will have blue or yellow eyes by placing them so that the glow can be seen, *i.e.* with a light in line with the observer's own eyes, those which will later develop a blue iris showing like rubies, and the future yellow or green iris like emeralds. Having at present six Siamese cats (fawn-coloured, with deep-blue eyes) and a Persian (black, with yellow eyes), I have considerable opportunities of observing them.

CHARLOTTE L. WHEELER CUFFE.

Braehead, Kokine, Rangoon, March 1.

THE phenomenon of "glowing" eyes (autophanous or not) is certainly observed in man. Without taking much interest in the matter, I have noticed three cases, one abroad and years ago, and the other two quite recently in London. In Room 10 of the L.C.C. Technical Institute, Dalston Lane, N.E., with all lights switched on, I observed the phenomenon over and over again by standing between the lecturer's table and the front bench and looking down at the student sitting in the middle (who should be looking up at you). I should add that I assumed the matter to be a function of the position after I had seen it in two students; before then I thought it was a peculiarity of the one student. H. DE S.-P.

Sibpur College, Calcutta, March 7.

RAND GEOLOGY.[1]

IN no other part of the world is the work of the geologist linked up with such varied interests as in the little strip—some fifty miles long—of high tableland in the Transvaal known as the Witwatersrand, on which are situated some sixty producing gold-mines with an annual output of 350 *tons* of fine gold, worth 35,000,000*l.*; and, indeed, in no other district has the geologist such opportunities for prosecuting his researches as are afforded by the innumerable prospecting trenches, shafts, and deep borings that have been put down on the Rand in the search of extensions, along the strike and on the dip, of the auriferous conglomerates. Hundreds of thousands of pounds have been spent on prospecting work of this nature. In one area alone near the Springs, in the East Rand, the writer of this review had the technical supervision of a series of deep borings, costing above 30,000*l.*, and successfully located the eastern end of the Witwatersrand syncline, with its valuable gold-bearing seam there concealed beneath a thousand-foot cover of the later unconformable Dolomite formation.

The Transvaal Geological Survey, which, since its reconstruction after the war, has been working mainly in the northern part of the Transvaal, has at last broken ground on the Witwatersrand, and the report for 1910 contains an important instalment of this work, in which Dr. Mellor[2] summarises the results of his mapping of the lower Witwatersrand beds between Maraisburg and Rietfontein, an area including the municipality of Johannesburg and the Bezuidenhout valley, the geological structure of which presents so many points of interest. The main features of this area have long been known: they were sketched broadly by Walcot Gibson in a paper read before the Geological Society in 1892; and the boundary lines of the various subdivisions of the Witwatersrand beds were mapped by Messrs. Hatch and Corstorphine, and published in the Transactions of the Geological Society for South Africa for 1904.

Dr. Mellor's mapping of these subdivisions agrees in the main with that of his predecessors; but he explains the duplication of the lower Witwatersrand beds by a new reading of the faulting, which on his view took place subsequently to the extrusion of the Klipriversburg amygdaloid. His map also records a hitherto unnoticed strip of sheared granite on the farm Rietfontein No. 145, that throws fresh light on the age of the movements responsible for the dislocations. The publication of the further work of the Survey on the Rand, especially at its extreme eastern and western ends, will be awaited with interest.

WESTERN CULTURE IN ANCIENT CATHAY.[1]

In the two magnificent volumes before us, Dr. Stein, the pioneer explorer of the now famous antiquities of the Central Asian deserts, gives us the personal narrative and general results of his last great expedition of 1906–08 to the more eastern deserts of Turkestan and north-western China.

The results achieved far surpass in importance and interest even those of his own former expedition in Western Turkestan, as well as those sent out in the interval by more than one European Government, attracted to that important historical field by Dr. Stein's great discoveries. For again Dr. Stein has been the first to explore systematically the ruins of the ancient settlements along a fresh section of the old-world highway between China and the Ancient West. His unequalled knowledge and equipment for this research, combined with his previous practical experience gained in those deserts, have enabled him to unearth from the protecting sand an astonishing amount of material for reconstructing several lost chapters in the history of the world's early culture. The sites excavated and otherwise explored proved to be connecting links between ancient Chinese civilisation and the classic West, and have revealed a remarkable intrusion of Western elements into the art and mythology of Ancient China.

Amongst these Western elements the Grecian influences are conspicuously prominent. They were obviously introduced about the first century of our era with Buddhism from the Greco-Bactrian provinces of Gandhara (Peshawar), Afghanistan, Swat, &c., to the north of India, in which Buddhism had become established as the State religion by the successors of Alexander's satraps. This school of Greco-Buddhist art, saturated with Western ideals, and known as "Gandhara," after one of its chief centres abovenamed, is represented in many of our museums by its fine friezes and statues obtained from the northern frontier of India. It is now found by Dr. Stein to have extended in the early centuries A.D. nearly two thousand miles further eastwards to the very threshold of China. At Niya, in Turkestan, the Caves of the Thousand Buddhas at Tunhuang in Western Kansu, and elsewhere, on the border of the Gobi Desert, Dr. Stein found a rich statuary had grown up and flourished, which faithfully reproduced the style and motive of the Gandhara, and was even more purely classical Hellenist. Transitional stages in the process of naturalisation on Chinese soil of those exotic influences are also represented, and connect the ancient types with pictorial and decorative art in medieval and modern China, and through the latter with Japan. Indigenous Indian Buddhist art is also present.

Fig. 1.—Ruin of ancient dwelling at southern end of Niya site, in course of excavation. From "Ruins of Desert Cathay."

One of the most dramatic and fruitful incidents in the history of archæological discovery occurred at the temples of the "Thousand Buddhas," where the piety of early times had honeycombed the rocks with hundreds of cave-temples, richly decorated with frescoes and stucco sculptures. Here our author had the good fortune to gain access to a great deposit of ancient MSS. and art relics which had lain hidden and perfectly protected in a walled-up rock chapel for about nine hundred years. Most of these treasures are now deposited by Dr. Stein in the British Museum and India Office, and the remainder was subsequently gleaned thoroughly by M. Pelliot.

The treasures of ancient art and industry recovered during the expedition include some of the actual frescoes and mural paintings, which are now safely deposited in admirable preservation in the British Museum. The infinite pains necessary for the successful transport of these fragile objects may be imagined when it is remembered that the author's caravan had to traverse the most difficult country in the world, and covered an actual distance by land of close on ten thousand miles.

Of the several thousands of ancient MSS. and

[1] "Ruins of Desert Cathay." Personal narrative of Explorations in Central Asia and Westernmost China. By Dr. M. Aurel Stein. Vol. i., pp. xxxviii+546+plates+map. Vol. ii., pp. xxi+517+plates+maps. (London: Macmillan and Co., Ltd., 1912.) Two vols., 42s. net.

other documents on wood, leather, and clay, as well as on paper, thus recovered, some are official secular documents throwing light upon the everyday life and history of that early period. The majority are religious, mostly Buddhist, but also Taoist, Manichæan, and Nestorian Christian; and the writing is in the ancient Indian Brahmi and Kharoshthi characters, in a Sanskritic language, also in Chinese, Tibetan, Sogdian, archaic Turkish, and several are in "unknown" script. The detailed reports on this vast mass of material are under preparation, with the collaboration of experts, and will take several years to complete. Of the geographical results, which gained for Dr. Stein the Founders' gold medal of the Royal Geographical Society, we have an instalment in several excellent maps in the volumes. Scientific observations were also made upon the general desiccation of the area, and the advance of the desert, with the resultant changes in the sites of the settlements under the altered economic environments. A large series of anthropometric measurements was secured, and is to be eventually published.

The personal narrative now chronicled is of fascinating interest. It is told with vivid clearness and in charming style, and through it all we feel the haunting presence of the great deserts. The splendid photographs, taken by Dr. Stein himself, which adorn the book are superb, and many of them reproduce the paintings and frescoes in colours by photomechanical processes with great technical accuracy and beauty.

FIG. 2.—Ruins of small Buddhist stupa and shrine at Kichik-Hassar, Turfan. From "Ruins of Desert Cathay."

The methods of research revealed by these pages are most instructive. The author combines in his personality all those qualities that are essential for the highest achievement in archæological research. A scholar and archæologist of repute with the practical experience, resourcefulness, and physical vigour of the trained explorer, he is able to penetrate to the most remote regions, and, though isolated, yet instinctively to miss no clue or opportunity that may present itself. His sympathetic insight and attitude towards the shy and usually suspicious nomads amongst whom he moved, and on whose assistance he largely depended in his research, won him at every turn the entire confidence of these people, who even became inspired with some of his own abounding enthusiasm. His unfailing tact smoothed over many difficulties; his foresight and business talent in leaving nothing to chance contributed much to the ultimate success of his plans. With inexhaustible energy and devotion in the pursuit of science he bravely and cheerfully faced and endured great privations and actual frostbite.

The magnificent results he has achieved are worthy of such great self-sacrifice. But what is the reward desired by this intrepid scholar, with such unique qualifications for archæological Oriental research? In his concluding sentence he says: "When may I hope that the gate will open for work in those fields to which cherished plans have been calling me ever since my youth, and which still remain unexplored?" It is to be hoped that this appeal in the interests of science may soon be realised. May the Government of India at no distant date enable our author to proceed to Badakhshan and the Upper Oxus region (to the north-west of India) to recover the Western connecting links between the ancient culture of the Orient and the Near East and West, which still await the masterly discovery by such a peerless explorer as Dr. Stein has proved himself to be.

L. A. WADDELL.

NOTES.

A CONSIDERABLE area of "submerged forest" has recently been laid bare at Freshwater West, Pembrokeshire, owing to extensive shifting of sand and shingle by a gale in conjunction with an unusually high spring tide, and has been examined by Lieut.-Colonel F. Lambton. Stumps of trees rooted in place are frequent, embedded in a foot or so of peat covering an old land-surface. No implements appear to have been found, but there is little doubt that the deposit is of the same age, viz. Neolithic, as the similar formation found elsewhere along our coasts.

The vegetable matter has darkened, but shows no other resemblance to coal, the statements in the daily Press on this, as on other points, being erroneous. Much is soft and pulpy, but some is still hard and flexible. In some overlying beach-sand of the same general age, part of the skull of a whale, probably the common rorqual, has been found, together with a great quantity of drift-wood in the same condition as the wood *in situ*. This beach-sand is now partly cemented with pyrites.

THE council of the Iron and Steel Institute has decided to award the Andrew Carnegie gold medal of the institute to Dr. Paul Goerens, of Aachen. Dr. Goerens has made many contributions to scientific metallurgy, and in 1910 he was awarded one of the Carnegie scholarships of the Iron and Steel Institute, to enable him to pursue his investigations on the influence of cold-working on the properties of iron and steel. The gold medal is now awarded to him in recognition of the highly meritorious character of his research work on this subject.

WE regret to see the announcement of the death of Prof. A. Pacinotti, professor of technical physics at the University of Pisa, at seventy-one years of age.

DR. J. C. WILLIS has retired from the post of director of the Royal Botanic Gardens, Peradeniya, Ceylon, and has accepted the appointment of director of the Botanic Gardens (Jardim Botanico) at Rio de Janeiro. He will sail by the *Orcoma* from Liverpool on April 4.

THE death is announced, at the age of seventy-six years, of Prof. Auguste Töpler, who from 1876 to 1900 was head of the physics department of the Technical High School of Dresden, and was the inventor of the well-known mercury pump bearing his name. We also notice the announcement of the death, at sixty-nine years of age, of Prof. Wilhelm Münch, professor of pedagogics at the University of Berlin.

THE death is reported, in his fifty-fifth year, of Dr. John Bernhardt Smith, a well-known American writer on entomology. He was educated for the Bar, and practised as a lawyer for several years. His first scientific appointment was as assistant curator of insects in the United States National Museum in 1886. In 1889 he became professor of entomology at Rutgers College, and in 1894 State entomologist of New Jersey. In the latter capacity he did much to get rid of the mosquito pest in that State.

DR. WILLIAM TRELEASE has resigned his post as the director of the Missouri Botanical Garden, familiarly known in the United States as Shaw's Garden. Dr. Trelease was appointed director of the garden by the late Mr. Henry Shaw, its founder, on the recommendation of Prof. Asa Gray, and has held the position since 1889. The garden is exceeded in size only by Kew Gardens. The director's report for 1909 shows that at the end of that year the garden contained 11,764 species, representing 1777 genera belonging to 197 families. The number of visitors during the same year was 120,748, a number exceeded only in 1907, when the total reached 135,407.

THE tenth annual session of the South African Association for the Advancement of Science will be held in Port Elizabeth from Monday, July 1, to Saturday, July 6, inclusive, under the presidency of Dr. A. Theiler, C.M.G. The sections and their presidents are as follows:—A, astronomy, mathematics, physics, meteorology, geodesy, surveying, engineering, architecture, and irrigation, Mr. H. J. Holder; B, chemistry, geology, metallurgy, mineralogy, and geography, Prof. B. de St. J. van der Riet; C, bacteriology, botany, zoology, agriculture, forestry, physiology, hygiene, and sanitary science, Mr. F. W. FitzSimons; D, anthropology, ethnology, education, history, mental science, philology, political economy, sociology, and statistics, Mr. W. A. Way.

THE annual general meeting of the Ray Society was held on March 14; Dr. B. Daydon Jackson, vice-president, occupied the chair. The report of the council announced a small increase in the membership of the society; the issue of two volumes for the year 1911, "British Desmidiaceæ," vol. iv., and "British Tunicata," vol. iii., completing that work; and that the volumes for 1912 would be a "Bibliography of the Tunicata," by the secretary, and the first volume of "British Parasitic Copepoda," by Dr. Thomas Scott and Mr. Andrew Scott, treating of the copepoda parasitic on fishes, which division of the subject would be completed by the issue for 1913 of an atlas of seventy plates, mostly coloured. The balance-sheet showed the finances of the society to be in a satisfactory condition. The Right Hon. Lord Avebury was re-elected president, Dr. F. DuCane Godman treasurer, and Mr. John Hopkinson secretary.

THE report of the Departmental Committee on Forestry in Scotland has been issued as a Blue-book (Cd. 6085). It will be remembered that the terms of reference to the committee were, among other matters, to report as to the selection of a suitable location for a demonstration forest area in Scotland, the uses to which such an area could be put, and the probable cost. The committee thinks the area should contain at least 4000 acres, including, if possible, 2000 acres already under wood. The plantable land might with advantage amount to 10,000 acres, but, says the report, such an extent, combined with the necessary growing woods, may be difficult to secure. Recommendations are made as to the staff required and to equipment, and so on. No estimate is given of the probable capital expenditure, though the estimate of capital outlay for establishment is placed at 15,500*l*., and the estimate of initial annual expenditure at 2400*l*. Three steps are recommended following on the establishment of a demonstration area for the promotion of sylviculture in Scotland: a flying survey to ascertain the best forest sites and their approximate extent; the appointment of an advising forest officer, with at least one assistant; and the establishment of a limited number of State trial-forests.

In a paper recently contributed to the Proceedings of the British Academy, Mr. D. G. Hogarth discusses certain problems of Hittite history in relation to the excavations now in progress under the control of the British Museum at the mound of Jerablus, the Carchemish of the Old Testament. These excavations are still only in a preliminary stage, but sufficient evidence has already been collected to prove that there were Hittites, or at least Hittite influences, in Syria before its conquest by the king of the Hatti of Boghaz Keui; that the Cappadocian occupation established by the latter did not eliminate the earlier stock at Carchemish, and was not very long-lasting; and that it was succeeded by a period of independence of Cappadocia and dependence upon Assyria, prior to complete conquest by the latter power. The exact relation of this Syrian culture to that of Mesopotamia, Assyria, and the Ægean is a problem on which these important excavations may be expected, at an early date, to throw welcome light.

In an article on megalithic remains in Gloucestershire, contributed to the March issue of *Man* by Mr. A. L. Lewis, the question is raised whether the chambered barrow at Uley was used for the cult of the dead so late as Roman times. This theory was advocated by Mr. W. C. Borlase ("The Dolmens of Ireland," p. 974), who laid stress on the discovery of a Roman lachrymatory in one of the side chambers. Mr. Lewis sees no reason to object to this view, but he points out that Thurnam ("Archæologia," vol. xlii.) speaks only of "a small vessel described as resembling a Roman lachrymatory." It is possible that this may have dropped into the chamber of the barrow from a secondary interment on the summit, the date of which is established by the discovery with the corpse of brass coins of the three sons of Constantine the Great.

Mr. R. Ridgway is to be congratulated on the issue of the fifth volume of his valuable descriptive catalogue of the birds of North and Middle America (published as Bulletin No. 50 of the U.S. National Museum). This volume brings the subject down to the end of the trogons. The number of species and subspecies (apart from certain extra-limital forms) recorded in the five volumes already published is 2038, leaving from about 1150 to 1200 to come.

Bulletin No. 101 of the Entomological Section of the U.S. Department of Agriculture is devoted to an account, by Mr. A. F. Burgess, of the elaborate measures taken to introduce and acclimatise in New England the European ground-beetle, *Calosoma sycophanta*, for the purpose of keeping in check the destructive gipsy and brown-tail moths (introduced inadvertently from Europe), on the caterpillars of which these beetles prey. After much trouble, the acclimatisation has been successfully accomplished.

In the section on marine biology in the Ceylon Administration Reports for 1910–11 and in the January number of *Spolia Zeylanica*, Dr. J. Pearson records the work that has been recently accomplished in connection with the pearl-banks, the windowpane-oyster (Placuna) fishery, and the fresh-water fisheries of the island. For some years past the Placuna beds in Lake Tamblegam have been commercially unprofitable, and a survey of the lake has been accordingly undertaken. This shows that in some parts there are beds of living oysters, while in others only dead shells are to be found, and it is considered that much may be done by transplantation. To make this effective, annual surveys are deemed necessary. Steps are also to be taken for introducing a fresh supply of that valuable food-fish the gurami, as only three survivors of those introduced by Dr. Willey were discovered.

Students of zoology should welcome the appearance of the third and fourth volumes of the delightful little monographs of indigenous animals prepared by Profs. Ziegler and Woltereck (Leipzig: Verlag von Dr. Werner Klinkhardt). The third volume, by Dr. Otto Steche, deals with Hydra and the Hydroids, and is an altogether admirable account of the fresh-water polypes and their marine relatives, including a most useful introduction to experimental biology. The fourth volume is devoted to the edible snail (*Helix pomatia*), which is treated in a very comprehensive and thorough manner. The beautiful coloured frontispieces form one of the most attractive features of these volumes, which are published at four marks each.

Assuming the observations to be trustworthy, a most remarkable case of the efforts of an organism to free itself from a parasite has been recently recorded. In 1910 Mr. O. Schröder (*Zeits. wiss. Zool.*, vol. xlvi., p. 525) described and figured, under the name of *Buddenbrockia plumatellae*, a parasite infesting the body-cavity of polyzoans of the genus Plumatella. At the time the parasite was provisionally regarded as a mesozoan. This determination was, however, on the face of it improbable, seeing that the Mesozoa are a marine group, and the author (*Verk. nat.-med. Heidelberg*, N.F., vol. xi., p. 230, 1912) has recently come to the conclusion that the parasite is in all probability a very degenerate nematode. Be this as it may, the interesting point is that after the parasite has become established in the body-cavity of its host some of the spermatozoa of the latter penetrate the eggs of the former, which thereupon swell up and undergo a kind of degenerate development, until they ultimately perish, the polyzoan thus making use of its male generative products as torpedoes to destroy an enemy. Such a mode of repelling a hostile attack appears quite unknown in any other group of organisms.

The Agricultural Statistics of India for the years 1905–6 to 1909–10 have recently been published at Calcutta by the Department of Revenue and Agriculture of the Government of India. The first volume, a large Blue-book of more than 400 pages, deals with British India; the second, a much smaller one, with the native States. The first section deals with the classification of areas in each district into forest, land not available for cultivation, land culturable but at present waste, and areas cropped; irrigation statistics are also given. In a later section the areas under the various crops are set out. Other sections deal with live stock and implements, incidence of revenue assessment, and transfers of land.

A remarkable instance, caused by a parasitic fungus, of the transformation of the flower into a number of leaf-like organs is described by Mr. S. Kusano in the Journal of the Tokyo Agricultural College (vol. ii., No. 6). The fungus, *Caeoma Makinoi*, infects the young buds of *Prunus Mume*, and causes great malformation of the organs of the flower. In some cases only part of the flower is affected, in others all organs are subjected to more or less complete phyllody. Occasionally flowers of enormous size are produced, which possess not only green leaves brilliantly spotted with the yellow pustules of the fungus, but also leafy shoots. The author describes the phyllody of the different floral organs with great care, and discusses the relation between the development of the fungus and the malformation of the flower. His paper, which concludes with some interesting etiological considerations, forms a valuable contribution to the literature on chloranthy.

In the *Atti dei Lincei*, xxi., 4, Dr. Diana Bruschi contributes some interesting studies on three fungi parasitic on fruits, namely, *Fusarium lycopeisici* on the tomato, *Movilia cinerea* on the plum, and *Fusarium niveum* on the pumpkin. It is found that the toxic action of the fungi is not proportional to the acidity of the extract produced by them, and disappears to a large extent with cooking. The enzymes secreted do not attack the cellulose, but rather the proteins, of the fruits.

The list of geological literature added to the library of the Geological Society of London in 1910 was issued at the close of 1911, price 2*s*. As we have previously pointed out, this annual work is practically an index to the geological publications of the world.

The study of eoliths has assumed such importance that it may not be too late to direct attention to a discussion of the alleged examples of Oligocene age found by A. Rutot on the plateau of Hautes-Fagnes, in Belgium. R. Bonnet and G. Steinmann conclude that they were formed by wave-action in a rapidly advancing sea (*Sitzungsber. vom naturhistor. Verein der preuss. Rheinlande u. Westfalens*, December 6, 1909, pub. 1910). A useful bibliography of some sixty works in French and German on eoliths is appended.

In *Scientia*, vol. xi. (1912), p. 36, Prof. J. W. Gregory discusses "The Structural and Petrographic Classification of Coast-types" in a manner that will appeal both to geographers and to geologists. He succeeds in showing how difficult it is to maintain Suess's original definitions of the Atlantic and Pacific types of coast in the broad regions from which their names were derived, and he criticises the attempt to connect types of igneous rock with types of tectonic structure.

The Weather Bureau of the Commonwealth of Australia has issued in the form of a picture postcard an average rainfall map of the Commonwealth, together with a table showing the comparison between the total area of the United Kingdom and the different rainfall areas shown by grades on the rainfall map of Australia. The map was prepared under the direction of Mr. H. A. Hunt, Commonwealth meteorologist.

"The Value of Non-instrumental Weather Observations" is the title of an interesting article by Prof. R. DeC. Ward in *The Popular Science Monthly* of February. Like some meteorologists in this country, he considers that such observations add greatly to the interest of everyday life, and develop in a surprising way powers of observation which one is unconscious of possessing. In relating his own experiences during a recent period of convalescence, he suggests the study of weather prognostics (comparatively few of which are found to be really good). In emphasising the value of non-instrumental observations, he refers at considerable length to the Journals of the Lewis and Clark expedition to the sources of the Missouri and across the Rocky Mountains in 1804–6, the leader of which was instructed by President Jefferson to report upon the climate according to a scheme drawn up by himself. No more striking illustration of the analogy between the winds of the ocean and those of the plains has been given than Captain Lewis's description of the occasion when one of his boats, which was being transferred on wheels, was blown along, the boat's sails being set. "Both [winds] sweep over a surface of little friction. Both attain high velocities in consequence."

An illustration of the growing importance of mathematics in the study of social and economic problems is afforded by Dr. L. Amoroso's note in the *Atti dei Lincei*, xxi., 4, entitled "Contributions to the Mathematical Theory of Economic Dynamics." In this system an individual is represented by a point capable of moving in a variety of n dimensions, which may represent different forms of wealth, and these are subject to certain equations of condition. From the fundamental premises the author deduces "equations of motion" corresponding to those of analytical dynamics. The first investigations on this branch of study are attributed to Cournot, Jevons, Malras, Edgeworth, Fisher, and, latterly, Pareto.

In a pamphlet called "Studies in Statistical Representation," reprinted from the Journal of the Royal Society of New South Wales, Mr. G. H. Knibbs discusses the application of Fourier's series to the study of fluctuating statistics. The paper deals mainly with the methods of obtaining the coefficients in such expansions, and of correcting for such irregularities as inequality in the lengths of months or years, variations in the time of Easter, and so forth. The author, as illustrating the method, claims to deduce a relation between the temperature and the number of suicides in Australia, but remarks: "The discussion as to whether this relation can be rationalised is really an extra-mathematical one, and is outside the scope of the present paper." A contribution to the higher mathematics of statistics is contained in Prof. C. V. L. Charlier's recent article in the *Arkiv* *for Matematik* on the theorems of Poisson and Lexis.

ACCORDING to an article reprinted from the Proceedings of the Academy of Science of Amsterdam, Prof. Zeeman, in the course of some experiments on the double refraction produced in liquid air by an electric field, has found that liquid air will stand an electric field of 90,000 volts per centimetre. In his double refraction measurements a difference of potential of 17,000 volts was maintained between the plates of a condenser 4·5 centimetres long, 1·0 centimetre wide, and 0·3 centimetre apart immersed in liquid air, and a beam of plane polarised homogeneous light traversed the liquid air between the plates. The phase difference introduced by the double refraction due to the electric field was estimated at 1/300 wave-length, so that the Kerr constant for liquid air is about 1/20 of that of carbon bisulphide.

THE therapeutic action of certain mineral springs has been recently attributed, at least in part, to the presence of the radium emanation in the water. Experimental evidence in support of this view is given by P. Mesernitsky in the current number of the *Comptes rendus* of the Paris Academy of Sciences. It was found that the radium emanation decomposes sodium urate, some ammonium salts being formed. The exact nature of the decomposition (which was shown to be due to the action of the α rays, the penetrating rays being without effect) has not been completely made out, but there is a marked increase of solubility of the urate. It is suggested by the author that this action of the α rays upon sodium monourate may furnish an explanation of the therapeutic effects of the emanation in gouty cases.

A PAPER by Mr. Andrea Naccari in vol. xlvii. of the *Atti* of the Academy of Sciences of Turin (December, 1911) takes as its starting point an old memoir by Samuel Hunter Christie in the Phil. Trans. for 1826, entitled "On Magnetic Influence in the Solar Rays." Christie found the amplitude of oscillation of a magnet to decrease more rapidly than usual when sunlight fell on the magnet. The phenomenon had since been studied by Baumgartner, who found that it was not confined to magnets, and concluded that the real cause was air currents set up by the heating. Naccari confirms the view that magnetism has nothing to do with the phenomenon, but he differs from Baumgartner as to the cause. He ascribes it to the effect of radiation on the air which is carried by the oscillating body and that immediately surrounding it. Under certain conditions, the effect of thermal radiation on the damping seems very large, and further study of the phenomenon from the point of view of the kinetic theory of gases might not unlikely prove profitable.

IN a paper read at the Concrete Institute on March 14, Mr. Reginald Ryves treated the question of high dams of great length, and proposed a form of thrust buttress dam of arches, in which the whole of the water load is taken by masonry in direct compression, and neither the weight of the buttress nor the weight of the arch is taken into account as regards stability, except for resistance to sliding bodily when the ground is comparatively soft. Under normal conditions, the best slope for the water face is 45°. The dam consists of inclined arches of increasing thickness as the depth increases, and sloping at 45°. The abutments rest against the up-stream faces of the buttresses, which are built of layers all inclined at 45°. Every part of such a dam is subject to the same stress, except that the top layer of the buttress and the upper part of the arch ring may have the minimum in each case for the materials used. The author claims that this type is suitable for heights up to 200 ft. with a stress of 10 tons per square foot, and up to 300 ft. for 16 tons per square foot.

MR. EDWARD STANFORD has published an excellent, well-coloured geological map of central Europe which will prove of great service to students of geology, and less directly to teachers of geography. The map is 16¾ in. by 10½ in., and costs 5*s.*

M. J. DANNE asks us to say that his laboratory at Gif for experiments on radio-active substances is about 26 kilometres from Paris, and not 206 kilometres, as stated in last week's NATURE (p. 69).

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES FOR APRIL:

April 1. 0h. 0m. Neptune stationary.
1. 1h. 0m. Jupiter stationary.
1. 10h. 14m. Moon eclipsed. Visible at Greenwich.
6. 8h. 32m. Jupiter in conjunction with the Moon. (Jupiter 5° 8′ N.).
10. 4h. 54m. Uranus in conjunction with the Moon. (Uranus 4° 46′ N.).
10. 19h. 0m. Neptune at quadrature to the Sun.
15. 0h. 0m. Mercury in inferior conjunction with the Sun.
15. 5h. 17m. Venus in conjunction with the Moon. (Venus 0° 5′ N.).
16. 22h. 51m. Sun eclipsed, partially visible at Greenwich, ends at 1.31 p.m. on April 17.
18. 18h. 31m. Saturn in conjunction with the Moon. (Saturn 4° 47′ S.).
20-22. Lyrid meteors at maximum.
22. 3h. 22m. Mars in conjunction with the Moon. (Mars 3° 25′ S.).
22. 21h. 53m. Neptune in conjunction with the Moon. (Neptune 5° 53′ S.).
23. 10h. 0m. Uranus at quadrature to the Sun.
27. 11h. 53m. Mercury in conjunction with Venus. (Mercury 0° 10′ N.).

THE ECLIPSE OF APRIL 17.—In the *Revue générale des Sciences*, the Abbé Moreux publishes an interesting summary concerning the chances of a total eclipse of the sun being observed on April 17 next. He points out that M. Landerer's very slight modifications of the data produced considerable changes in the figures showing the size and path of the shadow cone, but even then the maximum breadth of the latter was only 200 metres (about one-eighth mile).

Adopting the new figures given by Dr. Crommelin, the Abbé Moreux finds that totality will last 1·6s. just before reaching the Portuguese coast, 1·5s. between Penafiel, about twenty miles east from Oporto, and Cavez, and about 1s. as the shadow leaves the northern shore of the Peninsula. He calculates that at St. Germain and Namur the height of the apex of the shadow cone above sea-level will be 30 km. (19 miles) and 52 km. ($32\frac{1}{2}$ miles) respectively.

Further, he makes the suggestion that although totality may not yet occur, the corona may be seen, for at previous eclipses it has been seen well before and after totality, and in 1900 was photographed by Mr. Willis eight minutes after.

Finally, he presents the peculiar possibility of there being neither an annular nor a total eclipse; this would occur if the mean apparent diameter of the moon were just insufficient to produce totality, because of the depressions at the limb, yet was so great that the mountains at the moon's limb projected far enough to break up the continuity of the solar limb.

In No. 4562 of the *Astronomische Nachrichten* Dr. Graff also discusses the position of the lunar mountains, and also the possible observations of the lowest levels of the chromosphere. He suggests, finally, that suitably arranged astrophysical observations may not prove so unprofitable as it has been generally supposed they must be in the circumstances of the coming eclipse.

Nova Geminorum No. 2.—A number of messages concerning observations of Herr Enebo's new star have been received by the Kiel Centralstelle, and are published in No. 4562 of the *Astronomische Nachrichten*.

At Christiania, early on March 13, Prof. Schroeter estimated the magnitude as 4·0, while Dr. Hartwig at Bamberg on March 13, at 10h. 23·9m. (Bamberg M.T.), found it to be 4·3; he gives the colour as reddish, and the position, for 1912·0, as 6h. 49m. 11·87s., $+32° 15' 6''$.

On March 14 Prof. Pickering reported that the spectrum of the nova was of the F_5 type, but on March 15 he reported a change to a bright-line spectrum. In the Harvard classification the type F.G represents spectra similar to that of Procyon, the Procyonian type in the South Kensington classification, which is the next earlier type to the solar stars.

According to Dr. Hartwig, the nova corresponds very closely with a thirteenth-magnitude star on the Palisa-Wolf charts. An observation made at 11.45 p.m. on March 20 showed the magnitude of the nova to be about 5·4.

Analyses of Stone Meteorites.—A valuable contribution to the study of meteorites appears in Publication 151 of the Field Museum of Natural History, where Mr. O. C. Farrington publishes a list of analyses of 125 stone meteorites, and a scheme of classification. An "average" composition, derived from the whole, gives the following substances, and their percentages, as the principal constituents:—SiO_2 (39·12), Al_2O_3 (2·62), FeO (16·13), MgO (22·42), CaO (2·31), Na_2O (0·81), Fe (11·46), Ni (1·15), S (1·98); there are thirteen other constituents.

It is worth noting that this list does not truly represent the relative spectroscopic importance of the various substances in meteorites. In the "Spectroscopic Comparison of Metals present in Certain Terrestrial and Celestial Light Sources," published from the Solar Physics Observatory in 1907, the chief metals were arranged in order of the prominence of their strongest lines in the spectra of the eight or nine stony meteorites examined. The order was as follows:—Cr, Na, Al, Mg, Mn, Si, Ca, Fe, Ti, V, K, Sr, Ni, and Ba.

In the spectra of all the certain meteorites, chromium is very well marked, yet in the chemical analysis given by Mr. Farrington it is only represented by 0·41 per cent. of Cr_2O_3.

Observations of Novæ.—Observations of the magnitude of Nova Lacertæ are published by Prof. Nijland in No. 4562 of the *Astronomische Nachrichten*. Between January 1 and December 15, 1911, the magnitude sank from 7·50 to 11·40, and the plotted values show practically no oscillations of the brightness.

Observations of the suspected Nova 87·1911 Persei, discovered by Mr. D'Esterre, are reported by that observer in the same journal. The later photographs, showing fourteenth-magnitude stars, show, in the position of the nova, a nebulous patch in which appear to be involved three condensations or very faint nebulous stars.

LIFE IN THE OCEAN.[1]

MORE than twenty years have passed away since the veteran physiologist of Kiel—Victor Hensen—initiated a new era in plankton research characterised by the application of biometrical methods. His inventions and investigations culminated in the equipment of an oceanic expedition which was to be an experiment on a large scale. It was one of the first German scientific expeditions, and certainly the first oceanic expedition to be devoted entirely to the study of the floating organisms.

Hensen's pioneer work, with its enormous labour and brilliant negotiation of abstruse problems, was carried out in the face of much unfair criticism—the famous polemic of Haeckel, "Plankton Studien," will long be remembered by the Kiel school.

During the years that have elapsed since, the same kind of destructive criticism has been at times proclaimed, and almost always by those who seem to have taken no trouble to study the work they would demolish.

The material collected by this "plankton" expedition has been examined by specialists, and now, after twenty-two years, Hensen has taken up the pen and written what should be the final volume (1), the last word, were it not that two or three reports still remain unfinished.

The greater part of the volume deals with the quantitative geographical distribution of pelagic organisms in the North Atlantic. Numerous tables are appended, and these, with the reports, complete what must be considered the first scientific attempt to determine the distribution of the plankton of the high seas. The work as a record is of great value. It must be remembered, however, that the studies of recent years have emphasised the remarkable seasonal variations occurring in the plankton of both lakes and seas; hence, the observations of the Humboldt-Stiftung expedition, which lasted but three and a half months, must be regarded as only presenting a phase in the distribution of life in the ocean.

Perhaps the most interesting part of the volume is Hensen's *résumé*, which deals with contemporaneous plankton work and other problems which have been much discussed during the past few years, such as Putter's theory and the theories of de Vries.

The great aim of the plankton expedition was the determination of the actual number of the different organisms in the waters of the high seas. Within certain limits this has been carried out, but on the whole the figures looked at in this light are of little importance. It is the methodical manner in which quantitative nets are used, and the elimination of

[1] (1) "Das Leben in Ozean nach Zählungen seiner Bewohner: Uebersicht und Resultate der quantitativen Untersuchungen." By Prof. V. Hensen. (Ergebnisse der Plankton-Expedition der Humboldt-Stiftung. Bd. v. O.) Pp. v+406+Tabellen (pp. 8+xxviii tables+map.) (Kiel and Leipzig: Lipsius and Fischer, 1911.)

(2) "Ueber das Nannoplankton und die Zentrifugierung kleinster Wasserproben zur Gewinnung desselben in lebenden Zustande." By H. Lohmann. Pp. 38+5 plates. (Leipzig: Dr. Werner Klinkhardt, 1911.)

(3) "Leitfaden der Planktonkunde." By Prof. A. Steuer. Pp. iv+382. (Leipzig and Berlin: B. G. Teubner, 1911.) Price 7 marks.

the personal equation by the enumeration of the organisms, that makes biological work of this kind so valuable. Whatever errors creep into quantitative plankton studies—and no one knows better than the planktologist the inaccuracy of the methods—they occur in a similar way throughout, and affect all calculations to the same extent. The final result is a series of comparable observations, and the possibility of comparison is *the* keynote of quantitative plankton work.

Hensen's treatment of two of his critics does not seem quite fair. Kofoid's objection that the original net lost many of the smallest organisms has been upheld by the work of Lohmann. As for Herdman's work in the Irish Sea, the absence (which he has insisted on) of the uniform distribution of plankton necessary if observations made at stations far apart are to be of any value cannot be denied. Furthermore, it is just in waters like the North Sea and Irish Sea that most naturalists find it possible to work. Whatever may be the cause of the complexities in the Irish Sea, the variations which have been followed by the Port Erin workers have been of such magnitude that no small errors could invalidate the deductions drawn.

The influence of Hensen and his quantitative methods has been greater than at first sight would be imagined. There is no doubt that, as in many other cases, work along quite different lines has been stimulated or even created. Take, for example, the careful analyses of sea water, the study of the distribution of nitrogen, of silica, and hydrographic work in general. There was a continuous demand for very accurate knowledge from those who would explain distribution by the altered environment. It was the plankton expedition itself that startled biologists with the statement that life was more abundant in the Arctic and temperate waters than in the tropics, and out of this has arisen the ingenious attempts to explain the anomaly. Bound up with this is the search for the factors which govern the seasonal changes in the plankton and the detailed researches which have been made on the latter in seas and lakes throughout the world. The question of the food supply of aquatic organisms, now no longer a simple subject, but one bristling with unsolved problems, requires further research along many different lines, particularly chemical and physiological.

Finally, the systematist who follows the individual organisms, counting as they pass across the field of view, recognises the variations in shape and size, and hesitates before coining new species (especially if working through a year's catches). In fact, for the study of evolution we need to go to the simplest organisms existing under the most simple conditions of environment. For this purpose there is a wide field open for research in the plankton of warm waters. Hensen shows that the seasonal variations, which complicate so much plankton studies in our waters, are to a great extent absent in the tropics. It is probably the seasonal variations which are at the bottom of many strange features of distribution round our islands. It would be quite impossible to touch on the numerous points of interest (many of which should create discussion) in a short article. Victor Hensen must be congratulated upon the conclusion of a work to which he has given so much of an active life.

(2) Two other works which have recently been published may very conveniently be discussed here. The first deals entirely with those small organisms which pass through the finest tissue of which plankton nets are made.

Lohmann has proved himself to be one of the foremost plankton workers in the world, and it is to this man of science that we owe our knowledge of the limitations of Hensen's methods. Thus the methods of the Kiel school have received their critical tests at the hands of the Kiel school. Lohmann proposes to use the term "nannoplankton" for the very small organisms, both animal and vegetable, of the pelagic world.

At the present time Schütt's terms, macro-, meso-, and mikro-plankton, are usually employed. No exact definitions of these groups were ever given, but the macroplankton was understood to include such organisms as medusæ, whilst the rest of the plankton in a net catch belonged to the groups, meso- and mikroplankton. The former of these two divisions included the copepoda, worms, &c., and the protozoa and protophyta made up the second. To these three terms Lohmann adds two others: the "megaloplankton," for all large organisms visible from a ship's deck and varying in size from centimetres to metres, and the nannoplankton for the most minute forms.

Naturally, different apparatus is required for the collection of the nannoplankton, and the net has been supplanted by the centrifuge. Water can be bottled at any depth, and it has been found that quite small quantities suffice.

It must be remembered that though the actual volume of the nannoplankton is small, the degree of importance depends on the rapidity of multiplication and the duration of life of the organisms of this group, and in this respect their absence from the net catches of the plankton expedition is much to be deplored.

(3) The other work to be mentioned differs entirely from the above in being a text-book, and there can be no doubt whatever that such a book is necessary to-day in consequence of the great extension of plankton work during the last few years. This volume gives a detailed and fair description of all the methods employed, with the results of recent researches in seas, lakes, and rivers.

Its greatest value will be perhaps to those biologists and general scientific workers who wish to obtain information about this branch of biological science without wading through the vast number of small papers which have been already published. Prof. Steuer is to be congratulated on the very able way he has brought so many different lines of work together, and the volume ought to find a place waiting for it in most university libraries.

W. J. Dakin.

UNIVERSITY REFORM IN NEW ZEALAND.

It may be taken for granted that all universities are not built on the same pattern; that local conditions and the requirements of the population have to be taken into consideration. The American and German universities, with their plans of government and conditions of study, meet the requirements of the respective peoples; Oxford and Cambridge, with features in common with one another, differ widely from the rest of the British universities in many respects. The type of the Scotch universities is unlike that of the modern English institutions, such as Liverpool and Manchester, while that of London is organised in a fashion peculiar to itself.

It is not to be wondered at, therefore, that the University of New Zealand should present anomalies in its constitution; the peculiarly isolated position of the country, the great difficulties of communication between its chief towns, especially in early days; the paucity of university men both on the staffs of the colleges and outside their walls at the period of its foundation; the local prejudices, amounting almost to jealousies, which existed between the provinces into which the colony was once divided—these and other local conditions have led to a unique relation between the four university colleges and the University itself. The latter is governed by a Senate largely consisting of laymen without any connection with teaching, though a proportion of its members are professors at the colleges. Each of the colleges is governed by a council, on which, in three of the colleges, professors have no seat; while the professorial board in each deals with the real academic work of its college.

The constitution of the Senate and college councils is open to criticism, and it is felt in some quarters that the professors have not sufficient representation on these bodies.

But perhaps the most curious feature of the University is to be found in the method of granting degrees in arts, science, and laws. The University is purely an examining body; by it the examiners are appointed, and these examiners, eminent men in their subjects, are resident in Britain. They set the papers, to them the candidates' answers are transmitted, and their reports are sent out to New Zealand. Everyone agrees that this method is cumbrous, entailing much delay and inconvenience to candidates; while the professors at the colleges have no direct share in examining for the degrees. In early days, no doubt, various causes led to some such arrangement; but it is felt by some of the younger members of the professorial staff, fresh from English universities, with totally different traditions and local conditions, that the time is ripe for some change.

Hence has arisen a Reform Association, the executive of which has issued a booklet of some 200 pages,[1] dealing fully, and on the whole impartially, with the various grievances complained of, viz.: the organisation of the University; appointments to chairs in the colleges; finance; examinations; libraries; research; with suggestions for reorganisation; followed by an appendix containing the opinions of a large number of professors, British and American, on the questions of external examinations and the constitution of the governing bodies.

Many of the grievances are domestic in character, such as libraries, laboratories, appointment of professors, and can only be dealt with by the individual colleges; and it is all a matter of money; but there are one or two points of wider importance which may be discussed here.

It is within our knowledge that the originators of this reform movement are members of Victoria College, Wellington, and that the entire staff even of that college is not wholly in sympathy; nor can it be said that the staffs of the other three colleges are in complete accord with the views of the reformers. This is partly due to the failure of the originators to consult the professorial boards officially or to discuss with the older members of these boards the plans for reform advocated: so that the pamphlet must not be taken as expressing the views of the whole body of university teachers in New Zealand. There is no doubt room for reforms, though it appears to us that some of the grievances about the constitution of the Senate, for instance, are exaggerated. We may remind the reformers that even in the ancient universities of Oxford and Cambridge the final body court of appeal, Convocation, consists "of a fortuitous concourse of members who happen to be able and willing both to pay for keeping their names on the books and to be present in Oxford on a particular day"—to vote for or against reform. The majority of these men are "laymen" so far as university teaching is concerned; and it is interesting to note that the teachers and active members of the University of Oxford are hampered as much as—nay, more than—the teachers in New Zealand, in their efforts for reform.

As a matter of fact, in New Zealand, if the four teachers of a given subject are unanimous in desiring any alteration in the syllabus of their subject, the Senate invariably adopts their proposals. Even the appointment of the examiners is virtually in the hands of the teachers, for if the four professors of a given subject send up a recommendation to the Senate, it is acted on; but, of course, if no suggestion is made, the Senate has to make the appointment. Again, the professorial boards of the four colleges are consulted on nearly every point of importance before the matter is dealt with in Senate. It is true that more frequent conferences between these boards are desirable, and if annual conferences were arranged, many reforms would probably be introduced.

But the chief need seems to be an alteration in the present system of examination for degrees. We need not here discuss the advantages that have been claimed for this procedure—the uniformity and impartiality of the examinations; the maintenance of a standard and stimulation of the teachers; and the enhancement of the value of the degree—these are dealt with fully in the report, and it is claimed that the disadvantages outweigh these supposed advantages. The system is unanimously condemned by the British professors who have replied to the questions submitted to them.[2] The majority of the gentlemen whose replies are recorded have no acquaintance with the geographical conditions of the Dominion, nor is it clear whether the examinations for honours and scholarships were in their minds; we think that, in the case of these competitive examinations between men from different colleges, an external examiner is necessary, if only in justice to teacher and student. The discussion refers to pass examinations only.

But while it is easy enough to see the faults of the system, it is not quite so easy to substitute a new plan, as may be seen in the varied proposals submitted.

Three alternatives have been suggested:—

(1) That each of the four colleges should be an independent university. In theory, no doubt, this seems plausible; but when we remember that the highest number of students at any college is about 400 (and in others much less) and the total population of the Dominion only about one million, it does not seem desirable at present to have four different standards for the degrees in arts and science. For it must be borne in mind that while most of the professors have had a training in a British university, there are some who do excellent work indeed, but who have no experience of any higher standard of work than that at their own small college in New Zealand; and, especially in the case of science, this is detrimental. It is agreed that the present standard for the degree is a low one, at any rate in several subjects, and one understands that this must be the case when matriculation can be passed by children of fourteen years of age, and the entrance scholarship, for which the schools prepare, is almost of the same standard as the B.A.

[1] "University Reform in New Zealand." Published by the General Editors (Profs. Hunter, Laby, and von Zedlitz) under the direction of the University Reform Association. Pp. 196. (Wellington, N.Z., and London: Whitcombe and Tombs, Ltd., 1911.)

[2] Though the opinions of acting professors in New Zealand are not included, those of six past professors or graduates of New Zealand are recorded; it is noteworthy, however, that Prof. Rutherford, whose views would be valuable, offers no comments on the system. Each of these six men gives an opinion more or less different from the other five, and amongst them may be found all the various possible plans for degree examinations and for reorganisation.

(2) A second proposal is that the teachers of a subject at the four colleges should form a board of examiners—either four (or only two) to constitute the board. Presumably each member would set a portion of the papers; in this case, if the four men act, the students at each college would recognise the "pet" questions of their teacher, which, although forming only a portion of the paper, would receive fuller answers than the rest of the paper, and this would mean, practically, that each college would be holding its own examination. Consequently the result would be essentially the same as in the first case. Moreover, the suggestion that all four teachers should cooperate is not quite so feasible as would appear; they would, of course, have to meet on several occasions, and though it is easy enough for a man in Edinburgh or Glasgow to run up to London in a few hours to confer with his co-examiner, yet the geography of New Zealand renders travelling less easy. Auckland and Dunedin are separated by nearly 900 miles, and this journey occupies at least sixty hours. It would be very inconvenient, to say the least, for these two men to spare time to meet, even at a midway point, while the cost to the University of such a scheme would be very heavy. Moreover, details of procedure would be far from easy to arrange.

(3) The purely external system of examination is condemned by most authorities. The real feature of the grievance lies not so much in having the examination for degrees conducted by external examiners in Britain or elsewhere, as in the total exclusion of the teachers from this examination; and it seems to us that the best suggestion is one made by two or three of those consulted, viz. that the teacher of a subject should make a report on each student, which would be forwarded to the examiner, who would take it into consideration in his award. For it is manifestly unjust to a candidate who has worked well throughout the year to be judged only by his answers to a paper, written on a day on which he may be unwell or otherwise unfit.

Every student, before presenting himself for the degree examination, has at present to pass an examination held by his teacher, and in the case of science a practical examination in addition must be done to his satisfaction. The marks awarded in these, if sent to the external examiner, would influence him in his award.

Indeed, it happened on one occasion that the degree had to be awarded entirely on these college examinations, for the ship conveying to England the candidates' answers was wrecked, and all the papers lost.

The reformers cavil at the small encouragement the university colleges give to research, while, as the pamphlet points out, there is opportunity but for a limited amount of original investigation. They rightly complain of the bugbear of examination if it be regarded as the "be-all and end-all" of university training; but, since the examination is part of the British system precedent to obtaining a degree, it is hopeless for a small colony like New Zealand to attempt to eradicate this evil so long as the Mother Country adheres to it.

In New Zealand there is no leisured class who can afford to spend time in pursuing knowledge for its own sake, and the degree is chiefly required by those entering the teaching profession, who must have a fairly all-round training in subjects useful for their purpose.

To such men and women specialisation at an early stage in the university career would be fatal to their prospects; there is no demand for specialists in chemistry or physics or biology, and it would be a cruel thing to encourage a man to spend two or three years in research, with no available opening at the end. Moreover, the libraries and staffing of the colleges are insufficient, as the reformers emphasise, for extensive research, which is best left to the later stages of a man's career, viz. for honours. What sort of research can a student in New Zealand pursue in languages?

It seems clear, however, that certain reforms are needed, but we fear that the reformers must not expect that all their grievances will be rectified immediately.

EXPERIMENTAL ERROR IN AGRICULTURAL INVESTIGATIONS.[1]

In view of the large number of agricultural experiments carried out in the country it is very desirable that some attempt should be made to put them on a sound basis, so that the results shall have some permanent value and admit of definite interpretation. The experiments cost a good deal of money, practically all of which is found by public bodies, and the work is frequently carried out without any particular regard to scientific method.

Perhaps the most serious defect hitherto has been the ignoring of experimental errors, so that only in very few cases could the experimenter say what degree of accuracy he had obtained or what was the significance of the differences he observed. In order to provide a remedy a day was devoted to the subject at the agricultural subsection to the British Association in 1910, and some of the papers then read have been amplified, and are now issued as a supplement to *The Journal of the Board of Agriculture*.

They are all couched in simple language, and bring home the fact that the value of an experiment depends on the degree of confidence that can be attached to the result. The opening paper, by Messrs. Hall and Russell, deals with field trials, and the general conclusion is reached that the probable error attaching to a single experiment is at least ± 10 per cent. It is possible to reduce the error to about ± 2 per cent. by repeating the experiment simultaneously on a number of plots, which need not be more than 1/50th acre in extent.

The second paper, by Prof. Wood, discusses analytical results, the sampling of crops, field trials, and feeding experiments, and contains frequency curves and tables of odds, setting out the least significant differences in these usual conditions of the various classes of determinations. The agricultural experimentalist will do well to submit his figures to the simple tests suggested here.

Mr. Pickering deals with experimental errors in horticultural work, which are fairly considerable, and commonly ignored. The experiments and their interpretation are more difficult than in purely agricultural work, and according to the quantity estimated may vary from ± 16 to ± 20 per cent. for a single tree, or from ± 6 to ± 8 per cent. for a set of six trees.

Milk investigations are discussed by Mr. Collins. An ordinary fat analysis is shown to be liable to an error of $\pm 0{\cdot}03$ per cent., while the error in the solids-not-fat determination can be reduced to 0·05 per cent., but may be higher.

The Board of Agriculture has undoubtedly rendered very useful service by issuing these papers in so cheap a form, and it is to be hoped that they will be used as extensively as the importance of the subject warrants.

[1] Supplement No. 7 to the Journal of the Board of Agriculture, 1911.

COPPER AND ITS ALLOYS IN EARLY TIMES.[1]

WITH the discovery of metals, and notably the application of copper and its alloys in Neolithic times, we have one of the great turning points, if not the greatest, in the history of human development, the first-birth of the germs of that civilisation and culture to which we have attained at the present day. The discoveries of the properties of steam and electricity and their applications to our industries and other practical purposes of life we are apt to regard as wonderful and epoch-making, yet when we compare them with the results which have followed the discovery of metals, they are but trifling and insignificant.

The order in which the metals were discovered was not the same for every region, as their ores are very capriciously distributed in the world, and it is extremely probable, if not absolutely certain, that the metals which occur native, *i.e.* those which occur as metals in nature, must have been first known to the men inhabiting the localities in which they occurred. The metals so occurring most frequently are gold and copper. The former is much more widely distributed than the latter, and must have been the first metal to be known in many regions.

It is, however, one of the most worthless metals for practical purposes, so that until the rise of Greek and Roman civilisation but little use was made of it. Copper, too, we only find in use to a very limited extent, as it was not well suited for the construction of weapons or useful implements. On the other hand, its alloy with tin afforded a metal which in many physical properties could only be surpassed by iron or steel. According to the views of several ancient writers, Lucretius and Poseidonius, so momentous a discovery as that of metals contained in ores must needs have been brought about by no uncommon cause.

According to them a conflagration consumed forests which covered the outcrop of metalliferous veins, reducing the metals and bringing them to the notice of man, but there are no grounds for such inference. The discovery of metals other than "native" had no such poetic origin, but was brought about in a more commonplace and more humble way. It had its origin in the domestic fires of the Neolithic age.

The extraction of the common metals from their ores does not require the elaborate furnaces and complicated processes of our own days, as pieces of ore, either copper carbonate or oxide, cassiterite, cerusite, or mixtures of these, and even iron oxides which by chance formed part of the ring of stones enclosing the domestic fire, and became accidentally embedded in its embers, would become reduced to metal. The camp fire was, in fact, the first metallurgical furnace, and from it, by successive modifications, the huge furnaces of the present day have been gradually evolved.

First, a shallow cavity would be formed in the hearth of the fire for the reception of the molten metal, and this would be made larger as time went on and larger quantities of metal were required by deepening it or by surrounding it with a higher wall of stones. Furnaces of precisely this primitive form survived in Derbyshire up to the seventeenth century. In Japan the furnace for smelting copper, tin, and lead ores, a mere hole in the ground, which was in universal use there up to 1858, and is still extensively employed, is as simple and rude as that of the men of the Bronze age.

[1] Abridged from the Presidential Address to the Institute of Metals by Prof. William Gowland, F.R.S.

The alloys of copper and tin during the early Metal age, and even somewhat later, were obtained not by melting together copper and metallic tin, but by the reduction of oxidised copper ores containing tin-stone, or of copper ores to which tin-stone was added. As it has been stated by several Continental archæologists that when a copper ore containing tin ore is smelted the tin does not enter into combination with the copper, but passes into the slag, I have made several experiments under the conditions which were available to prehistoric man, which completely disprove their statements.

A furnace of the simplest form, merely a hole in the ground, was constructed in my laboratory at the Royal School of Mines. The fuel used was charcoal. A mixture of copper ore (green carbonate) and tin-stone was smelted in it, and a copper-tin alloy, a bronze containing 22·0 per cent. of tin, was obtained. The experiment was repeated several times, and in every case copper-tin alloys were obtained. This experiment proves indisputably that when a copper ore containing tin ore was smelted by primitive man, a bronze consisting of copper and tin was the result.

The shape and structure of the lumps of copper which have been found in the founders' hoards[2] of the Bronze age afford valuable evidence as to the size of the rude smelting furnaces, the method of smelting, and the manner in which the metal was removed from the hearth. These lumps are always fragments of rudely disc-shaped cakes of about 8 in. to 10 in. in diameter, and 1½ in. in thickness, having the largely columnar fracture of copper when broken near its solidifying point. They show that the furnace was simply a small shallow hole or hearth scooped in the ground, about 10 or 12 in. in diameter, and that the operation of smelting must have been conducted as follows:—A small charcoal fire was first made in the hearth, and when this was burning freely a layer of ore was spread over it, and upon this a layer of charcoal, then alternate layers of ore and charcoal were added in sufficient quantity to yield a cake of copper. The fire was doubtless urged by the wind alone in the earliest times, but later by some kind of bellows.

When all the charge had melted, the unburnt charcoal and the slag were raked off. The metal was not laded out, but was allowed to solidify first, and at the moment of solidification was rapidly pulled out and the cake broken up at once on a large stone. In Korea, at the copper mine of Kapsan, this primitive method of removing the copper from the furnace still survived when I travelled through the country in 1884.

The method of smelting copper ores in the primitive furnace which has survived in Japan from prehistoric times closely resembles that of the Bronze age. The copper of the Bronze age resembles modern blister copper in composition, but, unlike it, it often contains only traces of sulphur. When sulphur is present in the crude metal only in traces it undoubtedly indicates that the metal had been obtained by smelting oxidised ores. The percentage of copper in several characteristic specimens ranges from about 97·0 to 99·0.

I will now ask for your attention to the earliest alloys of copper and tin, those of the Bronze age. In the production of these alloys in the earliest part of the age, copper ores containing cassiterite can alone have been used; it is obvious, therefore, that

[2] Founders' hoards, many of which have been unearthed in this country and in Europe, contain generally worn out or broken implements, waste castings, and rough lumps of copper apparently brought together for recasting. In some the objects are new and ready for use or are in an unfinished state. They appear to have been the stock-in-trade of itinerant founders. A flat axe made of the alloy is in the British Museum.

the percentage of tin they contain must have varied with the percentage of cassiterite in the ore and the regularity with which the smelting operations were performed. Even in the later period of the Bronze age, when the alloys were made by smelting the copper ore with cassiterite, alloys of definite composition can only have been accidentally obtained. Further, it is very questionable whether the metal tin was ever employed in making the alloys until the Iron age was well advanced, as this metal has never been found in the founders' hoards. Consequently the implements and weapons are of very varied composition, at first generally containing but little tin, less than 3 per cent., but later having that metal frequently in satisfactory proportions for the uses they were intended for.

A curious feature of the alloys of which the early weapons were made in Hungary is the presence of antimony as an important constituent instead of tin. This doubtless arose from the alloys having been prepared by smelting the antimonial copper ores which occur in that country. Axes made of these alloys would be fairly serviceable on account of the hardness produced by antimony in copper. We hence find them in use, with antimony largely replacing tin, until late in the Bronze age.

The difficulties the earliest men had to contend with were extremely great, for it is self-evident that alloys of definite composition could not be ensured by the early practice of smelting mixtures of ores. It would seem, therefore, that when we find weapons or implements of suitable composition for their intended use, some physical tests must have been applied to the furnace product before it had been used for their manufacture.

We will now pass to a brief consideration of the methods followed by prehistoric man for the manufacture of his weapons and implements. Practically all copper celts were cast in open moulds, as if cast in closed moulds they would be more or less vesicular and worthless, except when the copper contained arsenic, tin, antimony, zinc, or nickel in not less proportions than 1 per cent., or an excess of cuprous oxide. The remains of his appliances which have been found show clearly that the metal from the smelting operation was remelted in crucibles and poured from them into moulds of clay or stone, perhaps of sand, but of this there is no definite evidence. The metal was not laded from the smelting furnace, as the small crucibles with rude handles which have occasionally been found, and have been erroneously supposed to be ladles, show no signs of having been exposed to a high temperature both on the inside and outside, as would have been the case had they been so used; the interior and upper edges alone bear marks of such exposure. The reason for this will be seen later.

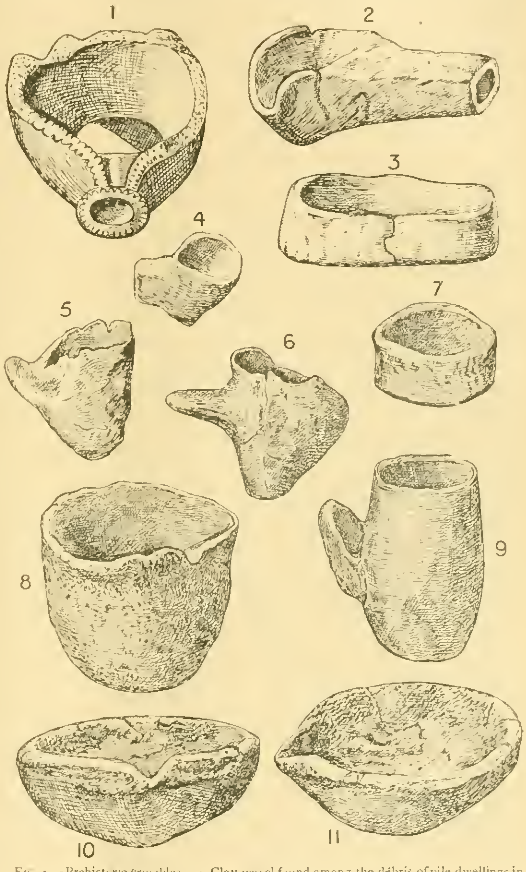

FIG. 1.—Prehistoric Crucibles. 1. Clay vessel found among the débris of pile dwellings in Carniola. It is open to doubt whether this is a crucible or not. 2. A common form widely distributed in the remains representing the early Bronze age in the pile dwellings of Switzerland, the Danubian basin, and Ireland. It is furnished with a socket for the insertion of a stick, by which it was removed from the fire and its contents poured into a mould. 3. A shallow oval dish of somewhat rare occurrence, found in the Mond See. 4. Found in the remains of a crannog in Lough Mourne, Ireland. 5, 6, 7, 8, 9. Crucibles found at Dunadd, Argyll, together with iron spear-heads and other iron objects. 10 and 11 were found together with copper and bronze implements and stone moulds in Mercia and Almeria, in the south-east of Spain.

Implements and weapons of bronze, unlike those of copper, were always cast in closed moulds. The method of melting the metal in each case was as follows:—The furnace or hearth was merely a shallow depression in the ground. The crucibles were made of clay, which was sometimes mixed with finely cut straw or grass. They were embedded in the ashes at the bottom of the hearth in such a manner that their bases and sides were thoroughly protected from the intense heat of the fire, their upper edges and interior only being exposed. This method had been adopted owing to the fusible character of the clay of which they were made. The fuel used was wood and the charcoal which was produced during the process. After a crucible had been thus placed and charged with copper, copper and tin-stone, or copper and tin, the fire was made up over it. A sufficiently high temperature for melting the metal could be obtained by the wind alone. When the contents of the crucible had melted, the crucible was removed from the furnace and the metal poured into a mould.

In consequence of this mode of heating, the lower parts of the crucible will, it is evident, bear but little traces of the action of a high temperature, whilst the upper edges and interior will exhibit a fused or semi-fused structure, and this is precisely what we find in all early crucibles.

Some of the most important types of crucibles are illustrated in Fig. 1.

The small capacity of by far the greater number of these crucibles which have been found is worthy of note. Few can have held more metal than would suffice for the casting of a single axe. This is, however, not surprising if we remember that they are the appliances of that remote time when metallic weapons were only beginning to replace those of stone.

The moulds used by primitive man are also of considerable interest. The earliest are of the class known as open moulds, and consist merely of cavities of the necessary form and size hollowed in the surface of a stone.

In casting swords and daggers of bronze the moulds must have been of clay and been heated to dull redness at the time when the metal was poured in—a method of casting which is still practised in Japan—as by no other means could such perfect castings of their thin blades have been obtained. The castings generally were hammered at the cutting edges, and it is to this hammering, and to it only, that the hardness of the cutting edges of both copper and bronze weapons is due, and not to any method of tempering. Much has been written about the so-called art of tempering bronze supposed to have been practised by the men of the Bronze age in the manufacture of their weapons; the hardness is also said to be greater than can be given to bronze at the present day. I should like to correct this error, as it can only have arisen owing to its authors never having made any comparative practical tests of the hardness of bronze. Had they done so, they would have found that the ordinary bronze of to-day can be made as hard as any, in fact, harder than most, of prehistoric times, by simple hammering alone.

We will now pass to the consideration of the copper alloys of Mycenæan, Babylonian, Greek, and Roman times. Until the introduction of iron, copper and bronze played an important part in the lives and struggles of the early races occupying the Greek peninsula and its islands, whilst in later times the alloy bronze afforded an imperishable material to the great sculptors of the golden age of Greece, by which many of their incomparable works have been preserved to us.

In Greek literature we have no records of metallurgical processes relating to copper or its alloys, such as are to be found in the writings of Roman authors, notably Pliny.

Strabo, the only Greek author who condescends to take any notice of metallurgy or metal working, confines his statements to gold, silver, and lead. But at Laurion the remains of ancient furnaces for smelting lead ores, which have been unearthed from time to time, indicate that low hearths resembling those of the Bronze age were extensively employed; and if we may reason from Japanese metallurgical procedure, similar furnaces would be used for copper. The island of Cyprus, once rich in copper ores, was doubtless the source whence the inhabitants of the Greek peninsula in early times obtained their copper.

Among the earliest specimens of the metal which have been found in Greece are some copper nails which were obtained by Dr. Schliemann at Orchomenos, a city in Bœotia, which was in a state of decay in the time of Homer. They belong to that remote period in Mediterranean civilisation to which the name Mycenæan has been applied.

They are interesting as showing that the men of that remote period were able to produce copper of tolerable purity, but this would not be difficult, as the ores which they worked would be oxidised ores, oxides, and carbonates from the outcrops of veins, viz. the parts which were exposed at the surface of the ground.

Bronze was also then in use for nails and cramps in building construction, but especially for weapons, and was of good quality.

There is abundant evidence to show that Egypt was the first in the field in artistic bronze casting. When it first began it is difficult to say, but objects of at least as early as 3000 B.C. are in existence.

Even in the early examples great technical skill is displayed. The most ancient Greek bronzes are solid castings, whereas in Egypt they are light and hollow, having been cast with a core of argillaceous sand, which still remains in many specimens.

The statuary bronze frequently contains considerable amounts of lead, sometimes with but little tin, and the question naturally suggests itself, whether this arose from scarcity of the latter metal. Only a few analyses have been made, and unfortunately few of the objects can have even approximate dates assigned to them.

Bronze was in extensive use in Nineveh about 1000 B.C. for vessels and utensils of many kinds, and curiously was sometimes employed for those which we should now make of more precious metals.

The Greek copper alloys of a later period, many examples of which are found in the coins of about the fourth century B.C., are true bronzes consisting of copper and tin, with lead or zinc only as impurities and not intentionally added.

A curious feature in them is the presence of nickel varying from traces up to 0·5 per cent. The percentage of tin is somewhat irregular, but in most examples ranges from about 8 to 11 per cent. The same is true of the Macedonian coinage alloys from the third to the second century B.C., but the percentage of tin in them is somewhat greater, generally being from about 10 to 12 per cent. These alloys were undoubtedly made by melting together the metals copper and tin, and not, as in the Bronze age, by smelting stanniferous copper ores, or by melting copper with tin ore.

The Macedonian alloys more particularly are the best of the ancient bronzes.

A little later in Greek coins we find lead as an intentional constituent in various proportions, ranging generally from about 6 to 10 per cent., or even more, with a proportionate reduction in the percentage of tin. The Macedonian coins, however, with few exceptions, preserve their character as true bronzes.

The alloys used for statues are frequently true bronze with 9 to 11 per cent. of tin, but in other examples about 5 per cent. of lead has been added, probably with the intention of increasing the fusibility of the alloy and its fluidity when molten.

The statements of Pliny as to the composition and mode of manufacture of the bronzes as imitated in Rome throw but little or no light on the subject; in fact, they are for the most part useless and misleading. As regards the Corinthian bronze, the beauty of which is so extolled by classical writers, he states that the alloy was discovered by the Romans at the sack of Corinth, when vessels of gold, silver, and bronze had been accidentally melted together during the burning of the city and produced a golden bronze.

The siege of Corinth, however, occurred in 146 B.C., but the excellence of Corinthian bronze had been recognised long before.

Whatever may have been the exact composition of this bronze, of which several statues are said to have been cast, I may say that no addition of gold or silver to any copper-tin alloy will cause it to resemble gold closely. Imagination must, I think, be responsible for the accounts given of this bronze by ancient authors, especially when we read also that its beauty was derived from being cooled in the water of the fountain of Peirene.

With the fall of Greece and the rise of the supremacy of Rome we enter an important period in the history of copper and its alloys. In Spain and in Britain we find copper-smelting being vigorously carried on by the Romans, and in Rome and the chief seats of the empire a further extension of the use of bronze, not only for statues and other objects of art, but for vessels of all kinds, furniture, and other articles of domestic life. Of special importance is the invention of a new alloy, brass, which comes into use for the first time in Europe.

Among the varied remains which are representative of the Roman occupation of Britain, few are of greater interest to the metallurgist than the cakes of copper found in North Wales and Anglesea. These cakes afford us, in their form and character, unmistakable evidence of their history. They had been obtained by smelting sulphide ores, or ores containing sulphides, in low hearths, in which they had almost certainly been allowed to solidify before removal. According to Pliny, who seems in this matter to have had access to fairly trustworthy sources of information, the copper obtained by smelting was brittle and useless, and in order to obtain malleable metal from it, it was mixed with lead and melted several times, and the oftener the operation was repeated the better was the quality of the copper. This brief account of copper-refining by a non-technical writer gives us an excellent *résumé* of the process as practised in Roman times. The operation was evidently conducted with free access of air, and the lead used would, by its oxidation, aid greatly in the removal of impurities from the copper.

The earliest Roman alloys which have come down to us are copper, lead, tin, alloys of the fifth century B.C. Their chief peculiarity is their very large content of lead, namely, from about 19 to 25 per cent., the tin being about 7 per cent. They were worthless for practical purposes, but formed the alloy of which the large coin of the republic—which weighed from 8 to 11 ozs.—the "As," was cast. These copper-lead-tin alloys continued in use as coinage alloys until 20 B.C., but from that date until two centuries later lead is seldom found in coins except as an accidental impurity.

The large percentages of lead were undoubtedly added in these cases on account of the cheapness of the metal as compared with copper and tin.

The copper-tin-lead bronzes appear also to have been used by the Romans for engineering and industrial purposes. An interesting example of this use is afforded by the broken shaft of a water-wheel which was found in the lower Roman workings of the north lode of the Rio Tinto mine. The water-wheel was probably built in the first century of our era, as coins of the time of Vespasian (70 to 81 A.D.) were found near it.

The bronze used for statues by the Romans also always contains lead in considerable proportions, as much as 6 to 12 per cent. being often present. In this they were doubtless influenced by Greek practice, the lead being added to the bronze to increase its fusibility and more especially its fluidity when molten, so that it might receive the sharpest possible impressions of the mould.

I may point out here that the addition of lead to bronze was and is largely practised by the Japanese, not only for the reasons stated above, but also to enable the objects cast of the alloy to receive a rich brown patina when suitably treated; and in this connection it is worthy of note that Pliny states that by the addition of lead to Cyprian copper, the purple tint is produced that we see in the drapery of statues.

The alloy used by the Romans for mirrors does not differ greatly from that in use in Europe for metallic mirrors in comparatively recent times, the percentage of tin ranging from 23 to 28 per cent., but lead is present in all from about 5 to 7 per cent.

Copper-zinc Alloys—the Brasses.

Zinc as a distinct metal was unknown in early times; in fact, as late as the sixteenth century it was not known in Europe; but there are strong reasons for the belief that the Chinese were acquainted with it as metal at least several centuries earlier. It is occasionally but rarely present in the implements and weapons of the Bronze age, and then only in small quantities as an accidental impurity, which has been derived from smelting copper ores containing it.

In somewhat later times it occurs in rings, armlets, and other personal ornaments found in the ancient burial mounds of Germany and Denmark, but these mounds are of post-Roman date, and the objects mentioned have really been made from Roman coins.

In Greek alloys zinc is never found as an intentional addition, but only as an impurity, about 1 to 2 per cent. or less; in fact, according to Gobel, all antique objects which contain zinc are not Greek; but this, in my opinion, is only true for those containing considerable proportions of the metal, and not for those with the small amounts just mentioned.

In Roman times it first appears in the coins of the republic as an impurity; as an intentional addition, however, it only begins in the time of Augustus (20 B.C. to 14 A.D.), when brass was made for the first time in the world's history.

One of the earliest examples is a coin of 20 B.C., which contains 17·31 per cent. of zinc.

The Romans were the first makers of brass. Although they were unacquainted with the essential constituent zinc, yet they had discovered that by melting copper together with a certain ore (calamine), a yellow alloy of a more golden colour than bronze could be obtained.

It was first employed for coins which appear to have had a higher value than those of bronze, even up to the time of Diocletian (286 to 305 A.D.), when six parts of brass are said to have been worth eight parts of copper. There is, too, a curious statement by Procopius in his *De Œdificiis* relating to its value in the fifth century A.D., in which he says that brass was then not very greatly inferior to silver.

The method employed by the Romans in making this alloy from copper and calamine was a very simple one.

It was conducted as follows:—The calamine was ground and mixed in suitable proportions with charcoal and copper in granules or small fragments. This mixture was placed in a crucible, and was very carefully heated for some time to a temperature sufficient to reduce the zinc in the ore to the metallic state, but not to melt the copper. The zinc being volatile, its vapour permeated the fragments of copper, converting them into brass. The temperature was then raised, when the brass melted, and was poured out of the crucible into moulds.

This process was so effective that, until a comparatively recent period, all brass was made in Europe by the ancient process, and even until a few years before 1861 it was thus made at Pemberton's Works in Birmingham. It was called "calamine brass," and was generally believed to be superior in mechanical properties to brass made by using metallic zinc.

The survival of this ancient process affords a striking example of the conservatism characteristic of British metallurgy, as brass had been made in England by Emerson, using metallic zinc, in 1781. This, so far as I have been able to ascertain, was the first to be made in Europe by melting copper and zinc together.

In Roman alloys the percentage of zinc was very variable, ranging from about 11 to 28 per cent. For ornamental purposes and scale armour they had an excellent alloy, of which the following are examples. Several rosettes and studs which had formed the mounts of a casket were unearthed in the excavations at the Roman city of Silchester in 1900.

Both the rosette and stud are of practically the same alloy. Now, of all the copper-zinc alloys, those which contain from 15 to 20 per cent. of zinc possess the greatest ductility.

This Roman brass is therefore one of the most ductile of the whole series of brasses. It is, besides, identical in composition with Tournay's alloy (copper, 82·5 per cent.; zinc, 17·5 per cent.), which, on account of this property and its rich colour, is used for the manufacture of all French jewellery made from thin sheets in imitation of gold. Hence the brass of which the rosettes are made is notably of the composition which is best fitted for making such ornaments, and is that which would be employed at the present day.

I have also examined the scales forming part of a suit of Roman scale armour dug up in the excavations of a Roman camp near Melrose, and found them to be of practically the same composition as the above.

The chief use of brass by the Romans, apart from the various coinages, appears to have been for fibulæ and other personal ornaments and for decorative metal-work, and for these, as we have already seen, they had invented a metal perfectly suitable, both as to its workable qualities and its beauty.

That they were the first inventors of brass is, I think, without doubt, as the alloy is not found in Greece or the Greek colonies or elsewhere until the time of the Roman Empire.

In the eleventh century great care was bestowed on the purification of the copper intended to be used in the manufacture of calamine brass for objects of art, more especially for the removal of lead, as it had been found that brass contaminated with that metal could not be satisfactorily gilt.

As regards the brass which was made in this country by the ancient method, *i.e.* "calamine brass," and that made with spelter, the former, according to Dr. Percy, was preferred for the manufacture of buttons and articles to be gilt, as it was said to take the gold better in "water-gilding." It was also preferred for other purposes. It is difficult to see why there should be any difference between the two brasses unless the spelter of those days was more impure than at present, possibly containing more lead and iron. Prejudice against the metal made by a new process may, however, have been one of the causes of the opposition which was raised to its use.

With the disappearance of the calamine brass, one of the last links in the chain connecting the modern metallurgy of copper and its alloys with antiquity is broken. An important link, however, still remains in the *cire perdu* process of casting bronze, a process in which it can scarcely be said that we are any further advanced than the Greek founders of some centuries before our era.

Further, it must not be overlooked that the principles on which copper-refining is based were carried out in practice in the time of Pliny.

The influence of copper, and particularly of bronze, from the age of Bronze to that of Imperial Rome, is an element which has played a greater part in the civilisation of Europe than that of any other metal. This is often lost sight of in this age of iron and steel. It hence seemed to me that it might be of interest and possibly of profit to present to the members of our Institute an account of the achievements which our fellow-workers in bygone ages were able to accomplish without the elaborate appliances and scientific knowledge of our own times.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LONDON.—Further gifts to the University are announced in connection with the scheme for removing the headquarters to a site behind the British Museum, to which we referred last week. The Duke of Bedford has offered 25,000*l* and a reduction off the price of the site of 50,000*l*., and an anonymous friend of the University has offered 70,000*l*., making a total amount, with the gifts announced last week, of 305,000*l*. Although Lord Rosebery's name has been published as representing the University on the board of trustees which has been formed in connection with the scheme, the approval of the Senate has not been given to the proposals. Strong exception was taken to the Chancellor's action at the meeting of the Senate of March 20, when the Vice-Chancellor (Sir William Collins) tendered his resignation in view of what had taken place. At the unanimous wish of the Senate, he afterwards consented to remain in office. Lord Rosebery's explanatory letter was subsequently published, in which he states that by consenting to act as trustee he was committing no one, not even himself, to anything except to his being trustee for certain sums collected for the benefit of the University. From official correspondence which has been communicated to the Press, it appears that both the Prime Minister and the Chancellor of the Exchequer approved the proposed site.

Prof. F. G. Donnan, F.R.S., was appointed by the Senate to the University chair of general chemistry at University College, in succession to Sir William Ramsay, the appointment to take effect from the opening of next session, in October. The Senate elected Dr. L. N. G. Filon, F.R.S., to the Goldsmid chair of applied mathematics and mechanics, tenable at University College, such appointment to take effect from the beginning of next session, in October. Dr. Filon succeeds Prof. Karl Pearson, who resigned the chair in question on his appointment to the Galton chair of eugenics.

At the same meeting of the Senate, E. C. Snow, an internal student of University College, was granted the D.Sc. degree for a thesis entitled "The Intensity of Natural Selection in Man," and other papers.

Additional grants from the London County Council, amounting to 28,000*l*. during the sessions 1911–12 to 1913–14, were formally announced to the Senate.

IT is announced in *Science* that Prof. R. Ramsay Wright, vice-president of the University of Toronto and dean of the faculty of arts, will retire from active service on September 30. He has filled the chair of biology for the last thirty-eight years.

THE Board of Agriculture has again made an increased grant of 1300*l*. to Wye College, and has promised a grant of 262*l*. (for six months) for the cost of investigations on hops, on the life-history of the parasitic stomach worms (Strongyli) of sheep, and on the disease of "struck" of sheep, whilst the institution of a fresh grant of 1000*l*. towards the expense of an advisory staff in entomology and mycology—more particularly for fruit-growers—has also been officially intimated to the college authorities.

THE treasurer of Columbia University has reported to the trustees, says *Science*, that he has received about 310,000*l*. from the executors of the estate of the late Mr. George Crocker. Accordingly, the work of cancer research, for which Mr. Crocker gave this sum as an endowment, will begin at once. The research fund will be entrusted for administration to a board of managers, to consist of representatives of the trustees and of the medical faculty, together with a director of cancer research to be appointed.

THE Cambridge University Press has published a report by Mr. E. R. Burdon on a visit, undertaken in accordance with a resolution of the Forestry Committee of the University of Cambridge, for the purpose of studying the research work and educational methods of the forestry departments and forestry schools in those countries in connection with the study of timber and other forest products. An excellent description is provided of the departments of the Products Branch of the United States Forest Service, including particularly the Forest Products Laboratory at Madison, Wis., and the Office of Wood Utilisation, Chicago. The forestry schools of Yale, Harvard, Michigan, and Toronto Universities were visited by Mr. Burdon, and the particulars here brought together should prove of great service in this country.

IN an article in the Bulletin of the Society for the Promotion of Engineering Education for the present month, Profs. W. S. Franklin and Barry MacNutt deal with the teaching of elementary physics. They confine their attention in this case wholly to lectures and text-book work, though they recognise fully the paramount value of laboratory practice. Commenting upon the answers of 164 freshman engineering students—who had taken elementary mechanics for half a year—to a series of simple questions, the writers come to the conclusion that the great majority of young men cannot realise the meaning of simple English when it is impersonal and non-anthropomorphic, and a large proportion of the failures to answer the questions were due to the inability of the men to read the questions intelligibly. The object of elementary physics, the authors urge, should be to develop "rational insights." It is not the duty to a teacher of elementary physics to give his students a survey of the science.

THE report of the Board of Education for the year 1910–11 is now available (Cd. 6116). From it we find that though there were 768,358 students in attendance at evening and similar schools in 1909–10, as compared with 752,356 in 1908–9, nearly 18 per cent. of the students enrolled failed to complete the small minimum of attendances required in order to enable grants to be paid towards their instruction. In the administrative counties (excluding London) each student received, on an average, 45 hours of instruction. There was reason to expect the average would be lower in rural than in urban areas; only in eight cases, however, was the average below 30 hours, and in three cases it was 60 or more. The total amount of advanced instruction of the kind provided in technical institutions is still disappointingly small. There were 49 technical institutions at which courses were recognised as eligible for grant in 1909–10. In the case of 37 institutions for which alone the statistics are complete, there were 3032 students enrolled, of whom 2664 qualified for grant, and 1806 of these took full courses of instruction. There is still a tendency, the report states, to admit students to technical institutions before they have had an adequate course of general education.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society March 21.—Sir Archibald Geikie, K.C.B., president, in the chair. Lord **Rayleigh**: The self-induction of electric currents in a thin anchor-ring.—Hon. R. J. **Strutt**: The after-luminosity of electric discharge in hydrogen observed by Hertz. Hertz observed that if Leyden-jar discharges were passed through hydrogen at a pressure of, say, 100 mm., the gas remains luminous for a small fraction of a second afterwards. It is concluded that Hertz's effect is due to the presence of sulphuretted hydrogen in the hydrogen employed. It is conjectured that sulphuretted hydrogen is decomposed by the discharge, that sulphur vapour emerges in a specially active state, and that it then unites with hydrogen, the blue glow accompanying this process. Prof. J. H. **Poynting**: The changes in the dimensions of a steel wire when twisted, and on the pressure of distortional waves in steel. In a former paper (Proc. Roy. Soc., A, vol. lxxxii., 1909) the author described experiments showing that when a loaded wire is twisted it lengthens by an amount proportional to the square of the angle of twist. In this paper it is shown that if the wire is previously straightened by heating it under tension, the lengthening is, within errors of measurement, the same for all loads which could be applied, so that, as was supposed, the only function of the load in the earlier experiments is to straighten the wire. In all wires examined so far, the lowering is symmetrical about a point a fraction of a turn always in the counter-clockwise direction from the condition of no twist. H. S. **Patterson**, R. S. **Cripps**, and R. **Whytlaw-Gray**: The orthobaric densities and critical constants of xenon. Using a carefully purified sample of xenon prepared from 150 c.c. of the gas lent by Sir William Ramsay, measurements were made of the orthobaric densities between the temperature limits of 16 and -66.8° C. The variation of the mean density of liquid and saturated vapour with temperature was found to follow closely Cailletet and Mathias's law, and the results are expressed by the equation $D_t = 1.205 - 0.003055t$, where D_t = mean density at t° C. The slope of the diameter is abnormally large, and is practically identical with the value for the argon diameter recently found by Onnes. The constants $T_c = 16.6^\circ$ C. and $P_c = 58.2$ atms. were found, and the following were calculated from the results:—critical density, 1.115 grms. per c.c.; density of liquid close to boiling point, 3.063 grms. per c.c.; atomic volume close to boiling point, 42.7 grms. per c.c.—W. A. **Harwood** and Dr. J. E. **Petavel**: Experimental work on a new standard of light. The source of light consists of a strip of platinum heated by an electric current. The thermopiles measure the radiation passing through (*a*) a plate of black fluorspar, (*b*) a water-trough. The thermopiles are connected in opposition. As the current through the strip is increased, the intensity of the luminous radiation increases more rapidly than the intensity of the radiation of longer wave-length. Therefore, for a given thickness of the absorbing media and distance of the thermopiles, there will be one definite temperature at which the reading of a galvanometer in the thermopile circuit will be zero. A long series of experiments showed that the light could be kept constant within ± 0.5 per cent. when a constant temperature was maintained by the above criterion.—J. A. **Crowther**: The distribution of the scattered Röntgen radiation. Experiments have been made to determine accurately the distribution of the scattered Röntgen radiation round a radiator. It has been found that the radiation can be divided into two parts: a true scattered radiation, distributed in accordance with the usually accepted theory of the scattering, and an additional or excess radiation. The curves representing the distribution of the latter have been found to resemble those previously obtained for a parallel pencil of β rays after passing through thin sheets of matter.—E. A. **Owen**: The passage of homogeneous Röntgen rays through gases. (1) The absorption coefficient of the different homogeneous radiation in a light gas such as CO_2 or SO_2 is proportional to the absorption of radiations in air. (2) The absorption of homogeneous radiation in a gas is proportional to the pressure of that gas. (3) For the homogeneous rays emitted by metals of atomic weight ranging from that of iron to that of molybdenum, the coefficient of absorption in the gases investigated is approximately inversely proportional to the fifth power of the atomic weight of the radiator which emits that characteristic radiation, *i.e.* $\lambda \alpha \omega^{-5}$. (4) The amount of ionisation produced in a thin layer of a gas is directly proportional to the pressure of the gas. (5) The ionisation relative to air is approximately constant in the same gas for the different homogeneous rays. (6) The total number of ions produced by homogeneous beams of equal intensity is approximately the same in each gas for any particular type of rays.—J. C. **Chapman**: Fluorescent Röntgen radiation from elements of high atomic weight.—J. A. **Gray**: The nature of γ rays excited by β rays. A determination has been made of the relative amount of emergent and incident γ radiation excited in "radiators" of different thicknesses and different materials. Results of the experiments are:—(1) The emergent γ radiation is generally greater in amount than the incident radiation, and is more penetrating. (2) The ratio of emergent to incident γ radiation is greater, for radiators of the same material, the thinner the radiator; for radiators of different materials thick enough to stop the β rays, the lower the atomic weight of the radiator. (3) The results obtained point to the conclusion that the excited γ ray is an entity, the direction of which is nearly that of the β ray exciting it. (4) The chance of a β ray making a γ ray is roughly proportional to the atomic weight of the radiator, provided the β ray spends its range in the radiator.

Geological Society, March 13.—Dr. Aubrey Strahan, F.R.S., president, in the chair.—Dr. R. L. **Sherlock** and A. H. **Noble**: The glacial origin of the Clay-with-Flints of Buckinghamshire, and on a former course of the Thames. The superficial deposits are divided into Clay-with-Flints with the associated Gravelly Drift, and the Fluvioglacial Gravels. Certain high-level gravels, older than any of these, and also the river-gravels and alluvium of the present streams, are not dealt with in the paper. The evidence shows that the Clay-with-Flints and Gravelly Drift were formed by an ice-sheet which came from the north or north-west over the Chiltern Hills. Only the clean upper layers of ice surmounted the escarpment, and this produced the Clay-with-Flints and Gravelly Drift. At that time the Thames flowed from Bourne End through Beaconsfield and Rickmansworth to Watford. The ice-sheet blocked the river-channel between Bourne End and Rickmansworth, and diverted the Thames southwards at Bourne End. The river beyond Watford was further blocked by the Eastern Drift. On the melting of the ice, Fluvioglacial Gravels were left over a great area. These gravels are composed chiefly of Eocene and Cretaceous materials derived from the Gravelly Drift. The floods from the melting ice, added to the waters of the Thames and Colne, produced the great flat through which the Thames now flows. After the retreat of the ice, the Wye and Misbourne extended their channels over the Fluvioglacial Gravel flat, and some other small streams were formed.—Jane **Longstaff**: Some new Lower Carboniferous gasteropoda. Eight species of gasteropoda are described, six being regarded as belonging to five new genera or subgenera, the others representing Pithodea, De Koninck, which has not previously been recorded from the British or Irish Carboniferous Limestone.

Linnean Society, March 21.—Dr. D. H. Scott, F.R.S., president, in the chair.—Dr. I. **Bolivar** and C. **Ferrière**: Orthoptera-Phasmidæ of the Seychelles.—J. A. **Liddell**: *Nitocrameira bdellurae*, a new genus of parasitic Canthocamptidæ.—W. **West** and Prof. G. S. **West**: The periodicity of the phytoplankton of some British lakes.

PARIS.

Academy of Sciences, March 11.—M. Lippmann in the chair.—C. **Guichard**: Osculating circles and osculating spheres to the lines of curvature of a surface.—M. Lucas-Championnière was elected a member of the section of medicine and surgery in the place of the late O. M. Lannelongue.—MM. **Fayet** and **Schaumasse**: The elliptical character of the Schaumasse comet (1911*h*).—E. **Vessiot**: Permutable functions and continuous groups of linear functional transformations. V. **Jamet**: Certain complexes of lines.—Rodolphe **Soreau**: Generalisation of Massau's construction and abacus for solving equations of the form $z^{\alpha+\beta} + nz^{2\beta} + pz^{\beta} + q = 0$.—MM. **Papin** and **Rouilly**: The gyropter. Two diagrams completing the note published on March 4. Samuel **Lifchitz**: The displacement of the particles in the Brownian movement. The explosive shock of the spark as the cause of the phenomenon.—Ch. **Féry**: A new thermo-electric combustion calorimeter. A calorimetric bomb is fixed by two discs of constantan in an external metallic envelope, the latter and the constantan discs forming a thermocouple. The rise of temperature observed, which is high owing to the absence of water, is read directly on a millivoltmeter. Jean **Escard**: Some practical arrangements for the determination of the densities of solid bodies of small volume. A description of a volumometer modified to measure accurately the density of solids having volumes from 1 c.c. to 3 c.c.—P. Th. **Muller** and E. **Carrière**: The refraction and dispersion of the mercury nitrates. J. **Meunier**: Some mechanical phenomena of gaseous combustion. The spiral flame.—H. **Baubigny**: Researches on the formation of dithionic acid in the reaction between alkaline sulphites and copper salts.—V. **Hasenfratz**: Apoharmine-carboxylic acid, apoharmine, and some derivatives of this base.—Marcel **Sommelet**: γ-Ethoxyacetoacetic ester. This ester is obtained by the interaction of ethoxyacetic acid, bromacetic acid, and zinc. Mme. **Ramart-Lucas**: The action of phenylmagnesium bromide upon pinacoline and on methylpinacoline.—H. **Pariselle**: Study of the unsaturated alcohol

$$CH_2=CH-CH_2-CH(OH).-CH_3.$$

This alcohol was prepared by the interaction of allyl bromide, acetaldehyde, and magnesium. Its properties are described, and also those of its acetate and chloride. Marcel **Guerbet**: The action of caustic potash on the tertiary alcohols: a new method for the diagnosis of these alcohols.—A. **Mailhe** and M. **Murat**: The nitro derivatives of phenyl oxide.—J. **Virieux**: *Achromatium oxaliferum.*—Victor **Dupont** and Jean **Gautrelet**: General anæsthesia by the rectum, using titrated mixtures of air and chloroform or the vapours of ethyl chloride. Details of experiments on the rabbit.—Jacques **Pellegrin**: The dentition of *Mobula olfersi.*—D. **Keilin**: The anatomy and development of *Belgica antarctica.* Work done on material collected by M. Gain in the course of the expedition of the *Pourquoi-Pas?* E. Daday **de Dées**: The polymorphism of the males in certain phyllopods.—A. **Cligny**: The marine migration of the common eel. In November, 1911, and January, 1912, about a dozen eels were caught in the English Channel about 20 miles from the coast of Cornwall. A detailed account of the condition of one of these, a female, is given. M. **Flajolet**: Contribution to the application of wireless telegraphy to the prediction of storms. A description of some arrangements for increasing the sensibility of the recording apparatus. With these modifications, the apparatus gives indications of electrical disturbances when the storm is from ten to twenty-four hours distant.—A. **Baldit**: The electrical charges of rain at the Puy-en-Velay in 1911.

March 18. M. Lippmann in the chair.—J. **Boussinesq**: The explanation of the instantaneous action of gravity and molecular forces, without successive propagation, at all distances at which the forces are produced round the material points from which they emanate.—A. **Haller**: Phenyl-, *p*-tolyl-, and diphenyloxyhomocampholic acids and their transformation into benzylidene-*p*-tolylidene- and diphenylmethylene camphors.—Ch. Ed. **Guillaume**: The expansion of commercial nickel. Although the coefficient of expansion of nickel is greater than that of invar (nickel-steel), it has the advantage of withstanding corrosion after prolonged immersion in water. The coefficient of expansion of bars of commercial nickel has been studied over a period of twenty years, and a gradual diminution in the coefficient has been noted. M. Constantin was elected a member of the section of botany in the place of the late M. Bornet. Emile **Belot**: The formation of rings in the Laplace nebula.—H. W. E. **Jung**: The invariant of Zeuthen and Segre.—Jean **Chazy**: A differential equation of which a coefficient is a divergent series.—Louis **Roy**: Waves of shock in the motion of flexible membranes.—Charles **Reignier**: The starting period in aëroplane motors. Unless the motor takes a certain minimum time to attain full power, there is a risk of breaking the propeller or transmission gear. The relation between this time and the strength of the moving parts is investigated in this paper. Georges **Meslin**: The interference fringes obtained with the Fresnel triprism. G. A. **Hemsalech**: The influence of capacity, of self-induction, and of the explosive distance on the velocity of luminous vapours in the electric spark. The velocity of the metallic vapour is not sensibly changed by varying the capacity; it varies inversely as the self-induction of the discharge circuit, and directly as the explosive distance. P. **Mesernitsky**: Contribution to the study of the decomposition of uric acid by the action of the radium emanation. Camille **Matignon**: The equilibrium of the system cadmium sulphate, hydrogen chloride.—P. **Mélikoff** and M. **Becaia**: The estimation of phosphoric acid in presence of colloidal silicic acid. G. **Chavanne**: The ethylene isomerism of acetylene bichloride. J. B. **Senderens**: The catalytic dehydration of the fatty alcohols in the wet way by means of sulphuric acid. Experimental evidence in favour of the view that the formation of ethylenes from alcohols by the action of sulphuric acid is a catalytic effect, and is not due, as is commonly supposed, to a direct withdrawal of water from the alcohols by the acid.—H. **Duval**: Researches on the endoazoic compounds.—Mme. Paul **Lemoine**: The general characters of the Arctic and Antarctic genera of the calciferous algæ.—L. **Cuénot** and L. **Mercier**: Study of cancer in mice.—A. **Trillat** and M. **Fouassier**: The influence of the nature of the gases dissolved in water on the vitality of micro-organisms. The nature of the dissolved gases in water is an important factor in the multiplication and preservation of pathogenic organisms. The results with the Eberth bacillus are especially emphasised. F. de Montessus **de Ballore**: Luminous phenomena accompanying great earthquakes.

MARINE LIFE IN NORTHERN SEAS.

Campagne Arctique de 1907: Duc d'Orléans.
Etude Lithologique de Fonds recueillis dans les Parages de la Nouvelle-Zemble. By Prof. J. Thoulet. Pp. 30+map. (1910.)
Journal de Bord et Physique du Globe. Pp. 101+10 plates+2 maps. (1911.)
Echinodermes. By J. A. Grieg. Pp. vi+40+1 plate+3 maps. (1910.)
Mollusques et Brachiopodes. By Ph. Dautzenberg and H. Fischer. Pp. v+25+map. (1910.)
Faune des Mousses: Tardigrades. By Ferd. Richters. Pp. 20+2 plates. (1911.)
Microplankton des Mers de Barents et de Kara. By Prof. Alph. Meunier. Pp. xviii+355+2 maps; also a volume of xxxvi plates. (1910.)
(Brussels: Charles Bulens, 75 rue Terre-Neuve.)

THE Arctic and Antarctic fauna and flora bid fair to be better known than those of the tropics. Successive expeditions are bringing us back abundant results from both polar regions, and amongst these the Duc d'Orléans's Arctic cruise of 1907 will form a noteworthy contribution to knowledge. The reports are being published in luxurious form by Bulens at Brussels, and the first six volumes of the series are now before us.

This, the second of the Duke's Arctic expeditions, took place in the ship *Belgica*, under the command of Captain A. de Gerlache, and was engaged in exploring the Barents Sea, the Kara Sea, and the Mourman Sea. The physical observations taken on board, including those on the state of the atmosphere, the sky, and the sea, are reported on by M. de Gerlache, who also records the higher animals (mammals and birds) that were observed.

The deposits collected from the bottom of these northern seas are discussed by Prof. J. Thoulet, and they seem to agree with other polar samples in being characterised by the very fine division of the mineral particles and the comparative scarcity of calcareous matter.

Only a few groups of the invertebrate animals from the sea bottom have as yet been reported upon. These include the Echinodermata, discussed by James A. Grieg, evidently a rich collection referred to twenty-five species, none of which, however, are described as new to science. This is not surprising, as, since the Austrian polar expedition under Payer and Weyprecht in 1872–74, the seas traversed by the *Belgica* have been explored by the Dutch *Willem Barents* expedition, the Russian *Yermak*, the successive Swedish expeditions of Nordenskiöld, the Danish *Dijmphna*, the Dutch *Varna*, and the Russian *Zarja*—possibly by others also. Eight of the twenty-five Echinoderm species are known to be circumpolar, and some of the others may prove to be so when we have fuller information as to their distribution to the north of the Pacific Ocean.

The report by MM. Ph. Dautzenberg and H. Fischer deals with thirty-eight species of Mollusca and the two Brachiopods, *Rhynchonella psittacea* and *Waldheimia cranium*. Twenty-seven species of Tardigrada were obtained from collections of mosses made at Novaya Zemblia, at Jan Mayen, Spitsbergen, Greenland, and the Franz-Joseph archipelago. We are told by Dr. Ferd. Richters that the best results were obtained when the mosses were thoroughly dried and sealed up in sterilised bags, from which the Tardigrada and other small game were months afterwards recovered, and revived by the addition of water. The microfauna of these dried mosses was found to contain Tardigrada, Protozoa, Rotifers, Oribatidæ, Oligochæta, Nematodes, and even Copepoda (*Moraria muscicola*). Richters describes for us, from the Tardigrada, two new species of Macrobiotus and three of Diphascon.

By far the most important, however, of these memoirs is that dealing with the Microplankton by Dr. Alph. Meunier, consisting of a large volume of text running to nearly four hundred pages and an atlas of thirty-six beautiful plates crowded with useful figures. This report, and especially perhaps the series of fine plates, will be of the greatest value to all planktologists working on these minute Protista. The groups of pelagic plants and animals dealt with under the convenient term "Microplankton" include Peridiniacea, Diatomacea, Microphyta of coloured snow (such as Diamylon and two new genera, Echinum and Folliculus), Cryptomonadacea, Silicoflagellata, Tintinnidæ, Infusoria, Radiolaria, Foraminifera, and some smaller groups of enigmatical organisms such as Halosphæra and Pterosperma, and quite a number of allied forms, for which no fewer than nine new genera have been created. Altogether twenty-five new genera and a large number of species previously unknown are described and figured in this report. All these planktonic forms, old and new, are the result of twenty-two vertical tow-net hauls and some horizontal ones taken in the Barents and Kara seas.

Dr. Meunier does not always follow the classification and nomenclature of other recent authorities, but whether we can agree with him or not on such points, at least we are grateful for his very beautiful drawings of the forms he is describing. In the Peridiniacea he describes a number of new species belonging to well-known genera, but nothing of a very novel or remarkable nature. A few new genera which are established for species of Peridinium scarcely seem to be sufficiently characterised, and may perhaps be accepted as subgenera.

New forms are added in every group of the Microplankton, but perhaps the most notable additions to knowledge are in "Groupe V—Organismes énigmatiques," where a large number of curiously shaped things are described and figured as being related to Halosphæra, Pterosperma, and their allies, but some of which one cannot help thinking may eventually prove not to be Protista at all, but the eggs and egg-coverings of some of the Metazoa.

The Tintinnidæ and allied Infusoria are very fully treated, and then a few Rhizopoda bring the first part of this report to an end; and the second part—nearly half of the volume—is found to be devoted wholly to Diatomacea. It is almost with a feeling of relief that one finds that not many new forms are added to this already enormous group, and that most of the space is devoted to a discussion of the occurrence and condition of known species, many of them common forms in our own British seas. In a final note to the Microplankton we are promised a supplement in tabular form dealing in detail with the distribution and abundance of the more common species when the remainder of the plankton has been reported on. We look forward with interest to the publication of the remaining volumes.

Altogether this is a notable series, upon the appearance of which the leader of the expedition, his collaborateurs, and the authors of the reports may alike be congratulated.

W. A. Herdman.

LEFT-HANDEDNESS.

Untersuchungen über Linkshändigkeit und die funktionellen Differenzen der Hirnhälften nebst einem Anhang: Ueber Linkshändigkeit in der deutschen Armee. By Dr. Ewald Stier. Pp. iv + 352 + 59. (Jena: Gustav Fischer, 1911.) Price 10 marks.

ONE of the most striking features that serve to distinguish man from all other creatures is his ability to learn to execute skilled movements of a much greater variety, complexity, and precision than are attainable by the rest of his order. But an even more interesting human trait is revealed in the fact that in the vast majority of mankind the right hand and the apparatus which controls its movements are more apt to acquire this skill and to develop its innate potentialities to a much higher degree than the left hand is capable of.

That in a small minority of people this state of affairs is reversed, and the left hand becomes more highly endowed with the inborn aptitude to learn and readiness to perform the more complex and finely adjusted movements, has ever provided food for reflection. For the condition of left-handedness interests not only the student of biology, but also those who concern themselves with educational policy, the devotees of sport, and the "man in the street"; and quite a considerable literature has grown up from the repeated discussions in which this interest has materialised, culminating in this characteristically Teutonic treatise or encyclopædia of all that bears upon the left-handed person, his anatomy, his mental and moral qualities and weaknesses.

It has been assumed as an axiom by almost everyone who has discussed these problems hitherto that the greater skill of the right hand, in the majority of mankind, necessarily implies a superiority of the left cerebral hemisphere, which controls the movements of the right hand—a superiority not only in the mere regulation of skilled motion, which is obvious, but also in its psychical potentialities, which has always seemed to me to be a gratuitous and wholly unjustifiable assumption.

The result of this confusion of ideas has been that most investigators have endeavoured to find some anatomical peculiarity in the left cerebral hemisphere, or some favourable circumstances in the arrangements for its nutrition which would explain this imaginary predominance. But most of such researches have led to a result which their authors regard as utterly enigmatic—that if there is any evidence of superiority of one cerebral hemisphere over the other it is more often the right, and not the left, that excels.

The most instructive illustration of this line of argument is the late Prof. Cunningham's Huxley memorial lecture, delivered in 1902, for he developed it in his usual lucid manner, and frankly admitted that he had reached conclusions precisely the reverse of what he had expected. But though he confessed that he had been baffled, his belief in the existence of the functional superiority of the left cerebrum was not lessened.

In the *British Medical Journal* of August 29, 1908, I protested against the whole assumption involved in this argument that the control of skilled movements of the right arm and the muscles of speech represent the sum total of the higher psychical manifestations of the human intellect. Dr. Stier does not seem to be aware of this criticism, for his treatise may be regarded as a great expansion and elaboration of the theme and the mode of treatment adopted by Prof. Cunningham. Its great value is that it contains a detailed summary of an enormous mass of data (with a full bibliography), including all that relates to left-handedness, asymmetry of the human body and especially of the brain, both as regards structure and function.

Dr. Stier gives the results of an attempt to discover evidence of Mendelian phenomena in the inheritance of left-handedness.

A great deal of curious statistical information is given regarding the frequency of the incidence of left-handedness in men and women, and also in different localities in Germany—sexual and racial distinctions—as well as to the psychology of left-handed persons. Left-handed children are said to be not only slower in learning to read and write, but are much more prone than right-handed children to stigmata of degeneration, as well as to functional disorders.

He protests, not perhaps without considerable justification, against what he calls the fanaticism of ambidextral enthusiasts.

Like many of his predecessors in this field of investigation, Dr. Stier attempts to institute large generalisations concerning the incidence of left-handedness in prehistoric peoples on the evidence of the forms of flint implements, but he does not seem to realise that in the asymmetry of the occipital region of the cranium (as I pointed out in the *Anatomischer Anzeiger* in 1907), more definite and trustworthy personal indications are to be found than any weapons or other handiwork can give.

The book can be recommended as a useful work of reference, provided the reader bears in mind that there is another way of looking at the facts.

G. Elliot Smith.

TECHNICAL CHEMICAL ANALYSIS.

Traité Complet d'Analyse Chimique appliquée aux Essais Industriels By Prof. J. Post and Prof. B. Neumann. Deuxième édition française entièrement refondue. Tome Premier, Quatrième Fascicule. Pp. iv+861–1352. (Paris: A. Hermann et Fils, 1911.) Price 18 frs.

THE most striking novel feature of this new French edition of Post-Neumann's well-known handbook of technical chemical analysis is probably the inclusion in the present volume of a section, covering some 220 pages of text and 30 plates, dealing with the whole subject of Metallography. The inclusion of such a section is typical of the importance which this new science has already attained in France, but it is a little disappointing to find that the section in question is little more than a translation of an elementary text-book of metallography issued by Goerens in German a few years ago.

The text as now printed in French has been considerably extended, and to some extent modified, by the editorship of M. F. Robin—himself one of the most active of the younger French workers in metallographic research—but the whole plan and type of treatment remain the same, and thus retain the inherent defects of the original. One of the more serious of these defects is the almost total neglect of the work done and the results achieved by British workers in this field; in the original German edition French and English workers were almost equally ignored, but the French translator and editor have remedied this as far as French workers are concerned. One consequence of this narrow attitude of mind on the part of the author is that the book in its present form contains many statements which have been shown to be inaccurate.

In the present edition a special feature has been made of the inclusion of "equilibrium diagrams" of as large a number of systems of alloys as possible; a considerable amount of space is therefore taken up by diagrams of this kind, many of which are known to be erroneous, while it is now admitted that the majority of them require substantial modification. The diagrams reproduced in this book have most of them been drawn up by research-students at Göttingen, using rough approximate methods of investigation which Prof. Tammann regarded as adequate for the special purpose which he had in view, viz., the determination of the number of well-defined intermetallic compounds. These methods, however, have been shown to be far too rough and inaccurate for fixing the less obvious portions of these diagrams, so that it is scarcely right to present the reader with many pages filled with these figures without warning of their proximate nature. In some cases, indeed, the diagrams as quoted have long been superseded by better-established results. This applies particularly to those dealing with the alloys of aluminium and copper, and of lead and tin.

A similar criticism might fairly be levelled at the account which is given of the methods of metallographic investigation and of the instruments employed. Thus, no mention is made of the use of the potentiometer for measuring the E.M.F. of a thermo-couple, and while the metallurgical microscopes of Martens-Heyn and Le Chatelier are fully described, equally well-known metallurgical microscopes of British design are not mentioned.

That section of the book dealing with the iron-carbon alloys is, as in the original German edition, far the most satisfactory; the treatment is clear and concise, although here also the latest developments are disregarded. A special word of praise is, however, demanded by the splendid photomicrographs with which this portion, and indeed the whole of the metallographic section, is illustrated. Both as regards the original photographs and the typographical reproduction, practical perfection has been attained—and, indeed, these photo-micrographs almost deserve the lavish setting of black margins and wide white spaces with which they are adorned.

The remaining portions of this volume, dealing mainly with inorganic acids, follow closely on the lines of the previous edition, and call for little special comment, except as regards the sections dealing with the estimation of carbon in steel. Here the simplest and most trustworthy of the available methods—that of direct combustion in oxygen—has not even been mentioned, while the various risks of error attaching to the other methods described are entirely ignored.

The perusal of the volume as a whole raises the question whether these large compilations really serve any useful purpose; they attain huge dimensions by endeavouring to cover the entire ground of technical chemistry so far as analyses and tests are concerned, and yet the treatment of each subject is limited and is liable to become one-sided and inadequate. It would seem that with the huge dimensions now attained by the various branches of the subject, the day of the general handbook has passed, and the era of the special monograph has dawned.

A HANDBOOK OF PHOTOTELEGRAPHY.

Handbuch der Phototelegraphie und Telautographie. By Profs. Arthur Korn and Bruno Glatzel. Pp. xvi + 488. (Leipzig: Otto Nemnich, 1911.) Price 28 marks.

THIS is a book which, by reason of its thoroughness and its exhaustive treatment of matters which bear upon the main subject, must be recognised as the standard work of reference on phototelegraphy for a long time to come. Such an immense amount of work has been done in this branch of telegraphy that the book must be regarded to a great extent as historical, for even Prof. Korn himself quickly rendered his own selenium apparatus obsolete by the rapid improvements effected in his telautograph.

The first chemical telegraph of Alexander Bain came really before its time, as although a suitable system has been based upon it for the transmission of half-tone photographs, half-tone photographs did not exist in 1843, when Bain started his experiments. Much of the apparatus for telegraphing pictures and photographs is, in fact, seen from Prof. Korn's work to have been the practical outcome of extensive experiments made originally for the purposes of ordinary word telegraphy.

The book is rendered of the highest possible practical value on account of the large number of diagrams and illustrations, particularly those relating to constructional points, and those who are to any extent conversant with the practical difficulties of picture-telegraphy may perhaps wish that still more space had been reserved for the discussion of the modern apparatus.

Perhaps the most interesting portion of the book is that relating to Prof. Korn's apparatus for transmission by means of selenium. This element is undoubtedly destined to find further uses in physical measurements, and the excellent work done by the authors in overcoming the inertia of selenium under the influence of light should prove of considerable value. The short chapter on photoelectric cells will, it is to be hoped, be made much fuller in a future edition in view of their important application to astronomical measurements; some data as to the constants of the cells prepared by Elster and Geitel would have been welcomed by many readers.

As will be seen from the reproductions of results obtained with Prof. Korn's telautograph, the amount of detail that can be obtained in a telegraphed picture is quite remarkable; the transmitter comprises a metal drum revolving under a stylus, the picture being drawn (or photographed in line) in insulating ink; this effects the interruptions of the current flowing through the telegraph lines, which are recorded by a special type of Einthoven galvanometer, the metal "string" of which is shifted on the passage through it of a weak current, the shift allowing a narrow beam of light to pass to the exposing box, where a synchronously revolving drum furnished with photographic paper is placed.

The systems or adaptations of Charbonelle, Berjeanneau, Belin, Thorne-Baker, and others are described, though the reader is not given an opportunity to compare their results with those obtained by the authors, and brief reference is made to the wireless experiments that have been carried out.

The book is thoroughly up to date, including references even to the new system of Prof. Tschörner, of Vienna, and will be found extremely interesting by the many people who are at the present time experimenting in the directions discussed.

T. T. B.

THE MEASUREMENT OF REFRACTION.

Refraktometrisches Hilfsbuch. By Prof. W. A. Roth and Dr. F. Eisenlohr. Pp. viii+146. (Leipzig: Veit and Co., 1911.) Price 6 marks.

A MEASUREMENT of the refractive power of a liquid, while of considerable practical value for identifying the liquid or for ascertaining its freedom from impurities, is of far greater importance from the purely scientific point of view. Investigation has shown that for each substance a relation subsists between the refractive index and the density that is independent of the temperature; and, further, that the specific refractive index, as this relation is termed, may be calculated when the molecular constitution is known. Various formulæ have been suggested for the specific refractive index. Thus Gladstone and Dale on empirical grounds proposed $\frac{n-1}{d}$; while a more accurate expression $\frac{n^2-1}{n^2+2} \cdot \frac{1}{d}$ was afterwards put forward simultaneously from theoretical considerations by two men of nearly the same name, Lorenz in Copenhagen and Lorentz in Leyden.

The little book which Prof. Roth and Dr. Eisenlohr have prepared will prove invaluable to investigators in the subject, and, in fact, to all who have need to measure the refractive indices of liquids with the highest possible degree of accuracy. They fully describe the various forms of refractometer in use for the purpose and the methods of using them, and state the corrections necessary when the temperature of the observations differs appreciably from the standard, and give in tables the indices corresponding to the divisions in instruments with arbitrary scales. The old method of determining the deviation of a beam of light passing through the liquid contained in a hollow glass prism has entirely given way to the more convenient and more accurate method based upon the principle of total-reflexion. They describe further with equal fulness the method of finding the density by means of a pyrometer, point out the corrections required by the expansion of the glass, and give tables to facilitate their application. Towards the end of the book the authors show by a few examples how closely the observed value of the molecular refractive index agrees with that deduced from the constitution, and discuss the meaning of the sensible differences that occur in certain groups of substances. The book closes with some useful tables, and a small book of five-figure logarithms is enclosed in a pocket within the cover.

OUR BOOKSHELF.

The Modern Locomotive. By C. Edgar Allen. Pp. ix+175. (Cambridge: The University Press, 1912.) Price 1*s.* net.

This volume belongs to the series of Cambridge Manuals of Science and Literature, and taken as a whole the information given in it is up to date and described in terms clearly evident to the lay reader.

As the boiler is "the heart and soul" of a locomotive, the author deals with it in chapter i. He claims that the multitubular boiler as fitted to the "Rocket" originated with Mr. Booth, the secretary of the Liverpool and Manchester Railway—an unwarrantable claim, and one made for the first time, so far as the present reviewer's knowledge of locomotive history goes. The "Rocket's" multitubular boiler was to the designs of William Henry James, son of William James—the father of railways. In an agreement dated September 1, 1821, W. H. James's patent was assigned to Messrs. G. Stephenson and Wm. Lush on certain terms, and it was with this boiler the prize of 500*l.* was won at Liverpool in 1827 by the "Rocket."

The chapter is interesting; it illustrates how old ideas are resuscitated even in locomotive engineering; for instance, the spark arrestor, so called, illustrated in Fig. 9, and the variable blast pipe in Fig. 10, were both in use on the Manchester, Sheffield, and Lincolnshire Railway, now the Great Central Railway, in the year 1878. The question of a satisfactory spark arrestor is a prominent one at the present time, and many experiments are in progress: a combination of Louvre plates on the smoke box and an ash-ejecting arrangement on the blast pipe is now giving satisfactory results. Chapter iii. is devoted to modifications and improvements in the standard boiler.

The volume will be found to contain much interesting and useful information. It should be of much use to those of the general public who take an intelligent and intense interest in the locomotive. To the apprentice in the works the information should be of particular value.

N. J. L.

The Gardener and the Cook. By Lucy H. Yates. Pp. x+260. (London: Constable & Co., Ltd., 1912.) Price 3*s.* 6*d.*

This little book is attractive in more ways than one. It stimulates the imagination as to what can be done both in garden and kitchen, more especially in the kitchen. It leaves, however, a little sediment of despair in the mind, after all, for where out of France are "Charlottes" to be found? So much depends upon "Charlotte," the cook.

What use is a kitchen-garden, however successful, if you have a stupid, obdurate "Charlotte," who will not see that to be a real cook is to have a talent for taking pains, and that to be careful and wise is not to be mean? Who can persuade our English cooks that cooking is an art, and requires interest, care, and work, and some imagination, and not a thing to be undertaken only to be done with as soon as possible?

Would these women who are clamouring for the "right" to do work for which they are obviously unfitted turn their superfluous energies to training themselves and then training our "Charlottes" in the knowledge of the delights of the combination of thrift and dainty dishes, of which this book gives so fascinating and practical an account, then indeed would their now wasted energies have some real and useful result. There is no more needed reformation than that of work in our kitchens. To anyone with a conscience and some little knowledge, the wastes and missed opportunities, even in the simplest kitchen, are appalling.

This book should be a help to many a young housekeeper towards bettering things in her own home and perhaps inspiring a young "Charlotte" to realise the beauty and importance of her work, and to lead her on also to realise the importance of small things in the kitchen.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Acquired Characters and Stimuli.

I thank Sir Ray Lankester for the complimentary expression with which he begins his letter (Nature, March 21) and for the friendly feeling which prevents him saying I am quibbling. However, he gives his reason for thinking I am quibbling. I will admit my offence if he will indicate precisely how an inborn trait is more inborn and less acquired than an acquirement. In my letter I implied that by "acquired character" biologists mean a trait developed under the influence of use or injury. Sir Ray Lankester insists that I am wrong. He says that Lamarck, the original user, employed the term to indicate a trait which is "abnormal," because the individual who developed it was exposed to an "abnormal environment." To quote his own words, "The new character or characters developed in response to the abnormal environment (which we assume to be allowed to act on the growing individual only, and not on its parents) are called by Lamarck—and those who wish to discuss Lamarck's theory—'acquired characters' (*changements acquis*). The word 'acquire' is used to mean something 'added to' or 'changed in' the normal form of the species." He adds "That, I take it, is Lamarck's meaning, and it is what I, and others, have for more than twenty-five years accepted."

I cannot, of course, be sure of the identity of the "others" to whom Sir Ray alludes as having taken part in "a historical discussion," but the following passages are taken at random from men who were not unknown about that time. "Lamarck . . . attributed the changes of species chiefly to the effects of changes in the conditions of life—such as climate, food, &c.—and especially to the desires and efforts of the animals themselves to improve their condition, leading to a modification of form or size in certain parts, owing to the well-known physiological law that all organs are strengthened by constant use, while they are weakened or even completely lost by disuse."[1] "It seems difficult and well-nigh impossible to deny the transmission of acquired characters when we remember the influence which use and disuse have exercised upon certain special organs. It is well known that Lamarck attempted to explain the structure of the organism as almost entirely due to this principle alone."[2] "And so in the case of other animals, Lamarck believed that the adaptation of their forms to their habits could be explained by this simple hypothesis that the habits created the forms, through the effects of use and disuse, coupled with heredity. Such is what is ordinarily known as Lamarck's theory of evolution. We may as well remember, however, that it really constitutes only one part of his theory; for besides the hypothesis of the cumulative inheritance of functionally-produced modifications—to which we may add the inherited effects of any direct action exercised by surrounding conditions of life—Lamarck believed in some transcendental principle tending to produce gradual improvement in predetermined lines of advance. Therefore it would be more correct to designate the former hypothesis by the name either of Erasmus Darwin, or, still better, of Herbert Spencer. Nevertheless, in order to avoid confusion, I will follow established custom, and subsequently speak of this hypothesis as the Lamarckian hypothesis—understanding, however, that in employing this designation I am not referring to any part or factor of Lamarck's general theory of evolution other than the one which has just been described—namely, the hypothesis of the cumulative transmission of functionally-produced or otherwise 'acquired modifications.'"[3]

It will be seen that I have sinned, if I have sinned, in good company. The men from whom I quote evidently regarded an acquired character as, in essence, a "functional modification," an effect of "use or disuse," "to which may be added the inherited effects of any direct action exercised by surrounding conditions of life" (*e.g.* injury). I suppose I could cite scores or hundreds of similar passages. The fundamental errors expressed or implied in them all are (1) that there is a general law that *all* organs are strengthened by constant use and weakened by disuse, and (2) that use and disuse produce only "abnormal" traits. There is no such law; some structures (*e.g.* external ears, hair, teeth) in the higher animals (*e.g.* man) are not in the least affected by use; there is no clear evidence that animals low in the scale of life develop at all under this influence; and very clear evidence that the power, the potentiality, of so developing has undergone such increase in the higher animals that it constitutes the main feature of their evolution. To it they owe all their physical and mental adaptability—their intelligence, for instance. The child grows into the adult just as much under its influence as the adult grows into the exceptional adult (*e.g.* the trained athlete). We have every reason, therefore, to believe that the potentiality to develop under the influence of use, at any rate to any considerable extent, is a late and a high product of evolution. The point raised by Sir Ray Lankester is, however, as far as I am concerned, immaterial—a distinction without a difference. If he prefers, let us, by all means, consider abnormality resulting from abnormal use as the distinguishing characteristic of an acquirement. To take an illustration, the muscular development, both of the ordinary individual and of the blacksmith, is due to use. Sir Ray Lankester regards the former as normal, and *therefore* inborn

[1] Wallace, "Darwinism," p. 3.
[2] "Weismann on Heredity," English translation, 2nd edition, vol. i., pp. 83-4.
[3] Romanes, "Darwin and After Darwin," vol. i., p. 255.

and inheritable, and the latter as abnormal, and *therefore* acquired and non-inheritable. If almost all men laboured as blacksmiths the positions would be reversed; that which to-day is normal and inborn would become abnormal and acquired. I regret, however, I am still unable to follow the line of thought which connects normality with innateness and inheritability, and abnormality with acquiredness and non-inheritability. In what respects is the normal character more innate and inheritable than the abnormal trait? If Lamarck's words, or the words of those who controverted him, had any meaning, what was that meaning?

Sir Ray Lankester objects also to my use of the word "stimulus." It seems, for example, that I express myself wrongly when I say that a muscle grows under the stimulus of use. I fear, if he is right, I do not know the meaning of the word. Here again, however, the point is immaterial. His own word "influence" will serve. The substitution does not affect the argument.

Darwin's theory of evolution through the natural selection of favourable variations—or at any rate what is known as the neo-Darwinian theory—is intelligible. It separates *likenesses and differences* between individuals (*e.g.* parent and offspring) into those which are inborn and inheritable and those which are acquired and non-inheritable. An inborn likeness or difference is one which depends on a likeness or difference in germinal potentiality; an acquired likeness or difference is one which depends on a likeness or difference in the action of the environment. On the other hand, the Lamarckian hypothesis, founded as it is on the notion that some *characters* (*e.g.* heads) are inborn, and others (*e.g.* scars) acquired, is not intelligible. The terms used are meaningless in the connection in which they are employed. Obviously, all characters depend equally on an interaction between germinal potentiality and external stimulus. They are all, therefore, as inborn and acquired, as blastogenic and somatogenic as they can possibly be. No such things are conceivable as purely blastogenic and somatogenic characters, or characters which are more blastogenic or somatogenic than others. The whole "historical discussion," therefore, is of the same order as would be one in which physicists discussed whether gravitation was blue or yellow.

The Lamarckian controversy is, in effect, ended. The great majority of biologists reject the hypothesis that acquirements are transmissible. The next step, I think, will be a rejection of the very notion that some characters are inborn and others acquired, and an acceptance of the reality that the different classes of characters are distinguishable from one another because they are responses to different kinds of stimuli—nutriment, use, injury, and the like. Doubtless we shall then have a discussion as to what characters, in the different species, develop under this stimulus, and what under that, and ultimately a general recognition of the immensely important truth that the peculiar characteristic of the higher animals is that the individual develops after birth more under the influence of use than under any other stimulus—hence the fact that man, the highest animal of all, is, as Sir Ray Lankester has often insisted, pre-eminently the educable animal both in mind and in body.

G. ARCHDALL REID.

Southsea, March 29.

Red Water.

A SAMPLE of red water from a crater lake in Uganda, which "looks like blood at times," sent by Dr. R. van Someren presents some features of interest.

The colour was separated by filtration through a Berkefeld filter, but not through filter paper. It disappeared on the addition of a mineral acid or caustic alkali, and was not extracted by ether. The red deposit on the Berkefeld filter consisted of disintegrated organic remains. From the water itself mixed with nutrient agar a bacterial culture was obtained, which did not develop either in an artificial brine or in ordinary culture media.

A litre of the red water contained 247 g. sodium chloride, 96·8 g. sodium carbonate, 53·8 g. sodium sulphate, 10·5 g. potassium chloride, 5·1 g. sodium bicarbonate, and 2·4 g. sodium phosphate.

As the chemical composition of the water gives no clue to the colouring matter, it is probably due to an organism capable of growing in a practically saturated alkaline brine.

We should be glad to know of the occurrence of similar red brines and the causes of coloration.

April Meteor-showers.

THE following are the most important meteor-showers that become due between April 5 and the end of the month:—

Epoch April 6, 20h. (G.M.T.), 1st order of magnitude. Principal maximum, April 7, 12h. 45m.; secondary maximum, April 8, 5h. 30m.

Epoch April 9, 3h., 11th order of magnitude. Principal maximum, April 7, 16h. 15m.; secondary maximum, April 8, 14h.

Epoch April 7, 14h. 30m., 10th order of magnitude. Principal maximum, April 8, 5h.; secondary maximum, April 10, 10h. 40m.

Epoch April 14, 12h. 30m., approximately 16th order of magnitude. Principal maximum, April 14, 4h. 10m.; secondary maxima, April 13, 6h. 30m. and 10h. 30m.

Epoch April 13, 22h., 3rd order of magnitude. Principal maximum, April 15, 13h. 30m.; secondary maximum, April 15, 16h. 30m.

Epoch April 16, 17h., approximately 10th order of magnitude. Principal maximum, April 17, 4h.; secondary maximum, April 19, 0h. 45m.

Epoch April 21, 4h., 1st order of magnitude. Principal maximum, April 20, 21h. 30m.; secondary maxima, April 20, 10h. 20m., and April 21, 11h. 30m.

Epoch April 23, 6h., approximately 10th order of magnitude. Principal maximum, April 24, 10h. 55m.; secondary maxima, April 23, 11h. 50m., and April 25, 10h.

Epoch April 26, 6h., approximately 4th order of magnitude. Principal maximum, April 26, 11h. 50m.; secondary maxima, April 26, 7h. 40m., April 27, 10h. 50m., and April 28, 0h. 55m.

Epoch April 29, 14h., 7th order of magnitude. Principal maximum, April 28, 2h. 15m.; secondary maximum, April 28, 8h. 35m.

The maxima about April 20–21, though belonging to an epoch of the first order of magnitude, are not so strong as they might be, the night maxima especially being rather weak. The maxima have been so computed that when observations are possible shooting stars should be seen within a few minutes from the predicted times. The heaviest maxima of the month are the principal maxima that occur on April 17 and April 24 respectively.

Dublin.

MAN OF NEANDERTHAL TYPE IN THE CAMBRIDGE FENS.

THE bones of primæval man are so rare, and there is so much uncertainty as to the mode of occurrence and association of the earlier specimens, that it is important to place on record any new case which may be brought under our notice. I have had the good fortune lately to assist in digging out the skeleton of a man whose skull was distinctly of Neanderthal type. In this case I think I am justified in using that name, because as much as was preserved of the Neanderthal man is represented in the skull now described, and is similar to it.

We cannot compare the Neanderthal man, whose lower jaw was lost, with the man of Mauer, near Heidelberg, of whom only the lower jaw has been preserved. But we have the lower jaw of the man found near Shippea Hill in the Cambridge Fens, and it differs in essential characters from that of Mauer. The skull of the Shippea man differs also in form from those of Sainte Chapelle, described by M. Marcellin Boule. The general section across the ground is as shown in Fig. 1. An island of Kimeridge Clay, known as Shippea Hill, rises out of the fen about 3 miles E.S.E. of Littleport, and on it a farm represents the site, and preserves some of the ancient masonry, of a monastic retreat connected with Ely.

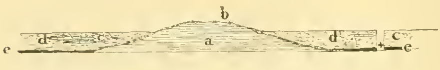

Fig. 1.—Shippea Hill. *a*, Kimeridge clay; *b*, gravel; *c*, peat; *d*, white marl; *e*, Buttery clay; +, position of skeleton.

On the Littleport side the peat, with beds of white marl in it, rests at a depth of from 4 to 6 feet on a blue-grey fine unctuous clay, which we refer to as the Buttery Clay. This contains large shells of the common cockle with valves adherent, *Tellina* (*Tacoma*) *balthica*, *Scrobicularia piperata*, and other estuarine shells, and, in the peat above it, bones of the Urus, wild boar, and beaver have been found.

On the south side of Shippea Hill the section is much the same, but here we have not, so far, found the estuarine shells in the Buttery Clay. Freshwater shells occur commonly in the white marl and less commonly in the peat.

The skeleton was found in digging trenches through the peat in order to obtain the underlying clay to lay on the land, so that a clean cut was made down to the Buttery Clay in each trench.

Mr. Luddington, to whom the property belongs, and Mrs. Luddington, who has a collection of objects from the fens, informed us of the discovery, and gave us every facility for investigating the circumstances on the spot at once. We were thus able to examine the section and collect a large number of the fragments of the skull and other bones of the skeleton which had been overlooked at first.

The skeleton was found between Shippea Hill Farm and the railway, about 4 feet down in the peat, and a few inches above the Buttery Clay. It was bunched up so that all the bones were packed into a space not more than two feet square. It looked as if the man had been mired and sunk straight down exhausted, and not as if a dead body had been carried down by water. The character of the peat also precludes this supposition, for it is peat grown on the spot, and not travelled peat, though in that often-flooded area it readily becomes sludge, and penetrates into any cavity. I lay stress upon this point because I know from my own experience in excavations that there are sources of error in speculations as to the original form of fossil skulls.

If a sepulchral urn has not been tightly filled before interment, and the interior is capable of compression, it is commonly crushed, or, if not well fired, squeezed out of shape, without much fracture, and on drying retains its flattened form. Skulls also, if buried under conditions which do not allow of their being filled *pari passu* with the disappearance of the organic matter inside, are sometimes, of course, crushed flat, but sometimes only deformed by the pressure, and, when dried, appear to be of abnormal shape. In the example now described, however, the peat filled the skull and preserved its form against the small pressure of the overlying spongy material. Unfortunately it got broken in the first excavation, but the fragments were not deformed, and readily fell into their place in the rotundity of the cranium. It has now been skilfully restored by Mr. C. E. Gray, and I hope on a future occasion to be able to offer a full description of it by an expert.

I will only point out now that it is a good round skull, somewhat largely developed posteriorly, but not elongated into a conical projection in the occipital region. It agrees very well in its *norma verticalis* with the Neanderthal skull. (See Fig. 2.)

The most conspicuous feature is the prominent brow, its strong supraciliary ridges and flattened forehead bringing it again into comparison with the Neanderthal skull. (See Fig. 3, side view, and Fig. 4, front view.)

There is very little of the face or upper jaw preserved. The lower jaw of the Neanderthal man is missing; so here our comparison with that example ends. In the Shippea Hill man the lower jaw (see Fig. 5) [1] is well preserved. It does not show the flat or receding chin of the Mauer jaw or of some of those recently described by M. Marcellin Boule. The teeth are large, strong, and sound, but curiously worn down obliquely on the outer margin, as if the upper jaw had been somewhat broader than the lower.

Here, therefore, is a man whose skull shows all the characteristics of that of Neanderthal, including the prominent supraciliary ridges, but having in addition a powerful lower jaw, and large terminations to his limb bones, and found undoubtedly *in* the peat of the fens.

[1] The drawings Figs. 1 to 5 are by the skilful and experienced pencil of Mr. Edwin Wilson.

I reserve discussion of the possibility of this part of the peat being of more ancient date than that to which it has generally been referred an opinion which might be suggested by the occurrence of *Rhinoceros tichorhinus* under the peat at Little Downham, or of the still older *Elephas antiquus* under the margin of the fen deposits near Whittlesea, and will content myself now with stating my own conviction that the peat in which the Shippea man was found cannot be older than Neolithic times, and may be much newer.

Notwithstanding his Neanderthal character I should not be surprised to find that he was a man of much later date, even a monk from Ely, perhaps a foreigner, who had lost his way and sunk down in the peaty swamp of the then undrained fens.

T. McKenny Hughes.

THE INTERNATIONAL RADIUM STANDARD.

THE committee formed at the Brussels Congress of Radiology and Electricity in September, 1910, for the purpose of fixing an international standard of radium, of which a full account appeared in Nature of October 6, 1910, met in Paris from March 25–28. There were present Mme. Curie, MM. Debierne, Rutherford, Soddy, Hahn, Meyer, and Schweidler. MM. Geitel, Eve, and Boltwood were unable to attend. The main purpose of the meeting was to compare the standard prepared by Mme. Curie with others prepared by Hönigschmid from the material in possession of the Académie des Sciences at Vienna, during the course of his new determination of the atomic weight of radium, referred to in Nature of March 21 (p. 68). Mme. Curie's standard consisted of 21·99 milligrams of radium chloride specially prepared by methods similar to those used by her for atomic weight determination, and sealed up in a thin glass tube with every precaution against error. The Vienna standards consisted of three tubes, containing respectively 10·11, 31·17, 40·43 milligrams of radium chloride, which were sealed up in somewhat wider glass tubes, but of the same thickness of wall (0·27 mm.) as the other, and were prepared by methods based on those devised by T. W. Richards for weighing hygroscopic substances.

It may be recalled that Hönigschmid found the value 225·95 for the atomic weight of radium, which is 0·45 lower than that found by Mme. Curie. This is a difference of only 1 part in 500, and, considering the small amount of material, is probably not due to differences in the purity, especially as certain corrections, such as for the solubility of the silver chloride, were introduced into the calculation of the atomic weight from the later determinations. It was therefore of the greatest interest to compare directly these two sets of entirely independent standards. Mme. Curie was sufficiently recovered from her recent illness to take some part, both in the deliberations and measurements of the meeting. Prof. Rutherford was chosen as the president of the committee.

After a visit to Mme. Curie's laboratory in the rue Cuvier, the committee proceeded to the Sorbonne, where, in Prof. Lippmann's department, a room, uncontaminated by radium, had been set apart for the measurements. Here M. Debierne had set up an interesting installation, capable of comparing the γ-rays of the standards by two distinct methods. The first method is based on the well-known null-method, largely employed in Paris, but hardly anywhere else, involving the quartz piézo-électrique of Pierre Curie. The ionisation current due to the γ-rays of the preparation was balanced by the electricity generated by relieving the tension of a stretched quartz lamina, by gradually lifting a weight from the pan, the electrometer needle so being held to its zero and the time measured from the commencement to the end of the lifting of the weight. This requires practice, and the admirable skill of the French observers with the method was humorously illustrated by the attempts of some of the visitors to emulate them. The form of ionisation chamber adopted calls for special remark. The radium standard was laid on the centre of a large circular disc of lead, 1 cm. thick, which formed the upper plate of a condenser, the distance between the plates being small compared with their diameter. A potentional of 800 volts was used to ensure saturation.

The other method was that recently described at the Physical Society by Rutherford and Chadwick, and is also a null-method, the γ-ray ionisation being exactly balanced by a special form of Bronson's "air resistance." The special feature of the arrangement is that the radium standard is mounted on an optical bench at a distance from a lead ionisation chamber, and the distance is varied until exact balance is obtained. The strengths of different preparations are proportional to the square of the distances, correction being made for air absorption of the γ-rays. Each method naturally has its own advantages and range of applicability.

After comparisons by both methods, the gratifying result was arrived at that the Paris and Austrian standards agreed perfectly with one another within the limits of error of the measurements. Naturally, to obtain the highest possible accuracy with the methods, a much more extended series of measurements than was possible in the short time available would have been necessary. But it was clear that the error of measurement was certainly not greater than 1 part in 300, and was probably much less. For example, for two single comparisons, the 31·17 mg. Vienna standard came out as 31·24 mg. and the 10·11 mg. as 10·13 mg. in terms of the Paris standard. The standards being entirely independent, this result reflects the greatest credit on the care and accuracy bestowed by Mme. Curie and the other investigators responsible for their preparation and for the methods of measurement. In future it will be possible to evaluate the quantity of radium in a preparation, in the absence of other radioactive substances giving γ-rays, by simple γ-ray comparison with these standards without any chemical operations and without opening the tube in which it is sealed, with an accuracy of at least 3 or 4 parts in 1000.

The committee also had the advantage of having a standard, sent by Sir William Ramsay, and prepared from material employed in the just-published atomic weight determinations by him in conjunction with Whytlaw Gray (Proc. Roy. Soc., 1912, 86 A, 270). The quantity of radium was much smaller than in the others, and corresponded to less than 4 mg. of radium chloride. In addition, it was not comparable, either in the manner of its preparation or of its mounting, with the others, the tube in which it was contained being of quartz, relatively thick in the wall. For these reasons no definite comparison was possible of the same degree of accuracy as for the others.

The committee accepted Mme. Curie's standard as the International Radium Standard, and will ask for its preservation in the Bureau International des Poids et Mesures in Paris. They have arranged for the 31·17 mg. Austrian standard to be similarly preserved in Vienna as a reserve standard. These standards are hereafter only to be used for purposes of comparison by the committee, and are not to be taken away from the cities mentioned or to be used for experiment. Arrangements have been made for the preparation of secondary standards, of between 10 and 40 milligrams of radium chloride, to be provided to the Governments of the various countries desiring them for their official testing institutions. These secondary standards will be compared independently at Paris and Vienna with the international and reserve standards, and will be supplied with a certificate showing the result of the comparisons. Further particulars may be obtained from the secretary of the committee, Prof. Stefan Meyer, Institut für Radiumforschung, Waisenhausgasse 3, Wien IX, Austria.

In the course of a few months it will be possible for each country to possess a radium standard which has been compared directly with the international standard, which will enable measurements to be made in future with complete confidence, and will be invaluable both for scientific and commercial comparisons.

The necessity of refunding to Mme. Curie a quantity of radium equivalent to that contained in the international standard has been a source of anxiety to the committee, who have no funds at their disposal. It is therefore most satisfactory to be able to announce that as soon as the need was made known, the sum necessary was generously donated in this country by Dr. and Mrs. G. T. Beilby as a personal tribute to Mme. Curie and her work.

NOTES.

The *Terra Nova*, the vessel of the British Antarctic expedition, arrived at Akaroa, New Zealand, on April 1, and brought the news that on January 3 Captain Scott and five other members of the expedition were within 150 miles of the south pole, and that he intends to remain another year in the Antarctic. A detailed account of the work accomplished by the expedition has been obtained by the Central News, Ltd., agency, and appeared in the daily papers on Tuesday and Wednesday. Captain Scott left the base at McMurdo Sound on November 2, 1911, for the poleward journey, and had arrived at latitude 87° 32′ S. on January 3. Nearly three weeks before this date Captain Amundsen had reached the south pole. Though Captain Scott has thus been forestalled as regards the first arrival at lat. 90° S., the scientific results of the British expedition promise to make up for any disappointment which may be felt from the point of view of national sentiment. Specimens of coal of economic value, and well-preserved fossils, have been found near Granite Harbour by the western geological party. Marine biological work has been carried on continuously, and every phase of seal, penguin, and skua-gull life has been photographed with the kinematograph. By means of small balloons the direction of atmospheric currents has been studied up to a height of six miles, and the temperatures have been recorded up to a height of five miles. Valuable magnetic, electrical, tidal, pendulum, and other observations relating to terrestrial physics have been made, and much has been done also in the fields of ice work and physiography. A summary of scientific work accomplished was published yesterday, and we hope to refer to its details next week. Meanwhile, we offer to Captain Scott and the other members of the British Antarctic expedition the thanks of the scientific world for the attention being given to systematic observations, which are of far greater value than the attainment of the south pole. By deciding to spend another winter in the Antarctic, Captain Scott has given us additional cause to be grateful to him, and we may look forward confidently to a harvest of results of prime importance when the expedition returns to civilisation next year.

A summary of the weather for the first quarter of the present year, as shown by the results for the thirteen weeks ended March 30th, issued by the Meteorological Office shows that the conditions were generally mild and wet over the United Kingdom. The mean temperature for the whole period was everywhere above the normal, the greatest excess occurring in the eastern and midland districts of England. The aggregate rainfall was in excess of the average everywhere, except in the north of Scotland, where the deficiency was rather more than 3 in. The largest total measurement of rain was 13·56 in. in the south-west of England, where the excess on the average was 4·15 in. The next greatest excess was 3·54 in. in the Channel Islands, and this was followed by 3·28 in. in the midland counties and 3·05 in. in the south-east of England. The largest number of rainy days in any district was 72 in the south of Ireland and 70 days in the south-west of England. The number of rainy days was in excess of the average in all districts, except in the north of Ireland. The duration of bright sunshine for the period was everywhere deficient, except in the north of Scotland, where there was a slight excess. At Greenwich the mean temperature for the three months was 44°, which is 3·5° in excess of the average, and it was 3·5° higher than for the corresponding period in 1911. The mean temperature was in excess of the average in each month, the excess for the three months being respectively 1·7°, 3·7°, and 4·7°. The aggregate rainfall for the three months at Greenwich was 7·18 in., which is 2·30 in. more than the average; the excess of rain in the three months was respectively 1·07 in., 0·11 in., and 1·12 in. The total duration of sunshine at Greenwich was 159h., which is 28h. less than the normal, the deficiency in the three months being respectively 6h., 14h., and 8h.

The crisis through which the country has passed during the last few weeks in relation to its fuel supply should expressly bring home to us the necessity for a more general appreciation of what lies ahead, and at no distant future, in the possible exhaustion, or at least very restricted output, of our coal measures. Many have directed attention to this grave problem, but the public attitude has been one of indifference, or, at most, a pious hope that something will replace coal. A useful pamphlet on "Natural Sources of Energy," being the report of a committee of the British Science Guild, just issued by the guild, appears at a particularly opportune moment, emphasising as it does the improbability of that useful find within the horizon of scientific knowledge and the need of serious efforts to check that enormous waste of coal which characterises our present methods. As Dr. Beilby shows, the saving by adoption of scientific methods might amount to 40 to 60 million tons per annum. How the turbine, gas-producer, and gas-engine—especially with utilisation of blast-furnace and coke-oven gas, so much of which is annually wasted or inefficiently utilised—can contribute to this economy is clearly shown. Oil engines, especially of the Diesel type, are shown to give high efficiency, but the enormous economic question of supply and output are clearly dealt with by Sir Boverton Redwood, according to whom the total crude oil output used under the best conditions is only equal to 15 per cent. of the coal. Other contributors to the report are Sir William Ramsay, the Hon. R. J. Strutt, Prof. V. B. Lewes, Mr. Dugald Clark, Sir Charles Parsons, and Mr. W. F. Reid.

The photography of colour by purely optical means, that is, without the use of pigments, dyes, or coloured screens, has been shown to be possible in two or three different ways. One of these methods was described and demonstrated with remarkable success by Messrs. Julius and Ernest Rheinberg at a meeting of the Royal Photographic Society held last week. These gentlemen have eliminated the practical difficulties of the process one at a time, and by their patient perseverance have produced a camera that conveniently serves for the taking of the photographs, for the viewing of them by means of an eyepiece, or for the projection of them upon a screen. An image of the view or object to be photographed is produced upon a ruled plate that has transparent lines alternating with much wider opaque lines. Behind the lined screen is a low-angled compound prism, so constructed and adjusted that it disperses the light that passes through each transparent line into a spectrum, which covers the otherwise blank space that corresponds to the adjacent opaque line. The whole surface, therefore, instead of being white and black is covered with these long, narrow spectra, which are narrow enough to be indistinguishable to the unaided eye, however the final picture is viewed. These spectra serve the same purpose as the three colours of an autochrome plate. A second lens focusses the image on to the photographic plate, which thus becomes a record of the original and all its colours. The optical part of the apparatus is so compactly arranged that it is all contained in a tube that is rather longer than a moderate-sized lens mount. Landscapes from nature, portraits, copies of pictures, photographs of jewellery, and of other subjects showed that the resulting colours were wonderfully true to the originals.

Mr. C. E. Adams has been appointed Government astronomer for the Dominion of New Zealand.

Prof. E. Metchnikoff, assistant director of the Pasteur Institute at Paris, has been elected foreign associate of the French Academy of Sciences, in succession to Sir Joseph Hooker.

The Turin Academy of Sciences has awarded the Vallauri prize of 800*l.* for contributions to the progress of physics in the period 1907–1910 to Prof. A. Righi and Prof. J. Perrin.

The council of the Manchester Literary and Philosophical Society has nominated the president, Prof. F. E. Weiss, to represent the society at the celebration of the 250th anniversary of the foundation of the Royal Society.

Prof. H. F. Newall, F.R.S., has been elected a member of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public services."

Sir David Gill, K.C.B., F.R.S., has succeeded Lord Cromer as president of the Research Defence Society; and Lord Cromer, Mr. Balfour, Sir Edward Elgar, O.M., Mr. Rudyard Kipling, and Lord Rayleigh, O.M., have consented to be vice-presidents of the society.

The death is announced, at the early age of thirty-nine, of Dr. T. H. Montgomery, jun., professor of zoology in the University of Pennsylvania. He had been assistant professor at the same University from 1898 to 1903, and professor at the University of Texas from 1903 to 1908. He was the author of an "Analysis of Racial Descent in Animals," and of numerous monographs on biological subjects.

Prof. Ralph S. Tarr, of Cornell University, has died suddenly of cerebral hæmorrhage. He was born at Gloucester, Mass., in 1864, and graduated at Harvard. He served for a while at the Smithsonian Institution, and in connection with the United States Geological Survey. He went to Cornell in 1892 as assistant professor of geology, and had since held successively the chairs of dynamical geology and physical geography. He had written a "Physical Geography of New York State," in addition to several valuable text-books of geology and physical geography. His special work was done in the study of earthquakes and glaciers, upon which he wrote a number of important papers.

The death is announced of Mr. Charles Edward Leeds, who made the first part of the remarkable collection of fossil reptiles from the Oxford Clay of Peterborough which now occupies a large portion of a gallery in the British Museum (Natural History). Mr. Leeds attended the lectures of the late Prof. John Phillips, and some of his earliest discoveries were described in the professor's "Geology of Oxford." He left England in 1887 to spend the remainder of his life in New Zealand, and since his departure the collection has been extended by his brother, Mr. Alfred N. Leeds, who still resides at his birthplace, Eyebury, Peterborough.

We regret to see the announcement of the death of Prof. P. N. Lebedew, professor of physics in the University of Moscow, who first succeeded in 1901 in demonstrating the pressure of light experimentally. Maxwell pointed out that the concentrated rays of an electric lamp falling on a thin metallic disc, delicately suspended in a vacuum, might perhaps produce an observable mechanical effect. This effect was thought to have been obtained in the Crookes's radiometer, but the magnitude proved many thousand times too great. Prof. Lebedew eliminated the radiometer action by using a large bulb with high exhaustion, and by excluding rays capable of heating the tube walls. His investigations proved that light exerts a true pressure on a surface on which it is incident, and the absolute magnitude of the pressure was found to be equal to that predicted by Maxwell. Prof. Lebedew's work led other investigators to take up the subject of the mechanical pressure of light, and the results obtained have been most valuable and suggestive.

The annual general meeting of the Chemical Society was held at Burlington House, W., on Thursday, March 28, Prof. Percy F. Frankland, F.R.S., the president, occupying the chair. The adoption of the report of the council on the progress of the society during 1911 was carried, and the president presented the Longstaff medal for 1912 to Dr. H. Brereton Baker, F.R.S. The president then delivered his address, entitled "Some Stereochemical Problems." Prof. Percy F. Frankland was re-elected president; Prof. E. J. Mills, F.R.S., and Prof. G. T. Morgan were elected vice-presidents; Dr. S. Smiles as hon. secretary, and Dr. H. G. Colman, Dr. A. Harden, F.R.S., Dr. T. M. Lowry, and Dr. E. J. Russell as new ordinary members of council.

The sixty-fifth annual general meeting of the Palæontographical Society was held in the Geological Society's rooms at Burlington House on March 22, Dr. Henry Woodward, F.R.S., president, in the chair. The annual report referred to the completion of the monograph of English Chalk fishes, and of the second volume of that of Pleistocene mammalia. It also acknowledged the help of the Carnegie Trust for the universities of Scotland in providing the plates for another instalment of Dr. Traquair's monograph of Carboniferous palæoniscid fishes. A special effort had been made to complete works in progress before beginning new undertakings. Miss Margaret C. Crosfield, Mr. George Barrow, Mr. H. R. Knipe, and Prof. W. W. Watts were elected new members of council. Dr. Henry Woodward, Dr. George J. Hinde, and Dr. A. Smith Woodward were re-elected president, treasurer, and secretary respectively.

The Easter Vacation Classes and the number of workers at the Port Erin Biological Station promise this year to be considerably larger than on any previous occasion. Seventy-six senior students or post-graduate researchers in zoology, botany, or physiology (representing six universities) have now engaged work-places at the laboratory during April, and all the accommodation in the institution seems likely to be taxed to its utmost capacity. Planktologists elsewhere may be interested to know that the vernal phytoplankton has made its appearance in the Irish Sea this year at an earlier date than usual. Diatoms were present in great force in the plankton of Port Erin bay on March 18 for the first time this spring. On the other hand, this season's prospects in the hatchery are unfavourable. The spawning of the plaice in the ponds is later than usual, and the number of eggs produced is comparatively small.

The whole of the famous collection formed by the Rev. Canon Norman, F.R.S., consisting of North Atlantic and Arctic invertebrates other than insects, arachnids, and myriopods, has now become the property of the Natural History Museum, the fourth and last instalment having been received recently at Cromwell Road. The extent of this consignment may be judged when we state that of Mollusca there were specimens in 7114 glass-topped boxes, of Crustacea there were 7376 bottles and tubes containing specimens, and there were, in addition, 5544 microscopical slides. The Polyzoa were contained in 1063 glass-topped boxes, while there were 497 spirit specimens and 185 microscopical slides. The "lower invertebrata" were numerously represented in the earlier instalments. Students who desire to examine any specimens in the Norman collection should apply to the keeper of the Department of Zoology at South Kensington.

Announcement has been made of the following awards just decided by the council of the Royal Geographical Society:—With the approval of the King the two Royal medals have been awarded to Mr. Charles Montagu Doughty and Mr. Douglas Carruthers, the founder's medal to the former, in recognition of his explorations in Arabia, and the patron's medal to the latter, for his expedition in north-west Mongolia, including the upper basin of the Yenesei, the Altai mountains, and neighbouring regions, and for other explorations. The Victoria medal, for scientific research in geography, has been awarded to Sir George H. Darwin, K.C.B., F.R.S.; the Murchison bequest to Captain W. C. Macfie, R.E., who was appointed to the charge of the Uganda Topographical Survey in 1908, and in twenty months surveyed an area of 14,000 square miles; the Gill memorial to Captain F. M. Bailey, who in 1904 accompanied the expedition from Lhasa through Tibet, and last year travelled from the valley of the Yangtse westward to Sidiya, passing through about three hundred miles of unexplored country; the Cuthbert Peek fund to Mr. Cecil Clementi, who has travelled extensively in Central Asia, and made a careful series of astronomical observations for latitude and chronometric differences of longitude during his journeys; the Back bequest to Mr. L. A. Wallace for his explorations and surveys of the Tanganyika Plateau and the country round it.

At Hull, on Saturday last, March 30, a museum devoted entirely to objects connected with the fishing and shipping industries, which play so prominent a part in the city, was opened to the public. The museum, which is a large building, and top-lighted, is the gift of Mr. C. Pickering, J.P. The exhibits, which have been arranged by the curator, Mr. T. Sheppard, include an exceptionally fine series of harpoons, harpoon guns, flensers, blubber-spades, and other objects connected with the old whaling trade, which commenced at Hull in the sixteenth century, and may be said to have started the present flourishing oil and fishing industries. There are also dozens of models of ships, illustrating the evolution and growth of the vessels from the old "wooden walls" to modern battleships and liners, all built at Hull. The various phases in the evolution of the old fishing smack to the modern steam trawler are also shown by models. A valuable set is shown of Eskimo boats and fishing appliances, brought to Hull during the early part of last century, by the old whalers. Preparations are exhibited showing the growth of the prawn, trout, eel, carp, oyster, &c., and others illustrating the nervous system, blood-vessels, skeleton, and other parts of fishes. There is a representative set of skeletons of whales and fishes, large and small, and a large number of mediæval and later earthenware vessels, which have been dredged up from the Dogger Bank by the Hull trawlers.

In the *National Geographic Magazine* for January Mr. F. E. Johnson describes the remarkable series of Greek bronzes discovered by M. A. Merlin in 1907 in the wreck of a sunken galley near the little town of Mahdia on the coast of Tunis. The almost life-size statue of Eros attributed to Praxiteles is a wonderfully beautiful object, and it is almost equalled by the Running Satyr and the Hermes of Boethus, the Chalcedonian. There seems good reason to believe that this galley was chartered to convey to Rome the spoils of Athens after the attack by Sylla in 86 B.C., just as Mummius appropriated for himself, his friends, and the temples of Rome the spoils of Corinth. It is very creditable to M. Merlin, director of antiquities and fine arts in Tunisia, that with little assistance from his Government and by means of very rude appliances he has been able to recover this wonderful collection of works of art.

In the Bulletin of the Royal Academy of Sciences of Belgium (1912, No. 1, pp. 8–9) Prof. L. Dollo describes the remains of a fresh-water tortoise of the genus Podocnemis, from the Lower Eocene of the Enclave de Cabinda, Congo State. Although now restricted to tropical South America and Madagascar, the genus is represented in the Eocene of England, India, the Fayum, and the Congo, and would thus seem to have reached its present isolated habitats from the north.

Starting with the premiss that an increase in the weight and dimensions of a flying animal involves a still greater increase in the power necessary to drive the animal through the air, and that in consequence a limit is soon reached under existing physical conditions beyond which flight is impossible (such limit having probably been approximately attained by the largest existing flying birds), Messrs. E. and A. Harlé, in a paper published in vol xi., p. 118, of the *Bull. Soc. Géol. France*, urge that the power of flight possessed by the giant pterodactyles of the Cretaceous and the huge dragonflies of the Carboniferous was due to an augmentation of the atmospheric pressure as compared with that of the present day.

In a recent paper published in the Bulletin of the Imperial Academy of Sciences of St. Petersburg (February, 1912, pp. 219–236), Prince Galitzin considers the dispersion and damping of the seismic surface-waves due to the friction of the displaced material. He concludes that the velocity with which the waves spread over the surface decreases as the period of the waves increases, from 3·70 kms. a second with a period of one second to 3·07 kms. a second with a period of forty seconds.

The last four numbers of the *Bollettino* of the Italian Seismological Society contain the notices of the earthquakes recorded in Italy during the first 10½ months of 1908. Even for so short a time the catalogue contains accounts of more than 500 local shocks and ninety-four distant earthquakes. Among the former, it is interesting to note the frequent recurrence of the names of Messina, Reggio, and other places ruined towards the close of the year, pointing to the gradual preparation for the great earthquake which was unheralded by warning tremors. The eruption of Etna in 1908 was accompanied by a remarkable series of earthquakes, of which full details are given. Under the editorship of Dr. G. Martinelli, the catalogue has been recently enlarged and improved. If, however, to the details usually given for each earthquake, the approximate position of the epicentre, the maximum intensity of the shock, and the dimensions of the disturbed area could be added, the value of the "notices" would be greatly increased.

Messrs. Negretti and Zambra have recently devised a new type of instrument for recording continuously the direction of the wind. The record is traced on the chart by means of a single pen actuated by the vane. The pen is carried by a pivoted lever, having at one end a roller engaging with the cam surface of a spiral groove, which is attached to the spindle of the vane. As the vane rotates, the lever moves up or down and the pen records the motion on an appropriately ruled chart. In order to surmount the difficulty introduced by continuous rotation in one direction, the cam is provided at the highest point with a gap through which the lever falls, while at the lowest point a spring is brought into action by a secondary cam, and raises the lever. This arrangement involves duplicate points on the chart, and for half the compass the pen may be in one of two positions. This is a disadvantage which will probably be removed in the course of time. The makers are to be congratulated on the ingenious manner in which the primary difficulty has been overcome.

According to hydrodynamical theories, wave motion in deep liquids is accompanied by a gradual displacement of the liquid as a whole, this displacement being greatest at the surface. A general investigation, embracing an extension of Stokes and Rayleigh's theorems, is given by Prof. T. Levi Civita in the *Atti dei Lincei*, xxi., 1, for the case of waves in canals of any type whatever.

Messrs. E. Leitz have sent us a large wall-diagram which they have issued illustrating the construction and optics of the microscope. The mechanical parts and lenses are drawn in section, so as to show their construction, and coloured lines depict the paths of the rays of light through the optical system and the formation of the magnified image. The diagram should be very useful in laboratories for demonstrating to students the construction and optics of the instrument. A descriptive pamphlet is issued with it.

Bulletin No. 53 of the University of Illinois deals with the inductance of compact coils of wire without iron cores, and is written by Prof. Brooks and his assistant, Mr. Turner, for the use of engineers. It collects together a large amount of information as to the dimensions and weights of bare and cotton- or silk-covered wire, and gives a general formula for the inductance of coils of almost any shape the wire of which is wound without considerable spaces between the turns. If l is the length of wire on the coil, R the outer radius, b, the length, and c the radial depth of the coil, the self-inductance

$$L = \frac{l^2}{b+c+R} \times \frac{10b+12c+2R}{10b+10c+1\cdot4R} \times 0\cdot5 \log\left(100+\frac{14R}{2b+3c}\right) \times 10^{-9} \text{ henries.}$$

The ratios of the dimensions which give the maximum inductance for a given length of wire are $b:c:R = 12:10:20$. The inductance formula has been tested on nineteen coils of different shapes, the inductances of which were determined at the Bureau of Standards, and in no case was the calculated value so much as 3 per cent. different from the observed.

According to theory, two stereoisomers of symmetrical dichloroethylene should exist. Two symmetrical diiodoethylenes are known, and in the *Comptes rendus* of the Paris Academy of Sciences for March 18, G. Chavanne describes the isolation of the corresponding chlorine derivatives, hitherto unknown. Commercial dichloroethylene was fractionated in a Young column of eight sections, and was separated into approximately equal amounts of two isomers, boiling at 49° C. and 60·2° C. respectively; both gave figures on analysis corresponding with the constitution $C_2H_2Cl_2$. Contrary to expectation, the dibromides $C_2H_2Cl_2Br_2$ obtained from each by the action of bromine are identical, and further work on the space relations of these isomerides is in progress.

An index to Nos. i.–xvi. of the *Annual* of the British School of Athens has been compiled by Mr. Arthur M. Woodward. Its main purpose is to make more accessible the contents of the reports of the excavations undertaken by the school, or in connection with it, especially those at Knossos, Palaikastro, and Sparta. The index may be obtained from Messrs. Macmillan and Co., Ltd., and its price is 10*s*. net.

Messrs. Watts and Co. have published for the Rationalist Press Association, Ltd., at the price of sixpence, a new and revised edition of Sir Ray Lankester's "The Kingdom of Man." The author has revised "the text so far as to alter here and there the terms of reference to events and discoveries which are now six years older than they were when the book was first printed." An improved figure showing the relative size of the cerebral hemispheres in the extinct mammal Dinoceras and large mammals now living has been substituted for that previously published.

OUR ASTRONOMICAL COLUMN.

The Spectrum and Orbit of β Scorpii.—In No. 14, vol ii., of the publications of the Allegheny Observatory, Drs. Daniel and Schlesinger discuss the measures of seventy-three spectrum plates of β Scorpii and deduce an orbit. They confirm Dr. Slipher's statement that the H and K calcium lines do not share in the large oscillations shown by the other lines. As in δ Orionis and o Persei, the velocity shown by these lines is approximately the velocity of the centre of mass of the system, thus indicating that the absorbing material producing the lines is really part of the system. Other notable features are the great eccentricity of the orbit, excessive for a star of the B type with so short a period, and the comparatively large masses of the components.

The Axis and Compression of Mars.—Including observations up to 1909, Dr. Struve has determined the axis of Mars, from the shifts of the orbital planes of the satellites, which confirm similar values found by him in 1896. He finds the obliquity of the planet's equator to the orbit to be 25° 10·2′, a value which, as Dr. Crommelin points out in the current number of *The Observatory*, is about the mean of previous determinations from observations of the snowcaps; Herschel gave 28°, while Prof. Lowell's latest value was 23°. The compression of the planet is given as 1/190·4, and the mass as 1/3,090,000, the same as formerly adopted. The daily angular motion of Phobos is 1128·844°, and of Deimos 285·162°.

OBSERVATIONS OF NOVA GEMINORUM NO. 2.

Many observations of the nova, of which we give a selection below, are reported in No. 4563 of the *Astronomische Nachrichten*. The observations of magnitude are not very accordant, but they indicate that the nova was probably discovered before it reached its greatest brightness.

Prof. Wolf reports that there was a star brighter than magnitude 12·0 in the position of the nova on March 7, while two Harvard photographs showing eleventh-magnitude stars do not show the nova on March 10; but two plates taken on March 11 show it as a fifth-magnitude star. A plate taken by Dr. Kopff in 1909 shows the image of a fifteenth-magnitude star which is probably identical with the nova. Some of the magnitude estimations are given in the following table:—

Date	G.M.T.	Magnitude	System	Observer
	h. m			
March 13	7 45	4·1	Harvard Revised	Strömgren
14	10 30	3·6	—	Wirtz
15	6 30	4·18	P.D.	Guthnick
15	9 30	4·31	..	Freundlich
15	11 42	4·5	..	Guthnick
16	7 15	5·42	Harvard Revised	Felix de Roy
17	8 40	5·37	P.D.	Graff
20	7 29	5·34	,,	..
20	11 49	5·51	,,	..
24	—	4·0±	—	Nijland
24	—	5·0±	—	Easton
26	—	5·5	—	..
27	—	6·5	—	Easton; Nijland

In communicating the last four values, Dr. C. Easton directs attention to the oscillations of brightness indicated by the recrudescence observed on March 24, when he observed at Amsterdam and Prof. Nijland at Utrecht; both observers were hampered by clouds and moonlight.

M. de Roy estimated the colour to be orange-yellow, 5·5 c. on Osthoff's scale, as seen in an 8-in. reflector, and Dr. Hartwig gives it as reddish.

Prof. Wolf states that the spectrum on March 15 was similar to that of Nova Aurigæ, but on March 17 it was more like that of Nova Lacertæ during the period January 6–14, 1911. On March 14 Herren Struve, Guthnick, and Freundlich saw broad absorption lines at Hα and Hβ, and the last-named suspected bright condensations in several places; a bright line in the yellow is given as probably D or D_3. Prof. Hertzsprung saw the H and K absorption lines doubled on March 15, the one part being very narrow and in its normal position, the other being about 7 A.U. broad, and, in the mean, displaced by an amount corresponding to −650 kms. per sec. A large number of fine absorption lines similar to those in a spectrum of F type were also seen. Prof. Schwarzschild states that the observations made with the Potsdam spectrograph, No. 1, on March 15, showed a number of absorption lines about 1 A.U. in breadth. Among these are well-defined lines of the spark spectrum of titanium, indicating by their displacements a radial velocity, referred to the sun, of −540 kms. per sec. On March 17 the displacements of these lines indicated a motion of −350 kms. per sec. in the line of sight. Observations on March 17, 18, and 19 indicated that the continuous spectrum was becoming weaker relatively to the bright bands.

Some interesting spectroscopic results secured by MM. Hamy and Millochau at the Paris Observatory are published in No. 13 of the *Comptes rendus* (March 25). Two spectrographs were employed, one with a slit giving a spectrum 40 mm. long from Hβ to K, the other an ultra-violet prismatic camera giving the same length of spectrum between λ500 and λ300. On the plates secured with the latter the continuous spectrum is seen easily to extend to λ315, a fact which is accepted as showing the extremely high temperature of the light-source.

A large proportion of the total radiation from the star is shown to be concentrated in the bright hydrogen lines, which are about 20 A.U. in width, and become more and more diffuse towards the violet end of the spectrum. Hβ is divided into three equal parts and a similar division is suspected in Hγ; Hδ, Hϵ, Hζ, and Hθ are also shown. These broad, bright hydrogen lines are strongly displaced towards the red by an amount equivalent in Hβ, Hγ, and Hϵ to 3 A.U., and each is accompanied by a broad absorption band on the more refrangible side; the dark hydrogen bands are, as usual, considerably displaced, and have fine, bright reversals running down their centres. The displacements are equivalent to those that would be produced by a radial velocity of the order of −1300 kms. per sec. in the atmosphere of hydrogen, which produces the double reversals. The authors, however, attribute the broadening and the displacement of the lines to the enormous pressures which might be produced in the cataclysm following the impact of a star and a nebula, such as was outlined in Seeliger's theory.

Many apparently bright lines occur between λ470 and λ390, but the authors are not sure that these are not merely the interspaces between feeble absorption bands; they do, however, affirm the existence of a fine absorption band at λ394. Between λ370 and λ315, only continuous spectrum is seen, and the spectrum as a whole is similar to those of Novæ Aurigæ (1892), Persei (1901), and Geminorum (1903).

THE SHUMAN SUN-HEAT ABSORBER.

MOST of the experimenters who have attempted to make direct use of the sun's heat for the production of power have adopted the practice of greatly concentrating the sun's rays and focussing them on to a comparatively small and strong boiler generating steam at a fairly high pressure. Mr. Frank Shuman has used a concentration of only two to one, though in the next plant, which will be materially different (due to certain recommendations of Prof. C. V. Boys, F.R.S.) from the one herein referred to, the concentration will be three to one. The boilers are lamellar, about a yard square, and only about one-quarter inch thick. They are made of thin tinned copper, painted dull black on the outside, with a number of opposed indentations, the tinning holding the two sheets together where these indentations touch.

The boilers are fixed in shallow boxes placed nearly horizontally, and having double glass tops with an air space of one inch between the two sheets of glass. Between the lower sheet of glass and the top of the boiler there is another air space of one inch, and below the boiler an air space of about half an inch; then a sheet of millboard one-quarter inch thick, then two inches of granulated cork, and, lastly, a second sheet of millboard three-eighths of an inch thick forming the bottom of the box. Each such unit is a yard square, but twenty-two of them are constructed side by side in one frame, forming one section, and in the plant tested there were twenty-six such sections, thirteen on each side of the main steam pipe. To the top edge of each unit a silvered glass mirror a yard square is attached making an angle of 120° with the glazing of the unit. To the bottom edge a similar mirror is similarly fixed. The top edges of the mirror are thus six feet apart, while the bottom edges are three feet apart; hence the concentration of two to one.

FIG. 1.—Showing one section of absorber on left, steam main and safety valve in centre, and part of engine on right

Along the bottom of each section there is a small pipe for supplying the feed water, while a larger pipe runs along the top edge to collect the steam and convey it to the eight-inch main steam pipe. Each section is supported by, and pivoted to, steel A frames, each with a notched quadrant, so as to enable the section to be inclined at different angles. Herein is another distinct feature of the Shuman sun-heat absorber. Practically all the absorbers using great concentration of the sun's rays have had to be focussed continuously on to the sun, but the absorber now being described needs adjusting only once about every three weeks, the adjustment being such that the rays at noon are perpendicular to the top surface of the boilers.

When experimenting at Philadelphia in July, 1910, with a single unit *and no mirrors*, the maximum temperature I recorded under the lower cover glass was 250° F., and temperatures of over 200° F. were common. Even in the latter cases steam was formed freely, showing that the temperature of the boiler was 212° F.

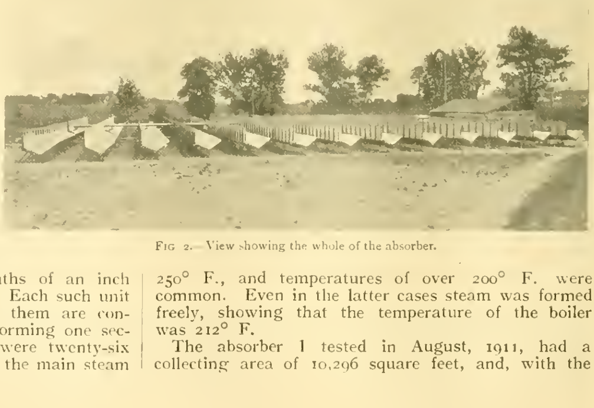

FIG 2.—View showing the whole of the absorber.

The absorber I tested in August, 1911, had a collecting area of 10,296 square feet, and, with the necessary gangways, occupied an area of nearly two-fifths of an acre. The maximum quantity of steam produced in any one hour was more than 800 lb. at atmospheric pressure, and while this is by far the greatest quantity ever produced by sun power, it must be pointed out that Philadelphia is by no means an ideal situation for such a plant, for we had to wait weeks to get a nearly cloudless day, and then fortunately had three in succession. 800 lb. of steam per hour is equivalent to a boiler efficiency of 43 per cent. The plant was built at Philadelphia simply for the convenience of being close to the inventor's house, offices, and laboratory. In places like Egypt, Africa, Arizona, and California, I should expect to get about 25 per cent. more steam for the same collecting area.

A. S. E. Ackermann.

THE FLYING REPTILES OF THE CHALK PERIOD.[1]

In the remarkable collection of fossil vertebrates obtained by the late Prof. O. C. Marsh for the Peabody Museum of Yale University, there are many groups of which he only published preliminary notices. Among these the toothless Pterodactyls, which he was the first to discover in the chalk of Kansas, are specially deserving of attention. During the past ten years they have been studied in detail by Dr. George F. Eaton, who has now completed his researches and published a beautifully illustrated memoir, which will be welcomed by palæontologists. So long ago as 1904 Dr. Eaton prepared for the St. Louis Exposition a model of the skeleton of Pteranodon, of which a copy was subsequently given to the British Museum (Natural History), where it is exhibited in the Gallery of Reptiles. In his new work he now reviews the whole of the material which forms the basis of this restoration (shown in the accompanying figure), and his concise descriptions are illustrated not only by admirable photographs of the fossils themselves, but also by explanatory sketches of several of the most important parts.

Dr. Eaton is, indeed, to be congratulated on the clearness with which his facts and conclusions are presented, and he displays commendable caution in his references to crushed and distorted specimens. The bones are so delicate that nearly all have collapsed by pressure in the laminated chalky rock, and it is therefore often difficult to determine precisely their original shape.

Restoration of Pteranodon, Marsh; from the left side. For convenience of representation the right limbs are omitted.

The species of Pteranodon and its allies are the latest and most specialised flying reptiles, and so attain the greatest size. A nearly complete pair of wings mounted in the British Museum (Natural History) measures 18 ft. in span, and Dr. Eaton estimates that some specimens had a span of more than 22 ft. The adaptation of their bones to unusual mechanical needs is therefore of extreme interest. The well-known firm articulation of the scapula with a mass of fused thoracic vertebræ, for the support of the large wings, is now described in detail, and Dr. Eaton thinks there were not more than three separate dorsal vertebræ between this fused mass and the equally rigid sacrum. The tail is very short and small, and the slender hind limbs must have supported the postero-internal borders of the wing-membranes.

The elongated jaws of Pteranodon itself are completely toothless, and Dr. Eaton observes that there is never an indication of vestigial tooth-sockets. The articulation for the mandible is obliquely ridged and grooved, so that the two branches would be thrust a little apart when the jaw opened, as in the pelican. It is therefore inferred that the animal was a fish-eater and had a small pouch below the mandible.

In two species, though apparently not in a third, the supraoccipital crest is enormously extended, and would probably serve for the origin of very large temporal muscles giving great snapping power to the jaws. Even for such a purpose the crest appears to be sometimes too large, but Dr. Eaton concludes that it could scarcely be needed as a counterpoise to the long jaws, because "the form of the cervical vertebræ indicates a strong musculature of the upper part of the neck." He alludes to "the general theory that growth along certain lines may be initiated through the exercise of one function, while further development is dependent upon another totally distinct function." The crest may be an illustration of the so-called momentum in evolution.

It will be remembered that many years ago the late Prof. H. G. Seeley devoted much attention to the fragmentary remains of these gigantic specialised Pterodactyls found in the Cambridge greensand, and attained great success in interpreting them. The new work on the better-preserved specimens of Pteranodon from the North American chalk will excite renewed interest in the corresponding English fossils, and facilitate more exact studies of them.

A. S. W.

[1] "Osteology of Pteranodon." By Dr. G. F. Eaton. Pp. 38+xxxi plates. Memoirs of the Connecticut Academy of Arts and Sciences, vol. ii. (New Haven, Connecticut: [Published under the auspices of the Yale University, 1910.)

THE INSTITUTION OF NAVAL ARCHITECTS.

THE annual meeting of the Institution of Naval Architects opened on Wednesday, March 27, at the Royal Society of Arts, and extended over Thursday and Friday. The annual gold medal of the institution was presented to Prof. E. G. Coker for his paper on the determination of stresses by the photo-elastic method. Premiums were also awarded to Mr. C. E. Inglis and Mr. J. Montgomerie for papers read at the last spring meeting. The first award of a scholarship of 200*l*. per annum from the 1851 Exhibition Commissioners has been made to Mr. Arthur Cannon on the recommendation of the council of the institution. Mr. Cannon is pursuing a course of research work at Glasgow University in problems connected with the rolling of ships, and read a preliminary paper at this meeting on the effect of an internal free fluid upon the initial stability.

The president (the Marquis of Bristol) delivered an address in which he directed attention to the record in shipbuilding achieved during the past year. Merchant shipping launched in the United Kingdom advanced by 58 per cent., and warships by 71 per cent., as compared with the previous year. There is no lack of orders at present, but the labour unrest threatens to arrest many of the benefits which should follow on the recent revival of trade.

Admiral Sir Reginald Custance, in his paper on some military principles which bear on warship design, advocated the development of fire effect to the fullest extent possible. The decline in the value of armour and its possible reduction, coupled with the increased range and power of modern guns, are the changed conditions which may enable a return to be made to this old and well-tried principle. There is reason to doubt whether batteries of comparatively few large guns form the most effective armament. The admiral's views that armour, speed, and size of guns should be sacrificed in order to secure more guns were strongly contested by several speakers.

A paper on the law of comparison for surface friction and eddy-making resistances in fluids was read by Dr. T. E. Stanton. The prediction of wave-making resistance from experiments on models according to Froude's law of comparison is usually carefully treated by authorities on naval architecture, but there does not appear to be any suggestion of a similar treatment of the surface friction and eddy-making problem. Prof. Osborne Reynolds showed nearly thirty years ago that, in two pipes in which the lengths, diameters, and surface irregularities were in a constant ratio to each other, if the velocities were made in the inverse of this ratio, the total frictional force was the same for each pipe. Lord Rayleigh has shown that, in cases where there is no resistance due to surface waves and the velocity is not high enough to produce cavitation, the resistance per unit area can be expressed by

$$R = \tfrac{1}{2}\rho V^2 k,$$

where k is an expression depending solely on $\rho\frac{vl}{\mu}$, μ being the coefficient of viscosity of the fluid and ρ its density. This law of comparison applies equally well to cases in which the resistance is made up partly of surface friction and partly of eddy making. Experimental verifications of the truth of this relation have been obtained at the National Physical Laboratory in two cases, viz., the determination of the frictional resistance of two different fluids (air and water) on the same surface, and the total resistance in water of models of a dirigible balloon to different scales. The latter tests are of particular interest. Two models of the same dirigible to different scales were towed in the experimental tank and their resistances measured. If the law of comparison holds, their resistances will be equal for the same value of vl, and this was found to be the case very closely. It thus becomes possible to estimate the resistance in air of a dirigible balloon by experiments in which a model is towed under water. Obviously the same method is applicable to torpedoes and submarines.

In the course of the last seven years considerable data have been collected regarding the rolling of Irish lightships. The results were summarised in a paper read by Messrs. George Idle and G. S. Baker. (*a*) The greatest rolling amplitudes are attained by the old ships, wooden or composite, having double bilge logs. These ships have generally small initial stability and a low metacentre, and show that the metacentric height does not by itself give any indication of the ship's probable behaviour in a heavy sea. (*b*) Large amplitudes are reached when the sea is breaking or confused and when the waves are advancing on the bows or quarters. Maximum amplitudes have been recorded when the ship has been nearly head to the advancing wave. The differences in amplitude of "head to" and "beam to" positions in heavy swells averaged 16 to 20 degrees for the single oscillation in favour of the latter, suggesting that there are causes productive of heavy rolling other than mere assonance between the ship and the wave. (*c*) The greatest angle of heel is always away from the advancing wave, no matter what may be the direction and force of the wind. (*d*) When the bilge keels are efficient the ship's normal period of oscillation is increased by one up to three seconds, sometimes more. The amplitudes of roll are generally moderate in this increased period. There is apparently an attempt on the part of the wave to bring the ship to its own period, and the function of the bilge keel is evident in the fact that it prevents assonance between the ship and the wave. It may be safely asserted that without bilge keels these small vessels could scarcely live in the seas to which they are sometimes exposed. A valuable series of experiments was undertaken last year at the William Froude National Tank on a model of an actual ship built for the Commissioners of Irish Lights. The experiments have been taken beyond the immediate requirements of the commissioners with the view of testing the ordinary equation for the decrement of roll per single swing of the ship, viz.:

$$-\delta\theta = a\theta + b\theta^2,$$

θ being the mean angle of swing port and starboard, and a and b coefficients which depend, the former on wave-making resistance and the latter on friction and head resistance. The results show discrepancies, and that there should probably be a term in θ^3 if the bilge keel is sufficiently near the water line.

The propulsion of modern vessels is developing along various lines, viz. internal-combustion engines, the steam turbine with speed-reduction appliances interposed between the turbines and the propeller, and in steam generation oil fuel finds many advocates. Papers on the Diesel-engined sea-going vessel *Selandia* and on gas power for ship propulsion were read respectively by Messrs. W. I. Knudson and A. C. Holzapfel, and Prof. J. H. Biles read a paper on the geared turbine Channel steamers, *Normannia* and *Hautonia*, in which the relative merits are discussed of mechanical gearing, electrical transmission, and hydraulic transmission for speed reduction between the turbine and the propeller shafts. The maximum efficiency of electrical transmission is about 90 per cent.; this method may be useful in cases where a great range of speed at high efficiency would be advantageous. Dr. Föttinger's system of hydraulic transmission gives an efficiency of about 90 per cent. at full speed. Both electrical and hydraulic systems admit of very large powers astern without separate prime movers. Helical gears with machine-cut teeth (made by Messrs. Parsons) were fitted to the steamers forming the subject of the paper. The loss in this gearing amounts to 1·5 per cent. only. There is practically no noise; a slight whistling sound can be heard by listening carefully when in the passenger quarters. There are no vibrations or trepidations. Sir Charles Parsons stated that most of the 1·5 per cent. waste occurred in the pinion bearings. There is no wear in the teeth, the oil film apparently being preserved unbroken. Dr. Föttinger raised the point of the limit of power which could be transmitted; his hydraulic gear was being fitted for very large powers. Mechanical gearing has been used for comparatively low powers up to the present, but no doubt can be developed to a much greater extent.

The discussion of the previous day on Mr. W. I. Knudson's paper on the *Selandia* provoked further comments on the Diesel engine from speakers in the discussion on Prof Bile's paper. The height of Diesel engines for a warship would be much greater than that of geared turbines; with the oil engines the most vulnerable parts of the machinery might be above the water line. The *Selandia* was reported at the meeting to be making good progress on her first voyage, and was passing through the Red Sea at above eleven knots.

In all seventeen papers were read and discussed at the meeting; the limitations of space have forbidden reference being made here to other than the more important papers.

THE INTERNATIONAL SMOKE ABATEMENT EXHIBITION.

THE remarkably clear atmosphere which has been observed in many industrial centres during the coal strike has afforded an excellent object-lesson in smoke abatement. It should emphasise the desirability of making these conditions permanent. That the removal of smoke comes well within the range of practical achievement has been amply demonstrated by the International Smoke Abatement Exhibition which has just been held under the auspices of the London Coal Smoke Abatement Society. In the official catalogue of the exhibition we find references not only to the exhibits of smoke-saving and smoke-preventing appliances, but to practical demonstrations of their use. The exhibition has further provided opportunity for a series of excellent lectures and addresses by well-known authorities, which include men of science, engineers, and manufacturers of English, German, and American nationality.

The exhibits may be divided into two categories, those which are devised for burning coal or partially coked material smokelessly, and those which replace the solid fuel by oil, gas, or electricity.

Anyone who may have watched the cookery demonstrations with gas cookers or observed the great improvement in the appearance of the various gas fires, or examined the electrical heating apparatus for domestic use, must have been impressed with the great advantage in cleanliness, convenience, and efficiency which these methods of heating possess over the coal fire. Indeed, it is impossible not to carry away the conviction that in the use of gas and electricity for heating and cooking, lies our future hope of salvation from the smoke fiend. The chief obstacle at present is their cost. Yet in spite of the high price of gas as compared with coal of the same calorific value, it is interesting to learn that during the last ten years there has been an increase of nearly two million gas cookers in the United Kingdom, whilst the total number of gas heating and cooking appliances installed by the London gas companies in 1910 reached 1,300,000.

This is a matter of considerable importance when it is remembered that the domestic hearth not only turns out by far the greater proportion of soot on the coal burnt, but soot of that particularly obnoxious quality which, by its high content of tar, is the most adhesive and permanent.

We have not space to refer to the numerous papers read at the conference, but must refer our readers to the small volume which has been issued by the Coal Smoke Abatement Society, 25 Victoria Street, Westminster, price 2*s*. 6*d*., which is well worth perusal by those who are interested in the various phases of the smoke question.

The papers may be divided into those dealing with (1) the causes, (2) the cure, and (3) the effects of smoke. Among the last, valuable information was contributed by Sir A. Church and Mr. N. Heaton on the important subject of the disintegration of building stone and the destruction of mural decoration by atmospheric sulphuric acid arising from burning coal, and experimental evidence showed that the stonework of ancient historic buildings was being slowly corroded. Dr. Rideal, who dealt with the effects on metal work, found that the rust on a roof girder of Charing Cross Station which collapsed in 1905 contained 4·25 per cent. of sulphuric acid, equal to nearly 9 per cent. of ferrous sulphate. The effects on vegetation are even more disastrous, and striking experimental results were recorded by Mr. W. J. Bean, assistant curator of Kew Gardens, and Mr. A. G. Ruston, of the Agricultural Department of the University of Leeds. The effects on health were discussed by Mr. W. B. Smith, chairman of the Air Purification Committee of the Glasgow Corporation, who gave statistics proving the high mortality from bronchial diseases during town fogs.

Though there has been some repetition of old arguments, opinions, and facts, these are subjects which cannot be too frequently dinned into the ears of an indifferent public in the hope that an echo of them may ultimately reach the local authorities and rouse them to a sense of their duty.

It is satisfactory, however, to learn from Mr. Lempfert, of the Meteorological Office, and Mr. J. B. C. Kershaw that matters are slowly improving. The number of hours of bright sunshine in the year in industrial centres, compared with certain country places, has steadily increased, showing that either the country stations are making more smoke or the towns less. The author of the paper, Mr. Lempfert, takes the latter and more sanguine view. He makes the significant remark that "the great difference between the figures for winter and those for summer suggests that domestic smoke rather than factory smoke is mainly responsible for the loss of sunshine." Now legislation in this country has not yet ventured to invade the sanctity of the domestic hearth, yet it is proved beyond question that it is the worst offender. Mr. Nicholson, smoke inspector for Sheffield, asks, with perfect justification, "Why should our domestic fireplaces be allowed to create an unnecessary nuisance any more than any other fireplace or furnace?" The answer is: provide cheap gas and electricity. The splendid combined exhibit of the gas companies and of the London electric supply and other manufacturers of electric appliances leaves little to be desired in the apparatus designed to utilise these two forms of energy.

Though we may yet have to wait a little time for cheaper gas and electricity, there is no doubt that much more might be done by the authorities to mitigate the smoke nuisance. We have only to consider the fact that not more than 10 per cent of the local authorities in the United Kingdom administer the law against smoke, and not more than twenty-five authorities have special smoke inspectors.

In conclusion, a word of acknowledgment is due to the London Coal Smoke Abatement Society and the Smoke Abatement League of Great Britain for their praiseworthy and persistent efforts to enlighten the British public on the methods available for the economic and cleanly utilisation of fuel.

J. B. C.

THE SURVEY OF EGYPT.[1]

WHERE the region is not too large there is a certain convenience in treating the various branches of study relating to the earth's surface in a single organisation, and in Egypt this arrangement has given good results. The report of the Survey Department on the work done in 1910 has recently appeared, and in the same way as in former years geodetic triangulation and precise levelling furnish the primary control for topographical surveys, cadastral surveys, and to some extent for the geological survey, which has to cover a wider area than that which has been accurately mapped up to the present time.

Astronomical work at Helwan Observatory was carried on regularly, Reynolds's 30-inch reflector being used to expose 249 plates, principally on Halley's comet. The geodetic triangulation has been carried southwards, reconnaissance having reached Tema, about 450 kilometres south of Cairo, while angular measurements and latitude observations were completed as far as Etsa, about halfway. Precise levelling in the delta is nearly complete, and is being pushed on towards Aswan, up the Nile Valley, Assiut having been reached, and a branch line having been carried into the Fayum to the Birket Qurun. The gravity survey of the Nile Valley has been commenced, and observations were being made at a series of stations between Cairo and Khartoum. The magnetic survey of the Nile Valley up to Wadi Halfa was completed, and in 1911 its extension into the Sudan was to be undertaken. Topographical surveying added considerably to the material which is utilised for the publication of maps of the Nile Valley and Delta on 1 : 50,000 and 1 : 10,000, and completed the survey of Alexandria town on the scale of 1 : 1000, that of Cairo being also considerably advanced. The cadastral survey was occupied in the re-survey of Beheira Province, since the original survey was made without any controlling triangulation, and hence left much to be desired. In geology the department's labours were mainly directed to the Red Sea coast, and especially that part lying round about the petroleum region at the south end of the Gulf of Suez, where much accurate surveying, as well as triangulation, was carried out.

Besides the normal series of cadastral maps on the scale of 1 : 2500, and topographical maps on the scales of 1 : 10,000 and 1 : 50,000, others of the whole of Egypt on 1 : 250,000 are in hand and should soon be published. Their early appearance will be welcomed. The report shows clear evidence of a large amount of work carefully and scientifically controlled, and the report sets an example which might well be more generally followed in showing not only the progress made, but also the rate of work and the cost of work in every branch, as well as the accuracy attained.

H. G. L.

[1] A Report on the Work of the Survey Department in 1910. (Cairo, 1911.) Price £T10.

PROMOTION OF RESEARCH BY THE CARNEGIE INSTITUTION OF WASHINGTON.

THE Year Book for 1911 of the Carnegie Institution at Washington has reached us, and is, as usual, full of evidences of unremitting activity in the encouragement of research in science.

The following list shows the departments of investigation to which the larger grants were made by the Trustees of the Institution and the amounts allotted from these grants by the executive committee during the year:

	£
Department of Botanical Research ...	7,336
Department of Economics and Sociology	2,000
Department of Experimental Evolution	6,747
Geophysical Laboratory	10,896
Department of Historical Research ...	4,700
Department of Marine Biology	6,596
Department of Meridian Astrometry ...	6,296
Nutrition Laboratory	6,076
Division of Publication	1,800
Solar Observatory	27,211
Department of Terrestrial Magnetism ...	18,902
	£98,560

Numerous minor grants were made amounting to 18,863*l.*, and the grants made to research associates for their investigations amounted to 4840*l.* Grants for publication authorised during the year amounted to 11,200*l.* During the year 1911 the income of the institution was 201,114*l.*, and the expenditure reached 134,320*l.*

The president of the institution, Dr. Robert S. Woodward, says in his *résumé* of the investigations of the year 1911 that it has been, on the whole, the most fruitful year on record for the various specially organised departments of research in the institution. Although some of these are not yet fully equipped, they are all so well organised and provided for that their energies may now be chiefly directed to the attainment of definite results.

Among the more salient aspects of the affairs and researches of the various great departments, the following may be mentioned.

The investigations of the Department of Botanical Research during the year have embraced, among others, studies of the evaporation, the increasing salinity, and the changes in vegetation following close after the receding shores of the Salton Sea; of the influences of temperature, rainfall, sunlight, soil-moisture, &c., on plant organisms; of the effects following transplantation from low to high altitudes and from arid to humid localities; of the variations in water and acid content of plants; of the chemical effects induced in plant tissue by light and heat; and of the physiological functions of leaves in plant life. One of the most interesting investigations under way during the year is that of Dr. Ellsworth Huntington, research associate of the department, on the secular variations of climate of the south-west desert area in recent geologic time. From this work it is believed that some of the salient fluctuations in climate during the past two or three thousand years may be clearly made out. Another noteworthy investigation of the year is that of the respiration of cacti, undertaken by Prof. H. M. Richards in collaboration with the department. This has developed the remarkable fact of a definite diurnal periodicity in the acid content of the sap of the cacti under observation.

One of the most promising investigations of the year in the Department of Experimental Evolution is that of the director in reference to the heredity of epileptics. Another investigation continued during the year, which involves prime utilitarian application, is that of Dr. Shull on the effects of self-fertilisation in maize, or Indian corn. His earlier conclusions, published in 1908, have been confirmed by the later studies. A striking result from the latter is that, other conditions being the same, the yield of cross-fertilised plants proved 50 per cent. greater than that of the self-fertilised plants. Observational and experimental work has been carried on also along many other lines The total number of zoological individuals under study exceeded 2000, while the range of plants observed included nearly 500 species and upwards of 40,000 individuals.

Among the papers issuing from the Geophysical Laboratory is a noteworthy contribution to general physics, in which the scale of precise thermometry is extended by 1250° C. This extension was an essential incident to the studies of mineral fusion, crystallisation, &c., carried on in the laboratory, but it is of equal importance to other branches of physical research. Another noteworthy paper is a preliminary contribution to the long-standing question of the constitution of Portland cement. The complexity of this substance proves to be far greater than hitherto supposed, but its general characteristics have been determined, and the resources of the laboratory are adequate to complete the remaining quantitative details of the investigation. Of numerous investigations under way at the laboratory, attention may be directed to some preliminary studies of an active volcano, which indicate that the phenomena of vulcanism are within range of practicable determination, and that progress in this direction is only a question of time and adequate effort.

In the Department of Meridian Astronomy, the deductions of stellar positions and motions are proceeding expeditiously in the computing section of the department at the Dudley Observatory, so that the final catalogue, giving precise positions of all stars up to the seventh magnitude inclusive, may be expected to appear in due time. As often happens in such extensive scientific investigations, many by-products are arising of hardly less importance than the primary ends in view. One of these, deduced from the preliminary Star Catalogue, published by the institution about two years ago, shows the mean velocities relative to the solar system of stars of different spectral types. The values derived from the "proper motions" of the catalogue are in striking agreement with those derived for the same stars by Prof. W. W. Campbell from direct measurements of the motions of these stars in the line of sight. The remarkable result which is thus brought out from independent investigations is that the speed of a star through space increases with its age.

Although the construction and equipment of the Solar Observatory are still incomplete, the members of the staff are making rapid progress with their programmes of solar, stellar, and physical observation and of computation and deduction. Thus the attainment of tangible results proceeds along with the development and installation of equipment. The observatory has now, nearly fully equipped and in use, four highly effective telescopes: the Snow, horizontal, 30-in. reflector; the two tower-telescope refractors; and the 60-inch reflector mounted equatorially. The 150-ft. tower telescope, together with its auxiliary apparatus, constitutes the most important addition of the year in the way of equipment. Varied use of the 60-in. equatorial proves it to be alike effective in visual, photographic, and spectroscopic work. It is especially penetrating in its capacity to reveal the characteristics of globular star clusters and spiral nebulæ.

The magnetic survey of the globe undertaken by the Department of Terrestrial Magnetism is proceeding effectively on both land and sea. Observations of the magnetic elements of declination, dip, and intensity have been made at numerous points on the continents of Asia, Africa, Australia, Europe, South America, and on the Polynesian Islands; while the non-magnetic ship *Carnegie* has secured a large quantity of data of immediate practical utility to navigation, and of still greater importance, doubtless, in their relations to the general problem of terrestrial physics. During the year the *Carnegie* traversed upwards of 23,000 nautical miles, measuring magnetic declinations at 252 different points, and dip and intensity at 172 different points at sea. In addition to this work, corresponding complete determinations were made on land at seven ports, and intercomparisons of magnetic instruments were made at three ports.

Unexpectedly large errors have been found almost everywhere, except in the South Atlantic Ocean, in the best compass sailing charts now in use. This is especially the case in the Indian Ocean, for which some recently issued charts are in error as much as 4° to 6° in the "compass variations" assigned. To meet the pressing needs of mariners for more trustworthy charts, the data obtained by the *Carnegie* are promptly furnished to the hydrographic establishments of the world engaged in the publication of magnetic charts. It appears from the investigations of the department that the chief source of the errors in existing charts lies in a lack of knowledge of the secular variation of the magnetic elements. It is worthy of note, also, in this connection, that observations of atmospheric electricity and atmospheric refraction have been carried on during this voyage of the *Carnegie*. The importance of precise navigation in recent times gives special interest to the outstanding uncertainties due to atmospheric refraction.

THE ROAD: PAST, PRESENT AND FUTURE.[1]

The Present.

A GREAT improvement took place when Macadam and Telford brought the results of their study and their inventive powers to bear, giving a road well laid below and a crust of small angular stones, which when pressed down close produced an infinitely better road than had been known before. But it must be admitted that while they provided better materials for a good highway, their mode of completing it entailed upon the road user and his horse and vehicle a great deal of unpleasant road-making work, involving much temporary discomfort, and much wear and tear to animal and carriage. The road user had to apply his vehicle to roller work, to force the stones into a closely packed surface. When completed it was a good road for the traffic of the day, but oh! it was trying work when the road user's vehicle not only conveyed his passengers or his goods, but was compelled to act the part of a road roller.

A great change took place when the heavy steam roller was introduced, which in one operation pushed the stones down into position. It afforded a blessed relief to those who used the roads with horses. But though advantageous in saving the road user and

[1] From a discourse delivered at the Royal Institution on Friday, February 16, by the Right Hon. Sir John H. A. Macdonald, K.C.B., F.R.S. Exigencies of space prevent what was said on the Past being given.—Ed.

his horse and carriage, and more expeditiously completing the new surface, it was not possible to provide a closely fitted road, which should have its interstices filled up by the chip and grit from the stones themselves, and which was an essential desideratum according to the Macadam theory. His principle was that no water should enter the surface of the road or penetrate beneath the crust. To keep water out of the road was one of the most essential points, if it was to be efficient. He strongly condemned any insertion of loose material into the interstices of the metal, or allowing water to enter between the stones of the crust. These maxims of Macadam came to be disregarded when steam rolling was introduced. When rolling was to be done in one operation, a device had to be resorted to, that the spaces between the stones might be closed by added packing, and this has been done by making what can only be described as a soup of dirt and water and pouring it upon the stones and brushing and rolling this liquid mud into the crust of the road. The road thus when opened for use is crusted with a coating of stones, the only binding of which is water thickened with dirt, or perhaps dirt diluted with water is the proper description. The result is that it can never be a good road in wet weather, and can never be a good road in dry weather. As long as it is in a slightly damp state, and not subjected to severe wet weather or long-continued drought, it may be a fairly good road. In wet weather water can get in where it has come out, reproducing the mud soup, and the traffic squeezes it up and out of the road. In dry weather, the binding being reduced in bulk and loosened by the evaporation of the moisture which gave the inserted dirt some cohesion, the stones move and are picked out of the surface, and so holes are left for the water to lodge in the dirt below when again rain begins to fall. What would Macadam say, if he could visit the scene of his scientific labours, to hear the phrase "water binding" used to describe the means employed for consolidating the crust. To call a water-formed road a macadamised road is a contradiction in terms. His emphatic declaration was: "Every road is to be made of broken stones, without mixture of earth, clay, chalk, or any other matter that will imbibe water."

But further, the road roller has not in another aspect proved to be an unmixed blessing. For it is not uncommon to see that its use has developed another evil. The heavy road roller coming on to a layer of stones, surrounded with liquid and therefore non-resisting mud, and pressing down the stones by its weight, necessarily must move the water and the dirt in suspension, otherwise the stones would not go close together. The liquid is therefore squeezed out of the way, and as the great width of the roller prevents its escape sideways, except at the edges, it must go forwards, and (water being practically incompressible) forces the water and the dirt and the stones in front upwards, forming a ridge in front. The roller advances, and when it cannot force the ridge farther forward, it then mounts it and descends in front, and so *da capo*, with the consequence that the road becomes a series of ridges and furrows, and when drying up resembles a mackerel's side, a series of dark-toned wet hollows and light-toned dry mounds. No worse state of matters for the traveller and his vehicle, or for durability of the road surface, can be conceived.

The Future.

What is the road of the future to be? It is a question which all who are associated with the management of roads have come to see calls imperatively for an answer. The problem is to find the best mode by which a road can be constructed, which will not have its surface broken by traffic, and will make transit easier both for passengers and goods, and shall neither form puddle holes nor exude mud to clog the vehicles and to form thick dust when the weather is dry; in short, that there shall be no loose material from the road, except the small quantity caused by surface wear, which it is found is but trifling when a sound crust has been rolled in. That such a road can be laid anyone may see by paying a visit to the Thames Embankment, the traffic on which was small formerly, the road being shunned as one of the worst in the country, but which is now used by an enormous number of vehicles, often as many as 1600 in an hour. It will be seen there that water on the surface dries off very quickly, there being no mass of mud to hold it, and that in the driest weather there is practically no dust. No watering is done during the day, the surface receiving one washing during the night, because of the horse traffic. But there is no need for the use of water carts by day. Even during the long drought of 1911 there was no watering, yet there was no appreciable dust.

The necessity for the development of road improvement as a matter of national concern is now recognised, and this has led to the establishment of the Road Board, as a Government department, to the charge of which the money raised by taxation of motor vehicles and motor fuel is handed over to be administered in aid of road improvement.

The Board encourages road improvement by giving grants in aid to those road authorities who undertake works of improvement in their districts. The Board has also been conducting, and will continue to conduct through their engineer and technical advisers, experiments, both in the laboratory and on the road itself.

I shall conclude by directing your attention to some of the results of recent experiments, by which I think you will see that it has been possible for the Board with the aid of its staff, and the experience of numerous surveyors who have been experimenting for many years, to obtain valuable and practical information, as regards the choice of material, its manipulation, its proportions, and the mode of laying it, which may ensure that good roads can be made, roads which will keep their surface sound for twice as long as the water-bound macadam road, and will not become uneven and break into holes, which was the fate of all the roads of the past.

The question: "What shall be the weight-bearing crust?" is one of vast importance, and this is engaging the attention of the advisers to the Road Board. I do not intend to dogmatise on the subject, but only to show you what steps of progress are being made, what has already been consummated in the production of roads which are to the old water-bound macadam what the genuine macadam was to the old track of foot-deep mud and bulky stones. One thing is now universally recognised, that the road of the future shall be a truly bound road, in which, whatever kind of stone is used—a matter into which there is not time to enter—that stone shall be held together by some pitchy or bituminous material, so that it shall be indeed a crust and not something which has no real cohesion, and into which Macadam's enemy, the water, can make its way whenever water falls. That this result has been attained in a practical way is manifest from the pieces of road crust cut out after they have been under traffic for long periods.

Roads formed as regards the crust in this way are now common. Many can be seen in Kent and other counties near London, and stretches are being laid throughout the kingdom. Great success was attained by many surveyors, and notably at an early date by Mr. Hooley, of Nottingham, in putting together road crusts with the aid of tarry components substituted for mud binding.

I have probably said enough to show that a good road, which shall keep smooth, be impervious to water, and not tend to disintegrate, is now an accomplished fact, and I only need to add that the cost, taken over a series of years, will not be more—indeed there is good ground to believe it will be less—than that of a road as it has been constructed in the past.

One question remains—will it not be well to endeavour to provide an elastic skin or carpet to lie between the vehicle and the bearing crust? The laboratory experiments made seem to indicate that this will be accomplished. Research has been made with pitch and with bitumen, and the conclusion has been reached that pitch will not give satisfactory results, but bitumen will do so. A stick of pitchy material has very little resiliency when subjected to strain. A bitumen stick of the same size is capable of being twisted without fracture, and when freed slowly resumes its shape.

It is expected that with such material laid on the top of the main road crust and integrated with it a valuable road protection will be supplied, so that the road crust will be practically permanent, the upper protecting sheet being remade up and relaid as required.

For the carpet or topping, the case is somewhat different from the crust. Here strength is not of so much importance as the elastic and silencing qualities, and the freedom from liability to produce any dust in summer or mud in winter. Another requirement which is very difficult to meet in this transition age is that of giving a surface good for motor and mechanical transport, and which will not be slippery, and will afford good foothold for horses. The carpet must be a compromise; it must not be as hard as motorists would wish for, but just so hard that it will wear a little and yet be cheap and easy to maintain.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Science announces that the Massachusetts Institute of Technology has received from a donor whose name for the present is anonymous a gift of 500,000*l.* for the erection of the buildings on its new site.

Since our last issue, Lord Haldane, chairman of the Royal Commission on University Education in London, has received a promise of 50,000*l.* towards the purchase of the site on the Duke of Bedford's estate north of the British Museum for London University. This brings the total amount subscribed for a new site and Senate house for the University to 355,000*l.*

The new buildings of the Spinning Section of the Textile Department of the University of Leeds will be opened by the Master of the Clothworkers' Company on Friday, April 26. The ceremony, at which the chancellor of the University (the Duke of Devonshire) will be present, will take place in the hall of the University. The Clothworkers' Company, whose liberality has made the new extension possible, will be represented by the Master (Mr. F. G. Fitch), the Warden (Mr. G. H. Nussey), Mr. A. W. Snow, Sir Owen Roberts, Sir Swire Smith, Mr. William Latham, K.C., and the Right Hon. G. W. Balfour.

A prize fellowship of 120*l.* was offered by the Federation of University Women in December last, open to women who have been engaged during a number of years in research, the results of which have been published. Thirteen applications were received, investigations in zoology, geology, physiology, botany, physics, history, Oriental religions, English literature, French literature, and philosophy being submitted. The fellowship has been awarded to Miss C. E. Spurgeon, docteur de l'Université de Paris, lecturer in English literature at Bedford College, London. Miss Spurgeon's published work deals chiefly with mysticism in poetry and with Chaucer criticism.

The annual report on the work and progress of University College, London, has just been issued. The total number of students during the session 1910–11 was 1600; of this number there were in the faculty of science 197 undergraduate and non-matriculated students, and 90 postgraduate and research students. The report contains a *résumé* of the chief activities of the year, together with appendices showing the list of original papers and other publications recording the results of investigations carried on in the college. There is also a summary of the important developments of the year. Among these, the two most noteworthy are to be found in the progress made in the scheme for new chemical laboratories, due especially to the gift by Sir Ralph C. Forster of 30,000*l.* towards the buildings, and in the anonymous benefaction of 30,000*l.* primarily for the building of the new School of Architecture. The report shows that a sum of about 10,000*l.* is still required to complete the new chemical laboratories.

In an address at Boston on March 6, Dr. R. C. Maclaurin, president of the Massachusetts Institute of Technology, said nearly everyone recognises to-day the power and might of science, and nearly everyone pays it at least the homage of the lips. He reviewed some of the controversies that marked the foundation of the Massachusetts Institute of Technology. It was attacked only a half-century ago on the ground that science is antagonistic to humanity. The idea was that science was unsuited to be an instrument of education because it dealt with nature rather than with men. This limited idea can find little favour to-day, when science is seen to be human to the core. Even when it deals with nature it deals with man's views of nature; but, apart from this, half a century of its sway has displayed to the world something of the immensity of its power to make for human betterment. "Science in the service of man," continued Dr. Maclaurin, "is indeed the watchword of modern progress, and men and women who could serve their fellows in the future will find themselves handicapped unless they have learned to serve with the method and in the spirit of science."

The recently published report of the Board of Education for the year 1910–11 (Cd. 6116) gives much useful information concerning the number of efficient secondary schools in England and of pupils in them. The total number of schools regarded as eligible for grant during 1910–11 was 862, as compared with 841 during 1909–10. In these schools there were, on January 31, 1911, 79,506 boys and 66,378 girls, as compared with 76,699 boys and 64,450 girls in 1910. There were 96 other schools recognised by the Board as efficient during 1910–11, though they were not on the grant list. In these schools on the date given above there were 9946 boys and 7666 girls. So far as the number of pupils in public elementary schools is concerned, the report shows that in 1910–11 the number under five continued to fall, as in previous years, and, in addition, during this year there was a decrease of 8118 in the number of pupils over twelve;

the number between five and twelve rose by 32,169, and the net decrease of pupils of all ages was 7482. During 1910–11 the average number on the registers decreased by 0·11 per cent., the average attendance increased by 0·09 per cent., and the percentage of regularity rose to 89·15.

SOCIETIES AND ACADEMIES.

London.

Royal Society, March 28.—Sir Archibald Geikie, K.C.B., president, in the chair.—Dr. G. J. **Burch**: A confusion test for colour blindness. A sheet of perforated zinc is fixed in the focal plane of a convex lens of about eight diopters, through which the observer looks. On a card six in. or so farther off is painted a design in confusion colours, *e.g.* red and blue letters on a dark-green ground. The red-blind can distinguish the blue letters but not the red, though these are far more conspicuous to the normal. The letters being out of focus, brush marks are invisible, and new designs can be easily drawn. Other colours are: Geranium red with French grey; emerald green with yellow ochre; lilac with blue—this last being a test also for the green-blind.—Clifford **Dobell**: The systematic position of the Spirochæts. The paper is a brief summary of certain results obtained from a detailed study of the morphology of a large number of Spirochæts and related organisms. It is maintained that the Spirochæts cannot be regarded as Protozoa, but that they must be classified among the Schizophyta, and that in the latter group they must be placed among the Bacteria and not among the Cyanophyceæ.—E. C. **Snow**: The influence of selection and assortative mating on the ancestral and fraternal correlations of a Mendelian population. Using the simple hypothesis of Mendel, the author investigates by analytical methods the numerical effect on the ancestral and fraternal correlations of dealing with samples (*a*) which are not true random samples of the general population and which mate with no sexual selection; (*b*) which are perfectly random samples of the general population but mate with certain intensity of assortative mating; (*c*) which are selected samples showing assortative mating. So far as *numerical* results are concerned, the investigation supports the view that the Mendelian hypothesis can be employed to give confirmation to results which have at first sight appeared paradoxical (*e.g.* the closeness of the resemblance between first cousins) and to give a rough indication of the probable results in cases for which actual statistical data are inadequate (*e.g.* the inquiry into the effects on the offspring of inbreeding of various degrees).—T. **Lewis** and M. D. D. **Gilder**: The human electrocardiogram; a preliminary investigation of young male adults, to form a basis of pathological study.—C. **Revis**: The production of variation in the physiological activity of *Bacillus coli* by the use of malachite-green. *Bacillus coli* can be trained to grow in nutrient broth containing malachite-green. By gradually increasing the percentage of the malachite-green the organisms will develop readily in presence of 0·10 per cent. In most cases the organism at the same time undergoes a profound change in its physiological activity towards sugars and polyhydric alcohols, acid only being produced in certain of these, from which the organism originally produced both acid and gas, the power of gas formation being permanently lost. In one instance this change in physiological activity was accompanied by equally profound morphological and cultural changes, the resultant organism being quite different from that from which it had been produced. The change brought about by malachite-green indicates a connection between the typhoid and coli groups and the possibility of development of organisms of the one into those of the other.—Muriel **Robertson**: Notes on some flagellate infections found in certain Hemiptera in Uganda.—Muriel **Robertson**: Notes on certain aspects of the development of *T. gambiense* in *Glossina palpalis*.—Dr. H. L. **Duke**: Antelopes and their relation to trypanosomiasis.—F. P. **Knowlton** and Prof. E. H. **Starling**: The nature of pancreatic diabetes (preliminary communication).

Zoological Society, March 19.—Dr. S. F. Harmer, F.R.S., vice-president, in the chair.—E. W. **Shann**: Observations on some Alcyonaria from Singapore, with a brief discussion on the classification of the family Nephthyidæ. All the specimens had been obtained in shallow water, from low water-mark to a depth of about 10 fathoms, and of the eleven species dealt with in this paper, representing six different families, four were described as new.—Sir George H. **Kenrick**: A list of moths of the family Pyralidæ collected by Felix B. Pratt and Charles B. Pratt in Dutch New Guinea in 1909–10, with descriptions of new species.—T. H. **Withers**: Some early fossil cirripedes of the genus Scalpellum. Attention was directed to the form of the carina of the geologically older species of Scalpellum, and it was shown that the earliest forms known resembled more closely the carina of Pollicipes, from which Scalpellum is considered to be derived.

Royal Meteorological Society, March 20.—Dr. H. N. Dickson, president, in the chair.—Prof. Otto **Pettersson**: The connection between hydrographical and meteorological phenomena. Experiments carried on during the last four years at Bornoe, in Sweden, have shown that the inflow of the undercurrent from the North Sea into the Kattegat—which brings the herring shoals in winter to the Swedish coast—is oscillatory, the boundary surface of the deep water rising and sinking from 50 to 80 ft. about twice a month. The phenomenon is governed by the moon's declination and proximity to the earth. From astronomical data, Prof. Pettersson concludes that the influence both of the sun and of the moon upon the waters of the ocean in winter about the time of the solstice must have been greater 600 to 700 years ago than at the present time. This must have caused a more intense circulation, of which we have conclusive evidence in the fact that the migrations of the herring—which now only reach as far as to the Kattegat—in those centuries extended into the Baltic. The hypothesis first proposed by A. W. Ljungman in 1879 that the periodicity of the great secular herring fishery of Bohusland should agree with that of the sun-spots is by no means incompatible with the phenomena here described, since the fourteenth century is noted in Chinese annals as an epoch of maximum solar activity, and since the sun-spot frequency curve of Wolfer can be reconstructed by harmonic analysis, using the moon's apsides and nodal period as the basis of the analysis.

Royal Microscopical Society, March 20.—Mr. E. Heron-Allen, vice-president, in the chair.—C. F. **Rousselet**: Four Rotifera from the Devil's Lake, a large brackish-water lake in North Dakota. The point of interest was that all four species lived in brackish water only. One, *Pedalion fennicum*, was first found in Finland; another was a new species, *Brachionus spatiosus*; the third, *Brachionus satanicus*, Rousselet, known only from this locality, and the fourth was *Asplanchna silvestrii*, Daday, ♂♀, showing dimorphism in the female.—F. **Enock**: Fairy flies and their hosts.

MANCHESTER.

Literary and Philosophical Society, March 19.—Prof. F. E. Weiss, president, in the chair.—Prof. S. J. **Hickson**: Note on a specimen of a recent coral, *Endopachys grayi*, from the Persian Gulf. Three out of the four known specimens of this species were until quite recently in the possession of the Manchester Museum, but one has, however, been presented to the British Museum of Natural History. One specimen was reported as having been found in the China Sea.—C. E. **Stromeyer**: Note upon the surface ridges and hollows of tramway and railway lines.—R. F. **Gwyther**: The complete formal solution of the equations of stress in cartesian, and in cylindrical and spherical coordinates. The paper dealt with the stresses in materials, independently of any assumption as to their nature, and so applicable to all structural materials, such as iron, steel, and concrete, as well as to stresses of earth on retaining walls, and perhaps of grain in grain tins or bunkers. Most theoretical applications have been made to substances assumed to obey Hooke's law connecting stress and strain, and also applied to substances which are certainly not of that character. The method can be applied to the subject of geophysics.—Dr. H. G. A. **Hickling**: Variation of *Planorbis multiformis*. The shell exhibited every gradation from a perfectly flat type to one with a high spire. The mean type is represented by a large number of specimens, while the extreme types are scarce. The curve representing the various types is a simple variation curve, thus proving that all the forms belong to a single species. Great variation occurs in other characters of the shells, and these variations appear to be independent of one another.

EDINBURGH.

Royal Society, March 4.—Prof. T. Hudson Beare, vice-president, in the chair.—Dr. J. W. **Evans**: The geometry of twin crystals. The paper contained a somewhat novel way of considering the mathematical relationships in twin crystals.—E. M. **Wedderburn**: Temperature observations in Loch Earn, with a further contribution to the hydrodynamical theory of temperature oscillations in lakes. With the help of some two dozen students of science in Edinburgh and Dundee, Mr. Wedderburn made a careful study of the simultaneous temperature variations at a number of selected stations along Loch Earn during August of last year. The oscillations of the temperature seiche could be clearly traced. At certain stations measurements of current were also made. A modified theory gave a formula for the period of the seiche which agreed within 5 per cent. of the observed period.—James **Russell**: Transverse induction changes in demagnetised and partially demagnetised iron in relation to the molecular theory of magnetism. Iron tubes were magnetised spirally by applied longitudinal and circular magnetic fields, and these were reduced by diminishing alternations until the tube was left in an apparently neutral condition. The æolotropy left in the material was proved by the *transverse* induction change produced by application of a given field. These transverse changes were compared with what was deduced from a special theory of molecular magnetism. The comparison was satisfactory.

March 18.—Dr. James Burgess, C.I.E., vice-president, in the chair.—Dr. W. T. **Gordon**: *Rhetinangium Arberi*, a new type of fossil stem from Pettycur. This new genus and species is important on account of its relationship to other forms. It resembles Heterangium in many points, but is most closely allied to Kidston's new genus, Stenomyclon. The new form seems to be a phyllogenetic link between the lower Pteridosperms as represented by Heterangium and the higher members of that group.—Dr. John **Aitken**: The sun as a fog-producer. It was noticed some years ago that at Falkirk fogs frequently began to form just at sunrise. Observations during the last four winters showed that when the wind was light and came from an impure direction (that is, from densely inhabited areas), and was damp, but not necessarily saturated, a fog invariably formed if the sun shone, but did not form if there was no sunshine; also that when the wind came from a pure direction, the sun had no fog-producing effect. Experiments were then made on vessels filled with various products of coal combustion, and the conclusion was come to that the fogs were caused by the action of the sun on the products of the sulphur in the coal, and also to the sunshine forming hydrogen peroxide in the air. In this way particles are formed which can condense vapour in unsaturated air. Radio-activity and the electric discharge had a similar action.

PARIS.

Academy of Sciences, March 25.—M. F. Guyon in the chair.—Maurice **Hamy** and M. **Millochau**: The new star in the constellation of the Twins (see p. 121).—H. **Poincaré**: The diffraction of the Hertzian waves. Remarks on a dissertation by M. March, in which conclusions are drawn which are in contradiction to those previously published by M. Poincaré. It is shown that this difference is due to an error in the method employed in the approximation of an integral.—A. **Lacroix**: The deposits of corundum in Madagascar. These deposits result from the metamorphism of aluminous sediments under the influence of granite; their practical utilisation is doubtful owing to the discontinuous nature of the deposits.—W. **Kilian** and Ch. **Jacob**: The tectonic of the mountains situated between Mt. Blanc and the small St. Bernard.—M. Metchnikoff was elected a Foreign Associate in the place of the late Sir Joseph Dalton Hooker.—Fr. **Iniguez**: The new star, *Nova Geminorum*. Observations made at the Observatory of Madrid. The spectrum showed two superimposed spectra, one with bright lines of hydrogen, the other an absorption spectrum rich in lines in the neighbourhood of $H\gamma$.—Ch. **Platrier**: Contribution to a theorem on the integral equations of Fredholm of the third species.—Rodolphe **Soreau**: The graphical resolution of the trinomial equation with any exponents.—A. **Leduc**: The specific heats of vapours in the immediate neighbourhood of saturation. The theoretical investigation given is applied to the case of water.—Louis **Dunoyer**: New observations on the fluorescence of sodium vapour. Details are given of the special precautions taken to ensure the purity of the sodium employed. The fluorescence obtained was yellow, and examined spectroscopically was found to show only the D line.—A. **Cotton** and H. **Mouton**: Magnetic double refraction and chemical constitution.—Ed. **Chauvenet**: The hydrates of zirconyl chloride. Thermochemical data for the hydrates of zirconyl chloride.—M. **Dublancq-Laborde**: The existence of metamorphosed limestone blocks in the older tufa of Mount Pelée.—Pierre **Lesage**: The limits of germination of seeds submitted to the action of various solutions.—J. E. **Abelous** and E. **Bardier**: The mechanism of anaphylaxis.—Ch. **Gravier**: Some parasitic Crustacea arising from the second French Antarctic expedition.—Mieczyslaw **Oxner**: Experiments on memory and its nature in a marine fish, *Serranus scriba*. The proof has been obtained that this fish can clearly associate the sensation of feeding with the red colour of a cylinder in which the food was placed.—O. **Duboscq** and Ch. **Lebailly**: *Spirella canis*, a new genera and new species, a spirillum from the stomach of the dog.—Gabriel **Bertrand**, M. and Mme. **Rosenblatt**: Increase in the activity of the sucrase of Aspergillus in presence of various acids.—Pierre **Gérard**: The amount of potassium and sodium in the different organs of the dog.

CALCUTTA.

Asiatic Society of Bengal, March 6.—G. R. **Kaye**: Mediæval references to "Indian mathematics." This paper gives numerous references to so-called "Indian mathematics," &c., by Western mediæval authors—Arabic and European. Mahommed Vin Musa, Avicenna, Masùdi, "Omar-al-Khayyām," Leonardo Finbonacci, John of Holywood, Jordanus Saxo, Maximus Planudes, and many others have often been quoted as expositors of Hindu mathematics, and many of them actually themselves designate their arithmetic and the arithmetical notation they use as "Indian." But the "Indian" arithmetic they exhibit has practically nothing in common with the Hindu mathematical works of Aryabhati, Brahmagupta, Bhāskara, &c., and the "Indian" symbols they show are all of Arabic forms. We have, then, to choose between the exotic and the indigenous or orthodox Hindu exposition. The present author prefers to accept the Hindu works as really representative, and rejects the Western evidence where it does not agree with the Hindu evidence.—W. **Kirkpatrick**: Primitive exogamy and the caste system. The *Sirki Wálás*, or the reed-mat folk, "he that lives under a mat," are an aggregate of tribes of a Gipsy character distributed over the United Provinces. There are numerous branches of this nomadic race. The fact that none of these branches intermarry only points to their being endogamous sections of one original family. Each endogamous section is subdivided up into exogamous septs of occupational, ethnic, eponymous, and totemic origin. All these casteless people are gradually coming under the influence of the caste system. Caste in India, in whatever direction its evolution, is dominated by the *Jus Connubii*. The constant creation of separate connubial groups in modern Hinduism has its origin in the instinct which taught man to seek his bride from another camp, which goes back to marriage by capture, which is exogamy in its most primitive form.

BOOKS RECEIVED.

A Manual of Structural Botany. By Prof. H. H. Rusby. Pp. viii+248. (London: J. and A. Churchill.) 10*s*. 6*d*. net.

Bericht über die Tätigkeit des Königlich Preussichen Meteorologischen Instituts in Jahre 1911. Pp. 190. (Berlin: Behrend and Co.) 6 marks.

Handwörterbuch der Naturwissenschaften. Edited by E. Korschelt and others. Fünfte Lief. Pp. 161–320. Vierte Lief. Pp. 321–480. (Jena: G. Fischer.) Each 2.50 marks.

Handbuch der Morphologie der Wirbellosen Tiere. Edited by A. Lang. Zweiter Band, Erste Lief. (Jena: G. Fischer.)

The Kingdom of Man. By Sir E. Ray Lankester. New edition. Pp. x+114. (London: Watts and Co.) 6*d*.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

INDEX NUMBER.

No. 2215, Vol. 89] THURSDAY, APRIL 11, 1912 [Price One Shilling

Registered as a Newspaper at the General Post Office.

ROYAL INSTITUTION OF GREAT BRITAIN.

ALBEMARLE STREET, PICCADILLY, W.

Tuesday next (April 16), at Three o'clock, EDMUND GOSSE, Esq., LL.D. First of two lectures on "Algernon Charles Swinburne: His Early Life and Work." Half-a-Guinea the Course.

Thursday (April 18), at Three o'clock, Professor ARTHUR W. CROSSLEY, D.Sc., F.R.S. First of two lectures on "Synthetic Ammonia and Nitric Acid from the Atmosphere." Half-a-Guinea.

Saturday (April 20), at Three o'clock, REGINALD BLOMFIELD, Esq., A.R.A, M.A. First of three lectures on "The Architecture of the Renaissance in France, 1494-1661." Half-a-Guinea.

Subscription to all the Courses in the Season, Two Guineas.

The Friday Evening Meetings will be resumed on April 19, at Nine o'clock, when ALAN A. CAMPBELL SWINTON, Esq., M.Inst.C.E., M.I.E.E., will give a discourse on "Electricity Supply: Past, Present, and Future."

To these Meetings Members and their friends only are admitted.

EAST LONDON COLLEGE.

(UNIVERSITY OF LONDON.)

Patron—HIS MAJESTY THE KING.

Classics	F. R. Earp, M.A.
English	H. Belloc, M.A.
French	Mina Paquier.
German	J. Steppat, Ph.D.
History	Thomas Seccombe, M.A.
Mathematics	The Principal.
Physics	C. H. Lees, D.Sc., F.R.S
Chemistry	J. T. Hewitt, D.Sc., F.R.S.
Botany	F. E. Fritsch, D.Sc.

Telephone: 899 Western.

An Introductory Course of Lectures with Practical Work on the

BIOLOGY OF THE SEA WITH SPECIAL REFERENCE TO FISHERIES,

BY

J. T. CUNNINGHAM, M.A., F.Z.S.,

Tuesdays, 7 p.m., commencing May 7, 1912.

Fee for the Course, 3s.

THE SIR JOHN CASS TECHNICAL INSTITUTE,

JEWRY STREET, ALDGATE, E.C.

Principal - - Charles A. Keane, D.Sc., Ph.D., F.I.C.

The following Special Courses of Instruction, suited to the requirements of those engaged in Chemical and Metallurgical Industries, will be given during the Summer Term, 1912.

The scope of the instruction will, as far as possible, be adapted to the individual requirements of the students.

TECHNICAL GAS ANALYSIS.

By Charles A. Keane, D.Sc., Ph.D., F.I.C.

A Course of Practical Work. Wednesday evenings, 7 to 10 p.m., commencing Wednesday, April 17, 1912.

FUEL ANALYSIS.

By J. S. S. Brame.

A Course of Laboratory Work in the methods employed for the Analysis and Examination of Fuels. Monday evenings, 7 to 10 p.m., commencing Monday, April 15, 1912.

Detailed Syllabus of the Courses may be had upon application at the Office of the Institute or by letter to the Principal.

BIRKBECK COLLEGE,

BREAMS BUILDINGS, CHANCERY LANE, E.C.

COURSES OF STUDY (Day and Evening) for the Degrees of the UNIVERSITY OF LONDON in the

FACULTIES OF ARTS & SCIENCE

(PASS AND HONOURS)

under RECOGNISED TEACHERS of the University.

SCIENCE.—Chemistry, Physics, Mathematics (Pure and Applied), Botany, Zoology, Geology.

ARTS.—Latin, Greek, English, French, German, Italian, History, Geography, Logic, Economics, Mathematics (Pure and Applied).

Evening Courses for the Degrees in Law and Economics.

SESSIONAL FEES { *Day:* Science, **£17 10s.**; Arts, **£10 10s.** *Evening:* Science, Arts, or Economics, **£5 5s.**

POST-GRADUATE AND RESEARCH WORK.

For particulars apply to the Secretary.

G. ARMITAGE-SMITH, M.A., D.Lit., Principal.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON.

INCLUDING THE

ROYAL COLLEGE OF SCIENCE, the ROYAL SCHOOL OF MINES, and the CITY AND GUILDS (ENGINEERING) COLLEGE.

A Special Course of Advanced Lectures with practical work will be given on

PROTISTOLOGY

by Mr. C. CLIFFORD DOBELL, M.A., beginning on April 24 next.

For further particulars and for admission to the Course application should be made to the Secretary.

BEDFORD COLLEGE FOR WOMEN

(UNIVERSITY OF LONDON),

YORK PLACE, BAKER STREET, LONDON, W.

Principal—Miss M. J. Tuke, M.A.

The EASTER TERM begins on THURSDAY, APRIL 25, 1912.

Lectures are given in preparation for all Examinations of the University of London in Arts, Science and Preliminary Medicine; for the Teacher's Diploma, London; the Teacher's Certificate, Cambridge; and for the Cambridge Higher Local Examination.

Six Laboratories are open to Students for practical work.

There is a Special Course of Scientific Instruction in Hygiene designed to furnish training for Women Factory and Sanitary Inspectors and Teachers of Hygiene.

The Art School (which is conducted at South Villa, Regent's Park) may be attended by students who are not taking other subjects at the College.

A single Course in any subject may be attended. Regular Physical Instruction is given free of cost to students who desire it by a fully qualified woman teacher.

REID TRUSTEES' SCHOLARSHIP.

ONE SCHOLARSHIP, value £60 a year for three years, is offered by the Trustees on the result of the College Entrance Scholarship Examination. The scholar will be required to come into residence at the College in the October following the award.

Further particulars on application to the Hon. Sec. to the Reid Trust, Bedford College.

COLLEGE ENTRANCE SCHOLARSHIPS.

THREE ENTRANCE SCHOLARSHIPS (one in Arts and two in Science) will be offered for competition in June next, viz.:—

Reid, in Arts, value £30 a year for three years.
Pfeiffer, in Science, value £50 a year for three years.
Henry Tate, in Science, value £40 a year for two years.
Full particulars on application to the Principal.

RESIDENCE.

Accommodation for 67 Resident Students is provided, partly in the College and partly in an additional residence at South Villa, Regent's Park.

Full particulars on application to the Principal at the College.

SECONDARY TRAINING DEPARTMENT.

Head of the Department—Miss S. Melhuish, M.A.

The Course includes full preparation for the Examinations for the Teaching Diplomas granted by the Universities of London and Cambridge.

Students are admitted to the Course in October and in January.

One Free Place (value £26 5s.), one Scholarship of the value of £20, and a limited number of grants of £10 are offered for the Course beginning in October, 1912. They will be awarded to the best candidates holding a degree or its equivalent in Arts or Science.

Applications should be sent to the Head of the Department.

THE UNIVERSITY OF LEEDS.

DEPARTMENT OF AGRICULTURE.

Applications are invited for the appointment of ASSISTANT LECTURER in AGRICULTURAL CHEMISTRY. Particulars may be obtained from the Clerk to the Senate.

THURSDAY, APRIL 11, 1912.

KRÜMMEL'S HANDBOOK OF OCEANOGRAPHY.

Handbuch der Ozeanographie. By Prof. Dr. O. Krümmel. Band ii., Die Bewegungsformen des Meeres (Wellen, Gezeiten, Strömungen). Zweite Auflage. Pp. xvi+766. (Stuttgart: J. Engelhorns Nachf., 1911.) Price 32 marks.

METEOROLOGISTS and oceanographers are blessed beyond most scientific students in having at their disposal standard works which not only give an exhaustive list of important books and papers relating to their subjects, and a trustworthy statement of their contents, but an ordered survey of the present state of those sciences and a just, critical estimate of current progress. What Hann is to meteorology, Krümmel is to oceanography. The "Handbuch der Meteorologie" of the former, and the "Handbuch der Ozeanographie" of the latter, with their hundreds of pages of expensive printing—formulæ and footnotes—would surely be the despair of most British publishers, and yet they are somehow kept fairly up to date by new editions.

We are concerned here with the second volume of the new issue of Krümmel's great book, which follows the first after the interval of four years. It deals with dynamical oceanography, and falls into three major divisions—waves, tides, and currents; the first two occupying about half the book, with two hundred pages each, and the last the other half with some four hundred pages.

In the first division we find accounts of the theory of surface waves in deep and shallow water, and of observations of the size of waves. The relation of surface waves to the winds is next considered, and then comes an extremely interesting chapter on modifications of waves in shallow water and along coasts. A chapter on waves produced by earthquakes and similar disturbances is followed by one on stationary waves and *seiches*, with a summary of the late Prof. Chrystal's researches. The final chapter of this section discusses the phenomena of internal waves and "dead water." In all there is so much that is recent that this division of the work may not unfairly be said to constitute the first general treatise on a new subject.

Prof. Krümmel treats the tides in a novel and extremely suggestive manner. After general descriptions of the phenomena of the tides and of methods of observation, the equilibrium, dynamical, "canal," and stationary-wave theories are stated and discussed. Harmonic analyses of tidal observations, tidal currents, *bores*, and allied phenomena are each given a chapter, and the section concludes with a full and masterly description of the tidal characteristics of the great divisions of the ocean.

The last division, on oceanic currents, has practically only two chapters; after a short introduction on methods of observation, a chapter of 100 pages deals with the surviving theories of the causes producing and modifying translational movements, and the work concludes with a monumental chapter of 180 pages on the currents of each of the great oceans and the enclosed and fringing seas. Here the great feature is the treatment of horizontal and vertical movements together, giving a complete view of the circulation in each case and not merely of one of its components at a time.

It is, of course, impossible to "review" a work of this kind in detail. The features which are most impressive in this case are three, and they concern only the broader aspects. First, we note the immense value of the geographical point of view which is adopted and persisted in throughout. The results of recondite research in many branches of pure and applied science are laid under contribution almost all through the book, but there is never any doubt left that the essential problems are those of distribution—the work belongs in more than name to a series of "geographical handbooks." Secondly, we appreciate the conspicuous fairness of the author in reviewing the work of different observers. No one disputes the importance of the improved methods of observation which have come into use in recent years in, for example, the measurement of temperature in the depths; but Prof. Krümmel fully admits the value of the earlier work, and of work done by sailors and other observers to whom the new methods were, or are, not accessible; and he makes profitable use of the old data as well as of the new. Lastly, we are profoundly impressed by the extraordinary completeness of the work. There are few fields in which the recent output has been greater and more widely scattered in all sorts of unlikely places than in oceanography, but we have failed to discover the omission of any important contribution.

THE INSURANCE ACT, 1911.

National Insurance. By A. S. Comyns Carr, W. H. Stuart Garnett, and J. H. Taylor. With a preface by the Right Hon. D. Lloyd George, M.P. Pp. xxxi+504. (London: Macmillan and Co., Ltd., 1912.) Price 6*s*. net.

IN the brief preface with which the Chancellor of the Exchequer introduces this book to the public, he repeats the statement that "we have swept into the National Insurance scheme some

10,000,000 workers hitherto unprovided for," in other words, that one-fourth of the population of the United Kingdom are workers (not of the lowest class) who have not hitherto "provided for" themselves in sickness. He ignores the multitude of members of unregistered friendly societies, and of other persons who have hitherto provided for themselves in sickness to their own satisfaction. The authors of the book have fallen into the same error (see p. 98).

The Bill, which is now an Act, was introduced without that patient and systematic inquiry into facts which ought to have preceded a measure so comprehensive; its defects were hastily patched up from day to day as they were brought to light, vital alterations were made in its very last stages, and it is being over-hastily brought into operation. As an almost necessary consequence of this haste, the Act is probably one of the most complicated and perplexing statutes ever passed.

Mr. Lloyd George is therefore right in commending this book to all who wish to bear their share in working out the scheme of the Act, and it will also be useful to those who are compelled to work out that scheme, whether they wish to do so or not. He says truly that the authors have collected a mass of information, which cannot fail to be of value. When it is remembered that the Act only became law on December 16, 1911, immense credit is due to them for their industry and insight. They have cited nearly three hundred law cases, and have shrewdly and acutely commented upon each section of the Act. The preliminary chapters are clearly written and full of interest. In one of them the financial side of the Act is discussed and vindicated. A scientific journal cannot but take note of the manner in which science has been misused in support of the Act. Eminent actuaries have made calculations based upon the unverified hypothesis that the probable experience under compulsory insurance may be deduced from that under voluntary insurance; and have held that by the manipulation of reserves you can remedy the inherent error of charging a uniform contribution for a varying risk.

Unforeseen and dangerous consequences may follow if certain sections of the Act become operative. For example, Section 63 (4) directs that the "average expectation of sickness" is to be "calculated in accordance with the tables prepared by the Insurance Commissioners for the purpose of valuations," and that if in any place the actual amount of sickness is 10 per cent. more than that assumed average, the local authorities, the water companies, and the owners of land are to be mulcted in that excess. If the tables to be prepared by the commissioners should be based upon the same unverified hypothesis as those upon which the Act has been framed, this section may result in great mischief and wrong.

The disregard shown in the Act to the just claims of the medical profession is another grave defect in it from the scientific point of view.

Some slight errors in the book are to be noted. At p. 163 "periods" should be "persons." At page 186, "Registrar-General" should be "chief registrar." The index is not sufficiently copious.

JAEKEL'S CLASSIFICATION OF VERTEBRATES.

Die Wirbeltiere. Eine Uebersicht über die fossilen und lebenden Formen. By Prof. Otto Jaekel. Pp. viii+252. (Berlin: Gebrüder Borntraeger, 1911.) Price 10 mk. 60 pfg.

In this volume, which is apparently intended to be a text-book for students, the author further exemplifies his distinctly original views—some of which have been previously mentioned in Nature—with regard to the taxonomy and phylogeny of vertebrates. In the preface he tells us that particular attention has been directed to the illustrations, as a good figure, in his opinion, is worth half-a-score pages of descriptive text. On the selection and execution of these text-figures, Dr. Jaekel may be cordially congratulated, as they are a long way above the average of those to be found in the great majority of text-books, and thus serve in great degree to justify the aforesaid assertion, and likewise render his work highly useful to students and teachers, whether his views on classification be accepted in their entirety or no.

The first sixteen pages of the volume are devoted to a general discussion of the classification of vertebrates—a term which Dr. Jaekel uses in the same sense as the chordates of other writers—with special reference to the taxonomic position of the tunicates; this introductory section concluding with a table of geological horizons. The rest of the book is devoted to a systematic survey of the various groups. Dr. Jaekel divides the Vetebrata into three "Unterstamme," or sub-kingdoms; namely, Protetrapoda, Eotetrapoda, and Tetrapoda. The first includes tunicates alone; the second comprises fishes, in the widest sense of that term; while in the third are grouped the whole of the remaining vertebrates. As regards the Eotetrapoda, it must suffice to mention that this is divided into three classes: (1) Malacostomata, which includes as sub-classes the extinct pterichthyds and cephalaspids, and the existing lampreys and lancelets; (2) Hypostomata, embracing the Palæozoic placoderms, and the living sturgeons, chimæroids, and selachians; and (3) Teleostomata, with all the more typical fishes.

As regards the Tetrapoda, the most striking innovation is the interpolation of the class "Paratheria" between Aves and Mammalia, as originally proposed by the author in the *Zoologischer Anzeiger* for 1910 (vol. xxxvi., pp. 113–124). At the risk of repeating what has been already mentioned in this journal, it is advisable to remind our readers that this group is taken to include therapsidans (as represented by the African Triassic Lycosaurus and its relatives), chelonians, typical anomodonts (Dicynodon, etc.), theriodonts, and monotremes. Such, it should be mentioned, is the classification given in the table of contents, although in the text we find some departure from this, the Therapsidi there forming a "Hauptordnung," with the Testudinata and Anomodontii as "Nebenordnungen," while the Theriodonti constitute a second Hauptordnung, with the Monotremati as a Nebenordnung.

To recapitulate the characters on which the author relies as a reason for including such diverse types as chelonians and monotremes in a single class would occupy too much space; but it may be questioned whether any of these are really sufficiently important to justify such a sweeping change. Clearly neither the production of young by means of eggs nor the formation of secondary noses by means of an under-roofing of the palate comes under this category; while such features as a depressed and small-brained skull, large and lateral eyes, certain points connected with the dentition, and the structure of the occipital condyle or condyles are of little or no importance. Similarly, the constancy of the phalangeal formula (except when it has been specially modified, as in turtles) throughout the group can scarcely be regarded as more than an inheritance of a common archaic feature. On the other hand, the author allows no value to the possession by monotremes of hair and certain other mammalian features (exclusive of warm blood, which may be regarded as a secondary character). Accordingly, while giving full credit to Dr. Jaekel for his careful and painstaking investigations, we are not yet prepared to accept his views of the classification of the higher vertebrates in their entirety. R. L.

THE PRODUCTION OF WHEAT.

Wheat-growing in Canada, the United States, and the Argentine: including comparisons with other areas. By W. P. Rutter. Pp. x+315. (London: A. and C. Black, 1911.) Price 3*s*. 6*d*. net.

THIS book represents an inaugural dissertation submitted by the degree of Master of Commerce of the University of Manchester, and constitutes a general examination of the conditions under which our present wheat supply is grown and marketed.

It opens with a discussion of the nutrition of the wheat plant, the effect of climate, and the limits within which wheat can be commercially grown, the varieties and their appropriate regions and soils. While it is easy to perceive certain relationships between environment (including therein latitude, soil, and such meteorological factors as temperature and rainfall), it proves as yet impossible to give these factors any quantitative expression; we can only say generally that wheat is most suited by what climatologists call "steppe" conditions, and that the hard, strong wheats are generally spring sown and grown in areas with a dry, cold winter and a summer of progressive heat and desiccation. Some discussion then follows of the character of western farming, the systems of land tenure, and the labour conditions that prevail, following which come tables setting out the yield per acre and the total production in the countries under consideration.

An account of the methods of transporting wheat in America will be of particular interest to the English reader; here are described the great railroad systems, the ports, and waterways, the freights, both local and overseas, so that one can get an idea of the charges which the foreign grain has to bear before it is marketed in competition with our home-grown produce.

Later chapters explain the system of elevators, the storage charges, the inspection and grading which enable dealings to be made without the purchaser seeing samples or even knowing where may be the parcel of wheat that he is buying. The great grain markets are described, and the dealing in futures and the effect of such speculations on the consuming farmer and the public are discussed.

Finally, Mr. Rutter examines the prospects of the future, and considers to what extent the export is likely to be maintained at its present magnitude. To do this it is necessary to consider how far the conditions of farming in America are changing, to what degree the soil is becoming exhausted and what new land is available, also what increase is probable in the consumption in America. Upon these questions to a large extent depends the future profitableness of British farming; the rise of prices that has been slowly gathering headway during the last dozen years represents to some extent the depreciation of gold, but also the manner in which the consuming population has been increasing faster than the wheat areas available. Englishmen are perhaps not much in the habit of paying attention to these general surveys, and certainly Mr. Rutter's dissertation is the first of its kind in this country, but no serious student of agriculture, and particularly of its relation to the trend of commercial and social development, will fail to derive profit from Mr. Rutter's book. It represents an immense amount of painstaking work, such as can only be appreciated by one who has himself tried to reduce to some common denominator the scattered statistics and information about various countries, and it should find an interested public now that agriculture is being systematically studied and taught in the United Kingdom. A. D. H.

ACTUAL ELECTROCHEMISTRY.

Applied Electrochemistry. By Prof. M. de Kay Thompson. Pp. xii+329. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1911.) Price 9s. net.

THERE have been many books written on this subject, and they are apt to come under two heads, the purely scientific, in which the principles of modern electrolytic theory are discussed very fully, without much information as to their practical application; and the purely commercial, in which the various industries are described, with views of the various kinds of plants. A third variety might be included which discusses all sorts of processes, most of them never having had any real existence, the information and illustrations being taken entirely from the rather imaginative patent literature of the subject.

Dr. Thompson does not begin with an elaborate treatise on what is known as "theory"—he assumes that the reader is well acquainted with the first principles; he merely refers to them, and utilises them and their formulæ as he needs them. He discusses first such subjects as electrochemical analysis. This chapter is a mere sketch, but a good sketch of the subject, which is now far too large to be treated so shortly. A reader would get a good idea of this sort of analysis from the book, but in order to utilise it he would have to study a special treatise. Electro-plating is treated very shortly, but in a refreshingly common-sense way. This common sense runs through the whole book. It is not necessary to give a list of the contents; it may be taken that the book gives a concise account in clear and scientifically accurate language of all the important electrolytic and allied processes in commercial use, and that it does not discuss all sorts of inventions that have been failures in practice. It is a great pity that such failures are not discussed as failures, the reasons of their non-success being given. These would be very valuable, but most difficult to give. In science, both applied and unapplied, people are far too reticent about failures, yet there is much to be learned from them. Dr. Thompson deals very fully with the electrolysis of salt in the wet way, and one of the most interesting chapters is that on ozone. Though there are books on ozone there is not much trustworthy information, and this chapter is very welcome.

The book is American, with heavy American paper but no aggressive American spelling. It has involved a great deal of literary work, and references are always given. There can be little doubt that the amount of matter read and rejected was greater than that utilised. The work is, in short, an admirable, intelligent account of the electrochemical industry as it exists.

J. Swinburne.

A TREATISE ON CHOLERA.

Cholera and its Treatment. By Prof. L. Rogers. pp. xiv+236. (London: Henry Frowde and Hodder and Stoughton, 1911.) Price 10s. 6d. net.

THIS book is a complete treatise on cholera, containing all the essentials of the subject without being over-burdened with details which are of little practical importance. The first and second chapters deal with the history of cholera epidemics and their lessons, and the epidemiology of the disease. In chapter iii. the etiology and prophylaxis of the disease are discussed, and it commences with a description of the specific organism of the disease, the comma bacillus of Koch, which the author fully accepts as the cause of cholera. In this section we should have been glad to see a somewhat fuller discussion of the significance of the various cholera-like comma bacilli which have been isolated during the last few years. The hypothesis of Emmerich that cholera is a condition of nitrite poisoning is not accepted by the author. Prophylactic vaccination by means of cholera vaccine is regarded as being of considerable value, and the measures to be taken for the disinfection of infected wells are described.

Chapter iv. deals with the clinical aspects of cholera and its diagnosis, chapter v. with the morbid anatomy and pathology. In the final chapter the treatment is discussed at some length, and to many this will be considered the most important part of the book, for the author himself has contributed in no small measure to the rational treatment of this terrible malady. Dr. Rogers is entirely opposed to the purgation method except at the very early stage and before the onset of the typical watery evacuations, the "rice-water stools." Opium also has to be used with extreme caution. Injections of saline fluid, either per rectum, subcutaneously, intraperitoneally, or intravenously, according to circumstances, are regarded as potent remedial measures, but still better is the similar use of a hypertonic salt solution, introduced by Dr. Rogers, and minute details are given for its proper administration.

Dr. Rogers also advocates the administration of permanganates, either in solution or in pill form, their action being to oxidise and destroy the toxin. By the adoption of the hypertonic salt injections plus permanganates the mortality in the Calcutta Hospital was about 23 per cent. in 1909–1910, a reduction of more than half the rate obtaining among cases treated with physiological saline solution given intravenously (mortality 51·9 per cent. in 1907). This is a splendid record, and we can only hope that Dr. Rogers's interesting book will be widely read and his methods adopted by all those who have to deal with cholera.

R. T. H.

OUR BOOKSHELF.

A Monograph of the Mycetozoa: a Descriptive Catalogue of the Species in the Herbarium of the British Museum. By Arthur Lister, F.R.S. Second edition, revised by Gulielma Lister. Pp. v+302+201 plates (120 coloured). (London: printed by order of the Trustees of the British Museum, and sold by Longmans and Co., B. Quaritch, and Dulau and Co., Ltd., and at the British Museum (Natural History), 1911.) Price 30*s*.

The Mycetozoa are miscroscopical organisms possessing some of the attributes of both animal and vegetable life, as commonly understood, but they are now generally referred to the vegetable kingdom. They differ from the lower fungi inasmuch as the spores give birth to swarm-cells or moving cells, instead of a mycelium. The swarm-cells coalesce to form a wandering plasmodium, which ultimately develops sporangia, bearing spores inside, or sporophores, bearing spores on the outside. Further, the Mycetozoa feed on bacteria. The first edition of the late A. Lister's monograph was published in 1894, and the second edition, now before us, is a revision and augmentation by his daughter, Gulielma Lister.

This work is an official publication of the Botanical Department of the British Museum, and Dr. A. B. Rendle, the keeper, says, in his preface: "A special feature of this edition is the replacement of the collotype plates by a new and more complete series. A large proportion has been reproduced by the three-colour process, and greater justice has thus been done to the original drawings by Mr. and Miss Lister. . . . That so large a proportion are reproduced in colour is due to Miss Lister's generosity. A bibliography has been added, and also a short glossary." The most important alteration is in the nomenclature: the earliest specific name, under whatever genus it may have been published, has now been adopted, and the starting-point for those names, as well as those for the genera, is the "Species Plantarum" of Linnæus, published in 1753. This has necessitated very numerous changes.

Miss Lister deserves the congratulations and thanks of students for the admirable and authoritative work she has completed. Letterpress and illustrations alike are good, and it should give an impulse to the study of some of the most elegant organisms in nature, open to everyone who can afford a microscope—organisms that abound wherever there is other vegetation, and a collection of which might be contained in a match-box.

W. B. H.

Evolution in the Past. By Henry R. Knipe. Pp. xv+242. (London: Herbert and Daniel, 1912.) Price 12*s*. 6*d*. net.

Just as the researches of Arthur Evans in Greece, and Flinders Petrie in Egypt, have added whole chapters to the history of those countries, so the labours of Cope, Marsh, Osborn, and others in America, Dollo in Belgium, Andrews in the Fayûm, and elsewhere, have contributed so largely to the past records of our earth that we are now almost as well acquainted with its ancient denizens as if they formed a part of its living fauna.

In this happy condition of time and circumstance Mr. H. R. Knipe has brought out his new book, "Evolution in the Past," and having gathered together, from every available source, the latest information on the life history of our planet—from the earliest traces of living things up to the coming of man—and being furthermore aided by the spirited restorations of animals by Alice B. Woodward, and of plant life by E. Bucknall, he has produced one of the most fascinating and readable books of the year.

As a guarantee for the accuracy of the restorations made, the author and the artist have both received valuable help from Dr. Arthur Smith Woodward, Dr. Andrews, Drs. Calman and Bather, and other eminent authorities in the Natural History Museum, who have given them the benefit of their up-to-date knowledge, and carefully criticised the work throughout.

Fifty full-sized plates of animals and six of landscapes in the past render the book attractive to the veriest tyro, whilst the avoidance of technical terms makes the text more agreeable to the general reader, and an excellent holiday companion.

Leisure Hours with Nature. By E. P. Larken. Pp. xv+263. (London: T. Fisher Unwin, n.d.) Price 2*s*.

Mr. Larken here provides interesting reading-matter and a profusion of well-reproduced photographs relating to various objects and scenes in nature. The rapid increase in the number of books dealing with nature-study indicates, it may be hoped, not only a growing interest in animate nature, but the development of keener observation of plants and animals among young people.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Skull of a Neanderthal Type in the Cambridge Fens.

The manner in which Prof. McKenny Hughes applies the term "Neanderthal" to a human skull recently discovered in the peat of the Cambridge fens (Nature, April 4, p. 114) will certainly mislead anthropologists abroad and also at home as regards the true nature of his discovery. From the excellent figures which he appends to his article there cannot be the slightest doubt that the skull he describes is a fairly typical specimen of the round-headed race which came into England during the Bronze period.

Far from being of the Neanderthal type, the specimen he describes is as opposite to that type as has ever been produced in the evolution of the human race. It is apparently a short skull, 180 mm. long; the length of the typical Neanderthal skulls is 200 mm. or more. While the proportion of the width to the length is 84 : 100, in the Neanderthal crania the proportion is about 75 : 100 or less. The mastoid processes, the inion, the lambda, the joint for the lower jaw, and the lower jaw itself are all of the form we are familiar with in people of the Bronze age, and are totally unlike these parts in Neanderthal man. Even the pronounced supraorbital ridges are of the form and size we frequently see in skulls of the Bronze period, and not at all of the Neanderthal form. The correct designation in my opinion is the discovery of a brachycephalic skull with pronounced supraorbital ridges.

There is one point in which Prof. McKenny Hughes could greatly assist those who are at present studying the remains of ancient man in England. I believe he has in his keeping a human molar tooth which Prof. Boyd Dawkins discovered with remains of the hippopotamus and other extinct animals representative of the early Pleistocene fauna while carrying out excavations in a cave at Pont Newydd, near St. Asaph. That molar is probably the most ancient part of man yet discovered in England, and it would be of the greatest interest to know something of its characters—whether or not it showed those features which we know to occur in the teeth of Neanderthal man. I presume that these characters are absent, otherwise they would certainly have attracted the sharp eye of Prof. Boyd Dawkins. A. Keith.

Royal College of Surgeons, April 4.

Are Eyes Autophanous?

Seeing the interest which Colonel Herschel's letter (Nature, January 18) has attracted, and the various animals he has himself observed, it may be useful to record as many animals as possible which exhibit the phenomenon. Going into the aquarium one evening with a reading lamp, I found the eyes of the crayfish (*Jasus lalandii*, M. Edw.) shining like rubies out of the darkness. I soon discovered the correct position in which the source of light should be. Even more brilliant and beautiful are the eyes of the prawn (*Leander squilla*, Linn.), but the colour is more an orange tint.

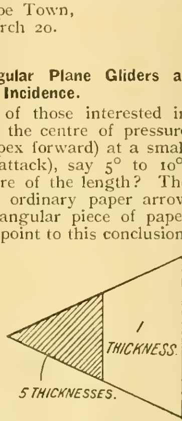
Amongst fishes the eyes of the barbel (*Galeichthys feliceps*, C. and V.) appear salmon, while those of the two dogfish (*Scyllium africanum*, Gm., and *Mustelus laevis*, Risso) shine silvery. So far these five animals are the only ones in which I have noticed the phenomenon, though doubtless it has been observed in other marine animals, if only the records were forthcoming.

A very simple arrangement would enable the sight to be seen by visitors to public aquaria, and would well repay for the extra trouble of opening for an hour or so on some nights. K. H. Barnard.

South African Museum, Cape Town, Cape of Good Hope, March 20.

Centre of Pressure on Triangular Plane Gliders at Small Angles of Incidence.

May I direct the attention of those interested in aërodynamics to the fact that the centre of pressure on a triangular plane glider (apex forward) at a small angle of incidence (angle of attack), say 5° to 10°, lies almost exactly at the centre of the length? The good gliding qualities of the ordinary paper arrow (folded from a square or rectangular piece of paper with its c.g. necessarily central) point to this conclusion, which may be further tested by the following form of glider.



Cut out two equal isosceles triangles in thin card or thick paper. Cut one of these into four equal triangles similar to the whole. Paste these four successively on the apex of the other large piece (see figure). When the paste has dried so as not to affect the weight, it will be found that the glider runs quite well with the usual gliding angle for planes of about 1 in 5.

A knowledge of this fact will probably be useful in estimating the righting torques of triangular tails, &c. Herbert Chatley.

The College, T'ang Shan, N. China. March 17.

Red Water.

As regards the "red water" from a crater lake in Uganda, referred to in Nature of April 4, p. 113, I would direct attention to a similar phenomenon which occurs at the great salt lake of Sambhar, in Rajputana. The lake brine contains sodium chloride, sulphate, and carbonate, and when it is quite saturated during the very hottest dry weather a red coloration appears of organic origin. It varies from a delicate roseate hue to a deep claret red, and there is a demand for salt which contains it, because the consumers are accustomed to the colour. H. Warth.

SIAM.[1]

Siam has a double interest, for not only is it a rich and fertile country, inhabited by a pleasant people who have an undoubted part to play in the world, but it lies between two great Powers, and owes its safety to that fact. *Consule Planco* it nearly caused a war. Now it is a "buffer" State, and it is to the interest of both England and France that it should be strong and progress. It is the only country inhabited by an Indo-Chinese people which is under independent government, and it will be an interesting

[1] "Siam: a Handbook of Practical, Commercial, and Political Information." By A. W. Graham. Pp. xvi+637+plates+map. (London: Alexander Moring, Ltd., 1912.) Price 10*s*. 6*d*. net.

study for the future to compare its progress in various ways with that of the kindred races on each side, one under French and one under English rule.

Mr. Graham's book is not one to read through. It is a handbook to consult when any particular subject connected with Siam arises, because it gives a summary of essential facts on almost all points connected with that country. Its geography, science, races, history, local organisation, education, government, industries, commerce, communications art, archæology, architecture, religion, language, and literature are all touched on. There are five appendices, a bibliography, and an index. The whole 637 pages are crammed with facts, and the author has spared no pains to be full and accurate. A great deal of hard and honest work must have gone to the making of this book. What it lacks are ideas. The facts are lifeless, and have no general coherence; perhaps this cannot be helped in a book of this nature.

If Mr. Graham wants really to interest us, he should select one of these many subjects which he has touched and tell us all about it—the art, for instance. Could he not tell us the ideas that underlie the carving and silver work, their relation to other national ideas, their comparison with those of kindred art, their limitation by material and method? That would make a fascinating book.

The illustrations (one of which is here reproduced by the courtesy of the publishers) are from photographs; they are excellent in their way, but they suffer from the defect of many such illustrations, that they are not always directly connected with the text. Finally, we take exception to the Gaudama on the binding. This is a sacred emblem to many millions of people, and is out of place on a handbook.

Typical scene in Central Siam. From "Siam: a Handbook of Practical, Commercial, and Political Information."

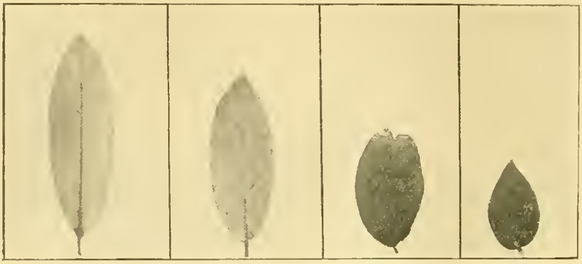
THE SMOKE PROBLEM.[1]

THE first twelve years of the twentieth century will be memorable for many advances, but few will bear more important fruit in the future both as regards our health and welfare than the strenuous attempts that have been made continuously during that period to arouse the public to a sense of the criminality of wasting the fuel supplies of the country by the methods employed in the generation of heat and power from bituminous fuel, which have resulted in a pollution of the atmosphere that towards the end of the last century had become a national scandal.

In view of the widespread interest which is being taken at the present time in smoke abatement, Prof. Julius B. Cohen and Mr. Arthur G. Ruston, of the University of Leeds, have collected the records of experiments and observations made by them during the past twenty years, and have embodied with them the results of other observers, thus making a most welcome addition to the literature of the subject.

[1] "Smoke: a Study of Town Air." By Prof. J. B. Cohen, F.R.S., and Arthur G. Ruston. Pp. vi+88. (London: Edward Arnold, 1912.) Price 5s. net.

The portions of the book devoted to the effects of soot on vegetation and the influence of deposits from smoke on the assimilation of carbon dioxide by the growing plant are specially well done, as is also the influence of smoke on the intensity of light, and the effects of sulphuric acid on vegetation. In these portions of the book the effect of smoke deposits in dwarfing and finally killing town vegetation is shown clearly to be due to at least three well-defined actions—(1) the blocking up of the stomata by soot; (2) the reduction of the intensity of sunlight by the coating formed on the leaf, which reduces the assimilation of carbon dioxide; and (3) by the action of sulphuric acid partly condensed in the soot and partly in the rain water.



Weetwood Lane 100 | Headingley 52·8 | Clarendon Road 15·2 | City Square 11·6

FIG. 1.—Laurel leaves and their respective assimilations.

The photograph (Fig. 1) reproduced here from the book shows in a striking way the effect of locality on the development and power of assimilation possessed by the leaf. The laurel leaf grown at Weetwood Lane on the outskirts of Leeds shows in marked contrast to the one from the City Square, which may be taken as the centre of the town, the assimilative power of the latter being only 11·6 per cent. of the former.

The disappointing part of the book is that which deals with the nature of smoke and the soot which it contains, and from the commencement of the first division on page 4 it is marked by loose expressions. For instance, we read that "soot is a product of incomplete combustion, and is formed partly by the mechanical removal of dust by the chimney draught, and partly by the decomposition of the fuel, such as occurs in the process of destructive distillation." Dust is not, as a rule, a product of incomplete combustion, nor is the tar and free carbon formed in the destructive distillation of coal.

Again, on page 5, analyses of soot from various sources are given, and also analyses of the coal that gave rise to them, from which the reader learns that these "original" coals contained 0·88, 0·92, and 1·64 per cent. of tar respectively. Surely the authors do not believe that a ton of these coals contains about a couple of gallons of ready-made tar.

In describing the experiments by which they sought to ascertain the amount of soot carried up the chimney, they say, "The chimney gases were drawn off at the rate of about a litre a minute, which would approach the speed of the gases passing up the flue," and they add that a good fire was maintained all the time. They probably mean that the rate of flow through the aspirator tube was about that of the rate of flow in the flue, but they do not say so, and if the flue draught was a litre a minute, it is no wonder their figures are abnormal.

The method of taking the carbon in the carbon dioxide of the flue gas as representing the amount of carbon burnt on the fire cannot give anything but incorrect results: if soot is formed, there is incomplete combustion, and carbon monoxide and hydrocarbon gases are also produced, and the percentage of soot found will be far too high. In any case, the percentage of soot to carbon burnt is of no practical importance. It is the percentage of loss on fuel used that is the important factor, and the soot is only a small proportion of this, unburnt hydrogen and hydrocarbon vapours and gases being by far the most important items.

FIG. 2.—Black fringe of soot on Coniston Lake, Lake District.

The authors evidently believe in broad generalisations, and on page 61, in discussing town fog, they state that "without dust there is no mist, rain, or dew." No one will deny the important part played by dust, but few will accept the statement that without it there would be no rain or dew.

Most of us have probably seen such soot deposits as is illustrated by the photograph (Fig. 2) of a soot fringe on Coniston Water, but only when a rain cloud formed over one of the large manufacturing towns has drifted and burst, depositing its sooty cargo directly on the surface of the lake.

The condition of the water in a rain gauge in the north of Scotland would soon convince the authors that it is not every drop that has a dust core, whilst as dew is formed by the deposition of condensing moisture on the rapidly cooling smaller forms of vegetation, which are playing the same part in condensation as the dust particles, it seems unjust to put all the onus on the latter. It is an ungrateful task to have to point out these weaknesses in what is otherwise so excellent a work.

THE BRITISH ANTARCTIC EXPEDITION.

THE arrival of the *Terra Nova* at Akaroa in New Zealand with the reports from Captain Scott's south polar expedition brings the last Antarctic news that can be expected this season. The despatches published by the Central News and referred to last week summarise the progress of the south polar party until January 3, the work of the two expeditions in South Victoria Land of the geological party under Mr. Griffith Taylor, and of Lieut. Campbell's party at Cape Adare.

Captain Scott's two despatches describe the work of the expedition during the first winter in the establishment of depôts for the main journey to the south pole, and his advance to a point only 150 miles from the pole. The preliminary work on the Great Ice Barrier was greatly hampered by unfavourable weather. For two months there was a succession of heavy storms, and the wind is described as having been more than a gale during nineteen per cent. of that time. Three of the ponies were lost by the breaking away of an ice floe, and the main start for the south pole was begun somewhat later than was intended in order to avoid exposing the others to the severe cold. Captain Scott with his party left the winter quarters on November 2. They were preceded by the motor sledges, which broke down, owing, inappropriately, to the overheating of the engines, after a journey of sixty miles, and were abandoned. Captain Scott appears confident that with the experience gained from this experiment, motor transport can be successfully adopted in the Antarctic. The weather during the march appears to have been very unfavourable; there were "prodigious" snow-falls and fierce gales of wind. The ponies were killed at successive stages and used to feed the dogs. No longitudes are given, so that the southward route cannot be followed in detail, but from the localities mentioned it was apparently in the main the same as that used by Sir Ernest Shackleton. On January 3 the party was 150 miles from the pole, and as it had attained the plateau at the height of 9,800 feet, and had a month's provisions, there can be little doubt that it soon attained its goal.

The cables announce but little new geographical information, for Captain Scott at the time of the despatches had not reached "Shackleton's Farthest," the geological party had been working mainly in an area already explored, Lieut. Campbell's journey from Cape Adare was limited by unfavourable ice conditions to the known coast, and there is no news of his results from Terra Nova Bay. The last-mentioned expedition may secure results of great interest, for Lieut. Campbell started near the point whence David, Mawson, and Mackay reached the south magnetic pole, but he was to use a more northerly route, between Mount Melbourne and Mount Nansen, and would thus explore new country which may yield especially instructive geological results.

The western party under Mr. Griffith Taylor made two expeditions on the mainland to the west of McMurdo Sound. The first expedition, from January 27 to March 14, 1911, landed at Butter Point, ascended the Ferrar Glacier, and returned across the Barrier to the south of McMurdo Sound. The second expedition continued the exploration of this district to the north. The sledge party crossed to Granite Harbour, ascended the Mackay Glacier, and continued northward the survey of the district geologically mapped by Ferrar. Some coal was discovered which is believed to be interbedded in the Beacon Sandstone, a conclusion consistent with Shackleton's discovery of coal and a fossil plant in the same formation on the Beardmore Glacier. Still more important was the discovery of "numerous well-preserved fossils," apparently in the Beacon Sandstone. The determination of the age of that formation would be a most important contribution to the geology of South Victoria Land; but as so competent a geologist as Mr. Griffith Taylor describes the fossils as "probably crustacea," they are perhaps not sufficiently well preserved to give conclusive evidence as to their age. The fossils had to be left at Granite Harbour, and it is to be hoped that they will be recovered by the *Terra Nova* next season.

Mr. Griffith Taylor's report upon the glacial features of this area will no doubt prove very instructive.

Lieut. Campbell's party from its station at Cape Adare sledged westward in order to explore part of the eastern coast of Wilkes Land; but owing to the breaking away of the ice from Robertson Bay the survey was not carried further west than Cape Barrow. Its field was limited in the main to the area explored by the members of the Southern Cross Expedition. Lieut. Campbell's party maintained continuous observations at their station from February, 1911, till January, 1912. These records will doubtless add greatly to the value of the simultaneous observations which were being made, apparently by Dr. Simpson, at McMurdo Sound. It is, indeed, probable that the systematic meteorological, magnetic, and physical work may yield the most important results of the expedition; for records were made at two stations, and the weather conditions appear to have been very different from those of the previous seasons during which expeditions have wintered beside the Ross Sea.

The biological collections should also prove very valuable. The material obtained by the seven hauls of the deep-sea trawl will probably contain many new species and interesting additions to the Antarctic fauna. The line of soundings made by the *Terra Nova* to the south of New Zealand is also an important contribution to the ocean contours of that area.

Apart from the oceanographic work, perhaps the most interesting geographical information in the despatches is that dealing with the meteorology. Unlike the calms and fine weather experienced by Amundsen in his more easterly route, Captain Scott was harassed by a succession of southern gales similar to those met by Shackleton, although the weather on the plateau appears to have been milder. It has been suggested that the low temperature of these southern winds indicated their anticyclonic origin, but as Captain Scott reports for one of them a temperature of only 35°, they do not support the existence of the hypothetical south polar anticyclone. The *Discovery* expedition reported a very slight snowfall in the area around the Ross Sea, and the recent diminution of the glaciers was thus explained. The evidence collected by that expedition was recognised at the time as inconsistent with that conclusion, and the heavy snowfalls now reported show that there is no difficulty in explaining the formation of the barrier ice by the accumulation of snow.

The reports show that the expedition has made most important contributions to Antarctic knowledge. Subjoined is a summary of the scientific results published by the Central News (Ltd.) Agency.

Summary of Scientific Results.

The general plan arranged for the scientific work of the expedition has been carried out so far almost in its entirety. The self-registering meteorological instruments have given a continuous record of pressure and temperature and of wind velocity and direction. These have been checked by the eye every four hours. The upper atmosphere has been investigated by means of small balloons, which have shown the direction of the upper currents of the air to a height of six miles and have recorded temperatures to a height of five miles. Absolute magnetic observations have been made every week. Self-registering magnetic instruments were installed in a room excavated in the side of a small glacier, this eliminating the changes of temperature which are a serious cause of error in this class of work. All through the winter the aurora was observed every hour, but very few brilliant displays occurred. Atmospheric electricity has also been studied, and ice work and physiography have afforded much fieldwork.

Vexed problems regarding the origin of Alpine topography when Europe and other temperate regions were undergoing an ice age are being studied in the examples offered by the retreating glaciers of Victoria Land, where the ice age still obtains. The mainland offers a rich field for petrology, with an abundance of mineral-bearing quartz veins, but none of any economic value.

Specimens of coal of economic value and well-preserved fossils have been found near Granite Harbour. An excellent field exists at winter quarters for ice work in miles of glacier, while in front of the hut stands a cape formed largely of massive moraine with lava flows from Erebus. Pendulum observations for the value of gravity have been carried out; a tide gauge has given a continuous record, and marine biological work has been done throughout the winter at a hole kept open in the sea ice for nets, water samples, and sea temperatures.

The quantitative and qualitative observations of minute organisms at various seasons are giving interesting results. The parisitology of all seals, penguins, and others birds and fish available has already given good results. Some new protozoa have been found.

The above has fully occupied the time of the scientific staff and indicates that there is an ample field for further research in every direction.

Successful biological work has been carried out on board the ship. With seven trawls a large collection of the deep-sea fauna of the Antarctic has been obtained. A number of catches with the tow net have been secured which show a vertical distribution in the transparent floating organisms of the sea. Continuous meteorological observations have been taken in the ship, linking up Australasia with Antarctica.

Natural history research has been greatly assisted by the use of the kinematograph. Many thousands of feet of film have been used in securing permanent animated records of the interesting bird and animal life of these regions, and every phase of seal, penguin, and skua-gull life has been thus illustrated. Some remarkable kinematograph films have been secured showing for the first time the "Killer" whale, the wolf of the seas, in its native element.

NOTES.

We notice with regret the announcement of the death on March 8, in his seventy-fifth year, of Dr. Edward Divers, F.R.S., the distinguished chemist, and Emeritus professor of chemistry in the Imperial University, Japan.

At a meeting of the committee of the Lawes Agricultural Trust held on March 30, Mr. A. D. Hall, F.R.S., director of the Rothamsted Experimental Station, tendered his resignation. Mr. Hall's resignation takes effect in September, after which he will give his whole time to the work of the Development Commission. The committee of the Lawes Agricultural Trust will proceed to the election of a new director in June.

The Philosophical Institute of Canterbury, New Zealand, which came into existence on August 30, 1862, will celebrate its jubilee this year. It is proposed to mark the occasion by holding a gathering in Christchurch.

The council of the New Zealand Institute, at its annual meeting, held in Christchurch at the end of

January this year, decided to award the Sir James Hector memorial medal and prize to Dr. L. Cockayne as the investigator, working in New Zealand, who has done most to advance botanical science.

A seismological Observatory has been added to the Geological Department of the Georgetown University, Washington, D.C., U.S.A. The equipment consists of two Bosch-Omori tromometers of 25 kilos. mass, a Wiechert horizontal pendulum of 200 kilos. mass, two Mainka conical pendulums of 130 kilos. mass each, and a vertical pendulum of 80 kilos. mass, after Wiechert. A separate cave, fitted with a Bosch photographic recording horizontal pendulum, is under construction.

The sixty-fourth annual meeting of the Cotteswold Naturalists' Field Club was held at Gloucester on April 2. Dr. C. Callaway and the Rev. Canon Razeley were elected honorary members. The retiring president, Mr. William Crooke, after reviewing the work of the club during the past year, dealt with the evidence for the antiquity of man that had been obtained of recent years. The Rev. Walter Butt, J.P., was elected president for the coming year, and Mr. L. Richardson hon. secretary.

On Thursday next, April 18, Prof. A. W. Crossley will deliver the first of two lectures at the Royal Institution on "Synthetic Ammonia and Nitric Acid from the Atmosphere." The Friday evening discourse on April 19 will be delivered by Mr. Alan A. Campbell Swinton on "Electricity Supply: Past, Present, and Future," and on April 26 by Sir George H. Darwin on "Sir William Herschel." In addition to the Friday evening arrangements already announced, the discourse on May 24 will be delivered by Mr. A. D. Hall on "Recent Advances in Scientific Agriculture: the Fertility of the Soil," and on June 14 by Mr. A. H. Savage Landor on his recent journey through unknown parts of South America.

By the will of Lord Lister, the sum of 20,000*l.* is bequeathed to the Lister Institute of Preventive Medicine, and 10,000*l.* each to the Royal Society, King Edward's Hospital Fund, King's College Hospital, and the North London and University College Hospital. In the will Lord Lister requests his nephews, Mr. Rickman John Godlee and Mr. Arthur Hugh Lister, to arrange his scientific MSS. and sketches, destroying or disposing of such as are of no permanent scientific interest, and to present the remainder to the Royal College of Surgeons, England. Lord Lister's orders and medals are bequeathed to the Edinburgh University, and the will states:—"I expressly declare that it is my intention that the University authorities for the time being shall be perfectly at liberty to dispose of all or any part of the gift—for example, by having the medals melted down or the diplomas or other writings destroyed—at any time and in any manner that may seem to them desirable."

The Essex Field Club has recently appointed a committee for the purpose of raising a small fund to put in order the tombs of John Ray and Benjamin Allen (which stand adjacent to one another in the churchyard at Black Notley, but have been allowed to fall into disrepair), and to erect at Braintree a memorial to Samuel Dale, of that town, to whom no memorial exists. These three naturalists were friends and contemporaries, living at Braintree or in its immediate vicinity in the closing years of the seventeenth century and the opening years of the eighteenth. John Ray (1627–1705) was by far the most eminent British naturalist of his day, and has been rightly described as "the Father of Modern Natural Science." Samuel Dale (1659–1738), though a younger man and of less eminence, was widely known in his day as a naturalist, especially as a botanist. Dr. Benjamin Allen (1663–1738), the youngest and least eminent of the trio, was an excellent naturalist and a skilled physician. For carrying out the work of restoring the two tombs, and erecting a memorial to Dale, the sum of about 50*l.* is required, and subscriptions are invited to make up this amount. Such subscriptions may be sent to Mr. Miller Christy (115 Farringdon Road, E.C.), or the Rev. J. W. Kenworthy (26 Inglis Road, Colchester).

The one hundredth anniversary of the foundation of the Academy of Natural Sciences of Philadelphia was celebrated on March 19–21. The actual date of the anniversary was March 21, but the celebration began on the evening of March 19, when delegates to the number of 133, who had been appointed by corresponding societies to represent them, were welcomed by the Hon. Rudolph Blankenburg, mayor of Philadelphia. After the delegates had presented their letters of credential and congratulation, the president delivered an historical address setting forth the early struggles of the society for existence, alluding briefly to the distinguished men whose work had prepared the way for the celebration, directing attention to the special features of the museum, and insisting on the importance of natural history studies in their utilitarian aspect, more especially in connection with the parasitic origin of disease. In conclusion, he handed over to the society on behalf of the building committee the enlarged hall of the Academy, which, through the liberality of the Legislature of the State, had received important additions and had been made thoroughly fireproof during the past year. The works to be issued in connection with the centenary celebration consist of a quarto volume of illustrated scientific memoirs, the commemorative volume, an index to the entire series of Proceedings and Journal, and a detailed history of the Academy by the recording secretary, Dr. E. J. Nolan. At the sessions on March 20 and 21, summaries were given of communications presented for publication in the commemorative volume, and of other papers on scientific subjects. The scientific sessions concluded with a lecture by Mr. Witmer Stone, one of the curators of the Academy. On the evening of March 21, 163 members and guests sat down to a banquet in the new geological hall, formerly occupied by the library. The banquet, in common with all the other details of the programme, was a brilliant success, and the entire celebration will be long remembered as one of the most interesting events in the history of American science.

The alleged traces of primitive man in Argentina, the *tierras cocidas* of Monte Hermoso, have been often referred to in these pages. The views of the late Florentino Ameghino have found a supporter in Colonel A. A. Romero (*Anales del Mus. Nac. de Buenos Aires*, vol. xxii., 1911, p. 11). It is argued that we know little of man's precursors, that they may go back to a high antiquity, and that the grouping of the "scoriæ" sometimes suggests a united camp-fire. The petrographic arguments now adduced, and the very defective photographs of thin slices, do not add much to the discussion. The scoriaceous earths containing vegetable remains, as shown in plate viii., are much more to the point, as opposing a volcanic origin.

In the Journal of the College of Agriculture, Imperial University of Tokyo, vol. ii., No. 7, Mr. Kamakichi Kishinouye describes an interesting collection illustrating prehistoric fishing in Japan. This collection was made from a large series of shell-mounds of the Neolithic period, associated with numerous flint implements, pottery, the hard parts of molluscs, fish, turtle, birds, marine, and land mammals. The fishing implements are of the most varied description, including stone arrow and harpoon heads, others of bone or horn, sinkers, &c. In their form they closely resemble implements of the same period found in these islands. The fishing-hooks have usually barbs on the outer side of the stem. One fine landing-hook or gaff, the only example found, is made of horn, about 130 mm. in length, and bent in the middle at an angle of about 90°. This prehistoric race seems to have possessed little of the artistic capacity of their successors, but some clay dishes bear representations of *haliotis* or *anodonta* shells, and on another appears a design which may represent the head of a shark. This valuable paper is accompanied by excellent illustrations of typical specimens.

Parts iii. and iv. of vol. viii. of *Biometrika* have been issued together as a double number. Of the principal articles three—on Egyptian, negro, and pygmy crania respectively—deal with craniology; the two former are from the pen of Miss H. Dorothy Smith, the latter edited by Prof. Pearson from the work of the late Dr. Crewdson-Benington. Mr. Carr Saunders discusses the relation between pigmentation and disease on the basis of data derived from the medical survey of school children at Birmingham, but, unlike earlier workers in the same field, such as Shrubsall and Macdonald, fails to find any appreciable relation. Of the remaining articles we may specially direct attention to three, by Dr. Maynard and Prof. Pearson, bearing on the interpretation of data relating to the appearance of multiple cases of disease in the same house. The supplementary tables calculated by Mr. Everitt for facilitating the determination of Prof. Pearson's coefficient for a fourfold table should also be mentioned.

A new "quarterly review of scientific thought," with the somewhat imposing title of *Bedrock*, has been launched on its career this month by Messrs. Constable. Of the articles included in the first number, several are distinctly noteworthy. Prof. Welton discusses the value, to the teacher and to the scientific worker, of a logic of method, and his comments on teaching should prove useful and stimulating. The good teacher, says Prof. Welton, shows his pupil how to go along the high road; the old-fashioned bad teacher plumped him down at his destination, as if he had been transported there on a magic carpet; the bad new-fashioned teacher turns him adrift, giving him no indication of the way. Dr. Archdall Reid contributes a characteristic discussion of recent researches in alcoholism, and the reader will find it interesting to follow this by a perusal of Dr. Gossage's article on "Human Evidence of Evolution." Prof. Poulton's examination of the facts of mimicry as a crucial test between the theories of Darwin and of Bergson is both admirable and timely, but would have been more easy to follow if the publishers could have seen their way to give the illustrative plates in colour instead of in black and white. The articles on "Interaction between Passing Ships," by Prof. Gibson, and on "The Stars in their Courses" (substantially the Halley lecture) by Prof. Turner, take the reader into different fields of thought, and are both written in a simple and attractive style. Altogether the new quarterly opens well.

The report of the Rugby School Natural History Society for 1911 records the retirement of its late president, Mr. Henderson, one of whose last official acts was the inauguration of the successful exhibition held in March of the year under review. The astronomical section, which lapsed a few years ago, has been revived, and is doing well, but in the zoological section (which appears to be restricted to ornithology, entomology forming a section by itself) the secretary deplores the lack of enthusiasm displayed by the members.

Two unusually interesting new mammals from Tonkin were described at the meeting of the Zoological Society on March 19. The first was a civet resembling the banded *Hemigale hardwickei* of the Malay countries in colouring, but distinguished by the spatulate crowns of its milk-incisor teeth—a difference which its describer, Mr. Thomas, regards as of generic value. The second, described by Mr. Dollman, was a snub-nosed monkey of the genus Rhinopithecus, of which three species, from western and central China and the Mekon valley, were previously known.

The insects causing damage to the chir pine (*Pinus longifolia*) in the north-west Himalaya form the subject of vol ii., part 2, of the Indian Forest Memoirs. The timber of the chir is much used for a variety of purposes in India, owing to the ease with which it is worked, and the tree is also tapped for resin, as a source of turpentine. The long list of insect pests by which this tree is attacked given by E. P. Stebbing shows how sorely it stands in need of protection, one of the worst of these being the beetle *Platypus wilmoti*, the larvæ of which bore into the very heart of the timber. Special attention is directed to the insects parasitic on, or preying upon, the mischievous species.

In the *Journal of Genetics*, vol. ii., No. 1 (February), Mr. A. W. Hill deals with the history of *Primula obconica* under cultivation, and concludes that the amelioration and development in form and colour of the flowers, &c., which have taken place during the past thirty years, must be attributed to selective processes, also that there is not sufficient evidence in favour of the view that hybridisation with other species has taken place. It is of the greatest importance that the history of other species which are made the object of extensive breeding experiments should be thoroughly cleared up, as in this paper, which is illustrated by two beautiful coloured plates.

The difficult problem of the morphological nature of the endosperm of angiospermic plants forms the subject of a paper by Prof. Coulter in the *Botanical Gazette*, vol. lii., No. 5. From a critical review of the literature, the author concludes that endosperm formation is not dependent upon the presence of a male nucleus, nor even upon fusion of the two polar nuclei of the embryo-sac, hence these fusions may be regarded as supplementary rather than determinative. Further, the formation of endosperm does not even depend upon having been preceded by a reduction division. The author is therefore led to the view that the fusions associated with endosperm formation do not represent a definite process, but are miscellaneous in number and order; and that the product of such fusions as do occur is merely an undifferentiated tissue, which practically continues the tissue of the gametophyte, that is, it is simply *growth* and not *organisation*.

The concentric growths of chalcedonic silica known as beekite appear as disease-spots in fossil shells, and have spread in some cases until the organic remains are replaced by lumpy masses of silica. Mr. James Strachan brings his considerable experience as a chemist to bear on the origin of beekite in a paper read before the Belfast Naturalists' Field Club on March 27. He concludes that the chalcedony is precipitated by osmotic action in the colloid matter of the shells, where it replaces calcium carbonate. The rings around the central disc of chalcedony represent the periodic movement of the chemical action. Mr. Strachan points out that this mode of origin has been suggested by Prof. Sollas for banded flints. It will be noticed that, if animal matter is requisite for the precipitation, the formation of beekite is referred to an early stage in the history of the rocks in which it occurs.

The views of Lugeon and others as to Alpine mountain-structure have been so widely accepted that Mr. Bailey Willis probably does good service by a criticism based on personal observations. In a "Report on an investigation of the geological structure of the Alps" (Smithsonian Miscell. Coll., vol. lvi., No. 31, 1912), he urges the efficacy of thrust-planes as against recumbent overfolds, and shows how the exotic masses of strata known as *klippen* may be explained by the intersection of two thrust-planes of opposite slope. He believes that the earlier thrusting in the Alps came from the north-west, and was followed by erosion carried on until a mature type of surface had been produced. The far more recent thrusting from the south-east is regarded as Pliocene, since the scarp weathered out in the Bernese Oberland on the Alpine mass that was moved forward remains still fresh and young. This short paper clearly gives matter for large discussion. The spelling of some of the place-names seems to want revision.

An important memoir on the climate of the Italian capital has been issued by the Italian Meteorological Office. Rome is one of the few places for which meteorological observations extending over more than 100 years are available. In this volume Dr. F. Eredia has gathered together and summarised the available data. For all the principal elements monthly means or totals are given for each year from the commencement of the record up to the end of 1910, the whole forming a historical record of great importance. The observations of precipitation go back to the year 1782 in unbroken sequence. The temperature record also begins in 1782, but there is a gap in the series from 1792 to 1811. Monthly normal values have been computed for all elements, and for pressure temperature, humidity, and wind velocity the diurnal variation has been determined from the records of autographic instruments. The observations are not strictly homogeneous throughout. There have been changes of site, instruments, and methods of observing, but in preparing the results for publication every effort has been made to minimise the effects of such disturbing causes.

The Danish Meteorological Institute has distributed (as in previous years) an excerpt from its nautical meteorological year-book, containing useful information relating to the state of the ice in the Arctic seas in 1911; the monthly summaries for April–August are illustrated by maps. The details seem to us to show that the conditions were, on the whole, somewhat more severe than usual. At the entrance to the White Sea there was much pack-ice in April and May, and Archangel was closed until near the end of the latter month. Novaia Zemlia was not ice-free until comparatively late, and in Barents Sea the ice was more closely packed than usual; the west coast of Spitsbergen became clear in August, but round the north-east coast navigation was impracticable during the year. On the east coast of Greenland there was more ice than usual during the summer, but at Angmagsalik the sea was open unusually early. In Baffin Bay it was difficult to penetrate the ice throughout the summer. So few reports were received from Bering and Beaufort Seas that it was difficult to form a general opinion; in May and June, however, the conditions seem to have been normal.

In the *Zeitschrift des Vereines deutscher Ingenieure* Dr. Th. von Kármán, of Göttingen, shows that the ordinary theory of the flexure of beams cannot be applied to cylindrical tubes of small thickness owing to the considerable changes which take place in the form of the cross section when the tubes are bent. The author gives formulæ which take this effect into account, and it is found, both from theory and from experiment, that in certain cases the deflection may be from three to five times as great as that given by the usual EI/ρ formula.

In the case of sudden explosions or volcanic eruptions anomalous sound phenomena frequently occur, the noise of the explosion being sometimes heard at abnormal distances, while it is inaudible at other places nearer the source. These phenomena were discussed in 1910 by Dr. G. v. d. Borne. In the Proceedings of the Tokyo Mathematico-Physical Society, vi., 9, Mr. S. Fujiwhara gives an analytical investigation based on a formula for the velocity potential subject to the assumptions that the atmospheric density follows the adiabatic law, and that the wind velocity varies very slowly with the height, the velocity of sound thus varying with the altitude.

In Blatt 4, 1911, of the Royal Observatory of Wilhelmshaven, in continuation of similar previous work, Prof. Bidlingmaier gives a graphical representation of the hourly magnetic character of the last half of 1911, based on a scale "0," "1," "2," of disturbance. As an extension, he develops a scale of magnetic "activity," ultimately dependent on the range of the magnetic elements in each hour. If this lies between $50(n-1)\gamma$ and $50n\gamma$, the measure of the activity is $n^3-(n-1)^3$. This idea is applied to the ten years 1890 to 1899, and conclusions are drawn as to the activity of the earth's horizontal magnetic field in the several years.

In his Nobel lecture to the Academy of Sciences at Stockholm in December last, now issued by Messrs. Barth, Leipzig, Prof. W. Wien gave a valuable survey of the recent advances made by the theory of radiation and of the difficulties which still beset it. Lord Rayleigh's form of the law of radiation of a black body, based on the equal distribution of the energy amongst the degrees of freedom of the vibrating system, agrees with observation over the longer wave-lengths only. Prof. Wien's formula, based on his "law of displacement" or compression of radiation, agrees, on the other hand, with measurements over the shorter wave-lengths only. Prof. Planck's form of the law agrees with observation over the whole of the range of wave-lengths at present available, but rests on the conception of energy as atomic in structure. The difficulties which such a conception raises are very grave, and Prof. Planck himself has substituted continuous for discontinuous absorption of radiation (see these "Notes" for March 16, p. 90, and June 15, p. 528, 1911), while Sir Joseph Larmor devoted his Bakerian lecture in 1909 to a possible alternative. Prof. Einstein's attempt to bring Dulong and Petit's law of atomic heats under Planck's theory has met with partial success only, and Prof. Wien thinks the processes going on in the atoms themselves must be taken into account before the theory of radiation can be placed on a satisfactory footing. A commencement has already been made by Prof. Sommerfeld, who gives the constant h of Planck's theory an atomic significance.

An interesting series of papers on the chemical effects of light on organic compounds appears in the *Gazzetta chimica Italiana* (vol. xlii., p. 65 *et seq.*). In the first paper, by Prof. Paternò and C. Maselli, the synthesis is described of a substance having alkaloidal properties, by exposing acetophenone dissolved in alcoholic ammonia to bright sunlight during several months. The alkaloid $C_{18}H_{18}N_2$ forms well-defined measurable crystals, and appears to owe its origin to a complex change in which two molecules of acetone, two of ammonia, and one of alcohol are involved. In the absence of light the alkaloid is not formed. In the later papers, by L. Mascarelli, a striking change brought about in aromatic aldehydes by traces of iodine under the influence of sunlight is dealt with. It has been known for some years that benzaldehyde polymerises to trimeric and tetrameric forms under the influence of the sun's rays; it is now shown that in the presence of traces of iodine a dimeric form is produced which has the structure of benzyl benzoate. There has, in fact, been reduction of a portion of the benzaldehyde at the expense of the remainder, a result similar to that well known to be induced by the action of alkalies, such as potassium hydroxide.

In the January number of the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale,* M. H. Gault gives a summary of the additions which have been made during the last few years to our knowledge of natural perfumes and other essential oils. Among the principal oils dealt with are those of cloves, eucalyptus, fennel, juniper, geranium, jasmine, lavender, lemon grass, and peppermint. The article is a continuation of one on the same subject published in 1908. Various sources have been drawn upon for the information, Schimmel's "bulletins" figuring frequently in the references, which include also a fair number of English and American periodicals. A short account of the origin of each oil is given, with particulars of its physical and chemical characters, including its density, boiling point, refractive index, rotatory power, saponification value, and so on; usually also the chief chemical components are indicated. Special points in the chemistry of individual oils are discussed incidentally, but the author reserves for a future article the more general consideration of the chemical constituents of essential oils, as well as a fuller discussion of certain researches. To those interested in the subject the contribution will be useful as a convenient *résumé* of investigations, the accounts of which have been disseminated hitherto over a number of publications.

Bulletin No. 52 of the University of Illinois contains an account of investigations of the strength of rolled zinc carried out by Mr. Herbert F. Moore. From the results it appears that zinc, either rolled or cast, has no well-defined yield point, and its elastic limit is very low. Zinc possesses a relatively high degree of plasticity. The ultimate strength of thin rolled zinc plate (not more than 0·05 inch thick) is about 24,000 lb. per sq. in. The modulus of elasticity of zinc in tension is about 11,500,000 lb. per sq. in. The stress per square inch of area sheared developed in punching or shearing rolled zinc plates is about 40 per cent. of the stress developed in punching or shearing mild steel plates; the energy required in punching or shearing rolled zinc plates is about 30 per cent. of the energy required to punch or shear mild steel plates. The ductility of rolled zinc is much less than that of mild steel, and the ductility of zinc plate with the grain is greater than the ductility across the grain.

In the new Liverpool Adelphi Hotel of the Midland Railway Company, which was opened a few days ago, uniform and accurate time is secured throughout by an installation of upwards of 200 electrical impulse dials on the "Synchronome" system, all operated by one controlling pendulum. It is necessary that electric clocks in bedrooms should be silent in action, and this condition is fulfilled by those on the "Synchronome" system.

Prof. Kamerlingh Onnes directs our attention to an error in our note of March 14 (p. 41) on his measurements of the resistance of mercury at low temperatures. The values there given are not resistivities, but the resistances of a wire of solid mercury.

OUR ASTRONOMICAL COLUMN.

The Eclipse of April 17.—Anyone intending to see the eclipse of the sun from a station on the central line as it crosses France will find several points of interest in M. Fayet's article in the *Revue Scientifique* for March 30.

After explaining eclipses in general, M. Fayet describes the conditions of the coming eclipse, and illustrates his description with several maps and diagrams; he also gives numerous tables of position angles, times, &c., for many stations in France. It would appear that a total eclipse is not likely to be seen in France, and in any case spectrographic and any long-exposure work are out of the question; but M. Fayet shows that from the point of view of geometrical astronomy the eclipse is a most important one, giving exceptional facilities for delicate determinations of the moon's place, the apparent size of the moon, and the figure of the earth. There are, then, plenty of possibilities of a large number of amateurs making observations of great value, even if the eclipse is only an annular one; no expensive instruments will be necessary, and the value of the observations will be greatly enhanced as they are multiplied in number. In France the observers are being officially organised, and preparations are being made for the distribution of the exact time and the coordination of the results. St. Germain-en-Laye, a few miles west of Paris, would appear to be one of the most readily accessible points near to the central line.

In the *Comptes rendus* (No. 14) for April 1 M. Bigourdan discusses very clearly, and explains in detail, the observations which may be made for the better determination of the moon's apparent diameter and position, and the reasons for making them during this particular eclipse.

The El Nakhla el Baharia Meteorite.—The meteoritic fragments which fell in Lower Egypt on June 28, 1911, are described in detail by Dr. John Ball in Survey Department Paper No. 25. Altogether some forty stones, weighing nearly 10 kgms., have been collected, but, as the explosions producing the fragments are supposed to have taken place at a considerable altitude, scattering the pieces over an area about 4·5 kms. in diameter, this probably does not represent the total mass as it entered the earth's atmosphere. The weight of the heaviest fragment is 1,813 grams, and of the smallest about 20 grams; some small fragments have a fused skin all over their surfaces while others are only partially covered, thus indicating a succession of explosions. A portion of the stone was submitted to Sir Norman Lockyer for spectroscopic analysis, and his report places the spectroscopic prominence of the various elements in the order Cr, Na, Ca, Al, Mg, Si, Mn, Fe, V, Ti, and K; the last is very weak. A chemical analysis by Mr. W. B. Pollard gives SiO_2, 50; FeO, 20; CaO, 15; MgO, 12; and Al_2O_3, 1·65 per cent.; Cr_2O_4 appears as 0·23 per cent., and traces of the other elements were found. Although this is the first "find" in Egypt, Dr. Ball believes that a large meteorite fell in a direction 32° W. of true N. from Philæ on April 5, 1902; such phenomena as attend these falls were then observed, but no stone was found.

A Daylight Meteor.—The director of the Meteorological Office informs us that at Brocklesby, Lincs, on March 28, Mr. F. J. Gibbons observed a vivid meteor at 2.50 p.m. in broad daylight on a bright afternoon. The meteor appeared to move from south to east in a downward course. It would be interesting to know if the meteor was observed elsewhere. Observations of meteors in daylight appear to be uncommon, although particulars of a certain number are given in the annual reports of the British Association Committee on luminous meteors.

The Stonyhurst Observatory.—Father Sidgreaves's report of the meteorological and magnetical observations made at Stonyhurst during 1911 contains the usual tabular summaries with a few notes on the more important points. The observations of sun-spots and of magnetic declination point to 1911 being a minimum epoch for each, but later observations must be awaited to fix this point with certainty.

Photographs of Halley's Comet.—The first fascicule of vol. v. of the *Annales de l'Observatoire astronomique de Tokyo* is devoted to Halley's comet as observed at Dairen, Manchuria, during the months April–June, 1910, by MM. Sotome and Hoasi; photographs taken at Tokyo by M. Toda are also included. The form, changes, and length of the tail and the acceleration of its particles are discussed at length, and there are nineteen plates of excellent reproductions of photographs, 131 in all, at the end of the work.

CYCLES OF THE SUN AND WEATHER.

Since Sir William Herschel suggested that variations in the visible changes of the sun's surface might be sensibly reflected in the meteorology of our planet, many investigators of high authority have endeavoured to determine the precise nature of the relationship between solar and terrestrial phenomena. In the seventies of last century it was decisively shown that the variation of certain meteorological elements coincided with that of photospheric activity as revealed by observations of sun-spots. The conclusions arrived at were expressed very definitely by Prof. A. Schuster in a paper presented to the meeting of the British Association in 1884. "There can," he said, "be no longer any doubt that during about four sun-spot periods (1810 to 1860) a most remarkable similarity existed between the curves representing sun-spot frequency and the curves of nearly every meteorological element which is related to temperature. This is not, in my opinion, a matter open to discussion: it is a fact."

But though a connection was established, further studies of its character seemed to lead to contradictory conclusions. High air temperatures were associated with lowest sun-spot conditions, while the frequency of tropical cyclones and abundance of rainfall, which should *prima facie* show the same relationship, suggested that there was increased movement and evaporation about the maximum epoch of the sun-spot period. As the results obtained from the different groups of facts could not be reconciled, the discussion of the subject was for some years in abeyance. Broader views are, however, now being taken; and it is realised that many sun-spots may mean increased rainfall in one part of the world and decreased in another, or the like inversion of any other meteorological element. Also, the development of means of obtaining more complete records of changes upon the sun's surface, in addition to those manifested by sun-spots, has encouraged further inquiry into the subject of solar influence.

Full knowledge can only be secured when the new methods have been used for many years, but, so far as the discussion has proceeded, it indicates that there is no real inconsistency in the earlier conclusions, and that studies of the sun offer the most promising prospects of success in long-range weather prediction. Meteorological analysis of observations made at a solar physics observatory has become even more important than consideration of the results from an astronomical point of view. As was remarked in a report of the U.S. Weather Bureau a few years ago:—"Advances in the period and accuracy of weather forecasts depend upon the exact study and understanding of atmospheric pressure over large areas, and a determination of the influences, probably solar, that are responsible for ordinary and extraordinary distributions of atmospheric pressure upon the earth's surface."

We may take it for granted that the weather of any region is determined mainly by the barometric pressure and the interchange of areas of high and low barometer. The most important variations to consider are, therefore, those of atmospheric pressure, and the conclusions arrived at may then be used for comparison with variations of solar phenomena independently determined. The unit of inquiry should, however, be the world, and not one particular region; and there should be no assumption, as was formerly common, that solar changes indicated by sun-spots or other phenomena would affect the whole of our globe simultaneously and in the same direction at any particular epoch. Investigations carried on in recent years in this spirit have led to results which are both stimulating and valuable. For convenience we will refer first to the meteorological conclusions, then to solar changes, and finally to the relationships found between sun and earth.

Periodic plus and minus "pulses" of rainfall in India were described by Sir Norman and Dr. W. J. S. Lockyer in a paper read before the Royal Society in November, 1900, and were shown to be related (sometimes inversely) to similar variations at Mauritius, Cordoba (South America), the Cape of Good Hope, and other places. Attention was then devoted to an examination of the variations of pressure over the Indian and other areas, and a period of about 3·5 years (always referred to later as the 3·8-year periodicity) was found in the mean variation of pressure over the whole of India and at individual stations, and also in other large areas. An inverse variation was found in the pressures at Cordoba, and, referring to it, the authors remarked:—"The cause, therefore, which raises the mean value for the low-pressure months over the Indian area would appear to lower the mean value of high-pressure months at Cordoba simultaneously. In fact, we have a see-saw" (Proc. Roy. Soc., lxx., June 19, 1902). The area affected by this barometric see-saw was extended in a later paper (Proc. Roy. Soc., lxxi., December 4, 1902) to Ceylon, Java, Mauritius, and Australia, and further results were described in 1904.

H. F. Blanford and Hildebrandsson had previously found similar evidence of reciprocal barometric variations in widely separated regions, but the extension of the investigation to about a hundred stations in various parts of the earth led to the important result that there exists a world-wide barometric see-saw between two nearly antipodal parts of the earth, one region about India and its neighbourhood showing exactly opposite effects as regards atmospheric pressure in any year to those felt in a region which includes South America and the southern parts of the United States.

The pressure variations in the British Isles year by year do not go up or down with either side of this see-saw, but appear to be a mixture of both types. During some years the British area is enveloped in the pressure system that extends over the large region of which India is about the centre, while for another series it is dominated by the conditions of atmospheric pressure experienced in the region of which South America is the middle portion. On this account the cycle of 3·8 years distinctly exhibited in the meteorological records of two great regions of the world appears in British meteorology at a period of about three years, in the course of which variations are sometimes very noticeable. An examination of the records of annual rainfall at Greenwich for sixty years shows this three-year cycle very clearly. Taking a series of years, it is found that two wet years are followed by a dry year; but after eight years a reversal takes place, two dry years being followed by a wet one. This peculiar result is due to the combination, in the British Isles, of the Indian and South American pressure systems, which have a definite period of change—one going up while the other goes down—in a period of about 3·8 years.

Passing now to solar conditions, we have, first of all, the well-known sun-spot period of about eleven years. This is the mean length of the period; and it must be remembered that epochs of maximum activity, as indicated by frequency and magnitude of sun-spots, do not follow those of minimum activity at constant intervals, but vary from about three to five years. Moreover, when a critical examination is made of solar phenomena, it is found that successive cycles differ from one another in certain respects. Dr. Lockyer discovered that underlying the ordinary sun-spot period there is another of greater length, namely, about thirty-five years. In other words, the sun has to pass through about three cycles of activity before it reaches the same state as it was before. Sun-spots must not, of course, be taken as the sole criteria of the sun's condition; and it was pointed out by the Lockyers in 1900 that "there seems little doubt that in the future the measure of the change in the amount of solar energy will be determined by the amount and locus of the prominence area" (Proc. Roy. Soc., lxvii.). The solar latitudes in which sun-spots most frequently appear vary with the epoch of the sun-spot period, and the eruptive prominences have their maxima in the same latitude as the spots. A detailed examination of the records connected with solar spots and prominences revealed subsidiary maxima and minima of about 3·8 years (*ibid.*, lxx., 503), so that three waves of solar activity have to be considered having approximate periods of four, eleven, and thirty-five years. The condition of the sun at any time represents the algebraic sum of these coefficients of activity.

The correlation of the factors of terrestrial weather now becomes possible. In the first place, the old view that the sun's influence upon weather must be general has been abandoned—as it should have been long ago. As the earth's atmosphere is a constant quantity, the crest of a wave in one part must be compensated by a trough in another. Solar action must thus have a double effect of opposite nature upon the atmosphere. High pressure in one region must be counterbalanced by low pressure elsewhere, and maximum rainfall in one region will coincide with minimum rainfall in another part of the globe. This is the explanation of the apparent inconsistent conclusions arrived at in earlier investigations of relationships between solar and terrestrial weather. There is now no room for doubt that the earth's meteorological conditions vibrate in sympathetic response to solar periods of about four, eleven, and thirty-five years. There may be other periods of oscillation, but in any case these three exist upon the sun and earth, and can be traced in the records of many phenomena. The shortest wave has been established by the Lockyers for solar and terrestrial variations, and the longest, represented by Brückner's cycle on the earth, was discovered by Dr. Lockyer to have its counterpart on the sun.

It is not surprising that other investigators have arrived at much the same conclusions independently. In a paper published in *The American Journal of Science* of December, 1894, on "Inversion of Temperature in the 26·8-day Solar Magnetic Period," Prof. F. H. Bigelow showed that the northern low-pressure and the southern high-pressure belts of North America vary in latitude directly with what he described as "solar magnetic intensity." He referred in the paper to a period of about three years, but his curves (reproduced in *The U.S. Monthly Weather Review* of November, 1903) only relate to meteorology and magnetism, and not to solar activity, the connection between magnetism and prominences not being described by him, so far as we know, until 1902. In the following year Prof. Bigelow published a paper on "Synchronism of the Variations of Solar Prominences with the Terrestrial Barometric Pressures and the Temperatures," and showed direct and indirect changes of both pressure and temperature. In an article in Nature of January 8, 1903, Dr. Lockyer gave full credit to Prof. Bigelow, and stated that the two investigations were in agreement as regards three main points, namely:—(1) close connection between solar activity and barometric pressure; (2) great extent of areas over which very similar pressure variations exist; (3) presence of two large areas over which the pressure variations are reciprocal to each other.

Quite recently a paper has reached this country (Bulletin No. 1 of the Argentine Meteorological Office) in which Prof. Bigelow deals with "The Synchronism between the Variations of Solar Phenomena and the Meteorological Elements in Argentina and the United States." It is not clear whether the Bulletin is intended to be a semi-popular statement of the position of the subject or a contribution to scientific literature, but the almost complete absence of reference to the work of others suggests the former conclusion. Anyone not familiar with the points of progress would be led to believe that Prof. Bigelow is personally responsible for practically all that is known of solar and terrestrial relationships. *L'Etat, c'est moi*, said Louis XIV. on one occasion, and this spirit prevails in the paper before us. The only reference to South Kensington relates to photographs with a spectroheliograph, and no mention whatever is made of the investigations of solar and terrestrial meteorology, which, as may be judged from the foregoing account, form a substantial part of the work of the Solar Physics Observatory.

R. A. Gregory.

THE ETNEAN ERUPTION OF SEPTEMBER, 1911.

PROF. A. RICCÒ, director of the Observatory of Catania, has issued a preliminary report on the eruption of Etna which took place last September (*Boll. Sismol. Soc. Ital.*, vol. xv., pp. 273–280). The eruption may be said to have begun on the preceding May 27, when a new vent appeared on the north-east flank of the central crater less than a hundred metres below the rim, from which there issued hot white smoke, but no solid matter. In August, rumblings were heard in the central crater and in the new vent, and, from both, smoke and lapilli were discharged. This continued until the night of September 9–10, when a series of very strong earthquakes occurred, and a great radial fracture, eight kilometres in length, was formed, running in a N.N.E. direction from the new vent. Some of the earthquakes were felt as far as Mineo, 60 km. from the volcano. In the Observatory of Catania, 30 km. distant, the Vicentini microseismograph was almost continuously agitated from midnight to 6 a.m. on September 10. The strongest shock occurred at 2.14 a.m., and at the same moment a new vent was opened, about 4 km. from the central crater, from which smoke, ashes, lapilli, and stones were ejected. Later in the day, three new vents were opened, and by the next day there were sixteen in action, of which two emitted lava.

On September 12, the number of new vents was greatly increased. They seem to have followed the line of the great fracture. The highest group consisted of six vents in a N.N.E. line, from which a great quantity of fragmentary material had been ejected, but which on September 12 had become almost inactive. A little lower down, in the same direction, was a row of four vents; and, still farther, a line of six others, very active, which discharged incessantly great masses of smoke and large stones. Lower still was a fourth group, of four vents, arranged in a line bending towards the N.E., of which the two lower emitted small streams of lava. Continuing in the same direction is a tract of land to the south-east of Monte Nero, much fissured, and containing a long string of about thirty vents, from the lowest and largest of which issued an important stream of lava. To the north-east of Monte Nero, there started another line of craters (the sixth), about a score in number, from the lowest of which issued a second and larger stream of lava. This stream followed the course taken by the lava in 1646, and, travelling with great rapidity, crossed the Circumetnean railway on the evening of September 12. Between the two craters emitting lava was a seventh group of cones, throwing out incandescent matter.

On September 15 and 16, great masses of smoke were still emitted from the central crater and the vent of May 27. The two upper groups of vents were almost spent, the third continued very active; the fifth group of thirty or more vents emitted dense smoke and incandescent materials; in four days they had piled up cones some tens of metres in height; from the lowest lava still issued. The sixth group was also surrounded by lofty cones, from the lowest of which lava continued to flow at the rate of three metres a second.

The eruption ended tranquilly on September 23.[1] On October 1 the vents were again examined, and several changes were noticed. Those of the third group were united in four large craters; the fourth group consisted of twenty-seven vents, the fifth of

[1] The date is given as the 13th inst., but this is clearly a printer's error. On October 1 the eruption had been ended about a week.

forty-two cones, the sixth of twenty-eight high cones, while the seventh group had disappeared, probably beneath the lava-streams. The Circumetnean railway was occupied by the lava-streams for a length of 800 metres, the lava being piled up over it to a height of 30 metres. The front of the lava reached the Vallone Crasso, about 2 km. beyond the railway. Great quantities of sand and ashes were erupted continuously from the central crater, especially between September 11 and 16. On the days on which the dust fell over Catania, the air was thick, the sun and moon near the horizon were redder than usual; sometimes also the sun, when high up, was reddish and surrounded by a reddish-yellow aureole; but there was no sign whatever of a Bishop's-ring.

C. D.

WATER RESOURCES OF THE UNITED STATES.[1]

CONFRONTED with eight water supply papers, varying in size from 78 to 370 pp., embracing an area of country which is half the United States, and exhibiting a comprehensiveness of treatment which covers river-gauging, well-sinking, water analysis, irrigation, topography, physiography, geology, and meteorology, one is constrained to admit that any attempt to do justice to such a mass of material within the brief compass of a short notice is an impracticable proceeding, foredoomed to failure. It will only be possible, in fact, to turn over the numerous pages of carefully recorded data and valuable information, and pick therefrom, almost at random, one or two of the more interesting and salient facts.

At the outset one is arrested by a photograph exhibiting in a marked degree that wonderful illimitability and fascinating monotony of the desert which is only to be likened to the corresponding spaciousness of "old ocean's grey and melancholy waste," and one learns that there is good evidence to show that the central portion of the Estancia Valley, in New Mexico, with its area of 2000 square miles, was once the bed of a lake, at the margin of which are still to be seen beach ridges and other features of littoral formation. Debouching into this central plateau are a number of broad avenues, or arroyos, of gradually increasing depth, which extend backward to the cliff-edged cañons in the mountainous borderland. These arroyos, generally speaking, hold no permanent stream, but form avenues for the escape of storm waters, which disappear even before they reach the lowest level, leaving behind them the sediment and detritus which they carried.

This vanished lake of New Mexico has a counterpart of vaster dimensions in western Utah, where, in the Pleistocene epoch, it is affirmed, there existed a lake some 20,000 square miles in area. Its surface was about 5200 feet above the present sea-level, or about 1000 feet above the present level of the Great Salt Lake. More or less distinct shore lines can be traced as the lake gradually sank and dwindled through the later stages of its history; two, particularly, can generally be recognised, one marking the time of its maximum development, and the other an intermediate condition.

[1] United States Geological Survey. Water Supply Papers:—No. 263, Surface Water Supply of Ohio River Basin, 1909; No 266, Surface Water Supply of Missouri River Basin, 1900; No. 267, Surface Water Supply of Lower Mississippi Basin, 1909; No. 268, Surface Water Supply of Western Gulf of Mexico; No. 273, Quality of Water Supplies of Kansas; No. 275, Geology and Water Resources of Estancia Valley, New Mexico; No. 277, Geology and Underground Waters of North-Eastern Texas; No. 279, Ground Water in Juab, Millard, and Iron Counties, Utah. (Washington, 1911.)

In Texas there is the problem of the mounds. Scattered over the north-eastern portion are innumerable small mounds, varying from 20 feet to 100 feet in diameter, and from 2 to 5 feet in height. In general they are circular in outline, but in some localities they show a tendency towards elongation in a north-east to south-west direction. Various suggestions have been put forward to account for their origin: human or animal agency, water erosion, glacial action, wind. No definite evidence in favour of any one is forthcoming, and the question remains an open one.

Other points might be noticed, but these few will suffice to show that, apart from the columns of figures, there are many items of interest and much wealth of general information contained in these water supply papers of the United States Geological Survey.

THE PORT ERIN BIOLOGICAL STATION.

THE twenty-fifth annual report of this station shows that it continues to be an active instrument in advancing biological teaching and research, sixty students and research workers having occupied the tables during the year. Among the several researches in progress may be mentioned a biometrical investigation of the variation in the shells of the common limpet, which shows that specimens collected near low-water mark are flatter than those taken near high-water mark, and that, contrary to expectation, there was no difference in height between shells obtained from exposed and from more sheltered positions, if taken at the same water-level. *Biddulphia sinensis*, a diatom from the Far East, which made its appearance in European seas eight years ago, and was recorded from Port Erin in the last report, was found again in quantity and in vigorous condition, in September and October, 1911.

Prof. Herdman gives an account of the occurrence of the Peridinian *Amphidinium operculatum* at Port Erin. This flagellate organism was first observed there on April 7, and from this date to May 1 it occurred in such profusion as to form brown deposits in the ripple-marks on the sand at about half-tide level. On the same patch of sand there were, from June 3 to July 22, deposits similar in appearance to those already noticed, but on microscopic examination they were found to be composed of diatoms, chiefly Navicula (probably *N. amphisbaena*), and careful search failed to reveal the presence of any specimens of Amphidinium. On September 9 and 10, however, dense swarms of the latter organism were again present, but diatoms were absent, and this condition was maintained for a few days. On September 16 the naviculoid diatoms returned in force, and remained abundant during the two following days. By October 2 the diatoms had again vanished, but Amphidinium had reappeared, and it continued to be more or less in evidence until the 27th. Between October 28 and November 1 no specimens of Amphidinium were found, but on November 2 three small patches composed of this flagellate made their appearance in the usual positions on the beach, and then died away. From this date to the time of writing neither the flagellate nor the diatoms had been observed. Prof. Herdman suggests that the alternate occurrence, in the same area, of these two organisms is probably due to a physiological cause, and that each organism in turn exhausts or alters some essential constituent of the environment, so as to prevent its own continued existence in quantity, but leaves the ground suitable, or even favourable, to the physiological needs of the other set of competing organisms.

HEAT-WAVES IN ASIA: SUNSHINE AT TRIESTE.

Dr. H. von Ficker contributes to the *Sitzungsberichte d. K. Akad. der Wiss.*, of Vienna (vol. cxx., part vi., June, 1911), a comprehensive discussion of "heat-waves" travelling across northern Europe and Asia during the years 1898–1902. He deals with eleven cases in which the mean daily temperature increased by at least 10° C. in twenty-four hours, and the course of the change could be traced over a large area. The majority of the "heat-waves" occurred in winter, and three of these and the single summer-"wave" are discussed in detail. The mean values for the eleven cases are treated very fully, the synchronous conditions of wind, pressure, change of pressure, humidity, and cloud each receiving as full a consideration as the available data permitted.

In a previous investigation of cold waves in the same region, Dr. Ficker found that the wind in the cold area was roughly perpendicular to the wave-front, indicating that the change of temperature was produced by the horizontal transference of a mass of cold air. The result may be compared with the deductions of Lempfert and Corless from a detailed investigation of line squalls in this country. With heat-waves, however, the wave-front travels towards the east or south-east, while the wind is from south-west. The author concludes that there is a continuous south-west current which is lifted temporarily by the mass of cold air in the cold waves, and that in the general circulation of the atmosphere this warm south-west current is the medium through which air is carried polewards. He does not attempt to determine the motive power which pushes the cold air equatorwards. It may be the unexpended momentum of a south-west current which has crossed the polar regions, or it may be due to the effect of the earth's rotation on the south-west current in the rear of the cold wave.

In the northward progress of the warm current, the cooling is less than the warming which the cold wave experiences as it moves towards the equator, and this is attributed to the lifting of the warm current, which is thereby removed from the cooling effect of the earth. The latent heat of the vapour carried by the current ought also to be an important factor.

The maximum temperatures at different places in the "heat-wave" differ much less from one another than in the cold wave, and the increase of temperature is greatest in the coldest places. There are exceptional cases in Central Asia which are explained by the dynamic warming of descending air (Föhn).

The velocity of the wave-front is about 33 km. per hour, which agrees fairly well with the corresponding velocity found for cold waves. The latter would naturally expand laterally as they progressed, so that the actual velocity of the wave-front ought to be less in the case of heat-waves, for which no such lateral expansion is possible.

The relative humidity frequently increases with the advent of the "heat-wave," and the absolute humidity invariably does so. The amount of cloud also increases in general. The conclusion is drawn that the "heat-wave" cannot be attributed to descending air, but must be due to the horizontal flow of warmer and more humid air. It is difficult to reconcile this with the conclusions based upon the observations of wind, and it is possible that the surface wind does not provide a satisfactory basis for the theory developed by Dr. Ficker. It is now established that the upper wind, at moderate altitudes, deviates considerably from the wind at the surface, and has approximately the same direction as the surface isobars. Above the south-west winds found by Dr. Ficker, there would probably be a general current from west to east, or approximately in the direction of motion of the wave-front, and the general progress of the wave may be governed by this upper current.

The paper will contribute to the solution of the problem of scientific forecasting in its wider aspects, and the author is to be congratulated on the excellent use which he has made of the data contained in the publications of the Russian Central Observatory.

The same number contains a discussion by Dr. E. A. Kielhauser of nineteen years' records of the duration of sunshine at Trieste.

In the daily variation the maximum occurs at 1 p.m. in winter and at 2 p.m. in the other three seasons, but in summer there is a secondary maximum at 11 a.m. with nearly the same value as the principal maximum. At Kew the principal maximum in summer occurs at or before 11 a.m., and is considerably in excess of the secondary afternoon maximum.

The most interesting table is one giving the number of occasions in each month on which series of 1, 2, 3 . . . consecutive days without sunshine occurred. October had the greatest number of single days, and December of series of 2, 3, 4 days, but January had the greatest total number, and stands out as the month in which the longest sunless periods occur. No period, however, exceeded eleven days, so that Trieste is more favourably treated than London in this respect. At Westminster in January of the present year there were thirteen consecutive sunless days, at Kew fourteen. The difference in favour of Trieste is not sufficient, however, to justify its inclusion in the "sunny south."

In winter the chances are in favour of a sunless day being followed by a second sunless day, but the case is reversed in summer, and on no occasion did two consecutive sunless days occur in August, which had only ten such days in the nineteen years. July is the month with the greatest total duration, but August had the smallest number of sunless days.

E. Gold.

THE TOTAL ECLIPSE OF THE SUN, APRIL, 1911, AS OBSERVED AT VAVAU, TONGA ISLANDS.[1]

Owing to very unfavourable weather, the eclipse of last year was observed in the presence of a large amount of cloud. The lecturer, while only being able to refer to the few results that were secured, took the opportunity of explaining why expeditions were sent out to observe eclipses, and how a large expedition is organised when it is known that the assistance of one of his Majesty's ships is available. Introducing the subject with a few words as to the conditions which cause total solar eclipses, their occurrence in families, &c., he then pointed out that the sum total of time spent in useful observation at all the eclipses which have been observed up to date is very short, and amounts probably to less than three hours, for an eclipse cannot last longer than eight minutes, and does not, as a rule, exceed three minutes.

The line of totality of last year's eclipse extended across the Pacific Ocean, commencing at New South Wales, Australia, and terminating in the ocean just to the west of Central America. The central portion of the track passed near the islands of Tofua, Vavau, Tau, Nassau, and Danger Islands. Tofua being an active volcano, and Tau, Nassau, and Danger Islands difficult of access, most of the expeditions located themselves on Vavau, where there was a very safe anchorage for ships and where stores were obtainable. All the parties settled close to Neiafu, the chief village

[1] Abstract of a discourse delivered at the Royal Institution on Friday March 1, by Dr. William J. S. Lockyer.

of Vavau, and there the duration of totality was computed to be three minutes thirty-seven seconds, or 217 seconds.

In the earlier days of eclipse expeditions those who took part in them had to be content with eye observations alone. The discovery of and rapid advance made in the sensitive photographic plate, and its successful application in 1860 to eclipse work, revolutionised eclipse programmes altogether, so that an abundance of facts may now be photographed in a brief interval of time, and these be examined at leisure at a less exciting moment.

It is well to remember that many inquiries, which in the earlier days formed part of eclipse programmes, need attention no longer. Thus, for example, the corona was first thought to be the illuminated lunar atmosphere until observations proved it to be a solar appendage. Further, during eclipses the corona was supposed to be either quickly rotating or pulsating visibly, but subsequent observations have shown that during those times it is apparently as rigid and stationary as an Indian order suspended in the sky.

The prominences, those ruddy, brilliant tree-like forms which appear during totality at the edge of the moon's limb, were also considered as belonging to our satellite, until observations in 1860 demonstrated them as belonging to the sun. While we know that they are solar, there is even now no necessity to waste time during eclipses on either the study of their forms, positions, or chemistry. The reasons for this are that in 1868 a method was devised by which they can be individually studied *visually* any day when the sun shines, and in 1891 a means was afforded of *photographing* in a few minutes, on one plate, all the prominences situated on the sun's limb.

The solution of these and other problems which might be mentioned are gradually reducing the importance of observing eclipses, and it is well within the bounds of possibility that in the near future all the main solar inquiries will be able to be conducted without waiting for their occurrence.

In recent years, among the most important work of eclipse expeditions, that of the study of the form and chemistry of the chromosphere and corona has taken first place.

Even now the research on the chemistry of the chromosphere is in process of being divorced from eclipse work. This is due to the magnificent work that is being carried on at the Mount Wilson Solar Observatory with large-scale instruments. At that observatory the chromospheric spectrum has been photographed in full sunlight. The method employed, while surpassing in accuracy of wave-length measures those made from eclipse spectra, may in time equal, or even possibly exceed, them in detail.

Thus the chemistry and form of the corona are practically the only large inquiries which are restricted to eclipses, and probably we may not have long to wait before even these form part of the daily routine of solar physics observatories situated in good observing localities.

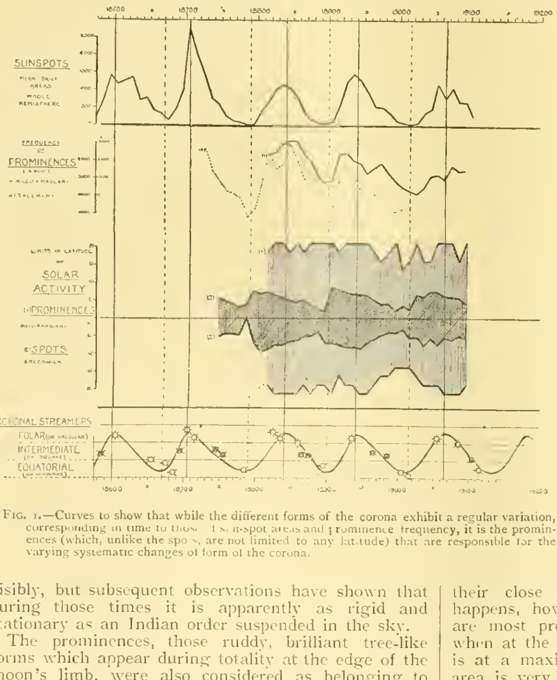


Fig. 1.—Curves to show that while the different forms of the corona exhibit a regular variation, corresponding in time to those of sun-spot areas and prominence frequency, it is the prominences (which, unlike the spots, are not limited to any latitude) that are responsible for the varying systematic changes of form of the corona.

Time will not permit me to tell you even briefly how the special results obtained during eclipses help the advancement of solar and celestial physics.

When it is remembered, however, that our sun has a temperature of about 7000° at its surface, and perhaps several hundreds of thousands of degrees at its centre—that the very sun-spots which appear to us as black spots on its surface are brighter than the brightest arc lamp—then the importance of the study of every attainable part of this very effective group of furnaces in and out of eclipse is imperative for the advancement of knowledge.

If one be permitted to refer briefly to the progress of our knowledge of the form, origin, and chemistry of the corona, you are well aware that its shape is not the same at every eclipse, but that there seems to be a systematic change going on, extending over several years (Fig. 1). A study of these forms has shown that the changes repeat themselves about every eleven years, and since the mean daily areas of sun-spots are known to have a periodicity of this length of time, their close association is generally conceded. It happens, however, that when the coronal streamers are most prominent in highest solar latitudes, and when at the same epochs the mean daily spotted area is at a maximum, the mean latitude of the spotted area is very low, being only about 15°. Thus there seems reason to question the conclusion that sun-spots at such a low latitude can originate coronal streamers so distant as the solar poles.

It must not be forgotten that a study of the frequency of solar prominences has disclosed the fact that not only have these phenomena a periodicity of about eleven years, synchronising exactly with the spotted area, but that when their frequency is at a maximum they are conspicuous at the highest solar latitudes. Thus there occur at the same time prominences and coronal streamers near the solar poles, a very possible and probable condition for cause and effect.

In the eclipses of 1901 and 1905 several striking photographs were secured illustrating intimate association between prominence and the overlying coronal material, thus affording further evidence of their close connection.

While, therefore, prominence activity is most likely responsible for providing and raising the material from the body of the sun in the various latitudes according to the different epochs of prominence activity, what action is it that organises and arranges the streamers which extend sometimes five or six millions of miles into space?

The close association between the occurrences of terrestrial magnetic storms and solar disturbances, and the results of the researches which were described in this institution in 1909, namely, the discovery of solar vortices and the presence of powerful magnetic fields which result from the revolution of the negatively charged particles, termed corpuscles, in them—these suggest strongly a cause, namely, electromagnetic action, to explain the effect.

Fig. 2.—A view of the eclipse camp (Solar Physics Observatory expedition).

So long, then, as the corona can only be observed during eclipses, the study of its general form and its structure in close proximity to prominences should be minutely recorded and discussed.

About the chemistry of the corona nothing is known. The spectroscope on many occasions has permitted observers to photograph the many radiations that it emits, and while numerous determinations of the wave-lengths of these radiations have been made, no terrestrial equivalents have yet been discovered. Thus its composition is still a mystery.

For the occasion of last year's eclipse the main work intended to be accomplished by the expedition of which I was in charge was a study on a large scale of the spectra of the chromosphere and corona, together with the form of the corona.

For the spectroscopic work, two instruments giving large dispersion were constructed, adjusted, and taken out, and several coronagraphs of different focal lengths were utilised for recording the form of the corona.

The large spectroscopes were of two kinds, one being of the "slit" type, employing a 10-ft. concave grating, while the other was of the "slitless" or prismatic camera type, in which the dispersion was secured by four 6-in. prisms of 45° angle.

The lecturer then referred to the various eclipse parties, namely, the two British official parties under himself and Father Cortie, a private party under Mr. Worthington, an Australian party under Prof. Baracchi, and two other observers who went out separately. The great assistance which the officers and men rendered to the lecturer's party can be gathered from the fact that 14 officers and 107 men took part in the observations.

Vavau was reached on April 2, and a camp was set up about a mile and a half up the harbour.

Work was commenced at once to clear the ground for the eclipse and living camps, to cut paths, and to erect landing-stages and steps. The various groups of volunteers confined themselves to their several duties, and general working parties were formed for fetching dead coral, sand, and water for the concrete pillars, for building the pillars, and putting together and covering the instrument-huts and dark-room.

The weather experienced for the first week was all that could be desired in the way of absence of rain, but the high humidity, coupled with a high temperature and the presence of millions of flies and thousands of mosquitoes, rendered the work of the camp formation extremely arduous. In the water we had other enemies in the form of sharks and sea-snakes.

At a later stage a rainy type of weather set in, and it was the exception to have a day free from it. Tropical downpours were very frequent, and special precautions had to be taken to have efficient coverings for every instrument and to trench the small compounds in which each instrument was enclosed.

By April 20 arrangements were sufficiently advanced to warrant the commencement of rehearsals, and on six days before the eclipse these rehearsals took place (Fig. 2).

During the period occupied in preparing the instruments for the eclipse, transit observations were being conducted for time and position, meteorological observations were being made at fixed times, and continuous records were being secured by a barograph, thermograph, and hygrograph.

In order to eliminate any doubt as to the possible inaccuracy of the computed times of the contacts of the limbs of the sun and moon, and also to give certain prescribed signals to those observers whose programmes necessitated them, a special telescope was set up (in conjunction with the siderostat of the 6-in. prismatic camera) to throw an image of the sun on a previously marked disc. The face of this disc was so graduated as to enable the observer to estimate the angle subtended at the centre of the dark moon by the remaining bright crescent of the uneclipsed portion of the sun; previous calculations had shown that when the crescent subtended angles of 90°, 45°, and 30°, there remained 42, 9, and 4 seconds respectively before totality began. This method only holds good when clouds do not obstruct the view of the sun.

In order to allow for the contingency of second contact not being seen on account of clouds, the observer was furnished with a deck-watch to give all the necessary signals at their computed times. The actual code of signals was as follows:—

10 minutes before totality (wind clocks, caps off, lamps lit)...	Bugle	"Rouse up"
5 minutes before totality ...	,,	"Alert"
42 seconds ,, ,, ...	3 blasts (whistle)	
9 ,, ,, ,, ...	2 ,, ,,	
4 ,, ,, ,, ...	1 ,, ,,	
Totality begins, "217" on eclipse clock	Voice	"Go"
Totality ends, "0" on eclipse clock	,,	"Stop"

Eclipse day, April 28, or, as we had not altered our date since we crossed the "date line," April 29, dawned. It was a cloudy morning, and too cloudy to make one believe that it would clear up for the eclipse.

The lecturer here referred in the main to the account of eclipse day which he gave previously in these columns (vol. lxxxvi., p. 567, June 22, 1911).

The following table shows the observed and calculated times, and it will be seen that second contact occurred about 23 seconds before the expected time, and the duration of totality was nearly five seconds shorter than was anticipated:—

—	Contacts		Duration
	Second h. m. s.	Third h. m. s.	m. s.
Calculated (Downing) .	9 37 1·7	9 40 38·5	3 36·8
Observed (Lockyer)... ..	9 36 38·6	9 40 10·7	3 32·1
Difference	23·1	27·8	4·7

Large differences of time were experienced also by the Australian observers, whose time arrangements were quite independent of those of my party.

With the spectroscopic cameras of my party practically no results of any value were secured, while in the case of the coronagraphs nearly all the negatives displayed strong images of the clouds which marred the coronal streamers. Only two of the large number of plates exposed are of value, and these are restricted to the structure of the lower corona.

There is little doubt that the gradual fall of temperature during the eclipse, which was found to be 5° F., favoured the conditions of cloud formation in such a humid atmosphere, and thus prevented us from making satisfactory observations.

The work of all the other groups, such as those for sketching the corona, for the observation of the shadow bands, shadow phenomena, &c., was all for the main part spoilt by the presence of the clouds, in spite of the care taken in widely distributing the parties. Some interesting observations were, however, made by those who watched the behaviour of animals, &c.

While my party, together with that of Father Cortie, fared very badly, the Australian observers were more fortunate, and Mr. Worthington and his staff more fortunate still. With regard to the results secured by these parties, I can only show you in the

Fig. 3.—H.M.S. *Encounter* weighing anchor at Suva, Fiji, after landing the S.P.O. observing party.

case of the Australian observers a combined sketch carefully made from Mr. Dodwell's negatives and visual observations. This shows clearly the extensive equatorial streamers and the open spaces at the solar poles filled with the beautiful forms of the polar plumes. This corona is undoubtedly one of the "minimum" type, representing the wind-vane form. When this was compared with the sketch I made at the time of the eclipse, it was seen that both were in fair agreement in most of the main features.

Through the kindness of Mr. Worthington, I have been allowed to show you some of the beautiful results which he secured. Unfortunately, like us, he did not obtain any spectra, although he was equipped with a very fine instrument specially adapted for the ultra-violet region of the spectrum, but, unlike us, he was compensated by success on other lines. Both the long and short exposures with his coronagraphs met with success. Beautiful structure is displayed in the regions of the solar poles, and the equatorial streamers are extensive and full of detail. These photographs also exhibit a "minimum" type of corona, corroborating the observations of the other parties; they are of considerable value as records and for future study, and form the main contribution to solar physics which this eclipse has afforded.

Although the astronomical results of my party were chiefly negative, we managed to get together at odd moments a collection of specimens for the Natural History Museum at South Kensington, the Botanical Gardens at Kew, and the Physic Garden at Chelsea.

In concluding this account, I should like to place on record in this institution the fine way in which the volunteer observers of my party worked in sometimes very trying circumstances; the magnificent assistance rendered by the captain, officers, and men of H.M.S. *Encounter*; the great liberality of the Orient Steam Navigation Company in again transporting out and home all our instruments, baggage, &c., free of charge; and lastly, the assistance of many individuals who at various stages of our journey made matters as easy as possible for us.

THE RELATIONSHIP OF NEANDERTHAL MAN AND PITHECANTHROPUS TO MODERN MAN.[1]

THE more the remains of Neanderthal man are studied, the more it becomes apparent that Prof. Schwalbe is right in regarding this Pleistocene race as being totally distinct from all existing races of mankind. It is true that Neanderthal man in some characters, for instance, the teeth, shows a certain degree of specialisation, but in the vast majority he is infinitely more simian than any race now living. He serves in some degree to carry human history towards an ape stage. Those who believe that modern man has been evolved in a comparatively brief and recent geological period are inclined to accept the Neanderthal type as representative of mankind of a late stage of the Pleistocene epoch, and to suppose that modern man has been evolved from the more primitive type since that date.

Two lines of research have rendered such beliefs untenable. All the remains of Neanderthal man so far discovered in France and Belgium are referable to a limited and late part of the Pleistocene epoch. The flint implements and accessory evidence show that Neanderthal man flourished in Central Europe during the Mousterian and earlier part of the Aurignacian periods. All trace of this type then disappears; the races which immediately succeed it are of the modern type; the evidence points to an extermination of the ancient or Neanderthal type early in the Aurignacian period.

In those long stretches of the Pleistocene epoch—the Acheulean and Chellean—which precede the Mousterian period, and are characterised by flints of great beauty of workmanship, no trace of Neanderthal man has been found in Europe. The remains which have been discovered show that the Europeans of the Chellean and Acheulean periods were of the modern type. Lately, M. Rutot, of Brussels, has tabulated a list of the human remains which he regards as referable to pre-Mousterian periods, and in every case these belong to mankind of the modern type.

Prof. Keith reviewed the evidence relating to the human mandible found by Boucher de Perthes at Moulin Quinon in 1863, and came to the conclusion that it was an authentic document. Boucher de Perthes found it in a stratum containing implements of the Acheulean period. The mandible is peculiar in form, but is clearly of the non-Neanderthal type. No trace of Neanderthal man has been found in Italy, but human remains of the modern type have been found in Lombardy and Tuscany in strata which in point of formation long preceded the Mousterian period.

The most convincing evidence of the early existence of the modern type of man is to be found in England. The Galley Hill remains from the 100-ft. terrace of the Thames Valley are at least Chellean in date; according to M. Rutot they are much earlier. The fragmentary Bury St. Edmunds skull, of which Prof. Keith has lately made a minute examination, is of the modern type, and in point of date belongs to the Acheulean period. The human skeleton lately discovered by Mr. J. Reid Moir beneath a stratum of weathered chalky Boulder-clay near Ipswich is much older than the Galley Hill remains, yet in all its characters the Ipswich skeleton represents the modern type of man.

The only remains of man so far discovered in Europe which certainly antedate the Ipswich skeleton is the Heidelberg mandible, which must be assigned to the oldest part of the Pleistocene epoch. The Heidelberg jaw clearly formed part of the skeleton of a primitive form of Neanderthal man. On the evidence at present available, it must be inferred that two types of man were in existence in Europe during the Pleistocene epoch: (1) the Neanderthal type, represented by the Heidelberg mandible, near the beginning of that epoch, and by the various skeletons found in Belgium and France near its end; and (2) the modern type, represented by remains of many races belonging to the inferior, middle, and superior formations of the Pleistocene epoch. It is evident, too, that the point at which these two types of mankind emerged from a common stock must be assigned to an earlier date than most anthropologists are inclined to admit at present—probably to the older part of the Pliocene period.

That the modern type of man must be of great antiquity is evident from the degree of divergence which is to be seen amongst existing races of mankind. All the evidence at present at our disposal indicates that human races change very slowly in their physique; to produce the negro of Africa and the fair-haired European from a common stock clearly demands a very long period of time. Of all the races now existing in the world, the native Australian most nearly approaches the type which might serve as a common ancestor for African and European. He combines the characters of each, and at the same time has certain features which link him to the Neanderthal type. At least such a surmise serves as a convenient working hypothesis.

The structural differences between the Neanderthal and modern types of man are similar in nature, although somewhat less in degree, than those which separate the gorilla from the chimpanzee. Those two anthropoids are more nearly related structurally than is usually supposed. There is a similar differentiation among the modern gibbons of the Far East and among the extinct Miocene gibbons of Europe. The siamang and Paidopithex represent the gorilla or Neanderthal form; the gibbon and Pliopithecus correspond to the type represented by the chimpanzee and modern man. In all these groups of higher Primates the same process of evolution seems to be at work.

Although the results of more recent inquiries place

[1] From Hunterian Lectures delivered at the Royal College of Surgeons, England, on February 26 and 28, March 1, 4, 6, and 8, by Prof. Arthur Keith.

Pithecanthropus at the beginning of the Pleistocene period, the Pliocene date originally assigned by Prof. Dubois seems the more probable one. There can be no doubt that the Javan fossil form is human in every point of structure save that of size of brain. Pithecanthropus, like Neanderthal man, was evidently a primitive form which had survived long after much higher types of mankind had been evolved. If we look upon Pithecanthropus as representative of mankind at the close of the Pliocene epoch, then we must suppose that the human brain was doubled in size during the earlier part of the Pleistocene period. Such a rapid degree of evolution is unknown in the whole history of palæontological discovery. It will probably be found that Pithecanthropus is representative rather of a Miocene than of a Pliocene stage in the evolution of man.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—An exhibition of 50*l.* a year, tenable for two years, is offered each year by the governing body of Emmanuel College to an advanced student commencing residence at Cambridge as a member of Emmanuel College in October. The governing body may award additional exhibitions of smaller value should properly qualified applicants present themselves. The exhibitions will be awarded at the beginning of October. Applications, accompanied by two certificates of good character, should be sent to the master of Emmanuel not later than September 24.

The sixth annual report of the president and treasurer of the Carnegie Foundation, covering the year ending September 30, 1911, has just been received, and is here summarised. The endowments now amount to 2,424,600*l.*, comprising Mr. Carnegie's original gift of 2,000,000*l.* in 1905, an accumulation from income of 224,600*l.*, and 200,000*l.* received in 1911 as the first instalment of Mr. Carnegie's additional gift of 1,000,000*l.* in 1908. Of the income of 118,000*l.* for the year 1910–11, 105,200*l.* was expended in retiring allowances and pensions, 7200*l.* in general administration, and 3200*l.* in educational publication. Thirty-one retiring allowances and seventeen widows' pensions were granted during the year, increasing the number in force to 373, the average annual payment being 326*l.*, and the total distribution to date 349,200*l.* The exchange of teachers conducted through the Foundation sent nine American teachers to Prussia during the year and received seven Prussian teachers in the United States, in both instances with gratifying results.

The second part of the report referred to above is a comprehensive survey by the president of educational progress and tendencies from a national point of view. Private and local educational initiative without guidance and federal and State grants without supervision are so wasteful financially and so hurtful educationally that agreement and cooperation must inevitably increase. The great variation in educational efficiency that now exists is shown to be unnecessary and wasteful. It is neither necessary nor desirable that some States should spend only one-eighth as much as others *per capita* for education, have only half as long a school year, enroll only half as large a proportion of their school children, and spend only one-fifth as much in educating each teacher. A better adjustment is developing between the colleges and the high schools. Many universities and colleges have advanced within ten years from competing with high schools, while other institutions, like Harvard, have broadened their entrance requirements so that they can be met by the average good high school. The increase in the number and size of post-graduate schools—50 per cent. in the last decade and tenfold in the last thirty years—has been much greater than the natural need. Poor and pretentious graduate schools, conducted with the funds of undergraduate colleges and attended chiefly by subsidised students, often merely impair the appreciation of good undergraduate teaching and hamper real research, through the multiplication of mechanical seminars, dissertations, and the like. Professional education, also, is hampered by an enormous duplication of facilities, resulting in great financial waste, and often in a competition in low entrance requirements and poor instruction. Some States have four, five, seven, and nine schools of engineering each; New York city alone has six, and Pennsylvania has thirteen, five of these having fewer than forty students each. The report will be sent to any address upon request to the Carnegie Foundation, 576 Fifth Avenue, New York City.

SOCIETIES AND ACADEMIES.

London.

Geological Society, March 27.—Dr. Aubrey Strahan, F.R.S., president, in the chair.—Bernard **Smith**: The glaciation of the Black Combe District (Cumberland). After a brief discussion of previous work and literature, a short sketch is given of the geological structure of the district. With the exception of the western coastal plain the main topographical features are pre-Glacial, but they have been either subdued or accentuated by glaciation. The chief pre-Glacial drainage-lines determined those of the present day.—J. F. N. **Green**: The older Palæozoic succession of the Duddon Estuary.

Dublin.

Royal Dublin Society, February 27.—Mr. R. Ll. Praeger in the chair.—Prof. T. **Johnson**: *Heterangium hibernicum*, sp. nov., a seed-bearing Heterangium from Co. Cork. This is a fossil plant from the Carboniferous slate, near Bandon, and is contained in the National Museum. The specimens were described in 1864 by W. H. Baily, of the Geological Survey, as "linear plants" under the name of *Filicites lineatus*. They represent the recently discovered group of seed-bearing ferns which connect the ferns with the lowest group of flowering plants. The Bandon specimens are of special interest in that one of them bears a small "seed" in direct continuity with the parent plant.—Prof. Henry H. **Dixon** and W. R. G. **Atkins**: (*a*) Changes in the osmotic pressure of the sap of the developing leaves of *Syringa vulgaris*. The osmotic pressures were calculated from the depression of freezing point of the sap, determined by a thermo-electric method, before described. Measurements were made from February to October, and it was found that the osmotic pressures ranged from 11 to 13 atm. in the buds, from 10 to 15 atm. in the leaves, increasing with age. Mean molecular weight determinations of the sap solutes usually lay between 160 and 180. (*b*) Variations in the osmotic pressures of some evergreens. The leaves of deciduous plants showed an increase of pressure with age. Ilex and Hedera were found to behave similarly. The highest pressures were observed in March and April, and also from October to December, as the leaves are then at their maximum average age just before the growth of young leaves and elongation of the shoots. No correlation was found between the pressures and the rainfall or sunshine. Specimens of Hedera from a north and south aspect were examined, and the former were found to have a slightly lower pressure than the latter.—Miss Genevieve V. **Morrow**: The ultimate lines of the vacuum tube spectra of manganese, lead, copper, and lithium. The author described the methods adopted for obtaining the quantitative spectra of metals by means of the vacuum tube, and pointed out the importance of obtaining such data in order to make spectrographic analysis complete. It was proved that the presence of an extremely minute trace of a substance could be detected by means of these tubes; one-tenth of a milligram of a metal gave almost a complete spectrum in some cases, and a much smaller quantity gave the ultimate lines.

March 26.—Mr. R. Ll. Praeger in the chair.—Dr. Jean **Timmermans**: Experimental researches on the density of liquids below 0° C. The author has devised a method by which the density of a liquid below 0° can be accurately determined, and has established a series of fixed points between 0° and $-160°$. He has determined the boiling points and the densities from 0° to the freezing points of twenty-five carefully purified organic liquids. The law of Cailletet and Mathias is not found to hold absolutely even in the case of normal pentane. None of the liquids examined show a point of maximum density. The law of corresponding states, as modified by Mme. K. Meyer, is found to hold even at the lowest temperatures. The ratio of the maximum density (calculated at $-273°$) to the critical density is found to be approximately equal to the ratio of the actual to the theoretical density in the cases examined.—Dr. A. F. G. **Kerr**: Notes on *Dischidia rafflesiana* and *D. nummularia*. This is an account of the external morphology of the vegetative organs, and of the structure of the flowers of these two plants, worked out on fresh material gathered in the neighbourhood of Chiengmai, Siam. There are also observations on the relationship of the plants to the ants which they harbour, and to the part played by the latter in the dispersal of the seeds. The disposition and the contents of a large series of pitchers of *D. rafflesiana* were examined *in situ*, and it was found that out of 227 pitchers 88 were so situated that the retention of water in the pitcher was a possibility, while of these only fourteen actually contained water. In a discussion of the theories as to the functions of the pitchers, the author concludes that they are organs for economising water. The water vapour given off by the stomata on the inside of the pitchers is absorbed by the nest material of the ants, which is plastered over the contained roots and is transmitted through them into the plant.

Paris.

Academy of Sciences, April 1.—M. H. Poincaré in the chair.—G. **Bigourdan**: Some observations of position which may be made during the solar eclipse of April 17, 1912. An outline of observations requiring special attention during the coming eclipse.—M. **Bertin**: The relation between the increase of displacement of a vessel and increase of load.—W. **Kilian** and Ch. **Jacob**: The non-parallelism of the isopic zones and tectonic folds in the Franco-Italian Alps and in the Valais.—E. **Waelsch**: Bipedal functions, triple orthogonal systems, and isostatic efforts.—Arnaud **Denjoy**: An extension of the integral of Lebesgue.—L. E. J. **Brouwer**: The invariance of the closed curve.—A. **Friedmann**: Isodynamic surfaces.—J. **Pionchon**: The solution of copper in water. An element formed of two plates of copper with water as liquid shows a momentary current when one of the plates is tapped. If the water has been in contact with metallic copper for some time, this effect is not observed, and this is supposed by the author to be due to the solution of minute traces of copper by the water. The amount dissolved is too small to be detected by chemical means.—P. **Vaillant**: The influence of temperature and of light on the conductivity of a phosphorescent body (calcium sulphide). The electrical conductivity of a film of calcium sulphide increases under the action of light to a maximum and then diminishes. For a given apparatus, the relative variations of conductivity are independent of the initial conductivity.—R. **Fortrat**: The telluric bands due to oxygen. It is shown that each band may be regarded as being composed of two equal series obeying very nearly the law of Deslandres.—G. A. **Hemsalech**: The relative velocities of the luminous vapours of various elements in the electric spark. Applying the experimental method developed in previous papers, it is shown that the elements studied can be divided into groups, in each of which there is a relation between the velocities of the vapours in the spark and the atomic weights.—A. **Aubertin**: The appearances of the discharge of a condenser.—Louis **Hackspill**: The vapour pressure of the alkaline metals between 250° C. and 400° C. The metal was sealed in a U tube, one limb of which was maintained just above the melting point of the metal and the other at the temperature at which the vapour pressure was required. The vapour pressures were determined from the observed change of level in the two arms of the tube. The results obtained are shown graphically for cæsium, rubidium, potassium, and sodium.—Alfred **Henry**: The determination in absolute value of the mass of the molecules of liquids, and more especially that of the mercury molecule.—Marcel **Boll** and Paul **Job**: The photochemical kinetics of the chloroplatinic acids in very dilute solutions. The decomposition of the chloroplatinic acids, H_2PtCl_6, $H_2Pt(OH)Cl_5$, $H_2Pt(OH)_2Cl_4$, and $H_2Pt(OH)_4Cl_2$, by the light from a mercury arc was studied in tenth-millinormal solutions; in each case the reaction was found to be bimolecular.—P. **Pascal**: Thermal analysis of hexachloroethane and its binary mixtures. The cooling curve of solid hexachloroethane showed that three forms exist with transition points at 125° and 71·6°. The melting points of mixtures of hexachloroethane with naphthalene and with phenanthrene were also studied, and the results shown graphically.—M. **Lespieau**: The dimethyl ether of 1 : 5 pentinediol and its hydrogenation.—A. **Guilliermond**: The mitochondria of the sexual organs of plants.—Raoul **Combes**: A method for the culture of the higher plants in sterile media. An apparatus is figured and described in which the roots of a growing plant remain in a medium rigorously sterile whilst the stem and leaves are in the open air.—F. **Jadin** and A. **Astruc**: The presence of arsenic in some plants used as food. The researches of Gautier and G. Bertrand have definitely demonstrated that arsenic exists normally in man and animals. The examination of a number of edible plants and fruits shows that some of this arsenic may be taken as vegetables. Arsenic was found in all the thirty-nine substances examined in quantities between 0·03 part per million in the leek and 0·25 part per million in almonds and beans.—H. **Arsandaux**: The presence of rocks belonging to the charnockite series at Gabon.—R. **Tronquoy**: Modification of the tin-bearing lodes of Villeder (Morbihan).—M. **Laquerrière**: First results of the application to gynecology of the electrolysis of radium salts (Haret's method).—E. **Doumer**: The treatment of tubercular osteitis by the high-frequency discharge. Eleven cases were treated, and in all these a cure was effected, the time taken varying from one month to two years. In four cases the clinical diagnosis was confirmed bacteriologically, and in these the course of the treatment and its results are described in detail.—J. Vallot: The existence of dust in the air on the upper glaciers of Mt. Blanc and its effects.

BOOKS RECEIVED.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 2216, Vol. 89] THURSDAY, APRIL 18, 1912 [Price Sixpence

Registered as a Newspaper at the General Post Office.]

UNIVERSITY OF LONDON.

KING'S COLLEGE.

FACULTY OF SCIENCE.

Courses of Study are arranged for Degrees in the University of London. Students may also join for any of the subjects without taking the complete course. Several valuable Scholarships and Prizes are offered.

The Laboratories of the College are open to post-Graduate and Research students.

	Heads of Departments.
Mathematics	Prof. S. A. F. White, M.A.
Physics	Prof. C. G. Barkla, D.Sc.
Chemistry	Prof. John M. Thomson, LL.D., F.R.S. Prof. H. Jackson, F.I.C., F.C.S.
Botany	Prof. W. B. Bottomley, Ph.D., F.L.S.
Zoology	Prof. Arthur Dendy, D.Sc., F.R.S.
Geology and Mineralogy	T. Franklin Sibly, D.Sc.
Physiology	Prof. W. D. Halliburton, M.D., B.Sc., F.R.S.
Psychology	W. Brown, M.A., D.Sc.

The TERM commences WEDNESDAY, MAY 1, 1912.

For information and prospectus apply to the Secretary, King's College, Strand, London, W.C.

EAST LONDON COLLEGE.

(UNIVERSITY OF LONDON.)

Patron—HIS MAJESTY THE KING.

Classics	F. R. Earp, M.A.
English	H. Belloc, M.A.
French	Mina Paquier.
German	J. Steppat, Ph.D.
History	Thomas Seccombe, M.A.
Mathematics	The Principal.
Physics	C. H. Lees, D.Sc., F.R.S.
Chemistry	J. T. Hewitt, D.Sc., F.R.S.
Botany	F. E. Fritsch, D.Sc.
Geology	W. L. Carter, M.A.
Civil and Mechanical Engineering	D. A. Low, M.I.M.E.
Electrical Engineering	J. T. Morris, M.I.E.E.

Fees moderate. Valuable Entrance Scholarships awarded by Drapers Company.

Special facilities for Post-Graduate and Research Students. Particulars of fees, courses of study, &c., on application to the Registrar, or to

J. L. S. HATTON, M.A., Principal, at the College.

BEDFORD COLLEGE FOR WOMEN.

(UNIVERSITY OF LONDON.)

YORK PLACE, BAKER STREET, W.

Principal—Miss M. J. TUKE, M.A.

COURSE OF SCIENTIFIC INSTRUCTION IN HYGIENE.

Recognised by the Sanitary Inspectors' Examination Board.

The Course is designed to furnish training for Women Sanitary and Factory Inspectors and Teachers of Hygiene.

A Post-graduate Scholarship of £35 for one year is offered for the course beginning October, 1912. Applications should be forwarded not later than June 1 to the Principal, from whom further particulars may be obtained.

LONDON HOSPITAL MEDICAL COLLEGE AND DENTAL SCHOOL.

The SUMMER SESSION opens on MAY 1. Students entering then are eligible to compete for the Entrance Scholarships in September.

For prospectus and particulars apply to the Dean, William Wright, M.B., D.Sc., F.R.C.S., who will be glad to make arrangements for any one wishing to see over the Medical College and Dental School.

London Hospital Medical College, Mile End, E.

PRIFYSGOL CYMRU. UNIVERSITY OF WALES

THREE FELLOWSHIPS of the annual value of £125, tenable for two years, are open to graduates of this University.

Applications must be received before September 1, 1912, by the Registrar, University Registry, Cathays Park, Cardiff, from whom further information may be obtained.

THE UNIVERSITY OF LEEDS.

DEPARTMENT OF AGRICULTURE.

Applications are invited for the appointment of ASSISTANT LECTURER in AGRICULTURAL CHEMISTRY. Particulars may be obtained from the Clerk to the Senate.

FOR SALE. Five milligrams of Radium

Bromide. Offers to be addressed to "Box No. 1912," c/o Nature, St. Martin's Street, London, W.C.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON.

INCLUDING THE

ROYAL COLLEGE OF SCIENCE, the ROYAL SCHOOL OF MINES, and the CITY AND GUILDS (ENGINEERING) COLLEGE.

A Special Course of Advanced Lectures will be given, beginning on Wednesday, May 15 next, on the

MAGNETIC PROPERTIES OF METALS AND ALLOYS,

by S. W. J. SMITH, A.R.C.S., M.A., D.Sc.

For further information and for admission to the Course application should be made to the Secretary.

BOROUGH OF WIDNES.

MUNICIPAL SECONDARY SCHOOL.

Principal—J. A. Cooper, B.Sc.

WANTED, in SEPTEMBER, an experienced MASTER, with Honours Degree in Science. Principal Subject, Chemistry, to University Scholarship Standard; Subsidiary Subjects, Physics, Mathematics. Assistance with Games essential. Secondary School Diploma and Musical ability desirable. The present Master has been appointed to a Headmastership. Initial salary, £130-£170 (four years' previous experience in recognised Secondary Schools requisite for the latter), with annual increments of £10 to £200, and, if specially recommended, to £250, according to the Lancashire County Council scale.

Applications from those without previous Secondary School experience will not be considered.

Master appointed required to undertake about six hours' Evening Work per week, at 5s. per hour.

Forms of application, which must be filled up by all applicants, to be had, on receipt of stamped addressed envelope, from the Principal, to whom they must be returned not later than APRIL 30, 1912.

CITY OF BIRMINGHAM EDUCATION COMMITTEE.

HEAD OF DEPARTMENT OF METALLURGY.

Applications are invited for the post of HEAD of the DEPARTMENT of METALLURGY of the MUNICIPAL TECHNICAL SCHOOL. Commencing salary, £300 per annum.

Full particulars will be forwarded on application to the Secretary of the School (Mr. G. Mellor), Suffolk Street, Birmingham. The last date for sending in applications is May 1, 1912. Personal canvassing of Members of Committee by applicants or their friends will be a disqualification.

JNO. ARTHUR PALMER,
March 21, 1912. Secretary of Education.

Sales by Auction.

STEVENS' AUCTION ROOMS. Estd. 1760.

LEPIDOPTERA.

Tuesday, April 23, at One o'clock.

MR. J. C. STEVENS will Sell by Auction

at his Rooms, 38 King Street, Covent Garden, London, W.C., the Fourth Portion of the Collection of Lepidoptera formed by the late J. W. Tutt, Esq., F.E.S., comprising long series in fine condition of British Tortrices, including long and varied series of Peroneas, also British Tinea; good series of Psychidæ and Nepticulæ in excellent condition, and the remainder of the British Geometers, together with the Cabinets in which they are contained.

On view day prior and morning of Sale. Catalogues on application.

STEVENS' AUCTION ROOMS. Estd. 1760.

A Sale by Auction is held EVERY FRIDAY

at 12.30, which affords first-class opportunities for the disposal or purchase of SCIENTIFIC AND ELECTRICAL APPARATUS, Microscopes and Accessories, Surveying Instruments, Photographic Cameras and Lenses, Lathes and Tools, Cinematographs and Films and Miscellaneous Property.

Catalogues and terms for selling will be forwarded on application to

Mr. J. C. STEVENS,

38 KING STREET, COVENT GARDEN, LONDON, W.C.

BOOKS!

Books on Scientific, Technical, Educational, Medical, all other subjects, and for all Exams.

SECOND-HAND AT HALF PRICES! New, at 25% Discount.

Catalogues Free. State Wants. Books sent on approval.

BOOKS BOUGHT: Best Prices Given.

THURSDAY, APRIL 18, 1912.

PROGRESS OF THE STEAM TURBINE.

Steam Turbine Design. With especial reference to the Reaction Type, including chapters on Condensers and Propeller Design. By Dr. J. Morrow. Pp. viii + 471 + chart. (London: Edward Arnold, 1911.) Price 16*s.* net.

Marine Steam Turbines. (Forming the Supplementary Volume to "Marine Engines and Boilers.") By Dr. G. Bauer and O. Lasche; assisted by E. Ludwig and H. Vogel. Translated from the German and edited by M. G. S. Swallow. Pp. xvi + 214 + entropy chart. (London: Crosby Lockwood and Son, 1911.) Price 10*s.* 6*d.* net.

The Steam Turbine. The Rede Lecture, 1911. By Sir Charles A. Parsons, K.C.B. Pp. iii + 57. (Cambridge: University Press, 1911.) Price 1*s.* 6*d.* net.

THE literature of steam turbines grows apace. This growth is seen to be natural enough when one considers the immense developments which have taken place in prime movers of the type during recent years, as well as their varied applications for land and marine purposes. On land, steam turbines are now almost universally preferred to reciprocating engines for electric generating stations; while low-pressure turbines are largely utilised—as auxiliaries to reciprocating engines—in iron works, factories, and engineering establishments. One of the most notable developments in modern mechanical engineering consists in the adoption of methods for utilising heat which had previously been wasted in carrying on manufacturing processes. In this endeavour to secure increased economy the steam turbine has played a great part, although its successful applications have unquestionably been greatly assisted by the work of electrical engineers. The fundamental principle of this increased economy is found in the capability of steam turbines, especially those of the "reaction" type, to carry the expansion of steam much further than is practically possible with reciprocating engines. Superheating, higher vacuums and greatly improved arrangements for condensing steam have necessarily had to be devised in order that the full efficiency of turbines might be realised; and it is worth noting that these advances have not only produced beneficial results in association with the use of steam turbines. Their range of usefulness has been much wider, and has affected the economical use of earlier types of reciprocating engines, both afloat and ashore.

Marine engineering has benefited quite as much as, if not more than, mechanical engineering on land from the introduction of steam turbines. It is indeed a simple statement of fact to assert that steam navigation could not have reached its present position had not steam turbines been introduced. This statement applies to the largest and swiftest ocean passenger steamers, to the latest battle-ships and battle-cruisers, to fast cross-channel and coasting steamers, and to the wonderful little craft classed as the "torpedo flotillas" of modern war-fleets. When such a revolution has been effected, and further advances are in progress, it is, as was said above, quite natural that text-books and treatises on steam turbines should be multiplied in number, and multiplication has been attended by greater specialisation of treatment in successive publications.

The first and second of the three volumes now under notice have been issued with the distinct intention of serving as text-books for men actually engaged in the design of steam turbines. In both these books is contained a clear, yet brief, statement of thermo-dynamical principles underlying designs of turbine machinery; but the authors have assumed that readers desiring to master these principles will turn to existing text-books in which the subject has been treated thoroughly, and in a fashion adapted to the needs of students.

Dr. Morrow is lecturer in engineering at the Armstrong College, Newcastle-on-Tyne; and, as everyone knows, the Tyne was the birthplace of the Parsons type of turbine. In the hands of Sir Charles Parsons and his licensees in the Tyne district, this type of machinery has been manufactured on a gigantic scale; but it is right to add that the Tyne district in no sense stands alone in its acceptance and use of steam turbines. In the circumstances it is natural to find the author devoting by far the greater portion of his book to the "reaction" type of steam turbines, and to the Parsons type in particular. "Impulse" turbines are also dealt with briefly, but students must turn to other works for full details of their designs. The characteristic features of Dr. Morrow's book are clearness of description, excellence of illustration, a wealth of examples of methods and details of design, and a strict regard for fundamental principles. Dr. Morrow concludes his preface with the remark that "in a work containing so much original matter, the author cannot but feel that errors of judgment and mistakes in details will be found"; and he invites readers to favour him with corrections and suggestions. This is the attitude which an author ought to assume in such

H

a case; and later editions will benefit therefrom. Taking the book as it stands, it will undoubtedly prove of much use to men who are engaged in the design of steam turbines. For that reason it will be likely to find a large circulation, although it is probable that its interest will not be limited to engineering draughtsmen and students.

The second volume in our list is a translation of a German book on "Marine Steam Turbines," issued as a supplement to a treatise on "Marine Engines and Boilers," which one of the authors published a few years ago, and which has also appeared in an English translation. The author of this earlier work (Dr. Bauer) is the director of the great marine engineering works at Stettin. Mr. Lasche, who is joint-author with Dr. Bauer, is a director of the Allgemeine Electricitäts Gesellschaft (better known as the A.E.G.) works in Berlin. Both these gentlemen have had large experience in the design and construction of steam turbines of various types, and they have been interested in the application of the A.E.G. turbine and the American Curtis turbine to the generation of electricity and the propulsion of ships. The present book, however, relates entirely to marine steam turbines, and the greatest prominence is naturally given to that class of turbine with which the authors have been mostly concerned. They very properly point out that only these two types of marine steam turbines and the Parsons type have as yet been practically tried on a large scale. As a matter of fact, the Parsons type has been used in by far the greater number of turbine-driven ships yet constructed. The Curtis type has been hitherto its only real competitor in the United States, and in Germany the A.E.G. type is being steadily developed for marine purposes. Proof of the relative progress of the Parsons type up to date is found in the circumstance that in the two huge Atlantic steamers now building in Germany for the Hamburg-American Steamship Company, and in all the largest and swiftest armoured cruisers built or building for the German fleet, that type is still preferred.

The general line of treatment followed by Dr. Bauer and Mr. Lasche closely resembles that adopted by Dr. Morrow. The book is of a very practical character, giving methods of calculations and examples of the application of those methods to the design of details of steam turbines of various types, the settlement of the dimensions of shafting and propellers, and the arrangements of condensing apparatus. It will have special interest for English readers as coming from a German source, and containing a considerable amount of information in regard to German practice. In size, the book is only about half as large as that noticed above. It is exceedingly well produced, and very tersely expressed, the authors stating their own conclusions on many points where differences of opinion prevail, without entering into elaborate arguments in support of those opinions. No objection need be taken to this method of treatment; in fact, it has distinct advantages for the men who are expected to be the principal users of the volume; but it is necessary to note that in many points, especially in those where comparisons are made between British and German or American types of turbines, the opinions expressed by the writers are not shared by no less competent authorities. In some cases the endeavour to compress statements within narrow limits has been accompanied by what, no doubt, is an unintentional omission of important facts. These, however, may be regarded as minor blemishes on what is, on the whole, a good performance; and there can be no doubt that such a book will naturally find a place on the shelves of all who are interested in the design of steam turbines, representing as it does the experience of two leading German engineers.

The third book in our list is a slender volume of less than sixty pages, in which the Rede Lecture for 1911 by Sir Charles Parsons is reproduced. The authorities of Cambridge were fortunate enough to secure, on this occasion, a lecturer who is one of the most distinguished living graduates of the University, and to find him ready to describe the principal features of his own great invention, as well as those of competing types of steam turbines.

This little book contains a wealth of illustrations, an epitome of the history of the progress of steam turbines, and a summary of the matured opinions of the man who knows most about that class of prime movers. Sir Charles Parsons has set down in modest and simple fashion his main conclusions on a subject of which he is the acknowledged master. The utterance is itself but a brief summary of facts and opinions; consequently, it is impossible even to mention its main points in this review. All who are interested in the subject should read the book itself, and its low price ought to ensure for it a large circulation

One characteristic feature of the book, however, deserves mention. Throughout his references to types of turbines which have been originated by other inventors, the author displays great fairness of judgment and a generous appreciation of merits possessed by machines which are in competition with turbines designed by himself. Sir Charles Parsons has thus taken a course differing from that which many inventors have followed when dealing with the work of rivals; in doing so, he has added—if that be possible—to the high reputation which he had previously acquired as an engineer. W. H. W.

INFERIOR RACES.

The Mind of Primitive Man. By Franz Boas. A Course of Lectures delivered before the Lowell Institute, Boston, Mass., and the National University of Mexico, 1910–11. Pp. xi+294. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1911.) Price 6*s.* 6*d.* net.

A FAMOUS psychological novelist has asserted that racial differences are irreducible, and that even when love unites two members of distinct races their life, however harmonious, is lived over a slumbering volcano of hate. There is a popular fallacy that racial antipathy is based on physiological foundations. But in so far as such antipathy is real, there is nothing physiological in its causation; and its emotional strength depends on the law that the more automatic and unconscious a habit is, the greater is the displeasure felt and the disgust aroused by infractions of the habit. The most plausible form of this racial habit is one which even scientifically trained minds find it difficult to transcend. This is the attitude of superiority consciously or unconsciously adopted by civilised men towards the semi-civilised, and among the civilised by the so-called Caucasian race. As Prof. Boas puts it, "Proud of his wonderful achievements civilised man looks down upon the humbler members of mankind." The European looks down on the civilised Oriental. The point of interest, however, is that he claims to be of a higher type, possibly physical, but certainly psychical, on the assumption that achievement depends solely upon aptitude for achievement.

In these lectures, delivered before the Lowell Institute and the National University of Mexico, the main thread of Prof. Boas's argument is that this assumption and this claim of superiority of type are unproven. In support of his argument he employs data from the whole field both of physical and of social anthropology, and the resulting exposition of the salient features of difference between the civilised and the primitive types of man has the advantage of the author's first-hand experience and personal investigation.

He notes that the ancient civilisation of the Old World, not essentially superior to that of the New, reached its height 3000 years earlier for accidental reasons. He explains the European aptness for civilisation as not necessarily due to superior faculty. Due regard is had to heredity and environment, and several confusions of thought on the subject are cleared up. In reference to environment, his own remarkable observations are introduced, namely, that the American-born children of European immigrants (European-born) respond at once in a curious way. The short, dark-haired, and longheaded Sicilian loses in stature; the head increases in width and loses in length, becoming brachycephalic. The medium-sized, short-headed native of Central Europe gains in stature and in narrowness of head. The tall, long-headed European of the north-west grows taller.

The observation made by Fritsch on the Bushman is applied generally to man. Europeans, for instance, are to savages as domesticated animals are to wild. Their bones, that is, become, though heavier, less solid and less slender; their structure is more open. The mental change in domesticated animals is undoubted. Modifications of type, physical and mental, he concludes, are largely due to the progressive domestication of man incidental to the advance of civilisation.

The author's discussion and explanation of the causes and results of variation within a race, brief though they are, supply the most convincing theory that has yet appeared. The whole question of permanence and variation of type, in fact, is treated in a masterly way.

The ordinary view of the mental deficiencies of the "inferior races" is remorselessly criticised. The lowest savage *does* possess self-control. He is not improvident, but rather optimistic. He *can* concentrate his mind. He possesses originality. Savages who do not count beyond three or ten easily adapt their language and intellect to civilised methods of reckoning. The same is the case with abstract and general ideas, as Prof. Boas has himself proved by experiment. The point is that these civilised methods are not needed in the primitive state, where each man on a war-expedition is known by name, though the number of the troop may not be reckoned.

Both in mind and in body there is little to choose between the ordinary barbarian and civilised man. The thesis is applied to a practical purpose in the last lecture, the question of the influence of the negro and of the European immigrant upon the type of the American citizen. No one interested in this or in other racial questions can afford to pass over this most sane and scientific critique. The whole volume is conspicuous both for balanced reasoning and for brilliance, and as a practical application of anthropology is of the first importance.

A. E. Crawley.

APPLIED CHEMISTRY.

A Dictionary of Applied Chemistry. By Sir Edward Thorpe, C.B., F.R.S. Assisted by Eminent Contributors. In five volumes. Vol. i. Revised and enlarged edition. Pp. viii+758. (London: Longmans, Green and Co., 1912.) Price 45*s.* net.

IT will be remembered that the first edition of Thorpe's "Dictionary of Applied Chemistry" appeared in 1890, when the great "Watts" was at the same time abridged and edited by Dr. Foster Morley and Mr. Pattison Muir. Since that time it has served as a standard reference book, and has had a most useful life. But in a subject so progressive as applied chemistry, twenty-two years are a very long period, and the call for this new edition has been imperative. It is very characteristic of Sir Edward Thorpe's inexhaustible energy and enterprise, that on the eve of his retirement from his official position—a time when most men would be looking for some leisurely occupation he should undertake a task which might daunt the most vigorous of his juniors. We have reason to know that his editorship has been of the most active and real kind. We have heard from many sides of an almost inexhaustible flow of autograph letters of courteous but insistent character, addressed to gentlemen who, in some cases, were looking with unstable resolutions on approaching holidays; and we have seen on proof-sheets the track of the same pen constraining the exuberance of a contributor's verbosity. We feel sure that all chemists will unite in their admiration of Sir Edward Thorpe's achievement, and in acknowledgment of the latest of many great services which he has rendered to his time and generation. We may be permitted to anticipate that on his retirement he will return to the field of scientific biography, where he has accustomed us to look to him for work of such rare excellence.

The new edition of the dictionary is both revised and enlarged, and the five volumes, which are to replace the original four, will evidently constitute, as the editor says, practically a new book. The scope of the work has also been extended so as to include articles on important topics that are not strictly those of applied chemistry.

The list of contributors to the first volume fully justifies the satisfaction which the editor expresses in regard to the collaboration he has secured, and certainly the chief value of a dictionary of applied science must arise from the cooperation of genuine experts who are able and are at liberty to speak from personal knowledge and experience. In the present volume we have this very notably before us. Dr. G. H. Bailey writes on aluminium, Mr. Bertram Blount on cement, Dr. Colman on ammonia, Dr. Hübner on bleaching, Prof. Lewes on acetylene, and Dr. T. K. Rose on assaying. Mr. L. J. Spencer deals with a number of minerals.

Among the organic subjects we have various series of colouring matters dealt with by Prof. W. H. Perkin, Mr. A. G. Perkin, and Dr. Cain. Mr. A. D. Hall writes on cereals, Dr. E. F. Armstrong on bread and carbohydrates, Mr. C. F. Cross on cellulose, Mr. John Heron on brewing, Dr. Lewkowitsch on various oils and fats, and Mr. Stubbs on butter. Prof. Senier treats of a number of drugs, and there are also articles on topics of chemical physiology by Prof. Halliburton, and of agricultural chemistry by Mr. Herbert Ingle.

Germany is represented by Dr. O. N. Witt, who has an article on azines. Miss Beatrice Thomas and Dr. M. A. Whiteley are important lady contributors. Among articles lying a little outside the main current is an admirable one on chemical affinity by Dr. J. C. Philip, whilst the old and valuable article on the balance by the late Prof. Dittmar is reprinted.

Special mention must be made of an article on analysis by Dr. G. T. Morgan, with a supplementary one on electrochemical analysis by Dr. F. M. Perkin. These occupy a hundred pages, and constitute, indeed, an excellent, compact treatise. The only fear is that it may be rather lost in a dictionary, and this is the only important case where the present writer has been struck with any disproportion in the allotment of space.

It is, of course, not to a general dictionary that anyone engaged in a branch of applied chemistry will go for detailed information on his own subject, but it is of great service to have concise and authentic summaries of other people's subjects, and this requirement is admirably met in the work under review. A comparison of the new articles with those of the original edition has convinced the reviewer, in those cases where he is at all competent to form an opinion, that the revision has been thoroughly carried out. Such a comparison gives a vivid impression of the great advances which have been made in chemical industry; see, for example, the manufacture of aluminium and acetylene.

In concluding this notice with renewed congratulations to the editor on his success in producing a most serviceable dictionary, we must allow a word of acknowledgment to the rank and file of workers, who have contributed a vast amount of indispensable information on minor copies. The binding of the book is strong, plain, and apparently durable; the edges of the leaves are coloured with the lurid pigment usually indicative of specially pious literature. Perhaps, however, it will mellow rapidly in chemical surroundings. S.

AGRICULTURE IN THE SCHOOL AND AFTERWARDS.

Beginnings in Agriculture. By Albert R. Mann. Pp. xii + 341. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1911.) Price 5*s.* 6*d.* net.

Dairy Cattle and Milk Production. Prepared for the use of Agricultural College Students and Dairy Farmers. By Prof. Clarence H. Eckles. Pp. xii + 342. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1911.) Price 7*s.* net.

IT is universally agreed by all who have considered the subject that the education of the child ought to have some relation to the surroundings among which its life will be passed, and that, in consequence, the education of the country school should be directly connected with country life and the great rural industry. In America this principle has long since been translated into practice—how completely is best seen by the flood of agricultural books issuing each year from the publishing houses—and we have in the first of these volumes an illustration of how it was done in a particular case.

Wherever reformers have tried to make rural education fit country life, the question has sooner or later cropped up: Ought agriculture to be taught in schools? and this speedily raises another: Can agriculture be taught in schools? Mr. Mann's little book is a serious attempt to show that a great deal can be done to educate the American child through the experience that it has, or can easily get, of farm life, and, further, that the thing can be done without doing any violence to the exigencies of village school conditions or assuming too much from the teacher. That he has achieved a certain measure of success is undeniable; how much can only be ascertained by actual use in a school.

Setting out with the assumption, probable enough throughout wide areas of the western States, that the child is a member of a new community the older members of which broke up the prairie, the author begins with a history of a typical community and shows the interdependence of the various sections. But of all the members the farmer is the most important, because he is the producer of food and of clothing material. Hence farming is an honourable occupation; it has, besides, many collateral advantages over other professions. But if it is to be done properly it must be well organised. The farm should be laid out so that the farmer will lose little time in getting to his work, and can take full advantage of natural features specially adapted to any particular treatment. Further, the farm should be attractive and beautiful, with a "neat and picked-up appearance," to use the author's expressive Western phrase. So much for generalities; the author then passes on to deal with the special factors in agriculture, the farm plants, the soil, and the animals. Liberal use is made of photographs, and at the end of each chapter a number of problems are set for the scholars to work out, some arithmetical, some observational, and some experimental. Thus the child is taught to observe and to think—in other words, he is educated—and at the same time he learns to think in terms of country things and acquires a stock of knowledge that cannot fail to be helpful to him afterwards. He is shown that country life and country work are interesting, and he has their other attractive features put before him in a very pleasing way.

The book will prove interesting to educationists in this country who are seriously studying our rural educational problems, and it will be appreciated most by those who have some knowledge of the American child, with its strangely serious outlook on life and its premature realisation of its responsibilities.

Prof. Eckles's book on dairy cattle deals with a specialised branch of agriculture in a manner well suited to the requirements of the advanced student. The animals described in detail are Holsteins, Jerseys and Guernseys, Ayrshires, and Brown Swiss as pure dairy cows, and Shorthorns as dual-purpose cows. A short but sufficient history of the breed is followed by an account of its chief characteristics and typical requirements. Photographs of good pedigree animals are given, and finally a score card is set out showing the number of marks to be allotted to each of the various points in estimating relative values. This feature is specially useful. The score card is a well-recognised method of instruction in the States, where it has repeatedly justified itself by its results; one or two teachers of agriculture have adopted it in this country also, and wherever it has been tried it has been found advantageous. Anything, therefore, that popularises so useful an instrument is to be commended.

A good deal of attention is devoted to feeding. The author considers it safe to say that "the yearly average milk production per cow could be increased one-half or three-fourths by following better methods of feeding." The importance of sufficient food is emphasised, but the author might have dealt even more fully with this point. As the dairy industry advances, cowkeepers increase their rations, until, in districts where the industry is very highly developed, as in many parts of the home counties, they tend to give too much food for *profitable* milk production.

It has been shown by experiment that an increase in the quantity of the ration leads to an increased production of milk, but the return obtained per unit of food becomes less and less, and finally is not worth as much as the food costs.

The great difficulty about dairy farming in the States seems to be the labour supply. "The special objections raised to the labour on the dairy farm are the long hours, the steady, regular work, and the nature of the work." The same difficulty is felt in British agriculture, and to meet it machinery is being invented. Strenuous efforts are being made to perfect the cow-milking machine, which will considerably ease matters.

E. J. RUSSELL.

ALGEBRAIC NUMBERS.

The Elements of the Theory of Algebraic Numbers. By Prof. L. W. Reid. With an introduction by Prof. D. Hilbert. Pp. xix + 454. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1910.) Price 15*s.* net.

IT is almost a misfortune that Gauss and Smith were such consummate masters of mathematical style. Nearly everyone who writes on an arithmetical topic is tempted to imitate them, at least in their brevity and severe deductive method, and the result is that many are frightened away from a delightful study because of its dry, and, so to speak, inaccessible aspect.

Prof. Reid's book ought to do much to remove this misapprehension; he has assumed no previous knowledge of the subject beyond elementary arithmetic, and he has been careful to give a very large number of special examples, as well as discussions of special fields. Thus the reader is able to see, much more than is usually possible, the really inductive character of arithmetical research, and is provided with material on which he may make experiments of his own.

As an introduction to the general theory of algebraic numbers, the work follows mainly the treatment of Hilbert and Dedekind; the principal difference from the latter being that, for instance in a quadratic field, an ideal (α, β) is (ultimately) defined as the aggregate of integers $\lambda\alpha + \mu\beta$, where λ, μ are any two integers in the field, and α, β are given integers therein. This saves a good deal of rather delicate reasoning, necessary if Dedekind's own definition of an ideal is adopted, and detracts little, if anything, from the naturalness of the sequence of theorems.

After four chapters dealing with the ordinary rational theory (including the law of quadratic reciprocity), we have four others, each devoted to a special quadratic field, namely, those derived from $\sqrt{-1}$, $\sqrt{-3}$, $\sqrt{2}$, $\sqrt{-5}$ respectively. In the last of these it is made perfectly clear how the law of resolution into prime factors appears to break down, and how it is restored by the introduction of ideals. Moreover, examples are given to show the distinction, in this field, between principal and non-principal ideals.

The next four chapters give general theorems on algebraic numbers, a discussion of the general quadratic field, its discriminant and ideals, and the theory of congruences with respect to ideal moduli in such a field.

Finally, there are two chapters, of a rather more advanced kind, on the units of the general quadratic field, and on the number of its ideal classes. In the latter use is made of Minkowski's remarkable theorem that every ideal class contains an element whose norm does not exceed $|\sqrt{d}|$, where d is the discriminant of the field. Prof. Reid has elsewhere published a list of classes of cubic fields calculated on the same principle; but the work is tentative and laborious, and it is still a desideratum, even for cubic fields, to determine, by some simple method, the fundamental units and representatives of each ideal class. Fortunately, however, in working with an ideal, any one of its forms will do in using it as a modulus, finding its prime factors, and so on: just as (6, 9) or (6, 9, 27) define 3 (as a greatest common measure) just as well as 3 itself for purposes of this kind.

It is very gratifying to see that the higher arithmetic is attracting more and more attention, and it is certain that books like Prof. Reid's will greatly help to popularise "the queen of the sciences," as Gauss so affectionately called it.

G. B. M.

A HISTORY OF EUROPEAN CULTIVATED PLANTS AND DOMESTIC ANIMALS.

Kulturpflanzen und Haustiere in ihrem Uebergang aus Asien nach Griechenland und Italien sowie in das übrige Europa. Historisch-linguistische Skizzen von Victor Hehn. Achte Auflage. Neu herausgegeben von O. Schrader. Mit botanischen Beiträgen von A. Engler und F. Pax. Pp. xxviii + 665. (Berlin: Gebrüder Borntraeger, 1911.) Price 17 marks.

VICTOR HEHN'S book, the result of years of labour, first appeared in 1870. A second edition was called for in 1874, to which the essay on the horse was added, and in which replies to critics fill most of the preface. A third edition was issued in 1877, a fourth in 1883, and a fifth in 1887. Hehn died on March 21, 1890, leaving his book in the hands of Prof. O. Schrader, editor-in-chief of the three editions which have appeared since that date.

The work opens with a long extract from the preface to the sixth edition, from which the above particulars have been taken. In nearly a quarter of a century (1870–94) knowledge had increased greatly, and many additions and corrections were necessary. Herr Schrader addressed himself to his task on the lines laid down by De Candolle. To cope with the botanical work became the duty of Prof. Engler, assisted later by Prof. Pax, of Breslau. With regard to the sections treating of domestic animals, the editor called in the help of Prof. A. Nehrings. The general revision and philology were Prof. Schrader's special care; but he is very ready to acknowledge help received from Dr. Kurt Muller, Dr. Hugo Prinz, and others.

All additions and corrections are placed, in small type, at the end of each essay. The adoption of this plan was no doubt due to respect for Hehn's work. Even then the method is a bad one, and the present writer cannot see anything in Hehn's original text to warrant such respect. To a reader coming fresh to the book it is somewhat irritating, and causes waste of time. The writer of this notice worked carefully through the essay on the horse, making critical notes, only to find that the editors had made all necessary corrections in their notes placed at the end of the section. Articles dealing with domestic animals are scattered about among those dealing with cultivated plants. No fewer than ninety-nine pages are occupied by original "notes"—pp. 531–629. This adds another drawback to the work. Either the reader must turn away from the page to the "note" at once, breaking the thread of attention, or the "notes" must be left to be read later, when it may easily happen that the point referred to is not clearly remembered. The book contains a good table of contents and a satisfactory index.

In the introduction we get a record of the good and harm that man may work upon virgin soil. The early Aryan invasion found Greece thickly forested and with a fruitful soil. Much harm was subsequently done by exhaustive cultivation and destruction of forest. Such ruined areas recovered partly when deserted, often to pass through similar stages as is recorded by Fraas, in 1847, of parts of the peninsula. About one hundred cultivated plants are dealt with, the most important being the vine, olive, fig, citrons, plums, almonds, flax, hemp, maize, rice, and tobacco. Of the domestic animals—a more limited class—an almost complete account is given. In the original text, and in all subsequent additions, the authority for borrowed statements is given with scrupulous care. If genius is taking pains—a definition ascribed to Sir Isaac Newton—Victor Hehn was a genius. That his work needed correction as the years went by is to be expected. The work has been well done, and the line quoted by Prof. Schrader is well applied:—

"Was fruchtbar ist, allein ist wahr."—Goethe."

J. H. T. W.

GENERAL SCIENCE.

Introduction to General Science, with Experiments. By Percy E. Rowell. Pp. xxix+302. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1911.) Price 3s. 6d. net.

THE author of this book has a great belief in what he calls general science, which apparently amounts to a slight knowledge of many sciences. A pupil who knows a little about a great many subjects will, he considers, be able to obtain a bird's-eye view of the whole ground of knowledge, and to reason from many points of view on the phenomenon of nature. Further, a general course of this kind should reach every pupil somewhere and stimulate his ambition to learn more of at least one subject. Thus in the three hundred or so pages of this little volume we find sections devoted to almost all known sciences, illustrated by 100 experiments, with cross references to a large number of textbooks and bulletins.

To say that the book is sketchy, incomplete, and not infrequently inaccurate is to make an obvious criticism applicable to any book of this kind. At the same time one must feel sympathy with the object of the author and admiration for his courage in tackling so formidable a list of subjects and writing about them. He usually confines himself to applications of science to the common things of daily life, and does not concern himself with great generalisations. A few experiments on combustion thus lead to oxygen, then to fuels, and so by easy transitions to blasting, animal heat, flames, first aid to the burnt, sterilisation, disinfectants, &c., throughout the book. Indeed, as the author says with some pride, the course may be commenced anywhere, and it will always lead to a study of all science. The only danger the author sees is that the teacher may specialise in some particular part that he likes and knows something about; unless this temptation is resisted the course ceases to be general. In order that the pupil should be kept up-to-date, he must be urged to get the "bulletin habit," and to obtain as fast as they appear the very numerous publications of the Department of Agriculture.

Reaction was bound to set in sooner or later against the specialisation that has of late years characterised science teaching in many schools, and the book before us is one of the fruits of this reaction. Whilst we do not think that the author has found the final solution of the difficulties connected with the problem, we distinctly like his plan of utilising the experience of the child for all it is worth in the science course.

OUR BOOKSHELF.

South African Zoology. A Text Book for the use of Students, Teachers, and Others in South Africa. By Prof. J. D. F. Gilchrist. Pp. xi+323. (Cape Town and Pretoria: T. Maskew Miller. Pietermaritzburg and Durban: P. Davis & Sons, n.d.) Price 10s. 6d. net

The object of this book, as stated in the preface, is "to give illustrations of the South African fauna with special reference to the more familiar forms, for the benefit of students of nature study, as well as the agriculturalist." Dr. Gilchrist, therefore, has a fine opportunity of replacing the hackneyed examples that have done duty so long in zoological teaching by Ethiopian types. In this, however, the book is disappointing. The European *Rana temporaria*, *Hydra*, *Bougainvillea*, *Aurelia*, the liver-fluke, the beef tapeworm, the common *Lumbricus terrestris*, the cockroach, the snail *Helix aspersa*, the dogfish, rabbit, and pigeon are once again employed for descriptive purposes.

It is a more pleasing task to point out the share devoted to African animals in this work. The section upon insects is in this respect the best in the book, the accounts of the locusts, termites, and ants being particularly interesting. The ticks are briefly considered, but the spiders are summarily dismissed. An African crawfish, Palinurus, is described as an introduction to the Crustacea. The life-histories of certain African parasitic Protozoa are also given. The African vertebrates, however, are only briefly referred to; the antelopes, for example, are not described, though their distribution is given. Incidentally, a number of interesting points are mentioned, *e.g.*, the use of the ascidian Polycarpa as a bait in seafishing, the habits of th rain-frog in burrowing into the nests of ants and termites, and the almost entire absence of eels from the westerly-flowing rivers.

More bionomical information would have been valuable. For example, we are not told anything about the habits of African Annelids, whereas the introduced forms are referred to at some length. Dr. Gilchrist's experience as an officer of the South African Fisheries investigations must have made the marine fauna of the Cape very familiar to him, but we are unable to form any picture of the common objects of the Cape shores. The book has been carefully revised, but the irritating forms "Rhodent" and "Rhodentia" are surely an oversight. An excellent index has been compiled for this work, which is illustrated throughout.

Physiology. By Prof. W. D. Halliburton, F.R.S. (Dent's Scientific Primers. Edited by Dr. J. Reynolds Green, F.R.S.) Pp. xi+176. (London: J. M. Dent and Sons, Ltd., n.d.) Price 1s. net.

In this volume Prof. W. D. Halliburton "aims at presenting the main facts of modern physiology in an elementary way and in language as free from technical terms as possible." In a sense, he has succeeded in this aim. The facts are nearly all there, crowded into 167 pages of excellent and not very small type, with many illustrations, and the language is not obtrusively technical but has an appearance of simplicity. Technical language, however, is a species of shorthand, and in compressing into so small a space without its aid all that Prof. Halliburton considers main facts, there is an inevitable loss of real intelligibility. Without some rigorous selection a book of this size tends to become a succession of statements hardly assimilable by a mind not previously acquainted with the subject, and so of little educational value. Yet the work is obviously intended for students extremely junior, not so much in age as in knowledge. It is not, indeed, quite obvious what public the author seeks to reach, but perhaps we may be guided by such remarks as those on the "need for diligent use of the tooth-brush, . . . tooth-powders are not to be recommended," and "it is hardly necessary for me to preach to readers the necessity for temperance in the use of alcohol." The complete absence of any reference to the reproductive system of either sex—a remarkable omission in a scientific primer on physiology—may perhaps be also taken as an indication that here we have "popular" science of a familiar kind.

Colour-Music. The Art of Mobile Colour. By Prof. A. Wallace Rimington. Prefatory Notes by Sir Hubert von Herkomer, M.V.O., and Dr. W. Brown. Pp. xx+185. (London: Hutchinson and Co., 1911.) Price 6s.

It is difficult to give a fair impression of the value of this book. Its author obviously lacks scientific training (hence the inclusion of a chapter "on some scientific opinions") and adequate knowledge of the "laws" of colour mixture; he fails to describe the apparatus and the methods he employs with sufficient detail; his acquaintance with the psychology of æsthetics is defective; the analogies which he presses between tones and colours are unsound. Yet, despite these manifest shortcomings, the book is to be welcomed as the sincere attempt of an enthusiast, who has spent much time and money on his hobby, to give the world some idea of its interest and of its value. No doubt, seeing is here verily believing; but it is easily imaginable, as Sir Hubert von Herkomer states, that to sit at the author's "instrument and improvise for half an hour whilst watching the ever-varying combinations of colour on the screen produced by the playing is not only an unspeakable delight, but of real health-giving effect on the sense of colour." Apart from his absurd division of spectral colours on the basis of our musical scale, "the main advantages of colour-music as an art" would, as the author rightly says, "remain unaffected, and the force of the chief arguments, which can be advanced in support of it as a separate and distinct art, would not be weakened in the least." It is, as we have said, impossible to describe such æsthetic enjoyment; one must experience it. C. S. M.

Annals of the Royal Botanic Garden, Calcutta. Vol. xii., Part i.:—"Asiatic Palms—Lepidocaryeæ." By Dr. Odoardo Beccari. Part ii.:—"The Species of Dæmonorops." Vol. i., Letterpress. Pp. vii+237. Price Rs. 8 or 12*s.* Vol. ii., Plates. Pp. vii+109 plates. Price Rs. 39 or 2*l.* 18*s.* (Calcutta: Printed at the Bengal Secretariat Press, 1911.)

The appearance of the first portion of Dr. Beccari's monographic account of the Asiatic Lepidocaryeæ, devoted to the genus Calamus, was recorded in Nature of August 12, 1909. It affords us pleasure to announce now the appearance of a second instalment of this great work, dealing with the genus Dæmonorops, which, like Calamus itself, consists of "Rotangs," and, among the genera of Palmeæ, is only less important than Calamus because it includes a smaller number of recognisable forms.

The methods and the style adopted in the treatment of the previous genus have been followed in the case of Dæmonorops. These have already been noticed in detail, and, therefore, do not require further discussion. The ample descriptions and excellent illustrations are equal in merit to those in the earlier contribution, and this further instalment of the author's monograph places systematic students once more under a great obligation to him and to the Calcutta Botanic Garden, of the "Annals" of which it forms part. All who are interested in palms will look forward with interest to the conclusion of the task on which Dr. Beccari is engaged, and to which, as the two contributions already at our disposal testify, he has devoted himself with such patient enthusiasm and so great a fund of accurate knowledge.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

The Principle of Reflection in Spectroscopes.

The application of a reflector to pass light back through a prism, or prisms, is usually ascribed to Littrow. Thus Kayser writes ("Handbuch der Spectroscopie," Bd. I., p. 513), "Der Erste, der Rückkehr der Strahlen zur Steigerung der Dispersion verwandte, war Littrow" (O. v. Littrow, *Wien Ber.*, 47, ii., pp. 26–32, 1863). But this was certainly not the first use of the method. I learned it myself from Maxwell (Phil. Trans., vol. 150, p. 78, 1860), who says, "The principle of reflecting light, so as to pass twice through the same prism, was employed by me in an instrument for combining colours made in 1856, and a reflecting instrument for observing the spectrum has been constructed by M. Porro."

I have not been able to find the reference to Porro; but it would seem that both Maxwell and Porro antedated Littrow. As to the advantages of the method there can be no doubt. Rayleigh.

Acquired Characters and Stimuli.

In my letter in Nature of March 21, I pointed out the fact that Dr. Archdall Reid does harm by declaring that the term "acquired characters" as ordinarily used by biologists is not intelligible (is, in fact, nonsensical), giving as his reason that all characters are acquired. That is a "quibble," because the term used by Lamarck (which has been translated as "acquired characters") is "changements acquis," and it is abundantly clear that the *change* spoken of by Lamarck is a change from the normal characters of a wild species. Such normal characters may be, of course, described as "acquired" when considered in comparison with those of the germ from which an individual develops. But that is not the comparison made by Lamarck or by anyone else who uses his term or the English modification of it, and it is a perversion of fact to pretend that it is. It is the plain fact that the *acquired changes* indicated by Lamarck are *changes* as compared with the *normal characters* of the species. There was no allusion in my letter to the terms "innate characters" or "congenital characters." They, of course (as Dr. Reid says), do not mean the same thing as "congenital variation." Dr. Reid in condemning them is beating a mannikin dragged in by himself, diverting attention from the matter in hand. The "acquired changes" or "acquired characters" of Lamarck are properly contrasted with normal characters and not with Dr. Reid's imaginary congenital characters. Considerations as to whether the blacksmith's arm or that of an ordinary man is "normal" are not to the point, since Lamarck was concerned with wild species of plants and animals, of which the "normal specific form" and the "normal specific environment" are understood and known in some detail.

Nor is Dr. Reid justified in attempting to limit the influences under which "acquired changes" or departures from normal specific form are developed to "use and injury." A variety of factors of the environment, not to be described as use or injury, but broadly classed as excess or defect of heat, light, strain, moisture, chemical constituents of food, may set up in an organism changes of growth, structure, and function of the most striking and obvious character, greatly in excess of the apparent magnitude of the responsible factor. Take, for instance, such cases as that of the rest-harrow grown in dry upland as contrasted with that grown in moist meadowland.

I also objected (and do so again) to the loose use of the word "stimulus" in this connection by Dr. Reid. A particular, definite, measurable agent setting up by its action on living matter a reaction is, in biological terminology, said to stimulate that living matter, and both it and its immediate action are called "a stimulus." The exact nature of the stimulating activity, whether set up by this or that chemical substance, by this or that fluctuation of light, heat, or by electrical conditions, is stated with precision, and its amount and duration compared with the effect on the living matter. To call the nutrition—the normal, persistent nutrition of a growing seed or young plant—"a stimulus" is inadequate and misleading. A good deal of analysis is omitted by so doing. When nutrition, the necessary normal supply of chemical materials in the presence of which a seedling grows and unfolds or develops its specific qualities, is described baldly as "a stimulus," whilst a slicing cut, removing a man's ear and leaving a growth of scar tissue in its place, is also dismissed as "a stimulus," it is obvious that two things profoundly different in character and importance are confused under a common heading. The first is the absolutely essential and widely distributed condition for the continued existence of a living thing; the second is exceptional—an abrupt change with correspondingly exceptional result. Neither is correctly described as "a stimulus," though many stimuli of different nature occur in connection with both.

Dr. Reid says he will admit that he is quibbling about the meaning of the term "acquired characters" if I will indicate how an inborn trait is more inborn and less acquired than an acquirement. The term "inborn trait" has nothing to do with the matter, as I have explained above. The words "change" and "acquire" imply an existing standard *from* which there is change or *to* which there is addition. The fact that the standard is itself an acquirement when viewed in relation to another phenomenon, namely, a reproductive germ, is irrelevant.

Dr. Reid quotes passages from Wallace, Weismann, and Romanes which do not treat of the matter under discussion, and suggests that he "sins with them," and that they agree with his forced interpretation of the term "acquired characters." The suggestion seems to me to be devoid of justification.

Chiefly, however, I object to Dr. Reid's stating that I have called this "a historical discussion," implying that I attach historical importance to it. I have used no such words. This statement by Dr. Reid is erroneous, as is also his attribution to me of certain opinions about the muscular development of an ordinary individual and of a blacksmith. He says, "Sir Ray Lankester regards the former as normal and *therefore* inborn and inheritable, and the latter as abnormal and *therefore* acquired and non-inheritable." This is entirely imaginary. I never wrote a word on the subject of muscular development, nor have I stated that abnormal qualities are necessarily acquired and non-inheritable, or anything of the kind. I do not desire to continue a discussion in which fictitious words and opinions are attributed to me. Nor do I desire to obtain any "admission" from Dr. Reid. I am content to leave the matter to the judgment of your readers.

April 5. E. Ray Lankester.

Clouds and Shadows.

On the evening of Easter Monday I noticed in the western sky an effect which was unlike anything I had ever seen before. The sun was just setting behind a great bank of cloud, the rest of the sky being fairly clear, except for a thin veil of alto-stratus (it was not very high), which was moving at a good rate from the north-west, and stretched across the whole sky. This stratus was scarcely noticeable at first, as the sun's rays shining through it produced a milky kind of light in the sky. In startling contrast to this there appeared about halfway between the horizon and the zenith, to the south-west, what looked like an extraordinary "cloud," which compelled attention. It was obvious, however, that this was no cloud, as it remained quite stationary, while the stratus (which I now observed) and also a few small lower clouds were driven quickly across the sky.

I became greatly interested in the phenomenon, and watched it closely for half an hour or more, and the impression I got was that the apparent cloud was really a heavy shadow, cast upon the otherwise brightly illumined stratus by some unseen object away in the west, which was intercepting the sun's rays. The "dark patch" varied in shape and size, expanding and contracting, but preserving on the whole a shape somewhat like a fan, and keeping the same position in the sky.

After a time I noticed an exactly similar effect growing into shape, halfway between the first one and the point where the sun had set, so that a line drawn through them from the sun would be at an angle of about 45° with the horizon.

I made notes and rough sketches at the time, and could give more complete details as to the conditions existing, and the varying shapes and positions of the dark "shadows." It may be that this effect is not uncommon, and is easily accounted for; but although I have studied the skies for many years I have never before seen anything like it, and I feel confident that it must have been, at any rate, unusual.

While freely confessing ignorance of any scientific knowledge on such matters, I should be very glad to be enlightened as to the explanation of the phenomenon, and also to hear whether anyone else noticed the occurrence.

Chas. Tilden Smith.

"Chisbury," Little Bedwyn, Wilts, April 15.

Winter in India.

I notice that in Nature of February 15 your reviewer quotes without comment a passage from "Freshwater Sponges, Hydroids and Polyzoa" (Fauna of British India Series) which implies that winter in India is the *driest time* of the year as well as the coolest. This must be a slip on the part of the author. Not only is there a considerable quantity of water in rivers, tanks, and pools in winter compared with the spring and early summer, but the relative humidity is very much higher. In cases where I have collected figures the mean relative humidity is at about the average of the whole year in December and January, and then drops continually up to the first half of May, but it would doubtless vary in different parts of the country. H. H. H.

Camp, Central Provinces.

RECENT RESEARCHES ON CAST IRON.[1]

THE volume before us is an able work, containing much original matter, in which an attempt is made with considerable success to reconcile the theory of the physical chemist with the practice of the scientific metallurgist. The author is obviously impressed with the broad reality of the iron-carbon equilibrium diagram. No doubt this has some value, but its teachings are very limited from a practical point of view. For instance, the area usually marked in such diagrams "martensite," instead of "hardenite," gives no indication that steel quenched at the

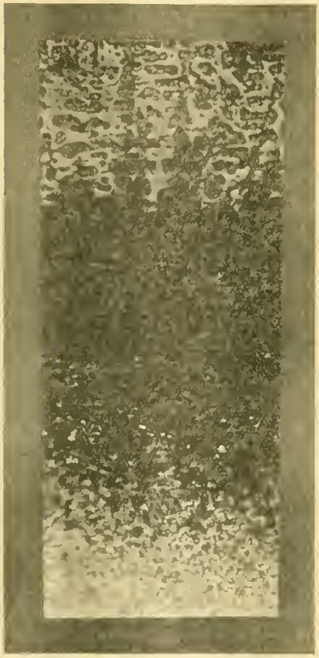

Fig. 1.—Stages of decarburisation of white iron by iron ore. Magnified 150 diameters. Etched HNO_3.

lower end of the range is good, and at the upper end worthless, a matter of some little importance to the steel maker.

The influences of various ordinary elements on cast iron, viz., silicon, manganese, sulphur, and phosphorus, are very well dealt with. The influence of more rarely present elements, such as vanadium, chromium, titanium, is also considered.

In his treatment of malleable cast iron, the author, as one of our ablest authorities on the subject, is naturally at home, and publishes many original and interesting photo-micrographs. It is clear that the author's experiments in the higher ranges of the iron-carbon diagram have led him to the conclusion, long held by many steel metallurgists, that the carbon at high temperatures is in solution as carbide, and not in the free state. A section is devoted to a consideration of the "growth" of cast iron.

The appendices contain a well-expressed series of definitions and a useful set of typical analyses of cast and malleable cast irons. All makers of such products should study this excellent book.

A figure showing micrographically the stages of decarburisation of white iron is here reproduced (Fig. 1). Another figure (Fig. 2) reproduces an excellent photo-micrograph (lent to the author by Wüst) of a 1·76 per cent. carbon steel quenched from 1130° C.

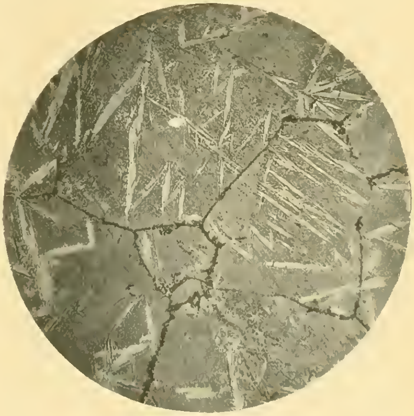

Fig. 2.—1·76 per cent. carbon steel quenched from 1130° C. Etched. Magnified 200 diameters.

In view of the experimental facts contained in the advance copy of a paper to be read at the Iron and Steel Institute in May, 1912, the author's views on the influence of allotropy on the hardening of steel will require revision in any future edition.

J. O. Arnold.

THE INTERNATIONAL CONGRESS OF AMERICANISTS.

THE eighteenth session of the International Congress of Americanists will be held in London, with Sir C. R. Markham as President, from May 27 to June 1 of the present year, at the Imperial Institute, South Kensington. The object of the Congress is to promote scientific inquiry into the history of both Americas and of their inhabitants. It will be divided into six sections—Palæoanthropology, Physical Anthropology, Linguistics, Ethnology and Archæology, General Ethnology, and Colonial History. This meeting, which has been organised under the invitation of the Royal Anthropological Institute, has already received the patronage of the universities and leading scientific societies both at home and abroad, which will be represented by delegates. The programme of papers already contains contributions from the best known authorities on the history and ethnology of the vast region over which its operations extend. It may be hoped that the many persons interested in prehistoric America will assist in the work of the Congress, and that collectors will contribute specimens of antiquities to the exhibition which will be organised in connection with it.

In view of the approaching Congress, Mr. Harlan J. Smith, superintendent of the Archæological and Ethnological branch of the Geological Survey of Canada, appeals for the aid of trained field-workers in the exploration of the vast number of prehistoric sites in various parts of the Dominion. In one township in Ontario a casual investigation disclosed no fewer than thirty ancient sites, and on the seacoast the kitchen middens are of great extent and interest. Canada at present cannot supply a sufficient staff of trained workers to carry on this survey, and the scheme suggests a promise of interesting scientific work in which some of the younger anthropologists trained in our university schools may be inclined to cooperate.

PROF. EDWARD DIVERS, F.R.S.

WE regret having to record the death of Prof. Edward Divers, F.R.S., which occurred on April 8. Born in London on November 27, 1837, he was educated at the City of London School, at the Royal College of Chemistry, and at Queen's College, Galway. In 1870 he was appointed lecturer on medical jurisprudence at the Middlesex Hospital Medical School, and in 1873 he went to Japan as professor of chemistry in the College of Engineering of the Imperial University at Tokyo, of which he became principal in 1882. He remained in Japan until 1899, when he was made emeritus professor and received the Order of the Sacred Treasure, in addition to that of the Rising Sun, which had been previously conferred upon him.

During the whole period of his active professorship, Dr. Divers alone and in collaboration with a succession of his Japanese students, Shimosé, Shimidzu, Haga, Kawakita, Nakamura, Ogawa, and Hada, was a prolific contributor to chemical science—hyponitrites, the constitution of fulminates, the quantitative separation of tellurium and selenium, the production of hydrosulphides, the constitution of sulphazotised salts, the red sulphur of Japan, hydrocarbon from Japanese petroleum, the composition of Japanese birdlime, the economical preparation of hydroxylamine sulphate, and many other subjects were dealt with in papers published in the Journal of the Chemical Society and the Philosophical Transactions. In 1893 he was elected a Fellow of the Royal Society.

On his return to England, Professor Divers did not cease his activity. He was a Vice-President of the Chemical Society and of the Institute of Chemistry, President of the Chemical section of the British Association, President of the Society of Chemical Industry, and at the time of his death was still serving as the representative of the last-named society on the governing body of the Imperial College of Science and Technology, whilst as late as last year he contributed to the Society of Chemical Industry a lengthy paper on "A modification of Raschig's theory of the Lead-Chamber process."

Prof. Divers married in 1865 Margaret Theresa Fitzgerald, daughter of D. G. Fitzgerald, of Mayfield, Co. Cork, by whom he had one son and two daughters. His son died in early life, and he lost his wife in 1897, shortly before his return from Japan, but his two daughters survive him. A man of fine physique, and, until within the last few months, of splendid health, he appeared to suffer only from defective sight, largely the result of a laboratory explosion, which practically destroyed the sight of his right eye. This accident happened in 1885, but he did not allow it seriously to interfere with his work, though it was painful to others to watch him read or write with the book or paper held within a few inches of his eyes. In public he always felt the disability of being unable to recognise acquaintances that were more than a few feet distant, and this naturally gave him an appearance of reserve. But in small gatherings and among intimate friends he was a delightful companion, genial and humorous, especially pleased to talk about Japan and the Japanese, for everything connected with which he was always most enthusiastically appreciative, ever ready to discuss a chemical problem, and, to the last, keenly interested in chemical progress.

Prof. Divers leaves behind him in England and Japan a host of friends who will long mourn the loss of a very sterling character. He was buried at Brookwood on Thursday last, April 11, and though, in consequence of the Easter holidays, many of his friends were away from home, the Royal Society, the Chemical Society, the Society of Chemical Industry, the Institute of Chemical Industry, and the Institute of Brewing were all represented at his funeral and the memorial service. In addition to the members of his family, the following were present, viz.:—Sir Wm. Tilden, Prof. Emerson Reynolds, Prof. Gowland, Prof. Mondy, Prof. Hodgkinson, Dr. Rudolph Messel, Messrs. Tyrer, Reid, Hemingway, Grant Hooper, Coste, Baker, Cresswell, Pilcher, Carr, and others.

NOTES.

THE appalling disaster to the *Titanic* on Monday morning, by which more than 1300 of the passengers and crew have lost their lives, has brought several scientific subjects into prominence. Such subjects are: the dynamic effects of a mass of 50,000 tons moving at a speed of about 15 knots, the conditions of stability of a vessel built upon the watertight bulkhead system when an extensive injury has been isolated by closing the watertight doors, the beneficent use of wireless telegraphy in summoning assistance to a vessel in distress, and the means of detecting the presence of icebergs at a distance. The *Titanic*, which was making her maiden voyage from Southampton to New York, was the largest vessel in the world, and the most luxuriously equipped. She was installed with Marconi wireless telegraphy instruments having a sphere of influence with a radius of about 500 miles by day and treble this distance by night. The first news was the appeal for help which went throbbing through the æther and was detected by the wireless telegraphy operators on several vessels. The message was: "Have struck an iceberg 41·46 north, 50·14 west. Are badly damaged. Rush aid." This was at 10.25 p.m. on Sunday, New York time (3.25 a.m. Monday, Greenwich time). Several vessels hastened to the place of the disaster, but the nearest ship appears to have been 170 miles distant from the *Titanic* when the message of distress was received, and none of them was able to reach her before she foundered at 2.20 a.m. (New York time) on Monday morning—four hours after the collision with the iceberg. The *Carpathia* reached the *Titanic's* position at daybreak, and found boats and wreckage only. In the boats were 868 survivors of the crew and passengers—mostly women and children—the remainder of the human freight of 2200 souls having found a grave with the vessel in the Atlantic.

No more terrible disaster at sea than this has ever occurred; and that a vessel which was said to have been designed with all the precautions which engineering science can provide should meet with such a calamity on her first voyage is almost unbelievable. It was claimed that the vessel was practically unsinkable, yet she was only able to keep afloat a few hours after crushing against the iceberg. The existence of immense fields of ice and great icebergs, the visible parts of which are only about one-eighth the mass of the portions submerged, constitutes a danger in the North Atlantic against which no satisfactory safeguard has yet been devised. A vessel which represented the best work of science applied to marine engineering has disappeared with its burden of human lives beneath the waters of the Atlantic as the result of a catastrophe which could only have been avoided by following a course south of the danger zone caused by ice. Until science has suggested a practical means of detecting masses of floating ice at a distance sufficiently great to enable vessels to avoid them, and thus prevent calamities such as that which the nation now mourns, it is to be hoped that the steamship track across the Atlantic will be more southerly than that hitherto recognised.

The Memorandum on Naval and Military Aviation issued on April 12 provides for seven aëroplane squadrons of twelve machines each, one airship and kite squadron of two airships and two flights of kites, and one line of communication flying corps workshops—the total number of flyers required being 182 officers and 182 non-commissioned officers. It sounds the death-knell of the airship, in that it specifically states that the only advantage that this type of aircraft possesses over that of heavier-than-air lies in its ability to receive and transmit wireless messages over a large area. "It is hoped, however," says the memorandum, "that means will be found for overcoming difficulties in this respect, and experiments in this direction are now being conducted which give prospects of success." The other scientific aspect of this scheme is the desire to subsidise flying grounds or aërodromes, where safe landing places are available, all over the kingdom in order that cross-country flying—an essential for practice in military work—may be carried out in comfortable circumstances. This practically amounts to mapping out the whole country into air-ways, and from the meteorological point of view is of the greatest importance. From a settled system of cross-country flying, most valuable data will be obtained as to general wind direction and to the existence of "remous," or eddies, and what are now termed "holes in the air." No coordinated information is at present available as to where such aërial phenomena may be expected or as to their actual cause. The whole science in this respect is lamentably deficient, and the *hiati* may be filled up by the system of cross-country flying proposed. It is to be hoped that ample funds will be allotted to this new and important branch of both services, not only for the defences of the country but also on account of increased knowledge of meteorology.

We regret to learn of the death of Mr. A. Lawrence Rotch, director of the Blue Hill Meteorological Observatory, Mass., U.S.A.

The sixth annual meeting of the British Science Guild will be held at 4 p.m. on Friday, May 17, at the Institution of Electrical Engineers, Victoria Embankment, W.C. The dinner will be held on the evening of the same day at Prince's Hall, Piccadilly.

A Reuter message from Mobile, Alabama, U.S.A., states that the captain of a steamer which arrived there on April 10 reports the destruction of thousands of people and a number of Indian villages by an eruption of Chiriqui Peak, near Bocas del Toro, Panama, on April 5.

A course of four lectures on some mathematical subjects will be delivered at the University of London, South Kensington, on May 3, 4, 10, and 11, by Prof. Henri Poincaré, professor of mathematical astronomy in the University of Paris. Two of the lectures will deal with the philosophical aspects of mathematics, one with a subject in pure mathematics, and one with a subject in applied mathematics. Further information and tickets of admission may be obtained on application to the Academic Registrar, University of London, South Kensington, S.W.

The Board of Agriculture and Fisheries has been informed that the Lords Commissioners of his Majesty's Treasury, on the recommendation of the Development Commissioners, have sanctioned the payment from the Development Fund of a sum of 2,500*l*. per annum for three years to be distributed by the Board as grants to certain institutions in England and Wales to enable them to supply technical advice to landowners and others interested in forestry. Owing to inadequate resources, institutions possessing forestry departments have hitherto restricted their attention for the most part to imparting instruction to students. It is now proposed to attach an experienced forest expert to the forestry departments of two universities and three colleges, whose chief duty will be to supply to landowners and others advice as to the general and detailed working of their woods. Each institution will, therefore, become for a given district a centre for information, to which application may be made on all questions relating to the formation, treatment, utilisation, and protection of woods.

The annual meeting of the Iron and Steel Institute will be held at the Institution of Civil Engineers, Westminster, on May 9 and 10, commencing each day at 10.30 a.m. At the morning meeting on the first day, the retiring president, the Duke of Devonshire, will induct into the chair the president-elect, Mr. Arthur Cooper; the Bessemer gold medal for 1912 will be presented to Mr. J. H. Darby; and the president will deliver his inaugural address. On the morning of May 10, the Andrew Carnegie gold medal for 1911 will be presented to Dr. P. Goerens, of Aachen, and the award of research scholarships for the current year will be announced. Among the papers to be read and discussed during the meeting the following may be mentioned:—Dr. J. O. Arnold will deal with the chemical and mechanical relations of iron, vanadium, and carbon; Sir Hugh Bell, Bart., will described a bloom of Roman iron from Corstopitum (Corbridge); Mr. C. Chappell will discuss the influence of carbon on corrosion; and Dr. J. N. Friend, J. L. Bentley, and W. West the corrosion of nickel, chromium, and nickel-chromium steels and the mechanism of corrosion. Sir Robert A. Hadfield, F.R.S., will describe Sinhalese iron and steel of ancient origin, and Dr. H. Nathusius, of Friedenshütte, Upper Silesia, the improvements in electric steel furnaces and their application in the manufacture of steel.

In the House of Commons on April 10 Mr. Lewis Harcourt, Colonial Secretary, announced that the terms of reference to the Royal Commission on the Trade Resources of the Empire are as follows:—To inquire into and report upon the natural resources of the Dominion of Canada, the Commonwealth of Australia, the Dominion of New Zealand, the Union of South Africa, and the Colony of Newfoundland; and, further, to report upon the development of such resources, whether attained or attainable; upon the facilities which exist or may be created for the production, manufacture, and distribution of all articles of commerce in those parts of the Empire; upon the requirements of each such part and of the United Kingdom in the matter of food and raw materials, and the available sources of such; upon the trade of each such part of the Empire with the other parts, with the United Kingdom, and with the rest of the world; upon the extent, if any, to which the mutual trade of the several parts of the Empire has been or is being affected beneficially or otherwise by the laws now in force, other than fiscal laws, and, generally, to suggest any methods, consistent always with the existing fiscal policy of each part of the Empire, by which the trade of each part with the others and with the United Kingdom might be improved and extended.

We record with regret the death on April 12 of Dr. William Ogle, a distinguished statistician and physician, in his eighty-fifth year. He held the office of superintendent of statistics in the department of the Registrar-General of Births, Deaths, and Marriages for England and Wales from 1880 to 1903, in succession to Dr. William Farr. In that capacity he continued the practice of his predecessor by contributing to every annual report of the Registrar-General a memoir on some subject of interest arising out of his researches. He became a member of the Statistical Society in 1885, served on its council, and contributed papers on the alleged depopulation of the rural districts of England, on marriage rates and marriage ages with reference to the growth of population, and on the trustworthiness of the old bills of mortality. In 1891 the well-deserved compliment was paid to him of election to the Athenæum under rule 2 of that club, as distinguished in science and for his public services. He was also a member of the Institut International de Statistique. His services to medical science as secretary of the Royal Medical and Chirurgical Society, lecturer and physician at St. George's Hospital, medical officer of health, and in other positions, were conspicuous, and he contributed to medical literature translations of Aristotle and other works. He belonged to a medical family, being a son of the Regius professor of medicine at Oxford. There he took the degree of M.D. He became a fellow of the Royal College of Physicians in 1866. In official, scientific, and academic circles he was highly esteemed, and many friends will mourn his loss.

In the January-February issue of *L'Anthropologie* MM. Breuil and Obermaier contribute an account of the operations of L'Institut de Paléontologie Humaine, recently founded by that enthusiastic student of the sciences, Prince Albert I. of Monaco. Its work is at present largely devoted to an exploration of those caves in the Spanish peninsula which were occupied by primitive man. That at Valle, in the province of Santander, has produced some harpoons of the Azilian and Magdalenian periods, and a bone engraved with a group of horses. From the Hornos de la Peña cave we have a frontal bone of a horse, with a drawing of that animal. The newly discovered cave containing frescoes at La Pasiéga supplies drawings of a stag and a chamois. Of special interest are the sketches of primitive hunters pursuing stags with their bows and arrows, and some rudely conventional representations of human beings from caves in Almeria, Andalusia, and Murcia. The Institute founded by Prince Albert has thus undertaken a wide scheme of exploration which is sure to supply material of the highest importance to students of primitive man.

M. J. Dechelette, in *L'Anthropologie* for January-February, suggests a new interpretation of the origin of the spiral carvings at the grave-mounds of New Grange and Gavr Inis, which Mr. G. Coffey and other British authorities recognise to be an extension of the great Ægean spiral motive which passed through a large part of Europe in the early Bronze age. M. Dechelette now endeavours to trace the pattern through seven types: tattooed images of the Mother goddess of the Ægean area, and figurines from the second stratum at Hissarlik; anthropomorphic pillars from Fivizzano in Italy; Sardinian menhirs; plaques from the Iberian peninsula; menhirs and cave sculptures, with fragments of vases, from France; cylinders from Folkton Wold in Yorkshire; and Scandinavian vases. This essay, which is well provided with figured representations of the assumed transitional types, is sure to furnish material for discussion. The art student will probably desire more evidence of the approximation of these motives in their original home, the Ægean area, whence, whatever the exact source may be, the type was certainly derived.

In the April issue of *Man* Mr. Harold Peake describes an elaborate scheme for an anthropological survey of the British Isles. It is intended to include not only the physical types from which the existing population has been derived, but extends to all forms of human activity, both in the past and at the present day. It is proposed, as part of the project, to compile a series of maps showing the course of distribution of trade articles in prehistoric times—bronze celts, amber, pigs of lead, and the like—with the position of the mines of gold, copper, and tin known to the ancients. In order to afford facilities for comparing the culture of the past with that of the present, he suggests the preparation of maps showing soil and vegetation, the distribution of woodland and marsh, the mineral supply, the distribution of the Neolithic people, the early centres of metallurgy, and the movements of invading tribes. As regards existing facts, we need surveys of the density of the present population and its economic conditions, such as the prevalence of lunacy, poverty, and crime. He proposes to initiate this elaborate scheme through a central bureau working in cooperation with field clubs, county museums, and the like. There can be no question that such material, if collected in a scientific way, would be of great service; but it needs an amount of cooperation between the unorganised body of workers which, for the present at least, is not within the range of practical politics.

Mr. H. Habenicht of Gotha, in a pamphlet on "Die antediluvianischen Oasen bei Taubach und Tonna," attributes the occurrence of northern erratics in the Thüringian loess to catastrophic flooding, which took place at the close of the steppe-epoch that followed on the first extension of the continental ice. A picturesque detail is drawn from the fossil birds' eggs in the Taubach tufa; the flood broke across Thüringia "on a fine day of early summer." This overflow, however, was general, owing to a sudden subsidence, and the mammoth—its hairy covering notwithstanding—is said to have been thus transported northwards. The damp atmosphere, checking the sun's rays, is held responsible for the second extension of the ice. The author, however, does not hope for general sympathy in his revival of the belief in a universal deluge.

Last year the Marine Biological Station at St. Diego celebrated the twentieth anniversary of the movement that led to its foundation, and advantage was taken of the occasion to publish an account of its rise, progress, and future. This has been drawn up by Mr. W. E. Ritter, and issued as No. 4 of vol. ix. of the University of California Publications in Zoology. The scope of this report is very wide, taking into consideration the larger meaning of science in general, and of biology in particular. Reference is made to the present condition of the station, to the work already accomplished, and to projects for the future. In the concluding section it is urged that every scientific institution ought to do something towards diffusing an accurate knowledge of modern scientific work among the general public. This should be done—largely through the public press—by persons who have themselves been engaged in scientific work, and should by no means be left to those who merely read up science.

For several years past Prof. E. C. Case has been working at the wonderful Permian vertebrate fauna of North America, and some of his latest results are embodied in "A Revision of Amphibia and Fishes" of this formation, published as a quarto memoir by the Carnegie Institution of Washington (1911). The memoir opens with a review of previous work on the subject, this being followed by a table of the classification of the Amphibia as now revised, after which comes a detailed synopsis of the various groups. With the exception of one genus referred to the same group (Urodela) as modern salamanders, the whole of the amphibians are referable to the stegocephalians, or labyrinthodonts, in the classification of which the author follows in the main the lead given by Cope. A discussion of the fishes is given by Mr. L. Hussakof, who concludes with a comparison of the fish-fauna of the Permian of America with that of Bohemia, in which it is pointed out that there is a great similarity between the two, with the exception that the acanthodian sharks are unrepresented in the American formation.

The Journal of the Royal Society of Arts of March 29 contains the report of a lecture on modern whaling, delivered by Mr. T. E. Salvesen at the sixteenth ordinary meeting of the society. After an historical account of whaling, the lecturer stated that the great recent development of the industry has taken place in the southern hemisphere, where the chief objects of pursuit are rorquals and humpbacks. In South Georgia 7000 whales, yielding some 200,000 barrels of oil, were taken last year; in the South Shetlands the catch was 3500, and in South Africa 4000, the total number of whales taken during the season to the south of the equator being about 17,500, with a yield of some 500,000 barrels of oil, and a gross value of about 1,750,000*l*. For the whole world, the catch was about 22,500 whales, with a yield of some 620,000 barrels of oil. The present year's take is expected to exceed that of 1911 by at least from 10 to 15 per cent. It is a matter for regret that in the discussion which followed the paper no one pointed out the serious nature of this enormous drain and the urgent necessity of an inquiry to ascertain what effect it is having on the numbers of the whales. On the face of it, no species appears likely to be capable of holding its own against such tremendous slaughter for any length of time.

THE threatened extinction of the sandal tree (*Santalum album*), which occurs over a limited area in India and is practically absent elsewhere, and the great economic value of sandalwood oil, have led to many attempts to extend its area by plantings and sowings, but these have been rarely successful, owing to the fact that, although the sandal is a root parasite, absolutely dependent upon other plants for its nourishment, it has in most cases been treated like other trees in the methods adopted for its propagation. M. Rama Rao has just published (*Indian Forest Records*, ii., 4) an elaborate account of the host-plants of the sandal, in which he describes the relations between the roots of this tree and those of more than 250 species found growing in association with it. Of this number no fewer than 150 species are actually host-plants attacked by the roots of sandal, and the author believes that further investigation will result in additions to this remarkable census. Apparently evergreen plants are better hosts than deciduous species; sandal plants growing on evergreen hosts themselves remain evergreen, while those on deciduous hosts actually become deciduous; and there is a marked tendency for the sandal to become deciduous in very dry localities, where the plants associated with it are few and are deciduous.

A SEVERE earthquake was felt in South Africa on February 20 at 3.4 p.m., especially in the south-western portion of the Orange River Colony. The shock is remarkable for the large area over which it was strong enough to damage buildings. This area, so far as can be judged from the numerous accounts published in *The Cape Times*, is about 150 miles in diameter, and contains more than 17,000 square miles. In Kimberley and Bloemfontein a few houses were injured, but the epicentre of the earthquake lies about 50 miles to the south-east of Kimberley, in the neighbourhood of Koffyfontein, Jagersfontein, and Fauresmith, at which places, also, most of the after-shocks were felt. Although many buildings were demolished and the ground fissured in this district, the earthquake was not one of very great intensity, though unusually strong for the South African colonies. It was felt, however, over a very wide area, from Paarl (480 miles to the south-west of the epicentre) to Mafeking (250 miles to the north), Johannesburg (290 miles), and Durban (360 miles to the east). The disturbed area must therefore have contained about half a million square miles.

THE last Bulletin (vol. iv., No. 3, 1912, Tokyo) of the Imperial Earthquake Investigation Committee consists of Prof. Omori's third paper on the applications of the seismograph to the measurement of the vibrations of railway carriages. The recent experiments were made in a new imperial carriage and a first-class carriage, both six-wheel bogie-cars, and weighing 36 and 27·3 tons respectively. The trains containing these carriages were similarly made up and run along the same course with approximately the same velocities. The records in the two carriages in the same portions of the course were so similar that individual vibrations could be identified, especially in the lateral-vibration curves. The intensity of the vertical vibrations in the imperial carriage was 40 per cent. less, and of the lateral vibrations 26 per cent. less, than in the other. Under ordinary conditions, the maximum acceleration recorded in the imperial carriage amounted to 1100 mm. per second per second for the lateral vibrations and to 2000 mm. per second per second for the vertical vibrations, the latter being nearly as great as that experienced at Nagoya during the great Japanese earthquake of 1891. The vertical vibrations in the same carriage were practically unaffected when the train entered on a curve of from 20 to 60 chains radius, but the lateral vibrations, though unchanged when the velocity ranged from 25 to 30 miles an hour, were nearly double as large as on a straight road when the velocity was as low as 15, or as high as 40, miles an hour.

THE report of the work of the Prussian Meteorological Institute in 1911, issued by Prof. G. Hellmann, states that the existing materials are so great that it was thought advisable to devote as much time as possible to the deduction and publication of results, rather than to take up fresh observations. The report contains several interesting and useful short discussions, to one or two of which we hope to refer later on. The arrears in the discussion of magnetic observations have been brought up to date. A curious incident relating to the uncertainty of the needle-inclinometer is reported. Four needles had been in use, three of which gave concordant results, and the fourth very discordant values, and its use was given up; but some years later it was discovered that the discarded needle was the one which had given correct results. At the end of 1911 the meteorological stations numbered 201, exclusive of a very large number of rainfall and thunderstorm stations. The Potsdam, Brocken, and Schneekoppe observatories are entirely maintained by the institute. It is pleasing to note that his Majesty the Emperor confers from time to time special honours on both officials and observers of long standing.

IN the Trans. Roy. Soc. of Canada (vol. v., sec. iii., 1899) Dr. W. Bell Dawson gave illustrations of some remarkable sea-seiches, or secondary tidal undulations, which occurred in the estuary of the St. Lawrence. He remarked that they seem to be connected with stormy weather. The subject is resumed in a paper jointly by Mr. Kôtarô Honda and Dr. Dawson, published in the Science Reports of the Tôhoku Imperial University, vol. i., No. 1, p. 61 (1912), in which they discuss the periods of the Canadian seiches, showing that they conform to the Japanese theory. The authors are of opinion that the seiches are due to meteorological causes. In the Proceedings of the Tokyo Mathematico-physical Society for February, p. 196, Mr. Honda traces the connection between the advance of a barometric depression and the sea-seiches observed at eight ports in Japanese waters.

The new catalogue of physical apparatus issued by Messrs Baird and Tatlock (London), Ltd., is a quarto volume of 650 pages, and is well illustrated. It contains descriptions of several new pieces of apparatus, as, for example, the induction solenoids on p. 536, and Milner's automatic mercury pump. It would be an advantage if British instrument makers would in their new catalogues cease to figure and describe apparatus hopelessly out of date, like Lavoisier and Laplace's ice calorimeter.

The theory of the universe which was propounded eight years ago by the late Prof. Osborne Reynolds in his "Sub-mechanics of the Universe" has found a popular exponent in the person of Mr. J. Mackenzie, a copy of whose lecture on the subject, delivered before the Minnesota Academy of Sciences and the American Association for the Advancement of Science at Minneapolis, has just reached us. It contains a clear account of a theory which is not by any means easy to follow in the original, and is illustrated by several figures of Prof. Reynolds's experiments, including that of the thin indiarubber bag partly filled with sand which supports 200 lb. on its edge. A good portrait of the late professor serves as a frontispiece.

Special Publication No. 9, 1911, of the U.S. Coast and Geodetic Survey contains a magnetic declination chart for the United States for the epoch January 1, 1910. It also gives secular change data—in continuation of similar data in earlier publications—for a number of selected stations. In the east, westerly declination is increasing more rapidly than in 1905. In the North Atlantic States, where the change is most rapid, it is now about 6′ a year. In the western territories easterly declination is increasing, also more rapidly than in 1905. The rise is now as much as 5′ a year in some places a little inland from the Pacific coast. The changes in progress at present throughout the United States are so complicated that it is impossible to predict their course even a few years ahead.

It has long been known that traces of hydrogen peroxide are found in rain water and in snow, and that during the day the proportion is greater than at night. In 1900 it was shown by Miroslaw Kernbaum that the ultra-violet rays from a quartz mercury-vapour lamp decompose water according to the equation $2H_2O = H_2O_2 + H_2$, a fact which suggests that the hydrogen peroxide in rain water owes its formation to the action of solar ultra-violet rays on water vapour in the upper region of the air. The correctness of this hypothesis has been since verified by M. Kernbaum (*Bull. International Acad. Sci. Cracovie*, 1911, p. 583), who finds that ordinary sunlight even at the earth's surface is capable of demonstrably producing the same result in water enclosed in a quartz flask, both hydrogen and hydrogen peroxide being formed in minute quantities after a few days' exposure to the rays of the sun in July. In such a case the action of the ultra-violet rays is necessarily less than in the upper atmosphere, owing to their absorption in passing through the air.

An illustrated description of the Ljungström steam turbine appears in *Engineering* for April 12. This machine is of the reaction type, and has been designed by its inventor—a Swedish engineer—so as to avoid some of the defects which are inherent to this kind of turbine. The flow is radial, the steam being admitted between two discs, and in its passage from their centre to their circumference, passing between concentric blading rings carried alternately by the two discs. In the usual design, both the discs revolve, driving their shafts at equal speeds, but in opposite directions, and to each shaft is coupled an electric generator. The relative speed of each set of blades is thus twice as great as in a standard reaction turbine of equal revolutions and diameter, hence for equal efficiency the total number of blade rows is only one-quarter as great. By the disc arrangement distortion troubles are avoided, hence the machine lends itself to the use of steam superheated to the highest degree. The general design makes an astonishingly small turbine for the power developed. Experiments have been made with a 500-kw. machine, and one of 1000-kw. capacity has just been finished and thoroughly tested.

OUR ASTRONOMICAL COLUMN.

The Solar Eclipse of April 17.—At the moment of going to press, the following telegram has reached us from Dr. Lockyer and Mr. F. Maclean, *viâ* Paris:—"Camp American line on road three-quarters mile north-east Chavenay practically central Bailey's Beads no corona prominences eight and two o'clock duration about two seconds. Weather perfect.—Lockyer, Maclean."

A Daylight Meteor.—Mr. Hugh Ramage, organiser of higher education, Norwich, sends us some extracts from *The Eastern Daily Press* of April 3, 4, 6, and 8, containing observations of the daylight meteor of March 28, referred to last week (p. 147). Mr. W. F. Bushell, Gresham's School, Holt, states that the meteor was observed at about 2.45 p.m. It was seen by several observers, who agree in stating that "it left behind a yellowish-green track, which faded away almost directly. The meteor appeared in the northern part of the sky, and seemed to be travelling in an easterly direction. The sun was shining at the time."

The Nova, or Variable, in Perseus, 87.1911.—The supposed nova discovered by Mr. D'Esterre is the subject of some further notes in No. 4564 of the *Astronomische Nachrichten*. This object is of especial interest at the present juncture, when so many attempts are being made to explain the appearance of novæ, for it appears to consist of several condensations, of changing aspects, surrounded by nebulosities, or themselves nebulous. Whatever the object itself may be, it is evident that the region is one of considerable interest, which should be carefully examined with more powerful instruments.

A New Star Catalogue.—Astronomers are indebted to Mr. Backhouse for a valuable new star catalogue of 9842 stars, containing all stars very conspicuous to the naked eye. The catalogue is intended as a complement to a set of maps designed especially for the use of meteor observers, but should be found very useful by all astronomers. In addition to the various designations of each star, Mr. Backhouse gives the magnitude as shown in eleven different publications, and then gives a weighted mean, the system of weighting being explained in the preface. Those amateur astronomers who have recently been struggling with the intricacies of various systems, in trying to understand the published magnitudes of Nova Geminorum No. 2, will appreciate the usefulness of such a catalogue. The work contains 186 quarto pages, and is published by Hills and Co., Sunderland.

The Photographic Transit.—The results of further experiments with a photographic transit, carried out by Prof. Hirayama during 1907–08, are published in the second fascicule of vol. v. of the *Annales de l'Observatoire astronomique de Tokyo*. They show that there is no change of the mean error either with the declination or with the photographic magnitude, and that the instrument is capable of producing very valuable results.

Physics and Astrophysics.—In No. 12 (1911) of *the Bulletin de la Classe des Sciences, Académie Royale de Belgique*, is published a most interesting lecture by M. J. E. Verschaffelt, in which the author shows how deeply the physical sciences are indebted to the results secured in astronomy for the suggestion, or the confirmation, of many of their fundamental concepts. For examples he quotes, *inter alia*, Newton's and Kepler's work on gravitation, Roemer's determination of the velocity of light reinforced by Bradley's discovery of aberration, and the idea of the pressure of light suggested by the solar repulsion of cometary matter. It is interesting to note that at the earth's surface the pressure of the solar radiation on each square metre of a black body amounts only to two-thirds of a milligram. In conclusion, M. Verschaffelt strongly expresses the hope that astrophysics may be officially included in the programme for the doctorate in the Belgian universities.

The Parallax of Nova Lacertæ, 1910.—From observations made at Yerkes Observatory during December, 1910, and January, 1911, Prof. Slocum finds the relative parallax of Nova Lacertæ to be $+0{\cdot}013'' \pm 0{\cdot}014''$. As the average parallax of his comparison stars, according to Kapteyn's table, may be taken as $0{\cdot}005''$, the absolute parallax obtained for the nova is $+0{\cdot}018''$. Too great an accuracy cannot be claimed for this result, but if it is correct the outburst producing the nova occurred some 180 years ago. (*Astrophysical Journal*, vol. xxxv., No. 2.)

NOVA GEMINORUM NO. 2.

An account of the discovery of Nova Geminorum No. 2 is given by Herr Enebo in No. 4564 of the *Astronomische Nachrichten*. After observing the variable SV Tauri, at 8h. 32m. (M.E.T.) on March 12, Herr Enebo's eye, wandering over the neighbouring constellation, was arrested by the appearance of a companion to θ Geminorum which he had not noticed when observing that region four days earlier; the new object was then of magnitude 4·31 on the Potsdam scale. Herr Enebo's subsequent observations indicate that the nova was at its brightest when discovered, or on March 13, when he estimated the magnitude as 4·23, although other observers found it to be about 3·5 on March 14.

Herr Jost publishes a list of comparison stars, ranging from 4·6 to 8·3 in magnitude, and gives the colour of each so that comparisons with the nova may be facilitated. Dr. Wolf publishes a photographic chart of the nova region taken in January, 1909, and gives the magnitudes of surrounding stars down to about 9·5.

Dr. Guthnick reports a brightening of 0·4 mag. on March 22, accompanied by a diminution in the redness of the star. The red colour is quite marked, and makes the nova stand out from the other stars in a field of 1½ degrees; the Rev. T. E. R. Phillips is of the opinion that it is one of the reddest stars he has ever seen.

A communication from Prof. E. C. Pickering, published in No. 4565 of the *Astronomische Nachrichten*, states that Dr. Curtiss found the magnitude on March 13·7 to be 3·9, the spectrum then being like that of Nova Aurigæ. The Harvard photographs of March 13, however, showed only dark lines, and Prof. Pickering suggests that the bright lines seen with a slit spectroscope at the Ann Arbor Observatory may have been too narrow on that date to appear on the Harvard objective-prism spectra. Dr. Curtiss's observations showed a recessional velocity of 5 kms. for the dark reversals of the H and K lines.

Prof. Pickering also states that on March 16 the spectrum was of the normal novæ type, and the nebular lines were first seen. Better weather evidently prevailed in the United States than in England on March 13 and 14, for Prof. Pickering reports that seven good photographs of the spectrum were secured on each of those nights.

At the Hamburg Observatory spectrograms were obtained on March 20, 23, and 27, and many broad bright lines, especially the hydrogen series $H\beta$ to $H\eta$, are shown. Prof. Schwassman identifies two of the other bright lines with lines at $\lambda\lambda$ 4230 and 4176 in Vogel's spectrum of Nova Aurigæ, while a third lies halfway between $\lambda\lambda$ 4315 and 4288. On March 27 the bright K line was indistinct, but other bright lines were more marked than on the previous dates. Prof. Schwassman identifies three of these, at $\lambda\lambda$ 4583, 4557, and 4525, with lines of Fe, Ba, and Ti.

Greenwich observations on March 15, reported in *The Observatory* (No. 447, April) showed the visual brightness to be one-quarter of a magnitude, and the photographic one magnitude, fainter than θ Geminorum. The photographic magnitudes were secured by placing a grating, made of zinc strips, with spaces of equal width, in front of the object glass, and are as follows:—March 20, 5·5; 21, 6·0; 26, 6·1; 28, 6·3; 29, 6·5; 31, 6·0, and April 1, 6·5.

At Cambridge, reports Prof. Newall, the nova on March 14 was at least one magnitude brighter than θ Geminorum; as the estimated magnitude on March 15 was 4·2, it would appear that the nova lost 1½ magnitudes in 24 hours. A series of photographs of the spectrum shows interesting changes in the relative brightness of the lines, in the structure of the hydrogen lines, and in the appearance on March 22 of a second pair of broad bright and dark lines on the more refrangible side of each hydrogen line.

According to observations by M. Luizet, published in *L'Astronomie* for April, the nova decreased in brightness to the extent of one magnitude between 10h. on March 15 and 7h. 50m. on March 16.

M. Baume Pluvinel's spectra observations on March 21 show each of the hydrogen lines $H\beta$ to $H\epsilon$ doubled or trebled, and all displaced towards the red.

Dr. Easton reports a second recrudescence of brightness on April 9, when, at 9h. 15m. (G.M.T.), the H.P. magnitude was 6·0, but the brightening probably occurred earlier than this, although bad weather prevented Dr. Easton observing it. A secondary maximum is plainly shown, in Dr. Ebell's series of observations, for March 30 (*Astronomische Nachrichten*, No. 4564). Dr. Strömgren's series shows that on March 24, the previous maximum, the colour became bluish instead of red as previously.

PORTLAND CEMENT.[1]

M. LEDUC has made a notable contribution to the literature of a subject which already possesses *matériel* more remarkable for quantity than merit, and, departing from topical traditions, has given us many useful data with few speculations.

An excellent historical preamble is succeeded by a description of the methods which he employed in his endeavour to throw light on the constitution of cement —a question which is taxing, and will continue to tax, the best efforts of the chemist, equipped as he must be with ample knowledge of physical methods of research. Provision of a suitable apparatus for working at high temperatures with relatively large quantities of material, say a couple of kilogrammes, needed much thought and many trials, and was attained by the device of a furnace heated by three burners fed with gas and air under pressure, these playing below the hearth on which the test pieces are placed and the gases being deflected back above the hearth before reaching the flue, so that as uniform a temperature as could be expected from any contrivance heated by fuel was secured. In many instances of this sort where the experimenter finds himself in a difficulty useful recourse may be had to some industrial apparatus, and M. Leduc, fully alive to this, used one originating with a famous firm of motor manufacturers, and records the result with a touch of sadness :—"Enfin, dans un essai qui, malheureusement, s'est terminé par la fusion complète et le mélange d'un grand nombre d'échantillons, j'ai utilisé le four à porcelaine dure de la maison de Dion-Bouton, que M. Guillet, professeur au Conservatoire des Arts et Métiers, avait bien voulu mettre à ma disposition."

The author prepared the first of the calcium silicates which may occur from the interaction of cement raw materials, that is, wollastonite, $CaOSiO_2$, and notes in passing that the product had a pale-green tint, which he attributes to the presence of a trace of iron. Seeing that the silicate is relatively acid, the reviewer would not care to contest this explanation, but he would point out when white Portland cement, necessarily a far more basic material, is made from the purest materials obtainable in commerce as distinct from strictly laboratory products, it also possesses a pale-green tint, and that this tint is due, not to iron, but to manganese, probably present as calcium manganate. Dicalcium silicate, that is, the orthosilicate, $2CaOSiO_2$, was also made with ease, as other experimenters have established; but, again confirming earlier results, the preparation of that illusive body $3CaOSiO_2$ proved to be impracticable. So far as we know, the only successful attempts have been those of Le Chatelier some twenty-five years ago, in which not pure $3CaOSiO_2$, but a body in which part of the CaO is replaced by $CaCl_2$ was prepared, and the recent work of Shepherd and his collaborators, who have shown that tricalcium silicate has a small range of stability in respect of temperature, and it is in consequence of this that its existence as an individual substance has been so much and so justly doubted.

M. Leduc's conclusions are such that we will quote them without fear of the accusation of laziness properly levelled at commentators on other men's work.

$CaOSiO_2$ has no hydraulic properties; neither has $2CaOSiO_2$, which can only be made in the dry way, and is decomposed by water into the monocalcium silicate and lime. $3CaOSiO_2$ has not been prepared. $CaOAl_2O_3$ and $2CaOAl_2O_3$ are hydraulic and stable in hot water. $3CaOAl_2O_3$ has not been obtained. The calcium-ferrites are not hydraulic, and no silico aluminates or silico-ferrites containing a high percentage of lime could be prepared, the products falling to powder on cooling in the manner characteristic of dicalcium silicate.

Concerning commercial cements, the fact recognised in practice, that the mechanical strength falls off rapidly as the content of clay is increased, is confirmed, and it is also shown that the coarseness of grain of both clayey matter and of sand has at least as large an influence on the "falling" of clinker as has the amount of their constituents. A normal clinkering temperature is set down at 1400–1450° C. Cements in which the alumina is replaced by ferric oxide are mechanically weak, and those containing considerable quantities of magnesia, *e.g.* 25 per cent., went to pieces when exposed to steam. It should be noted that M. Leduc took unusual pains to bring his raw materials to an extremely fine state of division, fully comprehending that in a mass which is almost plastic the occurrence and completion of the reactions concerned in the production of definite silicates, aluminates, and the like are dependent on the intimacy of admixture, as well as on the temperature and the time. Anyone who has prepared Portland cement experimentally knows that particles of sand which may be only 1/10 mm. in diameter will each produce its small centre of "falling," the dicalcium silicate oozing forth from the site of the grain in a very curious lifelike and vermiform manner, whereas the same raw materials, really finely ground, will not "fall" at all.

One more word, and we will close an appreciation of good work well done. M. Leduc has shown, in collaboration with M. Chenu, that Seger cones, useful as they are for many industrial purposes, are far from exact as indicators of temperature. They may well be used side by side with materials of the same class which are to be heated in the same way, but in all cases they must be checked by whatever kind of pyrometer is best adapted for the temperatures to be measured. Failing this the most careful inquiry may be misleading.

B. B.

PLAGUE IN INDIA.

THE sixth report on plague investigations in India, which, like preceding reports, has this year been issued as a supplement to *The Journal of Hygiene*, is in large part made up of a continuation by Dr. M. Greenwood of the statistical examination of plague as it occurs in the Punjab. In the application of statistical methods to a subject-matter so complex it is a considerable advantage to the investigator to have himself personal experience of the methods, particular conditions, and so on affecting the collection of the data with which he has to deal, and adds cogency not so much to the facts elucidated as to the conclusions based upon these facts. It is particularly unfortunate, therefore, that the death of Major Lamb deprived Dr. Greenwood of the assistance which his wide experience and knowledge of local circumstances would have afforded. Major Lamb, of whom a memoir is included in the report, was one of the most brilliant members of the Indian Medical Service, and his untimely death in this country has taken from plague research in India one of the ablest, keenest, and at the same time best-informed of its students.

In the Punjab cases of plague continue to occur, though in reduced numbers, during the off-season, and this persistence is met with chiefly in the larger villages. Dr. Greenwood's first paper is a contribution to the question whether in the smaller villages the seasonal outbreak should be looked on mainly as a reimportation of the disease from these larger centres or as an independent development of a local focus dormant during the off-season. If the former were the case, we might expect a larger incidence in the villages near the main lines of communication, and taking the Amritsar district as the area for investigation and the railways as the means of communication, Dr. Greenwood finds that in districts containing large centres, villages near a line of railway are, in fact, subject to a higher rate of plague epidemics than villages not so situated, while in districts purely or mainly agricultural, proximity to railways does not increase the liability. The greater liability in the former case is probably due to increased opportunity for personal intercommunication rather than to transport of merchandise, and he concludes that in districts favourably situated for such intercourse the spread of plague can be better explained on the hypothesis of reimportation than on that of recrudescence. The second paper bears on the problem of what circumstances determine the extent of an epidemic when plague has once shown itself, and why the mortality-rates in infected villages are subject to the variations actually observed. Dr. Greenwood is fully alive to the necessity of caution in accepting statistical conclusions based on the material at his disposal, and we give the barest indication of his results in saying that the rate of plague mortality is seen to depend on three factors: the length of exposure to infection, the number of inhabitants, and the situation of the village.

Besides some observations on the breeding of *Mus rattus* in captivity, and a summary of some recent observations on rat fleas, the report includes an interesting account of plague as it occurs in Eastern Bengal and Assam. This province has suffered from the present epidemic to only a limited extent, and the report, which is liberally illustrated by photographs, attributes this freedom chiefly to the scarcity of rats in the Bengali houses, a scarcity due both to the habits of the people and the structure of their houses. Two important papers by Dr. Rowland are sent from the research laboratory of the Advisory Committee, dealing respectively with a possible improvement in the preparation of plague-serum and with some of the problems connected with plague-vaccine. From the second of these it appears that it may prove practicable to obtain a vaccine of low toxicity, but undiminished immunising power, a result which if confirmed has a theoretical as well as practical significance not confined to plague only, but affecting the general question of immunity in infectious disease.

FOUR MAMMAL SURVEYS.

FOUR papers which have recently reached us serve to show the energy and vigour with which the collecting of mammals is being carried on in various parts of the world. If continued at the same rate for a few years longer, such surveys ought to go a long way towards completing our knowledge of the mammalian fauna of the globe, so far at least as external and cranial characters are concerned.

The first of the four papers is a report on the progress of the Indian mammal survey now being carried on under the supervision of the Bombay Natural History Society, in the Journal of which for October, 1911, the report is published. Collecting has been carried on in Kandesh and the Berars, where about 150 skins have been obtained. Apparently none of these represents new forms, thereby bearing testimony to the thorough manner in which collecting (for the most part amateur) has been previously carried on in this part of the country. Interesting results in regard to the geographical distribution of species and the occurrence of local races are, however, expected in the future.

To vol. iv., parts iii. and iv., of the Journal of the Federated Malay States Museums, Mr. C. Boden Kloss communicates an account of the results of a recent visit to the Trengganu Archipelago in search of mammals and other vertebrates. The chain of small islands, of which Great Redang and the Perkentians are the chief, runs at a distance of from seven to twelve miles from the coast of the Malay Peninsula in a nearly parallel direction for about thirty miles. The only previous visit of naturalists to the archipelago appears to have been made by the members of the Skeat expedition in 1899. During an eighteen days' cruise Mr. Kloss obtained thirteen mammals which he regards as representing new forms; all these were named in the *Annals and Magazine of Natural History* for January, 1911.

The penultimate number of the Proceedings of the Zoological Society for 1911 contains the fourteenth report by Mr. Oldfield Thomas on mammals from eastern Asia, collected with the aid of funds furnished by the Duke of Bedford. This particular fasciculus deals with mammals from Shen-si, the most interesting of these being the golden takin (*Budorcas bedfordi*), to which reference has been previously made in these columns, but the whole survey, despite the fact that no strikingly new forms were discovered, has vastly increased our knowledge of the mammal fauna of Eastern and Central Asia. It is, therefore, a matter for regret that it is not to be continued, at all events for the present.

The fourth paper, "Notes on the Mammals of the Lake Maxinkuckee Region," by Messrs. B. W. Evermann and H. W. Clark (Proc. Washington Acad. Sci., vol. xiii., pp. 1–34), is of a totally different type from the above, dealing solely with the habits and environment of the mammals met with during a zoological survey of the region, and is an excellent sample of the best class of American work of this nature. Particular interest attaches to the reappearance of the opossum in the district, from which it had long been absent. R. L.

TREASURY GRANTS TO UNIVERSITIES AND UNIVERSITY COLLEGES.

THE report of the Advisory Committee on the distribution of Exchequer grants to universities and university colleges in England, appointed by the President of the Board of Education last June, has now been published [Cd. 6140]. The committee as then appointed consists of seven members:—Sir W. S. McCormick (chairman), Prof. J. A. Ewing, C.B., F.R.S., Sir William Osler, F.R.S., Miss Emily Penrose, Sir Walter Raleigh, Sir John Rhys, and Sir Arthur Rücker, F.R.S., with Mr. G. M. Young as secretary.

The report states that in framing its recommendations for the distribution of the Exchequer grant, the committee has chiefly had regard to three factors—the needs of the several colleges, the amount of local support received by each, and the volume and quality of their work.

For the purpose of the present report the members of the committee have visited all the colleges coming within their purview except Nottingham, in considering which the committee had before it the report of the recent inspection conducted by the Board of Education. As a result of the visits to the various institutions, the committee says that the colleges generall are animated with a true university spirit and that the policy of their governing bodies is actuated by true university ideals. The committee does not imply that even among the stronger institutions all are equally efficient or have reached the same stage of development, but it rarely found occasion to think that where weaknesses existed the colleges were unaware of them or would be backward in applying the right remedy when circumstances permitted. The committee assures the Board of Education that in its opinion most of the colleges are fully competent to exercise that "freedom in organising" and "carrying out their important national and international functions" which it is the policy of the Board of Education to secure for them.

The committee recommends that the grant available be distributed in the following proportions:—

		£
University of Birmingham		13,500
University of Bristol		7,000
University of Durham: Armstrong College		8,500
University of Leeds		12,500
University of Liverpool		15,500
University of Manchester		17,500
University of Sheffield		7,000
University College, London		16,000
King's College, London	9,500	11,500
King's College for Women	2,000	
Bedford College, London		7,000
London School of Economics		4,500
East London College		5,500
Nottingham University College		5,700
Reading University College		5,500
Hartley University College		2,400
Total		£139,600

These grants have been calculated on a total of 149,000*l.*, and the committee recommends that the balance (9400*l.*) of the present grant, together with the balance of 2550*l.* from the previous year's Exchequer grant, be reserved pending consideration of a superannuation scheme to be reported on later and be regarded as applicable to the institution of such a superannuation scheme and to other contingencies.

A number of general recommendations concludes the report. The committee recommends, among other matters, that subject to unforeseen contingencies the grants be fixed for a period of five years as from April 1, 1911, and that the grants be regarded as strictly maintenance grants to meet annual expenditure on teaching and research of a university character and standard.

FIORDS IN RELATION TO EARTH MOVEMENTS.[1]

FIORDS have been a powerful influence on modern life, for the existing facility for intercourse oversea is the difference between modern and mediæval Europe which penetrates most deeply into all departments of life and work. The Roman Empire was held together by its roads, and as its conquerors from the wide plains of the east were neither sailors nor roadmakers, Europe was resettled on national instead of on imperial lines. While Europe thus fell naturally into independent States, the most efficient of all means of international communication was being developed on the shores of Scandinavia; for owing to the fiords travel overland there was even more difficult than through the forest-clad plains of Central Europe. In Norway the fiords were the only practicable highways, and they, with their labyrinth of smooth waterways, their tidal currents, which carried boats to and fro independent of wind or oar, and their unfailing supplies of food, fuel, and skins, attracted men to the sea as much as the barren highlands repelled them from the land.

[1] Abridged from a lecture delivered to the Midland Institute of Birmingham on January 22, by Prof. J. W. Gregory, F.R.S.

The poverty of their own country having driven the Norsemen to the sea, the wealth of the more fertile southern coast-lands tempted them to the career of piracy which made the berserkers the terror of the shores of western Europe. These pirates, however, amply repaid their debt by their contributions to modern seamanship, made in consequence of the geographical conditions of the Norwegian fiords. Eva Nansen's song contains a true statement of the influence of the fiords on the Norwegian race:—

Our mother, weep not! it was thou
 Gave them the wish to wander;
To leave our coasts and turn their prow
 T'wards night and perils yonder.
Thou pointed'st to the open sea,
 The long cape was thy finger;
The white sail wings they got from thee:
 Thou canst not bid them linger!

The white sails of the Norse and Danish Vikings, amongst other things, carried the name fiord far and wide. It is found on the Irish coast, for example, in Wexford, which is said to be derived from the Danish Weis-fiord, and in Waterford from Vadre-fiord; and the name is now accepted as a technical term in general geographical nomenclature.

The word fiord is used in Norwegian for any arm of the sea, including various types of gulfs, bays, and straits. But the name is adopted in international geography for arms of the sea of a special kind. A fiord in this restricted sense is a long inlet which extends far inland between steep parallel walls; it usually consists of long straight reaches, which are bent and receive their tributaries at sharp and regular angles. Its walls are high, as fiords are restricted to mountain regions.

Fiord districts combine the features of mountain and coastal scenery. Many authors have been impressed by a sense of the monotony of fiord scenery, owing to the constant repetition of the same form; it is, however, popular from the easy access to it along smooth waterways, the especial beauty of the cloud forms and the colour effects, which do not pass with the flash of a tropical sunset, but last for hours in the prolonged twilight of most fiord areas. The charm of fiord countries is, moreover, enhanced by the survival, owing to the special geographical environment, of primitive conditions of rural life.

The origin of fiords has given rise to prolonged controversy. The difficulty of the problem is due to the peculiar combination of geographical characters. The fiords are clearly valleys, of which the lower ends have been drowned by the sea. Sea-drowned valleys are of three main kinds.

The most familiar kind is that of ordinary river estuaries, which have been submerged by subsidence of the land. Such estuaries have gentle, rounded slopes and curved shore lines; they are typically funnel-shaped, as they increase seaward, both in width and depth. The Firths of the Tay and Forth, the estuaries of the Thames, Severn, and Humber, and Bantry Bay in south-western Ireland are examples of such drowned valleys. They are well illustrated in north-western Spain, where they are called rias, and this term "ria" has been adopted as the technical name of this kind of drowned valley.

The members of the second group are known as "fiards" from their typical representatives in south-western Sweden. They agree with rias by having curved lines, gentle slopes, and indented shores. They differ, however, from rias, as they often include deep basins, separated by rock bars from the outer sea, which may not for some distance reach the depth of the inner basins. Fiards, moreover, usually have no large rivers draining into them, and may receive only insignificant streams and brooks. Fiards are due to a lowland area with an irregular surface of hard rocks having been partially submerged beneath the sea. The essential difference from fiords is that fiards are characteristic of the coast lands which rise to but a slight height above sea-level.

The third group consists of the fiords, which, seen from a steamer or on an ordinary map, have seven chief characters.

(1) They are typically long, straight, narrow channels, and they are usually so crowded and run so far inland that they add greatly to the length of the coast line. Thus, whereas in Norway the length of the coast from headland to headland is 1700 miles, the actual length of the shore line along the fiords is 12,000 miles.

(2) The walls are typically high and steep.

(3) The fiord channels usually have parallel sides, and the fiords bend or branch at sharp angles, and the same angle tends to recur throughout a district. There is accordingly a striking parallelism in the geographical elements of neighbouring fiords.

(4) The fiord valleys are often arranged along intersecting lines like a network of cracks, in contrast to the converging tributaries of a river system.

(5) The fiords are characteristic of dissected plateaus. All the great fiord districts of the world were formerly plateaus.

(6) Owing to the plateau structure the land extends backward from the fiord walls with gentle slopes and shallow valleys. Streams flow gently across these uplands until they reach the fiord wall, and then plunge down it in great waterfalls, which are especially picturesque in spring, when the rivers are flooded by the melting snow. The highest waterfall in the world, the Sutherland Falls of New Zealand, sometimes leaps, it is said, in one jump of 1900 ft. on to the floor of the fiord valley of Milford Sound. The upland valleys which join the fiords have not been cut down to the level of the main valley, but enter abruptly high upon its side. They are therefore "hanging valleys."

(7) Finally, the amount of land beside the fiords suitable for cultivation is usually limited to small tracts at the head of the fiord or on small deltas along its sides. The amount of cultivable land in a fiord district is small, and fiord countries are therefore sparsely populated. One of their main values will be as the playgrounds for more crowded countries. They sometimes have rich mineral deposits, as in Alaska; but many American authorities claim that even there the scenery will prove the most valuable economic asset.

The previous characters can be observed by a tourist from the deck of a steamer, but if we could remove the sea and travel over the fiord floors three fresh geographical features would be revealed.

The walls which rise high above the sea surface would be seen to descend steeply to extraordinary depths. The deepest known fiord is the Messier Channel, in Patagonia, which reaches the depth of 4250 ft. The Sogne Fiord is the deepest in Europe, with the depth of 3780 ft. Some of the lakes which may be regarded as inland extensions of fiords are also surprisingly deep. Thus Lake Morar, in the western Scottish Highlands, of which the surface is 22 ft. above sea-level, is 1017 ft. deep; and this fact is all the more striking as the sea to the west does not reach that depth within the distance of 120 miles.

The deepest part of a fiord basin is usually at some distance from the sea; the floor rises seaward until it is covered only by shallow water, or projects above the surface and the fiord becomes a lake.

Fiords are therefore often separated from the outer sea by submerged thresholds. This fact was first discovered by Captain Cook in Christmas Sound, Patagonia; he found to his danger that on passing up that fiord he lost the anchorage which he had at its mouth. The existence of a threshold is such a frequent feature of fiords that it is regarded by some authorities as an essential character.

The removal of the water from a fiord would show that it has a flat floor. The valley is trough-shaped, whether empty or partially filled with water. The flatness of the floor can be learnt by cross sections from charts, or seen on the floor of the undrowned part of a fiord valley.

The problem presented by fiords is therefore that of the formation of systems of steep trough-valleys, which are arranged in networks so that the land beside them is broken up into rectangular blocks, and usually have deep inner basins separated from the sea by shallow thresholds.

The simplest explanation of valley formation is excavation by rivers; but this process will not explain the origin of fiords. Thus our British fiords, the Scottish sea-lochs, are not on river valleys; of the chief Scottish rivers, the Tay and the Forth. enter the sea through rias; the Clyde discharges into a compound basin which is not a fiord; and the Tweed, Dee, Don, and Doon have no long arms of the sea at their mouths. The chief sea-lochs, on the other hand, receive only small streams. The river systems of Scandinavia, North and South America, and New Zealand show the same independence of the fiords. The fiords are not the outlets of the main rivers. In fact, so far from fiords being made by rivers their existence depends on the absence of rivers, which would convert them into ordinary valleys by wearing back their banks and filling the main channel with sediment.

The failure to explain the formation of fiords by rivers of water therefore led to the invocation of rivers of ice, and many features of the fiord valleys are consistent with their formation by glaciers. The essential difference between the action of water and ice as agents of excavation depends on their difference in plasticity. Water, being very plastic, readily adapts itself to the irregular resistance of the adjacent rocks; it glances lightly off opposing hard surfaces and carves for itself sinuous channels.

Glacier ice flows around opposing obstacles, but as it is less plastic than water it is deflected less readily and bears with persistent pressure against the rocks in its path, and if armed with stones and grit it wears away the rocks like a grindstone. Therefore, whereas denudation by water tends to develop rounded surfaces with curved lines, ice, when confined in valleys, tends to produce straight lines, flat slopes, and angular, facetted surfaces.

The difference between the rounding action of water and the facetting action of ice may be illustrated by reference to the typical forms of pebbles in deposits laid down by rivers and by ice. The typical river pebble is rounded, and often egg-shaped. The typical ice-worn rock in a boulder clay has flattened surfaces, which often meet sharply along straight edges, like the facets of a gem. The same differences can be recognised on a larger scale in the topography of a glaciated district.

Further, a river flows around the base of the spurs from the sides of its valley, and often tends to lengthen them, whereas ice slowly cuts away the toes of these spurs until they end in triangular facets. These facetted ends are well shown on many of the spurs that run down to the Alpine glaciers, and they can be recognised on many Scottish mountains and valleys.

A glacier flowing down a valley presses against the spurs from the two sides and gradually rubs them away. It thus converts a sinuous river valley into a straight canal-like or trough-valley, which is the characteristic form of fiord valleys, of many glacier valleys, and of some of the lower Swiss valleys, such as that of the Rhone—though it is not the usual form of the higher level Alpine valleys from which glaciers have retreated.

There is also an important difference between the powers of ice and water in deepening their valleys. A river, except where it plunges over a waterfall, cannot deepen its valley lower than the outlet. Deep rock basins can only have been made by river action by a combination of three processes: first, the elevation of the country high above sea-level; secondly, the cutting of deep valleys by rivers; and thirdly, the uneven subsidence of the land, so that the mouth of the valley either sank slightly or remained stationary, and was thus left as a raised threshold. The existence of deep fiord basins and their thresholds cannot, however, be thus explained in many and in perhaps the majority of cases.

Ice, however, has greater powers of irregular vertical excavation than water. It moves slowly, and its great weight presses heavily upon its bed. Fragments of the loose material beneath the ice may be frozen into the sole of the glacier and be thus carried away. There is much evidence that the power of a glacier to cut away fresh, undecayed rocks is limited, except where they project into the path of quickly moving ice; but ice acting on weathered, decomposed rock can pick it up and remove it grain by grain. Mining experience shows that the depths to which rocks are weathered varies very irregularly; along the outcrop of a lode there may be a succession of places where decomposition has gone deeply, separated by ridges of fresh and hard rock. A glacier has greater powers than a river in eating out such weathered material, and thus forming rock basins.

The attack of glaciers on the rocks beneath them is aided by a second process. Many geologists hold that rivers owe their main power of cutting down hard bars of rock to pot-hole formation, which beneath a river cannot extend deeply below sea-level; but there is no such limit to the depths to which pot-holes are bored beneath a glacier; a stream of water plunging down a glacier mill may drill pot-holes into hard rocks deep below sea-level, and where many occur together the surface may be lowered into a rock basin. Hence glaciers have some powers of hollowing out basins greater than those of rivers. There are, however, other factors which counteract this process, and cause slowly moving glaciers and sheets of snow and ice to protect their beds, for the rock beneath them is preserved from the wear and tear of wind and water, from shattering by heat and frost, and from atmospheric decomposition.

The distribution of fiords has also been claimed as proof of their glacial formation. There are nine main fiord districts in the world, and of these the most famous are in high latitudes and in districts which were formerly occupied by ice. Thus in Europe they occur in Norway, Scotland, Iceland, and Spitzbergen. In America they are found in Greenland and down the western coast throughout Alaska and Canada. They disappear further south, and reappear again in the far south of South America in areas where glaciers still exist upon the mountains, and there is clear evidence of the former extension of the glaciers to sea-level.

The famous fiords of New Zealand are in the south-western corner of the country, where the glaciers formerly reached sea-level; while the North Island, where, according to many New Zealand geologists, there is no satisfactory evidence of low-level glaciers, has no fiords.

It is therefore claimed that fiords are limited to countries that have been glaciated, and that their restriction to such regions is proof of their glacial origin. Nevertheless, in spite of its attractiveness, the simple theory which explains fiords as due to the action of glaciers appears inadequate. Many fiords were no doubt occupied by ice, and have been moulded to their present form by ice; but they were not necessarily formed by it. Fiords are not limited to formerly glaciated areas, and even in glaciated countries their distribution is inconsistent with their glacial formation. Thus a sheet of ice covered nearly the whole of the British Isles, and, according to most authorities, it extended as far south as the line between the estuaries of the Thames and the Severn. The fiords of Great Britain are, however, almost limited to western Scotland, although the ice covered most of the eastern coasts, and there flowed over rocks of the same character as those beside the western fiords. Some of the glaciated areas in eastern England consist of soft beds, upon which glacial erosion should have been particularly effective. Nevertheless, there are no fiords in Yorkshire, for example, although the hills that reach the coast were buried under deep ice, and are composed of comparatively soft rocks. The best English fiords are in Cornwall, where some of the harbours, like those on the opposite coasts of Brittany, have many characters which show that they were originally true fiords; and Cornwall is one of the few English counties which admittedly were not glaciated.

Moreover, the plan of the fiord systems in each country does not appear to be that which would have developed as the result of glacial erosion. The chief fiord systems in the world have the same essential plan. Each fiord area is long and curved; in most cases a series of channels extend along the coast, and from them other fiords run inland, and are usually connected by others, or by deep valleys, so that the country is divided into angular blocks.

These networks are not the arrangement that would be expected if fiords had been excavated by glaciers, for in that case the main channels should be radial from the chief centres of snow fall. The course of the fiords is inconsistent with the lines of flow of the chief glaciers. The glaciers discharged from the highlands or from great domes of snow which sometimes formed on the lee side of the existing watersheds; the ice flowed by the most direct channels to the nearest low land or the sea. Many of the fiords owing to their directions were quite useless to the outflowing ice; they appear to have been simply filled with stagnant ice, and the main flow of the glaciers was above and across them.

The inconsistency between the direction of the lochs and the lines of flow is well shown in many parts of Scotland, as, for example, by the map of the ice movements in the area around Colonsay in a recent Scottish Survey memoir. It is also well shown in the Shetland Islands, where the main fiords, lochs, and other geographical elements trend north and south; but the ice movement was from east to west at right angles to the fiords.

The final and most convincing argument against the glacial origin of fiords is that they are preglacial. They are older than the ice which once occupied them. They are due to a series of uplifts which happened mainly in Pliocene times after the great Miocene movements which in Europe formed the Alps and the associated mountain chains. In nearly all cases the fiord valleys were formed in Pliocene times; hence the Pleistocene ice used the fiords and did not originate them.

It is therefore necessary to find an explanation of these complex valley systems independent of the ice action, which has given some of them their most conspicuous features. Facetted spurs and long parallel-walled valleys with hanging valleys upon their sides are formed by other than glacial agencies. They may be due directly to earth movements, as in the fiords of Dalmatia. Thus the famous fiord of Cattaro is flanked by facetted spurs, and the formation of the facets is due to recent faulting. The straight Dalmatian trough-valleys with their high walls and hanging valleys are due to recent earth movements, aided by the comparative weakness of the rivers owing to the porosity of the limestone which is the prevalent rock. These fiords are due to the earth movements which formed the Adriatic Sea, and all the fiord systems of the world are related to earth movements. Their networks do not resemble valleys cut by erosion, but intersecting fractures. The most striking features in the distribution of fiords connect them not with ice movements but with earth movements. The fiord systems of all parts of the world are arranged, not in radial lines from the highlands, but as angular networks resembling intersecting cracks in slabs of twisted glass. This fact is apparent from Kjerulf's plan of the fiords of southern Norway, which showed that all the fiords, lakes, and main valleys of that country can be arranged into a number of groups each with a definite direction, and the different series cross at sharp angles. The same arrangement of the fiords on intersecting lines is shown in Alaska, Patagonia, New Zealand, and Scotland.

The Scottish lochs and their valleys may be arranged in four groups. The most conspicuous lines in the coast of Scotland run east and west, as in the Pentland Firth and the southern side of the Moray Firth. Many of the western lochs, such as Loch Hourn, Loch Leven, Loch Eil, Loch Rannoch, and Lower Loch Etive, trend in this direction, which also occurs in the northern coast of Connaught in Ireland, and along the northern coast of Wales.

The second series of lines trend north and south at right angles to the first.

The members of the third group trend north-east and south-west; they include Glen More, the line of the Caledonian Canal, the Kyle of Tongue, the valley of the Spey, Upper Loch Etive, Loch Awe, Loch Fyne, many of the lochs around the Sound of Jura, and the central part of Loch Tay.

The direction of the fourth group is at right angles to part of the Glen More lines, and its series of valleys and lochs extend north-west and south-east, and include Loch Broom on the north-western coast and Lower Loch Fyne and Loch Crinan, and the Sound of Islay; also various inland lakes, such as Loch Shin.

These directions are not those that would be expected in valleys formed by glacial erosion. The largest centre of glacial accumulation in Scotland must have been the Grampians of eastern Aberdeenshire, for though the highest point of the area around Ben Macdhui and Cairngorm is slightly lower than the summit of Ben Nevis, it belongs to the largest area of highlands in Scotland. All this land was unquestionably covered by ice, and in no part of Scotland are glacial phenomena better displayed. Most of the ice probably flowed eastward and north-eastward and reached the North Sea; but nowhere along the eastern coast are there any fiords, and in spite of the great power of the glaciers, even the long narrow fresh-water lochs are confined to western Scotland.

Ben Nevis was also intensely glaciated, and the chief ice movements in that area were from south-west to north-east, for the great centre of accumulation was over the country between Ben Nevis and the coast, owing to the heavy precipitation of snow piling up a huge ice dome. Valley glaciers radiated from Ben Nevis in the last stages of the glaciation, but the chief lochs in this district are not radial from Ben Nevis, but form a circular series around it.

The angular fiord networks also occur in regions where there are no indications of the former existence of glaciers. Thus the colony of Hong Kong, including the adjacent peninsula on the mainland of China, has a fiord-like series of intersecting valleys, and a most beautiful example of the same arrangement occurs in the peninsula of Sinai. The Gulf of Akabah has many of the characters of a fiord, and Prof. Bonney has so called it; and, if Sinai were partially submerged, it would be divided into angular islands and peninsulas, separated by parallel-sided, steep-walled valleys, which would form a typical series of fiords.

The explanation of fiord valleys as due to intersecting fractures explains the chief facts of their distribution. It explains their restriction to plateau countries, as it is only where wide areas have been uplifted that they are shattered by regular intersecting cracks. It also explains their restriction to areas of old rocks, for the younger rocks yield by stretching and not by cracking.

The fiord valleys were not formed by gaping cracks of the full width of the present valleys. The cracks caused narrow clefts along the planes of weakness, which have been widened by denudation. Water and air enter them and cause the decay of the rocks. Streams remove the weakened rock material, and the clefts are gradually widened into river valleys, and if the country be subsequently glaciated the ice enters the valleys and completes their formation.

Uplift alone is, however, inadequate to produce fiords. Subsidence also is necessary to let in the sea. In nearly all fiord countries the last movement has been a fresh elevation. Many fiord thresholds appear to be due to a tilting of the country at the last uplift.

Fiords, therefore, are produced in regions which have undergone repeated earth movements. They mark out areas of the crust which in recent geological times have undergone alternate elevation and depression. These regions are mainly polar and circumpolar, as in the equatorial zone the uplifts have been more local. There are numerous raised coral reefs, but the tropical coasts of Africa, Australia, and America lack the widespread raised sea beaches which are so charactertistic of the chief fiord regions. The restriction of the fiord areas to high northern and southern latitudes gives a clue to the cause of the fiord movements. They may be explained as a deformation of the earth which is more marked in the polar than in the tropical zones. If a flexible circular band be rotated about its axis it becomes oval, and the radial movement is greater on the flattened polar sides than on the raised equatorial zone. The deformation of the earth which produced the fiords caused greater vertical movements in the polar and circumpolar regions than in the tropics, and thus fiords are characteristic of higher latitudes.

I have therefore endeavoured by this rapid survey of a wide subject to show that fiords are not only attractive from their unique scenery and their special historic interest, but that they give important evidence relating to the structure and mobility of the earth. The spirit of maritime adventure born in the Scandinavian fiords gave the European races the mastery of the sea and a political predominance which is world-wide in its influence. The geological study of fiords leads to geographical problems that are also world-wide in their range, for the view that fiords are due to local superficial agents chiselling out furrows on an impassive earth explains neither their features nor distribution. Fiords teach more significant and far-reaching lessons; they point to deep-seated forces which affect the earth as a whole. However greatly fiords may have been moulded by ice, wind, and water, they are not primarily due to those agencies, which have used the fiords, not made them.

The ultimate cause of fiords is the rupture of certain wide areas of the earth by the pulsation of the crust under the play of titanic forces set at work by the great Miocene disturbances which upheaved the chief existing mountain systems of the world.

SOCIETIES AND ACADEMIES.

London.

Mathematical Society, April 11.—Dr. H. F. Baker, president, and temporarily Prof. A. E. H. Love, vice-president, in the chair.—A. **Cunningham**: Mersenne's numbers.—G. N. **Watson**: A modification of Liouville's theorem.—G. H. **Hardy** and J. E. **Littlewood**: Contributions to the arithmetic theory of series.—G. B. **Mathews**: Complex binary arithmetic forms.—H. S. **Carslaw**: An application of the theory of integral equations to the equation $\nabla^2 u + k^2 u = 0$.—H. F. **Baker**: (i) Some transformations of Kummer's surface; (ii) the curves which lie on a cubic surface.

Paris.

Academy of Sciences, April 9.—M. F. Guyon in the chair.—E. H. **Amagat**: The variations of the pressure coefficient with temperature and on some points which depend on it in the study of the internal pressure of fluids. The pressure coefficients of argon are calculated from experimental data obtained in the laboratory of Prof. Kamerlingh Onnes for temperature ranges, $-121\cdot2°$ to $-109\cdot9°$, $-102\cdot5°$ to $-57\cdot7°$, $-57\cdot7°$ to $0\cdot0°$, and $0\cdot0°$ to $+20\cdot4°$; for hydrogen at temperatures $-217\cdot4°$ to $-182\cdot8°$, $-182\cdot8°$ to $-103\cdot6°$, $-103\cdot6°$ to $0\cdot0°$, and $0\cdot0°$ to $100\cdot2°$; for helium, at temperatures $-258\cdot9°$ to $-182\cdot8°$, $-182\cdot8°$ to $-103\cdot6°$, $-103\cdot6°$ to $0\cdot0°$, and $0\cdot0°$ to $100\cdot3°$. All the results point to a small diminution of the pressure coefficient as the temperature increases. The changes observed are much larger than would be expected from the values of the specific heat at constant volume.—E. L. **Bouvier**: The classification of the genus Caridina and the extraordinary variations of a species of this genus, *Caridina brevirostris*. The variations of this species have led the author to reject the existing classification of the Caridinæ based on the rostral structure; suggestions for a new scheme are put forward.—Paul **Sabatier** and M. **Murat**: The direct addition of hydrogen by catalysis to the benzoic esters: the preparation of the hexahydrobenzoic esters. The addition of hydrogen to methyl and ethyl benzoates by the catalytic action of reduced nickel requires the temperature of the reaction to be maintained exactly at 180° C. Good yields of ethyl and methyl hexahydrobenzoates are thus obtained.—Kyrille **Popoff**: The influence of the various methods of photometric measurements on the estimation of stellar magnitudes.—Ch. **Jordan** and R. **Fiedler**: Contribution to the geometry of convex curves and of certain curves which are derived from them.—A. **Cotton** and H. **Mouton**: New substances showing magnetic double refraction. The straight chain carbon-compounds and some of their derivatives remain inactive in a strong magnetic field. Substituted paraffins, however, containing the nitro-group or a halogen exhibit magnetic double refraction.—Albert **Colson**: The singular features of certain proofs in physical chemistry. A reply to a recent note of M. Langevin, dealing especially with the van't Hoff theory of solution.—Ed. **Griffon** and A. **Maublanc**: The microsphœra of the oak.—Paul **Macquaire**: Two combinations formed by iodine and the tyrosine obtained by the trypsic hydrolysis of albuminoid materials. Analyses are given of a definite diiodo-derivative of tyrosine; by the action of boiling water on this substance a new iodine derivative of tyrosine was obtained containing less iodine.—A. **Desgrez** and Mlle. Bl. **Guende**: The influence of an excess of sodium chloride on nutrition and on renal elimination. An excess of common salt in food favours auto-intoxication.—Gabriel **Bertrand** and F. **Medigreceanu**: The normal manganese in the blood. Traces of manganese were found in blood from the sheep and the horse; negative results were obtained with blood from man, rabbit, chicken, and duck. The amount of manganese present in the blood of man and the higher animals is much less than has hitherto been supposed.—Ed. **Bourquelot** and M. **Bridel**: The action of emulsion upon salicin in alcoholic solution. Salicin is hydrolysed by emulsion in solutions containing proportions of alcohol up to 90 per cent. In aqueous solution the hydrolysis is not complete, about 5 per cent. of the salicin remaining unchanged.

IN NATURE'S BYWAYS.

Die Pflanzengallen (Cecidien) Mittel- und Nordeuropas, ihre Erreger und Biologie und Bestimmungstabellen. By Dr. H. Ross. Pp. ix + 350 + x plates. (Jena: Gustav Fischer, 1911.) Price 9 marks.

Die Gallen der Pflanzen. Ein Lehrbuch für Botaniker und Entomologen. By Prof. E. Küster. Pp. x + 437. (Leipzig: S. Hirzel, 1911.) Price 16 marks.

AMONG the byways that lie in the borderland between botany and zoology and appeal to the students of both sciences, few, if any, offer more attractions than the study of galls. That certain organisms can change the modes of action of the living substance in some other, and can make it produce new structures to benefit themselves, is an intervention of a kind to arouse interest. But that power is shared by plants and animals of widely different types, and so related to others that do not possess the power as to indicate that it has often been independently acquired. The effects produced by some amount to little more than sufficient to heal wounds, while at the other extreme we find growths unlike any uninjured structure of the host; and between these are galls of varied forms and structure, each true to its type. The wide diffusion of the power to influence the work of the protoplasm seems to point to the readiness of that substance to respond to certain kinds of stimuli, and to give some warrant for the hope that means to regulate its activities may be discovered. As yet, however, the attempts to produce galls artificially have failed.

The literature on galls is already very extensive, though comparatively recent; but much of it is scattered in periodical literature, or forms large and costly works. The two before us are among the latest contributions to the mass, and though comprehensive in treatment are among the less expensive books. They treat the subject from different points of view.

"Die Pflanzengallen Mittel- und Nordeuropas," by Dr. Ross, is intended to supply a descriptive catalogue of the galls recorded from Central Europe and Scandinavia, including those caused by plants as well as those of animals. The descriptions are limited to the briefest possible statement of the distinctive features, in keys of tabular form, of all the galls in each genus. The characters have been carefully selected, though sometimes too brief; but contractions are freely used for the organs of the hosts, and the tables have not the clearness of those in Houard's "Zoocécidies des Plantes d'Europe." Somewhat above a hundred of the galls caused by animals are figured, often with details of structure, on the ten plates. All the galls in each genus are treated in a single table, the species of the hosts being named after the description of each gall, except under Quercus, where *Cerris* receives distinct treatment from the other oaks, owing to the multitude of galls on these trees. For ease of reference the genera are arranged alphabetically, but the gain is more than balanced by the loss in the separation of nearly allied host-plants, and the consequent obscuring of the relationships between the galls on them.

The tables are preceded by eighty pages of general discussion. The author defines "gall," in the widest sense of the word, as any deviation of structure due to growth produced (usually by a chemical stimulus) on a plant by an organism living parasitically or symbiotically on the plant. He treats of the forms and structure of galls, the various types of animals and plants that give rise to them, the effects on the host-plants, the distinction of galls into "organoid" (which allow recognition of the parts of which they are modifications) and "histoid" (not evidently comparable with parts present in the plant naturally), the limitation of the gall-forming response to the meristem, the nature of the stimuli employed by different gall-makers and of the response to each, the formation of "procecidia" (growths abandoned by the larvæ very early), and other topics of great biological interest, such as the different relations to production of galls exhibited within the limits of certain species of gall-makers. Some of these in alternate generations produce galls of different structure on the same host; or they pass from one host to another, producing galls on both, or on one host but not on the other; or the galls may be formed by some individuals (*e.g.* of certain weevils), and occupied by their larvæ, while other larvæ of the same species may live healthily on the same host without a gall being formed. The "ambrosia" galls, in which fungi grow, to serve as food for the larvæ, also find mention.

Brief directions are given for collecting and preserving galls, and for rearing the makers to maturity. Within the limits set, the book will be found a helpful and suggestive guide to the determination of the galls of Central and North Europe, and a good introduction to their study.

Dr. Küster's "Die Gallen der Pflanzen" does not attempt to give an exhaustive list of the galls of any one region or country, its aims being to afford a comprehensive and trustworthy introduction to the study of galls, illustrated by series of selected types, to indicate the progress already made, and to point out and direct attention to some of the many problems that suggest themselves more or less urgently at each step forward.

The term "gall" is employed in almost the same sense as by Dr. Ross, and the subjects treated of by him are also met with in this work; but the whole subject is discussed far more thoroughly, and from other points of view, with very copious notes and bibliographical references.

The introduction gives a historical outline of the investigation of galls from the earliest records onwards. Some of the earlier beliefs as to their origin are similar in kind with the strange explanations of the origin of fungi at the same period; and they form a striking contrast to the views expressed by Malpighi, the founder of the scientific study of galls, in his treatises, "De gallis" and "De variis plantarum tumoribus et excrescentiis." But for a long period after Malpighi, little interest was shown in them except by Réaumur, and a catalogue of galls due to animals (zoocecidia) published in 1858 included only about 300. How rapidly knowledge has advanced since then is evident from the catalogue by Houard, issued in 1909, enumerating more than 6000 from Europe and the Mediterranean area of Africa and Asia, while numerous records have recently appeared on the galls of many other regions.

Dr. Küster divides his book into comprehensive chapters devoted to the great divisions of his subject, beginning with one on the gall-producing animals and plants considered class by class. The second consists of a review of the gall-bearing plants, also treated systematically. The situations of galls on their hosts and their morphology receive very full consideration, as do also their internal structures and their relations to the healthy tissues of the host-plants. Then follows a brief account of the chemistry of galls, including the physiological processes that go on in them. The two last chapters are the most important and suggestive of all, the one being devoted to the etiology and the other to the biology of galls. Under etiology are considered the prerequisites for their formation, the varying degrees of ability shown by the gall-makers to originate and to develop them, general questions as to means employed by their makers, the formation of galls as affected by absorption, nutrition, and wounds, their connection with alterations of correlation in the members and tissues of the host, their tendency to induce permanent variations (very slight, as tested by cases where the growth extends beyond a gall), abnormal galls, and the information that they yield as to their etiology, and as to the effect on their growth of the death of the maker or its early abandonment of the gall. The great need of further efforts to produce galls experimentally is dwelt on, while the small result from the experiments of the past is fully recognised, and makes still more evident the need to observe very carefully the actual course of things in the development of galls, both normal and abnormal. Many show themselves to result from stoppages of advance in complexity, while increase goes on in mass of tissues.

Under the biology are included a number of most interesting topics, such as the grade of restriction to certain host-plants, alternation of generations, with or without alternation of hosts, tendency to produce "physiological species" or races restricted to certain hosts, though scarcely differing morphologically, relative frequency in various habitats (*e.g.* water plants, dry moor and mountain floras, deciduous trees, &c.), methods of distribution in space, palæontology, relations between galls and their makers (duration of life, sexual dimorphism of galls, methods of emergence of makers), effects of galls on welfare of host, and relations to other organisms (feeders on galls, inquilines, "ambrosia," and parasitic fungi, &c.).

A brief account is given in an appendix of the relatively few galls ("thylacia") upon the bodies of animals.

Space will not allow of quoting any of the remarks on the numerous problems to which the reader's attention is directed as in need of investigation. For these, as for much else, we must refer those interested in galls to the work itself, assured that they will find no better or more trustworthy guide. Its value will be most fully felt by those who have already gained some knowledge of galls in the field. As already stated, it does not aim at being a descriptive catalogue. Numerous good figures in the text (not always correctly referred to, however), and a sufficient index add to the value of this excellent work.

SOIL STRUCTURE AND PLANT GROWTH.

Boden und Klima auf kleinstem Raum. Versuch einer exakten Behandlung des Standorts auf dem Wellenkalk. By Prof. G. Kraus. Pp. vi+184+Taf. vii. (Jena: Gustav Fischer, 1911.) Price 8 marks.

NO one can pass from a sand to a chalk formation without being struck by the very sharp changes in vegetation, even where similar climatic conditions persist, changes which clearly indicate marked or even fundamental differences in soil conditions. But so far as we know no one has taken the trouble to investigate a particular case with anything like the completeness it deserves. The author of the present volume set out to remedy this deficiency by making adequate study of a little region near Karlstadt-on-the-Main, where the sandstone with its green woods and red, moist soil gives place to limestone and a dry, glistening white soil.

In similar instances it has been the practice to attribute the difference of flora to the presence of calcium carbonate in the limestone soil and its absence from the sandy soil, and the author began with this hypothesis in view by making numerous determinations of calcium carbonate in the soil. But he was soon driven to the conclusion that calcium carbonate is an exceedingly variable quantity; indeed, he doubts whether any estimate can be obtained of the amount in the layers of the soil immediately in contact with the plant root. Making the determination in the accepted way, however, and comparing the analytical results with the vegetation, he failed to find any plant that occurred exclusively on soils of even approximately the same calcium carbonate content; there were always variations within very wide limits. A vague relationship only could be traced: some plants showed a clear preference for soils containing a high amount of calcium carbonate, whilst others were found on soils containing only small quantities. Thus *Festuca glauca* occurred on soils containing 28 to 64 per cent., *Teucrium montanum* on soils containing 11 to 73 per cent.—more generally, however, when more than 35 per cent. was present—and *Melica ciliata* where 24 to 60 per cent. occurred. Against these the limits for *Brachypodium pinnatum* were 2 to 43 per cent., for *Koeleria cristata* 1·4 to 27 per cent., and for *Hieracium pilosella* 16 to 56 per cent.

A mixed flora was found where the limestone merged into the sandstone. True chalk plants like *Pulsatilla* and *Hippocrepis* grew in spots where calcium carbonate was absent, while calcifugous plants like *Calluna* and *Vaccinium* were found in places where more than 3 per cent. of calcium carbonate occurred, and alongside *Anemone sylvestris* flourished. With the exception of a few plants that require large amounts of calcium carbonate the author seems to have found most of the local calcicolous plants on soils entirely free from calcium carbonate. He has completely lost faith in the lime content of the soil as a true basis of discrimination, and looks forward to the time when every calcicolous plant shall have been found on chalk-free soils.

The wandering of plants for which calcium carbonate is supposed to be essential on to chalk-free soils has been already observed, but never accounted for. When exceptions to a rule begin to crop up, there is a strong temptation to invent a new name to describe the exceptional case and after a while to take the name as an explanation of the phenomenon, and the cynic might argue that something of the sort has happened with the word invented in this instance—heterotopism. The present author, however, goes further; since the calcium carbonate hypothesis fails, he turns to a second hypothesis, the view that the physical properties of the soil and not the calcium carbonate really determine the distribution of plants. The particular set of properties best suited to calcicolous plants are usually found in soils rich in calcium carbonate, while those suited to calcifugous plants are associated with soils poor in calcium carbonate; but the carbonate itself does not play the controlling part in the matter. The author is not prepared to say that calcium carbonate exerts no specific action on the plant, but he knows of no proof that it does. Even small quantities of calcium carbonate are known to affect markedly the properties of the soil; he therefore made mechanical analyses, determined water-contents and temperatures of the soils, and also noted their aspects and general relation to their surroundings. Working over very small areas in great detail, he finds distinct similarity in general physical conditions on spots where the same plants are growing. In the last instance the physical properties of the soil are some function of the soil structure, which therefore he considers to be the determining factor.

Whether the author's conclusions are wholly justified can only be ascertained by further experiments, but he certainly makes out a strong case for his main thesis that the botanist must pay more attention to the properties of the soil if he wishes to account for the distribution of plants. The book will be found of much interest to ecologists as a piece of painstaking and methodical work, and it emphasises the important fact that careful investigation over a limited area is likely to prove very fruitful in the study of ecology.

E. J. Russell.

THE ADVANCE OF PHOTOGRAPHY.

The Advance of Photography: its History and Modern Applications. By A. E. Garrett. Pp. xiii + 382. (London: Kegan Paul, Trench, Trübner and Co., Ltd., 1911.) Price 12*s.* 6*d.* net.

IT is about forty years since Dr. Hermann Vogel wrote his volume entitled "The Chemistry of Light and Photography in their Application to Art, Science, and Industry" for the "International Scientific Series," so well known by their red covers. The copy before us is a "new and revised" edition issued in 1876, and about two-fifths of its contents are devoted to historical facts and processes, two-fifths to the applications of photography, including photo-mechanical methods, while the remaining fifth is devoted to the action of light, the correctness of photographs, perspective, &c., with a final chapter on "Photography as a subject to be taught in art and industrial schools." In this last chapter Dr. Vogel makes an earnest plea for the inclusion of photography in the courses of study of technical institutions, not "to train professional photographers . . . but so far as it is of importance for art and science." He bases his plea, not only on the opinions of others, but also on his nine years' experience as professor of photography in the Royal Industrial Academy of Berlin.

This is the book that Mr. Garrett has sought to modernise, or "bring up to date," as the saying is. The present author has given the volume a new title, transferred Vogel's name from the title-page to the preface, and states that "although the present book is of necessity practically a new work, it is based upon the lines laid down in the original publication." The only noteworthy omission of the substance of the original volume that we observe is the last chapter, that is the plea for the consideration of photography as a subject to be included in the curriculum of colleges, because of the importance and the universality of its applications. Perhaps the author is justified, for, in this country at least, there is little "advance" to record with regard to this matter. The study of photography, even by those who need its aid, too often means no more than working from the instructions issued by manufacturers, with perhaps an occasional question across the dealer's counter.

The remainder of the volume is rearranged somewhat and added to. The chief additions are on gelatino-bromide dry plates (which, of course, were not in use when Vogel wrote), photography in natural colours, Röntgen-ray photography, photo-telegraphy, and animated photography. These final chapters are interesting, instructive, and well illustrated, though they sometimes wander rather far from photography, as, for example, in the consideration of the apparatus used in Röntgen ray work. When a matter such as this is treated and illustrated so fully, we naturally expect that the more purely photographic subjects will have received at least as much attention, but here we are disappointed. Within the space of four pages there is all that we can find with regard to carbon printing, the gum bichromate process, ozobrome (ozotype is not mentioned), printing-out papers, toning and fixing, phosphate papers, bromide printing, gas-light papers, and platinum printing!

Lenses are classified into (1) rapid rectilinears, (2) portrait lenses, (3) wide angle lenses, and, as a kind of supplement, telephoto lenses. All that we can find about Abbé and Schott, and the optical work they carried out which has revolutionised the construction of photographic lenses, is that when they "undertook to construct a lens suitable for this work," that is, exact work, "they had the very great advantage of having a definite aim in view."

The author's style is generally clear, but there are some sentences which need a little expansion or explanation, because as they stand they are liable to mislead the reader. For example, at p. 323 we are told that

"the superiority of apochromatic lenses in micro-photographic work is only very apparent when the preparation to be photographed is unstained, and extremely minute details are required such as can only be resolved with light of short wave-length. Hence it is that the cheaper achromatic lenses are much more frequently used in conjunction with stained preparations, autochrome plates, or orthochromatic plates and colour screens."

The unqualified statement that it is "essential" to have a stand of "a large type and provided with a rotating and centering stage" for the purposes of photomicrography, appears to us to be contrary to general experience. When such matters as these are elucidated, the volume will be an interesting and useful treatise, though it can scarcely claim to be comprehensive.

C. J.

THE GRAMMAR OF SCIENCE.

The Grammar of Science. By Prof. Karl Pearson, F.R.S. Part i., Physical. Third edition, revised and enlarged. Pp. xx + 394. (London: A. and C. Black, 1911.) Price 6s. net.

THE notices formerly given of the first and second editions of Prof. Pearson's well-written "Grammar of Science" (see Nature, vol. 46, pp. 97–99, 1892, and vol. 62, pp. 49–50, 1900) scarcely need to be added to in the way of a general review. The main feature of the new edition which differentiates it from the others is the addition of two new chapters: chapter v., on contingency and correlation, and chapter x., modern physical ideas. The former chapter is particularly noteworthy, presenting as it does in a wonderfully small compass the scientific significance of the two terms contingency and correlation. The general reader, whose mathematical symbolism is of the most elementary type, will probably find difficulty in appreciating the full scope of this chapter. A simple concrete example might not have proved amiss.

To keep the volume a reasonable size the addition of this new matter has compelled the author to reserve for a second volume the subjects which were formerly discussed in the last two chapters, namely, life and the classification of the sciences. In other respects there is singularly little change, the author being evidently convinced that the original statement could not be improved upon. It is a pity, perhaps, that some of the more polemical sections have not been modified so as to prevent misunderstanding as to the intention of some of the earlier writers who are attacked. Prof. Pearson himself speaks of "the acceleration of A due to B," but carefully adds a footnote to guard the reader against taking the phrase in its obvious meaning. Newton and others were guilty of similar anthropomorphism, for which they are denounced. They failed to add warning footnotes, partly because they had a grand faith in the common sense of their readers, partly because they were writing a constructive scientific treatise, and not a critical grammar of science. These attacks, however, add spice to the pages of a book which excels in the clearness with which the significance of natural law is discussed.

It should be mentioned in conclusion that chapter x., on modern physical ideas, is contributed by Prof. E. Cunningham. The scope of the chapter is sufficiently indicated by the titles of a few of the sections, such as: the electromagnetic constitution of the atom, electromagnetic mass, fluid or space distribution of electricity, and the theory of relativity. The expanded second volume of this interesting work will be looked forward to with great expectations.

A BIOLOGICAL DICTIONARY.

Wörterbuch der Biologie. By Dr. Heinrich Schmidt. Pp. viii+581. (Leipzig: Alfred Kröner, 1912.) Price 10 marks.

Writers on biological subjects have always used a rich vocabulary, but with the growth of information and knowledge there has arisen such a wealth of technical terms and of classificatory nomenclature that readers, and even writers themselves, are often at a loss, and it is difficult to refer an inquirer to any handy work containing an adequate glossary of terms used in anthropology, botany, and geology. Ziegler's "Zoologisches Wörterbuch" supplies the want for zoologists, and supplies it well, but there is undoubtedly room for such a dictionary as this which Dr. Schmidt has written. At a rough estimate it contains 10,000 definitions, and the labour of compiling it must have been very great, for not only are descriptive words explained but there are also many generic terms and expressions that appeal only to the advanced systematist. The derivations of the words are not given.

Use, and use alone, can test the value of this dictionary. So far as we have been able to determine its accuracy and inclusiveness, the work has stood the test very well. As an example of the unexpectedly interesting information afforded in dealing with arid or forbidding names, we select "Lebensdauer." Under this heading a most interesting summary is given of the relative longevity of plants and animals. We are told on the authority of Hesse's work, "Tierbau und Tierleben," that an earthworm lives ten years, a leech twenty or even twenty-seven years, a pond mussel twelve years, a (fresh-water) pearl mussel fifty to a hundred years. Most of the definitions we have examined seem well arranged, though here and there a little inaccuracy has crept in. For example, under "body-cavity" we are told that a true coelom is well-developed in limulus, spiders, millipedes, and insects, whereas, of course, the well-developed cavity in these animals is not a true coelom at all.

The terms used in classification seem needlessly numerous, and are sometimes very unhappily expressed. Protozoa, for example, are divided into "Cytomorphæ" and "Cytoideæ," a new and abominable classification. Certain cases of omission have occurred in the course of a few days' use. The term "lipoids," about which so much is heard just at present, might have been included. The class of pigments known as lipochromes is left out, whilst the melanins are included. But these considerations are of small account in comparison with the mass of successful definitions which testify to the author's tireless researches. A few illustrations are given, and a geological table is added as an appendix.

OUR BOOKSHELF.

Links with the Past in the Plant World. By Prof. A. C. Seward, F.R.S. Pp. ix+142. (Cambridge: University Press, 1911.) Price 1s. net.

The object of this neat little volume is best explained in the author's words. "I hope," he says, "that I may succeed in attracting some of my readers who are already interested in living plants to the study of plants of former ages." The book is likely to fulfil its purpose. Without attempting any serious discussion of evolutionary theories, the author brings home to the reader the deep interest of a number of problems in the history of plants and their distribution.

The introductory chapter begins with the always attractive subject of the longevity of trees, and explains very clearly how a tree grows and the nature of the so-called annual rings. From the age of individuals we are led on to archæological evidence of antiquity. "From the period claimed by archæologists we pass by gradual stages into the domain of the geologist."

Before entering on this field, a chapter on geographical distribution, a subject of which the importance has not always been realised by modern students, is appropriately introduced. Darwin's high appreciation of the study of distribution, which he called "that almost keystone of the laws of creation," is emphasised. Quite recently, interest in distribution, stimulated by the kindred study of ecology, has much revived.

In his sketch of the geological record, Prof. Seward points out that the history of the world's flora must go back immensely farther than our records show. "The relics of plant-life furnished by the Devonian and succeeding formations represent the upper branching-systems of a deeply rooted and spreading tree, the lowest portions of which have been destroyed or have left no sign of their existence" (p. 44).

The preservation of plants as fossils is the subject of chapter iv. A particularly striking picture of the flood-plain of the Rio Colorado, with drift-wood stretching over a tract 25 miles across, gives a vivid idea of how a fossil "pine-raft" may have been formed.

The four succeeding chapters illustrate the general theme by special examples of "links with the past," taken from the ferns, the big trees of California, the Araucaria family, and the maiden-hair tree.

The illustrations throughout are remarkably good. Mr. Tansley's photographs of Malayan ferns are of exceptional beauty. The book concludes with a full bibliography and a useful index.

D. H. S.

How to Attract and Protect Wild Birds. By M. Hiesemann. Translated by Emma S. Buchheim. With an introduction by Her Grace the Duchess of Bedford. Second edition, with many revisions. Pp. 101. (London: Witherby and Co., 1911.) Price 1*s.* 6*d.* net.

We have already directed attention (Nature, July 22, 1909) to the first edition of the useful little work by Martin Hiesemann on the practical preservation and protection of birds by the provision or creation of opportunities for their breeding, winter feeding, and by fighting the enemies of birds, and little remains to be said of the second edition except that it has been revised and enlarged in many essential points. This excellent little book was written for Germany, where the birds' natural conditions of life differ somewhat from those prevailing in this country. For instance, our winters are less severe, and so less systematic feeding at that season may be necessary; our country is, generally speaking, less open and more wooded (hedgerows, gardens, and ornamental grounds and plantations being taken as woodlands in this connection), so that the provision of special breeding plantations may not be desirable here. Our birds of prey have been closely killed down, and there seems to be no way (permitted by law) of dealing with the domestic cat, the birds' worst enemy in this country.

But the portion of the book dealing with the provision of nesting places for birds which breed in holes deserves the closest consideration by those who wish to encourage the different species which fall under this category; for the difficulty experienced by these birds in finding nesting places has greatly increased, since by the rules of modern forestry nearly every old tree is felled, without regard to the fact that the holes it contains serve as shelters and nesting places. Those men who care only for what is of practical use grudge the old, decayed trees the little space on which they stand, and prefer to convert them into firewood. The remedy for this is the provision of nesting boxes, and we are told here what is the right sort of box, and the right—and the wrong—way of hanging them up. The illustrations are numerous and very useful.

Applied Biology. An Elementary Textbook and Laboratory Guide. By Prof. M. A. Bigelow and Anna N. Bigelow. Pp. xi + 583. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1911.) Price 6*s.* net.

This volume has been prepared for use in higher schools during a year's course of five hours per week. The frog and the bean-plant are taken as types for the study of animal- and plant-structure and biology. The succeeding part of the book contains an account of the structure and life-histories of "seed-plants" and "spore plants" (ferns, mosses, algæ, fungi, and bacteria). The chief phyla of the animal kingdom are traversed in the third part of the book; but the authors have attempted to compress too much material into these 140 pages, with the result that many subjects are necessarily considered so briefly that only imperfect ideas of them are conveyed. For instance, "Paramecia reach a state when they are unable to continue to divide. Two such individuals come into contact, and through their delicate cell-walls some of the nucleus of each one passes over to join the nucleus of the other,"—is surely an incorrect and inadequate account of the conjugation phenomena. There are a few slips in this part of the work, *e.g.*, the sword-fish is placed among the cartilaginous fishes. The succeeding part of the work deals in an interesting manner with the structure of the human alimentary canal, digestion, food-values, blood, respiration, excretion, and nervous activity, and leads up to an application of biological principles to personal hygiene.

The book contains much information on biological subjects of public interest, *e.g.*, toxins and anti-toxins, mosquitoes and flies in relation to disease, the bacterial treatment of sewage, parasites in meat, and shows clearly the important bearing of a knowledge of biological science on many aspects of human life.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Insect Parasites on Trees.

THE note in NATURE of April 11 (p. 144) about the ravages of insect parasites upon the chir pine (*Pinus longifolia*) in the Himalayas suggests a consideration which, I think, is not enough present to foresters and planters in this country. I am too destitute of biological or physiological knowledge to venture an opinion upon the causes which lead to the excessive multiplication of parasites, whether animal or fungoid, upon animals and plants whereof the vitality has been impaired by some other agency; but the phenomenon must be familiar to most people, though it is generally wrongly interpreted. Normally vigorous organisms may, and do, entertain a reasonable number of parasitic guests without appreciable loss of vigour; but these guests seem to bide their time until the host is weakened by accident or disease, when they display a surprising amount of latent fecundity. In the case of the chir pine, the opportunity occurs when the vitality of the tree is lowered by tapping for resin; in other words, when it is depleted of its protective juices, the diminution of which gives easy access to the Platypus larvæ.

To an analogous process may be traced the prevalence of larch canker, which, during the last fifty years, has brought such heavy loss upon owners of woodland, having previously attracted no attention whatever from foresters. It has now become the most widely destructive tree disease in Britain. The hostile agent in this case is a pesizoid fungus, *Dasycypha calycina*, the ravages of which generally manifest themselves on poles from seven to fifteen years old. Many of these die or become hopelessly deformed, and all attempts to arrest the evil have hitherto proved futile, although recent works on forestry bristle with recommendations on the subject. Yet I am convinced that planters have the remedy in their own hands—at least as regards planting in the future.

The fungus Dasycypha is no new creation; it has always found a home on the larch. Dr. Hartig found traces of it in Swiss larch of 100 years' standing. I have found it also on Corsican and Scots pines, where it is quite innocuous. The European larch has succumbed to its attack in Great Britain because, under the conditions to which foresters too often expose them, the young plants receive a severe check at the critical time of planting, and do not recover strength before the mycelium has penetrated the tissues so far as to hinder or prevent recovery.

This check is the result of the drying of the roots during transport from a distant nursery. There is Dasycypha in the noble larch woods of Dunkeld, but no cankered larches. The parasite has never had a chance of overcoming its host, because these trees were all reared from seed in home nurseries and planted out straight away.

The Japanese larch (*Larix leptolepis*) is very nearly akin to the European species, but is distinguished by its immensely superior vigour in youth. Hence, although the characteristic larch parasites—Dasycypha, Chermes, and the large larch sawfly—may all be found in a plantation of Japanese larch here, the trees are none the worse for their presence.

The lesson to be learnt by our foresters seems to be that although the native climate of the European larch is very different from that of the British Isles, it adapts itself readily to British conditions, provided that care be taken to protect it from any check to its vitality, and that they may treat with indifference prescriptions against this and other tree diseases for exterminating parasites or checking their attacks, such as hand-picking, smoking, spraying, &c., all of which are childish in their futility and prohibitive in expense when applied to large woodland areas.

Monreith, April 15. HERBERT MAXWELL.

The Propagation of Long Electric Waves during the Solar Eclipse.

IT is now common knowledge that the long electric waves employed in wireless telegraphy over great distances appear to travel better during the hours of darkness than in the daytime. It is known besides that the natural electric waves produced by atmospheric electrical discharges—which are heard in the telephones of receiving stations as clicks or scratching noises, and are called "strays" or "X's" by those engaged in wireless telegraphy—are also propagated better in darkness than in light.

These differences between day and night propagation suggested to me that observations of the strength and number of strays, and of the strength of signals, during the solar eclipse of April 17, might prove to be of interest. Accordingly a record of strays and signals was made at my laboratory in London during the progress of the eclipse. The apparatus was set so as to receive signals of wave-length 5500 metres, which is approximately the wave-length of the signals emitted from the Marconi Transatlantic station in Ireland.

About the time of the eclipse strays were fairly numerous. The table below is a convenient summary of them. The number entered under each of the times was obtained by making a sort of rough time-integral of the number and intensity of the strays heard from half a minute before to half a minute after the beginning of the minute indicated.

Time	11.46 a.m.	47	48	49	50	51	52	53	54	55
Strays	10	10	11	12	13	17	21	20	21	22

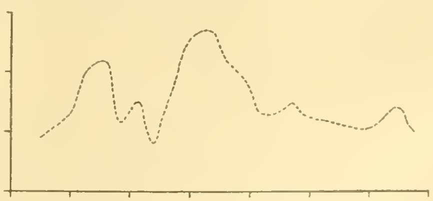
Time	11.56 a.m.	57	58	59	12.0 noon	1	2	3	4	5	6	7	8
Strays	22	17	12	12	13	15	14	9	8	12	14	17	23

Time	12.0	10	11	12	13	14	15	16	17	18	19	20	21
Strays	25	24	26	27	27	27	24	22	21	20	19	17	14

Time	12.22	23	24	25	26	27	28	29	30	31	32	33	34	35
Strays	13	13	13	13	14	15	14	13	12	12	13	13	11	12

Time	12.36	37	38	39	40	41	42	43	44	45	46	47
Strays	12	11	11	10	10	10	12	14	14	14	12	10

These results are exhibited in the curve, with the times as abscissæ.



The message-bearing waves from Clifden were brief and irregular, so no measurements of their intensity were obtained; but it was very noticeable that they were loud when the strays were loud, and *vice versa*.

The observations show that on the whole the darkness has its usual effect of facilitating the propagation of electric waves over great distances, but that there are portions of time during the period of greatest darkness at the receiving station when propagation is hindered. This minimum is not an accident, and was, in fact, not unexpected by me. It can be explained in some measure by a hypothesis which I have embodied in a paper and submitted to a learned society; but until the paper is published I feel precluded from discussing the phenomenon, and am writing to you merely to put the results of the observations on record.

I may add that Mr. Lempfert, of the Meteorological Office, has kindly informed me that there was not any trace of thunderstorm during the eclipse shown on the Daily Weather Reports of April 17 and 18. The distribution of pressure was not favourable for thunderstorms over the continent of Europe, though electric disturbances may have occurred in the low-pressure systems over the Spanish peninsula and the north of Norway. W. H. Eccles.

37 Chelsea Gardens, S.W., April 19.

Glazed Frost.

Judging from the letters recently published under this heading (Nature, pp. 414, 447, 484, 516, and 550), the phenomena known in New England as "ice storms" are of rare occurrence in Old England. They are of frequent occurrence along the Atlantic coast of North America, and the conditions which produce them are well understood.

In W. M. Davis's "Elementary Meteorology" (1893), p. 294, they are described as follows:—"Regions of strongly variable temperatures are subject to occasional winter storms in which the precipitation occurs as rain, but freezes as soon as it touches any solid body, such as the branches of trees, or telegraph wires, or the ground. This happens when the ground and the lower air have been made excessively cold during a spell of clear anticyclonic weather, when a moist upper current in advance of an approaching cyclone brings clouds and rain. Serious damage is caused by breaking down over-weighted wires and branches at such times. Wires may be increased in weight ten to twentyfold, and twigs even more than a hundredfold." Hann describes the phenomenon under the term "Glatteis" in his "Lehrbuch der Meteorologie" (1906), p. 190.

In a recent study of New England ice storms made under the direction of Prof. A. Lawrence Rotch by Mr. Charles F. Brooks in a research course in Harvard University, he found that twelve such storms occurred each year in the average for the period 1886 to 1911, inclusive. For the various months the frequency of occurrence was in the following order: January, February, March, December, November, and April. He concluded that the essential and ever-present conditions accompanying ice storms were: (*a*) rain falling; (*b*) when the temperature of the lower air was below freezing; and (*c*) with an inversion stratum aloft in which the temperature was above freezing. He found that the raindrops coming from the relatively warm stratum aloft are cooled below their freezing point as they pass through the colder stratum beneath, but are not solidified before reaching the ground or exposed objects, on which they form an ice sheet. On December 13, 1895, rain continued to fall when the temperature of the lower air was but 9° F.

Data obtained in kite flights during ice storms at Blue Hill Observatory verify the presence of this inversion stratum aloft. On February 9, 1905 (see Annals of the Astronomical Observatory of Harvard College, vol. lviii., part iii., p. 168), the temperature decreased with height from 29·3° F. at the observatory, 195 metres above sea-level, to 27·6° F. at 702 metres, the wind being uniformly E.S.E. in direction, and the air saturated. At 885 metres, however, the temperature was 32·9° F., the wind direction S.E., and the humidity 100 per cent. The base of the relatively warm stratum from which the moisture came in the form of raindrops was apparently between the last two heights quoted. The drops were undercooled as they descended through the colder stratum beneath, but did not change to ice until striking the ground. A somewhat similar condition was observed in the last international kite flight, that of March 7 last. On that occasion the auxiliary kites added to lift the line became so heavily coated with ice that they pulled the leading kite down instead of aiding its ascent, thereby rendering the maximum height reached during the flight considerably lower than usual. On that occasion the air was practically isothermal from the summit of Blue Hill to 625 metres above sea-level, the temperature being about 30·8° F. Above the latter level, however, the temperature increased steadily with height, and was 36·8° F. at 874 metres, the maximum height reached by the leading kite. Rain falling from this relatively warm stratum was undercooled by its passage through the colder air below, and changed to ice upon reaching solid objects.

In the vicinity of the observatory, after the occurrence of recent ice storms, it is not uncommon for the ice to accumulate to a depth of an inch on all exposed objects, and on one occasion, February 14–16, 1909, ice formed to a thickness of three inches, and did not disappear until February 20. During such storms we are able to keep the anemometer in operation only by frequently dashing hot water over the revolving cups and the other exposed parts.

Hyde Park, Mass., April 2.

Animal Intelligence.

The following incident may be of interest to readers of Nature.

We have a black retriever dog, very well trained. She is kept chained in a kennel in the yard, to which a number of fowls have access. During the last few days a black hen nearly every day lays an egg in the kennel, the dog meanwhile sitting outside. Unless someone takes the egg out directly afterwards, the dog takes possession of it and eats it.

This curious proceeding raises the question whether the hen lays the egg in the kennel for the dog's benefit, and whether the dog for her own advantage allows the hen to enter the kennel without molestation. M. N. W.

Frankland, St. Leonards, near Tring, April 19.

THE ECLIPSE OF THE SUN ON APRIL 17.

THE solar eclipse which occurred on April 17 appears to have been observed under ideal conditions all along the available track, and the question as to whether a *total* eclipse would occur is settled in the affirmative, for a totality of one-half to one second was witnessed in Portugal near Ovar.

No astronomical phenomenon of recent years appears to have attracted more general popular attention. Even the Lords Justices temporarily adjourned their sittings at the Law Courts in order to witness the unusual event.

A large number of well-known astronomers journeyed to various environs of Paris in order to locate themselves on the central line, and were rewarded by a magnificent view of an annular eclipse which was so near total as to present vividly the phenomenon of Baily's beads.

Among these was a party including Dr. W. J. S. Lockyer and Mr. Frank McClean, whose telegram we published last week. Dr. Lockyer states that at Chavenay they were located exactly on the line given by the American ephemeris, which corresponded with the amended path given by Dr. Crommelin. There is no doubt that the eclipse there was central; the phenomenon of Baily's beads, starting symmetrically from both ends of the diameter, made a glorious spectacle. No corona was seen, but there were two large prominences. Referring to the latter phenomena, Mr. A. A. Buss states that he observed two prominences, spectroscopically, in position angles 116°-120° and 182°-206°. The former was very bright, and agrees in position with one of those reported by Dr. Lockyer, and shown on a "disc" spectroheliogram taken at South Kensington at 12h. 6m. 18s. p.m.; but the position of the other is not in agreement. Unfortunately, Mr. Buss does not give the time of his observations, but they indicate that considerable changes were taking place among the prominence structures about eclipse time. We learn from Dr. Lockyer that some such changes are indicated on the excellent series of photographs secured by M. Deslandres, with the various forms of spectroheliographs, during the eclipse period.

Another party, located at St. Germain, also close to the central line, included Prof. Turner, Mr. Howard Payn, M. Antoniadi, Mr. Whitmell, and others. According to the *Times* correspondent, the eclipse commenced at 10h. 48m. 51s. G.M.T., and as the moon advanced three lunar peaks were plainly visible at the satellite's limb. Prof. Turner saw a narrow ring of corona round the southern limb of the sun, Mr. Whitmell, with a slitless binocular spectroscope, could discern numerous Fraunhofer lines at 11h. 52m., and Mr. Payn succeeded in catching sight of Mercury. The thermometric observations made by M. Antoniadi indicated a distinct fall of temperature nearly concurrent with the passage of the lunar shadow; at 11h. 25m. the shade temperature was 57° F., and gradually decreased to a minimum of 49° F. at 12h. 18m., *i.e.*, about 8m. after the maximum phase.

The reports from Portugal show that the party of British astronomers organised by the British Astronomical Association enjoyed ideal conditions at Milhiondos, near Oporto, and saw the whole sun covered except for two luminous points, probably prominences.

In a cablegram to Dr. Lockyer, Mr. Worthington—who was fortunate enough to be able to secure good photographs at Vavau last year—reports a totality of about one second, during which he obtained a photograph of the corona. This shows a corona of the "wind vane" type, such as one naturally expects at such an epoch as the present, when we appear to be in the trough of a minimum of solar activity. Mr. Butler, of the Solar Physics Observatory, was also in Portugal, and in a communication to the *Daily Express* reports that Mr. Dean and himself made observations from Olhomarinho, four and a half kilometres north of Ovar. Totality appears to have been certainly less than one second, and a glare around the dark moon was thought to be the lower corona, but no streamers were seen: nor were any large prominences detected. A portrait-lens camera of large aperture was employed to photograph the corona, and photographs of the chromosphere at the moment of the reversal of the dark lines were attempted. The visual observations showed bright chromospheric rings corresponding to the radiations of hydrogen, helium, &c. Both Mercury and Venus, but no stars, were visible.

Reports from Brussels show that the central line passed over Waremme, between Liége and Brussels, where an annular eclipse, with the apparent diameters of the sun and moon very nearly equal, endured for a few seconds.

Fig. 1.—Spectroheliogram taken at the Solar Physics Observatory on April 17, 12h. 6m.

At Berlin the conditions for observations were remarkably good, and Prof. Schwarzschild, director of the Potsdam Observatory, watched the eclipse from the Zeppelin airship, which ascended from Frankfurt-on-Main. At Gedser, Denmark, where the magnitude of the eclipse was 0·98, the air temperature fell 9° F. between the beginning and end of the eclipse.

At Cambridge, Prof. Newall secured photographs of the spectrum of the sun's limb near the cusps, which showed bright lines superimposed upon the ordinary dark lines of the Fraunhofer spectrum.

At the Solar Physics Observatory, South Kensington, a series of photographs was secured with the spectroheliograph throughout the various phases, and the "limb" photographs taken after the eclipse showed two small prominences. We reproduce here one of the "disc" photographs taken near mid-eclipse (Fig. 1), showing the thin crescent of the sun as photographed in the calcium radiation *K*. For visual observations the crescent was projected, by a 3¼-inch telescope, on to a white screen, the 4-inch image thus obtained showing exceedingly well the mountain peaks on the moon's limb. A noticeable feature was the ease with which one could produce crescent images through small apertures. The spaces between the fingers of an extended hand produced several, while thousands were seen projected on to a door by the uneven and dusty glass of a south window. The peculiar gloom which overspread everything near the maximum phase was very striking, being similar to that which precedes a dark thunderstorm.

The charts exhibited at the Meteorological Office show the thermometric effects of the solar obscuration very markedly. For the usual daily sheets, "quick-run" sheets were substituted on the various recording instruments for the eclipse period. The minimum air temperature during the run was recorded at 12h. 21m., 10·4 minutes after the maximum phase; during the eclipse the temperature ranged from 56° to 54° F., the maximum for the whole day being 59·3° at 2h. 45m. p.m. The Callendar radiation recorder showed an average rate of radiation received on a horizontal surface, during the eclipse time, of 0·030 watt per sq. cm., the maximum being 0·054 watt at 1h. 30m. p.m. and the minimum rate being 0·007 watt from 12h. 11m. to 12h. 15m., just after the maximum phase of the eclipse; the maximum rate of radiation for the day was 0·057 watt per sq. cm. at 1h. 50m. (1 cal. per minute = 0·07 watt).

The fall in temperature was very perceptible, but the actual readings are somewhat complicated, in their possible interpretation, by a breeze which sprung up about 11 a.m. and lulled at about 1h. 30m. p.m. At Balham Mr. Creeze recorded shade temperatures of 56° F. at the beginning, 52° at maximum phase, 51° at 12h. 30m. p.m., and 55·5° at 1h. 55m. p.m.

SARDINES.

A CASE recently decided at the London Guildhall by Alderman Sir George Woodman, in which a large part of both the evidence and the arguments turned on the question of the true meaning of the word "sardine," has excited considerable interest. On one side it was contended that sardines were the young of the pilchard (*Clupea pilchardus*) preserved in a particular way in oil and put up in tins, according to the methods employed on the west coast of France. On the other side, an attempt was made to show that the name "sardine" had in practice been extended, so that it included any small fish preserved in oil and put up in tins. Although the defendant, who was being prosecuted for selling Norwegian sprats or brisling put up in oil in tins as "sardines," won his case (without costs) on the ground that he had acted innocently, the decision on the question of the meaning of the name "sardine" followed closely the evidence given by the majority of the scientific experts. The Alderman's decision on this point was:—

"My decision is that the term 'sardine' is of French origin. It is the French name for the pilchard, the fish scientifically known as *Clupea pilchardus*. The industry of packing the immature pilchard in tins was started in France in 1882, and the fish so packed and imported into this country were universally known as 'sardines.' The word 'sardine' has now become anglicised, and I hold that the meaning of the term is 'the immature pilchard prepared and packed in oil in tins.' This is not what the defendant sold. The 'Skipper Sardines' sold by him were the Norwegian fish known as 'brisling.' The 'brisling' is the *Clupea sprattus* of the same family, but of a different species from the *Clupea pilchardus*, and it is the same fish, allowing for differences caused by local environment, as the English sprat."

The most interesting and complete account of the name "sardine" which we have seen was not, however, given in the evidence presented to the court, in so far as that evidence was published, but occurs under the signature "Quibbon," which we believe conceals the identity of a well-known and trustworthy authority on fishery questions, who writes in the *Fish Trades Gazette* (March 30, 1912) as follows:—

"The name 'Sardine.' This name is very widely applied either to the young of the pilchard, as with us, or to the pilchard itself. Thus the species *Clupea pilchardus*, our pilchard, is called *sardina* in Italy, *sardinha* in Portugal, *sardina* in Spain (where it seems also to apply to the anchovy), *sardine* in France and in Germany, *sardin* in Norway and Sweden (also *pilchard* in Swedish), *pelser* in Holland, and *pilchard* in Denmark; in Russia it is called *Ssardinka*. It is interesting to learn that it was the first of the Latin names to be used among the Anglo-Saxons for the herring. Eleven hundred years ago the Italian priests who endeavoured to instil a little learning into the Anglo-Saxon mind gave the name *sardinas* as the equivalent to the word *heringas*, but later on this gave way to the name *allec*. The smelt (Anglo-Saxon *smeltas*) was called *sardus*. The word is derived from the island Sardinia (Greek Σαρδώ), and the fish was known to the Greeks as *sardine* (σαρδίνη or σαρδῖνος). It is curious that to this day the term *sardyn* or *schardyn* is applied all along the Dutch coast to the sprat, and the usual net for catching sprats is called *sardynkuil*. A Dutch fisherman confines the term *sprott* to the smoked sprat; the fresh sprat, or the sprat fishing, is always referred to as above stated. This has been the case for a very long time, as is evident from an old work, 'Nieuwe Cronyk van Zeeland,' published in 1696. Centuries ago Dutch trade with the Mediterranean was very great, and no doubt the mariners brought back the term 'sardine' as applied in that sea, and used it in Holland for the small *clupeoids*, the sprats."

It is an easy matter to distinguish the sprat either from the young herring or from the young pilchard by the very much greater development of the spines along the ventral edge of the body in the sprat. The distinction can be made by the sense of touch alone, as is well known to many fishermen, for if the finger be passed along the belly of the fish from the tail towards the head, the sharp spines of the sprat are distinctly felt, whereas the pilchard and the herring both feel comparatively smooth. To distinguish between young pilchards and young herrings, especially after they have been preserved in oil, is a more difficult matter, the size of the scales, which are relatively much larger in the pilchard, being the best guide.

PROF. A. LAWRENCE ROTCH.

PROF. ABBOTT LAWRENCE ROTCH, whose death we recorded with regret last week, was born on June 6, 1861. He received his education at the Massachusetts Institute of Technology, whence he graduated in the department of mechanical engineering in 1884. He became interested in meteorological investigation, and in 1885 founded a meteorological observatory at Blue Hill, Massachusetts, at a height of 635 feet above sea-level, for the purposes of observation, research, and local prediction. He showed characteristic independence in refusing at the outset to accept official help in maintaining the observatory at the expense of fettering it with official control. His main work was done in connection with this observatory, which he maintained and directed throughout. The results obtained were published from time to time in separate parts of the Annals of the Astronomical Observatory of Harvard College. For the first ten years the work consisted principally of the routine of an ordinary first-order observatory with reduction and analysis of the records, and special investigations of certain problems.

In 1894 the exploration of the free atmosphere by means of kites was begun at the observatory, and continued through succeeding years, steel piano wire (first used by E. D. Archibald in the early 'eighties) and a winding gear driven by a steam engine being adopted as the work developed, until a complete series of records up to a height of three miles had been obtained. In this work Rotch was a pioneer, and his methods were adopted at a later date in this country and on the Continent and by the United States Weather Bureau at the Mount Weather Observatory. In 1904 and the three following years seventy-six balloons carrying self-recording instruments were sent up under his direction at St. Louis, and of these seventy-two were recovered. Some of these reached heights exceeding ten miles, and temperatures below $-70°$ C. were recorded. Our knowledge of the higher parts of the free atmosphere in the United States is almost entirely due to the results obtained in this series of ascents.

But Rotch's efforts were by no means confined to his own country. He was a constant visitor to meteorological meetings in Europe, and he was ever alert and ready to help in meteorological enterprise. With M. L. Teisserenc de Bort he fitted out expeditions in three successive years to explore the atmosphere over the tropical Atlantic, and the results obtained have exceeded in interest nearly all other contributions to meteorological discovery in recent years. Our knowledge of the variation of the height of the stratosphere with latitude rests almost entirely on the evidence obtained in these expeditions. His most recent work was an atlas of charts of the atmosphere for aeronauts and aviators, in which he included a chart showing the best aerial routes in summer for a dirigible balloon travelling across the Atlantic between Europe and America.

The importance of his work was recognised by scientific societies both in Europe and America, and the Governments of France and Germany conferred honours upon him.

He was generous in his recognition of the work of others, and gave kindly encouragement to younger men engaged in research. His death, which occurred suddenly on April 7, 1912, at his Observatory at Blue Hill, will be regretted by meteorologists of all lands. E. G.

NOTES.

We are informed that the provisional programme of arrangements for the forthcoming celebration of the 250th anniversary of the Royal Society are as follows:—Monday, July 15—An evening reception of delegates at the rooms of the Royal Society. Tuesday, July 16—In the morning a commemorative service in Westminster Abbey; in the afternoon the official reception of delegates at the Royal Society and presentation of addresses; in the evening a commemorative dinner at the Guildhall. Wednesday, July 17—In the morning visits to places of interest in London; in the afternoon the Duke of Northumberland gives a garden-party at Sion House; in the evening a conversazione in the rooms of the Royal Society. Thursday, July 18—In the morning visits to places of interest in London; in the afternoon H.M. the King gives a garden-party at Windsor, to which the delegates and fellows of the society will be invited. Friday, July 19—The delegates will visit Oxford and Cambridge Universities.

In *The Times* of April 17, and in *The Morning Post* of the following day, reference is made to the drift of a sealed bottle which was thrown overboard from the steamship *Indraghira* on November 17, 1908, in lat. 51° 38′ S., long. 96° 15′ E., by a passenger during a voyage from London to Melbourne. The bottle contained a note of the ship's position with a request that the finder would notify the sender, Mr. H. P. Adams, of Carshalton, Surrey, of the facts of the discovery. The bottle was picked up early last winter, it is thought, on the eastern coast of Wellington Island, south of Chili, in lat. 49° 42′ S., long. 74° 25′ W., having drifted eastward a distance of at least 7100 nautical miles, presumably in 1100 days or less, at a minimum rate of six miles per day. This drift, though remarkable, is by no means the longest on record. The late Mr. H. C. Russell, when Government astronomer at Sydney, contributed several papers to the Royal Society of New South Wales on "Current Papers," in which he recorded the drift of numerous bottle messages, ranging from 50 to 5000 nautical miles, and several from 8000 to more than 9800 miles. The ostensible reason for launching these bottles is to gain knowledge relating to ocean currents. It is difficult, however, and generally impossible, to obtain trustworthy information in this connection from the drift of bottles, because when a bottle is sufficiently weighted to present little surface to the wind, it sinks when covered with barnacles, and if not so weighted is influenced by winds as much as or more than by currents. Moreover, it is the resultant drift during a period of unknown length, not the direction and velocity of the various currents a bottle encounters, that can be estimated. Bottle messages might, however, be utilised with advantage to shipping were the drifts charted of even half those that have been recovered—their name is legion. Such charts would be useful for tracing the probable tracks of disabled steamers and thus locating them.

Mr. R. N. Lyne, director of agriculture in Portuguese East Africa, has been appointed the director of the new agricultural department of Ceylon.

The following have been nominated president and vice-presidents of the Institution of Electrical Engineers:—*President*, Mr. W. Duddell, F.R.S.; *vice-presidents*, Mr. W. Judd, Mr. C. H. Merz, Major W. A. J. O'Meara, C.M.G., and Mr. J. F. C. Snell.

An official announcement from Mr. C. E. Adams, Government astronomer for New Zealand, states that the adopted position of the transit instrument at the Hector Observatory, Wellington, is latitude 41° 17′ 3·76″ south, longitude 11h. 39m. 4·27s. east of Greenwich; height above 1909 mean sea-level, 418 ft.

Mr. Gustav Pollak, who is preparing a biography of Michael Heilprin and his sons, will be glad to receive any letters by the late Prof. Angelo Heilprin. They may be sent to Mr. Pollak at No. 21 West Eighty-fifth Street, New York, and will be returned to the senders promptly if required.

Reuter's Agency has received the first letters which have reached this country from Dr. Mawson's Australian Antarctic Expedition. It is stated that, although in the earliest stages of its work, the expedition has disproved the existence of Clairie Land, confirmed the existence of Termination Land, discovered by Wilkes, but not seen either by the *Challenger* or the *Gauss*, discovered numerous islets along the Great Barrier, and charted a great deal of previously unknown coast-line.

The death is reported, at the age of fifty-one, of Dr. Perry L. Hobbs, professor of chemistry at the Western Reserve University, Cleveland, Ohio. He was one of the first men in America to specialise as a chemical engineer, and was widely known through his experiments in the manufacture of concrete.

Mr. E. C. Hawkins, the chief engineer of the Morgan-Guggenheim properties in Alaska, has died in the New York Hospital after an operation. In his construction of the White Pass and Yukon and the Copper River and Northern railways he met and overcame several problems of engineering that were new to the profession. In building the Childs Glacier bridge across the Copper River, for example, he had to evade the Miles glacier on one hand and the Childs glacier on the other. Mr. Williams was born in 1860, and was educated at the Rensselaer Institute, Troy, New York State.

On Tuesday next, April 30, Mr. F. Balfour Browne will begin a course of two lectures at the Royal Institution on "Insect Distribution, with Special Reference to the British Islands," and on Thursday, May 2, Prof. J. Norman Collie will give the first of two lectures on "Recent Explorations in the Canadian Rocky Mountains." The Friday evening discourse on May 3 will be delivered by Mr. W. C. Dampier Whetham on "The Use of Pedigrees," and on May 10 by Prof. W. Stirling on "The Gaumont Speaking Kinematograph Films" (illustrated by the aid of M. Gaumont).

The Home Secretary has appointed a committee to inquire and report whether the following diseases can properly be added to those enumerated in the third schedule of the Workmen's Compensation Act, 1906, namely—(1) cowpox; (2) Dupuytren's contraction; (3) clonic spasm of the eyelids, apart from nystagmus. The following are the members of the committee:—Mr. Ellis J. Griffith, K.C., M.P., Sir T. Clifford Allbutt, K.C.B., F.R.S., his Honour Judge A. Ruegg, K.C., and Dr. T. M. Legge. The secretary of the committee is Mr. Alexander Maxwell, of the Home Office, to whom all correspondence on the subject of the inquiry should be addressed.

In *The Times* of April 22 appears a description by a correspondent of the archæological work of the Egyptian Research Account, directed by Prof. Petrie, during the past season. From this it appears that Prof. Petrie and his coadjutors have made very interesting discoveries of antiquities of the time of King Narmer, of the First Dynasty, which show that the crocodile worship in the Fayyûm was already established in his time. These finds were made in a necropolis at Kafr Ammar, in Middle Egypt. "Surprising discoveries" were made also at Heliopolis, where excavation has not hitherto met with any success whatever. These are to be described later. At Memphis an alabaster sphinx weighing 80 tons has been found.

The Manchester Oriental Society was recently started by that well-known scholar Prof. Hope W. Hogg, whose premature death was a serious loss to science and a subject of general regret. The first part of the Proceedings of the society, prepared under his supervision, has just appeared. The most interesting contribution takes the shape of a symposium of well-known scholars with the object of solving a problem suggested by Prof. Elliot Smith. In examining Egyptian mummies, he noticed that it was a general habit to leave the heart *in situ*, while this was not apparently the case with other internal organs. The psychological explanation of this differentiation of treatment is still uncertain, though it is suggested by Prof. Rhys Davids, on evidence from India, that the heart was regarded as the seat of the soul. Prof. J. G. Frazer remarks that among savage races little attention seems to be paid to the kidneys, save among some of the Australian tribes, and further evidence on this point from observers of savage life is much to be desired.

In the third part of the Journal of the Gypsy Lore Society for the current year Miss E. Lyster gives an interesting account of the custom of marriage over the broomstick which prevails among some branches of the tribe in this country and other parts of Europe. The editor suggests that as in many places the besom is supposed to be an efficient instrument for scaring ghosts from the house, the stepping over it is probably a method of getting rid of their undesirable attentions. Others, again, are inclined to believe that, being specially used by women, its employment at marriage points to a stage of belief when mother-right was in force. Others suggest that the object of the bride stepping over it at marriage is to promote her fertility by associating her with the productive spirit of the tree from the branches of which it is made. Prof. Frazer in the second part of the new edition of "The Golden Bough" describes the belief that harm is done to a person or thing by stepping over him or it. This, however, seems to depend on a train of thought different from that on which the Gypsy custom rests, and the exact explanation of the latter is still obscure.

We have been favoured with a copy of the first part of an illustrated account, in Spanish, of the "micro-fauna," that is to say, the fresh-water plankton fauna, of the Argentine Republic, by Dr. J. M. de la Rua, published under the auspices of the National University of Buenos Aires by J. H. Kidd and Co. of that city. This part is devoted to protozoans.

One remarkable result of the collecting cruise of the *Siboga* in the Indo-Malay Archipelago was the extraordinary number of new forms of free crinoids discovered. These were handed over to Mr. A. H. Clark, of the museum at Washington, by whom no fewer than twenty new species—one of which is referred to a new genus—belonging to the families Antedonidæ and Atelecrinidæ are described in vol. xxxiv., No. 2, of Notes from the Leyden Museum.

Articles on the proposed new library and art gallery at Manchester, and the London Museum in Kensington Palace, form the leading features of the April number of *The Museums Journal*. From the former it appears that the original intention was to erect the new building on the site of the old infirmary in Piccadilly, Manchester, and the article contains reproductions of the designs which have been accepted on that understanding. An alternative site has, however, been suggested, which would seem to require a building of a different type; and until the question of site is definitely decided, no further progress in the matter can be made. The estimated cost of the building approved for the Piccadilly site is 250,000*l*.

Bulletin No. 91 of the U.S. Bureau of Entomology (U.S. Department of Agriculture) contains a detailed account by Messrs. L. O. Howard and W. F. Fiske of the attempts made to check the increase of the gipsy moth (*Porthetria dispar*) and the brown-tail moth (*Euproctis chrysorrhoea*) by importation into the United States of their parasites and natural enemies from Europe. The task was much more arduous than was anticipated at the beginning, and a great deal of original research upon the enemies of the two moths had to be undertaken in order to deal with the problem intelligently. It was found that the rapid dispersion of the introduced species necessitated the liberation of larger and stronger colonies than had been contemplated. It is hoped, however, that an efficient and automatic control of the gipsy moth in the United States will be obtained by 1916. The report is fully illustrated, and is a valuable contribution to the bionomics of insects as well as an object-lesson in methods of dealing with a serious economic problem.

In 1895 Prof. Milne published his great catalogue of 8331 earthquakes recorded in Japan during the years 1885–92, the analysis of which has thrown considerable light on the distribution of earthquakes both in space and time. He has now further increased the debt of seismologists to him by compiling, at the cost of several years' labour, a "Catalogue of Destructive Earthquakes from A.D. 7 to A.D. 1899," a memoir of nearly a hundred pages issued under the auspices of the Seismological Committee of the British Association. Though containing only half as many entries as the earlier volume, its value, it may be anticipated, will be even greater. Being confined to shocks of an intensity sufficient to damage buildings, it deals with those movements which are of chief consequence in the moulding of the earth's crust. An analysis of the catalogue for different epochs should reveal to us some of the laws which govern the distribution of seismic energy within extensive regions, such, for instance, as the Pacific coast of the American continent.

Herr Fritz Klute contributes to the *Berichte der naturforschender Gesellschaft* (Freiberg in Breisgau, Band xix., Heft i., 1911) a paper on "Die Schneereste der Schwarzwalder im Frühsommer und die Beziehungen ihrer Lage zu den Stellen ehemaliger Vergletscherung." After the heavy snows which fell on the Schwarzwald during the winter of 1906–7, it occurred to Prof. L. Neumann to send round inquiries as to the times and places where it lingered longest. These brought him 182 forms duly filled up, which he placed in Herr Klute's hands to work out. He obtained others for the winter of 1910, which brought the number up to 230. In this paper he gives a sketch of the geology and physical structure of the Schwarzwald, with a separate discussion of each district in which observations were taken. The duration of the snow depends chiefly on height and meteorological conditions (sunshine, warm winds, and rain being favourable to removal), and a useful map shows the contour lines, stations, and traces of former glaciers in the southern Schwarzwald. Here, out of 128 places of observation, only 21 have no connection with these traces; in the central region as many as 49 out of 62, and in the northern 14 out of 40. In the last the snowfall appears to be heavier than in the first at the same elevation. The results, however, do not at present lead to any definite conclusion, which, indeed, was hardly to be expected, but they were worth undertaking, and it is to be hoped they will be continued, for they may enable more precise estimates to be made of the change of temperature that would bring back an ice age, and the meteorological conditions most favourable to it. The small glaciers in the Alps tell us the conditions under which they can exist at the present day, so that we may infer from the relics of similar glaciers in the Jura, Schwarzwald, and similar ranges that like conditions prevailed in them during the Ice age.

The Italian Ministry of Foreign Affairs has issued a useful report on the climatology of Tripoli and Benghazi, prepared at the Central Meteorological Office by Dr. Eredia, with an interesting preface by Prof. Palazzo. Some of the observations used have already been published in the Annals of the French and Italian Meteorological Offices and other publications, but the recent occupation of those parts by Italy has made it desirable to issue a separate publication, brought, so far as practicable, up to date. All the principal meteorological elements are dealt with in considerable detail; we have extracted the following notes :—*Tripoli* (July, 1892, to May, 1911): Mean temperature, January, 12·1° C.; July, 25·8°; year, 19·7°; absolute maximum, 43·0°, in June and September; minimum, 1·4°, in January. Mean annual rainfall, 420·4 mm.; wettest month, December, 113·7 mm.; driest, July, 0·5 mm. Average number of rain-days, 51·1. *Benghazi* (January, 1891, to May, 1905): Mean temperature, January, 13·2°; July, 25·6°; year, 20·3°. From another series (August, 1886, to February, 1891) the absolute maximum was 40·0°, in June; minimum, 6·6°, in February. Rainfall (1886–1905): year, 276·3 mm.; wettest month, 77·4 mm., in January; driest, 0·0, in August. The rain-days were 55·1 in the yearly average. June–August were practically rainless.

In *The Times* of April 16, and in *Symons's Meteorological Magazine* for April, Dr. H. R. Mill discusses the rainfall of the winter six months, October, 1911–March, 1912, in the British Isles. In this period the excessive rainfall was as remarkable as the drought of the summer of 1911. He shows in a very interesting manner, by selecting representative stations from the mass of materials at his disposal, that although as a whole excessive, the distribution of the rainfall was very irregular, and he remarks :—"It is very common, perhaps we might say usual, to find the rainfall at the opposite ends of Great Britain swinging to opposite sides of the average and the same divergence is also apparent in Ireland." The rainfall was below the average in Scotland, north and west of the Great Glen, but above the average everywhere else. In the eastern mountain mass between Perthshire and Aberdeenshire the excess was 40 per cent. and upwards. Most of South Wales and the south of England had an excess of more than 50 per cent., and Sussex 70 per cent. and upwards. In the extreme north-west of Ireland the excess was less than 10 per cent., while in the south-east a considerable area had an excess of more than 50 per cent. Expressed in percentages of the average, England and Wales as a whole had a mean of 141, Scotland 111, Ireland 136 per cent. For the Thames Valley above Teddington, an area of about 3800 square miles, the rainfall of the winter six months, 1911–12, was greater than the annual amount in seven years out of the last twenty-nine.

Many of our readers will remember that the management of the Kew Observatory (Surrey) and the Eskdalemuir Observatory (Dumfriesshire) was recently transferred to the Meteorological Committee. The meteorological and geophysical elements observed at these stations, together with those made at Valencia Observatory (Kerry), and the wind components for four representative stations are, from January, 1911, published monthly in *The Geophysical Journal*. This work forms a very useful addition to the "British Meteorological and Magnetic Yearbook." All the units employed are based on the C.G.S. system, and although these have to some extent been used in the "Weekly Weather Report" they are not necessarily obvious to ordinary observers; their meaning is, however, lucidly explained by Dr. Shaw in the preface. The following examples illustrate some of the changes from the usual notation: atmospheric pressure is expressed in "bars," one bar being approximately equivalent to the pressure of 750 mm. of mercury; temperature is given in degrees absolute measured from a zero of 273° C. below freezing point; solar radiation is expressed in "watts" per cm.^{2}, instead of the usual gram-calorie; the latter unit is equivalent to 0·07 watt.

The annual summary of the *Indian Weather Review* for 1910 contains abstracts of observations taken at a large number of stations, and special reports from the Kodaikanal and Bombay Observatories. One of the most notable features of the year observed at the former station was the rapid decrease in sun-spot activity. In 1909 the mean daily number was 3·9; in 1910 1·8. The sun's disc was free from spots on fifty-six days. In the valuable discussion of the meteorological elements the year is divided, as heretofore, into four seasons: cold and hot weather, south-west monsoon and retreating south-west monsoon periods, while the rainfall is illustrated by maps for each of the four periods. On the whole, 1910 was the coldest year on record since 1894. Only February and May had an excess of temperature. April, November, and December were much colder than usual. On the general average of all stations in the plains, 1910 had the heaviest rainfall since the above date, notwithstanding that the winter and spring seasons were drier than usual.

The remarkably fine weather recently has had decided effects upon plant and animal life. A correspondent states that he saw a cabbage butterfly, *Papilio brassicae*, flying in his garden in the Hampstead Garden Suburb on Wednesday, April 17, and on April 21 several were seen in the course of an hour. The earliest date given by Gilbert White is April 28. Cabbage whites were seen at Appledram, near Chichester, on April 13, and the cuckoo was heard for several minutes about 5 p.m. of the same day. White's earliest date for the cuckoo is April 7. The first Sulphur butterfly and a Peacock butterfly were seen at the same place on April 6. As is well known, the brimstone or sulphur butterfly is one of the earliest to make its appearance, and may sometimes be seen on a fine day in winter months; while Peacock butterflies which have hibernated are not infrequently seen in early spring.

There exists in France a technical committee the object of which is to study and extend the knowledge of the means of prevention and of extinction of fire, and of averting accidents. It is a voluntary organisation supported by public bodies, and includes amongst its members many well-known French officials. We have received from the committee two bulletins, one relating to the precautions to be taken against fire and accidents at exhibitions, the other to precautions against fire in villages. Both documents bear evidence of the thoroughness of the work done by the committee, and can be obtained for a few pence. We notice that in neither case does the committee advise the provision of "extinguishers" or "grenades," but insists on simple buckets of water. The headquarters of the committee are at 45 Avenue Trudaine, Paris.

The magnetic survey of Egypt, commenced in 1908, has been completed, and the results obtained at eighty-one stations are summarised in a pamphlet issued by the Survey Department. The field work has been carried out by Messrs. H. E. Hurst and C. B. Middleton with instruments standardised at the Helwân Observatory. In the delta the declination varies from 3° west in the west to 2° 30′ west in the east, the dip from 43° in the north to 40° 30′ in the south, and the horizontal intensity from 0·294 in the north to 0·302 in the south. In Upper Egypt the limits are nearly the same for the declination, but the dip decreases to 30° 36′ and the horizontal intensity increases to 0·325 in the south. In Nubia the declination is 4° in the west and 2° 42′ in the east; the dip decreases to 26° 32′ at Wadi Halfa, where the horizontal intensity is 0·328. Values for the western desert are also given, and when the present survey of the Sudan is completed a full report covering the whole country is to be issued.

Mr. Stephen Paget, secretary of the Research Defence Association, has written a book summarising in ten chapters the evidence given before the Royal Commission on Vivisection, as well as the Inspector's Report for 1910, and giving in a final chapter a brief account of the commission's report. The volume will be published by Mr. H. K. Lewis.

Messrs. Witherby and Co. will shortly publish "A Hand-list of British Birds," giving a detailed account of the distribution of each bird in the British Isles and a general account of its range abroad, together with details of the occurrences of rarities. The hand-list is the joint work of Messrs. E. Hartert, F. C. R. Jourdain, N. F. Ticehurst, and H. F. Witherby.

Messrs. Jack announce that among the volumes to be included in the second dozen of "The People's Books," which are to be issued on May 15, will be "The Foundations of Science," by Mr. W. C. D. Whetham, F.R.S.; "Inorganic Chemistry," by Prof. E. C. C. Baly, F.R.S.; "Radiation," by Dr. P. Phillips; "Lord Kelvin," by Dr. A. Russell; "Huxley," by Prof. G. Leighton; and "Francis Bacon," by Prof. A. R. Skemp.

OUR ASTRONOMICAL COLUMN.

Cometary Statistics.—Some interesting figures concerning comets have been educed by M. Borrelly, and appear in Nos. 51–52 of the *Gazette Astronomique.* For 376 comets discovered since the sixteenth century he gives the place of discovery, Marseilles heading the list with 64, Paris coming second with 46, and Geneva, Florence, Lick, Nice, and Berlin following with 16, 15, 14, 12, and 12 respectively. It is noteworthy that of British observatories, Slough is top with seven discoveries, and Bristol, twenty-second in the complete list, has four to its credit. Nearly two-thirds of the comets discussed were discovered in the morning before sunrise, and the second half of the year has proved more prolific in cometary discoveries than the first. Of these 376 comets, 106 were periodic and 19 have been observed at more than one return; only 56 have been visible to the naked eye, and seven could be seen during full daylight.

The Best Value of the Solar Constant.—In the current number of the *Astrophysical Journal* (vol. xxxv., No. 2, March) Messrs. Abbot and Fowle traverse Prof. Very's criticism of their determination of the solar constant noted in this column on January 18. Among other things they deprecate the deduction of a value for the constant from such unknown and fragmentary data as the reflection and emission of the earth, the moon, and Mars, the temperatures of the two latter, and the dependence of terrestrial temperature on insolation. They maintain that many other variables beside the insolation, *e.g.* cloudiness, distribution of land and water, mountains, &c., considerably complicate terrestrial temperatures, and show that they have not departed from Langley's methods except in so far as they are improved by thirty years' extra experience.

Observations of Saturn and its Rings.—To No. 4566 of the *Astronomische Nachrichten* Dr. H. E. Lau contributes a note describing his observations of Saturn, with the 10-inch refractor of the Urania Observatory, during the years 1908–1910. He found the colour of the south pole to be bluish-green changing to a brownish-green at a little distance from the actual polar region. For the various rifts he records various shades of colour and also places on record the appearance of whitish cloud masses in the equatorial zones in December, 1909, and September, 1910. Measures of the rings on seven evenings in 1909 and 1910 gave 40·03″ for the outer diameter of the A ring, 34·59″ for the Cassini division, 26·48″ for the inner diameter of the B ring, and 21·34″ for the inner diameter of the C ring; the breadth of the Cassini division was found to be 0·71″. Differences of colour between the different parts of the various rings are also recorded.

The Cañon Diablo Crater.—An interesting paper by Mr. Elihu Thomson appears in No. 19, vol. xlvii., of the Proceedings of the American Academy of Arts and Sciences, in which the author, having visited the famous Coon Butte or "Meteor Crater," speculates as to the probability of the crater having been produced by the impact of an enormous meteor. He states that the amount of rock blown out of the cavity could not have been less than two or three hundred million tons, and, on a moderate estimate, this would require some ten million tons of meteoric iron to be accounted for. Mr. Thomson advances many arguments, and evidently concludes that the crater was produced by a meteoric fall. To account for the non-discovery of the main mass, he suggests that, as the meteor would probably not fall vertically, bore-holes should be made under the southern and south-western walls of the crater where the strata are peculiarly disturbed; the twenty-eight bore-holes already made have all been near the centre and have revealed undisturbed sandstone at a depth of 850 ft. below the crater bottom.

NOVA GEMINORUM NO. 2.

THE brightness of Nova Geminorum would appear to have reached that stage when further diminution is very slow but steady. On Friday last at 8.45 p.m. an observation made in a 4-inch finder showed the nova to be but a shade brighter than the neighbouring star 984, of which the magnitude is given variously between 6·8 and 7·2.

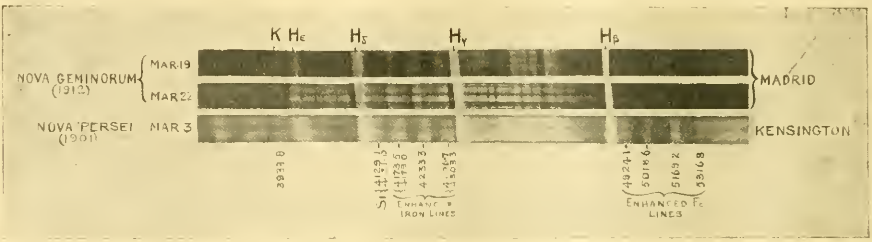
By the courtesy of Father Iñiguez we have been permitted to examine four excellent spectrograms of the nova, secured by him at the Madrid Observatory on March 17, 19, 22, and 24 respectively, and transmitted to NATURE.

was photographed, the lines became more prominent and also became more uniform *inter se*, more particularly between Hβ and Hγ; generally speaking, the dark lines are relatively diffuse and ill-defined.

A recrudescence of activity in the star was observed on March 23–25, since when the nova has gradually decreased in brightness. The increase of redness contemporaneous with the decrease in the intensity of the ultra-violet spectrum is remarked upon by Father Iñiguez, who further discusses his spectra in No. 16 of the *Comptes rendus*.

For the purpose of comparison we reproduce two of Father Iñiguez's spectrograms, taken on March 19 and 22 respectively, alongside a spectrum of Nova Persei photographed at South Kensington on March 3, 1901. It will readily be recognised that although there are important differences in the minor details, the two spectra are, in general, very similar; consequently the explanations of the chemical origins of the lines in Nova Persei given by Sir Norman Lockyer in 1901 hold good, generally, for those in the spectra of Nova Geminorum. In that paper it was shown that the chief bright lines other than hydrogen could be adequately represented by the principal enhanced lines of iron, and, in a less degree, of other metals.

Comparing the Madrid spectra, the abnormal decrease of the bright calcium radiation, K, between March 19 and 22 is very readily discerned. Attention



Father Iñiguez reports that between March 16 and April 10 the spectrum underwent important modifications, of which he especially mentions the changes in the structure of the hydrogen lines, the almost total disappearance of the bright calcium radiation, K, since March 20, and the marked diminution of the ultra-violet part of the spectrum. The principal radiations are those of hydrogen, each bright band being accompanied by the usual well-marked dark band on its more refrangible edge; during the last days of March the more refrangible bright hydrogen bands became relatively weaker, Hε becoming much weaker, relatively, than Hβ and Hγ, while the bright Hζ nearly disappeared.

In addition to the bright lines there are numerous dark lines, especially between Hβ and Hγ, which Father Iñiguez describes as absorption bands, and among which he recognises the helium lines at λλ4026, 4144, 4388, and 4472, and the spark line of magnesium at λ4481. He also directs attention to the apparent separation of the bright and dark hydrogen lines which attained its maximum between March 22 and 24; the apparition of a bright line traversing the dark companions gave the hydrogen pairs an appearance of duplication which, we believe, has also been recorded at the Cambridge Observatory.

Father Iñiguez states that considerable variation in the number, intensity, and definition of the numerous bright and dark lines has been very noticeable. From March 22, when a magnificent spectrum

should also be directed to the apparent reversal of the dark hydrogen lines, especially noticeable in Hγ on March 22, which is evidence in favour of these dark bands, at least, being true absorption phenomena.

While the comparison shows that the spectra of the two novæ are in general very similar, there are differences in the details, as is shown in the subjoined description by Mr. F. E. Baxandall, based upon a careful examination and discussion of the several photographs at the Solar Physics Observatory:—

Spectra of Nova Geminorum.

A comparison of the excellent spectra of Nova Geminorum obtained on March 19 and 22, by Father Iñiguez, of the Madrid Observatory, with that of Nova Persei photographed at Kensington on March 3, 1901, shows that in the main features the spectra of the two novæ are the same. The well-marked bright hydrogen lines in Nova Geminorum are accompanied by strong absorption lines on the more refrangible side, and the isolated bright bands between Hγ and Hδ typical of novæ spectra are present. The Nova Persei band at λ4130, probably due to protosilicum $\left\{\begin{matrix}\lambda 4128{\cdot}2\\ \lambda 4131{\cdot}0\end{matrix}\right\}$ and identical with the conspicuous double line in such stars as α Cygni, Rigel, and Sirius, is either lacking in Nova Geminorum or occurs only very faintly.

Between Hγ and Hβ the spectra show the usual complex set of bright lines seen in previous novæ.

Amongst these are what appear to be absorption lines, but, judging from other regions of the spectrum, the *bright* lines are the authentic ones, and the apparent absorption lines are more likely to be interspaces between bright lines, and have little or no significance as spectrum *lines*.

The well-known series of bright nova lines on the less refrangible side of $H\beta$ at $\lambda\lambda 4924$, 5018, 5169, 5276, 5317, seen in Nova Persei and Nova Aurigæ, are not well shown in the Madrid spectra, only the first two of these being faintly seen. This is probably due to the plates used by Iñiguez being not very sensitive to this part of the spectrum, and not due to any real lack of lines in the spectrum.

These bright lines and those previously mentioned between $H\gamma$ and $H\delta$ ($\lambda\lambda 4176$, 4233, 4300) were recorded by Sir Norman Lockyer in a series of Royal Society papers on Nova Persei in 1902, as being due to the enhanced lines of iron $\lambda\lambda \left\{\begin{matrix}4173{\cdot}5\\4179{\cdot}0\end{matrix}\right\}, 4233{\cdot}3, \left\{\begin{matrix}4296{\cdot}7\\4303{\cdot}3\end{matrix}\right\}$, 4924·1, 5018·6, 5169·2, 5276·2, 5316·9. These are the only enhanced lines of iron in the two regions mentioned, and they are *all* represented by strongly marked lines in α Cygni. A direct comparison of the α Cygni spectrum with that of Nova Persei will show that these isolated strong lines of α Cygni fall exactly on the middles of the broad, bright nova lines.

Some of the lines mentioned have, in previous publications on novæ spectra, been ascribed to various origins. The $\lambda 4924$ and $\lambda 5018$ lines have often been referred to as helium lines, although much stronger lines of the same element have been lacking. The line $\lambda 5018$ is also sometimes identified with the chief nebular line. The line $\lambda 5169$ is often referred to as being probably the "*b*" group of magnesium, and the line $\lambda 5316{\cdot}9$ as being probably the chief corona line. The fact that all these lines occur together as strong lines in the spectrum of a normal star—α Cygni—and that they can all be adequately accounted for by specially behaved lines of one chemical element—and those the *only* special lines of that element in the region discussed—must surely be taken as convincing evidence that the identity is a real one.

In the region between $H\gamma$ and $H\beta$, the nova spectrum is far more complex, but so also is that of α Cygni, and here again the chief lines in the nova spectrum agree in position with lines or groups of lines in α Cygni. In this part of the α Cygni spectrum there are enhanced lines of iron, magnesium, chromium, and titanium, but there is little or no doubt that in the nova spectrum the chief lines, other than those of hydrogen and calcium, are due to iron.

The most striking changes between the spectrum of March 19 and that of March 22 are: (1) the occurrence of what seems to be a fine bright reversal in the middles of the dark $H\gamma$ and $H\delta$ bands (more particularly the former), and (2) the appearance of a bright band, the centre of which is at about $\lambda 4440$, superposed on what was a broad, dark band on March 19. One of the strongest lines in Wolf Rayet spectra occurs at or near this position (4442), and the two lines may possibly be identical. Unless, however, some of the other strong Wolf Rayet bands, such as $\lambda\lambda 4652$, 5692, 5813, are also found in the spectra, little weight can be attached to the suggested identification.

F. E. Baxandall.

Magnitude observations of the nova are published in Nos. 4566–67 of the *Astronomische Nachrichten*, and Dr. Rosenberg describes his observations of the spectrum at the Tübingen Observatory. On March 19 a red-sensitive plate showed well-marked radiations corresponding to $H\alpha$, $H\beta$, and $H\gamma$. Their breadth was about 30 A.U., of which 9 A.U. was shifted towards the red, and 21 A.U. towards the violet from the normal positions. $H\gamma$ presented three maxima at $\lambda\lambda 4348$, 4339, and 4332 respectively, and an examination of the spectrum for polarisation effects gave a negative result.

In a report to the Harvard College Observatory Prof. Frost states that a spectrogram taken on March 15 shows the H and K lines bright, at about their normal positions; they are strong and broad and crossed by very sharp, dark lines. The lines at $\lambda 4923$ and $\lambda 5016$, which Prof. Frost ascribes to helium, are strong, both bright and dark, but the line at $\lambda 4472$ is not conspicuous, although probably present.

William E. Rolston.

THE LOSS OF THE "TITANIC."

The terrible loss of life on account of the disaster to the *Titanic* has directed emphatic attention to various aspects of the employment of wireless telegraphy in times of crisis at sea. The point which is at the moment attracting most of the public attention is that of the erroneous messages, or alleged messages, which appeared in the newspapers in the day or two following the disaster. Possibly some of these messages may have been invented by imaginative reporters, but others seem to have been perversions of messages which had actually passed between vessels at sea, but which were not concerned with the accident. This kind of mistake is well illustrated by the transformation undergone by a message containing the words, "Am towing oil-tank to Halifax." Such mistakes as these are possible in all kinds of telegraphy, but they probably arose in the present case at the hands of some of the amateur wireless telegraphists that swarm on the American coast. Some of these amateurs, it is widely believed, may indeed have originated of set purpose a number of the early reassuring messages, and it is clear that the possibility of rigging the insurance market by such messages affords motive enough for their concoction. It is most unlikely that intelligence of this character should have been sent in irresponsible moments by operators on liners, for the operators are under the direct control of the captains, the service discipline is strict, and every message has to be recorded.

All this raises more prominently than ever the chaotic condition of wireless telegraphy in the United States. For years the legitimate users of wireless telegraphy have complained of the unbounded freedom enjoyed and abused by the American amateur; perhaps they may now look forward to the imposition of some salutary restrictions. But besides that aspect of the matter just discussed, there is another which this catastrophe has brought into prominence. It is now impressed on us that the most urgent call for help will pass unheeded if none of the operators on the ships within hail are on duty. In fact, it seems to have been a mere chance that the *Carpathia* operator was at his apparatus at the time the *Titanic* called. On ships that carry only one operator—and very few carry more—the man cannot always be on the look-out. For this deadly contingency one obvious remedy is for each ship to carry more operators; another remedy lies in the provision of an apparatus that will ring up the telegraphist when a message reaches it. This latter desideratum is, unhappily, as yet unattained.

Engineering aspects of the disaster are discussed in the leading article in *Engineering* for April 19. As but little definite information is available as yet, the drawing of conclusions is premature, but several questions present themselves as ripe for discussion and settlement. The effect of centre-line or longitudinal wing bulkheads is one of these. Such have advantages in confining any water admitted to a part of the width, but have disadvantages even from the point of view of stability under disastrous conditions. The effect of impact on the superstructure of very large ships will have to be considered. In such ships it has become a practice to have two or three decks above the moulded structure. Would inertia have effects somewhat similar to those experienced in railway collisions, in which the body of the carriage is driven from the under-frame? As the boats and launching gear are carried on these decks, there is a possibility of damage to them under such conditions. The position of the Board of Trade in relation to lifeboat accommodation in large ships is regarded with considerable anxiety by the general public. The law, as at present laid down by this department, called for 8250 cubic feet only in the case of the *Titanic*, which would provide for 825 passengers. The American law requires, for vessels of 20,000 gross tons, that the boats carried should have a capacity of 12,420 cubic feet, and an additional 225 cubic feet for each successive 500 tons above 20,000 tons. The *Titanic* accommodation exceeded that required by British law, but was less than the American law lays down. The engineers of the ship have all been lost—their claim to recognition is the simplest and best; they did their duty to the end.

The leading article in *The Engineer* is also devoted to the loss of the *Titanic*, and raises other urgent questions besides those mentioned above: the arrangements adopted for securing water-tight subdivision, comprising not only the number and disposition of bulkheads, but also the height to which they extend and the watertightness of the deck at their upper extremity; the construction of transverse and longitudinal bulkheads, in connection with which it will not be found that any consistent standard of strength is observable under conditions implied by the existence of the bulkhead. The time is ripe for the revision of Table 2, Appendix B, of the bulkhead committee's report—a report which is taken as a standard by the Board of Trade. Prof. J. H. Biles contributes a separate article to *The Engineer* in which the effects of flooding compartments are fully dealt with. His conclusions are:—(1) the transverse bulkheads should in all cases be carried as high as possible; (2) the decks should be made effectively water-tight. If, however, the whole bow be smashed by hitting a vertical wall of ice, the value of watertightness of the decks would be reduced.

REPORTS UPON METEOROLOGICAL OBSERVATIONS.

Canada, Meteorological Service (1907).—This report, which extends to xx+748 quarto pages, is considerably belated, owing probably to the immense amount of data included in this extensive system. It should be borne in mind, however, that the results for about 300 stations, with synopses of the weather, are published one month after date in the *Monthly Weather Review*, and also that a map is issued three days after the close of each month. The present volume is divided into seven parts, which may be summarised as (1) observations at ordinary stations of various classes, mostly taken at local time; (2) observations at telegraphic reporting stations, taken at 75th meridian time; and (3) magnetic observations made at Agincourt Observatory. The tables, with monthly and yearly means, are very complete, but in the absence of maps it is difficult to obtain a general view of the annual distribution of the different elements. The outstanding feature of the year was the exceedingly cold weather experienced in the western provinces in January. In some of these it was the coldest January on record, the mean temperature being 6–22° below the average. At some stations in Alberta minimum temperatures as low as 56° F. below zero were registered. (On January 11, 1911, we note that a temperature of −76° was recorded at Fort Vermilion, Alberta.) The weather forecasts issued for all districts were very successful, the average of complete and partial success being 85·6 per cent.

Western Australia, Meteorological Observations (1907).—This volume, only recently received, and apparently published in 1910, contains results of observations made at Perth Observatory and other places. At the observatory the mean annual temperature was 64·7°; highest mean monthly maximum, 87·5° (February); lowest mean minimum 49·6° (June); absolute maximum, 103·6°; minimum, 39·5°; maximum solar radiation, 164·2° (January 30); bright sunshine, 2803 hours; rainfall, 40·12 inches; rain days, 132. Some very high shade temperatures at the outstations were recorded, especially on the north and north-west coast, and inland; at Onslow and Marble Bar readings of 116·1° and 116·8° respectively were reached. Morning and afternoon weather forecasts formed an important part of the work at the central observatory. The volume includes a useful rainfall map, with isohyets for 1907, and tinted areas showing where the fall was above the average.

Transvaal Meteorological Department (1910).—The results for the fiscal year ended June 30, 1910, are arranged as in previous reports. In some cases only the means of hourly or daily observations are given, but the original data are carefully preserved and are available if wanted. The observers for the year numbered 663, an increase of 64 since the last report; all those appointed by the observatory are volunteers or are attached to other departments. The year was generally mild and of a normal character, with the exception of a heavy snowfall in August and an unseasonable frost at the end of September. The rainfall was in most parts satisfactory, being equal to or more than the average; it was very deficient along the western border and in the northern Zoutpansberg. The average rainfall for the whole State for six complete seasons (1904–5 to 1909–10) was 29·5 inches on seventy-three days; this value is subject to some uncertainty, perhaps to the extent of 0·5 inch, owing to the want of observations in some localities. Weather reports and forecasts are drawn up daily, and the latter are transmitted to all postal telegraph offices for exhibition. The synoptic charts on which the forecasts are based are not published, because of the expense.

Christiania Meteorological Institute (1910–11).—The administration report for the fiscal year ended June 30, 1911, exhibits a large amount of useful activity. Observations were received during the year from 506 stations, dealing chiefly with rain and snow; the results are included in the publications, "Meteorological Year Book" and "Rainfall Observations," to which we have before referred. Among other important matters we may mention the installation of a station of the first order in Spitsbergen in connection with the radio-telegraphic station there. Meteorological data are regularly supplied to various institutions, including the International Solar Commission in London. The ordinary weather forecasts average a success of 87·1 per cent.; special forecasts are also issued at certain seasons for agriculturists and for fishermen. Storm warnings are issued from Bergen. Observations of the movements of the upper air by means of balloons and the drift of clouds are communicated to Prof. Hergesell at Strassburg.

THE ORIGIN OF RADIUM.[1]

THE theory of atomic disintegration, which affords a philosophical explanation of radio-activity, was based on simple chemical observations of the regeneration of radio-active constituents in substances from which they had been chemically separated, and not, as has sometimes been asserted, upon any physical or chemical theories as to the nature of the atoms of matter. Only two of the large number of new problems originally suggested by this theory remain at present unanswered. One had to do with the nature of the ultimate product or products of the distintegration of the atoms of the two primary elements, uranium and thorium. This problem may be likened to the task of trying to find a meteor after its flight, when its energy is spent and nothing but the matter remains. Much indirect evidence points to lead as the final product of uranium, although no direct proof has been obtained, whereas for the case of thorium there is still no hint of the answer. The other had reference to the origin of radium. This element in the intensity of its activity, and therefore in the rapidity of its disintegration, resembles the short-lived active constituents uranium X and thorium X, whilst in the apparent permanence of its activity it resembles the primary radio-elements. Even the first rough estimates indicated that the period of average life of radium was not greater than a few thousand years. The present estimate, due to Rutherford, is 2500 years. A few thousand years hence the radium in existence to-day will for the most part have disintegrated. Very little of the radium in existence at the time the Pyramids were being built can still exist. Hence arose one of the most interesting and crucial of the problems of atomic disintegration. Does the regeneration of radio-active constituents, observed in the cases where the period is short compared to the span of human life, apply also to radium—to an element, that is, with a definite spectrum, atomic weight and chemical character, filling a vacant place in the periodic system, and forming one of a family of common elements? After the separation of radium from a mineral does the non-radium part of the mineral grow a fresh crop with lapse of time, the quantity present before separation being the balance or equilibrium quantity when the rate of production is equal to the rate of supply? A somewhat similar prediction made with reference to the production of another well-defined element, helium, in the radio-active process had only to be tested, as it was first in 1903 by Sir William Ramsay and myself, to be proved correct. The question, however, of the origin of radium is still, in spite of many discoveries, not entirely solved.

At first sight the experimental trial of the view appeared easy. This problem is not analogous to the finding of a meteor after its flight is spent. The quantities of radium which can be detected and recognised unequivocally by radio-active methods are thousands of times smaller than can be detected even by the spectroscope, sensitive as the spectroscopic test of radium is. The first product of the disintegration of radium is a gas, the radium emanation, and the test for radium consists in sealing up a solution of the substance for a month, then boiling the solution in a current of air, and introducing this air into the electroscope. For the instrument employed and shown, a millionth of a milligram of radium would be rather an undesirably large quantity, whilst a few hundredths of this amount is the best suited for accurate measurement. The volume of radium emanation, measured at N.T.P., obtainable from one gram of radium is only 0·6 cubic millimetre, a volume comparable to that of a pin's head. If a thousandth part of this quantity were distributed uniformly through the air of this room, estimated as 50,000 cubic feet, or about $1\frac{2}{3}$ tons by weight, and the electroscope were then filled with the air of the room, it would produce an effect much greater than any dealt with in the work to be described. (The effect of breaking a tube containing the emanation in equilibrium with 3 mg. of radium, outside in front of the fan supplying air to the building, was demonstrated by the electroscope, through which a slow current of air from the room was aspirated.)

Since radium is found in uranium minerals and since uranium and thorium are the only elements known of atomic weight greater than that of radium, it was natural to suppose that uranium was the primary parent, in the disintegration of which radium results. Preliminary experiments nine years ago on a kilogram of uranyl nitrate, purified from radium by precipitating barium sulphate in the solution, proved that uranium could not be the direct parent of radium. For in this case, from 100 grams of uranium, the growth of radium should be readily detectable after the lapse of only a few hours. Whereas from a kilogram after 500 days, although a distinct increase of the quantity of radium was observed, it was at most only 1/1000 part of what should have been formed. In the meantime, indirect, though conclusive, evidence that uranium was the primary parent of radium was obtained by McCoy, Strutt, and Boltwood, who showed that in all unaltered minerals there is a constant ratio between the quantities of the two elements, and this is what is to be expected if they are genetically connected. Unfortunately, this is still the only evidence available of the connection between the two elements. To account for the excessively slow growth of radium in the first uranium preparations studied it was necessary to suppose that between the uranium and radium an intermediate product existed of period of life great by comparison with the time of the experiment. Such a product would enormously retard the initial growth of radium. Its existence complicates what first appeared as a very simple problem in many other ways. It is no longer a question of simply detecting a growth of radium. It is necessary to measure the form of the growth-curve accurately.

In the first place this intermediate parent must be present in uranium minerals, and therefore, to greater or less extent, in commercial uranium salts. The mere separation of radium therefrom initially, as in the first experiment, is not sufficient purification. In addition every trace of the intermediate parent must also be separated, or a growth of radium will not prove that uranium is the parent. On this account, in conjunction with Mr. T. D. Mackenzie, a fresh series of experiments was begun in Glasgow in 1905, in a new laboratory uncontaminated by radium. Three separate quantities, each initially of 1 kilogram of uranyl nitrate, were purified by repeated extraction with ether, which was considered to be the method most likely to separate all the impurities, not merely the radium. Observations on these preparations have now been in progress for six or seven years. At the same time a portion of the impure fraction separated from the original material was sealed up, freed from initial radium by the barium sulphate method, and tested for radium from time to time along with the pure uranium preparations. The diagram (Fig. 1) shows the growth of radium in this impure fraction. The unit used for expressing the quantity of radium is 10^{-12} gram. It confirms unequivocally the original

[1] From a discourse delivered at the Royal Institution on Friday, March 15, by Mr. Frederick Soddy, F.R.S.

observation that a substance is present in commercial uranium salts capable of generating radium and not removed from it by the barium sulphate method used first for separating the radium, but separated, at least mainly, by the ether method.

In the meantime a cognate discovery of first importance was made by Boltwood, in America, who

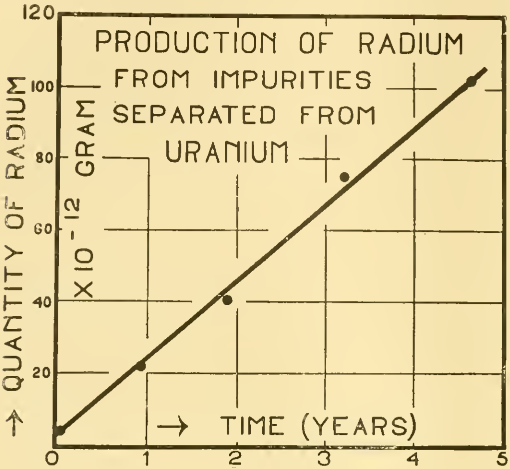


Fig. 1.

proved that actinium preparations obtained from uranium minerals, and initially free from radium, grow a fresh crop of radium with lapse of time. The growth is not by any means a very minute one as in my experiments, in which the growth can only be put beyond all doubt after the lapse of years. The growth of radium from constituents separated from minerals can be readily detected and measured in a relatively short space of time. The curve shown (Fig. 2) is taken from a paper by Keetman (*Jahr. Radioact. Elektronik*, 1909, vi., 270), who has worked upon this parent of radium in Germany. Although the total quantity of radium represented by this curve is only nine millionths of a milligram, it is enormous compared with that shown by the other diagram (Fig. 1), in which the quantity of radium produced in a period about eight times longer is nearly a hundred times less. Further work on this parent of radium proved that it was not actinium, but a new radio-element admixed with it, which Boltwood called ionium. It is radio-active, and its radiation consists entirely of α-rays of very low range. The chemical nature of this ionium is absolutely identical, so far as is known, with that of thorium, and it cannot be separated from it. On the other hand, it is easily separated from any mixture, however complex, by adding a trace of thorium and separating and purifying the latter. It is interesting to note that no fewer than three at least of the known radio-elements—ionium, radiothorium, and uranium X—are absolutely identical in chemical properties with thorium. This complete similarity with known elements is one of the features of the chemistry of radio-elements.

Returning to the experiments with the uranium solutions purified by ether, Fig. 3 shows the growth of radium therein. The three curves labelled I., II., III. refer to these preparations. No. III. was the last prepared, after experience with the others, and contained both the greatest quantity of uranium and the least radium initially. No. IV. refers to a much later experiment with no less than 6 kilograms of uranyl nitrate, purified by repeated crystallisation in the course of other work. In all, there has been a distinct growth of radium, but it is so small, and the period over which the measurements extend is so prolonged, that the errors of the individual measurements are relatively great. The general scope of the curves, as indicated in the figure, is, however, probably not far wrong. A conservative view to take is that in all cases the curves are straight lines. There is some indication in No. I. of an increasing slope, but it is negatived by the evidence of Nos. II. and III.

The quantity of uranium in the four preparations differs widely. In Fig. 4 the curves are replotted in a different way to eliminate this difference. The ordinates represent the quantities of radium formed in terms of the amounts of radium in equilibrium with the uranium. The equilibrium amount is the amount that theoretically should be formed after the lapse of sufficient time, if uranium is the ultimate parent of radium. It will be seen that the slopes of the four curves are all different and diminish in order, the growth in the first being the greatest, and in the last, after all the experience in methods of purification, the least. This is additional evidence that, so far, the radium formed is derived, not from the uranium, but from varying infinitesimal quantities of ionium still unremoved by the purification processes.

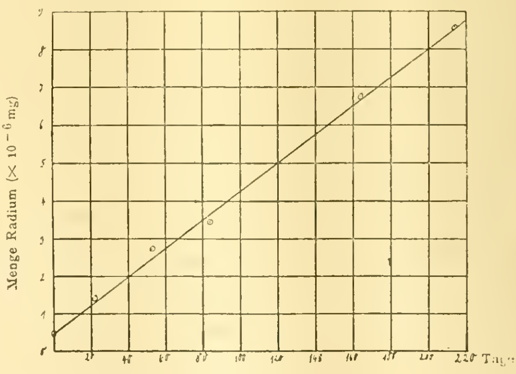

Fig. 2.

Taking No. III. as the best of the first batch of preparations, the growth of radium therein is only about 1/30,000 part of what would have occurred if uranium were the direct parent of radium. Some idea of the minuteness of the quantities of radium indicated by these curves can be got by the following consideration. Radium bromide at its present price costs about 16*l.* per milligram. For the element, radium, this is at the rate of 750,000*l.* per ounce. Fig. 3 represents a diagram 2 ft. high. To represent

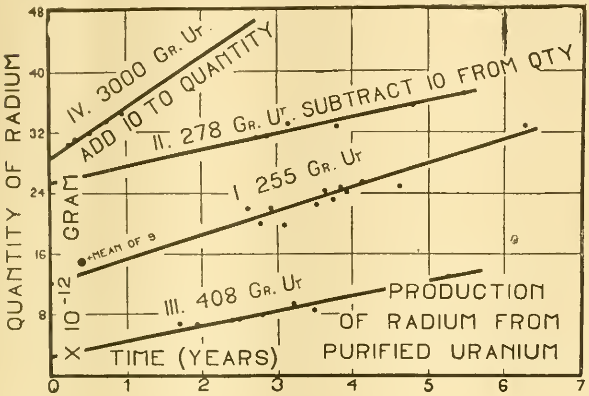

Fig. .

a pennyworth of radium on this scale would require a diagram more than 6000 ft. high, whereas to represent Keetman's curve (Fig. 2) would require one as high as St. Paul's Cathedral.

These results, therefore, confirm absolutely the view that uranium does not produce radium directly. As Rutherford first showed, if ionium is the only long-lived radio-element between uranium and radium, the growth of radium from uranium must initially be proportional to the square of the time, and should be represented by the equation $R=6\times 10^{-8}\lambda T^2$, where R is the radium formed per kilogram of uranium, T is the time in years, and $1/\lambda$ is the period of ionium. Hence, if uranium is the primary parent of radium, it is to be expected that the rate of growth of radium from the preparations will increase as time goes on according to some power of the time higher than unity. As Fig. 3 shows, there is still no evidence of this increase of slope in any of the preparations. This indicates, either that the period of ionium must be enormously long, or that several intermediate long-lived members intervene. If ionium is the only intervening member a *minimum* possible limit to its period may be arrived at by applying the above equation to the results. If it is assumed that the growth observed is due to uranium and that no ionium was initially present, the minimum periods calculated in the several experiments are as follow: No. I., 28,000 years; No. II., 41,400 years; No. III., 80,000 years; and No. IV., 69,200 years. Since, in all, certainly some of the growth is due to ionium initially present, the period of ionium must certainly be greater than the longest of these periods. We may safely conclude, if ionium is the only intermediate member, that its period is *at least* 100,000 *years*. This is forty times longer than the period of radium itself.

Entirely independent confirmation of this conclusion was obtained in another way. The gap in our knowledge is, strictly speaking, not between uranium and ionium, for the direct product of uranium is well known, and is called uranium X. It gives β-rays alone in disintegrating and has a period of only 35·5 days, so that in all the preceding work it has not been necessary to take it into account. It would retard the growth of radium inappreciably. But, if the view is right, the product of uranium X must be ionium, which gives α-rays. Concomitantly with the rapid decay of the intense β-rays of uranium X there should occur a growth of α-rays due to the ionium produced. Whether these α-rays can be actually detected will depend on the period of ionium. From experiments on the uranium X separated from 50 kilograms of uranium nitrate no growth of α-radiation, concomitant with or subsequent to the decay of the β-radiation, could be detected, and from these negative results the minimum period ionium can possess, if it is the only long-lived intermediate product, is 30,000 years.

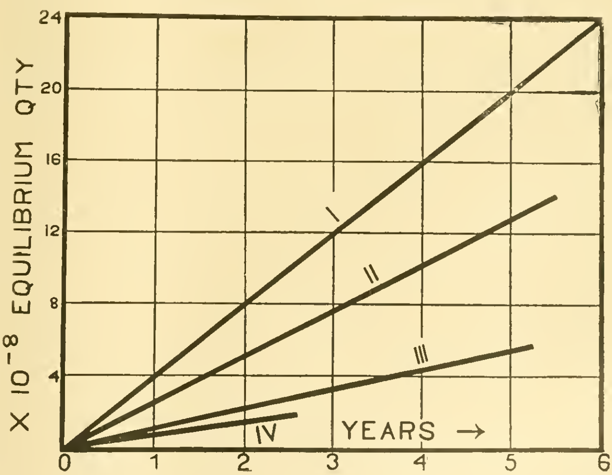

Fig. 4.

The question arose whether by any means an upper limit, or maximum value, for the period of ionium could be assigned. By the law already discussed there must be many times as much ionium as radium in uranium minerals, and if the actual ratio were known the period of ionium could at once be found. For example, if the period were 100,000 years, there should be 12·5 grams of pure ionium per ton of uranium. Auer von Welsbach, in a masterly chemical separation of the rare-earth fraction from 30 tons of Joachimsthal pitchblende, separated a preparation, which he described as thorium oxide, containing ionium, the activity of which was measured by Meyer and von Schweidler. To obtain a maximum estimate for the period of ionium, I assumed that Welsbach's preparation was in reality pure ionium oxide (which it certainly was not, as it gave the thorium emanation), and so I obtained the period of a million years as the upper possible limit. In proportion as the percentage of ionium oxide present is less than 100 per cent., this period must be reduced.[2] Thus we have fixed the period of ionium as between 10^{-5} and 10^{-6} years, if ionium is the only intervening long-lived member.

Quite recently a method has been devised for calculating the period of ionium from the range of its α-particles, which is based upon an empirical mathematical relation holding between this range and the periods of the substances giving α-rays in the case of the other members of the series.[3] The most recent estimate by this method is about 200,000 years, which may be accepted provisionally as the most probable at the present time. If this is correct, there should be 25 grams of ionium per ton of uranium in minerals. A variety of evidence thus leads to the conclusion that to detect the growth of radium from uranium either still larger quantities of uranium or still longer time is necessary. Even after ten years, that is, at the end of 1916, if the period of ionium is as estimated, the uranium in No. III. preparation should only have produced 12×10^{-12} grams of radium, which is rather less than half the amount that will then have been formed by the ionium initially present. Nos. I. and II. preparations are very much less favourable. But it is interesting to consider No. IV. preparation, which, though only 2·6 years old, has more than seven times as much uranium as No. III. From the present slope of the curve it appears to have little more than one-half as much ionium, relatively to the uranium, as No. III., whereas the relative initial quantity of radium is about twice as great as in No. III. After eight years, that is in 1917, the quantity of radium produced from the uranium should be about equal to that which will have by then been produced from the ionium present. A distinct upward slope should be detectable in the growth curve some time before this. But this is the best, if the estimate of the period of ionium assumed is correct, that the present set of experiments can offer to the solution of the problem. With the experience already gained, especially in dealing with large quantities of uranium and in the methods of measurements of the minutest quantities of radium, there should be no difficulty in obtaining and dealing with sufficient uranium, say 20 kilograms, of the requisite degree of purity as regards ionium and radium, to determine directly in a few years the period of ionium from the growth curve provided it is not greater than 200,000 years.

A favourable opportunity is being awaited to initiate this large-scale experiment. It requires a small room to itself in a permanent institution uncontaminated with radium, and some guarantee that once installed the preparations will remain undisturbed for a reasonable term of years, and that the measurements will be continued in a comparable manner should the period of life of the original investigator prove insufficient. It is not enough to set aside a quantity of uranium for our successors to see if any radium has grown in it. It is essential that the exact form of the growth curve should be known before the problem in question can be fully answered. There *may* be more than one long-lived intermediate product between uranium and radium. However, such indirect information as has been acquired as to the life period of ionium indicates that it alone is sufficient to account for the present results as regards the absence of growth of radium from uranium.

THE CROCKER LAND EXPEDITION.

REFERENCE was made in Nature of February 22 (p. 560) to the expedition organised by the American Museum of Natural History and the American Geographical Society to reach and map Crocker Land, in the north polar seas north-west of Grant Land, and to make all the scientific studies *en route* and in other parts of the Arctic regions that circumstances may permit.

The expedition will leave Sydney, N.S., by special steamer about July 20, 1912, and it is proposed to land on the south side of Bache Peninsula (Flagler Bay), lat. 70° 10′ N., and establish winter quarters. The ship will then be sent home. About the middle of September, sledging supplies to Cape Thomas Hubbard will be begun, and the work will be carried on throughout the winter during the moonlight periods. Cape Thomas Hubbard will be left with the return of dawn in February, 1913, and the expedition will push across the ice to Crocker Land. Crocker Land will be left about May 1, and a return will be made to Cape Thomas Hubbard. Scientific work will be carried on in Grant Land and along the return route to winter quarters on Flagler Bay, where the expedition expects to arrive in July, 1913. In the spring and summer of 1914 there will be an expedition from Whale Sound (Inglefield Gulf) directly eastward to the summit of the ice-cap of Greenland, at the widest part of that island. The return to New York will be in the autumn of 1914 by special ship.

The leaders of the expedition will be Mr. George Borup, assistant curator of geology in the American Museum of Natural History, and Mr. Donald B. MacMillan, both of whom are well known by their work done under Admiral Peary in his last polar expedition.

It is estimated that not less than fifty thousand dollars (10,000*l.*) should be provided for the absolute needs of the expedition, in order to enable it to accomplish the results that have been outlined above. On the proviso that sufficient funds are contributed from outside sources, the American Museum of Natural History has agreed to appropriate in the course of the expedition six thousand dollars in money, and has taken over its organisation and management. The American Geographical Society has made an appropriation of six thousand dollars toward the expedition, and Yale University an appropriation of one thousand dollars, while other subscriptions have been promised.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Glasgow.—The degree of Doctor of Science was conferred upon the following on April 22:—Leonard Findlay: *Thesis*, "The Etiology and Condition of the Blood in Spontaneous and Experimental Rickets, with additional papers." David Robertson: *Thesis*, "The Mathematical Design of Transformers; Electrical Meters on Variable Loads; and other original papers." George Duncan Campbell Stokes: *Thesis*, "A Critical Comparison of the Overlapping Section of the Oxford and Potsdam Astrographic Catalogues; An Original Solution of the Problem of Two Bodies; An Analytical Study of Plane Rolling Mechanisms."

Commemoration Day will be observed on June 25. A meeting will be held in the Bute Hall, when Prof. F. O. Bower, F.R.S., will deliver an oration on "Sir Joseph Hooker," and honorary degrees will be conferred. It is expected that a number of the delegates attending the Congress of the Universities of the Empire will be present.

The resignation is announced of Prof. Arthur Searle, Phillips professor of astronomy at Harvard University. Prof. Searle, who graduated from Harvard in 1856, has taught in the University for forty-two years.

A course of four lectures on "Heredity Considered from the Point of View of Physiology and Pathology" will be delivered by Dr. F. W. Mott, F.R.S., in the Physiological Laboratory, King's College, on Mondays, May 20 and 27, and June 3 and 10, at 4.30 p.m. The lectures are free to members of King's College, London, to internal students of the University, and to medical men.

At the celebration of the 75th anniversary of the foundation of the University of Athens, on April 10, honorary degrees in medicine were conferred on Profs. von Behring (Marburg), Celli (Rome), Ehrlich (Frankfort), Exner (Vienna), Golgi (Pavia), Kronecker (Berne), Laudouzy (Paris), Richet (Paris), Sir Ronald Ross (Liverpool), Roux (Paris), Schulze (Würzburg), Weichselbaum (Vienna), and others. The degree of doctor of philosophy was conferred on Sir Donald MacAlister (Glasgow), Delbrück (Jena), Dörpfeld (Athens), Gubernatis (Rome), Harnack (Berlin), Kenyon (London), Mahaffy (Dublin), Wheeler (Berkeley), and others; and the degree of doctor of science on Profs. Depéret (Lyons), Halácsy (Vienna), Lacroix (Paris), Lepsius (Darmstadt), Partsch (Leipzig), and Philippson (Bonn).

The programme of the annual conference of the Child-Study Society, to be held in the University of London on May 9–11 inclusive, is now available. The subject arranged for discussion is the health of the child in relation to its mental and physical development. The presidential address will be delivered on May 9 by Sir James Crichton Browne, F.R.S. Among papers to be read at the conference may be mentioned:—The influence of defects of hearing in relation to the mental and physical development of the child, by Dr. J. Kerr Love; the influence of defects of vision in relation to the mental and physical development of the child, by Mr. N. Bishop Harman; the tuberculous child, by Dr. Jane Walker; and mental hygiene in relation to the development of the child, by Dr. T. Hyslop. Fuller particulars of the meeting can be obtained from the secretary of the London Society, 90 Buckingham Palace Road, London, S.W.

The Department of Agriculture and Technical Instruction for Ireland will conduct summer courses of instruction for teachers on July 2–26 next, and on August 6–31. Among the courses arranged for July we notice for teachers in day secondary schools and in technical schools a course in experimental science; for those in secondary schools only, one in domestic economy; and for domestic economy instructresses one in advanced cookery, housewifery, hygiene, and sick nursing. In August the courses will be concerned with practical mathematics and mechanics, handrailing, metal work, and rural science. Though most of the courses will be held in Dublin, some have been arranged for other important centres. Teachers desiring to take advantage of these courses must fill up and return the appropriate form of application so as to reach the offices of the department, Upper Merrion Street, Dublin, not later than April 30.

Attention was directed, in our issue of April 4 (vol. lxxxix., p. 129) to the opening to-morrow of the spinning section of the textile department of the University of Leeds by the Master of the Clothworkers' Company. The new extension is intended to afford facilities for instruction in the principles and theory of the manufacture of worsted yarns on the Continental system. To secure the most suitable equipment for this branch of technological teaching, textile institutes, spinning works, and conditioning laboratories in Belgium, France, Germany, and Switzerland were inspected, and a full inquiry was made as to the commercial value and technical nature of this system of worsted yarn construction. The extension has been designed by Mr. Paul Waterhouse, and erected at a cost of 5000*l*., making a total amount of 75,000*l*. granted by the Clothworkers' Company for technical education in the textile industries and dyeing departments of the Leeds University.

SOCIETIES AND ACADEMIES.

London.

Zoological Society, April 2.—Dr. A. Smith Woodward, F.R.S., vice-president, in the chair.—R. I. **Pocock**: A rare stag (*Cervus wallichii*) from Nepal, recently presented to the Zoological Society by his Majesty King George. The author pointed out the distinctive peculiarities of this species, which, on account of its great scarcity, had never been satisfactorily classified since it was described by G. Cuvier in 1825 from a coloured illustration of a specimen living at that time in the Barrackpoor Menagerie.—F. E. **Beddard**: Species of tapeworms of the genus Inermicapsifer obtained from the hyrax, with notes on the genera Zschokkeella and Thysanotænia. An account of the structure and characters of the species was given, together with the description of a new genus and two new species.—Dr. Bashford **Dean**: Living specimens of the Australian lung-fish (*Ceratodus forsteri*) in the society's collection. This paper contained some further observations made by the author in June, 1911, supplementary to his previous communication published in 1906, and dealt with the coloration, size, and age of the specimens. Details of the rate of growth of this species were also given, with notes on their method of breathing, their food, and an account of the regeneration of a portion of the left ventral fin which had suffered an injury.

Royal Astronomical Society, April 12.—Dr. Dyson, F.R.S., president, in the chair. E. E. **Barnard**: Recent observations of Nova Cygni (1876). A series of measures of stars in the neighbourhood showed little evidence of motion; the nova seemed to have become stationary in brightness.—E. E. **Barnard**: Micrometrical measures and focal peculiarities of Nova Lacertæ (Espin). Photographs were shown, from which it appeared that the nova existed as a 13th mag. star in 1893.—H. F. **Newall**: Photographs of the spectrum of Nova Geminorum (Enebo) made at Cambridge Observatory. The remarkable changes that had taken place in the spectrum of the nova were described, and Mr. Stratton further dealt with the Cambridge results, no fewer than 200 features having been measured upon the plates.—W. E. **Curtis**: The spectrum of the new star in Gemini. Prof. Fowler showed the photographs taken by Mr. Curtis.—**Royal Observatory, Greenwich**: Observations of Nova Geminorum. The President showed a series of photographs of the spectrum of the nova taken at the Royal Observatory, and described the changes that had taken place. Photometric observations were made by the aid of a grating, which was shown to the meeting. The grating was placed in front of the object glass, causing it to give a number of images of the star, and much facilitating the observations. Father Cortie described the observations of the nova made at Stonyhurst, the measurement of the spectra giving velocities similar to those shown by Nova Persei. Mr. Storey described the spectroscopic observations of Nova Geminorum made at the Royal Observatory, Edinburgh, and showed photographs taken. Dr. Duffield urged that the effects of pressure should be taken into consideration in our interpretation of the changes in the spectrum of the nova. The Rev. T. E. R. Phillips had made visual observations, and spoke of the great intensity of the Hα line. The star was an intense crimson at the end of March; its brightness had shown fluctuations.—Prof. H. H. **Turner**: A tentative explanation of the "two star streams" in terms of gravitation. Second paper: The position of the centre of our system. In his previous paper he had propounded a hypothetical constitution of our stellar system round a centre of attraction, on which view the centre should lie in the direction of one of the vertices. A number of entirely independent lines of investigation pointed to a vertex at $90^\circ + 11^\circ$ It appeared that Boss's moving cluster in Taurus occupied a position near the centre of our system; the oscillation period of our sun would be about 400 million years, the sun having passed pericentron about a million years ago.

Royal Meteorological Society, April 17.—H. N. Dickson, president, in the chair.—J. E. **Clark** and R. H. **Hooker**: Report on the phenological observations for 1911. The outstanding features of the weather during the year were the severe cold of early April; the summer of abnormal dryness, heat and sunshine; and the continuous rainfall when once the drought thoroughly broke about mid-October. After referring to the flowering of plants, the appearance of insects and the song and migration of birds, the authors dealt with the yield of farm crops, and showed that potatoes and wheat were above the average, but most of the other crops were below the average, especially beans, roots, and hay. Throughout Great Britain harvest began generally a fortnight to three weeks earlier than usual, and the duration was very short, the result being that the termination of the harvest was fully a month earlier than the average..—R. G. K. **Lempfert** and H. W. **Braby**: A method of summarising anemograms. The tabulation of the hourly values of wind velocity and of wind direction as recorded by many anemometers in the British Isles forms part of the routine work of the Meteorological Office, but little has been done hitherto to summarise the tabulations. The authors have made a preliminary discussion of a few records, and in this paper they gave the results in the form of wind-roses for four stations, which had been selected as being typical of the extreme north, the extreme south, the east coast, and the west coast of Great Britain, viz., Deerness, Scilly, Yarmouth, and Holyhead.

Cambridge.

Philosophical Society, March 11.—Sir George Darwin, president, in the chair.—Prof. **Pope** and C. S. **Gibson**: The resolution of racemic benzoylalanine. An account was given of the resolution of racemic benzoylalanine by the method of Pope and Peachey.—Prof. **Pope** and J. **Read**: The optically active hydroxyhydrindamines. The authors described the resolution of hydroxyhydrindamine into optically active components by means of α-bromocamphor-π-sulphonic acid and the preparation of salts and other derivatives of the racemic and active bases.—C. T. **Heycock** and F. E. E. **Lamplough**: The boiling points of zinc, cadmium, mercury, sodium, and potassium, and their alteration with change of pressure. An account was given of the more trustworthy previous determinations of these data, the wide differences being noted. The authors' experiments, in which platinum resistance thermometers were used, were described, and the results of many closely agreeing experiments were given. At 760 mm. pressure the boiling points were found to be as follows:—Zinc, $905{\cdot}70^\circ$; cadmium, $765{\cdot}93^\circ$; mercury, $357{\cdot}70^\circ$; sodium, $882{\cdot}6^\circ$; potassium, $762{\cdot}2^\circ$.—F. E. E. **Lamplough**: The metastable condition of undercooling in metals. Investigations have been made to determine whether a metastable condition of undercooling before solidification exists in metals. In no case have positive results been obtained. Tin, which on solidifying exhibits superfusion in a notable degree, does not show a metastable undercooling greater than at most half a degree.—J. **Satterly**: The quantities of radium and thorium emanations contained in the air of soils. (1) The amounts of radium emanation in the air of different soils have been measured at intervals extending over a year. For depths of from 100 to 150 cms. in gravelly soil the amount of emanation is, on the average, equal to approximately 200×10^{-12} curie per litre or 2000 times as much as there is usually in atmospheric air. (2) Experiments showed that a litre of soil-air was in association with 14,000 gm. of damp soil (12,000 gm. when dry), whence the apparent radium content of the soil is $1{\cdot}7 \times 10^{-4}$ gm. per gm. of (dry) soil. As the actual radium content is more likely to be seventy times this it follows that little of the emanation generated in the solid particles of the soil can escape into the air around them. (3) The proportion of radium emanation to thorium emanation in soil-air has been measured for various depths and the ratio has been found to increase from 1600 near the surface to 26,000 at a depth of 400 cm. At a depth of 150 cm. it is 8600, whence, taking the radium content of the soil as $1{\cdot}1 \times 10^{-12}$ gm. per gm., the thorium content works out as $1{\cdot}4 \times 10^{-5}$ gm. per gm. This is of the right order.—J. A. **Crowther**: A theory of the dissymmetrical distribution of secondary Röntgen radiation.—A. E. **Oxley**: The variation of magnetic susceptibility with temperature. A criticism of the conclusions reached by Profs. du Bois and Honda concerning the invalidity of the Curie-Langevin laws.—H. H. **Paine**: The coagulation of colloidal copper. Rate of coagulation.—R. D. **Kleeman**: The different internal energies of a substance. The author showed that the internal energy of a substance can be divided into three parts, viz.: (1) the kinetic energy of the molecules due to their motion of translation; (2) their molecular internal energy; (3) the potential energy due to their attraction upon one another. It was proved that the kinetic energy of a molecule is equal to that it possesses in the gaseous state at the same temperature, that is, it is equal to $\frac{TR3}{2}$, where T is the absolute temperature and R is the gas constant. The internal energy of a substance is per molecule therefore $\left(U_1 + u_1 + \frac{3RT}{2}\right)$, where U_1 is the energy due to molecular attraction and u_1 the internal energy. Formulæ for the specific heat at constant volume and constant pressure, the Joule-Thomson effect, &c., were deduced and compared with the facts.

Paris.

Academy of Sciences, April 15.—M. Lippmann in the chair.—**J. Boussinesq**: The geometric theory for a non-rigid body of continuous displacements, as well as the deformations and rotations of its particles.—Yves **Delage**: A self-recording bathyrheometer. A description of an instrument for measuring and recording surface currents. It has the advantage of being capable of total immersion, and measures both velocities and directions of the currents.—M. **Le Chatelier**: Remarks on a work by F. W. Taylor dealing with the principles of scientific organisation of works.—J. **Bosler** and P. **Idrac**: The spectrum of the new star in the Twins. Observations made at Meudon showed a complete series of the bright lines of hydrogen. The principal nebular line was also noted.—Fr. **Iniguez**: The new star in the Twins. From March 15 to 19 the lines $H\beta$, $H\zeta$, and K were brilliant. The line K disappeared on March 20.—Etienne **Delassus**: The linkages of any order of material systems.—B. **Mayor**: The deformations of certain elastic systems.—Emile **Borel**: The geometric bases of statistical mechanics.—J. **Bergonié**: The phenomena of lightning. A description of some peculiarities caused by a lightning stroke on March 20 near La Flouquette.—C. **Dauzère**: The stability of cellular vortices.—M. **Deslandres**: Remarks on the preceding communication.—A. **Blondel**: An electro-chronograph with synchronised sparks. The vibrator of the secondary coil producing the sparks is controlled by a tuning-fork, not directly, but by the action of a current itself controlled by the tuning-fork. The necessary precautions are given in detail. C. **Camichel**: The measurement of the differences of phase of two alternating currents.—B. **Szilard**: The radio-activity of the thermal springs of Saint Lucasbad (Hungary).—Albert **Bruno** and P. Turquand **d'Auzay**: The estimation of sulphates in solution by a physico-chemical volumetric method. The changes in electrical conductivity are measured when a solution of baryta is added to the sulphate solution. In the case of wine the method was found to be untrustworthy.—Georges **Dupont**: The oxidation of some ketohydrofuranes.—André **Meyer**: The action of oxyurea upon some β-ketonic esters.—MM. **Amouroux** and **Murat**: Some syntheses starting with butyrone. Butyrone can readily be obtained in quantity by the catalytic action of thoria upon butyric acid. Various derivatives obtained by the Grignard reaction from this ketone are described.—Paul **Gaubert**: The circular polarisation of liquid crystals.—Lucien **Daniel**: The transformation of a chrysanthemum as a result of repeated budding.—Henri **Piéron**: The variation of the sensation lag as a function of the intensity of stimulation.—Raphael **Dubois**: The physical properties of physiological light. Remarks on a recent note by M. Ozorio on this subject.—Edmond **Hue** and Marcel **Baudouin**: The atavic characters of certain lumbar vertebræ of men of the polished stone period. A study of the lumbar vertebræ of Neolithic men from Vendrest proves three atavic characters, showing that these skeletons must be classed between anthropomorphs and modern man.—A. **Marie** and Léon **Mac-Auliffe**: The physiognomy of assassins. Results of researches on this class of criminals.—Raoul **Dupuy**: Contribution to the study and treatment of children of arrested development.—Maurice **Letulle** and L. **Nattan-Larrier**: The epithelioma of the embryonic ectoderm. Embryonic ectodermic carcinoma is always secondary to a mixed tumour either of the placenta or of the completely developed organism.—Louis **Gentil**: The tectonic of the Haut Atlas in Morocco, and its relations with the Atlas of the Sahara.—Henri **Perrotin**: An attempt at the representation of terrestrial temperatures as a function of the cloud conditions.

DIARY OF SOCIETIES.

THURSDAY, April 25.

Royal Society, at 4.30.—The Diffusion and Mobility of Ions in a Magnetic Field: Prof. J. S. Townsend, F.R.S.—On the Observed Variations in the Temperature Coefficients of a Precision Balance: J. J. Manley.—On the Torque produced by a Beam of Light in Oblique Refraction through a Glass Plate: Dr. Guy Barlow.—Contributions to the Study of Flicker. III: Dr. T. C. Porter.

Royal Institution, at 3.—Synthetic Ammonia and Nitric Acid from the Atmosphere: Prof. A. W. Crossley, F.R.S.

Royal Society of Arts, at 4.30.—The Central Provinces: Sir John O. Miller, K.C.S.I.

Institution of Electrical Engineers, at 8.—Third Kelvin Lecture: Prof. H. du Bois.

Concrete Institute, at 8.—Discussion on reports presented by the Tests Standing Committee, entitled (1) The Testing of Concrete, Reinforced Concrete, and Materials Employed therein; (2) The Testing of Reinforced Concrete Structures on Completion.

FRIDAY, April 26.

Royal Institution, at 9.—Sir William Herschel: Sir George Darwin, K.C.B., F.R.S.

Physical Society, at 5.—*Adjourned Discussion:* The Coefficients of Expansion of Fused Silica and Mercury: H. Donaldson.—The Solution of Net-work Problems by Determinants: R. Appleyard.—A Method of Measuring Small Inductances: S. Butterworth.

Institution of Civil Engineers, at 8.—The Principles and Practice of Accountancy in Relation to Engineering Design and Work: T. Frame Thomson.

MONDAY, April 29.

Royal Society of Arts, at 8.—Heavy Oil Engines: Captain H. R. Sankey.

Institute of Actuaries, at 5.—On the Superannuation and Pension Funds of certain Metropolitan Borough Councils, their Establishment, Administration, and Actuarial Investigation: H. W. Manly and T. G. Ackland With Tables of Progress of Typical Funds for Officers and Workmen and Examples: L. E. Clinton.

TUESDAY, April 30.

Royal Institution, at 3.—Insect Distribution with Special Reference to the British Islands: F. Balfour Browne.

WEDNESDAY, May 1.

Royal Institution, at 5.—Annual Meeting.

Royal Society of Arts, at 8.—Ancient Egyptian Ceramics: William Burton.

Society of Public Analysts, at 8.—The Analysis of Lithopone: W. L. Austin and Dr. C. A. Keane.—The Effect of Calcium on the Ammonium Molybdate Lead Assay: C. O. Bannister and W. McNamara.—The Constituents of Oil of Savin J. Watson Agnew and R. B. Croad.—The Detection of Heavy Petroleum in Paints and Vegetable Oils: W. B. Pollard.

Entomological Society, at 8.—The Colour-groups of the Hawaiian Wasps: Dr. R. C. L. Perkins.

Geological Society, at 8.—Insect Remains from the Midland and South-Eastern Coal-Measures: H. Bolton.—On the Geology of Mynydd Gader, Dolgelly, with an Account of the Petrology of the Area between Dolgelly and Cader Idris: P. Lake and Prof S. H. Reynolds.

THURSDAY, May 2.

Royal Society, at 4.30.—*Probable Papers:* Petrifications of the Earliest European Angiosperms: Marie C. Stopes.—The Distribution of Oxydases in Plants and their *rôle* in the Formation of Pigments: Dr. F. Keeble and Dr. E. F. Armstrong.—The Manifestation of Active Resistance to the Growth of Implanted Cancer: Dr. B. R. G. Russell.—The Nature of the Immune Reaction to Transplanted Cancer in the Rat: Dr. W. H. Woglom.—On the Instability of a Cortical Point: T. G. Brown and Prof. C. S. Sherrington, F.R.S.—The Measurement of *Trypanosoma rhodesiense*: Dr. J. W. W. Stephens and Dr. H. B. Fantham.

Royal Institution, at 3. Explorations in the Canadian Rocky Mountains: Prof. J. Norman Collie, F.R.S.

Linnean Society, at 8.—On the Structure of the Palæozoic seed *Lagenostoma ovoides*, Will: Miss T. L. Prankerd.—Additions to the Flora of Western and North-Western Australia: Dr. Karl Domin.—Freshwater Rhizopoda from the States of New York, New Jersey, and Georgia, U.S.A.; with a Supplement on the Collection from the Seychelles: G. H. Wailes.—*Ligidium hypnorum* a Woodlouse new to Britain: W. M. Webb.—New Light on the Linnean Herbarium: The General Secretary.

Institution of Electrical Engineers, at 8.—*Adjourned Discussion:* The Causes Preventing the More General Use of Electricity for Domestic Purposes.

FRIDAY, May 3.

Royal Institution, at 9.—The Use of Pedigrees: W. C. D. Whetham, F.R.S.

Institution of Mechanical Engineers, at 8.—*Resumed discussion:* Tenth Report to the Alloys Research Committee: on the Alloys of Aluminium and Zinc: Prof. J. O. Arnold

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

" To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 2218, Vol. 89] THURSDAY, MAY 2, 1912 [Price Sixpence

Registered as a Newspaper at the General Post Office.]

UNIVERSITY OF LONDON.

The following Advanced Courses of Lectures, to which admission is free, will be delivered :—

Eight Lectures on "The History of Carbohydrates in the Animal Body," by Professor J. J. R. MACLEOD, M.B., Ch.B., D.P.H., at the Physiological Laboratory of the University, South Kensington, on Tuesdays at 5 p.m., beginning on May 7, 1912.

Four Lectures on "The Use of Vertebrate Fossils in Stratigraphical Geology," by A. SMITH WOODWARD, LL.D., F.R.S., in the Geological Department of the Imperial College, Royal College of Science, South Kensington, on Mondays at 5 p.m., beginning on May 13, 1912.

Three Lectures on "The Evolution of the Mammalian Brain," by Professor G. ELLIOT SMITH, M.A., M.D., F.R.S., in the large Lecture Room of Bedford College, Baker Street, W., at 5 p.m., on Friday, May 24, Tuesday, May 28, and Wednesday, May 29, 1912.

P. J. HARTOG, Academic Registrar.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON.

INCLUDING THE

ROYAL COLLEGE OF SCIENCE, the ROYAL SCHOOL OF MINES, and the CITY AND GUILDS (ENGINEERING) COLLEGE.

A Special Course of Lectures will be given, beginning on Wednesday, May 15 next, on the

MAGNETIC PROPERTIES OF METALS AND ALLOYS,

by S. W. J. SMITH, A.R.C.S., M.A., D.Sc.

For further information and for admission to the Course application should be made to the Secretary.

EAST LONDON COLLEGE.

(UNIVERSITY OF LONDON.)

Patron—HIS MAJESTY THE KING.

Classics	F. R. Earp, M.A.
English	H. Belloc, M.A.
French	Mina Paquier.
German	J. Steppat, Ph.D.
History	Thomas Seccombe, M.A.
Mathematics	The Principal.
Physics	C. H. Lees, D.Sc., F.R.S.
Chemistry	J. T. Hewitt, D.Sc., F.R.S.
Botany	F. E. Fritsch, D.Sc.
Geology	W. L. Carter, M.A.
Civil and Mechanical Engineering	D. A. Low, M.I.M.E.
Electrical Engineering	J. T. Morris, M.I.E.E.

Fees moderate. Valuable Entrance Scholarships awarded by Drapers Company.

Special facilities for Post-Graduate and Research Students. Particulars of fees, courses of study, &c., on application to the Registrar, or to

J. L. S. HATTON, M.A., Principal, at the College.

BEDFORD COLLEGE FOR WOMEN.

(UNIVERSITY OF LONDON.)

YORK PLACE, BAKER STREET, W.

Principal—Miss M. J. TUKE, M.A.

COURSE OF SCIENTIFIC INSTRUCTION IN HYGIENE.

Recognised by the Sanitary Inspectors' Examination Board.

The Course is designed to furnish training for Women Sanitary and Factory Inspectors and Teachers of Hygiene.

A Post-graduate Scholarship of £35 for one year is offered for the course beginning October, 1912. Applications should be forwarded not later than June 1 to the Principal, from whom further particulars may be obtained.

BEDFORD COLLEGE FOR WOMEN.

(UNIVERSITY OF LONDON.)

YORK PLACE, BAKER STREET, LONDON, W.

REID TRUSTEES' SCHOLARSHIP.

ONE SCHOLARSHIP, value £60 a year for three years, is offered by the Trustees on the result of the College Entrance Scholarship Examination in June next. The scholar will be required to come into residence at the College in the October following the award. Further particulars on application to the Hon. Sec. to the Reid Trust, Bedford College.

COLLEGE ENTRANCE SCHOLARSHIPS

THREE ENTRANCE SCHOLARSHIPS (one in Arts and two in Science) will be offered for competition in June next, viz. :—

Reid, in Arts, value £30 a year for three years.
Pfeiffer, in Science, value £50 a year for three years.
Henry Tate, in Science, value £40 a year for two years.

Full particulars on application to the Principal.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.

Founded 1877. Incorporated by Royal Charter, 1885.

The next INTERMEDIATE EXAMINATION will commence on TUESDAY, JULY 2. FINAL EXAMINATIONS in (*a*) Mineral Chemistry, (*b*) Metallurgical Chemistry, (*c*) Physical Chemistry, (*d*) Organic Chemistry, and (*e*) The Chemistry of Food and Drugs, &c., will commence on MONDAY, JULY 1, or on MONDAY, JULY 8. The List of Candidates will be closed on MONDAY, JUNE 3.

Forms of application and further particulars can be obtained from the Registrar, Institute of Chemistry, 30 Bloomsbury Square, London, W.C.

The Regulations for the Admission of Students, Associates, and Fellows, *Gratis*. Examination Papers: 1908-09 (2 years), 6*d.*; 1910, 6*d.*; 1911, 6*d.*

"A List of Official Chemical Appointments." *Fourth Edition*, now ready, 2*s.* (post free, 2*s.* 3*d.*).

APPOINTMENTS REGISTER.—A Register of Fellows and Associates of the Institute of Chemistry who are seeking appointments is kept at the Offices of the Institute. Applications for the services of professional chemists should be forwarded to the Registrar, stating the requirements.

AUSTRALIAN INSTITUTE OF TROPICAL MEDICINE,

TOWNSVILLE, QUEENSLAND.

Applications are invited for (1) FIRST ASSISTANT at £600 per annum, to be an expert in Tropical Medicine, skilled in laboratory methods, capable of taking charge in absence of Dr. Breinl, the Director; (2) SECOND ASSISTANT at £500, to have a good general knowledge of Tropical Medicine and of laboratory methods, but specially to have a sound knowledge of tropical hygiene and epidemiology, preferably with Indian experience; (3) THIRD ASSISTANT at £400, to be a Biochemist with sound knowledge of Organic Chemistry and some experience in physiological work. Tenure in each case five years. Salary to commence on arrival at Townsville. £100 each for expenses from Europe. Applications to be sent to the Official Secretary, Commonwealth Offices, 72 Victoria Street, Westminster, S.W., not later than May 31, with qualifications, recent photograph, and not more than four testimonials. Age to be stated. The candidates chosen must submit approved certificates of health. New laboratories are in course of erection. The Commonwealth Government provides £4000 per annum.

ROYAL SOCIETY OF LONDON.

MACKINNON RESEARCH STUDENTSHIPS.

There are two Studentships each of the value of £150. One of them is awarded for research in the group of the Physical Sciences, including Astronomy, Chemistry, Geology, Mineralogy and Physics; the other is awarded for research in the group of the Biological Sciences, including Anatomy, Botany, Palæontology, Pathology, Physiology and Zoology.

The Studentships are awarded annually for one year, but are renewable for a second year. Under exceptional circumstances they may be renewed for a third year. The Studentships are restricted to British subjects.

The present holder of the Physical Studentship is a candidate for reappointment. The appointment will date from October 1.

Applications must be received not later than June 1. Further particulars and forms of application can be obtained from the Assistant Secretary of the Royal Society, Burlington House, London, W.

BRITISH MUSEUM (NATURAL HISTORY).

An ASSISTANTSHIP of the Second Class in the Department of Geology is now vacant, the duties being chiefly the Systematic arrangement of the collection of Fossil Plants.

Limits of age, 20 and 25 years.

The salary commences at £150 per annum.

Candidates will be required to undergo a competitive examination by the Civil Service Commissioners in English Composition, and translation from either Greek or Latin, and either German or French, as well as in Morphological and Systematic Botany and Physical and Stratigraphical Geology.

Applications, accompanied by not more than three testimonials, must reach the Director, Natural History Museum, Cromwell Road, London, S.W., not later than June 15, 1912.

COUNTY COUNCIL OF CUMBERLAND.

The Principal of the New County Technical and Secondary Schools, Workington, invites applications from qualified men for the post of HEAD of the ENGINEERING DEPARTMENT. The salary is at the rate of £200 per annum, and the successful candidate will be required to enter upon his duties on July 1.

Candidates should have a degree in Engineering, or the equivalent thereof, and have had experience in the teaching and organising of such a Department.

Applications, giving age, full particulars of training and experience, and copies of three recent testimonials, should reach the undersigned not later than May 15.

G. H. WOOLLATT,
Victoria Institute, Worcester.

THURSDAY, MAY 2, 1912.

CHEMICAL SPECTROSCOPY.

Introduction à l'Étude de la Spectrochimie. Par Prof. G. Urbain. Pp. iii+248+ix plates. (Paris: A. Hermann & Fils, 1911.) Price 10 francs.

PROF. URBAIN has written an exceedingly interesting and valuable introduction to spectroscopy treated more especially in relation to chemistry and chemical analysis. He has based this book upon his course of lectures delivered at the Sorbonne, and with undue modesty explains that it is mainly written for those younger chemists who, in their desire to enter a field full of promise, wish rapidly to acquire the fundamental ideas necessary for the theoretical and experimental study of the subject. Prof. Urbain is singularly happy in his preface, wherein he deals with the position of the spectroscope in relation to chemistry. Quite truly he points out the very valuable services that spectroscopy has rendered to chemistry and to astronomy. As for the former, it was a very long time before the subject formed more than a very restricted adjunct to chemical analysis. In truth, spectroscopy now deals with numerous facts which have but a dim connection with chemical analysis, and it deserves to rank as one of the principal branches of physical chemistry along with electrochemistry and thermochemistry.

The discoveries that chemistry owes to spectroscopy are many. To all is familiar the detection of rubidium and cæsium by Bunsen and Kirchhoff, followed by the isolation of indium, thallium, and gallium. The spectroscope, however, has also proved itself to be the only guide in that apparently insoluble labyrinth of elements, the rare earths. To the spectroscope we owe the discovery of samarium and dysprosium by Lecoq de Boisbaudran, of holmium and thulium by Soret, of neodymium and praseodymium by Auer von Welsbach, and of europium by Crookes and by Demarçay. Finally there is the brilliant work of Prof. Urbain himself, which has resulted in the separation of ytterbium into neoytterbium and lutecium, and the discovery of the new element celtium. Again, the value of the spectroscope in Ramsay's work on the rare gases is within the common knowledge of all. Modern chemistry would have been in debt to the spectroscope for its most beautiful discoveries had not M. and Mme. Curie found in radioactivity a method of investigation which, although less general in its application, is certainly more sensitive in certain cases.

When Bunsen and Kirchhoff published their method of investigation by flame spectra, chemists naturally welcomed this with enthusiasm. Ever since that time the textbooks of analysis have religiously incorporated their methods. Very few, if any, of these books describe the modern methods of investigation, although the value of these has clearly been proved. These modern methods are only to be found in specialised books which students have not the leisure to read and the skilled chemist rarely consults.

Prof. Urbain shows how the confidence felt by chemists in spectroscopy received a severe blow when the plurality of spectra was enunciated by Plücker and Hittorf. It was felt that spectrum analysis no longer possessed that rigour and infallibility at first attributed to it; nothing, after all, was so sound as the good old methods of pure chemistry; spectrum analysis was a complex subject, and it was abandoned to the specialist. In spite of this attitude of the pure chemist, the advance of spectro-chemistry has been enormous, and the variety of the modern methods is extraordinary. Flame spectra, spark spectra, spectra of gases and of solutions, arc spectra, absorption spectra, phosphorescent spectra, and infra-red emission and absorption spectra—all have their value in particular cases. The time has surely come for this subject to take the rank which it deserves in the chemical laboratory. At present the students of chemistry have a poor idea of the part played by the spectroscope in analytical research. The faint-hearted ones hesitate to take risks in so unknown a field, while the bolder ones perhaps try a few experiments, but are soon discouraged owing to their ignorance of the technique.

With the view of removing this ignorance, Prof. Urbain has written this book, and he treats in a most admirable way all the modern methods of work. In the first four chapters he describes the character and nature of spectra and the methods of illumination. Without going fully into the spectroscope itself, he gives in detail a most excellent account of the modern methods of illumination. The fifth and sixth chapters deal with phosphorescence and absorption, to the literature of which the author himself has contributed so largely. In the seventh chapter is to be found a concise description of series of lines and their relationships.

In fine it may be said that this book forms a most admirable introduction to chemical spectroscopy, and it is to be cordially recommended to every chemist, student, and expert alike, for it should go far to dispel that somewhat doubtful confidence which the author quite rightly complains is still felt by the pure chemist as regards this important and fascinating branch of science.

E. C. C. BALY.

THE CONSTITUTION OF THE SILICATES.

Die Silicate in chemischer und technischer Beziehung: unter Zugrundelegung der seitens der philosophischen Fakultät der Universität Göttingen preisgekrönten Hexitpentit-Theorie nebst Umwandlung derselben in eine allgemeine stereochemische Theorie. By Dr. W. Asch and Dr. D. Asch. Pp. xv+409. (Berlin: Julius Springer, 1911.) Price 16 marks.

THE present work, which is an expansion of an essay originally submitted for a prize offered by the philosophical faculty of Göttingen, is a bold and original attempt to grapple with the difficult problem of the chemistry of the silicates and related compounds. The authors have sought to give a structural explanation of the behaviour of such compounds consistent with the doctrine of valency. The "Hexite-Pentite" hypothesis, which forms the basis of the work, assumes that silicates and alumino-silicates are not, in general, derived from the simpler hydroxides, such as $Si(OH)_4$ and $Al(OH)_3$, but from compounds formed by the condensation of six such molecules, with elimination of water, to form a closed ring. Less frequently, five-membered rings may be produced, and complex molecules are built up by the union, according to certain definite principles, of two or more such "hexite" or "pentite" groups. By the replacement of hydroxylic hydrogen by metals, of hydroxyl by fluorine, &c., formulæ are constructed which are capable of expressing with remarkable completeness the properties and reactions of many silicates and aluminosilicates.

The formulæ, especially in the contracted notation chiefly employed in the text, strongly recall the Kekulé theory of aromatic carbon compounds, but the analogy is not a real one, as the linking is never from silicon to silicon or aluminium, but always through an intervening oxygen atom. Praise is due to the authors for the ingenuity with which the hypothesis is applied, and for the labour expended in recalculating the enormous number of analyses given, and expressing them in terms of the new structural theory. A certain arbitrariness in the choice of many of the formulæ is unavoidable, in the absence of experimental investigations specially designed to test the points in question.

The most serious defect of the work is its disregard of physical considerations, owing to the exclusively chemical viewpoint adopted. This one-sidedness is well seen in the lengthy and detailed treatment of Portland cement and blast-furnace slag. Definite hexite-pentite formulæ are assigned to a great variety of these artificial products on the evidence of ultimate analyses only, and the microscopical proof that such materials are heterogeneous is brushed aside in a single sentence. Thermal analysis, by means of which such great advances are being made, including the brilliant work of the Geophysical Laboratory in Washington, is not considered, and the names of Day, Shepherd, and their collaborators do not even appear in the bibliography, although this includes some 1500 references. Again, the great additions made in recent years to our knowledge of colloids and of the part played by them in the chemistry of silicates are passed over in silence or with a brief allusion, in spite of the intimate bearing of such work on the weathering of felspars, the setting of cements, the hydration of zeolites, and similar questions, all of which are discussed from a purely structural point of view. Even to glasses and porcelain definite structural formulæ are assigned.

By replacing silicon and aluminium atoms by other elements, and by introducing stereochemical considerations, the hypothesis is extended to complex salts, metal-ammonia compounds, and salts with water of crystallisation. Some shorter chapters are devoted to further and more hazardous speculations, the hexite-pentite arrangement being applied to aliphatic organic compounds, and even to the structure of the atom and the explanation of radioactivity. These extravagances, however, do not detract from the value of the main thesis, which certainly deserves the attention of inorganic chemists and mineralogists, as possibly affording assistance in the further study of a complex and difficult subject.

C. H. DESCH.

BRITISH VEGETATION.

Types of British Vegetation. By members of the Central Committee for the Survey and Study of British Vegetation. Edited by A. G. Tansley. Pp. xx+416+36 plates. (Cambridge: University Press, 1911.) Price 6s. net.

THE great impetus that has been given during recent years to the study of the British flora is largely owing to the development of that branch of botany known as ecology. This subject—the study of plants in connection with their habitat—has raised many questions, and amongst them that of plant-communities has received foremost attention, and has been zealously investigated. The committee which was formed in 1904 to organise and carry out a systematic survey of the vegetation of the British Isles has worked hard. Much surveying and mapping has been done, and several memoirs dealing with widely separated areas have been published. Though further work is required before a complete account could be presented, yet enough has been accomplished to obtain a general idea of the principal types occurring.

The volume now issued summarises in a clear and useful manner the results that have so far been obtained, and provides the student with a sketch of the British vegetation from an entirely new point of view. The book is based on the work of the committee referred to. Mr. A. G. Tansley has acted as editor, chapters being furnished by different workers, he himself, moreover, being responsible for a large proportion of the whole. The joint authorship works well, and results in a certain freshness of style, owing to each writer being specially familiar with the region he describes.

A short section in the first part of the book deals with the general conditions obtaining in the British Isles, the whole of part ii. being devoted to the description of the various formations and associations recognised. The plant-formations of clays and loams, of sandy soils, and of heaths are first described by the editor, and a chapter follows, by C. E. Moss, on the plant-formation of the older siliceous rocks. The vegetation of calcareous soils is next taken up, Tansley and Rankin dealing with the sub-formation of chalk, and Moss with that of the older limestones. A short chapter on general aquatic vegetation is inserted, though information on this subject is scanty. The fen and aquatic formations of East Norfolk are, however, dealt with in detail by Miss Pallis; and G. S. West gives a short account of the Phytoplankton of the lakes of the British Isles. The moor formation receives considerable attention, the lowland and upland moors being described by Rankin, and by Lewis and Moss respectively. A very interesting section on the Arctic-alpine vegetation is contributed by W. G. Smith, who deals chiefly with the slopes and corries of Ben Lawers, though here again much further work is required. The final chapter concerns the vegetation of the sea-coast, and contains, amongst others, an account by Oliver of the maritime communities of the Blakeney Harbour district.

The principal formations are in many cases divided into three associations, representing woodland, scrub, and grassland, and these, if need be, are subdivided into a number of smaller communities (sub-associations and societies). Progressive and retrogressive associations receive due attention, and the serious amount of degenerating woodland that exists in England is repeatedly emphasised.

Although many areas in Great Britain and Ireland remain to be investigated, Mr. Tansley's "Types of British Vegetation" forms a most welcome addition to ecological literature, and one which will be indispensable to every student of the subject in this country. Well arranged, and illustrated by a number of excellent photographs, the book will not only be valuable to botanists, but should attract and stimulate inquiry amongst all who take interest in the vegetation of our islands.

A. D. C.

RECENT BOTANICAL PUBLICATIONS.

(1) *Plant Life: a Text-book of Botany for Schools and Colleges.* By Prof. Eug. Warming. Translated from the fourth edition of the Danish (Eug. Warming and C. Raunkiær) by Metta M. Rehling and Elizabeth M. Thomas. Pp. viii+244. (London: G. Allen and Co., Ltd., 1911.) Price 4*s.* 6*d.* net.

(2) *Wild Flowers as they Grow: Photographed in Colour Direct from Nature.* By H. Essenhigh Corke. With descriptive text by G. Clarke Nuttall. Second series. Pp. vii+197. (London: Cassell and Co., Ltd., 1911.) Price 5*s.* net.

(3) *Plant Life and Evolution.* By Prof. D. H. Campbell. Pp. iv+360. American Nature Series. (New York: Henry Holt and Co., 1911.) Price 1.60 dollars net.

(4) *An Intermediate Text-book of Botany.* By Ernest Evans. Pp. viii+394. (London: Longmans, Green and Co., 1911.) Price 6*s.*

IN the first of these volumes the treatment of the subject matter is excellent, and follows a plan which is considerably different from that generally adopted in most of the English elementary text-books. The whole book bespeaks of the wide range of knowledge possessed by its illustrious author, and is written with a terseness and accuracy which is the outcome of a deep and extensive store of fact. A good feature of the book is the reference to so many plants with which the student has a common and almost every-day acquaintance.

The illustrations are for the most part very good, and not only are they more varied than is usually the case in such a small volume, but they are likewise considerably different in character from those found in most of the English text-books. The illustration of *Atropa belladonna* (on p. 178) is poor, and that of Sphagnum (on p. 210) presents a peculiar appearance owing to being inverted. On p. 214 the name "*Algæ*" should be in clarendon type so as to be in conformity with the other groups, such as fungi, lichens, &c.; and on p. 218 the spore-bearing plants with stem and leaves might be well termed Archegoniates, but not "Bryophyta."

The translators are to be congratulated upon putting before the English public a most interesting elementary work on botany, and one which cannot fail to be stimulating to the junior student.

The second work treats of the flowers of twenty-five species of British plants, each one of which is illustrated by a photograph in colours and small text-illustrations of various parts of the flower. The text is very well written, and is full of folk-lore and legends concerning the plants dealt with. One useful feature of the book is the description of the pollination of the various flowers, but it must be mentioned that throughout the book the author makes the technical error of using the word "fertilisation" for pollination. This is the only flaw in a book which is an excellent one of its kind, and which would make a charming gift to any person interested in wild flowers. The majority of the plates are good, the best of them being the illustrations of *Arum maculatum*, the crab-apple, the cowslip, and the toothwort. The colouring of the gorse, and especially that of *Orchis mascula*, is scarcely true to life.

In the third publication there are ten chapters dealing with "Plant Life and Evolution." All are good, from the admirable introductory chapter to the concluding one on the "Origin of Species." The chapters dealing with the factors in evolution, with environment and adaptation, are excellent, but perhaps the best section of the book is that on the "Problems of Plant Distribution." Prof. Campbell's account of the "Origin of Land-plants" is just such a brief summary as so many students require, but it should be remarked that in it the author inclines to Bower's antithetic view of alternation of generations. The chapter on "Seed-plants" is a good *résumé* on the evolution of Gymnosperms.

There is some doubt whether diatoms are so recent in origin as suggested by the author, and not everyone would agree that Euglena "is structurally more like an animal than a plant."

The book must be considered as a valuable addition to the smaller text-books on botany, and exactly suited to the student who has mastered the elements of botany, and requires an insight into the principles of evolution.

The intermediate text-book by Mr. Evans is an attempt by the author to condense a rather large amount of fact into a relatively small space. It is pervaded throughout by a looseness of expression, and the mistakes in the earlier part of the book are almost too numerous to mention. Some of these errors are serious from the point of view of the student. The treatment of the Spermatophytes is much better, but even here the author's account of photosynthesis would be much improved by careful revision. On the whole, one could not recommend this book to an "Intermediate" student unless considerably revised.

OUR BOOKSHELF.

Hydro-Electric Practice. A Practical Manual of the Development of Water Power, its Conversion to Electric Energy, and its Distant Transmission. By H. A. E. C. von Schon. Second edition. Pp. xvii + 383. (Philadelphia and London: J. B. Lippincott Company, 1911.) Price 25*s*. net.

WE heartily welcome this second edition of Mr. von Schon's admirable treatise on "Hydro-Electric Practice." Although only four years have elapsed since the first edition appeared, general interest in hydro-electric schemes has greatly increased, partly, no doubt, due to the way in which the public imagination has been fired by the possibilities of electrochemical and electrometallurgical processes, particularly as applied to the manufacture of iron and steel, and to the fixation of atmospheric nitrogen. It is on this, if on no other, account to be regretted that the book deals solely with conditions as they exist in America, and that no illustrations are drawn from the vast water-power schemes now in course of construction or operation in Norway, for example.

As in the first edition, the book consists essentially of two portions, the first a general survey of hydro-electric projects and possibilities, intended for the investor and capitalist rather than for the engineer, and the second portion a really valuable account of the design and construction of a water-power equipment which will be indispensable to engineers actually engaged in constructional work.

The sections dealing with the electrical equipment are somewhat meagre, and they should at least have been supplemented by a full bibliography of the extensive existing literature covering this branch of the subject.

It is a pity that the author should have disfigured his otherwise perfectly lucid descriptions by writing such a sentence as is to be found on p. 25, in which the terms "energy" and "power" are used indiscriminately in hopeless confusion. Again, why "cubic second feet" instead of "cubic feet per second"? These may seem, and no doubt are, small points, but a writer who uses scientific terms loosely is bound to arouse suspicion; in this instance at least the suspicion would be quite unfounded, and the author is merely putting an easily avoidable obstacle in the way of a general acceptance of his treatise by responsible engineers.

Mendelism. By Prof. R. C. Punnett. Third edition. Pp. xiv+176. (London: Macmillan and Co., Ltd., 1911.) Price 5s. net.

ALL who knew Prof. Punnett's little book entitled "Mendelism" in its original form will welcome the greatly amplified edition of it which he has now published. This edition has been entirely re-written, and is illustrated by five coloured plates. Prof. Punnett's book, in its original form, did so much to familiarise the public with Mendelian phenomena and hypotheses that the present work requires no recommendation from "the old shuffling bribed sots, called Reviewers," to use the words of William Cobbett.

The book is especially valuable because it is, in the words of the author, "in some measure a record of the work accomplished by the Cambridge School of Genetics." If the book were a complete record (which, of course, it is not), the work of that school would be an achievement of which a larger group of investigators working over a longer period of time might well be proud. The theories which have been put forward to explain the new facts may or may not survive the test of future experiment and criticism; they may be nearer the truth than the more cautious of us dare to hope. But whether they survive these tests or not, the new facts discovered constitute a solid advance in human knowledge which the carpings of those who criticise the theories put forward to explain these new facts cannot rob of one iota of its value.

The attempt to answer the question how far the Mendelian theory as held by Prof. Punnett approximates to the true explanation (if we may make the extravagant assumption that there can be such a thing) is a fascinating exercise for those who are more interested in the relation between the human mind and the so-called objective world than in the objective world itself. But this is neither the time nor the place to discuss the truth of the Mendelian hypothesis. It is enough, for the present, that the Cambridge School of Genetics has contributed handsomely to the capital of our knowledge of hereditary phenomena, and that the book before us is an admirable presentation of these contributions.

Boiler Draught. By H. Keay Pratt. Pp. vii+138. (London: Constable and Co., Ltd., 1911.) Price 4s. net.

IN this little book the author has endeavoured to assist those to whom the efficient working of steam plant is of importance by explanations of methods of determining whether existing arrangements are satisfactory. The book opens with a number of elementary calculations regarding the pressure, volume, weight, and temperature of air, and the resistance to flow. Calculations in relation to chimney, forced, and induced draught follow. There are also sections dealing with the construction of chimneys, the applications of mechanical draught for land and marine purposes, and the chemistry of combustion. The treatment of the subject is designed to suit those practical men whose knowledge of mathematics and science may be scanty. Indeed, the author states in his preface that while mathematical investigation is well appreciated, the results are likely to be greatly misleading if relied on too completely to the exclusion of practical experience. "It is for this reason that men of high scientific attainments are sometimes at fault when they have to tackle a problem in practical work."

That there may be another side to this question is also rendered very clear in the book. Thus in chapter vi. are given methods of calculating the approximate over-all dimensions of a fan. The methods employed can give rough results only, yet we find data stated to five significant figures and worked into the calculations, including one case of the weight of a cubic foot of water taken as 62·418 lb. While many valuable results and suggestions occur here and there, obtained from the author's practical experience, there is very little reference to recent experimental work, such as that conducted at the Manchester School of Technology and elsewhere.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Burdon Sanderson and Vitalism.

IN his interesting and sympathetic notice, in NATURE of March 21, of the Memoir of Burdon Sanderson, your reviewer discusses Burdon Sanderson's attitude towards "vitalism," and thinks that the editors of the Memoir (my sister and myself) have scarcely represented this attitude satisfactorily. Our task in this connection was a somewhat difficult one, and we may have failed in it; but the grounds of the difficulty are of so much general scientific interest that it may perhaps be worth while to refer to them more fully. We quoted in the Memoir from the following letter, written by Burdon Sanderson from Algiers in 1904 to Miss Florence Buchanan, D.Sc. (who was then assisting him), with reference to a general paper which he was endeavouring, in the face of ill-health, to prepare on the general results of his electro-physiological work.

"From your pencil notes on my MS. I take it that you regard as the *result* of an investigation of the excitatory process the complex of data relating to localisation, time-relations, and intensity of electrical change—all of these being measurements. To me it appears that when you have got by measurement a complete knowledge of what happens electrically (intensity, localisation, and time-relations), this knowledge, however exact it may be, is of no value unless it enables you to conjecture the nature of the *excitatory process* of which these phenomena are the concomitants.

"The excitatory process can best be defined as a sudden transition from less functional activity (the so-called rest state) to greater. It is not a measurable physical change, but a vital one which cannot be measured, and which *therefore* lies outside the scope of scientific knowledge. The two acts which seem to constitute the excitatory process, viz. excitation and response, are not continuous, but are joined together by a non-measurable link. This link is a subject of scientific conjecture, not of scientific knowledge; for nothing that is not measurable is known. It is, in short, something which is involved in *organism*, for which the most proper designation is ***organismal***.

"The point to be emphasised is that the organismal link or nexus is the *essential* part of the excitatory process; for neither the physical effect of the stimulus nor that of the response is effectual by itself. It is only when these two are coupled by the organismal nexus that the excitatory process is constituted.

"The propagation of the excitatory process thus constituted takes place, not through or by any measurable process, but is wholly and solely organismal, and therefore not measurable. The electrical machinulæ are acted on by the organismal stuff, and not by their neighbours. Propagation is a vital process, not a physical one.

"The purpose of the paper will be (in case it is ever written) to show (1) that the mere statement of measurable data stops short of its purpose because it misses the essential fact in the excitatory process; (2) that every electrical change accompanying excitation which is cyclical corresponds to a single organismal change; (3) that the organismal change is modified by (*a*) exhaustion and (*b*) injury, these being localised (*a*) at the proximal contact and (*b*) at the distal, and having opposite signs." (Here, of course, the ligatured muscle preparation is referred to.)

While your reviewer is certainly right in emphasising, as, indeed, we have done in the Memoir, Burdon Sanderson's strong objections to vitalism, it seems to me that in this letter he also lays his finger, deliberately and accurately, on the weak spot in the physico-chemical theory of life. It is the connection between "physical" or "chemical" stimulus and "physiological" response that is unintelligible from the point of view of the physico-chemical theory of life. Burdon Sanderson concluded that this connection lies outside the scope of scientific knowledge, and in this way he avoided the many scientific difficulties and defects of traditional vitalism. But we felt bound to point out the gap which is left if no attempt is made to deal scientifically with what he calls (the italics are his own) "the *essential* part of the excitatory process." In every department of physiology there is the same gap; and what remains for exact physical and chemical investigation would seem to be only the outer fringe of the real phenomena.

J. S. Haldane.

Oxford, April 16.

A Peculiarity in the Shadows Observed during a Partial Eclipse of the Sun.

During the recent partial eclipse of the sun, I observed a peculiarity in the shadows cast by the sun's rays which may be worth recording. If eclipses occurred more frequently, this peculiarity would be familiar to everyone; as it is, I am not aware that it has been noticed, which is probably due to the fact that the attention of most observers was concentrated on the appearance of the sun itself.

While the eclipse was progressing I was walking along a country road white with dust. Along the edge of the road were young trees about 15 ft. high, decked with small, undeveloped leaves. The shadows of these trees, cast on the road, presented a peculiar appearance. What first attracted my attention was the number of salient angles in the shadows: these angles were not due to the shapes of the leaves, which were practically oval. A closer scrutiny revealed the fact that, where a leaf was isolated, its shadow took the form of a crescent; in fact, each such shadow was *a negative image of the visible portion of the sun's disc.*

This observation recalled to my mind a phenomenon to which my attention was directed some years ago by Mr. L. H. Winn. Mr. Winn observed that if a white screen be placed at some distance from a window which looks towards the sky, and a pencil be placed between the window and the screen, the shadow of the pencil takes the form of a faint negative image of the window, the vertical sashes being represented by bright lines, while the clear panes are represented by dark rectangles. Mr. Winn explained this phenomenon correctly by tracing the paths of individual rays; he also performed a number of other experiments which confirmed his reasoning. The explanation which will be given in this communication is of a somewhat more general character, and is a particular instance of Babinet's principle. The following laboratory experiments illustrate the phenomenon to be explained in a striking manner, and, at the same time, suggest its explanation.

Let a magic lantern (preferably illuminated with an arc lamp) be directed towards a white screen at a distance of 15 to 20 ft. Remove the focussing lens and cover the condenser with tissue paper. Next, let the circular illuminated area of the tissue paper be partly covered with an opaque disc, so that a brightly illuminated crescent remains visible. Place a sheet of cardboard, in which a hole about a centimetre in diameter has been bored, between the lantern and the screen. An inverted positive image of the illuminated crescent is formed on the screen: this image is produced in accordance with the principles which are exemplified by the pinhole camera. When the perforated sheet of cardboard is removed, the illumination of the screen is approximately uniform; and if a small ball about a centimetre in diameter, suspended by a fine thread, is placed in the position previously occupied by the perforation in the screen, it will cut off those rays which, by themselves, would form a positive inverted image on the screen. The part of the screen which was previously rendered bright by the rays which passed through the perforation in the card is now rendered dark by the interception of these rays, and the shadow of the ball takes the form of a dark crescent, which is a negative inverted image of the bright crescent from which the rays emanate. The ball must be placed so far from the screen that the umbra of the shadow is not formed; for the rest, there is considerable latitude as to the position in which the ball is placed. A body of about the same size, but with a shape differing considerably from the ball, casts an identical shadow. If a larger body is used, its shadow still has the form of an inverted negative image of the extended source of light, but the definition is less perfect.

If the disc which partly covers the illuminated tissue paper be removed, and a sheet of card, in which a stencil letter has been cut, is substituted for it, an inverted negative image of the stencil letter is obtained on the screen. Instead of the stencil letter, we may use a letter painted in transparent red on the tissue paper, the remainder of the illuminated area being painted blue; in this case the shadow of the ball thrown on the screen takes the form of an inverted image of the letter in blue, on a reddish ground.

These experiments show that *when light from an* *extended source throws the shadow of a small object on a screen, under such conditions that the umbra of the shadow is not formed, then the shadow is the negative inverted image of the source of light.*

Another shadow phenomenon observed during the partial eclipse may be mentioned here, although its explanation is obvious. In cases where the leaves of trees were so far advanced that most of the sun's rays were intercepted by them, the rays which passed through the small apertures between the leaves formed on the ground positive inverted images of the visible part of the sun's disc. The oval patches of light seen on the ground beneath thick trees under ordinary conditions of sunlight are due to the same cause. During the eclipse, the rays of the sun reflected from the free surface of water in a small glass formed a positive inverted image of the visible crescent of the sun on the walls or ceiling of the room in which the glass was placed.

Edwin Edser.

Halo during the Solar Eclipse of April 17.

As Nature contains no mention of the circular halo that appeared for about half an hour during the solar eclipse on April 17, the following facts may be of interest, for possibly the appearance was very local.

I was in the south of the Isle of Wight, at sea-level, and noticed, just as the air began perceptibly to cool, that a faint and very gauzy film of cloud collected round the sun. This was transparent enough for the sun to appear through it unmasked, but just dense enough somewhat to relieve the glare and make it possible to take hasty glances at the sun itself with the naked eye. After the clouds drifted into position, they remained through the whole time of the eclipse, but disappeared when the sun's warmth returned. Shortly after their accumulation I saw a perfectly circular halo; this was coloured, but the bands of colour were only red, yellow, and greenish. The halo gradually increased in apparent diameter until it faded, as the eclipse waned.

Marie C. Stopes.

University College, London, April 27.

The Smoke Problem.

Under this head an anonymous notice appeared in Nature of April 11 of a little volume by Mr. Ruston and myself, in which the reviewer refers to certain "weaknesses in what is otherwise so excellent a work." As the "weaknesses" form the bulk of the review, I have permission to try to explain them.

The first "weakness" is in reference to the origin of soot, which we ascribe partly to mechanical removal of dust and partly to incomplete combustion. The reviewer denies that coal-dust is a product of incomplete combustion, and also that tar and free carbon are formed in the destructive distillation of coal. I had imagined that tar and coke were among the principal by-products of the gas industry.

The next criticism occurs in the paragraph that follows, and refers to the amount of tar (we call "tar" the oil extracted by ether from soot and coal) in the original coals. The reviewer concludes, after citing some of our analyses, "surely the authors do not believe that a ton of these coals contains about a couple of gallons of ready-made tar." But suppose the authors have the weakness to accept the results of their analyses, what then? The reviewer offers no suggestion.

In the next paragraph the reviewer finds fault with the statement: "The chimney gases were drawn off at the rate of about a litre a minute (*i.e.* through a narrow brass tube), which would approach the speed of the gases passing up the flue." Although he is good enough to interpret the passage for us in the only way in which it could possibly be interpreted, he concludes with the remarkable *non sequitur* that "if the flue draught was a litre a minute, it is no wonder their figures are abnormal." Of course, there is no such suggestion that the flue draught was a litre a minute (which has no meaning, unless the area of the flue is known), nor is it so stated. Having made this gratuitous assumption, on what grounds does he conclude that our figures are abnormal? What are the normal figures? I believe that the figures of the late Sir W. Roberts-Austen and our own are the only records of the kind, and they substantially agree.

In the next paragraph, among other remarkable items of information, is the statement that "the percentage of soot to carbon burnt is of no practical importance. It is the percentage loss on the fuel used that is the important factor." The reviewer apparently fails to see that (1) the entire object of the experiments was to ascertain the amount of soot emitted, and (2) the percentage of soot on carbon burnt can be easily calculated on the fuel used if the amount of carbon in the fuel is known (as it was in every case).

I do not wish to extend this reply by referring to our other "weaknesses," which are of the same gross order. I can only thank the editor for his courtesy in giving me his permission to show how and where some of them, at least, may have had their origin.

J. B. Cohen.

In the above remarks by Prof. J. B. Cohen on the review of "Smoke: a Study of Town Air," which appeared in Nature of April 11, the reviewer is first taken to task for denying that "coal-dust is a product of incomplete combustion, and also that tar and free carbon are formed in the destructive distillation of coal." The passage in the review was: "Dust is not, as a rule, a product of incomplete combustion, nor is the tar and free carbon formed in the destructive distillation of coal." The reviewer is still of opinion that coal-dust is not a product of incomplete combustion; by a strong chimney draught some coal-dust may be drawn up the flue, but it has certainly not been produced by combustion (unless Prof. Cohen looks upon the natural formation of coal as a process of incomplete combustion). Prof. Cohen elects to read the second part of the sentence as a denial that tar and coke are formed during gas manufacture, but it is doubtful if anyone else will do so; the reviewer's statement is that the tar and free carbon formed in the destructive distillation of coal are not products of incomplete combustion.

The authors give analyses of the original coal used in some of their experiments, and amongst the constituents of the coal figure certain percentages of tar, in one case amounting to 1·64 per cent.; and the reviewer says: "Surely the authors do not believe that a ton of these coals contains about a couple of gallons of ready-made tar." To this Prof. Cohen replies: "But suppose the authors have the weakness to accept the results of their analyses, what then? The reviewer offers no suggestion." If the authors do believe it, I am afraid they would take any suggestion the reviewer could make as an impertinence.

In replying to the criticism with regard to the rate of flow of the chimney gases in the flue, Prof. Cohen quotes from the book, and inserts five words which make the meaning clear, but which were not in the original paragraph.

Prof. Cohen claims that his figures for soot formation agree substantially with those obtained by the late Sir W. Roberts-Austen; but do they? Sir W. Roberts-Austen's figure was 6 per cent. of soot on the coal burned, whilst Prof. Cohen's figure is 6·5 per cent. of soot on the carbon burnt to carbon dioxide—carbon dioxide being the product of complete combustion, whilst soot has been defined by the authors as a product of incomplete combustion.

As pointed out in the review, no such method as that employed by the authors can give even approximately accurate results unless the carbon escaping as carbon monoxide and hydrocarbons is also estimated; and when Prof. Cohen says that the reviewer fails to see that the percentage of soot on carbon burnt can be easily calculated on the fuel used if the amounts of carbon in the fuel and carbon dioxide in the flue gases are known, he is truly stating the case.

In conclusion, I can only say that my opinion of the book is unchanged by Prof. Cohen's reply, and that it is a pity that so excellent a work has been marred by the points to which attention was directed in the review

THE REVIEWER.

Remains of Prehistoric Horse in the Stort Basin.

WITHIN the last few weeks a metatarsal and an astragalus identical in type with those previously found at Bishop's Stortford (see Report B.A., Portsmouth meeting, 1911, p. 521) have been exhumed from beneath 3 ft. of native peat and 2 ft. of an overlying pond-silt of probably outwash from the Boulder Clay capping of the Essex Plateau. The site is about 300 ft. O.D. at Pledgdon Hall Farm, in the parish of Henham, on the left bank of the brook which flows through Stansted Mountfichet into the Stort. I am contemplating further excavation, with the kind permission of Sir Walter Gilbey, the proprietor. I may say that the shallow cutting for the new light railway to Thaxted makes the stratigraphy of the high ground to the north of this minor upland valley quite clear; and there again we have evidence of the "rubble-drift" movement on the hill-slope, of which I have already recorded a good number of examples in the Stort Valley. I reserve details until the excavation has been carried further.

Meanwhile, it may be interesting to note here the exhumation of a fairly complete skeleton of probably a mediæval ox (a "stray," perhaps, of the time of the ancient Essex "forest-laws"). The characteristic structural features of the skull rank it very closely with the type furnished by the remains of Bos from Newstead, as described by Prof. J. C. Ewart, F.R.S. ("On Skulls of Oxen from the Roman Military Station at Newstead, Melrose," Proceedings of the Zoological Society of London, 1911, text-figure 74), while the lower jaw and its dentition present us with but a slight modification of those of the *Bos primigenius* of the glacial shingle of the Stort Valley, at the same time differing strongly from those of *B. longifrons* (see B.A. Report, *loc. cit.*). This Essex ox-skeleton was cut through by Mr. H. G. Featherby, of Bishop's Stortford, in sinking an iron cylinder on the site of a spring for water supply to the farm. It was found in what is probably interglacial gravelly sand, and beneath some 3 ft. of *remanié* boulder clay stuff, which had worked down ("rubble-drift" again) from the Boulder Clay capping of the plateau above. It was evidently one of a number of landslides, which have furrowed the sloping meadows on both sides of the brook at Collier Street Farm, on the Barrington Hall Estate, in the parish of Hatfield Broad Oak.

Bishop's Stortford, April 27. A. IRVING.

An Anode Dark Space in the Discharge in Oxygen.

IT may be of interest to readers of NATURE to know that I have recently obtained unmistakable evidence of an anode dark space in the discharge in oxygen at low pressures. The anode which exhibited this remarkable phenomenon was an aluminium plate which had been used as an anode during an extended series of measurements of the Crookes dark space with kathodes of different metals. As these were continued for some months, and as the phenomenon was not noticed when the anode was fresh, one is inclined to connect the occurrence with the excessive fatigue of the metal surface.

The anode dark space is a region of comparative darkness just in front of the anode, and can only be seen when the latter is immersed in the bright negative glow. Its thickness is small, but as its edge is exceedingly sharp, it can be measured with fair accuracy. The rough values already obtained are very interesting, as they show it to be entirely unaffected by changes of pressure and to vary inversely as the square root of the current density; with the latter at one-tenth of a milliampere per sq. cm., its value is about 1·2 mm. in pure oxygen.

The same anode showed it, though faintly, in air and nitrogen, but no trace of it could be observed in hydrogen. F. W. ASTON.

Cavendish Laboratory, Cambridge, April 25.

May Meteor-showers.

THE following meteor-showers become due during the period May 1–24, their arrangement being according to the times of the principal maxima:—

Epoch May 3, 0h. 30m. (G.M.T.), approximately tenth order of magnitude. Principal maximum, May 3, 22h. 50m.; secondary maxima, May 3, 18h. 50m., and May 5, 19h. 40m.

Epoch May 4, 5h., third order of magnitude. Principal maximum, May 4, 5h. 10m.; secondary maximum, May 4, 17h. 50m.

Epoch May 8, 11h., twelfth order of magnitude. Principal maxima, May 5, 13h. 25m., and May 7, 10h. 10m.; secondary maximum, May 7, 12h. 20m.

Epoch May 8, 14h. 30m., approximately fifteenth order of magnitude. Principal maximum, May 9, 13h. 10m.; secondary maximum, May 9, 0h. 40m.

Epoch May 12, 23h. 30m., twenty-fifth order of magnitude. Principal maximum, May 11, 16h. 15m.; secondary maxima, May 9, 19h. 30m., and May 12, 5h.

Epoch May 13, 10h., approximately twenty-fifth order of magnitude. Principal maximum, May 13, 15h. 55m., May 14, 23h. 25m., and May 16, 11h. 45m

Epoch May 19, 6h., fifteenth order of magnitude Principal maximum, May 18, 17h.; secondary maximum, May 18, 9h. 55m.

Epoch May 19, 18h., fourteenth order of magnitude. Principal maximum, May 18, 5h. 30m.; secondary maxima, May 19, 13h. 55m. and 16h. 5m.

Epoch May 19, 18h., thirteenth order of magnitude. Principal maxima, May 19, 20h. 55m., and May 21 16h. 55m.; secondary maxima, May 21, 5h. 45m. and 12h. 50m.

Epoch May 21, 22h., second order of magnitude. Principal maximum, May 23, 13h. 45m.; secondary maxima, May 22, 10h. 30m., and May 23, 7h. 30m.

The intensity of an epoch being inversely as its order of magnitude, the greatest meteoric activity occurs on May 4 and May 23. The epoch of May 21, 22h., apart from its high intensity, is a very interesting epoch, and this remark applies also to the double epoch of May 19, 18h.

April 29. JOHN R. HENRY.

THE SOLAR ECLIPSE OF APRIL 17.

The Annular Eclipse as Observed near Chavenay, France.

THE recent eclipse of the sun was of interest from several points of view, but chiefly in the opportunity it afforded of determining the

FIG. 1.—The region to the north-west of Paris, showing the several computed lines for the central eclipse from (1) "Berliner Jahrbuch, (2) "Nautical Almanac," (3) Dr. Crommelin, (4) "American Ephemeris," (5) "Connaissance des Temps," (6) "Carte du Bureau des Longitudes."

exact path of the moon's shadow and the duration of totality. It was well known that there existed a great deal of uncertainty as to both these items, the calculations depending on the different values employed.

It was generally considered fairly certain that the total phase would be observed from stations near the north of Portugal and Spain, and that totality would only last for a second or two at most if the correct position were selected.

It was my intention to have proceeded on April 5 to Ovar, in Portugal, and place myself as near the centre of the track as possible, relying on the calculations of Dr. Crommelin, but unfortunately unforeseen circumstances rendered it impossible for me to undertake the journey. I was enabled, however, at a later date (16th) to go to Paris and observe the annular phase from a station some miles outside that capital.

The present communication deals with the observations made by my companions, Mr. Frank McClean and Mr. W. N. McClean, and myself, for it is possible that these observations, combined with those made by other observers, may help to locate the exact path of the moon's shadow as it swept across the country, and so determine the differences between the observed and the numerous calculated tracks.

We arrived at Paris in the early morning of the eclipse day (17th), and decided to take up our position on a portion of the track which would possibly be less frequented by other observers. We had heard that the region about Saint Germain-en-Laye, a point easily reached by train from Paris, would be fully occupied, so we determined to intercept the track more to the south-westward.

The accompanying chart (Fig. 1) shows the region to the north-west of Paris, with Saint Germain-en-Laye near the centre. The several lines lying in the direction south-west to north-east are the positions of the tracks of the shadow in that region as given by the various authorities. Thus, commencing with the upper one and working downwards, they represent the positions as given by (1) the "Berliner Jahrbuch," (2) "Nautical Almanac," (3) Dr. Crommelin, (4) "American Ephemeris," (5) "Connaissance des Temps," and (6) "Carte du Bureau des Longitudes." This chart is a portion of a much larger chart published recently in

FIG. 2.—The main road (looking westward) from which we made our observations.

L'Astronomie, but here the track calculated by Dr. Crommelin has been indicated.

Being unaware of the position of Dr. Crommelin's line, we decided to place ourselves on that indicated by the "American Ephemeris." A motor-car made it possible easily to reach the spot we selected, which lay on a part of a main road about three-quarters of a mile to the north-east of the village of Chavenay. This village is marked with a black disc in Fig. 1, and our camp is shown by a black circle near it.

The locality in which we settled was rather high, in slightly undulating country and very open, so that we had a good view for miles in all directions. The accompanying photograph (Fig. 2) shows the country looking westward along the main road.

We had this region all to ourselves, for only four other persons were within a quarter of a mile of us on either side of our position.

The weather was all that could be desired, only very small patches of cloud moving lazily in the sky.

After first contact had taken place at about 10h. 48m. (the times mentioned are only approximate), we gave ourselves up to noting any peculiarities that might be worth recording. There was scarcely a breath of wind, and a balloon which was silently making captive ascents at about a mile from us appeared to go vertically up and down. A little later we experienced some small intermittent breezes from the south.

Numerous skylarks were singing merrily above and around us, and twice the whirr of the Gnome engine was heard when a biplane and monoplane came over in our direction from the south. Two hawks were soaring leisurely in the sky in our vicinity, and one went off south-eastward and seemed to try to outvie the captive balloon, which was then quite still at its greatest altitude.

As the sunlight grew appreciably more feeble and everything began to take on that weird, ashen hue so typical of eclipses, the skylarks were hushed and a few birds flew by as if homeward bound. This was at about five minutes past twelve, or about five minutes before the maximum phase.

Observing with a pair of binoculars (magnifying 2·5 times) shielded with dark glasses fixed to the front of the objectives, I watched the progress of the moon over the sun.

At first the crescent sun had been growing less and less in length, but at a later stage, as second contact was approaching, the thin remaining crescent began to lengthen out, at first slowly and then more rapidly.

Just beyond the end of the horn of the crescent in the south-eastern quadrant I observed the summit of a prominence (orientation about 8 o'clock), quite isolated, and I called to the others to notice it. The further movement of the moon allowed more of it to be brought into view, and the well-known "Baily's beads" had already begun to be clearly observed along the limb, successively forming in an anti-clockwise direction.

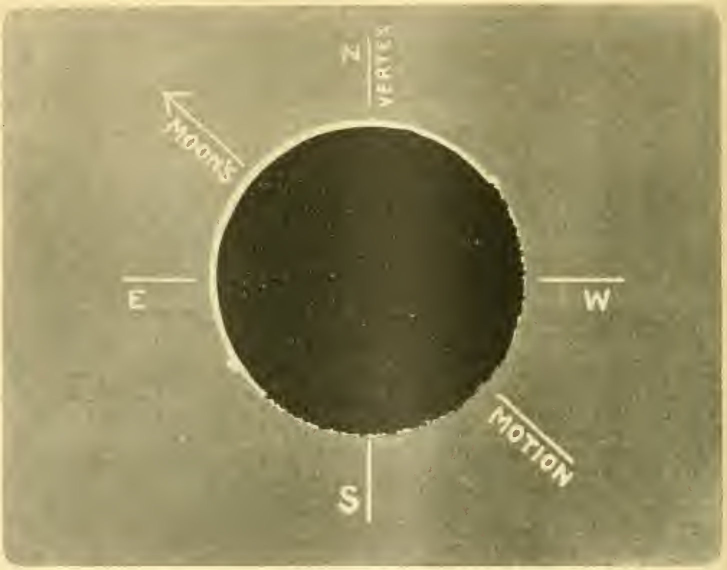

FIG. 3.—The eclipse as observed just before the beginning of the annular phase.

Almost simultaneously with the above appearance a like phenomenon was happening in the north-western quadrant. The "beads" were forming there in a clockwise direction, and a prominence also became visible (orientation about 2 o'clock), though of smaller dimensions (radially) than that seen in the other quadrant.

The successive formation of the "beads" in *both quadrants* reminded me vividly of the electric night sky-signs in London, when numerous nearly adjacent small incandescent lamps are successively lighted up.

So far as I could see, the phenomenon was symmetrical in both quadrants, neither quadrant predominating in intensity. Both these sets of strings of "beads" travelled, or rather were successively formed, until they almost met in the middle of the limb in the south-west quadrant.

Unfortunately I could not observe any longer, as I had previously arranged at this stage to move a lever on my Thorp grating camera to expose a plate for one second; thus my attention had to be turned to the instrument. When I looked up again, about two seconds afterwards, the sunlight had just begun to break out in the south-western quadrant.

The accompanying sketch (Fig. 3) illustrates approximately the conditions I observed just previous to the beginning of the annular phase. The impression I gained was that the eclipse, from our point of observation, *must have been very nearly if not actually central.*

Mr. Frank McClean, who was likewise observing, also concluded that the eclipse was central; he recorded prominences at about 9, 1, and 7.30 o'clock, and estimated the duration as two or three seconds.

Mr. W. N. McClean observed two prominences, one at 8 o'clock and the other at half-past one, and both were visible, according to him, "some time before Baily's beads flashed out round the dark arc." The eclipse "appeared to be quite central, and the duration of darkness about two seconds."

Our attention being fixed on the immediate region of the sun, no observations were made of stars, planets, shadow-bands, or such like phenomena.

Since my return to London, Dr. Crommelin kindly communicated to me the position of his predicted line of central eclipse, and this I have inserted in Fig. 1. This line, it will be seen, lies a little to the north of that representing the American prediction. Dr. Crommelin saw the eclipse well from a station on the road from St. Germain-en-Laye, just north-west of the railway crossing, and in the above mentioned communication he says, "But from the actual result I think that the true line was nearer the 'American Ephemeris' line than my line."

WILLIAM J. S. LOCKYER.

French Observations of the Eclipse.

In the *Comptes rendus* for April 22 (No. 17) there are seventeen papers giving accounts of the observations made, chiefly by French observers, during the eclipse of the sun which took place on April 17, but in the following notes we can only refer to some of the more important results.

M. Deslandres organised a very complete set of observations at Meudon, and also despatched observers to Grignon, where M. Bernard used a large spectrograph with a circular slit fed by a cœlostat, and other members of the expedition took direct photographs of the sun through red screens. At both stations excellent results were secured.

At Meudon M. Perot's attempt to measure the rotational velocity of the corona was frustrated by the fact that he could only be sure of measuring the wave-length of the green corona line on the west side of the sun, 1′ from the limb just before the maximum phase. By a rapid setting he found the wave-length to be 5303·7, the value published by Sir Norman Lockyer.

The spectroheliograms secured show that, although there were no spots or faculæ on the disc, there was considerable activity, in the form of prominences and dark filaments, in the upper layers of the solar atmosphere, especially near the poles. M. Deslandres suggests that at sun-spot minimum the activity is transferred from the lower to the higher layers and latitudes.

The positions, dimensions, and intensities of the chief prominences shown on the photographs in "K" (calcium) light, taken with the smaller spectroheliograph at 8h. 56m., are shown in the following table:—

Latitude	E. or W.	Breadth °	Height ″	Intensity (1–5)
22 N.	E.	1	40	1
47 N.	E.	3	75	4
17 N.	W.	2	10	2
53 S.	E.	2·5	50	5
47 S.	W.	15	60	5
28 S.	W.	7	30	3
12 S.	W.	2	25	2

It will be seen that the largest prominence (47° S.) was duplicated by one diametrically opposite, and it will be interesting to see the coronal extensions in these localities if such have been photographed. Photographs taken with the *spectroheliographe polychrome* show that the congeries of particles were more intense thereabouts than in the neighbouring regions, and a similar intensification is shown on the plates taken with the large spectroheliograph, using the green coronal line.

At Grignon the red-screen photographs show the larger prominences; but no details attributable solely to the corona. The photographs with the large photoheliograph are 10 in. in diameter, and should furnish exact measures of position; the central line was obviously south of the observing station at Grignon.

M. Bigourdan gives a chart of the positions of his several instruments at Cormeilles-en-Parisis, and finds that he was very near the central line; this was in longitude 0° 7′ 20″ W. of Paris, and latitude 48° 58′ 55″ N., the altitude being 163 m. Baily's beads were very fine, and frequently the horns of the decreasing solar crescent were completely detached by the interposition of irregularities on the moon's limb.

A little before second contact M. Bigourdan believed he saw the exterior edge of the dark moon projected against the lower corona or the upper chromosphere. M. Eysséric, who successfully observed shadow bands at the 1905 eclipse, was unable to detect any on this occasion.

In addition to those actually observing at the observatory itself the Paris Observatory had several parties located at various points along the eclipse path, and the results secured were so numerous and various in character that but a small part of them may be briefly mentioned here. It appears certain, however, that nowhere in Europe was the eclipse definitely total. Even in Portugal, M. Salet reports, Baily's beads were to be seen around the moon throughout the whole of the maximum phase, and no one at Ovar saw the corona; he was located near the Bay of Aveiro. Messrs. Slater and Worthington, located about 1·5 km. north of Ovar, saw it for the fraction of a second, and thus it would appear that the "Connaissance des Temps" line was too far south. M. Salet's report would place the central line about half-way between it and that given by the "American Ephemeris." This was confirmed by observations made from a dirigible, and a captive, balloon, by MM. Fournier and Bourgeois near St. Nom-de-Bretèche, where the respective observers quite independently registered the passing of the shadow at the same moment.

M. Giacobini saw Baily's beads form a chaplet of brilliant points, three or four seconds after maximum phase, which rotated about the lunar circle 180° in eight or ten seconds.

Many bright chromospheric arcs are shown on M. Millochau's plates, taken with the large spectroscope at the Paris Observatory, but the attempt to photograph the green coronal radiation was not successful.

At his station near St. Nom-de-Bretèche, M. Puiseux saw the bright annulus complete, except for the breaks caused by lunar mountains, for about two seconds, and estimates that he was but slightly north of the true central line.

MM. Esclangon and Stephan, at the Château de Talmont (Vendée), recorded that the eclipse was neither total nor annular; Baily's beads appeared almost instantaneously. They, also, conclude that they were very slightly north of the true central line, and to an observer 4 km. further north the eclipse was palpably not central.

Interesting observations were made at the Lyons Observatory, where some 6000 kinematograph pictures were made of a screen on which the images of the sun and moon were projected, and on which a carefully rated watch was also hung. On an average, ten photographs were taken per second, and it is hoped to derive very exact times for the contacts from the results.

Encouraged by the fact that at Vavau last year he was able to see, faintly, the green coronal line two minutes after totality, M. Stéfanik prepared to photograph the corona at Cormeilles-en-Parisis, using Wratten green-sensitive plates and suitable screens. But only the inner corona, as a very thin ring, is shown on his plate, and is easily distinguishable from the halation effect.

Prof. Iñiguez, at Madrid, found his observations seriously hampered by clouds, but succeeded in seeing, as very intense and long lines, the bright chromospheric radiations of H, Na, He, and Mg. Although the magnitude of the eclipse was only 0·9, he was able to observe the bright lines for some thirty minutes.

M. Eginitis, at Athens, observed the times of the contacts, and compares them with the predicted times as follows:—

	Observed	Calculated from the data of the Conn. des Temps	Nautical Almanac
	h. m. s.	h. m. s.	h. m. s.
First contact	0 54 17	0 54 33·6	0 54 48·0
Last "	3 20 23	3 20 53·4	3 20 51·6

As in 1905, the observed are seen to be in advance of the calculated times.

An important series of observations was made by L'École Polytechnique at the suggestion of M. Hamy, and under the supervision of M. E. Carvallo. Equipped with field-glasses (×8), the students were echeloned in twos across the eclipse track along a line 12 km. long on the route between Trappes and Neauphle; successive pairs were separated by a distance of 1 hectometre, the idea being to locate exactly the central line and to compare the relative sizes of the lunar and solar discs. At the extremities and at the middle of the echelon photographic and kinematographic observations were made. The results show that the central line was situated 35·5 km. along Route No. 12 from Paris to Brest, and lay between the lines predicted by the "Connaissance des Temps" and the "American Ephemeris," 500 m. from the former and 2400 m. from the latter. They also showed that the minimum diameter of the moon—between the valleys—was about 1·2″ less than that of the sun, while the maximum diameter—including lunar peaks—was about 0·8″ greater.

[In the article on the eclipse of the sun, in NATURE of April 25, for "disc" in line 23 of column 1 on p. 193 the author should have written "limb," and for 12h. 6m. 18s on the next line he should have given 1h. 31m.]

COLONIAL SURVEYS.[1]

THE report of the Surveyor-General of New Zealand for the year ending March 31, 1911, has recently been published, and shows both a larger outturn and a decreased cost under most headings. Topographical survey shows the largest output of more than two and a quarter million acres, while nearly half a million acres were covered by the triangulation. The previous report referred to the urgent need for an effective major triangulation as a control for the very extensive network of minor triangles, and the present report shows work on triangulation of the second order as being done in the Wellington district, but apparently not elsewhere, except a new base-line in Taranaki district.

This base-line was almost ten miles long, and formed one of the sides of a polygon of the major triangulation. It was measured twice with each of two standard 100-link steel tapes belonging to the survey, thus giving four values for the length. The tape was supported and strained to a tension of 25 lb. in the same manner as a previously measured base which was described in the report of last year, and satisfactory results were obtained; the mean values of the two measurements with each of the two tapes differ only by 0·0445 link on a length of 79,605 links, and the probable error derived from the measurement of the sections of the base is given as being 1 in 5,142,370; the probable error of the base when temperature, standardisation, and such other sources of error are taken into account is not given. Three months were occupied in preparing the line, and forty-five days were occupied in the measurement which gave such good results. At the present time, when base measurement has been so much simplified and cheapened by the use of wires, this base seems long, and the time it required was considerable, but no doubt local reasons were against the use of a shorter base and a base extension network of triangles. Surveyors will regret the absence of technical details in this report, for they would be most interesting and instructive. The accuracy of the triangulation, the density of the points, and the rate of its execution in different districts could be easily included, and would give a far clearer idea of the work described, and the same may be

[1] Report on the Survey Operations for the year 1910–11. New Zealand Department of Lands. By J. Strauchon, Surveyor-General. (Wellington, 1911.)

Colonial Report No. 685. Annual. The Surveys of British Africa, Ceylon, Cyprus, Fiji, Jamaica, Trinidad, and British Honduras for the year 1909–10. Price 1s. 6d.

said of the standard traverses. The regulations of the department (1908) admit the same closure error, 20″ for the triangles of both the major and minor triangulation; but doubtless in the new second order work the average error is much less.

Magnetic and seismographic records were regularly obtained at the observatory at Christchurch, and progress was made with the reduction of the observations of the magnetic survey, though no mention is made of an extension of the field work. The most important seismograph traces are reproduced.

Tide gauges are in operation at ten ports, and the methods of reducing the observations are discussed. To economise time and labour mechanical computation is largely employed, and mechanical plotting of coordinates with the aid of a co-ordinatograph is about to be introduced. In this connection we note the commencement of precise levelling at Wellington, but neither the instruments nor the permissible differences in the work are mentioned.

The report of the Colonial Survey Committee for the year 1910–11, dealing with the surveying work which is being carried out in the Crown colonies and in Ceylon, contains much interesting information, and shows a steady improvement in the quality of the work. The expenditure on land measurement and work connected with it in ten colonies amounted to about 65,000*l*., besides about 80,000*l*. which was expended by Ceylon.

Everywhere the need for accurate surveys is felt, and in every colony where work has been done cadastral (landed property) surveys are in progress. For these a higher accuracy for control is needed than for topographical surveys, which are on smaller scales and do not deal with so sharply defined boundaries. The employment of trustworthy triangulation is steadily increasing, but still it is in progress in five only of the nine colonies which report that cadastral surveys are being carried on. For some colonies the accuracy of the work is stated, and triangular closing errors of 2″ to 5″ for second order triangulation and of 8″ to 12″ for third order triangles speak of excellent work done under conditions which are frequently most trying. There are some survey departments which do not report on the accuracy of their work in this way, and the value and interest of the report would be greatly increased if not only the angular precision were stated but generally the accuracy, the rate, and the cost of the different classes of work.

The number of control points available for the detail survey is also a matter of great interest to surveyors, and the interchange of such information on a systematic plan, as is done in the reports of the survey of Indian and of most foreign surveys, would be of much value. In Fiji a base-line 19,320 ft. in length was measured with a probable error of field observation of 1 in 4,000,000, but including errors arising from coefficient of error and temperature of the tape and of standardisation, the probable error of the base is put at 1 in 260,000. The stereophotographic method of survey is being employed here for plotting on the scale of 1 : 31,250 with 100-foot contours.

Cyprus appears in the report for the first time, and here a cadastral survey of the landed property in the island has been commenced, as required by the law passed in 1909 for the revaluation and registration of property in the land; it is based on a triangulation originally executed for topographical purposes, and will therefore need some revision to make it adequate as a control of the registration of small holdings. H. G. L.

NOTES.

The first conversazione of the Royal Society for this year will be held in the rooms of the society at Burlington House on May 8.

Dr. C. H. Read has been elected president of the Society of Antiquaries for the ensuing year.

We regret to see the announcement of the death, on April 28, of Mr. J. Gray, honorary treasurer of the Royal Anthropological Institute and examiner at the Patent Office.

It is stated in *Science* that the late Prof. Abbott L. Rotch has bequeathed to Harvard University the Blue Hill Meteorological Observatory, which he established in 1885 and directed up to the time of his death. He has further provided an endowment fund of 10,000*l*.

On Friday, May 10, the third May lecture of the Institute of Metals will be delivered by Sir J. Alfred Ewing, K.C.B., F.R.S., on "The Inner Structure of Simple Metals." Cards of invitation admitting to the lecture can be obtained on application to Mr. G. Shaw Scott, secretary of the Institute of Metals, Caxton House, Westminster, S.W.

The annual dinner of the Society of Engineers (Incorporated) will be held at the Criterion Restaurant, Piccadilly Circus, W., on Saturday, May 11, when Mr. John Kennedy, the president, will take the chair. Among those who have promised to attend are Sir Wm. H. M. Christie, K.C.B., F.R.S., Sir David Gill, K.C.B., F.R.S., Sir Maurice Fitzmaurice, chief engineer to the London County Council, Mr. Alexander Siemens, past-president Inst.C.E., and Mr. H. P. Boulnois, chairman of the Royal Sanitary Institute.

The Royal Meteorological Society will meet at Southport at the end of next week, by invitation of the Mayor and Corporation. On Saturday, May 11, a popular lantern lecture, "A Chat about the Weather," will be given by Mr. W. Marriott, and on Monday, May 13, there will be visits to the Marshside Anemograph Station and the Fernley Observatory, Hesketh Park, succeeded by a meeting of the society, at which the papers to be read are:—Results of hourly wind and rainfall records at Southport, 1902–11, by Mr. J. Baxendell; the south-east trade wind at St. Helena, by Mr. J. S. Dines.

Dr. Ira Remsen has sent in his resignation of the presidency of Johns Hopkins University, Baltimore, to take effect at the end of the present academic year. He succeeded the late Dr. Daniel Coit Gilman, the first president of the University, in 1902. Dr. Remsen will retain the chair of chemistry, which he has held since 1876, and hopes to find time to return to research work. In his letter to the board of trustees, he points out that the University is confronted by new problems, and urges that the policies to deal with them should be entrusted to someone who has "a reasonable expectation of a long term of service.'

THE death is reported, at Beguio, in the Philippines, of Dr. Paul Caspar Freer, at the age of fifty. He was a graduate in medicine of the Rush Medical College, Chicago, and took the Ph.D. of Munich in 1887. After spending a short time as assistant to Dr. Perkin, at Owens College, Manchester, he joined the staff of Tufts College, Massachusetts. From 1889 to 1903 he was professor of general chemistry at the University of Michigan. He then went to Manila as superintendent of the Government laboratories there, and in 1905 was appointed director of the Bureau of Science for the Philippine Islands. He was the editor of *The Philippine Journal of Science*, and the author of various chemical textbooks and monographs. He had been mentioned recently as a possible successor to Dr. Wiley as chief of the Bureau of Chemistry at Washington.

THE council of the Association des Ingénieurs électriciens sortis de l'Institut électrotechnique Montefiore has circulated the conditions of award of the prize known as the Fondation George Montefiore. The prize represents the accumulated interest at 3 per cent. on a capital of 6000*l*., and is awarded every three years for the best original work on the scientific advancement and progress in the technical applications of electricity in all its branches. The prize was awarded for the first time in 1911, and will be offered again in 1914. The last date for receiving competing works is March 31, 1914, and they should be addressed to M. le Secrétaire-archiviste de la Fondation George Montefiore, l'hôtel de l'Association, rue St-Gilles, 31, Liége, Belgium.

A VERY promising career has been ended prematurely by the accidental death of Mr. George Borup, who was drowned in Long Island Sound a few days ago through the upsetting of a canoe. As announced in last week's NATURE, Mr. Borup was to be one of the leaders of the expedition which will shortly set out to reach and map Crocker Land, in the north polar seas. He was assistant curator of geology in the American Museum of Natural History, and was well known by his work with Admiral Peary in the expedition to the north pole, and his book "A Tenderfoot with Peary." During the past two and a half years he had been devoting his whole attention to studies in the field and at Yale to fit him thoroughly for scientific geological and geographical exploration. He took up geographical work seriously and from a scientific point of view; and it is with regret that we have to announce the loss of a life from which many years of valuable work were anticipated.

APRIL was almost rainless over the south-east of England, and without doubt in a few isolated positions there was absolutely no rain throughout the month. At Greenwich the only rain measured is 0·02 in. on April 9, and with the exception of 0·07 in. on March 31, this is the only rain since March 23. The monthly records of rain at Greenwich from 1815 fail to show any month with so small an amount of rain. The previous smallest amounts are in July, 1821, 0·04 in., and in February, 1891, 0·05 in. The total rainfall in April has only twice fallen below 0·1 in., these being in 1817, 0·06 in., and in 1855, 0·09 in. In the memorable spring drought of 1893 the rainfall for April was 0·12 in. The duration of bright sunshine at Greenwich for April was 225 hours, which is 85 hours more than the average of the past thirty years, but it is 25 hours less than the duration of sunshine in April, 1909. The mean temperature for April was 49·7°, which is 1·6° in excess of the average; and on three days, from April 19 to 21, the sheltered thermometer rose to 70° or above. The temperature was generally lower towards the end of the month, due to the setting in of a northerly and north-easterly wind. The aggregate rainfall for April was only 0·02 in. at Oxford, 0·14 in. at both Dover and Shields, 0·19 in. at Clacton-on-Sea, 0·20 in. at Nottingham, and 0·25 in. at Bath. The most recent summary of the weather issued by the Meteorological Office shows that for the eight weeks of spring ending April 27 the aggregate rainfall is in excess of the average in all districts, except in the east of Scotland and in the east and north-east of England, whilst the rainfall since the commencement of the year is everywhere in excess of the average, except in the north and east of Scotland.

A CONFERENCE of members of the Museums Association and others interested in the work of museums was held at Stockport on Thursday, April 25. Besides members of the committee of the Stockport Municipal Museum and local visitors, representatives attended from some twenty public museums in Lancashire, Cheshire, and Yorkshire, including those at Manchester, Liverpool, Sheffield, Hull, Salford, Ralton, Bootle, Rochdale, and Warrington. The conference assembled at the Vernon Park Museum, which was duly inspected. After tea, to which the members were invited by the museum committee, a meeting was held in the Town Hall, under the presidency of Alderman Briggs, Mayor of Stockport, and chairman of the Education Committee, who welcomed the conference on behalf of the Corporation, adding a few words on the value of museums as factors in the education problem of which insufficient use was made. Mr. T. Sheppard (Hull) in a humorous paper gave an interesting account of the development of the Museum of Fisheries and Shipping which was recently opened as a department of the Hull Municipal Museum. The paper contained many practical suggestions and a moral for other curators. Mr. R. Butterfield (Keighley) read a short paper advocating the use of three-ply board as a backing for cases and other purposes, which led to considerable discussion; he also exhibited and described a relief model of the district surrounding the Keighley Museum, which could be used as a basis for the elementary teaching of geology, natural history, and history, as well as for geography. Mr. Hewitt (Stockport) read an account of the history of the Stockport Museum, pointing out the difficulties under which it labours, and foreshadowing the lines on which it might profitably be developed.

Much new light is thrown on the possibility of the production of symmetrically formed prehistoric pottery without the use of the wheel or a regularly constructed kiln by the researches of the Rev. J. W. Hayes, recorded in the Journal of the Royal Anthropological Institute for July-December, 1911. At one small factory at Verwood, near Wimborne, he found most primitive methods in operation for the production of milk and water pans, the clay being worked up in a tank by barefooted boys, as Italian peasants tread the grapes in a wine-vat, the only tool used, besides a piece of string to cut the finished article off the wheel when finished, being a piece of hoop iron to smooth the edges of the pot. It is interesting to note that the process of building up the jar by the junction of separate pieces, the joinings being closed by tapping with a mallet, is still apparent in many prehistoric pots in the British Museum.

In the issue of the Journal of the Royal Anthropological Institute for July-December, 1911, Major A. O'Brien gives a graphic and interesting account of the difficulties experienced by a district officer in dealing with the guardians of the multitudinous shrines of Mohammedan saints which abound in the valley of the Indus. Devotion to these worthies constitutes the working faith of the majority of the population, and the appeal to Allah or the Prophet is forgotten in the reverence paid to their local vicegerents. All sorts of miracle-working powers are attributed to these holy men, and pilgrimages to their shrines are undertaken to provide for all the ordinary wants and hopes of the peasantry. The permanence of primitive animistic beliefs of this kind is shown in the fact that sanctity clings to certain sites from prehistoric times Thus at the shrine now occupied by the saint Sakhi Sarwar, in the Dera Ghazi Khan district, men, women and children, Sikhs, Hindus, and Mohammedans alike resort to make vows and present offerings to the officiating guardians, including a company of old women representing the wife of the holy man, who devote themselves to the collection of dues from female votaries.

A seventh report on research work, by Dr. Houston, director of water examinations, has been issued by the Metropolitan Water Board. The search for pathogenic microbes in raw river water, with special reference to the typhoid bacillus, has been continued. Taking all the results together, the study of 20,771 *specially selected* organisms derived from 215 samples of raw river water has resulted in the discovery of only two typhoid-like microbes. Typhoid bacilli derived directly from the patient, and without cultivation on artificial media, are found to be less resistant and to die out quicker in water than the same organisms after artificial cultivation. The temperature of the water influences the rate of disappearance of typhoid bacilli from water; the effect of low temperature (41° F. to 32° F.) is to delay considerably the diminution in numbers of typhoid bacilli. In a previous report, storage of the raw river water was shown to improve materially the condition of the water. Experiments are detailed on the use of a precipitation method (with "aluminoferric") antecedent to storage as an additional means of purification. This is found to possess considerable advantage, but it materially increases the cost of purification.

The April number of *The American Naturalist* contains the first part of a Harvey lecture delivered by Prof. H. F. Osborn on January 20 on the continuous origin of certain unit characters as observed by a palæontologist. Comment may be reserved until the completion of the report.

Eels, new and otherwise, from all parts of the world, form the subject of a long article by Dr. H. W. Fowler in the February issue of the Proceedings of the Philadelphia Academy. The forms described as new are nine in number, and two new subgeneric terms are also proposed. It may be noted that the name *Leptocephalus conger* is adopted for the conger, and that Echidna is employed for another genus, the latter usage barring the application of that term, in a generic sense, to the spiny anteater of Australasia.

Fossil whales akin to the modern finners form the subject of an article by Prof. F. W. True, published as vol. lix., No. 6, of Smithsonian Miscellaneous Contributions, which mainly consists of a summary of a paper in Danish by Dr. H. Winge. Both writers consider that among a multitude of extinct generic divisions which have been proposed, four are undoubtedly valid, namely, Aulocetus, Cetotherium, Herpetocetus, and Plesiocetus, and of these, as well as of the two allied existing genera, diagnoses based on osteological characters are appended.

As the first portion of a work entitled "The Fishes of the Indo-Australian Archipelago," Drs. Max Weber and L. F. de Beaufort have compiled an index to the ichthyological papers of Pieter Bleeker, published, as a volume of 410 pp., by E. J. Brill, Ltd., Leyden. Bleeker's papers are not only very numerous —the more important comprising no fewer than 432— but much scattered; and this index, not only of the articles themselves, but of the genera and species mentioned in them, will prove of great value to ichthyologists. The volume commences with a portrait and biography of Bleeker, who was born at Zaandam in 1819 and trained as an apothecary. In 1840 he qualified, however, as a surgeon and general practitioner, and in the following year was appointed surgeon in the Dutch East Indian Army. He arrived at Batavia in the spring of 1842, where he spent the greater portion of the next sixteen years, the intervals including sojourns at other stations and a trip to Celebes and the Moluccas. Here he soon commenced the study of the local fish-fauna, which culminated in the issue of the "Atlas Ichthyologique des Indes Orientales," the completion of which was prevented by the death of the author in 1878.

In *The Kew Bulletin* (1912, No. 3), J. H. Holland gives a useful review of the sources whence alcohol is obtained, these sources being treated under the heads of fruits, grain, roots, rhizomes, stems, leaves, inflorescences, wood, and peat. Interesting statistics are given with reference to the distillation of industrial alcohol from the potato in Germany and Poland, from the beet in France, and from maize and wood in the United States. There appears to be no bar, apart from fiscal and transport difficulties (which could readily be overcome), to the development of flourishing industries of this kind in our own country. The statements available at present regarding the production of alcohol on a commercial scale from peat are, unfortunately, meagre and contradictory; success has been reported from Sweden, failure from France. The Swedish experimenters claim that alcohol made from peat can be sold at less than one-half the present price of alcohol, and lower than the present price of petroleum.

Prof. R. Peppert, in a memoir issued by the Ministry of Agriculture in the Argentine Republic, deals with the world's supply of citric acid, which comes chiefly from Sicily, and gives interesting details concerning the species and varieties of Citrus, chemical analyses of the fruits used in the industry, and the methods of extraction on the commercial scale. Mention is made of Wehmer's discovery that citric acid can be made from artificial glucose by fermentation by various micro-organisms (*Citromyces pfefferianus*, *Penicillium lutem*, *Mucor pyriformia*), but it seems that this process yields only 2 or 3 per cent. of citric acid instead of the 50 per cent. promised by the laboratory experiments. The author points out that the climate and soil in the fertile Tucuman province of Argentina are admirably suited for the growing of lemons, that the fruits grown locally are in no way inferior to those of the Mediterranean region in their yield of citric acid, and that with capital and enterprise a flourishing citrate industry may well be established in Argentina.

Mr. P. Macnair, whose useful "Introduction to the Study of Rocks" has been already noticed (Nature, April 13, 1911), now issues an "Introduction to the Study of Fossils and Guide to the Palæontological Collections in Kelvingrove Museum," Glasgow, price 3*d*., with some forty illustrations. The Silurian eurypterids and fishes of Lesmahagow are well referred to, and Scottish fossils are properly emphasised throughout. The book will no doubt soon reach another edition, and certain misprints in generic names can then be rectified.

The prehistoric human remains near Cuzco, in Peru, which occur low down in the face of a high gravel cliff, are dealt with in considerable detail in three papers by H. Bingham, T. Bowman, and G. F. Eaton in *The American Journal of Science* (vol. xxxiii., pp. 297–333, April). The bones described appear to be contemporaneous with the bedded gravels, which are regarded as a glacial series, an approximate age being assigned to them of 20,000 to 40,000 years ago. The valley of Ayahuaycco quebrada, or "dead man's gulch," in which they occur, has been used in modern times as a burial ground, and great caution is shown by the explorers in making the above suggestion.

Symons's Meteorological Magazine for April contains an account of the meteorological service of the Argentine Republic, by Sr. W. G. Davis (director), which is of much interest, owing to geographical position and large extent of country, as well as to the activity with which the science has been pursued. The service was established by Dr. B. A. Gould in 1872, and the results of the observations made up to the time of his retirement in 1884 were printed in four large quarto volumes. The service was continued on the same lines by the present director until the year 1900. The first daily weather chart was published in 1902, and forecasts are now issued for thirty-six hours in advance. The charts show the conditions existing from Para (Brazil) to the southernmost limits of the Republic, extending over 55° of latitude. In addition to the central office at Buenos Aires, there are two principal observatories at Cordova and Chacarita where special researches are carried on; and a fully equipped meteorological and magnetic station is maintained at South Orkney, in 61° S. latitude. The work of the meteorological office includes a seismological service, which will shortly embrace a line of stations along practically the whole of the north-to-south extent of the Republic.

A report on the daily sunshine in Russia was presented to the Imperial Academy of Science in January (*Bulletin*, February 15). The duration of sunshine in European Russia increases on the whole from north to south and from west to east, being, however, somewhat longer on the coast than in the interior. In the yearly means the lowest maximum is recorded at St. Petersburg, where it occurs between noon and one o'clock, and attains to 11·9 hours (this figure being obtained from the means of thirty days in each month). The highest maximum in European Russia is 19·8 hours in Uralsk; in Bairam-Ali it is 23·9 hours, and 23·6 hours in Chita. The monthly maximum occurs at Bairam-Ali in August, and amounts to 30·8 hours, *i.e.* during thirty-one hours of observation the sun is on an average obscured by clouds for only twelve minutes. In St. Petersburg the maximum is reached in July, and is 18·8 hours. Sunshine is more frequent in winter during the afternoon and in summer in the forenoon. Only in St. Petersburg is sunshine more prevalent after noon in all months, attaining 60 per cent. of the possible in December and 50·4 in October. In January sunshine is more frequent at all stations in the afternoon, and in May in the forenoon, except in St. Petersburg, but the difference between the morning and afternoon is much less in summer than in winter. The greatest difference occurs in Irkutsk, where the sunshine in the afternoon amounts in December to 65 per cent. of the possible. From twenty-five years' observations in Pavlovsk, it appears that in winter the maximum occurred later, and the afternoon sunshine was greater, in the clear months, that is, those in which the sunshine was above the average during the period; whereas in the summer months the reverse was the case.

The Journal of the Washington Academy of Sciences for April 4 contains a summary of the results obtained by Messrs. Day and Sosman, of the Geophysical Laboratory of the Carnegie Institution, in their recent determination of standard melting and boiling points on the constant volume nitrogen thermometer and in terms of the thermodynamic scale. In some cases the determination was made directly, in others by the intervention of platinum-platinum-rhodium or copper-constantan thermo-couples. The following melting points were found: cadmium 320·8°, zinc 419·3°, antimony 629·8°; and the following boiling points at normal pressure:—benzophenone 305·85°, sulphur 444·4°, on the constant volume nitrogen thermometer. These become on the thermodynamic scale 320·9°, 419·4°, 630·0°, 305·9°, and 444·55° respectively.

Two sets of measurements of the electric charge on rain made during last year are already available. The first, covering the short period March to June, were made in Dublin by Prof. McClelland and Mr. Nolan, and are published in the February Proceedings of the Royal Irish Academy; the second, from May to December, made at Puy-en-Velay, central France, by M. Baldit, appear in the March number of *Le Radium*. Both sets agree in giving an excess of positive over negative electricity brought down by rain, and the Dublin observations show that large drops are nearly always positively charged. At Puy-en-Velay the charge per cubic centimetre of rain is greater for negatively charged than for positively charged, while the reverse is true for Dublin. The mean electric current to earth per square centimetre of surface during rain, according to the Puy-en-Velay observations, is between 3 and 5×10^{-11} ampere.

Dr. Hans Strecker finds that if strong aqueous solutions of gelatine and gum arabic are shaken together they do not mix, but form an emulsion. On standing there is much agitation of the droplets of the one that is in the smaller proportion, they coalesce to a certain extent, and there results an even distribution of spherical globules of an approximately equal size, the size depending upon various conditions. He describes in the last number (April 15) of the *Revue générale des Sciences* the use of such an emulsion in various photomechanical processes. It will take the place of the asphalt grain in photogravure, and it will serve instead of the lined screen in the making of half-tone blocks. For these purposes the gelatine is in excess, and the particles of gum in the dried film are less easily penetrated by the etching liquid than the gelatine in which they have been formed. The making of half-tone blocks is much simplified by this process, which has the further advantage that solid or continuous lines in the original are not broken up as they are when reproduced by means of a lined screen. The author calls this process "stagmatypie," and gives two illustrations of it which certainly show that the process has the advantages claimed for it.

In vol. iv., part i., of the Transactions and Notes of the Concrete Institute is contained an interesting photograph of a rag bolt found last summer embedded in a slab of concrete composed of Portland cement, ballast, and broken bricks. The concrete formed part of the foundations of the 1862 exhibition buildings at South Kensington, and had not been disturbed up to the time of its removal. The bolt was found when cutting through the concrete slab for some alteration in connection with the Imperial Institute, and was at ground-level. Both concrete and bolt were under cover. Only the top end of the bolt where exposed to the atmosphere, and the bottom end where embedded in the soil, were corroded; the remainder was quite clean, with the original blue scale thereon. This may be regarded as another proof that the reinforcement bars in ferro-concrete work will be preserved for an indefinite time provided that the concrete is maintained free from cracks.

OUR ASTRONOMICAL COLUMN.

Astronomical Occurrences for May:

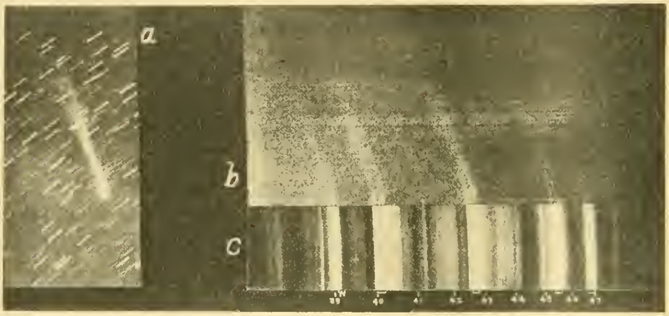
May 3. 14h. 9m. Jupiter in conjunction with the Moon (Jupiter 5° 2′ N.).
4. 2h. 0m. Mars at greatest heliocentric latitude N.
7. 13h. 36m. Uranus in conjunction with the Moon (Uranus 4° 41′ N.).
„ 23h. 0m. Uranus stationary.
12. 15h. 10m. Mars in conjunction with Neptune (Mars 2° 9′ N.).
„ 21h. 0m. Mercury at greatest elongation W.
14. 6h. 0m. Saturn in conjunction with the Sun.
15. 10h 45m. Venus in conjunction with the Moon (Venus 3° 11′ S.).
16. 9h. 11m. Saturn in conjunction with the Moon (Saturn 4° 58′ S.).
20. 5h. 1m. Neptune in conjunction with the Moon. (Neptune 5° 46′ S.).
„ 12h. 4m. Mars in conjunction with the Moon (Mars 3° 42′ S.).
27. 8h. 47m. Venus in conjunction with Saturn (Venus 1° 7′ N.).
30. 15h. 49m. Jupiter in conjunction with the Moon (Jupiter 4° 48′ N.).
31. 22h. 0m. Jupiter at opposition to the Sun.

Cometary Spectra.—In an article recently noted in these columns, MM. Pluvinel and Baldet, while agreeing as to the identity of certain doublets in the spectra of Morehouse's comet with similar doublets in Prof. Fowler's spectrum of carbon monoxide at very low pressure, pointed out that only twelve of their twenty-one cometary bands were represented in the published laboratory spectrum, and of these twelve there were serious discrepancies of wave-length in two cases.

Prof. Fowler now points out (*Astrophysical Journal*, vol. xxxv., No. 2) that there are probably far more doublets in the CO spectrum than he published, but, owing to the difficulty of producing the spectrum bright enough to photograph, and the admixture of other lines, he could not be absolutely certain of them. As the comet spectrum seems to be of nearly pure origin, it will probably serve as a key in the problem of recognising the CO doublets in the laboratory spectrum. The discrepancies in wave-length are probably produced by the difficulty of determining the wave-lengths accurately in the cometary spectrum. Prof. Fowler thinks the identification of their λ 4846 doublet with his "indication of a faint band" at λ 4887, 4916 is a mistake on the part of MM. Pluvinel and Baldet, and shows, by computation from his observed data, that in a brighter laboratory spectrum there should be a CO band at λ 4843.

He also suggests that the less refrangible doublets included by MM. Pluvinel and Baldet in their brighter series (A) should be placed in a distinct series by themselves, and, on this assumption, calculates wave-lengths which fit their observations equally well, while representing the blue bands with much greater accuracy.

We reproduce a photograph from which it will readily be seen how conclusive is the agreement between the CO doublets and those photographed in the spectrum of Morehouse's comet by Dr. H. D. Curtis at Santiago, Chile, on March 20, 1909. The strong band on the left of the laboratory spectrum is due to an impurity of nitrogen, and is suitably represented by a single band in the cometary spectrum, whereas those due to CO are double. As will be seen, the latter are represented, in this comet, both in the head and the tail, but in several other comets they occur in the tail only, and should be regarded as characteristic of that part of the comet.



Morehouse's comet (1908*c*). *a*. Direct photograph, 4 hrs.; *b*, Objective-prism spectrogram, 7 hrs.: H. D. Curtis, Santiago, March 20, 1909. *c*, Spectrum of carbon-monoxide at 0·01 mm. pressure: Prof. A. Fowler, South Kensington.

The Spiral Nebulæ.—An interesting article on spiral nebulæ is published by M. Puiseux in No. 14 of the *Revue Scientifique*. In it the author reviews, popularly, the history of the observations of these important structures, and shows how our knowledge of them has steadily increased since Marius directed attention to the great Andromeda nebula in 1612. But there are many questions, as to their structure and their position in sidereal evolution, still outstanding, and it is with reserve that M. Puiseux advances the opinion that they are huge agglomerations of stars, set at enormous distances from us in space, from which the condensations are moving outwards.

LEEDS UNIVERSITY: NEW TEXTILE EXTENSION.

THE Leeds University has gained in reputation by the work of its technological departments. One of the principal and earliest of these is that of textile industries, founded in 1874 as part of the Yorkshire College of Science, the institution which has developed into the Leeds University. Textile teaching was then regarded by literary and scientific men, and also by manufacturers and those associated with the weaving industries, as a doubtful educational experiment. It had to be proved in what way a course of textile study could be formulated which would contribute to industrial progress. Such has been, however, the growth of this department, the widening of the curriculum of study, and the success of the students trained, that the late Vice-Chancellor of the University (Sir Nathan Bodington) asserted that the expansion of the University as a whole has been largely influenced by the prosperity of the textile industries department.

A recent important extension of the spinning section was formally opened on April 26 by the Master of the Clothworkers' Company (Mr. F. G. Fitch, J.P.), and presented to the University. On behalf of the University, the buildings were accepted by the Chancellor (his Grace the Duke of Devonshire). Provision has been made in the equipment for experimental instruction in the methods of producing worsted yarns on the Continental system, and also for research in the use of wool and other fibres in manufacturing. Machinery and apparatus have been designed and arranged primarily in regard to educational utility, but the practical character of the operations of yarn construction has also been attained. Hitherto it has been possible in the department to treat wool and other fibres by the woollen system of machinery and by two standard English systems of worsted yarn manufacture. The various grades of cross-bred and Merino wools may be treated from the raw condition to the manufactured fabric.

The new addition affords facilities for experiment in a method of worsted yarn making not extensively practised by British spinners. One feature is that in the processes only a small percentage of oil is applied, and that removed after the processes of combing. This necessitates the employment of apparatus for humidifying the atmosphere, to minimise the electrification of the fibres, and to impart a quality of adhesiveness which is essential in the preparation of the material and in the spinning of the yarn on this principle.

Equipment has been provided for various operations of yarn production, and humidifying plant, a section for carbonising, garnetting, and other machines, and also class-rooms for colour-matching, testing, and machine drawing.

The building has been erected at a cost of 5000*l*. The Clothworkers' Company of London has now contributed for buildings and for equipment at the

Leeds University a sum of 75,000*l*., which has been augmented by donations from leading textile firms and machinists. The company's total contributions amount to 160,000*l*. for educational purposes in relation to the textile industries.

MEMOIRS OF THE GEOLOGICAL SURVEY.

THE "Summaries of Progress" issued by the Geological Survey of Great Britain are not by any means dry official reports, but contain a number of results available for general use, which otherwise might remain unknown for several years. One of the chief features of the Summary for 1910, issued in June, 1911 (price 1*s*. 6*d*.), is W. B. Wright's account of the district round Loch Ba in Mull. This is accompanied by a map and sections, one of the latter (p. 36) showing the immense number of inclined intrusive sheets of basic rock that penetrate the "hybrid" mass of gabbro invaded by granophyre on the slope of Glen Forsa. On p. 39 it is mentioned that G. W. Lee's work in Morvern has led to the detection of two new localities for Cainozoic sediments among the basalts. The thin Cainozoic coals of southern Mull are discussed on p. 40. Carboniferous strata have received attention in Denbighshire and Warwickshire, where the observations are certain to have a considerable economic bearing, since these areas have not previously been mapped on the six-inch scale. In Appendix iii. (p. 80), R. G. Carruthers describes a mass of Lower Cretaceous sandstone, associated with fossiliferous Cainozoic clay and Boulder-clay, which rests on Old Red Sandstone in the heart of Caithness. This huge block, in which a quarry 160 yards long has been opened, has been investigated with the aid of borings, for the expense of which a grant was made by the Royal Society—whether of London or Edinburgh is not stated. The results show that the mass is an erratic brought in by the North Sea ice, and we become impressed by this further evidence of the wide extension of marine Cretaceous strata between Scandinavia and Britain in former times.

A second edition of the Explanation of Sheets 326 and 340 of the English map appeared in 1911 (price 1*s*. 6*d*.). The joint colour-printed map was published (price 1*s*. 6*d*.) in 1906. On this, the Clay with Flints is shown, covering with great regularity the plateaus of Cretaceous rocks. The district includes the famous landslip between Lyme Regis and Axmouth, which occurred in 1839, and was described by W. D. Conybeare, then vicar of Axminster, and speedily illustrated in Lyell's "Principles of Geology." It is pleasant to find that active author A. J. Jukes-Browne still associated with H. B. Woodward and W. A. E. Ussher in the preparation of the present memoir. We are interestingly reminded on p. 4 that W. Buckland was born at Axminster, while H. De la Beche lived at Lyme Regis from 1817 to 1821.

The long-continued borings into the concealed Coal Measures in Kent have added to our knowledge of the overlying Mesozoic rocks, and the results are now described by G. W. Lamplugh and F. L. Kitchin ("On the Mesozoic Rocks in some of the Coal Explorations in Kent," 1911, price 3*s*. 6*d*.). Lower Lias rests on the Carboniferous at Dover, and the upward succession of Jurassic and Cretaceous strata is practically complete, with a break between the Kimmeridge Clay and the base of the Hastings Sand. At Brabourne, however, between Folkestone and Ashford, even Portland beds are represented, with Purbeck beds above them, while Triassic marl and conglomerate occur below the Lower Lias. The Palæozoic rocks, here of doubtful age, are reached at 1921 ft. from the surface, while the boring begins in Gault. Correlating the two sections, G. W. Lamplugh states (p. 35) that they are, so far as he knows, "unparalleled in Britain—or . . . in any other part of the world—in the geological range and continuity of formations proved by them to exist in actual superposition in a single small area." The shorthand habit of recording horizons merely by a specific name leads to the anomaly of frequent references to the "Mammillatus zone," as a familiar term, while the zone-fossil is called in the same pages *Douvilleiceras mammillatum*. The crypts bored by Pholadidea from the Sandgate beds at Dover down into the Atherfield Clay still retain the shells in them, and are interestingly illustrated in the frontispiece. This occurrence is described on pp. 12 and 102.

Clement Reid, George Barrow, and others of the staff write on "The Geology of the Country around Tavistock and Launceston" (1911, price 3*s*.). The accompanying colour-printed map, Sheet 337 (price 1*s*. 6*d*.), shows that for "around" we should read "between," and that those who visit Tavistock for its comfortable proximity to Dartmoor must consult Sheet 338. The section at the foot of the map is a pleasing illustration of the possibility of working without an exaggerated vertical scale, and would have pleased the master, De la Beche. The interesting lavas at Brent Tor—the memoir preserves this spelling, though the map does not—are shown (p. 52) to possess pillow-structure and to be of the albitic "spilite" type. We should like to know the author of the charming sketch on p. 53. Dr. Flett remarks that Rutley's memoir on Brent Tor was "the first to contain the results of microscopic investigation of rock sections." Clifton Ward, however, was probably the pioneer in his Lake District memoir of 1876, while the Brent Tor memoir appeared in 1878, not 1876, as is here stated. The radiolarian cherts of Carboniferous age form a considerable feature on the map, and the new boundaries introduced show the importance of revision in this historic area. D. A. Macalister describes the tin and copper mines in detail, including those of Calstock and of the granite land of Bodmin Moor.

An important memoir on "The Geology of the Glasgow District" (1911, price 4*s*. 6*d*.) has been prepared by almost the entire staff of the Scottish branch of the Survey. It is accompanied by a composite colour-printed map of the district, with vertical and longitudinal sections (price 2*s*.), and it seems almost unfortunate that either of these works should be procurable without the other. The numerous and energetic attendants at geological classes in Glasgow will welcome these publications, equally with the members of the well-known local Geological Society. The elaborate subdivision of the igneous rocks may be a phase of the present epoch; but it comes naturally from a land where mineral studies have been developed with a traditional aptitude for classification. By means of letters on the map, as well as by more general colours, five types of basalt of Calciferous Sandstone age are distinguished, and also four others intrusive in the strata of the district. The separation on a map of intrusive from clearly contemporaneous rocks of the same composition is easily defensible, since the forms of the outcrops may convey no information. The coloured vertical sections on the margins of the map serve admirably to illustrate the contrast between the coal-bearing beds of the Clyde Basin and those of central England or South Wales. The memoir takes its place at once among our text-books as a work to which all interested in European stratigraphy will refer. It will equally be the authority on the economic geology of a district where mines and quarries are of high importance. Among the many places where modern research has been aptly utilised, we may mention E. B. Bailey's preference (p. 9) for ascribing a continental origin to the Old Red Sandstone, and his comparison of the "cornstones" with the kankar of tropical Africa—the original Indian examples might well have received mention. The alleged unconformity between the Barren Measures and the productive Coal Measures is regarded (p. 61) as improbable, owing to C. T. Clough's observations, published in 1910. G. W. Lee contributes a chapter of sixteen pages on the palæontology of the Carboniferous rocks of the district, from which it is pleasant to see how much we owe to members of the Geological Society of Glasgow. The interesting paragraphs (p. 94, &c.) on the life-zones of the system show how difficult it is to define, to the satisfaction of palæobotanists and palæozoologists alike, the lower limit of the Upper Carboniferous series. The base of the upper, or Visean, division of the Avonian, or Lower Carboniferous, lies somewhere below the Hollybush Limestone in the Calciferous Sandstone stage. All the "Carboniferous Limestone" stage near Glasgow is thus correlated with beds high up in the "Carboniferous Limestone" of southern England.

E. B. Bailey (pp. 124–50) treats of the petrology of the igneous rocks with enthusiastic thoroughness. We are glad to note the use of "alkali" as an adjective, rather than "alkaline," for types of rocks rich in sodium or potassium. Nepheline has now been found in several of these in the Glasgow district, notably in the "alkali gabbro" of Lennoxtown. The influence of Rosenbusch in establishing rock-species has spread to the Central Valley of Scotland, since a rock, already described as a theralite, becomes thus qualified (p. 135):—"In these characters it approaches much more closely the bekinkinites of Madagascar, which are a highly melanocratic type of ijolite." We regret to read that several other ultrabasic rocks of the area "have a composition which places them near to the bekinkinites," so that the way lies open for at least one new name, indicating, as must so often happen, nearness rather than identity. May we quarrel also with the word "macroporphyritic," which does not quite represent the author's meaning? It is interesting to find Abich's term "trachydolerite"—a very bad one from the point of view of rock-structure—revived for rocks that might surely be styled trachytic andesites. Harker's "mugearites," those interesting fine-grained types with orthoclase, oligoclase, augite, and often olivine, are recognised in the Carboniferous rocks near Glasgow. The discussion and diagram of the composition of the quartz-dolerites (p. 146) are of especial interest.

The chapters on the origin of local topographic features, including details of recession and river-capture on the escarpment of the Campsie Fells, bear further witness to the thoroughness of the Geological Survey work. These pages could be read with appreciation by persons who have never seen the district, and they will tempt many from the smoke of the great city into the gaps in the highland border that open up another world.

The Scottish branch also issues a memoir, by E. H. Cunningham Craig, W. B. Wright, and E. B. Bailey, on the "Geology of Colonsay and Oronsay, with Part of the Ross of Mull" (1911, price 2*s*. 3*d*.) The one-inch geological map issued in connection with it (Sheet 35, price 2*s*. 6*d*.) is mainly concerned with the Atlantic Ocean, and Oronsay lies beyond it on the south. Plate i. of the memoir, however, completes the island group. Most of the sedimentary rocks are believed to be representatives of the Torridon Sandstone. There is a considerable range of igneous rocks, and W. B. Wright and E. B. Bailey describe and illustrate an attractive example of the interaction of an ultrabasic hornblende-rock with included blocks of quartzite (p. 29). The quartzite, during solution, has led to a local concentration of alkalies. Many of the blocks, "surrounded by a magma which is overwhelmingly hornblendic, are actually replaced by alkali felspars and quartz." Tectonic features are described in detail, and we wish that James Hutton could again come to life to see how, in this and other instances, physical geology holds its own in Scotland. The glaciation of Colonsay took place from the east, and a map (p. 61) shows the course of boulders over the island from the mainland beyond Loch Awe. A pre-glacial rock-shelf, due to marine erosion, with accompanying cliffs, is traceable as high as 135 ft. above high-water mark (p. 62). E. H. Cunningham Craig in part ii. describes part of the Ross of Mull, and supports Judd's view that the great mass of granite is of later Palæozoic age. Both in this memoir and in that on the Glasgow district the petrographic details owe much to the advice and notes of J. S. Flett.

A third Scottish memoir, by ten authors, deals with Knapdale, Jura, and North Kintyre (1911, price 3*s*.). The immense part played by quartzite in Jura is well brought out on the accompanying map, Sheet 28. The term "vitreous quartzite" (p. 99) seems a little misleading, like the "glassy felspar" of older writers. This series in Jura may be 15,000 ft. in thickness (p. 106). A pleasant feature of the memoir is the introduction by J. B. Hill, where the geological structure and the raised beaches are concisely brought into relation with the human interests of the district.

G. A. J. C.

DISCUSSIONS OF CLIMATOLOGY.

A DISCUSSION by Dr. A. B. Rosenstein of the conditions of temperature in central and southern Spain is published in vol. xxxiv. (part iii., 1911) of *Aus dem Archiv der deutschen Seewarte,* based on observations of the last twenty years of the last century, and including a longer series for Lisbon, San Fernando, Coimbra, and Madrid. The last four stations represent essentially different climatological types, as previously pointed out by Hellmann. The author deals with the observations in considerable detail (twenty-seven tables), but we can only very briefly refer here to one or two of the results. The amplitude of the daily range, being chiefly dependent upon the season, is smallest in winter (December) at the above-mentioned stations (at San Fernando in April), and greatest in summer (August); in the latter season the mean daily range at Madrid is 13·8° C., twice that at Lisbon and San Fernando. With reference to the yearly range, one of the tables shows the deviations of the monthly from the yearly means, the sum of the greatest *plus* or *minus* monthly departures being given as the expression of the mean yearly oscillation. The stations are divided into three groups: (1) coastal, where the aggregate mean yearly oscillation is between 11·5° and 15·3° C.; (2) more inland, oscillation between 15·9° and 18·2°; and (3) central tableland and plateaux, oscillation between 18·9° and 20·1°. This useful paper closes with tables showing the interdiurnal variability of temperature at Madrid (yearly mean 1·5° C.) and San Fernando (1·0°).

A discussion of "The rainfall of Jamaica from about 1870 to end of 1909," with monthly and annual maps, has been published recently by Mr. Maxwell Hall, Government meteorologist. It includes means from a large number of stations, so far as observations were available, and general averages for each of the several sections into which the island is divided for meteorological purposes. While the rainfall is fairly well distributed over the year, it is rather heavy in each division in May, June, September, and October; the north and north-east divisions have winter rains in November and December, and the north-east and west-central divisions have summer rains in July and August. The annual average for the whole island is 71·77 inches, maximum 90·61 inches in 1886, minimum 45·18 inches in 1872. The heaviest falls occur in the north-east division, where the aggregate average is 93·52 inches, the annual amounts exceeding 100 inches in many years. Some remarkable flood rains in twenty-four hours are reported during cyclonic disturbances, frequently exceeding 20 inches, and on one occasion (November 6, 1909) exceeding 30 inches on the Blue Mountain range. A table of the mean diurnal range at Kingston shows that the rainfall increases more or less regularly from the early morning until 3h. and 4h. p.m., after which it decreases to a minimum at midnight. The work is a valuable addition to our knowledge of the rainfall in the West Indies.

Dr. O. L. Fassig has sent us a useful paper on "The Climate of Porto Rico," chiefly based upon observations of the U.S. Weather Bureau during the years 1899–1909. The island, which is the most eastern of the Greater Antilles, and one of the most favoured regions within the tropics, has always been primarily devoted to the pursuit of agriculture. It has an equable and comfortable climate; the mean annual temperature at forty selected stations (combining all the records) is given as 76·4°, February 73·3°, August 79·1°, absolute maximum 103° in August, minimum 43° in February and March. The mean values naturally vary somewhat at individual coast and mountain stations; there is a fairly constant difference of 6° to 8° between the coast temperatures and those of the higher inland stations throughout the year. The average annual rainfall for the whole island is 77·30 inches; the amounts vary greatly from year to year, *e.g.* 93·72 inches in 1901, and only 64·18 inches in 1907, while in the Luquillo mountains, where rainfall is heaviest, the average annual amount exceeds 135 inches, and along portions of the south coast it is less than 40 inches. The average number of rainy days is 169 for the island as a whole; there are no well-defined wet and dry seasons. Porto Rico is comparatively free from storms of all kinds; the centre of a hurricane has only passed over the island three times in forty years, all in the month of August.

BIRD NOTES.

THE Agricultural Research Institute at Pusa, Bengal, has taken up the subject of the food of Indian birds, and issued a preliminary report (Mem. Dept. Agric. India, Entomology, vol. iii., January, 1912) by Mr. C. W. Mason, edited and supplemented by Mr. H. Maxwell Lefroy. To a great extent the report is a compilation of extracts from the writings of Indian ornithologists relating to the food of birds, but it also includes an analysis of the contents of the stomachs of a considerable number of specimens (1325) which have been examined in the laboratory. It is very largely a confession of ignorance, as at present little is known with certainty as to the economic utility or harmfulness of Indian birds, and it is consequently impossible in most cases to make definite statements. Mr. Mason is, however, of opinion that as weed-killers—by consuming seeds—birds are of no value at all in India. Such birds "may keep weeds down to a certain extent, but this is of minor importance in a country where labour is cheap and where farming is not practised on such intensive lines as elsewhere. Even in intensive cultivation we cannot rely on weeds being kept down by birds, and the expense of cultivation to eliminate weeds is, I believe, not reduced in the slightest by the action of birds."

It is noteworthy that although hawks and owls are regarded, in the main, as beneficial, yet they are considered to be undoubtedly harmful on account of destroying insectivorous shrewmice, toads, frogs, and lizards.

In the February number of Witherby's *British Birds* Mr. Ogilvie Grant points out that the partridge possesses two seasonal plumage-changes—one in the male and the other in the female—which have been hitherto overlooked. During the autumnal moult, lasting from July to September, the cock develops on the sides of the head and neck light umber-brown feathers marked by narrow buff, black-bordered shaft-stripes; this so-called eclipse-plumage replacing for about two months the normal black-waved grey feathers. In the hen during May the ordinary plumage of the same parts, as well as of the back, is replaced by sandy-brown feathers mottled or barred with black, and having buff shaft-stripes, and usually a terminal spot of the same hue. This breeding plumage, which is retained until September, produces a mottled appearance, especially round the neck, which is held to be protective to the sitting bird.

The April number of the same journal contains a supplementary record by the editor of the dispersal of little auks over the inland districts of England due to the stormy weather which prevailed in the early part of January. The birds seem to have struck the coast in greatest numbers between Norfolk and the Firth of Forth, those reported from the western and midland counties having probably travelled from the east. Although the number of birds appears to have been fewer than in the visitation of 1895, they seem to have been spread over a wider area of country.

Notes on the breeding of the white-headed stilt in a swamp near Melbourne are contributed by Mr. C. French to the January numbers of *The Emu* and *The Victorian Naturalist*. This is believed to be the first record of the breeding of these beautiful birds in Victoria. Unfortunately, the swamp dried up before the nesting was completed, thus causing many of the eggs and young to be deserted. The nests, which were from 10 to 15 ft. apart, and were made of dried water-plants, were constructed on tussocks of sea crab-grass (Salicornia); the first eggs were laid early in October.

In his review of Norfolk ornithology for 1911, published in *The Zoologist* for April, Mr. J. H. Gurney suggests that the breeding of a pair of bitterns in the county may have been due to the drying up of some of the Dutch swamps by the unusual heat and dryness of the summer. Another event was the nesting of a pair of curlews near King's Lynn.

We have received a copy of the second number of *The Austral Avian Record*, a new journal, edited by Mr. G. M. Mathews, and published by Messrs. Witherby and Co., primarily devoted to the study of Australian birds. This number contains a long list of new subspecies and other addenda to the Australian fauna, which from internal evidence is clearly from the pen of the editor, although there is no other indication of its authorship.

The birds of Lower Egypt form the subject of an article by Mr. C. B. Ticehurst in the February issue of *The Zoologist*; Mr. M. J. Nicoll is also writing on the same subject in *The Ibis*.

In a pamphlet published for Government at the National Printing Department, Cairo, Mr. Nicoll gives a list of the species of wild birds (other than those kept in captivity) observed in the Giza Zoological Gardens between the years 1898 and 1911 inclusive. The list includes 200 species, of which 187 are indigenous to Egypt, while the remaining 13 are foreign, and were doubtless represented by individuals escaped from captivity in Cairo. R. L.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Leeds.—On the recommendation of the Livesey Memorial Committee, the University Council has appointed Mr. John William Cobb to be Livesey professor of coal gas and fuel industries from the end of the present academic year, when the chair will be vacated by Dr. W. A. Bone, F.R.S., who has accepted the professorship of fuel and refractory materials at the Imperial College of Science and Technology.

On the recommendation of the advisory committee on higher commercial education, the University Council has decided to develop the teaching of geography in connection with the department of economics, and has appointed Mr. Llewellyn Rodwell Jones as assistant university lecturer in geography.

Mr. F. A. Duffield has been appointed demonstrator in experimental physiology and pharmacology at the University of Sheffield.

The annual meeting of the Parents' National Educational Union will be held at University College, London, on Tuesday, May 14, when an address on "Some Educational Ideals" will be delivered by the Rev. A. A. David, headmaster of Rugby School.

The committee of University College, London, will shortly proceed to make an appointment to the post of senior assistant in the department of zoology and comparative anatomy, which has been rendered vacant by the election of Dr. W. N. F. Woodland to the professorship of zoology in the Muir Central College, Allahabad.

The Maryland Legislature has, we learn from *Science*, voted the sum of 120,000*l.*, to be followed by an annual grant of 10,000*l.*, to establish a school of technology in connection with the Johns Hopkins University. Our contemporary also announces a gift of 60,000*l.* to Princeton University from Mr. W. C. Proctor, of Cincinnati, for the endowment of the Charlotte Elizabeth Proctor fellowships in the graduate school Mr. Proctor has previously given 100,000*l.* to the graduate school.

A scholarship of 35*l.* for one year is offered at Bedford College for Women (University of London) for the course beginning in October next. The scholar, who must hold a degree, or an equivalent certificate, will be required either to take the full diploma course at Bedford College or to pursue some special line of investigation in cognate subjects under the supervision of the lecturer in hygiene. Names of intending candidates, with particulars of previous study, should be forwarded not later than July 1 to the Principal, Bedford College, from whom further particulars may be obtained.

A conference on diet in public secondary and private schools will be held at the Guildhall on May 13, when the Lord Mayor will preside. A provisional programme has been circulated, and it is expected the following papers will be read and discussed:—Diet as a factor in physical, intellectual and moral efficiency, by Dr. Clement Dukes; existing methods and the main lines of reform, by Miss Robertson, Drs. Mumford and J. Sim Wallace, and Mr. Prosser; instruction in the elements of physiology and personal hygiene, by Mrs. Burn and Dr. Reddie; and problems in institutional feeding and training in institutional management, by Mrs. Stanley Hazell. Full particulars will be supplied to anyone sending a stamped addressed envelope to Mr. C. E. Hecht, National Food Reform Association, 178 St. Stephen's House, Westminster.

The Australian Institute of Tropical Medicine is inviting applications in connection with the appointment of three new officers, one to be a laboratory expert capable of taking charge in the absence of the director, the second to be an expert in tropical hygiene and epidemiology, and the third to be a biochemist. This is the outcome of the large increase of endowment recently granted by the Commonwealth Government. Extensive new laboratories are in process of erection at Townsville, Queensland, and special wards have already been equipped in the Townsville Hospital. The first report of the director, Dr. Anton Breinl, is full of hopeful augury. An Australian diploma of tropical medicine is being established simultaneously by the Universities of Sydney, Melbourne, and Adelaide, the bulk of the teaching being entrusted to the institute. The affairs of the institute are supervised by a committee including representatives of the Governments of the Commonwealth and of Queensland, and the Universities of Sydney, Melbourne, Adelaide, and Brisbane.

The second reading of the Education (School Attendance) Bill was agreed to in the House of Commons on April 26 by a substantial majority. The Bill provides that no child shall be allowed to leave a public elementary school below the age of thirteen, with the proviso that if a child leaves school between the age of thirteen and fourteen it shall only do so on condition that it is to enter into beneficial employment. The effect of the Bill would practically be to abolish half-time employment. It is generally admitted that the half-time system has little to recommend it so far as the great majority of districts are concerned. A recent departmental committee decided unanimously against it, and recommended its abolition. But, as the speeches in the House of Commons showed, some authorities wish to preserve the system in agricultural districts, though there has been a marked diminution of half-timers in country areas in recent years. The system is most in vogue in the textile districts of Lancashire and Yorkshire; but the debate served to demonstrate that its abolition would be greatly to the advantage of the children, and would result also in a marked improvement in the standard of the schools, where work has been retarded greatly by the regular absence from them of part of the children for a portion of the school day.

The fourth annual report of the governing body of the Imperial College of Science and Technology, for the year ended August 31 last, has now been published (Cd. 6132). It provides interesting particulars of the progress already made in the provision of adequate accommodation for the extended work and activities of the college. The governing body has had under consideration its position as regards the Royal Commission on University Education in London, so far as it has reference to the work of the Imperial College, and has resolved that the autonomy of the Imperial College should be maintained and incorporation with the University of London should not take place; also that some means should be found, either by the establishment of an independent department or faculty of technology or otherwise, by which students of the Imperial College who satisfactorily complete the associateship courses of the college, and students duly qualified by research, advanced study, or in other approved ways, may obtain degrees without further examination. To maintain the departments of applied science in the college, so that they may be of the greatest possible usefulness to their related industries, small committees of experts are being formed with the express object of keeping the college specially informed as to the needs of that industry. Throughout the report there are many instances of the strenuous endeavours of the governing body to equip and maintain the college in a manner worthy of its name.

IN a paper read before the Royal Colonial Institute on April 23, Mr. A. E. Shipley, Master of Christ's College, Cambridge, dealt with the problem of fitting men for their practical post-academic life. The Americans, he pointed out, set great store by the practical nature of education. Not infrequently boys who in the ordinary course of events would leave school at fourteen or so, go up to the high school, where they maintain themselves, altogether or partly. The path from the school to the university is a straight one. But the system in America is beset by many grave disadvantages. The teaching staffs of some of the great universities are far from adequate, and the priceless feature of individual instruction and attention is neglected. College degrees may, he said, be "crammed" for, and the system stifles originality. Several Americans have told Mr. Shipley that comparatively few things are actually invented in America—that most inventions come from abroad, but are eagerly taken up and exploited in the States. Where the American really shines is not as an inventor, but as a manufacturer. Originality is rare in America, and this must be accounted for by the educational system. The remedy is either a gigantic increase in the teaching staffs of the universities or else a rigorous elimination of the first-year students. At present, he continued, the older English universities are producing the best men, but the field from which they draw is small. By making slight reforms, America could be on the same footing as the English universities, with the added advantage of a universal field from which to select the raw material.

THE completion of another important addition to the many departments housed under the roof of the Battersea Polytechnic was inaugurated on Monday, April 22, when his Honour Judge Benson (Master of the Worshipful Company of Drapers) attended for the purpose of opening the new hygiene and physiology laboratories, presented by that body as a further step towards the thorough equipment of the polytechnic. The new laboratories with their classrooms are equipped and arranged on the latest principles for the study of hygiene, physiology, bacteriology, and geology. Dr. Rawson, principal of the polytechnic, presented an interesting report on the work of the past year, in the course of which he pointed out that the number of both day and evening students showed a gratifying increase. In the matter of examination results, thirty-eight scholarships and exhibitions (to the value of 2115*l.*) had been gained during the year, together with nine medals and sixteen prizes, and other awards. The number of university students and their successes at the university examinations also showed a great increase over previous years. In conclusion, Dr. Rawson referred to the great help the new laboratories given to the polytechnic by the Drapers' Company would prove. In the past, so far as the study of hygiene and physiology was concerned, the work had been seriously hampered for want of accommodation, but that has now been remedied. Judge Benson then distributed the prizes and formally opened the new laboratories. Later he delivered an address, in which he contrasted the present educational system with the opportunities which existed in his youth, and urged the students in their efforts to perfect themselves in technical arts and crafts, not to neglect that general culture which is necessary to the proper development of the human intellect.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, April 25.—Sir Archibald Geikie, K.C.B., president, in the chair.—J. S. **Townsend**: The diffusion and mobility of ions in a magnetic field. The mobility and diffusion of ions in a magnetic field is investigated on the same principles as those employed in the ordinary kinetic theory by considering the motion of an ion along its free paths between collisions with molecules. If U and K be the mobility and coefficient of diffusion when the magnetic force is zero, U_h and K_h the corresponding quantities in directions at right angles to a magnetic force H, then

$$U_h = \frac{U}{1+\omega^2T^2} \text{ and } K_h = \frac{K}{1+\omega^2T^2},$$

where $\omega = He/m$ and T the mean interval between collisions. The magnetic deflection θ of a stream of ions moving with a constant velocity in an electric field is also investigated, and a method is indicated of determining the velocity U due to an electric force X. When θ is small, $\tan\theta = HU/X$, and when θ is large, $\tan\theta X/ = HU_h$.—J. J. **Manley**: The observed variations in the temperature coefficients of a precision balance. In this paper is given an account of experiments which supplement and extend an earlier research (Phil. Trans., A, ccx., p. 387) dealing with changes which may be observed in the resting points of precision balances. Attention is directed to the following:—(*a*) the possibility of the change from a positive to a negative value for the temperature coefficient of a balance; (*b*) the *critical temperature range* of a balance; (*c*) the various causes tending to give rise to a temperature coefficient; (*d*) the necessity for the "ageing" of a beam either naturally or artificially. In addition to the above, certain minute and temporary lateral displacements of the whole beam are investigated. A method for measuring these movements is given, and their origin disclosed.—Dr. Guy **Barlow**: The torque produced by a beam of light in oblique refraction through a glass plate. In accordance with the principle that light carries with it a stream of momentum, the passage of a beam of light through a refracting plate should give rise to a torque on the plate, it being supposed that the reaction is on the matter through which the beam is passing. In 1905 Prof. Poynting and the author made experiments which confirmed this result, but as disturbances, due to gas action, were not eliminated, more exact measurements appeared desirable. In the present experiment the original double-prism arrangement was abandoned in favour of a single cube. A glass cube, of 1 cm. edge, was suspended axially by a fine quartz fibre. A strong beam of light was sent obliquely through the cube, the angle of incidence having been so adjusted that the beam entered through one half of one face, and emerged through the half-face diagonally opposite. The torque was determined from the observed angular deflection of the cube. Observations were made in hydrogen and air with pressures ranging from 0·1 to 76 cm. Hg. The disturbance due to radiometer action was found to be inversely proportional to the gas pressure, and could be eliminated. After allowing for the reflected beams, the observed torque (of the order 2×10^{-6} dyne cm.) was within 2 per cent. of that calculated from the energy of the beam.—Dr. T. C. **Porter**: Contributions to the study of flicker. Paper III. This paper is a continuation of two former papers: Proc. Roy. Soc., vol. lxiii., p. 347, and vol. lxx., p. 313. If n be the number of revolutions per second for a disc with white sector "w" and the rest black, just to appear flickerless under illumination "I," then

$$n=-27{\cdot}83+(8{\cdot}57+2{\cdot}79\log \mathrm{I})\log w\,(360-w);$$

this holds when I is greater than 3·98. If I be less than 3·98, then

$$n=-38{\cdot}6+(12{\cdot}4+0{\cdot}77\log \mathrm{I})\log w\,(360-w).$$

The existence of the remarkable break in the line connecting n and log I for $w=180$ has been confirmed. The relation of n and I for perfectly symmetrical discs of four or more sectors is established, and application made to the measurement of high illuminations. Asymmetrical discs are considered, and it is proved that n is independent of the direction of their rotation. With the aid of a reasonable assumption there is deduced a curve expressing numerically the rise and fall of retinal excitation with time when the eye has presented to it suddenly a white surface, which is afterwards suddenly withdrawn. This curve is drawn to scale for a given illumination of the white surface.

Royal Microscopical Society, April 17.—Mr. H. G. Plimmer, F.R.S., president, in the chair.—J. D. **Siddall**: The life-history of some marine diatoms from Bournemouth. Living and mounted examples, drawings, photographs, and lantern slides were exhibited in illustration of the author's observations, the chief interest of which centred in a Coscinodiscus, about 1/400 in. in diameter, furnished with very numerous radiating pseudopodial filaments. The specimens shown demonstrated the certainty of this beyond any possibility of doubt, and thereby set at rest the old and much-debated controversy as to the possession and utilisation of pseudopodial appendages, at any rate in this particular diatom, which, for the sake of convenience, he proposed should receive the specific name *heliozoides*. The presence of pseudopodial appendages, much smaller, fewer, and still more difficult to discern, was also notified in Melosira, Surirella, Biddulphia, and Triceratium. The cause of the peculiar movement of *Bacillaria paradoxa* was also briefly discussed in the paper, which concluded with the suggestion that further study of living diatoms with modern microscopical appliances would explain much of the meaning and purpose of the exquisite minutiæ of their siliceous skeletons.—E. B. **Stringer**: A modified form of the lever fine-adjustment, and a simple turn-out device for the substage condenser. The essential feature of the fine-adjustment was that the movement of the lever was carried to the top of the limb by means of a strong steel pin working through a guide, the opposing spring being at the bottom, and friction between the lever and the pin eliminated by means of a ball-bearing. Freedom from lateral movement and greater sensitiveness was thus secured. A simple two-speed movement was also provided. The turn-out device acted on the top lens of the condenser alone, thus affording illumination adapted to the power of the objective in use. A note was added on the value of the Bertrand lens in ordinary microscopical work.

Institution of Mining and Metallurgy, April 18.—Bedford McNeill, vice-president, in the chair.—E. **Hatschek** and A. L. **Simon**: Gels in relation to ore deposition. Actuated by the already known fact that dissolved substances will diffuse into and out of "gels," such as gelatine and silicic acid gels, the authors have made a series of experiments, from which it appears probable that many features of the occurrences of gold in quartz can be explained by the assumption that such occurrences originated in the reduction of gold salts in a medium of gelatinous silicic acid. In these experiments the agents employed for the reduction of gold chloride in the gels were various, and comprised two groups: in aqueous solution—oxalic acid, ferrous sulphate, formic acid with ammonia, and sodium sulphite; gaseous—sulphur dioxide, carbon monoxide, illuminating gas, and hydrogen. The reverse process of adding the reducing agent to the "gels," and afterwards pouring in the gold chloride solution, was also tried. The results of these experiments, as demonstrated in test-tubes, throw, in the authors' opinion, a new light on certain gold deposits, and afford a more satisfactory explanation of their genesis than has been hitherto suggested. This is a matter of some importance, as the finding of alluvial gold has frequently led to the expenditure of vast sums of money in the endeavour to locate the primary rock source, which is possibly non-existent if these experiments are interpreted aright. The authors are making further and more exhaustive investigations on the same lines which may lead to even more conclusive results.—J. I. **Hoffmann**: Recent practice in diamond drilling and borehole surveying. This paper may be regarded as supplementary to others on the same subject read previously before the institution, and described more recent practice, including a detailed account of the surveying instrument now exclusively employed on the Rand, the invention of Mr. Oehman, with improvements by Mr. A. Payne-Gallwey. In this instrument the survey is photographically recorded, two discs of sensitised paper being placed so that at a given moment they receive impressions from a small electric lamp, and the variation in the image transmitted to each enables a ready estimation to be made of both the dip and direction of the borehole at the point where the record is made. The paper contains folding plates giving diagrammatic views of two typical Rand boreholes surveyed by means of this instrument. A description of a deflecting wedge invented by Mr. Wm. Gallagher, used for the purpose of correcting the deviation of a borehole while in process of being drilled, or of making an offset from one already drilled, added interest to the paper and assisted in bringing it up to date.—Two other papers were on the agenda, but had to be taken as read; these were:—G. T. **Holloway**: Notes on the valuation of ores and minerals and on metallurgical calculations; and T. A. **Rickard**: The domes of Nova Scotia.

Linnean Society, April 18.—Dr. D. H. Scott, F.R.S., president, in the chair.—Dr. D. H. **Scott**: *Botrychioxylon paradoxum*, a Palæozoic fern with secondary wood. The plant is from the Lower Coal-measures, and is a member of the family Zygopterideæ, belonging to the Primofilices of Arber. The stele has a "mixed pith," consisting of internal tracheides and parenchyma; the surrounding zone of wood is entirely secondary, diminishing in thickness upwards. The branching of the stem, as in *Ankyropteris corrugata* and some other Zygopterideæ, is dichotomous. The leaf-trace, like the stele, shows a considerable development of secondary xylem, but in the petiole the tissues of the bundle are entirely primary. The structure differs from that of Ankyropteris in the apparent absence of "peripheral loops." "Aphlebiæ," forming branched, spine-like organs, are borne both on stem and petiole.—Dr. E. A. Newell **Arber**: *Psygmophyllum majus*, sp. nova, from the Lower Carboniferous rocks of Newfoundland, together with a revision of the genus, and remarks on its affinities. This paper deals with a rare and little-known genus of Palæozoic plants. A new species of Psygmophyllum (*P. majus*, sp. nov.) from the Lower Carboniferous rocks of Newfoundland is first described, and a full account of *P. flabellatum*, Lindl. and Hutt., the British representative, is added. The genus is revised and the affinities of the genus discussed.

PARIS.

Academy of Sciences, April 22.—M. Lippmann in the chair.—J. Violle, M. Bassot, H. Deslandres, G. Bigourdan, B. Baillaud, MM. Fournier and Bourgeois, Joseph Eysséric, Louis Fabry, M. Stéphanik, Fr. Iñiguez, D. Eginitis, A. Lebeuf, E. Cosserat, Charles André, Alfred Angot, Henry Bourget, E. Carvallo, and Maurice Hamy contributed papers dealing with the eclipse of the sun of April 17 (see p. 221).—Paul **Appell**: Remarks on the possible use of the energy of acceleration in the equations of electrodynamics.—A. **Lacroix**: The radio-active uraniferous niobotantalotitanates of the Madagascar pegmatites and their frequent association with minerals containing bismuth. Analyses are given of four of these minerals. Details of the radio-active properties of these substances are reserved for a later communication.—A. **Chauveau**: The stereoscopic inversions caused by the association of two systems of retinal impressions in opposition and of unequal power. The influence of the preponderating impression. It is shown that in the stereoscope, in the case of two retinal impressions in the same visual field and of unequal strength, the feebler retinal impressions are subordinated to the stronger ones. The latter can cause the inversion of the retinal impressions produced by the former.—Pierre **Termier** and Robert **Douvillé**: The rocks and fossils of the region of the high plateaux between Bou-Denib and the Mlouya, on the southern Algero-Morocco border.—Arnaud **Denjoy**: Calculation of the primitive of the most general derived function.—Harald **Bohr**: The $\zeta(s)$ function in the half-plane $\sigma>1$.—Ch. **Fremont**: The distribution of the deformations in metals submitted to forces. Case of the folding of tubes.—G. **Kœnigs**: Joule's cycle. A comparison of the efficiency of an internal-combustion motor working on a Carnot cycle and a Joule cycle.—Samuel **Lifchitz**: The path of particles in Brownian motion. The formation of vortices.—E. E. **Blaise**: Syntheses by means of mixed organo-metallic derivatives of zinc. Formyl-lactyl chloride with the zinc compound R—Zn—I gives lactic acid and the aldehyde R—CHO. The method is general, and in some cases furnishes a serviceable process for the preparation of aldehydes.—Mme. **Ramart-Lucas**: The dehydration of pseudo-diphenyl-carbinol.—Maurice **Lanfry**: The action of hydrogen peroxide upon the bromothiophens. Monobromothiophen is partially converted into the dibromo-derivative; tribromo- and tetrabromo-thiophens are not attacked by the reagent.—Edouard **Bauer**: Reduction of the β-diketones. Acetylacetone can be reduced to the corresponding diglycol by reduction with sodium in boiling alcohol.—A. **Wahl**: Researches on coal. A study of the substance extracted by boiling pyridine from various classes of coal.—R. **de Litardière**: The phenomena of somatic kinesis in the radicular meristem of some Polypodiaceæ.—M. **Ravin**: The carbon nutrition of Phanerogams with the aid of some organic acids and their potassium salts.—G. **André**: The displacement of the food substances contained in seeds by water.—Em. **Bourquelot** and Mlle. A. **Fichtenholz**: The presence of arbutin in the leaves of *Grevillea robusta*.—Albert **Robin**: Delay in the consolidation of a broken limb in a tuberculous case. Treatment based on the disturbances in the exchanges caused by tuberculosis.—MM. **Desgrez** and **Dorléans**: The hypotensive action of guanine. Experiments with dogs and rabbits proved that guanine lowers the arterial pressure, and is opposed in this respect to the action of adrenaline.—Jean **Effront**: The action of light and hydrogen peroxide upon albumenoids and amido-acids.—A. **Zimmern** and P. **Cottenot**: The effects of irradiation of the suprarenal glands in physiology and therapeutics.—A. **Trillat**: The favourable influence exercised on the development of certain cultures by association with *Proteus vulgaris*.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), parts i. and ii., for 1912, contain the following memoirs communicated to the society:—

March 7, 1908, and July 29, 1911.—The late K. **Zoeppritz**, L. **Geiger**, and B. **Gutenberg**: Seismic waves, part v.

December 10, 1910.—**Angenheister** and **Ansel**: The Iceland expedition of 1910, part i. (observations on terrestrial magnetism) and part ii. (observations on atmospheric electricity and meteorology from May 10 to June 2, with reference to the passage of Halley's comet).

DIARY OF SOCIETIES.

THURSDAY, MAY 2.

ROYAL SOCIETY, at 4.—Election of Fellows.—At 4.30.—Petrifications of the Earliest European Angiosperms: Dr. Marie C. Stopes.—The Distribution of Oxydases in Plants and their *rôle* in the Formation of Pigments: Dr. F. Keeble and Dr. E. F. Armstrong.—The Manifestation of Active Resistance to the Growth of Implanted Cancer: Dr. B. R. G. Russell.—The Nature of the Immune Reaction to Transplanted Cancer in the Rat: Dr. W. H. Woglam.—On the Instability of a Cortical Point: T. G. Brown and Prof. C. S. Sherrington, F.R.S.—The Measurement of *Trypanosoma rhodesiense*: Dr. J. W. W. Stephens and Dr. H. B. Fantham.

ROYAL INSTITUTION, at 3.—Explorations in the Canadian Rocky Mountains: Prof. J. Norman Collie, F.R.S.

LINNEAN SOCIETY, at 8.—On the Structure of the Palæozoic seed *Lagenostoma ovoides*, Will: Miss T. L. Prankerd.—Additions to the Flora of Western and North-Western Australia: Dr. Karl Domin.—Freshwater Rhizopoda from the States of New York, New Jersey, and Georgia, U.S.A.; with a Supplement on the Collection from the Seychelles: G. H. Wailes.—*Ligidium hypnorum*, a Woodlouse new to Britain: W. M. Webb.—New Light on the Linnean Herbarium: The General Secretary.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—*Adjourned Discussion*: The Causes Preventing the More General Use of Electricity for Domestic Purposes.

FRIDAY, MAY 3.

ROYAL INSTITUTION, at 9.—The Use of Pedigrees: W. C. D. Whetham, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—*Resumed discussion*: Tenth Report to the Alloys Research Committee: on the Alloys of Aluminium and Zinc: Prof. J. O. Arnold.

GEOLOGISTS' ASSOCIATION, at 8.—The Geology of Sunderland and District with special reference to the Whitsuntide Excursion: Dr. D. Woolacott.

MONDAY, MAY 6.

SOCIETY OF ENGINEERS, at 7.30.—The Effect of Intermittency in Limiting Electric Traction for City and Suburban Passenger Transport: W. Yorath Lewis.

ARISTOTELIAN SOCIETY, at 8.—Imagery and Memory: Beatrice Edgell.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—United Nigeria: C. L. Temple, C.M.G.

ROYAL SOCIETY OF ARTS, at 8.—Heavy Oil Engines: Captain H. R. Sankey, R.E.

VICTORIA INSTITUTE, at 4.30.—International Arbitration in the Greek World: Marcus N. Tod.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—A New Apparatus for the Coking Tests of Coal: R. Lessing.—A New Method for the Determination of Ferrocyanides: H. E. Williams.—A Drying Oven: J. H. Coste.—India Rubber as a Protective Colloid: E. W. Lewis and H. Waumsley.

TUESDAY, MAY 7.

ROYAL INSTITUTION, at 3.—Insect Distribution, with special reference to the British Islands: F. Balfour Browne.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Geographical Distribution of Certain Primitive Appliances: H. Balfour.

ZOOLOGICAL SOCIETY, at 8.30.—Lantern and Kinematograph Demonstrations of Photographs of Fishes and Aquatic Animals in Natural Illumination: Dr. Francis Ward.—On a Collection of Fishes made by Mr. A. Blayney Percival in British East Africa to the East of Lake Baringo: G. A. Boulenger, F.R.S.—Studies in the Fossorial Wasps of the Family Scoliidæ, Sub-families Elidinæ and Anthoboscinæ: Rowland E. Turner.—Notes on the Spanish Ibex: Abel Chapman.

RÖNTGEN SOCIETY, at 8.15.—The Education of the Brain, considered as an Electrical Machine: W. Deane Butcher.

ROYAL SOCIETY OF ARTS, at 4.30.—Colonial Vine Culture: Alan Burgoyne, M.P.

WEDNESDAY, MAY 8.

ROYAL SOCIETY OF ARTS, at 8.—British Rule in Nigeria: E. D. Morel.

THURSDAY, MAY 9.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On the Variation with Temperature of the Rate of a Chemical Change, with an Appendix by Prof. W. Esson, F.R.S.: Dr. A. Vernon Harcourt, F.R.S.—Some Phenomena of Sun-spots, and of Terrestrial Magnetism: Dr. C. Chree, F.R.S.—On the Ultimate Lines and the Quantities of the Elements producing the Lines in Spectra of the Oxyhydrogen Flame and Spark: Sir W. N. Hartley, F.R.S., and H. W. Moss.—The Transformations of the Active Deposit of Thorium: E. Marsden and C. G. Darwin.—On the β Particles Reflected by Sheets of Matter of Different Thicknesses: W. Wilson.

ROYAL INSTITUTION, at 3.—Recent Explorations in the Canadian Rocky Mountains: Prof. J. Norman Collie, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 7.30.—The Behaviour of D.C. Watt-hour Meters, more especially for Traction Loads: S. W. Melsom and H. Eastland.—Electric Meters on Variable Loads: Prof. D. Robertson.

FRIDAY, MAY 10.

ROYAL INSTITUTION, at 9.—The Gaumont Speaking Kinematograph Films: Prof. W. Stirling.

ROYAL ASTRONOMICAL SOCIETY, at 5.

MALACOLOGICAL SOCIETY, at 8.—A Synopsis of the Recent and Tertiary Fresh-water Mollusca of the Californian Province: Harold Hannibal.—On *Dosinia lucinalis*, Lam., and its Synonyms: A. J. Jukes-Browne, F.R.S.—New Generic Names and New Species of Marine Mollusca: T. Iredale.

PHYSICAL SOCIETY, at 8.—A Method of Measuring Small Inductances: S. Butterworth.—The Conversion of Starch into Dextrin by X-Rays: H. A. Colwell and Dr. S. Russ.—Demonstration of Apparatus for showing the Generation of Electricity by Carbon at High Temperatures: Dr. J. A. Harker and Dr. G. W. C. Kaye.—Calibration of Wave-meters for Radiotelegraphy: Prof. G. W. O. Howe.

INSTITUTE OF METALS, at 8.30.—The Inner Structure of Simple Metals: Sir J. A. Ewing, K.C.B., F.R.S.

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

" To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 2219, Vol. 89] THURSDAY, MAY 9, 1912 [Price Sixpence

Registered as a Newspaper at the General Post Office.]

THURSDAY, MAY 9, 1912.

MEDICAL MORPHOLOGY.

Morphologie Médicale: Étude des quatre types humains. Applications à la clinique et à la thérapeutique, par A. Chaillon and L. Mac-Auliffe. Pp. iv+248. (Paris: Octave Doin et Fils, 1912.) Price 5 francs.

THE title of "Morphologie Médicale," which the distinguished French authors have given to their book, did at first suggest to the reviewer that he was to have the pleasure of making a new subject of research known to the readers of NATURE. The subject, however, is not a new but a very old one, for in its essential nature "morphologie médicale" is really a resuscitation of the old doctrine of "constitutions" or "temperaments," which was so beloved by physicians who lived before the days of Pasteur and Lister. The names are changed with the times; certain "physical types," not "constitutions," are recognised. The exact methods of the anthropologist are employed to distinguish one type from the other.

Patients in the cliniques, according to our authors, can be classified into four types:—the respiratory, the digestive, the muscular, the cerebral. The names at once suggest the underlying characteristic of each type: in the first the respiratory is the dominant system of the body; in the second the digestive, and so on. The head offers certain features which assist the clinician to recognise these types. Two transverse lines are drawn across the face—one at the root of the nose, the other at the junction of the nose and upper lip. The zone between these two lines, containing the nose, is the respiratory zone; the segment above—the forehead and vertex of the head—represents the cerebral zone; the one below, comprising the mouth and chin, belongs to the digestive zone. The predominance in size of any of these three zones of the head helps to indicate the type to which the individual belongs.

Similarly as regards the trunk; if the thoracic part is relatively long, the individual is of the respiratory type; if the abdomen is unduly developed, then, of course, the patient is of the "digestive" type. The muscular type is represented by gymnasts and athletes with brawny limbs. It is strange that the authors cite the great Napoleon as an example of this type, and Edison as a representative of the cerebral type. Rossini, the composer, is their selected example of the "digestive" type, and Spinoza of the "respiratory."

The classification seems altogether unscientific and really unworkable, but at the same time one must confess that such types are clearly recognisable from the descriptions given by the authors. If the members of our Cabinet were to visit Paris and enter a clinique where this doctrine of type is put in practice, there could be no doubt as to which type some of the Ministers belong. The War Office would provide an excellent example of the digestive type; the Admiralty a representative specimen of the "cerebral"; the Foreign Office of the "respiratory"; and the head of the Local Government Board could stand as a fair example of the "short muscular" type. The difficulties arise when we come to the others; the Chancellor of the Exchequer cannot be fitted in anywhere; nor the Premier, nor the Home Secretary, and so with the others. The authors confess that the types are apt to be mixed. Indeed, it is not too much to say that 60 to 70 per cent. of men and women are so ill suited to fit the classification proposed that no two physicians or anthropologists would likely agree as to the types to which this great indeterminable class should be assigned.

In this work there are all the defects which were inherent in the work of Lavater and of Gall and Spruzheim. Yet for two things anthropologists will be indebted to MM. Chaillon and Mac-Auliffe: first for a very clear exposition of the manner in which they make their measurements; second, for the tables which include their anthropological data. In our opinion, the anthropological researches which have been carried out in connection with our hospitals are more satisfactory in method and in aim than those of the French authors. Two of these may be cited: the inquiry which Dr. Shrubsall made several years ago on the out-patients of St. Bartholomew's Hospital, and the research published in a recent number of *Biometrika* by Dr. David Macdonald. In both these papers the biometrical methods were employed to ascertain if there was any co-relationship between anthropological type and disease. The results obtained suggested there was such a relationship, and one which was capable of exact mathematical expression.

A. K.

HISTORY OF DETERMINANTS.

The Theory of Determinants in the Historical Order of Development. By Dr. T. Muir, C.M.G., F.R.S. Vol. ii.: The Period 1841 to 1860. Pp. xvi+475. (London: Macmillan and Co., Ltd., 1911.) Price 17*s.* net.

THE period covered by this volume is a very important one; it practically settled the notation, and, owing mainly to the rise of the calculus of forms, it brought into prominence various special types of determinants with their corresponding properties.

Too much stress can scarcely be laid on the matter of notation; again and again Dr. Muir, in his notes on a paper, brings out the essential meaning of its results by translating it, so to speak, into a more perspicuous language. On the whole, the merit of choosing a suitable notation appears to be mainly due to Cayley, although Cauchy and Grassmann must not be forgotten; their symbolical expressions are often extremely convenient, and are in every case nearly as economical as the current ones, although not quite so convenient typographically. The crowning advantage of the current notation is that $|a_{nn}|$ can be used as a symbol for a general determinant of n rows and columns.

As an expounder of symmetrical algebra, Cayley is unsurpassed, both in power and elegance; it is not surprising, therefore to find that nearly fifty of his papers are referred to. Mainly, these give examples of the application of determinants to particular problems; but as a contribution to the general theory we have the initial discussion of skew determinants, and various important notes on orthogonants.

On the other hand, Sylvester occupies a very curious position. The properties of compound determinants are a very important part of the general theory; some of them were discovered by Cauchy, and Sylvester more than once asserts that he had discovered a general theorem, including Cauchy's as particular cases, and virtually comprehending all properties of determinants. Now, when we turn to Sylvester's published papers on compound determinants, we are more than usually baffled by his inveterate habits of inaccuracy, stating theorems without proof, and hastily jumping at conclusions. Even Dr. Muir confesses (p. 197) that he cannot find or conjecture this all-embracing theorem. He does, however, point out what Sylvester has stated which is really true, and has put it into a more intelligible form; in fact, all his notes on Sylvester will be very useful to those who study the original papers.

Turning to other writers, we have Hesse and Jacobi, who have left their names permanently connected with the subject, developing it from the sides of geometry and differential equations; Hermite also, in his memoirs on ternary quadratic forms, contributes to the theory of orthogonants. Oddly enough, there is only one paper by Clebsch, although (at a later period) he applied determinants to geometrical theory with a mastery equal to Cayley's. Among the Italians we may specially note Brioschi and Faà di Bruno.

As to the arrangement of Dr. Muir's book, we may note that chapter i. contains references to two unimportant papers omitted in vol. i.; chap. ii. is on determinants in general, and the remaining fourteen deal with special types, such as alternants, &c.

There is a list of authors, showing at a glance to which parts of the subject each person has contributed; to find out any particular theorem, the reader has to rely on the table of contents, and this means looking through one or more sections. But from the nature of the case this is about all that could be expected; it is practically impossible to index a set of analytical theorems.

As a mathematical history, so far as can be judged by one who has not gone over the same ground in detail, Dr. Muir's work seems irreproachable in the cardinal points of proportion, completeness, and lucidity. He displays no bias, and his critical remarks are always to the point; while his analyses of the various papers are remarkably concise as well as clear. G. B. M.

CHEMISTRY OF CELLULOSE.

Die Chemie der Cellulose unter besonderer Berücksichtigung der Textil- und Zellstoffindustrien. By Prof. C. G. Schwalbe. Zweite Hälfte (Schluss des Werkes). Pp. 273–666 + xii. (Berlin: Gebrüder Borntraeger, 1911.) Price 14.80 marks.

THIS second volume is closely consistent with the former, reviewed in NATURE, vol. lxxxv., p. 67, and as a completed work we must assign it a high place in technical literature, principally, however, from the point of view of the German technologist, who now finds himself for the first time in possession of a full bibliography *in propria lingua* of this rapidly growing subject. Of an exhaustive and most carefully edited bibliography, in which equal prominence is given to all recorded investigations, and the authors allowed to tell their own story, little more can be said to commend it to the specialist as an indispensable addition to his library equipment.

A more important function, however, of authorship in this field is to influence the rising generation of students and workers, and for this a bold and critically constructive handling of the material was called for.

We may illustrate by selecting a section of the work dealing with the quantitative estimation of cellulose (pp. 613–624).

It should have been shown that the analytical processes available are sharply defined by the general principles of classifications now recognised; and that they are "normal" so far as they are based upon reactions, specific to the non-cellulose, that is, to its characteristic groups, and quantitatively accounted for. From this point of view the "Weende" method (Henneberg and Stohmann) of estimating "crude fibre" or "Rohfaser" has no place as a "cellulose" method.

Nevertheless, it is fully described, as is Dmochowski's modification (Diss, Göttingen, 1909), which consists in digesting these residues with nitric acid at 80°, and further purifying from soluble products, the final residue duly weighed being converted into cellulose by applying the correcting factor 1·1. These methods are not without interest for what they are, that is, as crude measures of resistance to hydrolysis and oxidation. But they should be assigned a corresponding position as representing the empirical or conventional, and of small utility in systematic research.

On the other hand, the author gives full value to the investigations of M. Renker, and of the International Commission. But it might have been pointed out that the formal endorsement of the chlorination method follows many years after its general adoption by specialists.

In other special sections the absence of critical effort on the author's part, and therefore of co-ordinated selection of matter, imposes a considerable strain upon the reader in assigning the proper values to the records of experimental work. Thus, in reviewing the various contributions to the "Constitution of the Lignocelluloses" (pp. 538–554), the views of Klason and Czapek, which are not without suggestiveness but demonstrably untenable, are reproduced at length. The classification of Fremy, long since rejected, finds a place.

As a conspicuous omission from this section, the author has overlooked the suggestive researches of W. J. Russell on the autoxidation of the lignocelluloses, and the action of wood surfaces on photographic plates (in absence of light).

In describing the cereal straws it is implied that they are lignocelluloses. But a straw is a heterogeneous assemblage of tissues, fibres and cells, and cannot be treated on the same plan as a homogeneous tissue, such as jute bast.

We mention this as an instance of the difficulty of treating "cellulose" as a matter of chemistry only, and disregarding structural essentials.

We revert to our more general criticism, which we make in the interest of progress. To attract the young workers, it appears to us a first duty of teachers to aim at didactic directness, even if sometimes at the expense of comprehensive exactitude. The author has, we think, inverted this order of ideas in defining his task and duty.

Hence a volume of very great value as a full record, not merely of the living, but of the moribund, and even stillborn; moreover, a very substantial evidence of the author's industry and capability, and, may we say, modesty; a volume invaluable to the specialist, but to the young student invaluable in the other sense, that is, he will not know how to value it. The author, we hope, may use this exhaustive compilation of records in producing a text-book based on a vital and vitalising ground plan, that is, designed to mould the student mind, equipping it with a critical basis for research work in a field which is one of the most attractive and least exhausted of any branch of natural history.

AN ASTRONOMICAL POET.

Manili Astronomicon Liber II. Edidit H. W. Garrod. Pp. xcix+166. (Oxonii: E Typographeo Academico, 1911.) Price 10*s*. 6*d*. net.

MR. GARROD has by this volume deserved the gratitude of every student of astrology, and in a less degree of every student of ancient astronomy, which is constantly illustrated by astrology. If the book which he has edited is of small value for the history of astronomical science, it is entitled to a high place in astronomical poetry, and Manilius's imagination may appeal to many who have no independent interest either in astrology or in the history of astronomy. As Mr. Garrod points out in his preface, the second book of Manilius is at once the longest and the most difficult. It requires close attention to geometrical ideas of no value to modern science, and these ideas are made the more difficult through being expressed in verse, and in a verse teeming with poetic metaphor, instead of in prose. "And not only is the second book hard, but the commentaries upon it are hard too. No one commentary suffices," says Mr. Garrod. This criticism might now be more appropriately expressed in the past tense. The Latin text of the second book is hard, though Mr. Garrod's painstaking study of the text has done much to make it easier, but there is no difficulty in following it with the aid of the translation and commentary that Mr. Garrod has supplied. In fact, the translation might be read with interest by one who has forgotten his Latin.

Mr. Garrod has brought to his work a rare combination of qualities. This is not the place, nor am I the person, to do justice to his gifts or achievements in the department of textual criticism, though it is here that the chief value of his work probably lies, and it is certainly this part of his work that will attract most attention from other scholars. Questions of grammar and prosody arise less often, but Mr. Garrod is a master of all these. He has, moreover, what is rare in these days, a taste for astrology, and, what is happily less rare, a genuine poetic feeling, which shows itself, not only in the taste of his renderings, but in his very pretty preface, and perhaps finds its best expression in the verses on the constellation Engonasin, the modern Hercules, with which the preface concludes. These verses are a perfect gem and an important addition to our not too large store of astronomical poetry. Another feature of the preface to which I would invite the attention even of those who do not wish to read the book is the brief, but critical, bibliography of modern works on ancient astronomy and astrology (pp. ix, x). Perhaps it is not too much to hope that the editor will permit this bibliography to be reprinted along with his verses in some astronomical journal, where they may interest readers who are not likely to see the present volume. J. K. Fotheringham.

OUR BOOKSHELF.

Practical Mathematics and Geometry. A Text-book for Advanced Students in Technical and Trade Schools, Evening Classes, and for Engineers, Draughtsmen, Architects, Surveyors, &c. By Edw. L. Bates and Fredk. Charlesworth. Part iii., Advanced Course containing numerous Practical Exercises, with Answers, and about 300 Illustrations. Pp. viii + 447–776. (London: B. T. Batsford, 1911.) Price 3*s.* net.

This volume is in continuation of the subjects treated in parts i. and ii. by the same authors; these were reviewed in Nature of February 9, 1911. The mathematical part of the present volume comprises sections dealing with trigonometry, mensuration, algebra, and rates of increase. The geometrical portion includes tangential arcs of circles, loci, conic sections, vectors, and descriptive geometry. The difficulty of coordinating successfully the two main branches of the subject is evident in this volume as in its predecessor. Chapters dealing with geometry stand isolated among others of a mathematical character, there being no apparent connection. Perhaps the chapter on conic sections is the only one showing a real attempt at coordination. The trigonometrical portion is very brief, containing little more than the definitions of the functions of an angle and the solutions of triangles. It would be useful to have the relations of the sum and difference of two angles included in this volume. In many cases the authors are content with the mere statement of a rule; this probably is the result of taking cases from practice, not in illustration of principles already discussed, but as problems needing a solution.

Descriptive geometry occupies the last seven chapters, and these may almost be regarded as a separate book. The matter includes projections of simple figures, planes, and plane figures in space, intersecting planes and lines, plane sections, and developments of surfaces. The treatment of this portion of the volume, apart from what has preceded it, is good, and will give the student reasonable grounds for believing that he is acquiring some systematic knowledge of practical geometry.

Principles and Practice of Poultry Culture. By John H. Robinson. Pp. xvi + 611. (London and Boston: Ginn and Co., n.d.) Price 10*s.* 6*d.*

Mr. John H. Robinson is one of the best-known poultrymen and one of the best-known writers on poultry matters in the United States. To say that his present work will be popular in the ordinary acceptation of the word with the British reader is perhaps saying too much. With the student, and more especially on the shelves of the professor of animal industry and in the college library, there it should be found, and not only found, but read.

The chapters one would particularly like to mention for special quotation (if space permitted) are: iii., economic aspects of poultry culture; iv., the poultry keeper's problems; vii., systems of poultry keeping; xii., poultry foods; xiii., rations and methods of feeding; xxi., types, breeds, and varieties of fowls; xxii., turkeys; xxiii., ducks; xxv., phenomena and principles of breeding. It must be remembered that America has given us the Rock, the Wyandotte, the Rhode Island Red, and one of the best utility types of Leghorn.

The Philo system of housing, the "dry feed" and "dry mash," and the score card for teaching purposes all emanate from the States. This country has learnt much from the "other side."

Even for the illustrations alone, the book is well worth buying. We have purposely omitted to comment on the somewhat elaborate plants, as the climate in this country does not warrant such expense. As indicated above, the thoughtful reader will find much food for reflection, while the purely practical man will devour eagerly the definite directions, particularly those referring to ducks, geese, and turkeys.

Geographical Pictures (from Photographs). Series iii.: Sculpture of the Earth's Crust. Packet No. 1. Plates 1–6. Packet No. 2. Plates 7–12. (London: A. and C. Black, n.d.) Price 6*d.* per packet of six pictures.

Messrs. Black issue these illustrations, which measure about six by five inches, as part of their scheme of school geography. Packets 1 and 2 are concerned with processes of weathering, and the pictures are described by Miss S. M. Nicholls. Their low price allows of the use of several copies in a class, the teacher pointing out the salient features, and the pupil following his remarks with the aid of the abridged description on the plate. The views of granite in the Scilly Isles, of wind-carved rocks in Colorado, and of the interior of a cave at Cheddar, seem particularly happy. The text is clear and to the point, though the two attempts to spell the Snowdon buttress, Crib-y-Didysgl and Cribs-y-Dysgl, will not please Welshmen. G. A. J. C.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Solar Eclipse of April 17.

THE study of the article by G. Fayet in the *Revue Scientifique* of March 30, an account of which was given in NATURE, convinced me that, with favourable weather, the solar eclipse of April 17 would prove to be interesting, although its totality was extremely doubtful.

I went to Paris on April 16 and put up at the Gare du Nord. At 10 a.m. on April 17 I took a suburban train from that station to Eaubonne, which was on the central line, as shown in the map given in Fayet's article. I arrived there about 10.35, and after looking round I took up a station at a seat by the roadside in front of the school. When I arrived the boys and girls were being dismissed, by order of the Minister of Education, so that they might see the eclipse. Some of them came round me while I was looking out for the first contact. They were much interested, and were very well behaved. They all had the red glasses supplied by an advertising firm, but they had a curiosity to see the sun through my glass, which showed it in its natural colour, and they were delighted with the effect.

During the first hour they played about, because watching the gradual encroachment of the moon on the sun was tedious. When the diminution of daylight made itself felt they began to gather round me; so I told them they must not look at me but look at the sun and moon, and notice all that they saw, and that, while the eclipse was going on, they must not speak to me or to each other. "*Ne pas parler?*" "Yes," I said, "*ne pas parler*—you must look and do nothing else." They retired into the back part of the playground and stood in a group, and they no doubt looked, for they were quite silent.

When the central phase was over and I had taken my glass away from my eyes, they rushed up in a body and surrounded me, and I asked them if the sun had become quite dark or if there had been some light all the time. Their opinion was divided. From this I concluded that the sun had been at no time completely obscured, for this would certainly have impressed them.

As I was working alone it was useless to try to take the times of contact. Moreover, the second and third contacts, which are the most important, would happen so close to each other that, if I attempted to time them, it would interfere with my seeing what happened. I therefore devoted myself entirely to following the eclipse and observing as well as I could everything that took place. It was certain that "Baily's beads" would be a feature of the eclipse, and I had great curiosity to study them.

The sky was cloudless and the sun very powerful. I had with me an ordinary binocular of low power, which I hoped to find useful when the short-lived central phase, whether total or annular, arrived. In order to be able comfortably to follow the eclipse from the beginning to the end, I had the hand glass which pleased the school children. It was a combination of three coloured glasses measuring 110×35 millimetres, so that the sun could be observed through it, using both eyes, whether it was used alone or in conjunction with the binocular. The effect produced by this combination of colours was that the sun, viewed through it, appeared of its natural hue. The density of the coloured medium was such that nothing but the sun's direct rays penetrated it, and the sky, in which the sun appeared to be set, was quite black.

I bought this glass of a hawker in the streets of Barcelona on the eve of the total eclipse of August 30, 1905, and I found it very useful, although the interest of that eclipse centred almost entirely in the total phase, which lasted nearly four minutes, and during it reducing glasses were not required. Very fortunately I was able to lay my hands on it before starting for Paris, and it was indispensable during the eclipse.

The three glasses have an aggregate thickness of 7 millimetres, and they consist of one green glass 3 millimetres thick and two pink glasses, the external one being $2\frac{1}{2}$ and the internal or middle glass being $1\frac{1}{2}$ millimetres thick. These seem to be pieces of the same glass, and differ from each other only in thickness. They have the same colour, which is very nearly that of a dilute solution of permanganate of potash. The colour of the green glass is a chromium-green, and the colour-intensity of its thickness of 3 millimetres has been successfully compensated by a 4-millimetre thickness of the pink glass. The result of the combination was most satisfactory.

Having noticed that first contact had taken place, I settled down to follow the progress of the eclipse, and I continued making observations every five minutes. The rate of encroachment on the periphery of the sun became less and less, though the augmentation of the area eclipsed proceeded rapidly.

At 11h. 35m. the eclipse appeared to be affecting the general illumination, and I looked round at the school-house to the north of me. The ultramarine blue of the sky was getting darker and more of an indigo. Looking towards the horizon, which was masked by trees, the illumination was becoming decidedly fainter. The indigo colour of the sky spread round and became deeper as the eclipse went on, and, by 11h. 50m., there was an impression of approaching nightfall.

At 11h. 40m. the invasion of the sun's disc had reduced it to a crescent with very sharp cusps. The limb of the moon still looked quite circular, but at 11h. 45m. it became somewhat ogival, and by 11h. 50m. this effect was very marked. By this time the schoolboys were observing the sun without coloured glasses.

I now noticed the peculiar appearance of the shadows of the foliage of a tree cast on the ground close to my station. I also noticed that the illuminated surface of the dusty playground became more and more sombre, while the shadows under the trees preserved the same tone, so that, while the illumination of the exposed ground diminished rapidly, that of the ground in the shade of the trees had already nearly reached its minimum of illumination before the eclipse was complete.

After this my attention was confined entirely to what was taking place in the sky. I was now using the binocular with the reducing glass in front of the eyepieces. With it the rapid diminution of the luminous crescent could be easily followed and the view furnished was very sharp.

As the area of the luminous crescent diminished rapidly before the advance of the dark lunar disc *the colour of its light suddenly changed to red.* This suggested to me that a brilliant display of protuberances might be expected. The tone of the red reminded me, at the moment, of that of nitrous fumes escaping into the air; it was therefore a very pure red. It became visible only after the overwhelming intensity of the relatively white light of the middle of the sun's disc had been screened off by the interposing moon; but it would have been impossible to perceive the red colour, intense though it was, had it not been for the perfection of my reducing glass, which, while it reduced the intensity, preserved the natural colour of the sun's light.

Before the most striking phenomena of the central phase began to crowd across my view, I noticed the beginning of the phenomenon which most impressed me when witnessing the eclipse of May, 1882, in Egypt. In the last moments before totality the rate of extinction of light was very great, and I compared it with that which would take place in a well-illuminated room when a shutter is rapidly drawn down over the window. In the case of the 1882 eclipse the shutter was drawn quite down, and nocturnal darkness was produced with the appearance, not only of all the principal stars, but also of an unsuspected comet in the immediate vicinity of the sun. In the case of the present eclipse the shutter was at first being drawn down quite as rapidly, but it stopped short, and was almost immediately pulled up again. I have no doubt whatever that if the eclipse had been total, it would have been a very dark one.

The central phase was now close at hand, and the appearance of the luminaries changed so rapidly that it was impossible to time the changes. After the light of the whole solar crescent had become quite red, my attention was attracted to the lower (S.E.) luminous cusp, which seemed to become indented by black bands or teeth. Then the upper (N.W.) cusp showed a similar phenomenon; and, almost in a moment, the black teeth spread over the whole crescent, which then offered a magnificent spectacle. The bands or teeth did not span the crescent always by the shortest path, but they crossed and intersected each other like a crystallisation. There was, however, but little time to study them. Very quickly the dark disc of the moon advanced and pushed the beautiful network over the eastern edge of the sun, which it totally obscured, and, apparently at the same moment, the network reappeared, coming over the western edge of the sun, attached to the black limb of the moon, and at the same time held by the limb of the sun. In a few moments the uncovered crescent of the sun had increased so much that the delicate lacework could no longer bear the tension; it parted and disappeared instantly, while at the same moment the dark limb of the moon recovered its perfect smoothness of outline.

The central phase of the eclipse was over, and I could not say that I had seen either a total eclipse or an annular one, but I had witnessed a very remarkable natural phenomenon.

All the phenomena were so astonishing and followed each other so closely that it was impossible to pay attention to every detail. The two crescents, the disappearing and the reappearing one, seemed to be situated diametrically opposite to each other. I perceived nothing on the upper (N.) or the lower (S.) edge of the common disc, but there might have been a thread of light or a string of minute "beads" on one or both of them; and, consequently, I cannot say if the light of the disappearing crescent passed round the northern or the southern limb of the common disc and so preserved continuity between the departing and the arriving crescents, or if it passed round at all. All that I *saw* was the extinction of the departing crescent, and, *post saltum*, the illumination of the arriving crescent.

When the moon is in conjunction and the sun is behind it, the mountains cut by a tangential surface cannot be very evident, because *they can only be the summits of the very loftiest peaks. The valleys are wholly masked.* My binocular, the magnifying power of which is only twofold, shows the mountains and valleys beautifully when the moon is in quadrature, but during the eclipse it made the edge of the lunar disc appear as a smooth and continuous line. The mountains were perfectly invisible on it; yet what we take to be their images were enormous. The phenomenon is not a subjective or an instrumental *spectre*, because it is seen by everybody, with every kind of instrument and without any instrument at all. It is a reality; it must therefore be due to a substantial cause, and to one which can be shown to be capable of producing the effect. May not this substance be the often suggested lunar atmosphere; and, if so, what is its exact specification?

May 3. J. Y. BUCHANAN.

The Distastefulness of Anosia plexippus.

REFERRING again to the above topic (NATURE, December 21, 1911), I wish to make clear my position on the subject. Mr. Pocock's experiments indicate that *Anosia plexippus* is distasteful to many birds, but it is desirable to know whether or not *Basilarchia archippus* is palatable to birds, and it is absolutely necessary, before the usefulness of this case of mimicry can be shown, to know that North American birds eat some butterflies, but scarcely, if at all, molest these two forms.

My former letter was prompted by the evident assumption in the note of October 12 that the case was necessarily one of useful mimicry.

The only case I know of North American birds taking butterflies to any extent only serves to emphasise the lack of attractiveness of butterflies to birds. In this case (referred to by the observer in NATURE, February 15, 1912) only five out of forty-five species of birds observed could be found by direct observation and stomach examination to eat the *Eugonia californica*, which occurred in such countless numbers as to constitute a pest. Two species of fly-catchers captured them to some extent, meadow larks were shown to take them sparingly, and the omnivorous blue-fronted jay, so far as the evidence went (two stomach examinations) ate the butterflies to the extent of one-third of their food. But the only avian species which was shown generally and extensively to utilise these butterflies as food, notwithstanding their excessive abundance everywhere, and the exceeding ease of their capture, was the Brewer blackbird (an omnivorous bird which habitually eats whatever is most easily available, from flies and stinkbugs to seedling grain and fruit), which, in common with the farmyard chickens and ducks, took them in great quantities. Even this rather moderate attack upon butterflies by North American birds (under conditions so exceptionally favourable) far surpasses the aggregate of all previous records.

That North American birds *very* rarely molest adult butterflies is indicated by at least two lines of evidence. In the first place, observers seldom or never see a butterfly pursued or eaten by a bird. One cannot ordinarily by field observation distinguish the insects taken by birds, because the majority of them are inconspicuous forms. But if butterflies were taken, even uncommonly, field naturalists should be able to note the fact more often than once or twice in a lifetime. It is a noteworthy fact to American observers how very seldom, if ever, they see a butterfly taken by a bird.

For a number of years trained experts of the United States Department of Agriculture have been engaged in determining the food of native birds by examination of the contents of thousands of bird stomachs collected in all sections of the country and in all seasons of the year. The bearing of these findings upon the question of butterflies as food for birds has recently been summed up by one of these experts as follows:—"Four records of birds eating butterflies are all that are afforded by the records of the examination of more than 40,000 stomachs in the Biological Survey, and one of these probably relates to the capture of a very recently emerged specimen, or to one torn from the pupa before emergence, as it was accompanied in the stomach by a pupa of the same species. This was an *Epargyreus tityrus* taken by a crow. The other records are *Eudamus* (sp.?) eaten by a yellow-billed cuckoo, and two pierid butterflies captured by king birds" (W. L. McAtee, *The Condor*, January–February, 1912).

Such a mass of evidence (obtained by most careful and painstaking methods from the time the bird is shot *in its natural habitat* until the last recognisable portion of the stomach contents is identified and tabulated) demonstrates that as a food for North American birds butterflies are negligible, so that the distastefulness of *Anosia plexippus* and its close resemblance by *Basilarchia archippus* appear of no possible advantage to these species so far as birds are concerned. Nor can this be lightly pushed aside as "negative evidence." It shows *positively* that our birds do not eat butterflies to an appreciable extent, else immensely more than four butterflies should be found in more than 40,000 stomach examinations.

In a recent article relating to the palatability of insects to birds (Proc. Zool. Soc., September, 1911) Mr. Pocock explains that the behaviour of birds experimented upon in the Zoological Gardens was probably due in a measure to "inability in the gardens to feed the birds on living insects other than meal worms. The living prey was evidently a great treat to them, and over and over again I was impressed with the persistence shown by birds in persevering with insects that were obviously not to their liking, returning to the morsels repeatedly as if food of such a nature was too good to be wasted." But in the first succeeding paragraph he says:—"The insectivorous birds in our aviaries seemed to know at once what the butterflies were; they were on the alert the moment one was liberated and pursued it with determination and precision, following its every turn and twist, and either catching it upon the wing or pouncing upon it after settling. It is true that this predatory deftness may have been acquired in relation to the chase of insects other than Lepidoptera, but unless the birds recognised butterflies in general—a group which cannot be mistaken for other insects—as part of their natural prey, it is difficult to understand their eager excitement at the sight of those I offered them."

As an explanation for the conduct of the birds in Mr. Pocock's experiments the first quotation above seems to me sufficient as regards the avidity with which the birds in the gardens pursued butterflies. As regards the deftness with which the birds caught them, it would seem very remarkable indeed if an insectivorous bird normally taking its prey upon the wing could not catch insects relatively so slow and clumsy on the wing as butterflies. The highly theoretical suggestion that "birds recognise butterflies as part of their natural prey" seems to me fanciful, entirely unnecessary, and certainly not preferable to Mr. Pocock's first explanation for the eagerness with which all insect food was received by the captive birds.

As to the converse, it would seem more reasonable and plausible to attempt to explain the deftness of the dodging butterflies as arising from the admittedly frequent pursuit of butterflies by one another rather than from the supposed attacks by birds.

The pertinency of experiments made under such abnormal conditions and the validity of conclusions reached from them are open to serious question. McAtee (*Journ. Econ. Entom.*, vol. iii., pp. 437–8, 1910) has very well shown the futility of basing conclusions as to their natural food upon experiments with birds removed from their natural environment. He cites a number of cases of captive birds which refused specific articles of food known to constitute a large part of their normal diet, and of others which willingly accepted food which they never get in their wild state. For examples, a confined blue jay refused acorns and beech nuts; a captive bluebird refused one of the ground beetles, *Scarites subterraneus*, and a caged song sparrow refused seeds of lamb's quarter and smartweed; yet these birds in a wild state are known to take these respective foods in quantity. On the other hand, a captive shrike willingly accepted and devoured a goldfish and a black bass, food it probably never takes in the wild state.

Since Mr. Pocock implies that I am one of "the dwindling minority of mimicry sceptics," I should like to suggest that before he assumes too much regarding this "dwindling minority," he make a census of the opinions of working zoologists (with reference to the usefulness of this particular case of mimicry, for example) and learn where the majority actually stands and toward which side of the question the dwindling really tends.

A. M. Banta.

Cold Spring Harbor, N.Y.

From Mr. Banta's concluding paragraph I am afraid my reference to the disbelievers in mimicry as a dwindling minority hurt his feelings. I hasten, therefore, to explain that it was written in a spirit of "chaff," without any intention to give umbrage. Apart from this, there is nothing in my contributions to the question of the distastefulness of *Anosia plexippus* which, in my opinion, needs explanation or qualification. The statistics Mr. Banta quotes to prove that North American birds do not eat butterflies are full of interest. They show at all events that the birds examined had not eaten butterflies within a few hours of being shot, and they justify the belief that the birds in the areas investigated do not trouble themselves to catch butterflies when other insects are obtainable. It would be very interesting to know if the Department of Agriculture found empty stomachs in any birds shot in districts where butterflies of various kinds were plentiful and other insects scarce. That would be a very important piece of evidence in favour of the contention Mr. Banta upholds.

There is perhaps nothing so impressive in connection with the theory of mimicry as the vast amount of corroborative evidence that has been accumulated since it was first propounded. This stands out in strong contrast to the complete inadequacy of the explanation of the facts on which it is based put forward by its opponents. The repetition of this truism is prompted by Mr. Banta's suggestion that the skill butterflies display in evading the swoop of insectivorous birds has been acquired, not, be it observed, in connection with the pursuit of voracious enemies, but in connection with the apparently often sportive chase of one butterfly by another. If we push this argument to its logical conclusion, we must also explain the vanishing of many butterflies when they alight as the result of that same factor. With this view I can only say that I do not agree.

R. I. Pocock.

Zoological Society, April 27.

Clouds and Shadows.

In a letter to Nature (April 18) Mr. Chas. Tilden Smith directs attention to a peculiar shadow he noticed in the western sky last Easter Monday after sunset, and which he no doubt correctly attributed to "some unseen object intercepting the sun's rays," and so casting a shadow on the high and still directly illuminated stratus he mentions.

Such shadows are by no means uncommon in lower latitudes, and are certainly caused either by clouds, especially the towering columnar cumuli (so common in the Caribbean Sea) or by mountains. For many years past the writer has been collecting data regarding such shadows and working out the position, size, and shape of the objects causing them. He has succeeded in (*a*) predicting correctly the form, position, and duration of the shadows caused by *mountains* for a sunset viewed from a known position (supposing that clouds did not interfere), *e.g.* from a ship to the east of Cuba, in which case it was possible to assign some of the observed shadows to definite peaks; and (*b*) he has succeeded in (conversely) deducing from the observed positions and forms of these shadows the general configuration of the mountain ranges which caused them—*e.g.* off the eastern coast of Brazil.

Such shadows to be seen well require (1) a clear lower atmosphere, and (2) a reflecting layer at a considerable height—*e.g.* six miles.

The writer hopes to be able before long to publish these and many other observations and deductions, together with the formulæ necessary for the analysis of this part of a sunset.

T. C. Porter.

Upton, Slough, May 3.

THE ROYAL ACADEMY AND NATURE-STUDY.

The annual exhibition of pictures at the Royal Academy always affords a good opportunity of examining the works of the several contributors as far as they may be considered representations of natural phenomena.

The following notes have therefore been made regarding such points as clouds, sun, moon, sunset skies, &c., and these are brought together under their respective heads.

Mists.

163. *The Cradle of the Storm. Frank T. Carter.* The mist or low drifting cloud about the mountains is here beautifully portrayed, and the swirl-forms indicate local eddies; the lighting is very true.

190. *A Highland Loch. Peter Graham, R.A.* Beautifully graded mists on the mountain sides, and the effect of the rift, which is an important feature in the picture, is well indicated.

Clouds (Nimbi or Rain Clouds).

22. *The Midlands. C. E. Johnson.* Cloud forms and colour very good. Excellent representation of a rain squall on the right.

169. *The Hunters. C. Napier Henry, R.A.* Form and colour and general arrangement of the clouds quite natural.

170. *Dryslwyn. T. Hodgson Liddell.* The cloud forms here are accurately shown, but the falling rain is not well represented, being not sufficiently transparent for such a close squall.

184. *A Passage Perilous Maketh a Port Pleasant. W. L. Wyllie, R.A.* The cloud forms and colour here are very natural, and the reflection on the water true.

189. *The Passing Snowstorm. Ernest Procter.* The clouds here are too dark and coarse. (When looked at from some distance the effect is improved.)

193. *Bredon on the Avon. Alfred Parsons, R.A.* Both form and colour of the clouds beautifully represented. A fine cloud study and one to be copied.

221. *Rain Clouds: Bosham. Moffat Lindner.* The large nimbus is far too solid-looking and lacking in detail. Such a cloud in nature is full of detail, both in structure and light gradations. As here depicted it looks like a lump of dough.

285. *The Approaching Shower. Beatrice Bland.* Both the clouds and falling rain are well represented. The shower, however, is not approaching but travelling nearly from left to right, as indicated by the slant of the falling rain.

117. *The Approaching Gale. Julius Olsson.* The clouds and waves are both good in form, but why the violet colour in both?

359. *Stormy Evening on the Cornish Coast. Julius Olsson.* This picture, like 117 above, is too violet all over.

360. *Evening on the Nebelhorn, Bavaria. Edward T. Compton.* The contrast between the fair weather on the right of the picture, the approaching rain clouds on the left, and the brightly illuminated snowfields in the foreground is well thought out and rendered very true.

Clouds (Cumuli, Fine Weather Clouds).

20. *Woodland and Hill. Sir E. A. Waterlow, R.A.* Very fine representation of clouds with excellent detail and gradation. Perhaps some of the upper portions of them are not white enough.

40. *The Incoming Tide: Porth, New Quay. B. W. Leader,* R.A. Good cloudscape, but must not be looked at too closely to obtain desired effect.

81. *Submarines and Torpedo Craft: Old Portsmouth. W. L. Wyllie, R.A.* Most excellent clouds, showing the result evidently of much observation. Indications of ascending air and upper horizontal air currents very natural. Reflection on water well graded.

115. *The Hills of Appin. J. Campbell Mitchell.* Forms of clouds most unnatural. Too much drawn out vertically, and little detail shown.

162. *Marazion Marsh, Cornwall. J. Noble Barlow.* Clouds badly formed, and, like those in 115, too vertical.

323. *The Home of Labour. E. Blair Leighton.* No idea of cloud form, and lighting all wrong. Clouds are drawn out like 115 and 162.

393. *"The Toiling Year's Last Breath." Frank Walton.* The clouds are good, both in form, detail, colour, and gradation. Their lower flat surfaces should be horizontal and not all inclined similarly.

461. *The Walls of England. R. Gwelo Goodman.* Absolutely impossible skyscape.

582. *Spring Sunshine. Alfred Parsons, R.A.* The cumuli clouds and sky are here very naturally depicted, and the artist has blended the sky with the landscape most successfully. The tints of the blossoms on the trees are true and admirably represented.

755. *A Fine Morning on the Sussex Coast. B. W. Leader, R.A.* A well-painted and natural skyscape with the same proviso as 40.

129. *The Mass at Dordrecht. Moffat Lindner.* Well-shaped cumuli and good reflections of clouds in water.

198. *Skirt of the Dunes at Condette, Pas-de-Calais. H. W. B. Davis, R.A.* Gradation of blue sky from horizon upwards is possibly changed too suddenly.

Clouds (Cirrus, High Clouds).

390. *A Gentle Breeze. Hon. Duff Tollemache.* Form and colour of the cirrus cloud very natural.

505. *Fifteen-metre Yachts Rounding the East Lepe Buoy: Cowes Regatta. Alice Fanner.* The cirrus cloud in this seascape is very good. The small cumuli and wisps of cirrus very natural.

689. *Six-metre Yachts Racing at the International Regatta, Solent,* 1911. *Alice Fanner.* The cirrus clouds are well represented.

Sunsets, Sunrises (Sky).

13. *Scur-na-Gillian, Sligachan. Finlay Mackinnon.* A beautiful picture with a bold effect of sunset. Is not the near side of the right-hand peak too much illuminated?

55. *Evening on the Sands of Towyn. B. W. Leader, R.A.* A fine sunset sky; shape and colour of clouds very true. Reflection in water and breaking wave very effective. A fine picture.

147. "*The Day was Sloping towards his Western Bower.*" *Joseph Farquharson, A.* Have we not here a too great diversity of colours? Should not the yellow tinge be more universal and be more represented on the hill on the left (which seems too pink) and also on the under portions of the clouds?

205. *Evening's Last Gleam. B. W. Leader, R.A.* A fine study and lighting excellent. The sunlight on the upper portion of the clouds very effective.

429. *The Matterhorn, from the Triftkummen: Sunrise. Edward T. Compton.* The colours here are very true in tone, and the wisps of mists on the mountains appear already to be in the process of being dissipated.

465. *The Prize. Donald Maxwell.* A bold picture. Very striking sunset effect, both in the sky and by reflection. Excellent colouring.

660. *A Peaceful Valley. Hon. Walter James.* This sunset scene is accurately painted, and the cloud forms, colouring, and general gradation of the tones very true. The atmospheric absorption in the distant landscape naturally indicated.

790. *Into the West. Robert W. Allen.* The sequence of the colouring at the different altitudes very natural. The type of cloud represented is true, but there is not sufficient of the sunset colours reflected in the water.

Sun's Disc.

29. *The Wane of an Autumn Day. J. Coutts Michie.* The disc of the sun is very much too large, and, judging by the angles subtended by the objects in the foreground, it is more than twice the size it should be.

Moon.

353. *Moonrise: the Dunes, Pas-de-Calais, France. H. Hughes-Stanton.* The full moon much too large, judging by the trees in the foreground.

369. *Moonlight on the Cornish Riviera. R. Borlase Smart.* Moon too large for similar reasons; also sky around the moon too blue.

782. *Moonrise over the Marsh. Stuart Lloyd.* The moon here is more natural, but still a little too big judging by the trees in the foreground.

122. *Evening. William Brock.* In this picture only a small portion of the upper part of the moon is seen above the horizon. By its horizontal extent and curvature it is very much too large, and calculations suggest that if the whole disc were visible it would be three or four times too large.

123. *Twilight. Fred Hall.* The size and colour of the moon are good. The woman and cattle in foreground are perhaps too much illuminated.

151. *An Autumn Evening in the Alps. Adrian Stokes, A.* The sun is here supposed to be below the horizon on the right, consequently the visible illuminated portion of the moon ought to be leaning slightly over to the right also, and not as shown. The clouds are also too bright relative to the moon.

Rainbow.

468. *The Home Port. W. Ayerst Ingram.* This would be a fine picture if the rainbow were omitted. The sun is setting on the right of the picture more than 90° away from the observer. This can be gathered from the position and sunlight on the ship in the centre of the picture and other illuminated objects. As one of the fundamental conditions for seeing a rainbow is that the sun should be at the back of the observer, it is not possible for a rainbow to be included in the picture under the existing sunset position.

Reflections.

167. *A Little Mishap. Sir E. J. Poynter, Bart., P.R.A.* An excellent study of reflections.

William J. S. Lockyer.

INTERNATIONAL ASSOCIATION OF CHEMICAL SOCIETIES.

The International Association of Chemical Societies held its first formal meeting in Paris in April, 1911, when the delegates nominated by the French, German, and English Chemical Societies met and ratified the statutes of the association, the council of which as at first constituted consisted of Profs. Béhal, Hanriot, and Haller representing the *Société Chimique de France*, Profs. Jacobson, Ostwald, and Wichelhaus representing the *Deutsche chemische Gesellschaft,* and Profs. Frankland, Meldola, and Sir Wm. Ramsay representing our Chemical Society. The second conference was held in Berlin last month, under the presidency of Prof. Ostwald and the vice-presidency of Prof. Wichelhaus, when the council was further enlarged by the addition of Profs. Carrara, Oglialoro, and Paternò representing the Italian Chemical Society, Profs. Kurnakow, Tschugaeff, and Walden representing the Russian Chemical Society, Dr. Day and Profs. Noyes and Richards representing the American Chemical Society, and Profs. Fichter, Guye, and Werner representing the Swiss Chemical Society. Certain other societies representative of Holland, Denmark, Austria, and Norway were also affiliated, but were not directly represented on the council. Prof. Meldola, having been unable to attend the meeting, withdrew from the representation of the Chemical Society, and was replaced by Prof. Crossley.

The first work of the Association is the consideration of the nomenclature of inorganic and organic chemistry and the unification of the notation of physical constants. In connection with the latter part of the programme, the committee has been strengthened by the addition of M. Marie, of the French Society of Physical Chemistry. The English committees appointed to report upon these preliminary branches of work are, for inorganic nomenclature, Sir Wm. Ramsay, Dr. J. C. Cain, and Dr. Harden; for organic nomenclature, Profs. Kipping and Wynne and Dr.

Cain; and for physical constants, Drs. Wilsmore and Cain and Prof. Findlay. Dr. Cain's services have been secured for all three committees in view of his editorship of the publications of the Chemical Society. The other chemical societies have also appointed influential committees to deal with these same subjects, and the reports of these committees were considered at the Berlin congress last month. At this gathering thirteen societies having a total membership of 18,000 were represented. The next meeting of the Association is to be held in London in September, 1913, under the presidency of Sir Wm. Ramsay, when, in addition to the subjects already being dealt with, the question of the possibility of arriving at an international understanding with respect to editing and to the publication of abstracts will be considered.

In view of the overlap and duplication of publication now being carried on by several societies all doing the same kind of work, it will be seen that great need exists in the interests of chemical literature for making a serious effort towards centralisation. This can only be done by international co-operation, and it is to be hoped that some practical scheme may be developed as one result of the useful and valuable labours which the new Association has entered upon.

MR. JOHN GRAY.

WE announced with regret last week the death of Mr. John Gray, one of the examiners of the Patent Office, and well known for enthusiastic and painstaking efforts on behalf of anthropology. Mr. Gray was born at Strichen, Aberdeenshire, on January 9, 1854. He was educated at the Aberdeen Grammar School and at Edinburgh University, where he took the second prize in Prof. Fleeming Jenkin's class in 1873. He obtained the first Royal Exhibition at the Royal School of Mines, London, in 1875, and later received the associateship in metallurgy. He took his degree in Edinburgh in 1878, and entered the Patent Office in that year.

Mr. Gray made a study of many electrical problems, especially those bearing on electrical influence machines. He published a book on this subject, in which he traced the historical development of influence machines, and described such modern forms as those of Kelvin, Voss, Holtz, and Wimshurst. He was well known for his connection with physical anthropology, and took an active part in all recent efforts to secure its recognition by the State. He was elected treasurer of the Royal Anthropological Institute in 1904, and his efforts to improve the financial condition of that body were crowned with complete success. In 1904 he gave evidence before the Interdepartmental Committee on physical deterioration, and, in conjunction with the late Prof. Cunningham, submitted a scheme for a national anthropometric survey.

At the request of the Royal Anthropological Institute, Mr. Gray organised a deputation to meet the late Sir Henry Campbell-Bannerman, the object of which was to impress on the Government the necessity of carrying out the recommendation of the Physical Deterioration Committee with regard to a national survey. He designed a number of novel anthropometric instruments, some of which are extensively used by anthropologists, and for which he received a diploma of honour at the Franco-British Exhibition.

Mr. Gray took a deep interest in his native county, and, in conjunction with Mr. J. F. Tocher, conducted a series of anthropometric measurements on the population of Aberdeenshire from 1895 to 1899, the results of which were published in the Journal of the Royal Anthropological Institute, and in the Transactions of the Buchan Club, of which he was president in 1899. In 1901–1902, along with Mr. Tocher, he advocated a survey of the colour characters of school children of Scotland, and joined the Scottish committee on its formation, the other members being Sir William Turner, K.C.B., F.R.S., Prof. R. W. Reid, and Mr. Tocher. Both he and Mr. Tocher published memoirs bearing on the results of the survey from different viewpoints. Mr. Gray's memoir appeared in the Journal of the Royal Anthropological Institute (Vol. 37, 1907). In this memoir Mr. Gray gave his views on the distribution of colour in Scotland, and displayed local groupings by a system of contour lines in a series of maps.

Mr. Gray's many contributions to anthropological literature include the following:—"Measurements on Papuan Skulls" (J.R.A.I., 1901), "Indian Coronation Contingent" (B.A. Report, 1902), "England before the English" (B.A. Report, 1906), "A New Instrument for Determining the Colour of the Hair, Eyes, and Skin" (*Man*, 1908), and "Who Built the British Stone Circles?" (NATURE, December 24, 1908). Mr. Gray is survived by a widow and one daughter.

NOTES.

THE French Ambassador took the chair on May 3 at the first of the series of four lectures being delivered by M. Henri Poincaré on mathematical subjects at the University of London: the two remaining lectures will be given on May 10 and 11. M. Poincaré, who was born in 1854, was educated at the lycée at Nancy, entered the École Polytechnique, being placed first on the list, and on leaving it became a Government mining engineer (*ingénieur des mines*), this employment being reserved for those who occupy very high places at the *examen de sortie* of the school. He exercised this profession only for a short time; in 1881 he was appointed to a lectureship in pure mathematics at the Sorbonne, and when M. Lippmann exchanged the chair of mathematical physics for a chair of experimental physics, M. Poincaré succeeded him. Later, on the death of M. Tisserand, M. Poincaré succeeded to the chair of mathematical astronomy. He has made contributions of the greatest importance to pure and applied mathematics, astronomy, and mathematical physics, and also to scientific method, with which he has dealt in his books, "Science et Hypothèse" and "La Valeur de la Science." There is no mathematician living of greater eminence, and probably none whose writings cover so wide a field. It is the historic custom of the French Academy to number amongst its members one or two of the members of the Academy of Sciences whose reputation is best known to the world at large, and after the death of M. Berthelot (though not, we believe, as his successor) M. Poincaré was appointed to that body. M. Poincaré is a cousin of M. Raymond Poincaré, the French Premier.

The Bill for the Protection of Ancient Monuments, introduced by Earl Beauchamp, has now passed its second reading in the House of Lords. The provision by which the right of pre-emption of valuable sites in the event of sale is reserved to the State was opposed by Lord Curzon in an impressive speech, in which he urged that the example of the destruction of historical buildings like Temple Bar and Tattershall Castle justified the extension of the powers at present possessed by the Government in such matters. But he pointed out the improbability of the Treasury granting funds for the purchase of such monuments, and he urged that the Society for the Protection of Ancient Buildings, which had been in existence for nearly forty years, should have a representative on the Advisory Board, and that a subordinate board should be formed in Scotland to report to London. Further additions to the staff of inspectors were also advisable. He made the startling suggestion that, as matters stand at present, the vicar and churchwardens of Stratford-on-Avon might remove the bust of Shakespeare from the church under their control. The Archbishop of Canterbury remarked that a faculty was necessary in the event of such a proposal, but he seemed to be inclined to admit that more rigid supervision over restorations and the disposal of church plate and stained glass should be provided through the diocesan courts.

In a recent letter to *The Times*, apropos of a case in the Law Courts, Dr. G. F. Herbert Smith commented on the difficulty with which jewellers are confronted owing to the success that has been achieved in the manufacture of rubies. In the case in question the stones were styled reconstructed, but they were no doubt synthetical stones formed by the fusion of alumina powder by the method described by Prof. A. Verneuil in 1904. The former term is properly restricted to the cloudy, inferior stones resulting from the fusion of fragments of natural rubies. In both processes the colouring agent is chromic oxide. According to one witness, an expert jeweller could immediately detect a reconstructed ruby, because it had a different colour and lustre. While possibly true of the reconstructed, it is certainly not true of the synthetical stones. Owing to the essential identity of the molecular constitution the latter have the same lustre as natural rubies, and, although the artificial stones are usually made of one particular shade of red, yet the same tint is common in natural stones. Discrimination is, however, easy, because the synthetical rubies invariably contain faint curved markings and a few tiny, spherical bubbles. A simple and trustworthy test of this kind is very important on account of the great disparity between the prices of the two kinds of rubies. Men of science may consider the synthetical stones of greater interest; the general public views them otherwise.

April, with its total rainfall of 0·02 in. at Greenwich, is not only the driest April on record, but it is drier than any month at any period of the year during the last 100 years. The absolute drought at Greenwich, which has now been brought to a close, continued for twenty-three days, from April 10 to May 2, which is the same length of time as the longest drought in the memorable summer last year, when no rain fell from July 1 to 23. The London area has only experienced about five droughts of a longer period during the last fifty years. The aggregate rainfall at Greenwich from March 24 to May 3, a period of forty-one days, was only 0·10 in., and the total fall from March 24 to May 6, a period of forty-four days, yields 0·29 in. The partial drought, not exceeding 0·01 in. per day, may be prolonged into May, but it cannot claim to be thrown further back into March. Some further results yielded by the observations published in the Daily Weather Report of the Meteorological Office show Oxford to have experienced an absolute drought for twenty-three days, and a partial drought from March 24 to May 3, with 0·18 in. of rain, whilst the total to May 2, a period of forty-one days, only measured 0·07 in. At Nottingham the absolute drought continued for twenty-two days, from April 11 to May 2; at Jersey twenty-two days, from April 12 to May 3; at Bath, twenty-one days, from April 13 to May 3, and the aggregate fall at Bath from March 24 to May 6, a period of forty-four days, is 0·57 in. The copious rains during the early part of March and throughout the past winter naturally rendered the recent drought far less serious than many previous spring droughts of somewhat recent years. An entirely different type of weather seems now to have set in, and the conditions have become favourable to a series of disturbances arriving over us from the Atlantic, so that fairly copious rains may be anticipated.

One of the chief objections to the Daylight Saving Bill is the dislocation the scheme would effect in the zone system of time reckoning established by international conferences held successively in Rome and Washington thirty years ago. Mr. W. Ellis, F.R.S., refers particularly to this point in a short article in the March number of *The Horological Journal*. At present the prime meridian of Greenwich regulates the time of the civilised world. If the clocks of Great Britain are put forward one hour in summer, as proposed by the Bill, they will not show Greenwich time, but mid-European time; that is to say, our prime meridian, accepted by nations as regulating the time of the world, will be discarded by us for five months in every year, in total disregard of existing well-considered and well-established international relations. An Act to enforce the alteration of clocks by putting them forward for one hour in summer would introduce confusion in a scientific system and disturb accepted international standards. We cannot believe that such a proposal will ever be seriously entertained by Parliament. A more promising subject to which attention may usefully be directed is the reckoning of hours from one to twenty-four in order to avoid the designations of a.m. and p.m. The Nord and Est Railway Companies of France have just introduced this twenty-four hour system for their clocks and time-tables, and the Orient express is now timed to leave the Paris Gare de l'Est at 19h. 13m. instead of 7.13 p.m. as heretofore, while on the station clocks the figures from 13 to 24 have been inscribed on the face within the outer circle of the existing hour figures. It would be a decided advantage if the 24-hour method of describing time were adopted in Great Britain.

AT the meeting of the Institution of Electrical Engineers on May 16, a marble bust of the late Lord Kelvin will be presented to the institution on behalf of Lady Kelvin.

THE governing body of the Imperial College of Science and Technology has appointed Mr. W. Frecheville to be professor of mining in the Royal School of Mines, in succession to Prof. S. Herbert Cox, who is about to retire.

MR. WALTER E. ARCHER, C.B., who, as assistant secretary, has been in charge of the Fisheries Division of the Board of Agriculture and Fisheries since its establishment in October, 1903, has been compelled to retire from the public service owing to ill-health. His retirement took effect on May 1.

WE are informed by Dr. Shaw, director of the Meteorological Office, that the superintendent of the observatory at Eskdalemuir, Dumfriesshire, reports that the seismographs at the observatory recorded a violent earthquake on May 6, at 7 p.m. The position of the epicentre is 63° N. latitude, 21° W. longitude, which indicates a place in the Atlantic not far from Iceland, to the south-west of the island.

MR. H. C. K. PLUMMER has been elected by the Board of Trinity College, Dublin, to be Royal Astronomer in Ireland, in succession to Dr. E. T. Whittaker, who was recently elected professor of mathematics at Edinburgh University. Mr. Plummer is the son of Mr. W. E. Plummer, director of the Liverpool Observatory, and has been second assistant to Prof. H. H. Turner at the Oxford University Observatory since 1901.

ON Tuesday next, May 14, Prof. W. Bateson will begin a course of two lectures at the Royal Institution on "The Study of Genetics," and on Thursday, May 16, Prof. H. T. Barnes will deliver the first of two lectures on "The Physical and Economic Aspects of Ice Formation in Canada." The Friday evening discourse on May 17 will be delivered by Mr. W. Duddell on "High-frequency Currents," and on May 24 by Mr. A. D. Hall on "Recent Advances in Agricultural Science—the Fertility of the Soil."

THE services of the official guide to the collections at the British Museum, Bloomsbury, have been so highly appreciated that a similar officer has been appointed, experimentally, at the Natural History Museum, South Kensington. Mr. J. H. Leonard has been selected for the position, and he will probably take up his duties before Whitsuntide. The guide will make two tours of the museum daily, each tour lasting an hour. Provision will also be made for special tours, and for these, special application will have to be made.

AT the annual general meeting of the Institution of Civil Engineers held on April 30, the following were elected president and vice-presidents:—*President*, Mr. Robert Elliott-Cooper; *vice-presidents*, Mr. A. G. Lyster, Mr. B. H. Blyth, Mr. J. Strain, and Mr. G. Robert Jebb. The council of the institution has made the following awards for papers read during the session 1911–1912:—Telford gold medals to Messrs. E. and W. Mansergh; a George Stephenson gold medal to Mr. R. T. Smith; a Watt gold medal to Mr. A. H. Roberts; Telford premiums to Messrs. J. Goodman, A. B. McDonald, G. M. Taylor, D. C. Leitch, W. C. Easton, and D. H. Morton; and the Manby premium to Mr. S. H. Ellis.

IN the report of the council of the Chemical Society presented at the annual general meeting on March 28, and published in the last number of the Proceedings, it is stated that in the opinion of counsel any person using the letters "F.C.S." without authority and for the purpose of wrongfully assuming the status of a fellow of the Chemical Society, can be restrained by injunction from so doing. Mention is made that the Becquerel memorial lecture is to be delivered by Sir Oliver Lodge in the place of Prof. Rutherford. In connection with the publication of the Journal it is stated that the cost is about 5200*l*. a year, which represents about five-sevenths of the society's income. The congratulations of the council have been offered to Mr. E. Riley, who has completed sixty years of fellowship, and to Major C. E. Beadnell, R.A., Mr. H. O. Huskisson, and Mr. F. Norrington, who, during 1911, attained their jubilee as fellows.

FURTHER particulars have been received of the arrangements in connection with the International Congress of Applied Chemistry, to be held in Washington and New York next September, to which reference has been made on previous occasions. It is stated that 573 papers have now been definitely promised to the respective sections. Five general lectures have been arranged: Mr. George T. Beilby, F.R.S., of Glasgow, on "Some Physical Aspects of Molecular Aggregation in Solids"; Prof. Gabriel Bertrand, of Paris; "Des rôles des infiniment petites chimiques en chimie biologique"; Prof. Carl Duisberg, of Eberfeld, "The Latest Achievements and Problems of the Chemical Industry"; Prof. Giacomo Ciamician, of Bologna, "La foto chimica dell' avvenire"; and Prof. Ira Remsen, of Baltimore, "Priestley in America."

MR. W. J. L ABBOTT contributes to the July-December issue of the Journal of the Royal Anthropological Institute a useful article on the classification of the prehistoric British stone industries. He points out the danger of assuming that the evolution of culture has progressed along a line of unbroken chronological sequence, and he shows that the evidence derived from our river deposits must be accepted with the qualification that in different areas there have been tectonic movements and phenomena attending differential elevation, depression, and denudation, which have contributed to destroy a consecutive altitudinal chronology. Palæolithic man being a nomad, he constructed his implements according to hereditary custom, while discoveries of improved methods were not easily disseminated over the wide areas occupied by these wandering groups. In the course of the discussion he suggests a new series of terms to designate various forms of implement. It is obvious that innovations such as these, unless accepted by a congress of anthropologists, are likely to lead to further confusion, and his proposal to assign the name "Prestwich" to one and "Evans" to another type, after two distinguished geologists and antiquaries, though based on the analogy of terms like "ohm," "watt," or "farad," is scarcely likely to meet with general acceptance.

To *The Field* of April 17 Mr. Lydekker contributes extracts from a letter from the British Resident in Nepal in regard to the so-called unicorn rams of that country, of which examples were exhibited some years ago in the London Zoological Gardens. Mr. Lydekker had previously suggested in the same journal that the fusion of the horns is due to artificial manipulation of those of young lambs of the barwal breed; and this is fully confirmed by the inquiries instituted by the Prime Minister at the request of the Resident. The budding horns of young lambs are seared with hot irons, and treated with soot and oil, after which, instead of spreading outwards, they coalesce and grow backwards.

In connection with the treaty between Great Britain, the United States, Russia, and Japan for the suppression of pelagic sealing, Dr. F. A. Lucas contributes to the *American Museum Journal* for April an article on the Alaskan fur-seal. "The fur-seal," he observes, "would long ago have been swept out of existence but for the fact that the breeding-grounds are carefully guarded, and while the herd is but a tithe of its former size, it still comprises many thousands. If pelagic sealing can be brought to an end, the seal-herd will recuperate rapidly, even though the death-rate is high, and not more than half the seals born in any one season live to return the next. Whether or not this desirable end can be brought about remains to be seen, and some of us are not very hopeful."

The twenty-second annual report of the Missouri Botanical Garden contains two long papers on the genus Agave, by Dr. Trelease, who also contributes a shorter paper on two new Yuccas. The Agave memoirs are illustrated by no fewer than eighty fine photographic plates, numerous new species being described, chiefly from Lower California. A further instalment of Griffiths's studies on the genus Opuntia is also included; this is illustrated by seventeen beautiful plates, representing ten new species.

From two articles on *Podophyllum emodi*, in *The Indian Forester* (April, 1912) and the Forest Bulletin (No. 9), by Puran Singh, it would appear that the Indian species has strong claims on many grounds for inclusion in the new edition of the British Pharmacopœia, which is now being revised by a committee of the Pharmaceutical Society. It has been definitely established that the Indian species yields a considerably higher percentage of resin, containing the active cathartic and purgative principle podophyllotoxin, than the American species (*P. peltatum*) which has hitherto been universally employed as the source of the drug podophyllin.

No. 48 of the Scientific Memoirs of the Government of India, by Major D. McCay, details investigations into the jail dietaries of the United Provinces. It contains a mass of statistical and analytical data on the subject which will be of the greatest value. The nutritive values of the diets at present in use, and the coefficients of protein and carbohydrate absorption of the different materials entering into those dietaries, have been determined, and from the data obtained eight new dietaries of practically identical nutritive values have been framed. Certain side-issues have also been investigated. The percentage of nitrogen in the fæces is practically constant, whatever the type of diet may be, and when inferior vegetable food-stuffs are made use of the loss of protein by the fæces is very great. A final conclusion is of considerable importance: from the facts collected with regard to the inhabitants of the United Provinces and martial races of the plains, it would appear that, other things being equal, diet is the all-important factor in determining the degree of physical development and general well-being of a people, and that with a low level of nitrogenous interchange deficient stamina, morally and physically, must be expected.

The meteorological chart of the North Atlantic for May, issued by the Meteorological Office on April 18, includes synoptic weather charts for April 8–17. During this period a large anticyclone moved north-eastward from the southern part of that ocean. The weather was fair over western Europe, but to the westward of longtitude 30° W. conditions were changeable and showery. The latest ice reports from Canada referred to the existence of heavy, close ice and numerous bergs in Belleisle Strait; off Cape Race (Newfoundland) no ice was visible. Mention is made of the fact that the bergs which appear annually in the North Atlantic have their origin, as a rule, in western Greenland; only a few come from Spitsbergen, and still fewer from Hudson's Bay. The mean limits of field-ice and of icebergs in May are laid down on the chart, the extreme boundaries being about 42° N., 45° W., and 39° N., 40° W. respectively.

A lecture on daylight delivered by Prof. E. L. Nichols before the Franklin Institute is reproduced in the April number of the Journal of the Institute. In addition to a summary of the facts about daylight, which are comparatively well known or can be found in a standard work like Pernter and Exner's "Meteorologische Physik," it contains an account of the measurements made by the author at home and in Switzerland by means of a spectrophotometer. These cover such subjects as the relative brightness of clear and partially or wholly clouded sky, the distribution of light of different wave-lengths in daylight at dawn and later, the effect of mist or an approaching storm on the distribution, and, lastly, the means taken in artificial illumination to imitate daylight.

IN the February number of the Bulletin of the Academy of Sciences of Cracow, Prof. Natanson has an article on the energy content of material bodies in which he points out an important distinction between Prof. Planck's theory of radiation and Prof. Einstein's idea that every material body consists of an assemblage of Planckian vibrators, the energy of which constitutes the heat energy of the body. While in the general theory of radiation it is unnecessary to inquire how many vibrators of a given period are present per gram of a material, so long as the interchange of energy of different wave-lengths can be effected by their means, in the latter theory it is of fundamental importance to determine the number of each kind present. Without this knowledge Prof. Einstein's interesting theory cannot be pursued further.

IN the course of a valuable paper on "Some Aspects of Diesel Engine Design," read by Mr. D. M. Shannon at the Institution of Engineers and Shipbuilders in Scotland, the author takes up the important question of the proper design of cams for operating the valves. The noise caused by some cam and roller gears is due principally to two causes, the first and greater being the speed with which the cam strikes the roller, and the second being the valve striking the seat. The latter need cause no inconvenience, since it occurs inside the cylinder, and is therefore of a muffled nature. To get rid of the former cause, the flat part of the cam profile should slide under the roller at a tangent, and should grip the roller with no velocity. If this is done, the valve can then be pushed open as rapidly as desired. The closing of the valve should be obtained in a similar manner. Diagrams are given showing the abrupt changes in speed and acceleration produced by a badly designed cam, and are contrasted with the curves given by a cam properly designed. There are many makers of internal-combustion engines who might profit by a careful study of Mr. Shannon's paper.

MESSRS. J. AND A. CHURCHILL have just ready for publication vol. vi. of the new edition of "Allen's Commercial Organic Analysis." This volume has been rewritten under the editorship of Mr. W. A. Davis and Mr. S. S. Sadtler.

AMONG the new books and new editions announced for publication by Messrs. C. Griffin and Co., Ltd., are the following:—"Practical Agricultural Bacteriology," Prof. Lohnis, translated by W. Stevenson; "Notes on Foundry Practice," J. J. Morgan; "Modern Road Construction," F. Wood; "Modern Pumping and Hydraulic Machinery," E. Butler; "Calculations on the Entropy Chart," Dr. W. J. Crawford; "The Evolution of the Internal Combustion Engine," E. Butler; "The Gas Turbine, Theory, Construction, and Working Results of Two Machines in Actual Use," H. Holzwarth, translated by A. P. Chalkley; "A Manual of Marine Engineering: comprising the Designing, Construction, and Working of Marine Machinery," A. E. Seaton; "A Treatise on Mine Surveying," H. Brough, revised by Prof. S. W. Price; "Electrical Photometry," Prof. H. Bohle; "Celluloid," a translation from the French of Masselon, Roberts, and Cillard, by Dr. H. H. Hodgson; "A Handbook on Metallic Alloys," G. H. Gulliver; "Mathematics and Mechanics for Technical Examinations," C. A. A. Capito.

OUR ASTRONOMICAL COLUMN.

A BRILLIANT METEOR.—A meteor of unusual brilliance and low velocity was observed by Mr. Rolston at South Kensington at 9h. 46m. (G.M.T.) on May 2. The approximate commencement and end of the flight were at $150°+14°$, and $142\frac{1}{2}°$, $0°$, respectively, and the time occupied in traversing the path was estimated as at least two seconds. Both in colour and brightness the meteor was very like Arcturus, and no train was visible along which it had passed. The position of the commencement of the apparition is a little uncertain, because Mr. Rolston was not actually engaged in watching for meteors, his attention being first directed to the phenomenon by its extraordinary brightness.

NOVA GEMINORUM, NO. 2.—In No. 4569 of the *Astronomische Nachrichten*, Prof. Max Wolf publishes some remarks on the apparently periodical changes in the structure of the complicated hydrogen bands in the spectrum of Nova Geminorum. As Prof. Iñiguez has pointed out, the most intense portion of each band has changed its position in the band, and Prof. Wolf finds that a certain periodicity is displayed by the variations. The brightest part moves gradually, first towards the red and then towards the violet, the changes taking place in regular steps in about fourteen, or seven, days. Thus on March 15 and 29 the dark absorption line in the $H\delta$ band, at $\lambda 4093$, became obvious, and on April 13 the structure of the band was similar to that which obtained on March 17. It is suggested that the seven-day magnitude variation remarked by Dr. Kritzinger may be related to these changes in the structure of the spectral bands.

FAINT STARS WITH LARGE PROPER MOTIONS.—The comparison of photographs of several star clusters taken in 1909–10 with the large Pulkowa astrograph with similar plates taken eleven to fifteen years earlier has disclosed a number of large proper motions, of which Herr Kostinsky gives particulars in No. 4569 of the *Astronomische Nachrichten*. The magnitude of the proper motions was measured in the first place with a Zeiss stereocomparator, and was shown in every case to be more than $10''$ per century on a great circle. The annual motions of the seven stars described range from $0.113''$ to $1.111''$ on a great circle. Four pairs of plates, having intervals of about one year, show that the star BD$+53°$ 2911 (mag. 9.5) has a mean annual proper motion of $1.23'' \pm 0.04''$; this star appears on the photographs of the Nova Lacertæ (1910) region, its position (1911.0) being 22h. 29m. 10.2s., $+53° 20' 3''$.

SOLAR PROMINENCES IN 1910.—Prof. Riccò publishes his annual (1910) summary of the prominences observed at Catania in No. 3, vol. i., series 2, of the *Memorie della Società degli Spettroscopisti Italiani*. It shows that while from month to month the mean frequency of prominences varied irregularly, there was, on the whole, a regular decrease in the northern hemisphere, while the frequency was fairly constant in the southern. For the four trimestres the frequencies were:—N. hemisphere, 2.3, 1.5, 1.1, and 0.4; S. hemisphere, 1.4, 1.3, 1.3, and 1.3, respectively, the mean frequencies for the year being 1.3 in each hemisphere. This gives 2.6 as the mean frequency for both hemispheres, a value notably smaller than that for the immediately preceding years; the dimensions of the prominences showed a similar decrease, while the mean latitude was a little higher, and the prominences more evenly distributed, in both hemispheres.

THE ECLIPSE OF THE SUN, APRIL 17.

Referring to Dr. Marie Stopes's observation of a halo about the eclipsed sun on April 17, Mr. Patrick Hepburn writes that Mrs. Hepburn, observing from near the central line in France, noticed what seemed to be rather of the nature of a corona than a halo, although they concluded that it had no connection with the true solar corona; it was coloured, with the violet outwards. Mr. C. O. Bartrum also discusses this phenomenon, and from two friends, one of whom saw the eclipse from near Paris, the other from Highgate, he gathers that "the appearance of a circle round the sun" seems to have been a corona due to diffraction, the colours appearing purer and brighter than usual because of the reduction in the effective size of the sun.

On photographs taken at Funchal (Madeira), and sent to us by Mr. Michael Grabham, there is obviously light cloud producing a "corona" effect around the sun, but the halo so plainly shown on them is palpably a photographic halation phenomenon. Another photograph shows several excellent crescentic images projected on to a wood floor through the foliage of stephanotis.

Mr. A. A. Buss writes that the time of his prominence observations (Nature, April 25, p. 193) was from 8.0 to 8.30 a.m. The positions he gave agree very well with prominences photographed by M. Deslandres (Nature, May 2, p. 221), although Mr. Buss did not note the large prominences in 47° N. lat. (E.) and 47° S. lat. (W.) as being especially conspicuous; the position angles would be about 17° and 197° respectively. But Mr. Buss observed visually in Hα radiation, while M. Deslandres used the K (calcium) radiation for his spectroheliograms; this and the difference in time would readily explain the apparent changes, especially as the fact that considerable prominence activity occurred on the day of the eclipse is confirmed by both observers. Mr. Buss states that prominences were seen near p.a. 117° from April 14 to 29, thus forming a chain extending more than half-way round the sun; the western extremity of the chain was detected at the W. limb towards the end of the month. Possibly the Hα spectroheliograms taken during this period will show magnificent "filaments" in the position indicated. Mr. Buss pictures the grandeur of such phenomena could they be spectroscopically observed from a position in space on the sun's axis prolonged.

Mr. Worthington, who, with Mr. Slater, was operating near Ovar, secured a photograph of the bright chromospheric arcs, which shows a large number of lines between λ3100 and D. Only the lower halves of the chromospheric circles are shown, the upper halves being lost in continuous spectrum, probably produced by portions of the sun which remained uncovered at the moment of exposure. The original negative is deposited at the Royal Astronomical Society's rooms, as were those secured at Vavau last year, where it may be inspected by anyone interested in the matter.

Several papers dealing with the eclipse appear in the *Comptes rendus* for April 20 (No. 18). MM. Carimey, Raveau, and Stablo describe bands of darkness which they observed from near the central line on the plateau de la Beauce. Comte de la Baume-Pluvinel was at St. Germain-en-Laye, and took a large number of kinematograph pictures of the eclipse, with a chronometer alongside, at the rate of 13 or 14 per second. A study of these gives the time of central eclipse at 12h. 10m. 4·5s. ± 0·2s., but this may be a little modified if the lunar depressions on opposite sides were not equally deep; for last contact the time determined was 1h. 32m. 7s. Four plates taken with an objective of 1·5 metres focal length show a slight aureole attributable to the corona, but no details of coronal structure. A three-prism spectroscope, with a wide slit, was directed to part of the chromosphere between two Baily's beads in p.a. about 130°. A considerable number of monochromatic images of the chromosphere were shown between λ486 and λ389, about forty appearing between H and K. At Clayes (long. 0° 21′ 9·8″ west, lat., 48° 49′ 13″ N.), MM. R. Jonast and P. de la Gorce determined the variations of the intensity of the light on a horizontal plane during the eclipse. There was a steady decrease from 50,000 units at 10h. 55m. 15·5s. to 16 units at 12h. 9m. 55·5s., then a more rapid increase to 50,000 units at 12h. 50m. 49·0s. Kinematograph pictures were taken by MM. Vlès and J. Carvallo at Cacabelos, in Spain.

MATTER AND MIND.

Sir George Reid is known to be a versatile thinker, and he shows himself to be also a philosopher in an address on "The World of Matter and the World of Mind" delivered by him recently before the Royal Scottish Geographical Society. We live on a single globe among millions of similar bodies, and we have no direct evidence of life elsewhere in space. Yet, "If living things exist only on this globe, living things are the loneliest of all the objects which the telescope can reach, or the microscope reveal, or the mind of man conceive. Man would be the loneliest of all, for he stands alone even among the living things of his own planet." Moreover, the achievements of man in the few thousand years of historic time are so brilliant in comparison with what was accomplished in the million years or so of geological man that Sir George Reid considers the argument derived from the remains of a physical structure resembling our own furnishes no conclusive proof that we are in body and soul the lineal descendants of fossilised ancestors. The principle of continuity breaks down when the evolution of mind is considered; if a Plato, Newton, or Darwin can be developed from a cave-dweller, "is not such an evolution a greater tax on human faith than the marvels of a direct creation can be?" Man, the intelligent centre of progressive life, is conscious of directive control: the will is merely the executive officer of the mind, and behind it there must be "some sort of pilotage."

This position is not new, and has been occupied by many philosophers from Aristotle to Bergson without any completely satisfactory view being obtained from it. The rise and progress of mental life, the emergence of volition, or the will to decide between reason and desire, and the idea of will behind phenomena, find no clear place in the naturalistic scheme of human evolution. Matter—whether organic or inorganic—is yielding to the importunate efforts of scientific investigators, but mind as a subject of serious study is given little attention even at the universities. Sir George Reid pleads for greater encouragement to the work of psychologists in these seats of learning, and his address should do something to save the Cinderella among the sciences from her present condition of neglect

AERIAL FLIGHT.[1]

BEGINNING with balloons, as having the priority in point of time, it may be remarked that the whole subject is included in the last 130 years dating from the experiment of the Montgolfiers, who made their first ascent in 1788, but were at work for some years before this, and that other designs quickly followed containing in principle most of the appliances which are in use to-day. The ballonet, for instance, was proposed and tried by Charles and Robert. We find also designs for dirigible balloons of much the same shapes as are now familiar to us.

All attempts at propelling these vessels naturally failed for want of adequate power, and in some cases the proposed form of propulsion was impracticable, but in others a screw of nearly the same proportions as that now in use was actually tried. It was soon found, however, that the speed which could be developed by man-power or by any engine that the balloon could lift only amounted to a few miles an hour, less, that is, than the speed of a very light breeze. Thus, so far as directing the course of a vessel was concerned, the mechanism was almost useless, and few further attempts at mechanical propulsion were made until the advent of the internal-combustion engine.

Independently of outward form, balloons may be divided into two classes, according as the lifting gas carried is (*a*) constant in mass, or (*b*) constant in volume, and these again may be subdivided according to the relation of the pressure or density of the enclosed gas to that of the surrounding air.

All the conditions, however, may be conveniently represented by supposing that the gas is contained in a massless vertical cylinder closed at the top by a fixed cover and below by a movable piston. The piston may be supposed to be free or clamped, and to be acted on by the gaseous pressures only or by any other additional force.

I do not propose here to go into the questions of the relative merits of the rigid and non-rigid forms, questions which turn on structural details rather than on general principles, but something may be said on the nature of the envelope used for retaining the hydrogen which is now usually employed for lifting purposes.

The best information on the subject is due to work recently carried out at the National Physical Laboratory at the request of the Advisory Committee for Aëronautics, and will be found in detail in their published reports.

It appears that among the fabrics in use there are enormous differences in their retentive power (that is, in the rate of the diffusion of hydrogen through them irrespective of actual leaks), differences of nearly two hundredfold appearing between the worst and best specimens.

Indiarubber coatings are the least satisfactory, allowing an escape in some cases of more than 0·7 cubic foot for every square foot of material in twenty-four hours when new, and deteriorating as time goes on. The most retentive hitherto tested are various oiled silks, goldbeaters' skin, and some other artificial membranes.

When the large surface which all dirigible shapes expose to the air is considered, it will be seen how important is the choice of material, and that with the best the necessary hydrogen renewal is not a small matter, even if no ascents are made, and may well be more than 1000 cubic feet a day for a moderately large vessel.

Much more than this, however, must be lost when the dirigible is in use. A thousand cubic feet of hydrogen gives a lifting force of about 75 lb., and the engines of one of the larger dirigibles will part with many times this weight in fuel and other ways in less than twelve hours. To keep the vessel at a constant height the lift has to be diminished or the downward force increased at the same rate. While travelling this may be effected to some extent by steering, but when stationary the balance can only be obtained by allowing the equivalent amount of gas to escape. To rise again an equal amount of ballast must be discharged. The number of ascents, therefore, which can be made without a fresh supply of hydrogen is limited by the quantity of ballast which can be carried.

We may now direct our attention to the more promising field presented by true flying machines—machines, that is, which are heavier than air and are supported by the reaction of a downward current of air called into existence by the engines in ordinary flying or by the diversion of natural upward components of the wind in soaring. It is theoretically possible also to maintain flight (without expenditure of work on the part of the flying machine) in a horizontal wind the velocity of which increases with the altitude or varies from place to place at the same level. In this case the flying machine has to descend in the direction of the wind and then turn and ascend against it. In each such cycle work is gained, and the work is obtained from the difference of wind velocities.

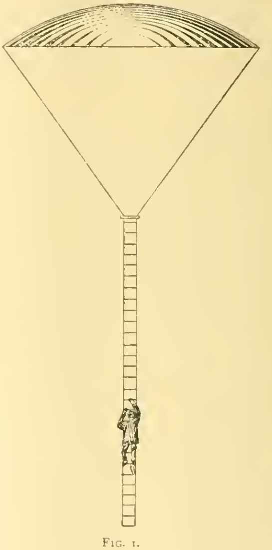

FIG. 1.

One or two examples may be given illustrating the dependence of the power required on the terminal velocity.

First take the case of a parachute, which may be supposed to be massless and to carry a long ladder up which a man climbs (Fig. 1). If the man is to maintain a constant elevation above the ground he must be able to climb as fast as the parachute falls. Now it is known from experiment that a surface such as a parachute experiences a resistance while falling through the air equal to about 14/1000 of a pound for every square foot of area at a speed of 1 foot per second. If we give the parachute a diameter of 36 feet, its area will be about 1000 square feet, and if we suppose the man to weigh 150 lb., the terminal velocity will be given by $v^2 = \frac{150}{14}$, or $v = 3{\cdot}3$ feet per second. This, of course, is much more than a man can do.

If we take a man-power as one-tenth of a horse-power, 55 feet per minute, or, at the outside, 1 foot per second, may be taken as the rate at which he can raise his own weight for any considerable length

[1] Abridged from the "James Forrest" Lecture, delivered before the Institution of Civil Engineers on April 19 by H. R. A. Mallock, F.R.S.

of time. The area which, when loaded with 150 lb., drops at the rate of 1 foot per second, is $\frac{150,000}{14\cdot 0}$, or 10,600 square feet, that is, a circle of 113 feet diameter.

With such a parachute a man could by climbing keep himself stationary in the air.

It is not necessary, in order to impart this momentum to the air, that the surface should itself have this area of 10,600 square feet. The same momentum may be given by a much smaller inclined surface moving horizontally.

If a perfectly efficient screw or inclined plane were a physical possibility, there would be nothing to prevent people from flying by their own muscular effort, and it is worth while to examine the causes which prevent the realisation of such a result.

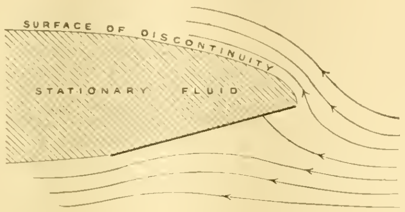

FIG. 2

We will now consider more closely the causes which produce the very marked difference between the theoretical curves given in Fig. 2 and the corresponding quantities as determined by experiment.

It is well known that the fluid with which mathematicians deal, and which is supposed to surround the plane in Fig. 2, is an ideal body which is without viscosity (that is, opposes no resistance to shear), and that in contact with a solid it experiences no frictional retardation.

In such a fluid pressure and velocity are connected by an invariable law, the sum of the potential and kinetic energies of any portion of the fluid remaining constant for all time.

This law, together with the necessary condition of continuity, which for an incompressible fluid merely implies that the volume of a given mass of fluid remains constant, no matter what shape it takes, constitutes the foundation of all the propositions regarding the stream lines of a perfect fluid which have hitherto been worked out, and for such a fluid the stream lines indicated in Fig. 2 are an exact solution of the problem.

Now real fluids differ from the perfect fluid in having both viscosity and surface friction. They require that work should be done if distortion is going on, and they adhere to the surfaces of solids immersed in them. Thus a plane which, if moving edgewise in a perfect fluid, would meet with no resistance, does meet with resistance in a real fluid on account of the adherence of the fluid to the solid surface and the consequent distortion produced in the neighbouring layers of the fluid.

It is true that for fluids such as water and air the viscosity is so small that the direct effects would hardly be noticeable. Indirectly, however, they have immense influence, and it is not too much to say that the most remarkable features in the flow of the winds, tides, and streams are due to the modification of stream-line motion set up by fluid friction and viscosity.

The indirect action referred to depends on the fact that when a stream is retarded by friction the velocity is reduced, although the pressure remains unchanged, and thus the fundamental relation which connects velocity and pressure in a perfect fluid is violated. So long as the stream concerned is of constant section and is neither accelerating nor retarding, as, for instance, when the flow is through a straight pipe of uniform bore, the effect of friction shows itself merely by rendering the stream lines irregularly sinuous, in a way which has not yet been investigated, and as giving rise to a resistance which is proportional to a power of the velocity something rather less than the square, *i.e.* to the 1·85th or 1·9th power.

When, however, the stream is divergent (so that in the absence of friction the velocities and pressures, although constant across each section, change from one section to another, but keep the total energy of the flow across each section the same), the effect of friction and viscosity is much more conspicuous.

On the up-stream side of the plane friction does little to modify the conditions except in the neighbourhood of the edges, but down stream we find, instead of a pond of still fluid, a complex wake consisting of a central current moving forwards towards the plane, bordered by a series of eddies the origin of which is of the same nature as those just referred to in the expanding channel, namely, to degradation of the streams passing round the edges of the plane, which, having insufficient velocity to follow the stream-line path of Fig. 2, are deflected inwards and become involved with the reversed central stream, about half the fluid in each eddy being supplied from up stream and half from the wake.

The eddies are formed periodically, growing to a certain size, and then, breaking away from their place of birth, they form part of the train which borders the wake current. The wake current itself is due to the constant removal of fluid in this way from the back of the plane, and the fact that the outflow from the back has its maximum velocity close to the edge where the composite eddy is being formed shows that the pressure on the back of the

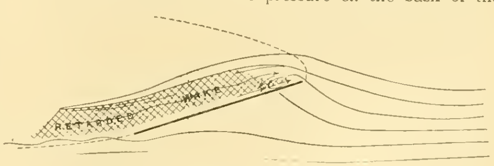

FIG. 3.—Frictional flow: stream oblique to plate.

plane is lower at the edges than in the centre. Hence it could be stated with certainty, even without any experiment, that the total resistance of a plane must be greater than $\rho v^2 \frac{\pi \sin \alpha}{4+\pi \sin \alpha}$, which assumes that the pressure over the rear surface is uniform and equal to the general pressure at a distance.

Experiment, however, is required to determine the actual resistance, and when the plane is broadside to the stream this is found to be about half as much again as the head resistance alone, or about 20 or 25 per cent. greater than the dynamic head × the area of the plane.

When the angle α is small, as it always is in flight, the character of the wake takes the form shown in Fig. 3. Here the wake stream is only recognisable as a reversed current quite close to the plane, and the small eddies as fast as they are formed are so rapidly degraded that after travelling a short distance they are merely recognisable as slight variations in the direction of the general current.

The abstraction of wake water by eddy-making continues, however, even for very small values of α, and has the effect of deflecting the upper boundary of the wake as shown.

The deflection may be considered from another point of view as the outcome of the defective pressure on the down-stream surface of the plane.

This short account gives a general explanation of the observed difference between results calculated for the discontinuous flow of a perfect fluid and those actually found by experiments in air and water, and if the nature of the flow over the back surface were accurately known, the value of α for the maximum of L/R could be predicted. Even in the absence of this knowledge, the assumption that surface friction varies as v^2 and acts only on the up-stream side, leads to a value of α that is not far removed from truth.

Let AB, Fig. 4, be the plane making a small angle α with the stream, and let L and R be the lateral force and resistance which would be experienced if there were no friction.

If L′ and R′ are the same quantities, taking friction into account, and putting Fv^2 as the frictional force parallel to AB, we have $L' = L - F\alpha$ and $R' = R + Fv^2$, and since $L = R_n\alpha$, and $R = R_n\alpha^2$, R_n being the normal resistance Av^2,

$$L' = L - F\alpha = \alpha v^2(A_n - F),$$

and

$$R' = R + Fv^2 = v^2(A\alpha^2 + F);$$

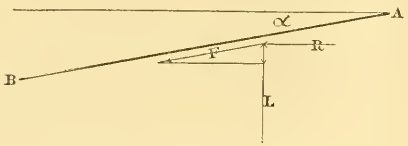

Fig. 4.

hence $L'/R' = \alpha(A - F)/(\alpha^2 A + F)$, and this is a maximum when $\alpha = \sqrt{F/R}$.

Lanchester's experiments make F/R = 0·0075; Zahn's experiments make F/R = 0·0037, which correspond to $\alpha = 6{\cdot}5°$ or $3{\cdot}5°$ respectively.

The actual value found from direct experiments on L and R lies between these two, and although 6·5° is nearer the truth than 3·5°, this does not imply that 0·0075 is the more nearly correct value of F/R, for the complete theory must take into consideration the action of the streams on both sides of the plane.

If ascending currents can be found, or if use can be made of differences of speed in the wind at different levels, there is no reason why engineless flight should not succeed, but the opportunities are rather limited.

The heaviest birds which can fly (great bustards, turkeys, and some of the vultures, eagles, and pelicans) weigh between 20 and 30 lb. Of these, bustards and turkeys are short-winged, and the load is more than 2 lb. to the square foot of wing. But their flights are short and their wing movements rapid, and the power expended while rising from the ground must be very great in proportion to their size.

The large birds which make long flights have wing areas giving a load of less than 2 lb. per square foot, and are all adepts at making use of ascending air currents, so that for the most part of their time in the air they have but little work to do.

Much controversy has arisen on the question of the sufficiency of upward currents or upward components of currents of air to account for such flights, but the more the circumstances are examined the more clearly it appears that soaring is in most cases effected in this way, although the origins of the ascending currents are very various. Sometimes they are caused by natural obstructions in the path of the wind, such as cliffs, hills, the sides or sails of a ship, or the slope of waves, but on a larger scale they are chiefly the result of air ascending after having been warmed by contact, direct or indirect, with the ground. At low levels such vertical movements are very small, and at the surface of the ground any motion must, of course, be parallel to the surface; but at considerable heights, especially in sunny countries, these convection currents must always exist, even when the weather is calm, except in the rare event of large tracts of sea or country having the same temperature as the air in contact with them.

To anyone flying at a height, the sense of true vertical which we have, and by which we adjust our balance when standing or moving on the ground, is replaced by the direction of the resultant force of gravitation and any acceleration which the machine may be subject to. In still air or in a uniform wind, acceleration can only be the result of an alteration of level or of the engine speed, and the effects due to the latter cause cannot be very large or rapid. When, however, the machine passes quickly from a region of still air into a wind, or *vice versâ*, which is what happens practically in gusts, the sensation of vertical direction is lost, and although the speed and direction of travel of the machine only change gradually, the resultant of the forces acting on it does so instantaneously, not only in direction, but in magnitude.

The three diagrams in Fig. 5 show the direction in which a short pendulum at the centre of gravity of the machine would point (*a*) when the flight is in uniformly moving air, (*b*) when in an overtaking gust, (*c*) in an opposing gust.

The connection between the angle (θ) which the pendulum makes with the true vertical being

$$\tan\theta = \frac{\text{Propulsive force} - \text{Resistance}}{\text{Lifting force}}.$$

It is hardly to be wondered at that such changes in the apparent vertical should be confusing to the pilot, and that accidents, which are often fatal, should happen while experience is being acquired.

Side gusts may produce still more embarrassing effects, the character of which depends on the class of machine and the disposition of the wings to a greater degree than is the case with gusts in or against the direction of motion.

At the present time the wings and framework of all machines are made as rigid as possible by wire stays, &c., with the result that the breakage of any one part is likely to wreck the whole, and it is probable that as time goes on more attention will be directed to increasing their pliability so as to allow a reasonable amount of distortion without crippling the structure. The problem of determining the greatest possible flexibility which can be given to a structure of a definite shape, size, and weight, which is also to have a definite initial stiffness, is theoretically capable of solution in terms of the strength, density, and dynamic worth of the materials (by dynamic worth is meant the worth which can be stored elastically in the unit volume), and although I am not aware that any case has been worked out, the subject is worthy of investigation.

The most important questions which can be raised about flying machines relate to their stability in flight and the ease or difficulty of starting or stopping them, and on each of these questions I will say a few words. First, as to the theories of stability which have been given from time to time. Some of these I believe to be correct so far as they go, but none of them are anything like complete, since they are all based on the pressures and variations of pressure acting on the up-stream surfaces of wings and omit the variations due to the eddy formation which goes on on the down-stream side.

Before proceeding further, it will be as well to define what I mean by stability in connection with flight. A flying body is stable if, when acted on by a propulsive force and the reactions of the air (but not steered), any small angular velocity imposed about a horizontal axis tends to die out, and any small displacement about a vertical axis to reach a constant

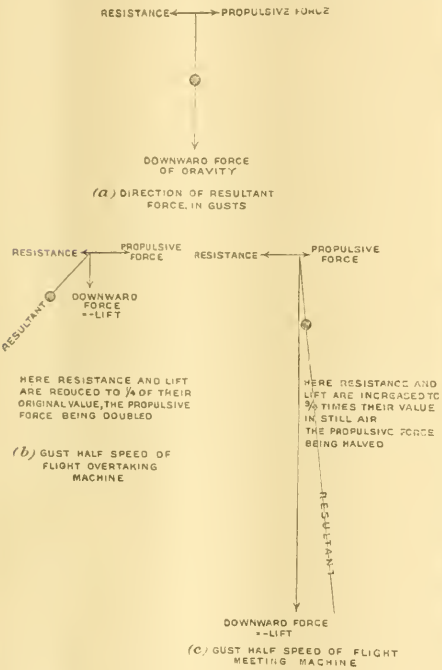

FIG. 5.

value. Or, in other words, any accidental motion of the nature of pitching or rolling must tend to disappear, while an arbitrary twist to the right or left must put the machine on a new, but straight, course.

Technically, stability is compatible with the presence of forces which produce increasing oscillations as the result of disturbance; but for the present purpose not only must the average force so called into play be a restituent force, but the disturbing motions must also tend to die out. The oscillations, in fact, must be damped, and not maintained.

None of the flying machines at present in use are stable in the sense in which the word is here used, but in the ordinary conditions of flight the eddies formed behind the wings are small and their period of formation so rapid that the change in the attitude of the wings (that is, in the angle α) which they can produce in one period is inconsiderable, and the stability or instability depends chiefly on the distribution of pressure on the up-stream surfaces, but the case is very different when the machine is passing through variable currents and the angle at which the air meets the wings is liable to large and rapid changes. The alterations in the arrangement of the pressures on the back surfaces are then much greater and take longer to go through their phases—long enough, in fact, to make the process of correction exceedingly baffling.

That flying machines should be unstable in ordinary circumstances is really of very little consequence. The same objection applies to walking. No conscious effort, however, is required to keep upright on *terra firma*, but on the deck of a small vessel in seaway we all know that sea legs are only got by practice, often involving many falls.

The flying machine in gusty weather is much in the same condition, but the falls have more serious consequences.

I think it very unlikely that any type of flying machine will be evolved which, without guidance, will be safe in bad weather, but it is quite possible that the necessary corrections should be applied by an automatic device, and if flight is to be anything but a fair-weather pastime, something of the kind will probably be found necessary.

What is required is an apparatus which will so trim the wings as to keep the machine related in a definite manner, firstly to the true vertical, and secondly to the direction of the resultant force at the time.

The various ways in which this could be done might furnish subjects for several lectures, and I will only say here that the many proposals which have been made to use pendulums or gyroscopes to act directly on the correcting mechanism are certainly bound to fail.

It is essential to the success of any automatic control that the forces called into play to make the corrections of trim should not react on the director of those forces, whether this is a pendulum or gyroscope or any other equivalent device. The only instance in which this condition has been fulfilled is the "steady platform" of the late Mr. Beauchamp Tower. In this Mr. Tower caused a gyroscope (which, in effect, was a pendulum with a very long period) to direct an axial jet of water on a group of openings connected by pipes to a series of rams in such a way that if the openings did not face the jet symmetrically water flowed into one or other of the pipes, and so altered the position of the openings until symmetry was restored, the restituent force having no tendency to alter the direction of the axial jet.

There may be other methods of attaining the same object in the case of wing-trimming or control for flying machines, but any device in which the correcting force tends to alter the position of the corrector is more likely to do harm than good.

The question of stability also becomes important when the flying machine is coming to the ground. In alighting, the machine either has to touch the ground at full speed and trust to retardation, supplied chiefly by the ground, for coming to rest, or it must alter the wing attitude with reference to the path so as to experience a greater resistance for a given lift. This latter method is adopted by birds when pitching on the ground, and in their case at the last moment is generally supplemented by flapping the wings when the velocity is so much reduced that the greatest lift the wing area is good for will not sustain their weight. Birds when pitching on any elevated perch, such as a bough of a tree or a rock, nearly always finish their flight in an upward direction; but neither this nor wing flapping is at present open to flying machines on account of the mechanical difficulties of construction.

Alteration of the trim of the wings, however, presents no great constructional difficulty, but when the angle between the wings and the path is large the effect of accidental variations of pressure due to eddy formation is more serious, and the instability is greater than when the angle in question is the gliding angle; and here, therefore, automatic correction would be very important. If this could be used successfully, a machine the flying speed of which was 40 miles an hour and which had a gliding angle of 1/7 could, as may be found from the resistance diagrams, reduce its velocity by alteration of the trim of the wings to 25 miles per hour before the weight ceased to be air-borne. Further, since for the whole time the resistance would average about one-fourth of the whole weight, the time taken in effecting the reduction of speed would be four times that required for gravity to generate the difference between 40 and 25, being 15 miles per hour. During this time—2·7 seconds—the average speed would be 32 miles per hour, and the machine would cover about 120 feet. These rough figures can be easily corrected from the curves giving lift and resistance for any particular machine, but there can be no doubt that it would be a substantial gain if the high speeds, which are becoming more and more common, could be quickly and safely reduced before reaching the ground.

It is quite possible to imagine a flying machine made with lifting screws which would rise vertically from the ground and remain poised and stationary in the air; but no success has hitherto attended any attempts in this direction, partly because the inventors have not realised the very large blade area necessary for reasonable economy of power. One way of realising the stationary condition would be to connect two flying machines travelling at the same speed in opposite directions with a length of rope and letting them circle round one another. No "banking" would take place, as the centrifugal force of each would be taken by the pull of the rope. If the latter were shortened as far as possible, the pair would, in effect, form a single machine with a lifting screw. The experiment would be dangerous, and is not recommended for trial, but is mentioned rather as indicating the size of the screw blades which the hovering type of machine would require.

In taking a general view of the present condition of the art of flying, it must be admitted that much remains to be done before it ceases to be a fine-weather sport, and I think the right course to pursue would be to try to evolve a type of machine which is fairly safe even in turbulent winds, and can arise and alight on the smallest possible area. When the essential features of the design which secures these results are recognised, the machines may be specialised for war or other purposes, and additional improvements may be introduced for convenience, comfort, or speed.

The opinion seems to be gaining ground that flying machines are more likely to be usefully developed than dirigible balloons, and in this opinion I fully concur, more especially as regards the larger dirigibles, which I have always considered too frail and too liable to accident to be of much real service.

All aircraft, whether heavier or lighter than air, will for some time to come be designed for the purposes of sport or war rather than for commerce, and although for war-machines cost takes a second place, it must be remembered that a dirigible costs rather more than a torpedo-boat, whilst a flying machine costs rather less than a torpedo. Further than this, there are very few services to be performed by a dirigible which could not be carried out as well, or better, by a flying machine, the only, and rather dearly purchased, advantages attaching to the balloon being its power of rising quickly and of leaving the ground without the necessity of taking a run; and I think the best policy for us would be, while recognising the occasional usefulness of dirigibles of moderate size (and building a sufficient number for experiment), to devote our attention chiefly to the elaboration of the most efficient means of destroying them.

From the purely scientific point of view it cannot be said that the ascents of any large balloon have added much to our knowledge.

The small balloons, however, recently used for carrying self-recording instruments have ascended to heights (60,000 feet or more) at which personal observation is impossible, and have brought back valuable information which could scarcely have been attained in any other way; and although the records, as a rule, only deal with pressure and temperature, there is no reason why solar radiation should not also be measured by suitable apparatus. Such measures would give a better knowledge of the temperature of the sun than could be got by direct observation, even on the highest mountains.

In conclusion, and speaking generally, I may say that it seems desirable to encourage experiment on the widest scale, even if much of the work is not on strictly scientific lines; bearing in mind that great improvements may result from the working out of ideas which, as originally conceived, were unsound or even absurd, and that this is the more likely to be the case in such a subject as flight, for which, as I have endeavoured to point out, a considerable part is not yet subject to accurate theoretical treatment.

APPENDIX.

The relative densities of different gases at the same altitude may be conveniently expressed in terms of heights of homogeneous atmosphere of each.

The height of the homogeneous atmosphere for a gas is defined as the height of a column of the gas of uniform density (equal to that which it has at sea-level) the weight of which produces the atmospheric pressure at its base. Thus the height of the homogeneous atmosphere H_a for air is in feet the number of cubic feet which weigh 2100 lb. nearly, and since 1 cubic foot of air weighs 0·080 lb., $H_a = 26{,}000$ feet nearly.

For hydrogen $H_h = H_a \times$ the ratio of the densities of the two gases (namely, 16), so that $H_a = 416{,}000$ feet nearly.

If the distribution of temperature in the atmosphere is isothermal, the actual height (h) above sea-level at which the pressure is p is $h = H \log \frac{p_o}{p}$. Thus when $h = H$ the pressure is p_o/e, and the pressure does not vanish until an infinite height is reached.

If, on the other hand, the temperature decreases according to the adiabatic law (that is, if the temperature of the air at height h and pressure p is what it would be if with surface temperature to start with it was lifted without loss or gain of heat to the given height),

$$h = H\frac{\gamma}{\gamma-1}\left(1-\left(\frac{p}{p_o}\right)^{\frac{\gamma-1}{\gamma}}\right), \text{ or } H\frac{\gamma}{\gamma-1}\left(1-\left(\frac{\rho}{\rho_o}\right)^{\gamma}\right).$$

In this case, therefore, there is a definite upper limit to the atmosphere, for when $p = o$, $h = H\frac{\gamma}{\gamma-1}$ (rather more than 17 miles for air and 275 miles for hydrogen).

What the actual limit of the atmosphere may be is not known, but experiment shows that for the lower strata, at any rate, the adiabatic distribution of temperature is not very far from the truth.

If we have two short columns, one of hydrogen and one of air, of the same length, and both at height h, then (putting $H\frac{\gamma}{\gamma-1}=K_a$ for air, K_H hydrogen, and N for the ratio of the densities, ρ_a/ρ_H at sea-level, the density of the air at h is $\rho_a(K_a-h)^{1/\gamma}$, and of the hydrogen $\rho_H(K_H-h)^{1/\gamma}$.

If the balloon carries no weight it will ascend until the densities are equal, which occurs when

$$h = NK_a\left(\frac{N^{\gamma-1}-1}{N^{\gamma}-1}\right),$$

or, since $N=16$ for air and hydrogen, and $\gamma=1{\cdot}41$, $N^{\gamma-1}=3{\cdot}1$, $N^{\gamma}=51$, and $K_a=17$ miles,

$$h=\frac{16\times17\times2{\cdot}1}{50}, \text{ or } 11{\cdot}5 \text{ miles},$$

and no hydrogen-filled balloon could ascend higher than this if the temperature was the adiabatic temperature.

The ascents of the balloons with recording instruments, however, lead to the belief that at heights exceeding 6 or 7 miles the temperature is constant, or nearly so, so that the practicable height of ascent may very considerably exceed the 11·5 miles just mentioned.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The General Board of Studies will shortly proceed to the appointment of a Stokes lecturer in mathematics, in succession to Mr. J. H. Jeans, who is resigning the lectureship. The appointment will be from June 24, 1912, to September 29, 1913. The annual stipend is 200*l*. Candidates are requested to send their applications, with a statement as to the branches of mathematics on which they are prepared to lecture, and with testimonials if they think fit, to the vice-chancellor on or before May 22.

DR. A. H. GARDINER, Laycock student of Egyptology at Worcester College, Oxford, has been appointed reader in Egyptology in the University of Manchester.

REUTER reports that the King of Siam has sanctioned a scheme for the establishment of a University of Bangkok. There will be eight faculties, including medicine, law, engineering, agriculture, commerce, pedagogy, and political science.

THE annual conference of the Association of Teachers in Technical Institutions will be held at Whitsuntide in London, at the Polytechnic, Regent Street. A paper will be read by Sir Alfred Keogh, K.C.B., on "The Relations between the Imperial College of Science and Technology and Technical Institutions." There will also be a discussion on the important question of the cooperation of employers in technical education, following a paper on this subject by Mr. E. A. Atkins.

THE Bethnal Green Free Library, one of the pioneer institutions of the free library movement in Great Britain, has now completed thirty-six years of work without endowment or State aid. We are informed that a million readers, borrowers, and students have used the library and attended the classes in connection with it. A plan is now on foot to secure the perpetuity of the work, and a reserve fund of 10,000*l*. has been started, to which the King has contributed. Donations may be sent to the treasurer, Mr. F. A. Bevan, 54 Lombard Street, London, E.C.; the bankers, Messrs. Barclay and Co., at the same address; or to the librarian, the Free Library, Bethnal Green, London, E.

IN the House of Commons on May 6, Mr. Runciman said, in reply to a question relating to agricultural education:—"I am carefully considering by what means the various agencies, actual and prospective, for the provision of agricultural education and research and of technical advice in agriculture may most effectively be brought into cooperation. I think it will probably make both for efficiency and for economy if county councils and agricultural colleges will combine for the purpose of joint action in respect of many of their agricultural activities. I am not yet, however, prepared to make a definite statement on the subject, as to which I shall hope, before taking any decision, to learn the opinions of county councils and agricultural colleges."

THE University of Chicago has established a system of retiring allowances for professors or their widows. A fund of 500,000*l*., says *Science*, taken from the 2,000,000*l*. Rockefeller gift of 1910 has been set aside for this purpose. This pension system will grant to men who have attained the rank of assistant professor or higher, and who have reached the age of sixty-five and have served fifteen years or more in the institution, 40 per cent. of their salary, and an additional 2 per cent. for each year's service over fifteen. The plan also provides that at the age of seventy a man shall be retired unless the board of trustees specially continues his services. The widow of any professor entitled to the retiring allowance shall receive one-half the amount due to him, provided she has been his wife for ten years.

THE University of the Philippines has, we learn from *The Manila Times* of March 7 last, conferred the honorary degree of doctor of science upon Father Jose Algue, director of the official weather bureau of the Government of the Philippine Islands. Dr. Algue, who was born in Manresa, Spain, in 1856, was in 1891 appointed assistant director of the observatory in Georgetown, D.C. In 1894 he became assistant director of the Manila Observatory, conducted by the Jesuit fathers, which in 1901 was made the official bureau. He held this position until the death of its founder, Father Faura, in 1897, when he was appointed director. Father Algue reorganised the meteorological service of the institution and perfected a system whereby the observatory receives daily telegraphic report from over thirty meteorological stations in the islands, ten in Japan, six in Formosa, four on the Chinese coast and three in Indo-China. He is a leading authority on earthquakes, and his observations in the Philippines, where seismographic phenomena are of such frequent occurrence, have been of great service. The University of the Philippines confers but one honorary degree each year, and its scroll at present bears only the names of Dr. Algue and one other honorary doctor.

THE experienced instructor appeals in teaching to as many of the pupil's senses as possible. The eye, for instance, is being more and more pressed into service to assist the ear in its work, and good lectures and school lessons are consistently illustrated by pictures and diagrams. The most recent of these pictorial aids is provided by the kinematograph, and it is satisfactory to learn that manufacturers and dealers are taking active steps to familiarise lecturers and school teachers with the possibilities of kinematography in increasing the value of their work as well as simplifying it. The proprietors of *The Bioscope*, for example, are organising a series of invitation demonstrations to be given at Cinema House, Oxford Street, London, on Wednesdays, June 5 and 12, and Saturday, June 15, at 11 a.m., to show the educational possibilities of kinematography. The first performance is exclusively for members of the medical profession, and the films shown will be purely technical; the second will be devoted to natural science, and the third to the educational uses of the kinematograph. Short addresses will be delivered by authorities associated with the particular subject of the demonstrations. Tickets may be obtained on application to the office of *The Bioscope*, 85 Shaftesbury Avenue, W.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, May 2.—Sir Archibald Geikie, K.C.B., president, in the chair.—Dr. Marie C. **Stopes**: Petrifactions of the earliest European angiosperms. The paper gives an account of the anatomy and the geological bearing of three new petrified angiospermic stems. These three fossils are all in the British Museum collections. Their age appears undoubtedly to be Lower Greensand (Aptian), and they are consequently the earliest angiosperms of which the internal anatomy is known. They are also of interest as coming from northern Europe at a time when angiosperms have hitherto been supposed not to have penetrated to that region. The three specimens differ so considerably in their structure that it seems justifiable to place them in three distinct, new genera.—Dr. F. **Keeble** and Dr. E. F. **Armstrong**: The distribution of oxydases in the plant and their *rôle* in the formation of pigment. The methods of investigation in general use do not admit of the determination in detail of the distribution of oxydases in the tissues of plants and animals. Hence the hypothesis that pigments are produced by the action of oxydases in colourless chromogens, though rendered probable by recent researches, cannot be regarded as established. Methods are now described which allow of the macroscopic and microscopic recognition of plant oxydases. By the application of these methods it is shown that in the Chinese primrose (*Primula sinensis*) the distribution of oxydases in the tissues coincides with that of the pigments of the flower and other parts of the plant. Thus, the hypothesis with respect to the *rôle* of oxydases in pigment-formation receives confirmation. It is proved that *P. sinensis* contains two peroxydases which differ from one another in their chemical reactions and in their localisation. It is proved definitely that dominant white flowers contain a substance which inhibits, but does not destroy, peroxydase. Experiments with recessive white flowers, the genetical behaviour of which indicates that they lack either peroxydase or chromogen, show that they contain peroxydase. Inasmuch as recessive whites contain no inhibitor of oxydase, failure to form pigment is to be attributed to lack of chromogen. The distribution of peroxydases in *P. sinensis* is to be regarded as typical of that in flowering plants generally, and the method appears to be capable of wide application in the study of the distribution of oxydases.—Dr. B. R. G. **Russell**: The manifestation of active resistance to the growth of implanted cancer. (1) The reaction which is evoked by the implantation of transplantable tumours of the rodent varies widely with different tumour-strains. The reaction has been determined by exercising all the growths in a series of animals on a given day, and then testing the suitability of the animals for the growth of a tumour-strain growing in 90 to 100 per cent. of normal animals. Some strains do not affect the natural suitability of the animals, others render every animal resistant to re-inoculation, and the remaining strains occupy intermediate positions. (2) The individuality of the animal inoculated may contribute to the development of the resistance, although not to so marked a degree as the tumour parenchyma. (3) Simultaneous inoculation of a tumour-strain which induces no resistance, and a strain which induces resistance, may be followed by marked inhibition of the growth of the former strain. (4) Mice bearing progressively growing tumours can be rendered resistant to re-inoculation, but the tumour first inoculated need not necessarily be affected. (5) Repeated inoculation of tissues, such as mouse embryo-skin, which renders animals resistant to subsequent inoculation, has not been shown to have a constant effect upon the growth of established tumours. (6) The conclusions drawn in (4) and (5) support the view previously expressed that immunity to cancer is directed mainly against the stroma-eliciting properties of the cancer cells.—Dr. Wm. H. **Woglom**: The nature of the immune reaction to transplanted cancer in the rat. The paper discusses the reactions to tumour grafts displayed by normal rats and by those rendered resistant through preliminary treatment with tumour or embryo skin. The elaboration of a stroma and the provision of blood-vessels observed in normal rats is absent in refractory animals, irrespective of the method of immunisation.—T. Graham **Brown** and Prof. C. S. **Sherrington**: The instability of a cortical point. The reflex reactions obtainable from simple spinal preparations, even when elicited from one and the same receptive "locus," are subject to a certain amount of variability. The variability is somewhat greater when preparations which are decerebrate are employed. With loci in the motor region of the cerebral cortex the variability is greater still. The experiments reported in this paper were undertaken to examine the nature and extent of the variability of response observable in the reactions from one and the same locus in the motor cerebral cortex. It is found that the inconstancy of response amounts under certain conditions to an actual reversal of the effect of the cortical point as examined in the muscles of the limb. The factors determining this reversal of cortical effect are examined, and the reversal itself is studied by graphic registration. A prominent factor in the conditions underlying the reversibility of the cortical effect appears to be the quiescence or activity of points of cortex antagonistic in their effect to the particular point under examination.—Dr. J. W. W. **Stephens** and Dr. H. B. **Fantham**: The measurement of *Trypanosoma rhodesiense*. The paper contains the results of the measurements of 1000 *Trypanosoma rhodesiense*, 400 of which were measured from different hosts, namely, man, monkey, horse, dog, rabbit, guinea-pig, mouse, while the remaining 600 trypanosomes were measured from rats only. The authors' chief conclusions are:—(1) That in the case of dimorphic trypanosomes, like *T. rhodesiense*, samples of twenty trypanosomes from a particular slide on a particular day are too small, because the average length may vary by as much as 4·7μ. (2) The day of infection on which the sample is taken is very important, as on one day 10 per cent. of stumpy forms may be found and on another day 95 per cent. The authors therefore recommend taking samples of trypanosomes from each day of infection of the host. (3) As the host from which the sample of trypanosomes is taken is probably also important, the authors suggest using the same animal throughout, *e.g.* a tame rat.

Geological Society, April 17.—Dr. Aubrey Strahan, F.R.S., president, in the chair.—H. H. **Thomas** and Prof. O. T. **Jones**: The pre-Cambrian and Cambrian rocks of Brawdy, Hayscastle, and Brimaston (Pembrokeshire). The district lies about eight or ten miles to the east of St. Davids, and consists of pre-Cambrian plutonic and volcanic rocks intimately associated with sedimentary rocks of the Cambrian system. The pre-Cambrian igneous and pyroclastic rocks are brought to the surface along an anticlinal axis which ranges in an east-north-easterly and west-south-westerly direction; they are divisible into two classes, an older volcanic series and a newer plutonic and hypabyssal series. The Cambrian has been divided into two main groups, the Welsh Hook group below and the Ford beds above. The Welsh Hook group consists of basal conglomerate, green sandstones, red shales, and purple sandstones. The position of the Ford beds, which are mostly shales, is not so certain. The basal bed of the Cambrian apparently rests upon rocks of different ages in different parts of the district, and indicates that the Cambrian reposes unconformably on a complex series of tuffs and lavas and of plutonic rocks intruded into these volcanic rocks. The structure of the district is that of a horst, faulted on all sides and surrounded by much younger beds. Much of the faulting is of pre-Carboniferous age.—Prof. O. T. **Jones**: The geological structure of central Wales and the adjoining region. This paper deals with the structure on a large scale of an area of about 1800 square miles, comprising the western portion of Wales, and is accompanied by a map, based partly on personal observations and partly on information gathered from various publications. There are two principal anticlinal axes, which follow in the main the valleys of the Teifi and the Towy, and are named after these rivers; between them is an important syncline (the central Wales syncline) which coincides nearly with the principal watershed of central Wales. Both the anticlines can be traced towards Pembrokeshire, but cannot be distinguished beyond the northern boundary of the area. The syncline becomes more important in a northerly direction, but is lost towards the south-west. The variation in the pitch accounts for the form of the outcrops.

Royal Anthropological Institute, April 23.—J. Reid **Moir** and A. **Keith**: Human skeleton found under a stratum of chalky boulder clay near Ipswich. The skeleton was discovered on October 6, 1911, at a depth of $4\frac{1}{2}$ ft. below an undisturbed stratum of decalcified chalky boulder clay in the brickfield of Messrs. Bolton and Laughlin, about one mile north of Ipswich. The stratum of boulder clay under which the skeleton lay is part of the great sheet of chalky boulder clay found in East Anglia. The skeleton was embedded at the junction of the boulder clay and the underlying strata of mid-glacial sands, and the section of the strata showed no sign of having been disturbed, and it was therefore inferred that the skeleton must have been *in situ* before the deposition of the chalky boulder clay. In Mr. Moir's opinion, the upper part of the mid-glacial sands on which the skeleton lay represented an old land surface. In these strata and in the overlying deposits of boulder clay he had discovered flint implements which, in the opinion of M. Rutot, belonged to the pre-Strépyean type. The skeleton lay on its right side, in an ultra-contracted posture; nothing was found with the skeleton; there was no evidence of burial. The skeleton was that of a man about 1·800 metres (5 ft. 10 in.) in height, and probably between thirty and forty years of age. In the characters of the skeleton and skull the remains resembled modern man, and showed none of the marked features of Neanderthal man. The skull is estimated to have had a maximum length of 192 mm., maximum width 144, auricular height 111, cephalic index 75. The only peculiar feature was found in the shape of the tibia. In place of the anterior border being raised into a ridge or crest, it was flat, thus differing from all known tibiæ, ancient and modern. In the opinion of the speakers, the modern type of man, as represented by the Ipswich skeleton, the Galley Hill skeleton, the Bury St. Edmunds cranial fragments, and by numerous human remains found in France, was evolved long before the Neanderthal type of man became extinct in Europe.

Zoological Society, April 23.—Dr. S. F. Harmer, F.R.S., vice-president, in the chair.—C. H. **O'Donoghue**: The circulatory system of the common grass-snake (*Tropidonotus natrix*). Several interesting features correlated with the loss of limbs and the elongation of the body were stated to occur in the blood-vessels. The vessels, like the viscera they supplied, were asymmetrical; not only were those on the right anterior to those on the left, but they were also noticeably larger. No indication of the descent of snakes from a limb-bearing ancestry was to be found in the circulatory system, save perhaps a small pair of veins which might correspond to the pelvic veins in Lacertilia.—Julian S. **Huxley**: The courtship of the redshank (*Totanus calidris*). The first purpose of this paper was to direct attention to the many valuable results to be obtained by simple watching of very common British birds; and the second was to show how the facts observed in the redshank bore on the theory of sexual selection. In this species there was no rival display between several males at once: a single female was courted by a single male, as in man. But in quite 90 per cent. of observed courtships the female rejected the male, either during the pursuit or during the display, by simply flying away. Thus the consent of the hen was absolutely necessary if pairing were to take place, and this consent was usually withheld; in other words, selection by the female was a reality in the redshank. Other interesting points were as follows:—The plumage of the two sexes was identical, and was decidedly cryptic when the birds were at rest. During flight the white underside of the wings and the white tail were conspicuously revealed, and probably served as recognition marks. The significance of the red legs was unknown. During display the male directed attention to the underside of the wings by raising and vibrating them, to the tail by fanning it out, and to the red legs by his slow, high steps; besides this he uttered a note heard at no other time. Thus, since the actual colours and structures used in display were found in both sexes, the only peculiarly male possession—the only secondary sexual character of the redshank—was a special behaviour, devoted to showing off these common colours and structures in a special way. This seemed to show that secondary sexual differences in birds were originally differences of behaviour, and that only when these were established did differences of colour and structure come to be developed.—Mrs. E. W. **Sexton**: Brackish-water Amphipoda from Bremerhaven. Special reference was made to a new species of Gammarus, which inhabited both fresh and brackish water, and was interesting as showing in a marked manner the effects of environment on development.—C. Tate **Regan**: Descriptions of ten new species of South American fishes of the family Loricariidæ in the British Museum collection.

Challenger Society, April 24.—Dr. E. J. Allen in the chair.—Dr. H. Muir **Evans**: Poison organs and venoms of poisonous fishes. After reviewing previous work, the author pointed out that the researches of Briot were incorrect, and that this observer had obtained his results by means of a filtered glycerine extract of the spines of Trachinus (the weever). Dr. Evans had used fresh venom for his experiments, and found that hæmolysis took place with fresh venom alone, that is, without the addition of heated serum. But if fresh venom were mixed with glycerine and filtered through filter-paper, the results were similar to those of Briot; they were, however, different if a Berkefeld filter were used instead of filter-paper, just as the action of liver extract is affected according as it is filtered through cloth or through filter-paper. Dr. Evans then described the conclusions of Porta, from examination of sections of the spine of the sting ray (*Trygon pastinacea*), conclusions which had been disputed by Pawlowsky, who stated that Porta had confused glandular tissue with deformed blood-corpuscles, and denied that poison glands with groups of small cells existed in the spine of Trygon. By photomicrographs Dr. Evans then showed not only that Porta's triangular glands existed, but that they were only part of a large system present throughout the whole spine. The latter was described as consisting of (1) an intracaudal portion, of bony meshwork, containing round-celled glandular tissue and masses of secretion surrounded by flattened cells; (2) an intermediate portion with the ventral ridge still embedded in the tail, with gland follicles either radiating towards the convex surface or running longitudinally in the ventral prominence; formed secretion can be seen leading into the lateral grooves; (3) the free portion with the triangular glandular masses of Porta, and cavities occupied by small-celled tissues and formed secretion; towards the tip of the spine these become three, one in each lateral portion and one in the ventral ridge. The hæmolytic properties of these venoms were described, and in the ensuing discussion the painful toxic effects of the sting were described by one speaker from personal experience.

MANCHESTER.

Literary and Philosophical Society, April 2.—Prof. F. E. Weiss, president, in the chair.—J. **Mangan**: The presence of Maxillulæ in larvæ of Dytiscidæ. It was shown that in this family of water-beetles the mouth of the larval form is armed with a pair of strong processes, at the base of the mandibles, which appear to be homologous with the maxillulæ or superlinguæ of certain primitive insects.—Prof. W. H. **Lang**: The interpretation of the vascular anatomy of the Ophioglossaceæ. The author described the anatomy of the stem and leaf-trace of rhizomes of Helminthostachys of various ages; and the progression of the stele towards the mesarch condition was followed. The occasional development of accessory or secondary xylem was recorded. The distribution of the tissues in the stele was compared with that in the stele of Zygopteris, the centripetal xylem in Helminthostachys being regarded as corresponding to the inner xylem of Zygopteris. The departure of the leaf-trace also exhibits points of resemblance. The occasional development of centripetal tracheids forming a mixed pith was described for *Botrychium lunaria* and Ophioglossum, sp. The pith of the Ophioglossaceæ appears to be of intrastelar origin and not due to intrusion of cortex. Ophioglossaceæ and Cœnopterideæ appear to throw mutual light on one another as regards morphological and anatomical structure. The anatomical evidence supports the view that there is a real, though it may be a collateral, relationship between the two groups.

DUBLIN.

Royal Irish Academy, April 22.—Rev. Dr. Mahaffy, president, in the chair.—The following papers were read:—M. J. **Conran**: The Riemann integral and measurable sets. In this paper a method is given of extending the notion of integration to measurable sets without making use of any theory of generalised integration. Following the analogy of Young's treatment of the theory of content, the integral is first defined for a single interval, then for a set of open intervals, then for a closed set, &c. In applying the method to double integrals, it has been found necessary to examine the conditions under which the double and repeated Riemann integrals are equal when the region of integration has a frontier of positive content. This has been done, and some results of a fairly general character obtained.—W. **West**: Fresh-water algæ (in connection with Clare Island Survey). About 1100 species, varieties, and forms are enumerated, some with many localities, others being local. The research has proved that the district, lying on the older Palæozoic rocks, is a very rich one for this class of plants, and has resulted in the addition of a number of species, varieties, and forms new to science, as well as adding many others to the already known rich Irish algological flora. This is one of the most comprehensive reports of the investigation.—G. P. **Farran**: Decapoda (Clare Island Survey). The Decapoda of the Clare Island district include most of those recorded from the west coast of Ireland, with the exception of the burrowing forms. The majority of the species represented range from the Mediterranean to Norway, those having a distinctly northern distribution being very few.—W. M. **Tattersall**: Schizopoda and Cumacea (Clare Island Survey). Thirty-five species belonging to these groups of crustacea are enumerated from the Clare Island marine area. None are new to science, but one Mysid is new to the fauna of Ireland and eight Mysidæ to the area under consideration.—N. H. **Foster**: Land and fresh-water Isopoda (Clare Island). The terrestrial isopod fauna of Clare Island is similar to that of the adjoining mainland. Nine species were observed on the island, and of these eight have likewise been taken on the West Mayo mainland. Detailed notes are given respecting these species, and it is noted that many specimens of *Oniscus asellus* and *Porcellio scaber* are of larger size and brighter coloration than usually obtains in Ireland. *Asellus aquaticus* was the only fresh-water species found on the island.—R. **Southern**: Platyhelmia (Clare Island Survey). This paper dealt chiefly with the free-living Turbellaria of the district. Fifty species were found, five of which live in fresh water and forty-five in the littoral and shallow waters of Clew Bay and Blacksod Bay. Five of these had not previously been recorded from the British Isles, and twenty-nine were additions to the Irish fauna.

PARIS.

Academy of Sciences, April 29.—M. Lippmann in the chair.—M. **Bassot**: The compensation of the new meridian of Quito. Remarks on the memoirs of the geodesy expedition to the equator, dealing with the observations obtained in the measurement of the arc of the meridian of Quito and the reduction of these observations.—Maurice **Hamy**: The temperature regulator in use with the stellar spectrograph of the Paris Observatory. The expansion of creosote, contained in a long serpentine tube, actuates through a mercury column an electrical relay. The instrument is capable of controlling the temperature to about 0·01° C.—A. **Chauveau**: The *rôle* of the preponderating retinal impression in stereoscopic inversions.—MM. **Carimey, Raveau**, and **Stablo**: Observation of a shadow on the sky after the central phase of the eclipse of April 17.—A. de La **Baume-Pluvinel**: The observation of the solar eclipse of April 17. A kinematograph was arranged to photograph the sun and a chronometer simultaneously, with a velocity of thirteen to fourteen images per second. The times were checked by wireless signals from the Eiffel Tower.—R. **Jonast**

and P. de la Gorce: Photometric measurements made during the eclipse of April 17. The curve expressing the results is unsymmetrical with respect to the time of the maximum phase.—Fred Vlès and Jacques Carvallo: The kinematographic registration of the solar eclipse of April 17 on the Spanish portion of its trajectory.—M. Tzitzéica: Isothermal networks.—E. Delassus: Lagrange systems with principal parameter.—Emile Borel: Arithmetical and analytical models of apparent irreversibility.—G. Ribaud: The appearance of new lines in a Geissler tube containing bromine placed in a magnetic field. The change of colour is a secondary effect due to a modification in the nature of the discharge. In a Geissler tube, the magnetic field transforms the continuous discharge into a more or less condensed discontinuous discharge.—R. Fortrat: The structure of some spectral bands. An analysis of the green carbon band, the bands of hydrocarbons and of water.—Jean Meunier: Gaseous combustion in vortices and its analogy with the appearance of nebulæ and comets.—Paul Bary: The approximate value of the molecular weight of india-rubber. On the assumption that vulcanised rubber is $(C_{10}H_{16})_nS_2$, experiments on the least amount of sulphur required to vulcanise a fixed amount of rubber gave a value for n of 18·4.—N. L. Müller: Remark on the communications of M. Pierre Achalme on the *rôle* of the interatomic electrons in catalysis and electrolysis. A claim for priority.—P. Achalme: Concerning the communication of M. N. L. Müller. A reply to the preceding paper.—Albert Granger: The methods of manufacture of earthenware obtained from the excavations at Suziane.—Camille Matignon: The function of the valency in the stability of binary metallic compounds.—Maurice Nicloux: The preparation of iodic acid for the estimation of carbon monoxide. The Stas method of preparing iodic acid by the reaction of fuming nitric acid and iodine is capable of giving much higher yields than those indicated by Stas, more than 90 per cent. of the iodine being converted into iodic acid if suitable precautions are adopted.—J. B. Senderens: The catalysis of the cyclanols in the wet way by means of sulphuric acid. The preparation of the cyclenes. The cyclanols lose water readily under the influence of diluted sulphuric acid, giving cyclenes. The reaction must be referred to a specific catalytic action of the sulphuric acid rather than to a direct dehydration.—Marcel Delépine: New classes of oxyluminescent substances.—E. Carrière: The acylic acid aldehydes. The acid aldehyde of succinic acid. Formyl-succinic ethyl ester, $(C_2H_5.CO_2).CH_2.CH(CHO)(CO_2C_2H_5)$, is readily hydrolysed by aqueous oxalic acid, the acid aldehyde, $OCH.CH_2.CH_2.CO_2H$, being formed.—Georges Dupont: The aci-nitro-derivative of tetramethylketofurane.—Henry Hubert: The gold-bearing strata in western Africa.—Ph. Nogier: Therapeutic methods based on increasing and decreasing the activity of the endocrinal glands by physical methods. The glandular secretions can be stimulated by using the electric current or reduced by using filtered X-rays or the γ radium rays.—A. Conte: *Encyrtus sericophilus* and its use in sericiculture.—A. Pézard: The determination of the secondary sexual characters in the Gallinaceæ.—Mieczyslaw Oxner: New experiments on the nature of the memory in *Coris julis*.—R. Fosse: The direct production of urea at the expense of albuminoids either by oxidation or hydrolysis. An account of the method of isolating the urea formed from albumin by the action of an aqueous solution of potassium permanganate.—H. Labbé and G. Vitry: Contribution to the study of non-dialysable substances in urine.—Louis Gentil: The origin of the folds of the Saharan Atlas.—Fernand Meunier: The Protoblattinæ and Mylacrinæ of the Commentry coal measures.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), parts i. and ii., for 1912, contain the following memoirs communicated to the society:—

July 1, 1911.—K. Försterling: Theoretical considerations on the propagation of light in absorbing active uniaxal crystals.

October 28, 1911.—C. Runge: The astronomical determination of position in ocean ships and aircraft.

December 9, 1911.—F. Körber: The two limiting volumes of a liquid at the absolute zero of temperature and under indefinitely high pressure.

December 23, 1911.—B. Dürken: Unilateral extirpation of the eye in young tadpoles.

December 23, 1911.—L. Bieberbach: Minkowski's reduction of the positive quadratic forms and the finite groups of linear integral substitutions.

January 13, 1912.—R. Fricke: Contributions to the transformation-theory of the automorphic functions (ii.).—G. Révész: Demonstration that in so-called musical pitch two independent properties of sound are distinguishable.

February 3, 1912.—E. Riecke: The molecular theory of the piezoelectricity of tourmalin.

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

" To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 2220, Vol. 89] THURSDAY, MAY 16, 1912 [PRICE SIXPENCE

THURSDAY, MAY 16, 1912.

RECENT WORKS IN EUGENICS.

(1) *Heredity and Society.* By W. C. D. Whetham, F.R.S., and Catherine D. Whetham, his wife. Pp. viii + 190. (London: Longmans, Green, and Co., 1912.) Price 6*s.* net.

(2) *An Introduction to Eugenics.* By W. C. D. Whetham, F.R.S., and Catherine D. Whetham, his wife. Pp. viii + 66. (Cambridge: Bowes and Bowes; London: Macmillan and Co., Ltd.; Glasgow: James Maclehose and Sons, 1912.) Price 1*s.* net.

(3) *Heredity in Relation to Eugenics.* By C. B. Davenport. Pp. xi + 298. (New York: Henry Holt and Co., 1911.) Price $2.00 net.

(1) THE authors of this volume record that one of them, on being presented to "a distinguished bishop and penetrating scholar of the last generation," was asked: "What is your opinion of the theory of politics?" The chapter entitled "Heredity and Politics" contains the answer, which was not ready at the time, namely, that the ultimate object should be to improve the innate qualities of the race; for if this be done improvement in environment will follow as a necessary consequence. It contains also an examination of the probable results of some of the more recent humanitarian legislation, which, hurriedly aiming at the relief of distress, does not stop to inquire whether that relief will not produce a few years hence a manifold increase of the distress which it is intended to eliminate. Yet the hurry manifested in some forms of legislation is no more noticeable than the delay in others. The case of the feeble-minded quoted in the following paragraph will serve as an example for the present:—

"A Royal Commission has taken voluminous evidence and issued a report in favour of compulsory care and detention. Nothing stands in the way of reform save the apathy of our legislature on a question where all competent opinion is agreed, but which does not appeal to the votes of the multitude, and the perversity of some of our educationalists, who persist in thinking that they can make a silk purse out of a sow's ear."

We rejoice that this reproach on our legislature is shortly to be removed.

Among the other points dealt with in this chapter is the eugenic effect of the present incidence of local and imperial taxation, tending as it does to penalise marriage and parenthood among the self-supporting. Separate chapters are devoted to the biological influence of religion, the birth-rate, and the position of women both in the past and in the present. To attempt to summarise them would be to do them an injustice. We can cordially recommend them to anyone interested in the bearing of these questions on the future of the race; the treatment is thoughtful and sincere, and could not be in any way offensive to people whose views are strongly opposed to those expressed by the authors.

(2) This volume should form a useful introduction to the study of eugenics, and should go far towards spreading eugenic ideas. It contains the short and simple annals of the subject, a statement as to what constitute "racial qualities," and an account of the various methods by which knowledge has been or may be acquired. It concludes with a chapter on the construction of society and a descriptive bibliography.

(3) The point of view of the author of this book is that Mendel's laws are universally applicable and the best, indeed the only, guide in practical eugenics. The chapter somewhat inappropriately headed "The Method of Eugenics" contains an illustration of these laws drawn from the results of crossing red- and white-flowered four o'clocks, together with an account of the phenomenon of karyokinesis, particularly in the maturation of the germ-cells. The reducing divisions are described as the mechanism by which segregation is brought about. The author rightly insists that it is the germ-plasm which is transmitted, and in order to avoid falling into the verbal error of describing somatic characters as inherited, the word germ-plasm is used very freely, and sometimes a little awkwardly, as, for instance, in the phrase on p. 207, "a germ-plasm which easily developed such traits as good manners, high culture, and the ability to lead in all social affairs."

More than half the volume is occupied by "The Inheritance of Family Traits." As something like one hundred different characters are dealt with, including many out-of-the-way diseases like congenital traumatic pemphigus, in 150 pages partly occupied with pedigree charts and photographs, it can be supposed that the treatment is not in all cases exhaustive; indeed, it may in parts be described as scrappy, but this is partly compensated for by the fullness of the bibliography. After this more general questions are discussed, such as the geographical distribution of inheritable traits and the modification of racial characters brought about by immigration and emigration. The extraordinary influence for good or evil which may be exerted by the descendants of a single individual forms the subject-matter of an interesting chapter, and the work concludes with a discussion of the relation between heredity and environment and some suggestions as to the organisation of applied eugenics.

M

With regard to the subject of immigration, the author makes a somewhat startling proposal for legislative action, namely, that the Federal Government should organise an army of "field workers" in foreign countries who would inquire into the family histories of all intending immigrants in order to ascertain whether their germ-plasms are suitable for introduction into the United States.

E. H. J. S.

STUDIES IN BIOLOGY.

(1) *Anleitung zum praktischen Studium niederer Tiere: Protozoa, Coelenterata, Vermes, Echinodermata.* By Dr. W. Schleip. Pp. vii + 154. (Berlin: Gebrüder Borntraeger, 1911.) Price 3 marks 50 pfennig. (Bibliothek für naturwissenschaftliche Praxis.)

(2) *First Book of Zoology.* By T. H. Burlend. Pp. viii + 159. (London: Macmillan and Co., Ltd., 1911.) Price 1s. 6d. (First Books of Science.)

(3) *More Animal Romances.* By Graham Renshaw. Pp. x + 252. (London and Manchester: Sherratt and Hughes, 1911.) Price 7s. 6d. net.

(4) *Lehrbuch der Biologie für Hochschulen.* By M. Nussbaum, G. Karsten, and M. Weber. Pp. xi + 529. (Leipzig: Wilhelm Engelmann, 1911.) Price 12 marks.

THERE is something in these new biological books for every class of reader, except for those whose interest is bounded by the study of genetics in the narrower sense of the word. The amateur microscopist will find in the first volume helpful practical instruction. The organiser of education in country areas will do well to recommend the second to the teachers of nature study in his district. Those who seek a melodramatic presentation of episodes in the wilds can have their fill of excitement by reading Dr. Renshaw's latest volume; and lastly, there is the magistral essay with full references for the specialist and university worker in the remarkable work that stands last on this list, for, as is explained below, the book is quite unsuitable in its present form to be adopted as a text-book in high schools, and we are anxious that its great merits should not be overlooked, as indeed may easily happen if the inadequacy of the title is not emphasised.

(1) Dr. Schleip sets out to assist the beginner in methods of microscopical technique as applied to the study of accessible examples of simple invertebrates, and proceeds to give short descriptions of each example selected. He begins by showing how to collect, mount, and cultivate different kinds of Amœbæ, which are certainly not easy objects for a beginner to find or manipulate. From this starting point the author proceeds to other groups of Protozoa (including such unusual forms as the ciliates of the ruminant stomach), and then to a brief consideration of the Hydrozoa. Sponges and Turbellaria are dismissed with a few words, whilst the more modified Cestodes and Trematodes are dealt with at some length.

A curious mistake seems to have crept into the section on "Earthworms-Nematodes." It is an excellent idea to obtain these eelworms by allowing earthworms to decay, but the author improves upon this idea, and advises the worker to fill up the body-cavity with soil. He then will find in a few days that the earth contains many adult and young specimens of Nematodes belonging to the genera Diplogaster and Rhabditis. Two precautions are here overlooked. In the first place, the Diplogaster is almost certainly not an earthworm-nematode, but a soil-form which the experimenter has introduced. In the second, Rhabditis, whilst possibly a true earthworm-nematode, will only develop if Lumbricus is used, and will not appear (or only very rarely) if the equally common Allolobophora is employed as a nutritive medium. . brief account of these Annelids follows, and the book closes with a very sketchy chapter on Echinoderms. Care has been taken to make the treatment throughout as simple as possible, and the book will be found useful to those who wish to begin the study of the lower animals.

(2) Teachers of elementary biology in rural schools will be glad of Mr. Burlend's brightly-written and well-arranged introduction to the study of animals. An attempt is made to interest the reader in such a way as to lead him or her to observe and record observations in an orderly manner. Many of the examples selected are such as are not usually described in so cheap a work (for example, the house-fly, garden snail, and brown trout), whilst all are obtained without difficulty. The figures appear to have lost something of their sharpness of outline and detail in the process of reproduction, but the three coloured plates are attractive. The remark about the different disposition of the wings in moths and in butterflies during repose on p. 62 needs altering, and the word Fritillaries as synonymous with Nymphalidæ is misleading, but these points do not detract from the value of the work as a means of stimulating powers of observation and of arousing an intelligent interest in the subject.

(3) Dr. Renshaw is known to many readers as an ardent naturalist and an imaginative writer. In this volume, a companion to an earlier one of similar title, he attempts ambitiously to "restore" the animal life of bygone times in a series of word-pictures, and he includes also a number of gorgeous descriptions of present-day episodes in dif-

ferent parts of the world. In his scene-painting the author shows an alert mind, in which the memory of his own travels and the knowledge that he has industriously acquired from direct observation and from books are ingeniously blended together.

In his own special line—that of describing the association and interaction of animals against a suitable background—Dr. Renshaw displays a notable gift, and his heart is in the work of attracting his readers to that which he himself finds so absorbing. The vividness, the fullness, the tenseness of tropic nature are ever in his mind, but the attempts to depict them would have been more successful had more restraint been exerted. "War to the adjective" might well be his motto. The gory element is certainly too obtrusive for most readers' tastes, and we could well have spared some of the tales of blood and fury which end in clouds of flies. However, the careful observation and the attractive illustrations make amends, and we can confidently recommend this volume to all who have found the earlier works by Dr. Renshaw a stimulating account of moving incidents by flood and field.

(4) This book differs from all other text-books of biology with which we are acquainted in describing organisms from the point of view of experimental morphology; that is to say, it takes for granted a knowledge of general anatomy, physiology, and classification, and proceeds to show what factors are at work in the production and maintenance of form and of structure. From the modernity of its point of view and its wide scope, this work goes far to provide what is so greatly needed—a really biological text-book; and it is only the immense and increasing amount of material and the rapid changes of knowledge involved thereby, that have prevented the authors from effecting a still more intimate association between the factors that govern the zoological side of the problem and those that condition the botanical one.

The book consists of three parts, which are severally the work of distinguished biologists. Prof. Nussbaum, of Bonn University, has written the opening section, and deals with that special aspect of experimental animal morphology which presents itself upon consideration of the regenerative and regulatory processes in animal tissues; Prof. Karsten deals in the second section with the ecology of plants; and Prof. Max Weber has written the concluding part upon the factors of animal life. From the student's point of view, the middle section should have come first, since it is not only simpler in its subject, but also because it is written in a more simple manner. For the same reasons the chapter on animal biology should have preceded Nussbaum's section on special problems. The order, however, is of comparatively little importance to those who wish to consult rather than to read the work consecutively.

On their several topics these writers are indisputable authorities, and write out of the fullness of their knowledge and experience. The result is a work of unusual value.

PLANT PHYSIOLOGY FOR AGRICULTURAL STUDENTS.

Plant Physiology, with special reference to Plant Production. By Prof. B. M. Duggar. Pp. xv+516. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1911.) Price 7s. net. (The Rural Text-Book Series. Edited by L. H. Bailey.)

"PLANT physiology," the author states in his preface, "finds its practical application in plant production. . . . It is somewhat strange, therefore, to find that as a separate course plant physiology is not yet offered in some of the colleges whose purpose is primarily to train persons for practical or rural pursuits." In helping to remedy this state of affairs, the author has produced a very readable book, useful to the student whose life is to be passed among plants and whose living is to be got out of them, and at the same time interesting to the general reader who loves his garden and has an appreciative eye for flowers and trees.

That the book is American goes without saying; the large proportion of our modern books for agricultural students comes from the States. Its distinguishing feature is that at every turn it brings in such practical applications of particular facts or principles as have been made, thus emphasising the economic importance of the subject while adding considerably to the interest. The general plan of the book is as follows:—After a description on the usual lines of the plant cell, the student is led on to the water relationships of the plant, to the root and soil, to absorption, transpiration, and water requirements of crops; then to a consideration of mineral nutrients and their special functions and relations. The student is now directed to the leaf, the intake of carbon and the making of organic food, the assimilation of nitrogen and the working up of simple nitrogen compounds into protein, and the general phenomena of nutrition, respiration and growth. Next comes the discussion of seed formation and reproduction. Then come three chapters that look out of place, dealing respectively with the effects of temperature, of light, and of deleterious chemical agents on plant life. Finally we get back to the main argument, with chapters on variation and heredity.

A general criticism, applicable not only to this but to many other American books, is that too little is made of the classical researches that have created the subject and too much of the latest results of the latest bulletin. To some extent this defect is remedied in the lists of papers given at the end of each chapter, where the classical papers are usually included, but there are some omissions; for instance, at the end of the chapter dealing with nitrogen fixation by bacteria there is no reference to Winogradsky's papers. This is a defect that the teacher will have little difficulty in remedying if he wishes to do so, while the inclusion of newer work has, at any rate, the advantage of familiarising the student with the work going on at the various experiment stations.

At the end of each chapter a number of practical exercises are given, bearing on the work that has been discussed. The experiments are simple and convincing, and cannot fail to be helpful to the student. References are also given to larger works so that any particular point can be looked up. The illustrations are numerous and very good.

Probably few teachers of plant physiology realise how many practical applications of their subject there are, or how much is added to the interest of the discussions by bringing in a few illustrations from agricultural or horticultural practice. Particularly in these latter days, when numbers of botanists and mycologists in different parts of the world are applying science to crop production, is there a great amount of material accumulating which must soon react on the study of plant physiology. The teacher, at any rate, will be well advised to look through this volume in search of illustrations, and he may find it worth while to adopt some of the methods.

NON-EUCLIDEAN GEOMETRY.

Bibliography of Non-Euclidean Geometry, including the Theory of Parallels, the Foundations of Geometry, and Space of N *Dimensions.* By Dr. D. M. J. Sommerville. Pp. xii + 404. (London: Harrison and Sons, St. Martin's Lane, 1911, for the University of St. Andrews, Scotland.) Price 10*s.* net.

CONSIDERING its subject, this bibliography seems at first sight extraordinarily large; but there are several reasons why it is not so formidable as it looks. The actual list of titles occupies pp. 1–261; this is arranged chronologically, each year's titles being indexed by the authors' names. Then (pp. 261–310) we have a subject index, an alphabetical list of subjects, and an author index. Finally, Mr. Sommerville has included various topics not strictly belonging to the subject, but more or less closely connected with it; for instance, quaternions, Cantor's theory of aggregates, Minkowski's "Geometrie der Zahlen," and so on. At the other extreme, we have reviews of books, references to the subject in fiction, and even "the realm of spirits."

In a work of this kind it is better to be inclusive than exclusive; so long as the list is reasonably complete, and the subject-index arranged on sound principles, the compiler has done his duty. There is every reason to believe that, in both respects, Mr. Sommerville has achieved success. As a few examples out of many that could be given, we may note the entries under "time of two or more dimensions," and "time as the fourth dimension," the latter including a reference to Lagrange; those on the philosophy of geometry, significantly headed by Bergson; and, on the lighter side, those on the extension of magic squares and cubes to n dimensions.

After making all deductions, we cannot fail to be impressed by the astonishing growth of this theory in recent times. Most remarkable of all, perhaps, is the fact that some eminent men of science are seriously suggesting time as, in a sense, a fourth dimension, the effect of which is to bring the physical universe *sub specie eternitatis* as a given configuration, parallel sections of which are realised by us as successive events, or aspects, in time. How far this is a mere way of speaking, or how far it may lead to a radical change in our assumptions of the ultimate undefinables of physics, it is too early to attempt to decide. Meanwhile, attention may be directed to M. Bergson's "Creative Evolution," in which a distinction is drawn, on purely philosophical grounds, between time as a metaphysical notion and the t of mathematical physics. This contention is not to be lightly dismissed, urged as it is by a philosopher who differs from the bulk of his profession in really understanding the methods and results of physical, biological, and mathematical science.

It is to be hoped that Mr. Sommerville's excellent index will help to arouse even wider interest in the subject, which is not only fascinating and educative in itself, but, as we have just seen, not unlikely to be of wholly unexpected importance in the applications of mathematics to physics. The very last entry that we find is that of Minkowski's collected mathematical memoirs: could anything be more suggestive?

G. B. M.

OUR BOOKSHELF.

Our Weather. By J. S. Fowler and William Marriott. (The Temple Primers.) Pp. xi+131. (London: J. M. Dent and Sons, Ltd., 1912.) Price 1*s.* net.

This book belongs to a series of small volumes intended to form introductions to the subjects of which they treat. Into its 120 pages Messrs. Fowler and Marriott have compressed a great deal of useful information. After a brief introductory chapter explaining why a popular book about weather is a practical necessity, they discuss in turn pressure, temperature, humidity, wind, and allied phenomena. They then deal with weather-forecasting, the upper air, and phenological observations, and conclude with a chapter on proverbs and rhymes.

The book is very readable, and the authors have carefully refrained from explanations or reasoning which might puzzle or bore the uninitiated reader. There are, however, a few points to which it may be useful to direct attention. The chapter on pressure contains a table showing the heights at which pressures of 29, 28, . . . 21 inches are reached when the pressure at sea-level is 30 inches, but the temperature with which the values correspond is not stated, nor is there any indication to the reader that temperature affects the results. In connection with the curve of annual variation of temperature, it is stated that the most noticeable irregularities are the cold days about the middle of May, and the warm spell at the end of November, but a reference to the curve shows that only the slightest irregularities occur in May. The most marked feature is the cold period in the second and third weeks of June, which is also mentioned by Hann as the general outstanding irregularity in the annual variation of temperature in Europe.

Months of unequal length are a general source of trouble in meteorological statistics, and the authors repeat the common mistake of including February with March as the driest of the twelve months at Greenwich, although the daily rainfall in the former month is greater than in April. In connection with forecasting, the statement that the information received by telegram is plotted on two maps, one for pressure and wind, and one for temperature and weather, is erroneous: the information is plotted on one working chart.

E. G.

Philips' Comparative Series of Wall Atlases. Edited by J. F. Unstead and E. G. R. Taylor. *Europe.* 8 maps. (Mounted complete as a wall atlas, on cloth, with roller.) Price 21*s.* Explanatory Handbook (to accompany the above). Pp. 16. Price 6*d.* net. (London: G. Philip and Son, Ltd.; Liverpool: Philip, Son, and Nephew, Ltd., 1912.)

This series of maps should prove of great service to teachers of regional geography, as they show political conditions, railways and configuration, climate, density of population, and economic conditions. The map showing communications illustrates admirably the influence of mountain ranges, passes, and river valleys on transport. It is generally complete, though for some reason the Algerian railways have been omitted. The Density of Population is a graphic map with sufficient detail for the comparison of regions with one another. Used with the other maps, it should help to indicate the dependence of population on manufacturing areas, railway lines, river valleys and lowlands, and the comparative isolation of mountain areas, tundra, and desert. Unfortunately, this comparison is not possible in Africa and Asia, as the map stops short at the boundaries of Europe.

The climate maps show winter and summer conditions of temperature, pressure, winds, and rainfall. Actual temperature conditions are not shown, but the orographical features are printed on the map of summer and winter lines of temperature, so that reference can be made to real temperatures by allowing for elevation at any particular place or along any given line of temperature. Detailed maps of actual temperature must, like detailed orographical maps, be very complex, but we cannot help regretting that some simple maps of this kind have not been added to the series for summer and winter, with perhaps only a few selected lines of critical temperatures, as their value is incontestable as a means of comparison between regions.

On the whole, we have nothing but praise for this series, which affords most valuable material for the study of regional geography. The textbook which accompanies the maps points out clearly the general way in which they may be used.

The Fauna of British India, including Ceylon and Burma. Edited by Dr. A. E. Shipley, F.R.S. Assisted by Guy A. K. Marshall.—*Coleoptera.* General Introduction and Cicindelidæ and Paussidæ. By Dr. W. W. Fowler. Pp. xx+529. (London: Taylor and Francis; Calcutta: Thacker, Spink and Co.; Bombay: Thacker and Co., Ltd.; Berlin: R. Friedländer & Sohn, 1912.) Price 20*s.*

The volume before us differs somewhat in plan from most of those which have preceded it. The first half (up to p. 218) consists of a very elaborate introduction to the Coleoptera, giving a detailed account of the whole series of families (103, exclusive of Strepsiptera) recognised by the author in the order, whether represented in the Indian region or not. The "Abnormal Coleoptera: Strepsiptera or Stylopidæ," incidentally alluded to, are not yet proved to be Indian. We may point out that it was Kirby, the original discoverer of these insects, who proposed to make them a separate order (Strepsiptera), and Westwood merely followed him.

The two families of beetles dealt with in the latter half of this volume are specially interesting: the beautiful and active Cicindelidæ, or tiger beetles, and the Paussidæ, which are remarkable for the curious structure of their antennæ, and also for their habits, several species being found in ants' nests, and detonating like the well-known bombadier beetles (Brachinus).

LETTERS TO THE EDITOR.

Clouds and Shadows.

IN NATURE of April 18 Mr. Charles Tilden Smith described a cloud-like appearance which he considered was no cloud, as it remained quite stationary while stratus and small lower clouds were driven quickly across the sky. I think I can throw some light on the subject, as I observed a similar appearance both on April 5 and on April 8, the date of Mr. Smith's observation.

On April 5 I was observing pilot balloons when my attention was directed to a cloud which formed in the east; it was a cloud with very soft edges, which were constantly changing their shape and were frequently ripple-marked. I enclose a photograph of the cloud taken about 6 p.m. What chiefly attracted my attention was the fact that the cloud remained stationary, though it was obvious from the motion

of the pilot balloons that there was a very strong wind in the upper air. The pilot balloon ascents at 5.27 p.m. and at 6.24 p.m. showed that at one kilometre above the surface the velocity was 20 metres per second or more, which is fairly high for such a low level; the velocity fell off a little at greater heights, but it was 15 metres per second or so at three kilometres.

As a north-west wind, which was the direction on this day, never seems to decrease very materially below the level of the stratosphere, it is obvious that the cloud in question was remaining stationary, though it was floating in a strong wind; presumably the particles of which it was composed were condensing on the windward side and evaporating on the leeward side of the cloud, as in cloud streamers seen round the peaks of mountains. That this was really the case I could not determine at the time, as I was taking observations of balloons, but on April 8 I noticed very similar clouds shortly before sunset, and by watching them carefully it was quite clear that in this case the above supposition was correct. There was a great development of these soft-edged clouds just before sunset; they were arranged more or less in parallel bands, with a vanishing point in the south-west; the particles of which they were composed were coming from the north-west. At one time I noticed that the edges of one cloud broke up into ripple clouds which moved rapidly from the north-west until they reached another cloud into which they merged.

If Dr. W. N. Shaw's supposition is correct that changes of pressure in the lower layers of the atmosphere are caused very largely by changes which occur in the level just below the stratosphere, it follows that a diminution of pressure at this level will cause a decrease of pressure through the whole of the underlying layers, and, as Dr. Shaw has pointed out, condensation and formation of cloud may take place wherever there happens to be a damp layer, and we get, what is so often seen, the simultaneous formation of sheets of cloud at widely different levels.

On April 5 there was a great development of cloud at different layers at sunset. If at any particular layer condensation is almost taking place, any uplift of air will hasten it, and any wave motion that may exist will become visible by condensation in the wave crests. On April 5 the strong wind passing over the irregularities of the surface, such as the South Downs in this neighbourhood, might have caused local uplifts of air which might have extended to considerable heights; thus at some particular layer condensation might take place, the cloud particles forming where the air was rising and evaporating further to leeward, where the air was descending. Soft-edged clouds, formed in a somewhat similar way, may sometimes be seen covering the tops of the Downs and closely following their contours, giving the hills a strange appearance of increased height, as recorded by Richard Jefferies in "Wild Life in a Southern County."

It is difficult to estimate the heights of the clouds seen on April 5 and 8, but I think, though I am not quite sure, that I saw a pilot balloon projected on one of them when it was at a height of about three kilometres; if this were so, the clouds must have been at a greater height.

CHARLES J. P. CAVE.

Ditcham Park, Petersfield, May 5.

Mammalian Remains at the Base of the Chalky Boulder Clay Formation in Suffolk.

MR. E. P. RIDLEY, Mr. Frank Woolnough, curator of Ipswich Museum, Mr. Fredk. Canton, and myself have to-day assisted in the removal of a large curved tusk which was found at the base of the chalky boulder clay formation, and on the top of the underlying middle glacial sand, at a depth of 11 ft. 3 in. from the present surface of the ground.

Numerous pieces of bone evidently belonging to the same animal have been found lying near the tusk, but were removed before we arrived. The spot where this discovery has been made is in a shallow valley at Charsfield, a village about eleven miles north of Ipswich, and it is owing to the kindness of Mr. W. H. Youngman that I was apprised of the find.

This shallow valley is a typical example of the dry valleys so often met with in Suffolk and elsewhere, and is not apparently connected with any present river system.

The section in the small pit, which is being worked for stone, shows 1 ft. of surface humus, 3 ft. of blackish gravel, 4 ft. of chalky boulder clay, developing into, and evidently a part of, a loamy gravel about 3 ft. in thickness.

At the bottom of the section the fine, stoneless middle glacial sand is exposed. The accompanying photograph, taken by Mr. Frank Woolnough with the camera suspended over the pit, shows the tusk *in situ*, it being afterwards removed by my man Baxter and myself, who, finding it very friable, had to use great care in getting it up intact.

The remains have been sent away for identification, but it was obvious that they presented the same amount of mineralisation as was present in the human bones found by me at exactly the same horizon at Ipswich, in October of last year. As in this latter case the remains were found lying partly embedded in glacial sand and partly in the different overlying material, also in both cases the amount of iron staining is very slight.

This discovery appears to me to be of some importance, and affords an answer to those of my critics who were dissatisfied with my discovery of the human skeleton because I had not found any other mammalian bones at the same horizon at which this occurred.

It is also an additional piece of evidence that the top of the middle glacial sand was a land-surface in pre-chalky boulder clay times. J. Reid Moir.

12 St. Edmund's Road, Ipswich, May 5.

Les Eclipses d'Hiver et les Éclipses d'Eté.

Nous venons d'assister à un phénomène très curieux le 17 avril dernier. Au premier abord il parait avoir été le résultat d'une faveur exceptionnelle d'Éole. Monsieur Angot, le savant Directeur du bureau central météorologique de France, a compulsé avec soin l'histoire de la science qu'il cultive si assidûment, il est arrivé à l'idée que les astronomes faisant d'immenses préparatifs pour observer l'éclipse à terre avaient très peu de chance de rencontrer un ciel serein permettant d'arriver à des mesures angulaires irréprochables; il leur en attribuait huit sur cent.

Monsieur Angot oubliait que l'éclipse qui a soulevé une si vive émotion se produisait dans les jours froids du printemps, que les vents soufflaient dans la direction de l'Est ou du Nord et que, par conséquent, le refroidissement produit par l'éclipse devait très difficilement déterminer la formation de nuées suffisamment épaisses pour empêcher d'observer le Soleil. D'après le compte rendu qui m'est communiqué des treize ascensions exécutées à Paris par Messieurs Bans et Barbotte, le refroidissement a été très énergique; à la hauteur de 2500 mètres où ils étaient parvenus ils ont constaté que leur thermomètre était descendu à plusieurs degrés centigrades au-dessous de zéro. Cependant grâce à la constitution atmosphérique qui est fréquente en pareille saison les observations terrestres ont été partout irréprochables. Si l'éclipse eut été réellement totale au lieu de l'être d'une façon hypothétique, on aurait vu les couronnes, les protubérances d'une façon merveilleuse sans avoir besoin comme l'ont fait si souvent Sir Norman Lockyer et J. Janssen de se transporter dans les Indes, dans l'Indo-Chine, en Égypte et dans les îles les plus isolées de l'Océan Pacifique.

Mais il existe une circonstance fort intéressante dont Mr. Angot n'a pas tenu compte et qui justifie parfaitement les efforts qu'a fait récemment le fils de Sir Norman pour suivre l'exemple de son illustre père.

En été dans le voisinage de la fin de juin, le disque du Soleil est réduit à son minimum parce que la terre arrive à son aphélie; alors notre satellite a beaucoup moins de peine à le recouvrir. Si par hasard à l'heure de l'éclipse la lune est voisine de son périgée le phénomène atteint son maximum; il peut durer plusieurs centaines de secondes, et on a tout le temps d'explorer le voisinage de l'astre qui malheureusement ne peut nous éclairer sans nous éblouir et nous cacher par conséquent tout ce qui se passe autour de lui.

Mais à cette époque, au moins dans notre hémisphère, l'air est saturé de vapeurs de sorte que les belles observations d'éclipse sont très rares; il est excessivement difficile d'en profiter pour résoudre les magnifiques problèmes dont on s'occupe si vivement depuis qu'Arago s'est immortalisé en les signalant lors de la grande éclipse totale visible à Perpignan en 1842. C'est ce qui fait qu'on a attaché tant de prix aux travaux de Sir Norman qui a imaginé et pratiqué avec tant d'habileté les recherches spectrographiques autour du Soleil sans se préoccuper des éclipses. Il est bon de faire remarquer que l'hémisphère austral se trouve à ce point de vue dans une situation beaucoup plus favorable que le nôtre et que les astronomes de Sydney ont beaucoup plus de chance que les nôtres d'observer de belles éclipses totales. En effet lorsqu'elles arrivent dans leur hiver qui correspond à notre été le Soleil est à son minimum.

Je ne peux terminer sans faire remarquer que l'éblouissement produit par le Soleil diminue rapidement par l'altitude à laquelle parvient l'aéronaute quoique la puissance calorifique du Soleil augmente. Il en résulte qu'on voit certaines étoiles plus voisines de l'astre que si l'on restait à terre. Par conséquent en s'élevant très haut lors du crépuscule ou de l'aurore on peut explorer d'assez près la banlieue du Soleil. C'est même cette circonstance qui faisait que Le Verrier avait désiré dans les dernières années de sa carrière faire exécuter des ascensions à l'observatoire de Paris pour découvrir la planète Vulcain à l'existence de laquelle il croyait fermement.

On peut voir du reste dans les comptes de ce grand établissement les dépenses qu'il a faites, lorsqu'il m'a chargé en 1875 de remettre en état le ballon de l'observatoire, malheureusement cet appareil avait été si maltraité par les aéronautes qui l'avaient eu entre les mains pendant la durée du siège qu'il fut impossible de le réparer et que les intentions presque testamentaires de Le Verrier n'ont pu recevoir aucune exécution. W. de Fonvielle.

St. Broing, 23 avril.

The Ammonia Flame.

It is generally recognised that Strutt's discovery of an active form of nitrogen is one of the most interesting results of recent investigations: it may be opportune, then, to direct attention to a phenomenon which seems to have some connection with active nitrogen. The colour of the flame of ammonia burning in oxygen is yellow, and of the same tint as the nitrogen glow in Strutt's experiment; the spectrum of the light emitted is similar. The structure of the flame is also exceptionally interesting; it consists of an inner bright yellow cone and an outer, almost non-luminous, flame. It would seem that the ammonia is first of all split up into nitrogen and hydrogen, and that the light of the inner cone is due to the combination of nitrogen atoms to nitrogen molecules, as is suggested in the case of the nitrogen glow, while in the outer flame hydrogen burns to water and some nitrogen combines with oxygen to give nitric oxide. An analysis of the products of combustion showed that nitrogen and water were the main resulting substances, but that nitrogen peroxide was also produced in considerable quantity.

There are one or two other points which support this view of the combustion. The shape of the flame is interesting; most flames which are due to the combination of substances have a pointed cone with more or less inflected sides, when the gases issue from a circular orifice; but in the ammonia flame the inner cone always asumes a rounded apex like a thimble, the outer flame being similar to the usual inflected pointed type of flame. The explanation of the difference in the structure of the flames appears to me to be plain, if in the inner cone a simple decomposition is occurring at a distance from the orifice depending on the velocity of the issuing stream of ammonia, while in the outer cone a combination is occurring with oxygen which is being drawn up along with the flame, as in an ordinary combustion.

Another point about the combustion which seems to support this view of the actions occurring in the flame is that it is difficult apparently to make oxygen burn in an atmosphere of ammonia or to get mixed oxygen and ammonia to burn, though such a mixture may explode if in correct proportions. I think, then, the above view of the cause of the luminosity is preferable to that which would ascribe it to the production of nitric oxide. Alfred C. Egerton.

R.M.A., Woolwich.

REPORT OF THE TUBERCULOSIS COMMITTEE.

In a report just issued, the Departmental Committee on Tuberculosis, appointed in February by the Chancellor of the Exchequer "to report at an early date upon the considerations of general policy in respect of the problem of tuberculosis in the United Kingdom in its preventive, curative, and other aspects, which should guide the Government and local bodies in making or aiding provision for the treatment of tuberculosis in sanatoria or other institutions or otherwise," has made a pronouncement the importance of which will be realised only as the advice followed in that report comes to be followed and its suggested provisions put into force.

Up to a recent date the treatment of tuberculosis has been left, to a very large extent, to voluntary effort, and whilst excellent work has been done by the various associations that have undertaken this work, aided later by municipal and other health authorities, and eventually by Government and the Local Government Board, there has been a sad lack of coordination and want of organisation. This has militated seriously against the success of the campaign undertaken against the white plague. In the report now before us we have the "opinion" of a body of experts who have considered the question of the prevention and treatment of tuberculosis on what may be described as a national scale. These experts have already been engaged in some department or other of the crusade. Legislators, administrators, heads of institutions specially designed for the treatment of tuberculosis, medical officers of health, and other members of the medical profession, each in turn has brought some special knowledge and experience to bear, with the result that we have no pressing forward of incomplete or ill-considered schemes, no exaggerated claim for any special method of treatment, and no presentation of a panacea for all cases of tuberculosis.

The committee has taken its duties and responsibilities very seriously, and is evidently impressed with a sense of the importance of its functions. It has looked beyond those who are already in an advanced stage of tuberculosis, and has brought within its purview the measures that must be adopted to prevent the affection of those who are still sound or who suffer but slightly. Further than this, however, it is in full accord with the framers of the Act that much of what is now being contemplated is based on the knowledge that has been gained by research, in the ward to some extent, but primarily in the laboratory. It is impossible, of course, to affirm that in time we might not have reached our present viewpoint as regards the general treatment of tuberculosis in its various forms by a careful clinical study of the disease and a prolonged study, by rule-of-thumb methods, of the various drugs and certain of the modes of treatment; but it may be affirmed, and that most strongly, that this could not have been during the life of the present generation, and probably for several of those succeeding. Experimental investigations carried on by Villemin and Chauveau, by Burdon Sanderson, by Cohnheim and Salomonsen, and finally by Robert Koch, brought us, however, by a "short cut" to a point from which the rate of advance along the above and other lines has been phenomenally rapid; of this we have evidence in the report now before us.

The first aim under the Insurance Act is to find out tuberculous patients, and this, it is suggested by the Committee, is to be done through the "dispensary"; the second is to prevent the spread of the disease by the administrative work of our public health departments and our hospitals;

the third is to bring the patients to as high a state of physical health as possible through the agency of dispensaries, hospitals, sanatoria, open-air schools, and the like. Whilst all this is going on, however, the laboratory investigator is to be encouraged to contribute to that stock of knowledge on which most of the administrative preventive and curative methods of dealing with tuberculosis are based. The public health authority, both central and local, the tuberculosis expert, the general medical practitioner, the voluntary anti-tuberculosis organisation, and the laboratory worker are brought together in the scheme of the committee; funds are provided—whether in sufficient amount still remains to be seen, but they are a good beginning—and the scheme starts under the most favourable auspices. That an enormous amount of good will be effected no one can doubt; that a whole-hearted attempt is being made to get the best of the scheme is equally certain; and should modifications or alterations have to be made in the future, it will be only as more light is thrown upon, and a better view obtained of, a very difficult and complicated question.

SARDINES IN SCIENCE AND COMMERCE.

IT has been suggested to us by a correspondent that the publication of the full text of Alderman Sir George Woodman's judgment in the recent "sardine" case, referred to in NATURE of April 25 (p. 194), would be of interest. In our article Sir George was incorrectly stated to have said that the industry of packing the immature pilchard in tins was started in 1882; this date, as will be seen from the subjoined report with which he has kindly favoured us, should have been 1822.

"My decision is that the term 'sardine' is of French origin. It is the French name for the pilchard, the fish scientifically known as *Clupea pilchardus*. The industry of packing the immature pilchard in tins was started in France in 1822, and the fish so packed and imported into this country were universally known as 'sardines.' The word 'sardine' has now become Anglicised, and I hold that the meaning of the term is 'the immature pilchard prepared and packed in oil in tins.'

"This is not what the defendant sold. The 'Skipper sardines' sold by him were the Norwegian fish known as the 'brisling.' The 'brisling' is the *Clupea sprattus* of the same family but of a different species from the *Clupea pilchardus*, and is the same fish, allowing for differences caused by local environment, as the English sprat. There was a false trade description.

"The defendant has not proved that, prior to the passing of the Merchandise Marks Act, 1887, the description 'sardine' was generally applied to any small suitable fish prepared and packed in oil in tins, but I am satisfied that for the last twenty years at least the use of the term 'sardines' has been extended in commerce, especially amongst retail traders, to include any such small fish so packed and prepared. To the defendant, who started his own business in 1903, and was selling Norwegian sardines twenty years ago, the word had this extended meaning. He also knew that the Norwegian Government had formally adopted the word 'sardines' to describe the brisling packed in oil. He, in my opinion, believed that the description he applied was a true description, and, notwithstanding the very able legal arguments I have just listened to from Mr. Bodkin, I hold that he has proved that he acted innocently within the meaning of Section 2, Subsection 2 (*c*) of the Merchandise Marks Act of 1887. I therefore dismiss the summons."

We should like to have similar legal pronouncements upon several other commodities which are sold under misleading trade descriptions. For instance, the names under which furs are sold in shops often conceal from the public the nature of the animals from which the furs have been obtained. It is regarded as permissible by dealers and tradesmen to describe the fur of white rabbit, dyed, as "chinchilla coney," Australian opossum as "Adelaide chinchilla," American opossum as "Russian marten," and Belgian hare as "Baltic lynx." Such designations seem to us to be just as misleading as describing sprats as sardines when they are packed in oil. Again, quarry-owners and contractors for road-metal claim that any stone used for this purpose may be described as "granite," with the result that limestones or other inferior rocks for road-making are purchased by local highway authorities under the impression that they are obtaining true granite. We make no claim to impose specific scientific terms upon the common vocabulary or the labels of commerce, but we are sure that the trade custom of describing one thing as another of a superior class cannot be justified by any satisfactory standards of precision or ethics.

THE ROYAL SOCIETY CONVERSAZIONE.

THE first of this year's conversaziones of the Royal Society was held at Burlington House on May 8, and was, as usual, largely attended. Many objects and experiments relating to recent work in science were on view, and in the course of the evening short demonstration lectures were given by Mr. C. V. Boys on soap bubbles, the Hon. R. J. Strutt on active nitrogen, particularly as to the striking effects of pressure and temperature on active nitrogen, and Dr. J. S. Haldane on mountain sickness and acclimatisation to high altitudes.

We are unable to find space for a list of the numerous exhibits, but we extract from the official catalogue a few descriptions of some of the chief objects of interest.

ANTHROPOLOGY.—*Mr. W. Dale:* Palæolithic flint implements from the gravel beds of the River Test at Dunbridge, Hants, at about 100 to 150 ft. above Ordnance datum. The implements are diverse in form and in the character of their patination. A marked feature is the presence of pointed forms quite unwater-worn, which have acquired the white colour of the upper part of the gravel. These are taken as dating the gravel, and assigned to the St. Acheul period. The largest and most pointed is even considered to belong to a later and transitional period. In the same gravels are found older and water-worn forms, which must have travelled from higher levels.

Sir Ray Lankester, K.C.B.: Flint implements from beneath the Red Crag of Suffolk. Many worked flints of a previously unknown shape, viz. that of an eagle's beak (rostro-carinate) and of other forms, have been discovered by Mr. Moir, of Ipswich, in the bone-bed of the Suffolk Crag. Several of these were exhibited, and also three rostro-carinate flint implements from the mid-glacial sands of Suffolk. Both the Red Crag sea and that of the mid-Glacial period swept these implements from an old Suffolk land surface. Those from below the Red Crag are of Pliocene, and possibly of Miocene, age.

Natural History.—*Dr. H. B. Fantham and Dr. Annie Porter: Nosema apis*, the parasite of Isle of Wight disease in bees. This pathogenic protozoon was discovered in 1906 by the exhibitors, and shown experimentally by them to be pathogenic, not only to hive bees, but also to wasps and mason bees. The parasite, which belongs to the Microsporidia, is allied to the organism causing pébrine in silkworms.

Mr. H. R. A. Mallock, F.R.S.: Apparatus for showing the disappearance of iridescent colouring under mechanical pressure. The coloured scales are placed between a flat plate and lens of quartz on the stage of a microscope and viewed during the process of compression with a low-power objective. The scales in the compressor were from Ornithoptera Poseidon. These are bright green by reflected light, but appear red when the light is transmitted. On applying pressure to a scale the colour first changes and then disappears, thus showing that its origin is due to the structure of the scale and not to colouring matter.

Dr. C. J. Patten: A selection of specimens and photographs illustrating some features in bird migration as observed during eight weeks' residence at the Tuskar Rock Lighthouse, Co. Wexford. The following points are noteworthy:—first, that in a comparatively short period, several rare birds—some new to Ireland—have been secured, which, had they reached the mainland, might never have been recorded; secondly, that birds supposed by some observers not to migrate, or at most to do so in a very desultory manner, have been found migrating in considerable numbers together; and thirdly, that remarkable variations in size and plumage may be seen in some species.

Prof. E. B. Poulton, F.R.S.: Butterfly mimicry and mutation. It has been argued, especially by Prof. Punnett, that the mimetic patterns of butterflies arose, ready-made and complete, by a sudden "mutation." The examples which he has specially mentioned are the mimetic females of the African *Papilio dardanus* and the two mimetic forms of *Euralia wahlbergi*. The exhibited series shows (1) the gradual origin of mimicry in the former, through the transitional form *trimeni* leading from the pattern of the non-mimetic females in Madagascar and Abyssinia to the mimetic *hippocoon* female; (2) the existence of a roughly mimetic representative of the two mimetic forms of the Euralia, in an allied species, *E. dinarcha*, and of intermediates which breed true, and are therefore not hybrids (heterozygotes), in a still more closely allied Euralia: all these bred by Mr. W. A. Lamborn in the Lagos district; (3) the four sharply separated mimetic patterns of a Pseudacræa, collected by Mr. C. A. Wiggins at Entebbe, connected by intermediates and running into one another on the islands in the Victoria Nyanza, where the Acræine models are relatively scarce. The latter collected by Mr. G. D. H. Carpenter.

Astronomy.—*Dr. Percival Lowell (Lowell Observatory, U.S.A.):* (1) Spectroscopic discovery of the rotation period of Uranus. Two enlarged copies of two (out of seven measured) of the original spectrograms taken in September, 1911, by Dr. V. M. Slipher, one with the camera to the west, one with it to the east, of the telescope, thus reversing the direction of the tilt. The spectrum of Uranus appears in the middle flanked by the two comparison spectra. The slit was parallel to the satellite's orbital planes. Measurement of the original negatives gives a rotation spin of 10h. 45m. retrograde. (2) Autumnal morning hoar-frost on Mars. Enlarged positives from the original negatives of Mars, taken November 14, 1912, 39° of longitude apart, showing hoar-frost on sunrise edge of the disc 30° to right of topmost point. The hoar-frost was studied for two months, and a memoir is in course of publication. Theory shows that 60° latitude is exactly where it should first have appeared. (3) Halley's comet: last appearance. Photographs with the 40-in. Lowell reflector by Mr. C. O. Lampland, on May 23, 27, and 30, 1911; also positive showing the positions in which the comet was photographed by him up to June 1 inclusive. These are the last views got of the comet as it left. (4) Comet Brooks, 1911. Objective-prism spectrogram taken on October 28, 1911, and November 2, 1911, show monochromatic images of the comet, and register the fact that the tail was composed almost entirely of carbon monoxide, while the hydrocarbons and cyanogen were conspicuous in the head.

Prof. H. F. Newall, F.R.S.: Photographs of the spectrum of Nova Geminorum, taken at Cambridge Observatory. Nova Geminorum was discovered by Enebo on March 12, 1912. It was not recorded at Harvard College Observatory on plates taken on March 10, but appeared as a star of fifth magnitude on a plate taken on March 11. Since its first maximum brightness (magnitude about 3·0) the star has faded, with fluctuations, to magnitude 5·0 on March 18, magnitude 6·0 on April 1, 7·0 on April 15. The photographs of spectra exhibited have been prepared from negatives picked out of a series of forty plates secured by Mr. Stratton on thirty-six nights, between March 15 and April 29, with the two-prism spectrograph attached to the 25-in. equatorial, with exposures varying from twenty-five minutes to five hours. They illustrate the rapid changes in the nature of the light emitted, especially in the first ten days after the outburst of the star on March 11.

Physics.—*The National Physical Laboratory:* Apparatus for measuring the visibility of point sources of light. (*Exhibited by Mr. C. C. Paterson and Mr. B. P. Dudding.*) The apparatus contains a pin-hole of known area with a flame of known intrinsic brightness behind it. The intensity of the transmitted light can be varied at will by calibrated absorption wedges placed in the beam to the observer's eye, the combination forming a variable standard point of light of known candle-power. The distant source of light is seen in the same field of view as the standard point source, and the latter is adjusted to be equal to it in brightness. There are arrangements for illuminating the background of the standard pinhole when observations are being made on nights which are not quite dark. The lower limit of visibility is that of a point source of about one ten-millionth of a candle one metre from the eye of an observer.

Mr. C. T. R. Wilson: (1) Apparatus for making visible the tracks of ionising particles by vapour condensed upon the ions set free along the paths. (2) Cloud photographs showing the nature of the ionisation produced by different kinds of rays. By the sudden dropping of the floor of a cloud chamber.

the moist air within it is cooled sufficiently to make water condense on any ions which may be present, no appreciable stirring of the air resulting from the expansion. Ionising particles passing through the air leave visible trails, consisting of cloud particles condensed on the ions.

CHEMISTRY.—*Sir W. Crookes, O.M.:* Properties of pure fused boron, and the volatility of metals of the platinum group. Pure fused boron, prepared by Dr. Weintraub by decomposing a volatile boron compound in the electric arc, is deposited on water-cooled copper electrodes. The agglomerated boron condenses in a crystalline form. Pure boron can be fused in a mercury arc furnace. It is very hard, and easily scratches quartz and corundum. The most remarkable property of pure fused boron is the abnormal value of its temperature coefficient of resistance. Between ordinary room temperature and a dull red heat the resistance drops in the ratio of 2×10^6 to 1. A small piece of fused boron mounted in series with an electric lamp, at room temperature, obstructs nearly all the current. Warming the boron reduces the resistance, and the lamp lights. Platinum, in the form of very thin ribbon, heated for many hours to a temperature approaching its melting point, sublimes and deposits beautifully formed crystals on the surrounding vessel. Iridium is more volatile than platinum at a high temperature. A plate of pure iridium, after having been heated for twenty-two hours at 1300° C., has a beautiful "moirée" surface. A crucible of iridium, showing signs of crumbling after long heating, was exhibited.

Messrs. Carl Zeiss (London), Ltd.: Apparatus for demonstrating liquid crystals with polarised light (projection on screen). This instrument consists of an automatic feeding arc lamp of 5 amperes, condensing lenses, water cooler, mounted on optical bench, a microscope, with specially wide body tube situated on the end of optical bench in upright position, and provided with a blow-pipe arrangement and air blast for the purpose of heating chemical preparations to a temperature up to 800° C. Analyser and objectives are provided with cooling chambers, and the object stage is arranged with electric terminals for passing a current across the stage. A specially constructed polariser is fitted below the object stage possessing a large aperture as compared with its length.

ENGINEERING.—*Mr. J. Dewrance:* An adhesion pump. A viscous fluid enters by gravity a shallow spiral channel cut on a revolving surface that is held against the smooth surface of a corresponding chamber. The fluid adheres to both surfaces, and progresses along the channel and is delivered at the other end at considerable pressure.

Prof. E. G. Coker: Special polariscope for examining engineering models under stress. The polariscope is constructed for examining long transparent models of engineering structures by circularly polarised light. Plane polarised light, obtained by reflection from a black glass plate, is afterwards circularly polarised by large quarter-wave plates of mica. The object under stress is viewed through an analyser constructed of glass sheets, and a model, 40 in. by 10 in., can be viewed at one time without the aid of Nicol's prisms.

Dr. J. G. Gray and Mr. G. Burnside: (1) Continuous-current motor-gyrostats for the demonstration of the properties and practical applications of the gyrostat. The gyrostats, which are motors of the Gramme Ring type, are provided with accessories for demonstrating the properties and practical applications of the gyrostat. Experiments (both qualitative and quantitative) can be carried out with convenience and precision. (2) Walking and climbing gyrostats. Motor-gyrostats are mounted in various ways within wooden boxes. By operating the gyrostats by means of electromagnets, the boxes, which are provided with arms and legs, are caused to walk on the floor and to walk arm over arm along wires stretched horizontally.

NOTES.

AT a meeting of the London Section of the Deutsche Kolonial-Gesellschaft on May 11, Dr. A. Smith Woodward gave an address on the significance of the recent discoveries of Cretaceous Dinosauria in German East Africa. Since 1909 excavations have been in progress in the Tendaguru Hills, under the immediate supervision of Prof. W. Janensch and Dr. E. Hennig, and an appeal is now being made for funds to proceed with a fourth year's work. In describing the results, so far as he had seen them in the Berlin Museum, Dr. Woodward emphasised the importance of an exhaustive comparison of the sauropodous dinosaurs of Africa with those of North America, which would now soon be possible. He also alluded to the problems suggested by the gigantic size of some species, which much exceeded the extreme limit of growth calculated to be possible by the late Prof. Marsh when he first discovered the femur of Atlantosaurus. Prof. W. Branca sent for exhibition to the meeting a plaster cast of the humerus of Gigantosaurus, 2·10 metres in length, which is shortly to be placed in the British Museum (Natural History); while Prof. Janensch lent an important series of photographs which he had taken at different stages during the excavations. The German society is to be congratulated on its enlightened interest in purely scientific work undertaken in a colonial possession, and English science will appreciate the compliment paid to one of its exponents by his being invited to deliver the address in question.

PROF. FRÜHLING, who died at Brunswick on April 24, at seventy-one years of age, did much towards enabling young men engaged in practical sugar work to obtain a scientific training. After graduating in 1866 with a thesis on the nitric acid contents of agricultural crops during the various periods of their growth, he started, in 1870, a public analytical laboratory, and two years later added a department at which instruction in sugar work was given. This "Schule für Zucker-Industrie zu Braunschweig" has flourished ever since, and been attended by students from practically every sugar-producing country in the world, among them being fourteen Englishmen. His "Anleitung," or methods of analysis for all products connected with the sugar industry, has been translated into several foreign languages; in 1911 it reached its seventh edition. He also published an "Anleitung," or laboratory guide, for soil analysis, and edited Stammer's pocket calendar for sugar manufacturers since 1894. The majority of sugar factories in the north of Germany retained him as their official analyst. He also invented several useful pieces of apparatus, which have been adopted for sugar work in a large number of Continental sugar laboratories.

Prof. Poynting being unable to deliver his lectures at the Royal Institution on May 30 and June 6, the lectures on those dates will be given by Prof. C. G. Barkla, F.R.S., upon the subject of "X-rays and Matter."

The final meeting of the British subcommittee of the Anton Dohrn Memorial Fund Committee was held on Wednesday, May 8, in the University of London. The hon. treasurer, Prof S. J. Hickson, presented the accounts, and stated that after all expenses had been paid there was a balance in hand amounting to 163*l.* 18*s.* 9*d.* It was resolved that the account of the British subcommittee be closed, and the balance forwarded to the treasurer of the International Committee.

A correspondent of *The Times* states that last week the Italian naval and military authorities, who have been carrying out experiments in wireless telephony, established communication between Monte Mario and the wireless station of Becco di Vela, on Maddalena Island, a distance of about 160 miles. A long extract from a newspaper was read in Rome and heard and repeated at Maddalena. The voices were perfectly distinct, so much so that the listener in Sardinia detected immediately the substitution of a different speaker half-way through the message.

We are officially informed that the post of Inspector-General of Agriculture in India has been combined with that of the director of the Agricultural Research Institute and principal of the Agricultural College, Pusa, under the designation of Agricultural Adviser to the Government of India and Director of the Agricultural Research Institute, Pusa. All communications, publications, &c., intended for either of the two offices should therefore be addressed to the Agricultural Adviser to the Government of India and Director of the Agricultural Research Institute, Pusa. The designation of the post of Assistant Inspector-General of Agriculture in India has also been altered to the Assistant to the Agricultural Adviser to the Government of India.

The London Institution (Transfer) Bill—or, to give the full title, "A Bill to provide for the transfer to the Commissioners of Works of certain property of the London Institution for the purposes of a School of Oriental Studies, and for the dissolution of the Institution, and for purposes in connection therewith"—has now been circulated. It is proposed that the property and funds of the institution shall be transferred to the commissioners, and that certain books and manuscripts will be retained by the institution. There will be paid to the institution, in consideration for the vesting of the property in the commissioners, 12,000*l.* out of moneys provided by Parliament. The books and manuscripts retained by the institution are to be transferred to such public institutions as may be determined by the committee of management. The institution will eventually be dissolved, and the charter of the institution revoked. The sums of money to be paid to the proprietors of the institution to discharge their shares are specified in a schedule to the Bill.

The Colonial Office has issued a memorandum announcing that from July 1 the Sleeping Sickness Bureau will be known as the Tropical Diseases Bureau. The Sleeping Sickness Bureau had its origin in the International Conference on Sleeping Sickness held in London in 1907 and 1908, to concert measures for the control of that disease, which was spreading rapidly in tropical Africa. After its establishment it soon became evident that what the Bureau was doing for sleeping sickness could be done in the same way for tropical diseases generally. Lord Crewe, during his term of office as Secretary of State for the Colonies, and Mr. Lewis Harcourt have interested themselves in the expansion of the Bureau, and the arrangements are now completed. The expansion entails increased expenditure, and the annual available sum is now approximately 3000*l.* The Bureau, having outgrown the accommodation provided by the Royal Society, will have its quarters at the Imperial Institute. The new Bureau will deal with all exotic diseases which are prevalent in tropical and subtropical regions, and will publish at frequent intervals a *Tropical Diseases Bulletin*, which will take the place of the present *Sleeping Sickness Bulletin.* The director will have the help of an assistant director and a number of experts, who will be responsible for the different subjects, and will furnish authoritative reviews and summaries of published papers, to appear in the *Bulletin*. Thus the results of the most recent researches on every tropical disease in every country, new methods of treatment, improved means of prevention, will quickly become available for the remote worker in the tropics. The tropical diseases of animals will be treated in a separate publication.

Many ethnologists are probably unaware of the important collections possessed by Marischal College, Aberdeen. These have now been rearranged and described in an admirable and well-illustrated catalogue, the work of the curator, Dr. R. W. Reid. At the present time, when proposals for the establishment of a folk museum are under consideration, it may be remarked that this class of objects is very fully represented at Aberdeen. Besides a fine collection of prehistoric objects, the museum is particularly rich in specimens of those domestic and rural implements and appliances which are rapidly passing into disuse and will soon be unprocurable. Thus there are numerous examples illustrating the arts of spinning and weaving, rude agricultural implements, household utensils, such as crusie lamps, the "puirman" for holding pine splinters used for illumination, and many others of equal interest. Of special importance is the marshal staff of Scotland, presented in 1760 by George, tenth and last Earl Marischal, great-great-grandson of George, fifth Earl Marischal, who founded the college in 1593.

The Report of the Bacteriologist and Bulletins Nos. 8, 9, and 10 of the State Board of Agriculture, Michigan, dealing with various bacteriological subjects, which have been sent us, indicate how actively agricultural biology is being applied in the United States to the elucidation of practical problems, *e.g.* diseases of stock, the treatment of hog-cholera with a serum, soil and dairy bacteriology, and so on.

We have received a report to the London School of Tropical Medicine on dysentery in Fiji during the year 1910, by Dr. P. H. Bahr, who was sent out specially to investigate the disease by funds generously provided by Lord Sheffield and Mr. E. W. Blessig. The disease in Fiji is of bacillary origin, and a number of varieties of the dysentery bacillus were isolated. Evidence is adduced that the housefly is the principal agent in its spread. Treatment with a polyvalent anti-dysentery serum seemed to give the best results. The report is a very valuable one, and is well illustrated.

Ever since 1857 British coleopterists have been on the look-out for *Claviger longicornis*, a species not uncommon in ants' nests on the Continent. Certain beetles taken in Oxfordshire in 1906 prove, according to Mr. J. J. Walker, in the May *Entomologists' Monthly Magazine*, to belong to the missing species.

The migratory British species of Salmo—in other words, salmon and trout—form the subject of a very fully illustrated article by Mr. Boulenger in *The Field* of May 4. Figures are given of the age-phases and the adults of the two sexes of both species at different seasons, and likewise of some of the supposed local species of the trout.

According to the third part of the *Bergens Museum Aarbok* for 1911, Norway experienced fourteen shocks of earthquake during 1910. The most severe was that of July 26, which was felt from Gildeskaal to Mo in Rauen. Four occurred in the earthquake district in Nordre Bergenhus Amt, on the west coast, another four in the disturbed district between southern Sondre Bergenhus Amt and Ryfylke in Stavanger Amt, two in the northernmost seismic area, and the remainder, which were all local, in districts usually free from disturbance.

In *The Field* of May 4 is recorded the birth of an Indian elephant calf at Copenhagen on April 6th, this being the offspring of the same parents which produced a calf in 1907. It is the third recorded instance of such an event in Europe. In the case of the first Copenhagen calf the gestation period was twenty-three and in the second twenty-one months. Both calves showed black bristles on the back, but not apparently the coat of fine hair which was present in the calf born in London in 1903, the skin of which is mounted in the Natural History Museum.

Dr. Mark Jansen has published, in a brochure entitled "Achondroplasia: its Nature and its Cause" (Leyden: E. J. Brill, Ltd., 1912), the results of his studies on the phenomena exhibited by human dwarfs. He suggests that these phenomena may be due in part to abnormally high amnion pressure during certain stages of development, which may disturb the nutrition and growth of part of the fœtus without interfering with the normal development of other parts of the body. He also discusses the influence of the pituitary body and the phenomena of acromegaly.

The April number of the *Quarterly Journal of Microscopical Science* (vol. lvii., part iv.) contains important additions to our knowledge of two of the smallest and at the same time most interesting groups of the animal kingdom. Mr. E. S. Goodrich gives a full account of the anatomy of the worm *Nerilla antennata*, hitherto regarded as a small Polychæte, and shows that it is really an Archiannelid. It occupies a central position amongst the somewhat heterogeneous members of that group, which it thus serves to bind together, and at the same time it in some measure bridges over the gap which separates the Archiannelida from the more highly organised Polychæta. Mr. C. L. Boulenger describes a new species of fresh-water medusa, *Limnocnida rhodesiae*, from Rhodesia. This form, which is very closely related to the well-known *Limnocnida tanganicae*, of Lake Tanganyika, was discovered by Mr. R. H. Thomas, in a tributary of the Hunyani River, which itself flows into the Middle Zambesi.

An important contribution towards a complete flora of the Chinese Empire has been published in the *Kew Bulletin*, Additional Series, No. 10, by E. T. Dunn and W. J. Tutcher, the former and present superintendents of the Botanical and Forestry Department at Hongkong. This consists of an account of the flowering plants, ferns, and fern-allies of Kwangtung, the southernmost province of China, and of Hongkong itself. The short introduction to the flora deals with the climate, geology, and ecology of the area. This is followed by a key to the natural orders, which is skilfully worked out, and will prove of great use to students of general systematic botany apart from its special purpose—that of enabling collectors in China to determine their plants. Keys are also given to the genera of each order and to the species of each genus, and the bulk of the work is occupied by an enumeration of the species. The price of this Flora, which contains 370 pages, is 4*s*. 6*d*.

Dr. C. E. Moss, curator of the Cambridge University Herbarium, who some time ago published a critical account of the British oaks, has just contributed to *The Gardeners' Chronicle* (Nos. 3718–3720) a much-needed revision of the British elms. After a critical discussion of the various species, varieties, and hybrids of the genus as represented in Britain, the author gives a concise key and conspectus of these forms. Of the five species noted, the Wych Elm (*Ulmus glabra*), the Smooth-leaved Elm (*U. nitens*), and the Small-leaved Elm (*U. sativa*) are regarded as being indigenous, while the English Elm (*U. campestris*) and the Cornish Elm (*U. stricta*) are not indigenous. Of the two *U. glabra* × *U. nitens* hybrids, the Dutch Elm (×*hollandica*) and the Huntingdon Elm (×*vegeta*), the former appears to be native in some localities. The Jersey Elm is described as a new variety (*U. stricta*, var. *sarniensis*, Moss). The articles are illustrated by photographs of herbarium specimens, and will undoubtedly be of great assistance to field botanists in the determination of the British elms, which have for so long remained in almost hopeless confusion.

We have received, by the courtesy of the director, an advance copy of No. 1 of the new issue of the Bulletin of the Imperial Institute, the publication of which has been undertaken by Mr. John Murray. The great activity in tropical planting enterprise in recent years has resulted in a large demand for this quarterly bulletin, which is now considerably enlarged, and will be the means of publishing the results of investigations of new raw materials from the Colonies and India carried out at the institute, and recent information regarding developments in tropical agriculture generally. This number (vol. x., No. 1) contains a concise introductory article on the history and activities of the institute, followed by articles dealing with the rubber resources of Uganda, the cultivation of cotton in Nyasaland and Uganda, the large deposits of diatom earth in East Africa, hemp and hemp seed, cultivation and preparation of ginger, and the first part of a long and detailed account of the cocoanut and its commercial uses—to mention only a few of the interesting papers in this issue of nearly 190 pages. A large number of reports on investigations of new Colonial products are included, and a special section of the bulletin is devoted to giving an account of recent developments of tropical agriculture throughout the world.

The pupils of Ferdinand von Richthofen have agreed to publish annually a collection of geographical memoirs under the title of "Mitteilungen des Ferdinand von Richthofen-tages," to commemorate their master, who passed away in 1905. The first part, issued by Teubner, of Leipzig, for 1911, appropriately contains three papers on China, that by M. Groll dealing with the progress that can now be made in the production of a general map of the country. The greatest difficulty still lies in the absence of details as to the relief. It seems unfortunate that these papers cannot be published as special contributions to one of the recognised geographical journals.

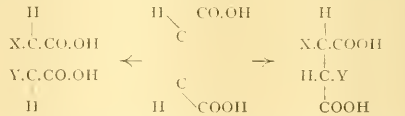
From the issue of December last of the *Monthly Weather Review* of the Department of Marine and Fisheries, Canada, some interesting details are given of the highest and lowest temperatures in each province of Canada during that month. The highest temperature recorded was 65° at Alix, Alberta, on December 3, and the lowest was −59° on December 28, at Fort William, in the same province. Other low temperatures recorded during the month were −51° at the Pas, Saskatchewan, on December 29, −50° at Swan River, Manitoba, on the same day, when −40° was recorded at Fort St. James, British Columbia.

The separately issued appendix No. 3 to the report for 1911 of the U.S. Coast and Geodetic Survey gives particulars of the magnetic observations made during the year ending at midsummer, 1911. Of the 351 land stations occupied during the year, seventy-one were old or "repeat" stations, and particulars are given of the values derived for the secular change of declination at these. Table I. summarises the results of the observations at the land stations, including nearly sixty stations along the Alaskan boundary, seven in Hawaii and one in British Columbia. Table II. gives particulars of observations made at sea, in both the Atlantic and Pacific Oceans, by three vessels attached to the Survey. The last fifty-nine pages are occupied with a description of the land stations and their exact positions.

The March number of the Journal of the Institution of Electrical Engineers contains a summary of the theory of the production of electric oscillations by Mr. A. S. M. Sorensen. After two short paragraphs dealing with oscillations in a single circuit having capacity and inductance, and in coupled circuits, he points out that in actual practice the capacities and inductances are not concentrated at particular points of the circuits nor are resistances and damping constant. In the case of an arc in circuit he shows how by the aid of the "characteristic curve" of the arc the main features of the oscillations produced in the three most important cases can be traced without the necessity of appeal to the differential equation of the circuit.

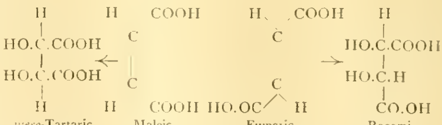
A year ago Dr. K. Fredenhagen, of the University of Leipzig, described in the *Physikalische Zeitschrift* some measurements he had made of the currents produced by the electrons emitted by metals at high temperatures. At the time he believed his results were free from secondary effects, but more recent work on the alkali metals distilled and tested in high vacua has, according to a short communication to the German Physical Society published in the *Verhandlungen* for April 15, convinced him that the whole of the current observed in such cases may be due to the reactions taking place between the metal and the trace of gas still present even in the highest vacua. Since the velocities of such reactions would follow exponential laws as the temperature increased, the currents obtained would be expressed by Prof. Richardson's formula.

In his presidential address to the Chemical Society, reprinted in the April number of the Journal, Prof. Frankland has directed attention to the extreme frequency with which the rupture of a "double bond" is accompanied by "*trans*-substitution." It has usually been thought that the addition of a substance XY to a compound such as maleic acid must result in the production of the *cis*-compound II., in which the radicals X and Y occupy the same positions as the ends of the broken bond.



II. *cis*-Compound — I. Maleic acid — III. *trans*-Compound

This view was confirmed by the oxidation of maleic acid to *meso*-tartaric acid and of fumaric acid to racemic acid.



meso-Tartaric acid — Maleic acid — Fumaric acid — Racemic acid

But, so far from being the rule, the *cis*-substitution shown above appears to be entirely exceptional, since it rarely (if ever) occurs except in the special case of oxidation. These facts are of considerable importance, as they throw doubt on the assumption, which is almost universally made, that a substituent group normally enters the same position as the atom or linkage which it displaces.

The seventy-eighth annual report of the Natural History, Literary, and Polytechnic Society of Bootham School, York, for 1912, is noteworthy as providing evidence of the enthusiasm for scientific work which can be developed among schoolboys when qualified masters of a boarding-school are willing to devote part of their leisure hours to what is nearly always entirely a labour of love. The Natural History Society has some eleven sections, each devoted to a separate science, and excellent practical work was done in them all during the year under review.

A convenient card for hanging in offices, entitled "Standard Metric Equivalent Tables, comprising Weights, Measures, and Prices in Francs and Marks," has been published by the Central Translations Institute, Eastcheap, London. The equivalent prices in francs and marks per foot, yard, square yard, cubic foot, gallon, and similar British units will be very handy for merchants. The price of the card is 1*s.* 2*d.* post free.

A new and cheaper edition of "The Grouse in Health and in Disease" is in the press, and will be published in July next by Messrs. Smith, Elder and Co. In the absence of Dr. E. A. Wilson in the Antarctic, the book has been edited by Mr. A. S. Leslie and Dr. E. A. Shipley, and Lord Lovat has contributed an introduction.

OUR ASTRONOMICAL COLUMN.

Reported Discovery of a New Comet.—We learn, from *The Daily Mail* of May 14, that the following telegram has been received at the Greenwich Observatory:—"A comet-like object with a tail has been observed by Mr. Hansen at Praestoe, Denmark. It is of intense magnitude, and its position, given on May 10 at two o'clock, was R.A. 20h. 53m. 20s.; decl. 31° 24′ N."

Probably the first statement of the second sentence should read, "It is of *the tenth* magnitude," for we are told that it is not visible to the naked eye. The position given lies about half-way between ζ and ϵ Cygni, and is on the meridian at about 5 a.m.; that is to say, it is above our horizon during all the hours of darkness.

The origin of the above telegram is not stated, and, so far, we have received no intimation of the discovery from the Kiel Centralstelle.

The Rotation of Uranus. When the axis about which a planet revolves makes a considerable angle with the observer's line of sight, the rotational motion can be detected, or even measured, spectroscopically, because as the planet rotates some regions of its limb must be travelling towards the observer, while others are travelling away from him. At the present epoch the orientation of Uranus is favourable to such an investigation, and spectrograms giving a measure of the planet's rotational velocity, secured at the Lowell Observatory, were exhibited and explained by Prof. Lowell at the recent meeting of the Royal Astronomical Society. On these spectrograms the lines are inclined because the slit was so placed that at the top was the approaching limb, while at the bottom was the receding limb. Thus, in accordance with Doppler's principle, the extremities of the lines were displaced towards the violet and the red respectively, that is to say, they are inclined to the normal lines of the comparison spectrum photographed on the same plate. Measures of the inclination of a number of these lines, on different photographs, indicate that the planet makes one complete rotation in about 10h. 45m.

The Recent Solar Eclipse.—A large number of communications describing the observations made during the solar eclipse of April 17 are published in No. 4571 of the *Astronomische Nachrichten*.

Observations of the bright-line spectrum were made by Drs. Eberhard and Ludendorff at Berlin, and, like Prof. Fowler at South Kensington, and Prof. Iñiguez, Prof. Eberhard found that he was able to study the bright lines for quite half an hour. Dr. Kempf found that the first and last contacts took place 0·4m. earlier than predicted by the *Berliner Jahrbuch*, while at Lemberg, Dr. Grabowski found they were, respectively, 0·3m. and 0·6m. earlier. Quite a number of observers remark on the unexpected darkness of the eclipse and its observed effect on various flowers (especially tulips), beasts, and birds.

M. Felix de Roy gives a very interesting account of the observations made by the mission organised by the Antwerp Astronomical Society, and located at Silenrieux (Hainaut, Belgium), where a true annular eclipse was seen. The inner corona was seen by one observer only, and the chromosphere and prominences were looked for in vain. Among the observers of contacts at the Kiel Observatory was Prince Henry of Prussia.

The Origins of the Bright Lines in Novæ Spectra.—At the meeting of the Royal Astronomical Society, reported in the current number of *The Observatory* (No. 448), a number of spectra of Nova Geminorum were exhibited on the screen and afterwards discussed. Prof. Fowler, after remarking on the unfavourable weather experienced at South Kensington, exhibited two small-dispersion spectra obtained on March 15 and 29 respectively, and stated that as regards the origins of the lines, those assigned by Sir Norman Lockyer to the lines observed in the spectrum of Nova Persei (1901) would probably serve. The bright lines appearing in novæ also appear in the chromosphere and solar prominences, and are mainly those of the enhanced iron spectrum. Prof. Newall also agreed that many of the bright lines may be identified as enhanced lines of iron.

Dr. R. H. Curtiss describes the early spectra secured at the Ann Arbor (Mich.) Observatory, in No. 3, vol. xxxv., of *The Astrophysical Journal*. Five photographs taken on March 13 show a continuous spectrum similar in general appearance to that of Altair, but differing in the positions of the lines. Few narrow dark lines were seen, and all the prominent lines of the F5 type, *e.g.* λ4481 and λ4549, appear to be absent. Hδ, Hγ, and Hβ are all strong lines and very complex, both absorption and emission being represented; lines at λ5016, λ4922, and λ4472, and the H and K lines of calcium have similar characteristics, the sharp reversals in the latter indicating a velocity of $+5$ km. ± 3 km. On a photograph taken on March 22 many of the maxima of emission on March 13 were maxima of absorption, and *vice versa* and no certain trace of the nebula lines was to be seen.

THE IRON AND STEEL INSTITUTE.

THE annual spring meeting of the Iron and Steel Institute was held at the Institution of Civil Engineers on Thursday and Friday of last week. Besides the presidential address, and the ceremonies of presenting the Bessemer medal to Mr. Darby and the Carnegie medal to Prof. Goerens, of Aachen, the meeting had to consider an exceptionally long and interesting list of papers covering a very wide range of subjects, and therefore likely to appeal to both the practical and the scientific members of the institute. The complaint is sometimes heard among the practical members of the institute that there are too many papers of a scientific character, and that discussions on scientific metallurgy, and more especially on metallography, are out of place at the institute. Such a view is surely unduly narrow, since the ultimate benefit of the steel industry must go hand-in-hand with the development of those branches of science which are more intimately connected with steel. It is true, of course, that a discussion on the constitution of hardened steel may not be of immediate and direct interest to the manager of a rolling-mill, but even for him the time will come when he must ask for scientific guidance in some new difficulty, and the value of the aid which can be given him will depend upon the accuracy and completeness of our theories on the constitution and transformations of steel.

Even the obvious fact that "professors" disagree need not alarm the practical man—the "professors" only discuss the few outstanding points upon which divergences of opinion exist—upon the main body of their scientific knowledge they are so completely in agreement that they would no more discuss it than the multiplication table. Where men are working to advance the outposts of our knowledge, divergent views are bound to arise, and vigorous discussion is needed to sift out the truth, but the practical man will make a great mistake if he interprets these discussions as implying uncertainty as to the main body of the science.

These considerations have been raised at the recent meeting because the entire afternoon of Thursday was occupied by the discussion—at times of a vigorous character—of scientific subjects, the constitution of steel and the nature and mechanism of corrosion being the two principal questions. On the former, Prof. Arnold, of Sheffield, contributed two short papers, which formed the subject of strong criticism by both Dr. J. E. Stead and Dr. W. Rosenhain. Prof. Arnold cannot yet reconcile himself to the equilibrium diagram of the iron-carbon system and to the attached nomenclature which has found general acceptance by the great majority of metallurgists; he points out, with obvious correctness, that the diagram in question does not explain the difference between the same steel when quenched from a moderate and correct hardening temperature, and when quenched from an excessively high temperature, which still lies in the same "field" of the diagram. That, however, is a criticism on the value of such diagrams in general, and not on the correctness of the particular example, and similar points could be raised concerning most of the well-established diagrams. The conclusion is evident that equilibrium diagrams, although they possess a very considerable value in their own special direction, cannot tell us everything about the behaviour of metals and alloys. Stable equilibria, which can alone be properly indicated on these diagrams, are comparatively rarely met with in metals as used in practical work, and the equilibrium diagram must therefore be regarded as a basis for the study of those more complex conditions which arise when meta-stable and labile conditions have to be considered.

The subject of corrosion was dealt with in three papers, one—on the influence of carbon on the corrodibility of iron—by Mr. C. Chappell and two, on the mechanism of corrosion and on the corrosion of nickel, chromium, and nickel-chromium steels, by Messrs. J. Newton Friend, J. Lloyd Bentley, and Walter West. The results obtained by the first-named author indicate that an increasing proportion of pearlite in rolled, annealed, and "normalised" steels causes increasing corrosion up to that concentration at which the steel consists entirely of pearlite, while an increase of carbon beyond that point appears to cause a reduction of corrosion, but only one hyper-eutectoid steel has been studied in the paper. In quenched steels, on the other hand, a continuous increase of corrosion appears to accompany increasing carbon-content.

The paper on the mechanism of corrosion by Dr. Friend and his collaborators is particularly interesting, as some rather unexpected sources of error in corrosion tests carried out in tanks of still water in the laboratory are indicated. These errors arise from the fact that there appears to be a "corrosion zone" around any piece of corrodible metal immersed in water, and throughout this zone there is an oxygen concentration gradient; if now the specimen under test is placed close enough to the walls of the vessel to allow these walls to lie within the "corrosion zone," then the rate of corrosion will be apparently diminished. In the case of bright surfaces of pure iron, the radius of the corrosion zone appears to be approximately equal to the linear dimensions of the specimen, so far as small laboratory specimens are concerned. In their study of the corrosion of nickel and chromium steels, the same authors suggest that the corrodibility of such steels is affected by two opposite factors; the galvanic action between such substances as cementite in ordinary carbon steels and the complexes containing nickel and chromium in the alloy steels on the one hand, and the more corrodible ferrite on the other, tends to increase with the addition of such metals as nickel or chromium, but this tendency to increased corrosion is counteracted by the fact that the presence of these incorrodible substances themselves affords a considerable mechanical protection against corrosion. These two factors are differently affected when acceleration tests are made in acids, so that these become untrustworthy for alloy steels. The most striking positive result obtained is the resistance of chromium steels to sea-water corrosion, and the authors consider that the "application of chromium steels in the construction of ships would be justified on this ground alone."

A particularly interesting and somewhat novel feature at the present meeting was formed by a group of four papers dealing with the ancient metallurgy of iron, both in the East and in England. Prof. T. Turner describes the "ham bones" found in the neighbourhood of Walsall, in Staffordshire, and discusses their probable mode of origin, while Sir Hugh Bell presents an account of a bloom of Roman iron found at Corstopitum (Corbridge), the investigation of this material by Prof. Louis and Dr. Stead being described. The conclusion appears to be established that this mass of iron is built up of small blooms obtained by a "direct" process from the local ore. The purposes ascribed to the object as found vary from a stake anvil to a battering-ram. Mr. H. G. Graves contributes an interesting note on the early use of iron in India, describing some of the large masses of iron utilised in the construction of certain ancient temples. Finally, Sir Robert Hadfield's account of "Sinhalese Iron and Steel of Ancient Origin" throws an interesting light on the materials and methods in Ceylon many centuries ago, particularly in the production of steel tools and implements. We hope to give a separate abstract of this paper in a later issue.

The exceptionally full and interesting programme of the meeting is completed by a series of valuable papers dealing more directly with steel manufacture, including an historical survey of forty years' progress of the industry by the president (Mr. Arthur Cooper) in his address, an interesting paper on steam engines for driving rolling-mills by Mr. J. W. Hall, and an account of the Nathusius electric steel furnace by its originator, with several other contributions of a similar character. Altogether the institute is to be congratulated upon a singularly successful meeting, which revives the traditions of the best days of its history.

M. POINCARÉ'S LECTURES AT THE UNIVERSITY OF LONDON.

I.—May 3.—*The Logic of the Infinite.*—Some years ago, M. Poincaré said, he had published a certain number of articles upon the subject, which had involved him in a veritable polemic. He would not attempt to renew the arguments that had been used on either side, or to bring forward any fresh arguments, as he believed that the divergence of the two schools was irreducible. It arose from an essential difference of mentality; he would therefore accept it as an experimental fact, and would endeavour to account for this divergence. For the first school, whom, for the sake of convenience, he would call Pragmatists, the infinite was derived from the finite; for the second, the Cantorians, the infinite pre-existed, and the finite was only a small piece of the infinite. From another point of view, to use the language of the scholastics, the Pragmatists were *extensionists*, while the Cantorians were *comprehensionists*. This appeared in the nature of the definitions used by the two schools. For the first a definition consisted in the addition of one new object, expressed in terms of the aggregate of known objects; for the second a definition was a fresh subdivision of the aggregate of all objects known and unknown. The Pragmatists were idealists, and for them an object did not exist until it had been *thought*. The Cantorians were realists for whom the existence of objects was independent of a thinking subject. For them the infinite was independent of man or any thinking being; it was pre-existent and was discovered by man.

II.—May 4.—*Time and Space.*—The conception of space arose from our muscular sense. When we saw an object we knew the movements necessary to attain it. The idea of space, then, was the association between certain sensations and certain movements. To the whole of space the principle of relativity applied, that is to say, we had no means of perceiving a transportation, a magnification, or a deformation of the universe, provided that in the transformation all objects were subject to the same law. Space, in fact, was "soft and without rigidity." We appreciated the relations between objects in space by means of our instruments of measurement, of which our body was one, and the science of geometry was a study of these instruments. But the instruments were not perfect, and therefore we replaced them by a series of ideal instruments for the purposes of our geometry, which thus depended upon an aggregate of conventions approximating to the actual laws, but simpler. The principle of relativity also applied to time; if all actions were retarded uniformly we had no means of perceiving it.

A revolution had recently been brought about by the researches of modern physicists, especially those of Lorenz. Formerly the action of one body upon another was supposed to be instantaneous. But if we supposed that such an action was transmitted through the intervening space at a finite speed, the question of priority of action became very difficult. Formerly we had considered an action α to be anterior to a dependent action β, when α could be regarded as the cause of β. But in the new mechanics, if β occurred too soon it might happen that α could not be regarded as the cause of β, nor β as the cause of α. It might be necessary at this stage to abandon our former mechanical conventions and to adopt new ones.

III.—May 10.—*Arithmetical Invariants.*—If an algebraic form, in two variables, say, $F(x, y)$, was subjected to the transformation

$$x \rightarrow \alpha x + \beta y,\ y \rightarrow \gamma x + \delta y, \text{ where } \alpha\delta - \beta\gamma = 1 \quad . \quad . \ (1)$$

there were certain functions of the coefficients of F which remained unchanged. These were algebraic invariants. Suppose now that α, β, γ, δ, and also the coefficients of $F(x, y)$ were restricted to be whole numbers, positive or negative, $F(x, y)$ would possess the same invariants as before, but it would also possess others which were termed *arithmetical invariants.*

The simplest form was $F(x, y) = ax + by$. This form possessed no algebraic invariants. Some arithmetical invariants, however, could be obtained which were related to the Weierstrassian elliptic functions, the thetafuchsian functions, and the functions of Jacobi.

In the case of quadratic forms it was necessary to distinguish between the definite and the indefinite. The definite quadratic form might be reduced for this purpose to a pair of linear forms, but for an indefinite form invariants could only be found if we took certain subgroups of the group of transformations considered instead of the group itself.

IV.—May 11.—*The Theory of Radiation.*—Planck had enunciated some ideas, which, if they were accepted, would bring about in the science of physics the most profound revolution that had occurred since the time of Newton. We owed to Newton the principle that the laws of nature could be expressed in the form of differential equations. According to Planck, phenomena satisfy not differential, but finite difference equations.

By the method of statistics applied to a very great number of separate molecules we arrived at one of the fundamental theorems of thermodynamics, that of Maxwell on the equipartition of mean kinetic energy. Upon the same basis we arrived at Wien's law of radiation and Rayleigh's law. The last was consistent with the theorem of Maxwell, but it was not justified by experiment.

Planck supposed that there existed in incandescent bodies a very great number of *resonators*, each corresponding to a certain wave-length of light; these resonators could only acquire or emit energy by a definite increment: a *quantum* or atom of energy. Planck obtained in this way a law of radiation, which was justified by experiment, but which was not consistent with Maxwell's theorem. M. Poincaré found that if, instead of considering the action of light upon a molecule, we applied the ideas of Planck to the action of a molecule upon light, we should be forced to conclude that diffusion took place with a certain retardation, and this was certainly not true. Thus the hypothesis of Planck was unsatisfactory, and no solution to the problem was at present in sight.

FOOD AND THE CHILD.

Two conferences held in London since our last issue show that increasing attention is being given to questions relating to the physical and mental development of children from a national point of view. At one conference, held at the Guildhall, the subjects considered related to diet at public and private secondary schools; and at the other, held at the University of London, the health of the child in relation to its mental and physical development formed the general basis of discussion.

Of all that mankind has attempted since the world began, there is nothing which it has practised so regularly, so persistently, and on the whole so successfully as eating and drinking. It is therefore somewhat disquieting to find the great civilised nations suddenly smitten with misgivings as to whether the rising generation is being suitably nourished. It is admitted that the provender provided for the better-class school children of to-day is more abundant in quantity, better in quality, and better served than that supplied to their immediate ancestors; that it is, indeed, exceptional for the fare to be actually deficient in amount, while, whatever its form, it certainly comprises those essential elements of proteids, fats, and carbohydrates upon which previous generations achieved a national pre-eminence. Yet, evidence accumulates to the effect that all is not well with the school child in relation to his diet; and, this being so, the impression arises that the fault lies with the eater at least as much as with the food supplied to him. This also appeared to be the opinion of most of those who spoke with authority and from experience at the recent conference on school diets.

The healthy normal child will eat with avidity of plain wholesome fare, and may even be trusted to eat of it to repletion without risk of injury, it was stated. But, by the healthy normal child was clearly meant one whose teeth were sound, who used them effectively for complete mastication, and whose natural appetite had not been vitiated by a too promiscuous feeding on more highly seasoned viands at home. Now only a small proportion of school children possess quite sound teeth. The rest have mouths more or less septic, and, consequently, infected digestive tracts. Practically none masticate their food completely, and their digestion is by so much the further hampered; while many of those belonging to the upper social classes, when at home, share the more delicately prepared and attractively flavoured foods which are needed to stimulate the faded appetites of their parents, and consequently come to regard simpler fare as insipid and unappetising.

The situation is one of national importance. It calls for a reform of the home dietary and upbringing —beginning in the earliest nursery days—quite as much as for a reform of school diets. The latter may, indeed, be here and there modified with advantage, both in matter and in method; these details, important enough in themselves, were more or less clearly hinted at, but a single-day conference did not provide the time for their adequate consideration. The conference, so far as it went, was as a useful and most suggestive troubling of the waters. Its repetition on a more complete and more comprehensive scale would serve to bring out with greater clearness the need for some effective collaboration between the home and the school in relation to one of the most important factors in determining the future of the race.

At the conference of child-study societies existing in various parts of the kingdom, held on May 9–11 in the University of London, an address was delivered by Sir James Crichton-Browne, the president of the central society. He took for his subject the need for proper classification and education of feeble-minded children, with especial reference to the discrimination of those who presented mentally abnormal qualities not amounting to feeble-mindedness, and those whose mental defects might by suitable education under medical guidance be removed and their minds strengthened. At the meeting on May 10, papers were read by Dr. Kerr Love, on the influence of defects of hearing in relation to the mental and physical development of the child, and by Mr. Bishop Harman, on the influence of defects of vision in relation to the mental and physical development of the child. Mr. B. P. Jones, as a teacher of the deaf, gave a successful demonstration with two ex-scholars of what may be done for the hard of hearing. Dr. Jane Walker read a paper on the tuberculous child. In the afternoon, a visit was paid to Sir Francis Campbell's normal college for the blind, where an excellent musical performance was given by members of the college. In the evening Dr. Saleeby lectured on eugenics and child-study. At the meeting on May 11, Dr. Hyslop read a paper on mental hygiene in relation to the development of the child, and a discussion ensued in which Dr. Percy Nunn and Mr. Kirkpatrick, of the Normal College, Fitchbury, Mass., took part. A discussion followed on the instruction of the young in sexual hygiene, in the course of which admirable addresses were delivered by several ladies. In the evening the delegates were entertained by Sir Richard and Lady Martin at their house in Hill Street. The next conference will be held at Liverpool.

THE REFORM MOVEMENT AT CAMBRIDGE.

The progressive party in Cambridge has lost heart about reforming the University from the inside, and a memorial asking for a Royal Commission, which has been signed by six professors and some twenty-two other members of the University, is being generally circulated for signatures. The signatories hope that power may be given to the commission to make statutes in regard to such matters as financial and other relations between the University and the colleges, and the administration of funds devoted to fellowships, scholarships, and exhibitions. A certain number of those usually associated with reform movements in the University have withheld their signatures, partly, apparently, because they mistrust the sort of commission they anticipate the present Government would nominate, and partly because they feel that the resident members have by no means made up their minds on what lines they would wish reform to be initiated; but some at least hold the view that it is not desirable that the commission should have power to frame statutes.

The petition is as follows:—

To the Right Hon. H. H. Asquith, Prime Minister.

We, the undersigned resident members of the Senate of the University of Cambridge, desire to lay before you a request that a commission may be appointed to inquire into the constitution of the University of Cambridge, the financial and other relations which exist between the University and the colleges, and the administration of funds devoted to fellowships, scholarships, and exhibitions; and that power may be given to the commission to make statutes in regard to these matters.

We venture to remind you that on July 24, 1907, in the House of Lords, the Marquess of Crewe, speaking on behalf of the Government, stated that the

Government were unwilling to appoint any commission for the Universities of Oxford or Cambridge until full opportunity had been given to these Universities to make necessary reform for themselves. In the five years that have since elapsed various proposals for constitutional reform have been brought before the Senate of the University of Cambridge by the council of the Senate, but they have been, without exception, rejected by the Senate; and it is clear to us that no further attempt of the kind is likely to be successful. We therefore make our present appeal for the appointment of a commission.

ELECTRICITY SUPPLY: PAST, PRESENT, AND FUTURE.[1]

It was in 1882 that Parliament passed the first of the Electric Lighting Acts. This Act was in part based upon recommendations made by a Select Committee on Lighting by Electricity that sat in 1879, and as an instance of the want of proportion in the ideas that then prevailed it may be mentioned that before that committee Mr. Joseph Rayner, the Town Clerk of Liverpool, explained that one of the reasons why the Corporation of Liverpool were seeking for Parliamentary powers to supply electricity within their borough was because they were in a specially advantageous position to do this, as they had an engine which was used during the daytime for working a fountain, and might well be used for supplying electricity during the night, that engine having a capacity of 20 horse-power. At the end of last year the electric supply plant of the Corporation of Liverpool amounted to about 50,000 horse-power, which, when compared with this 20 horse-power engine, affords a commentary on the parochial character of the ideas in accordance with which the first of the Electric Lighting Acts was framed.

In the year 1882, also, the first electric supply station for supplying incandescent lamps on a public scale in London was established by the Edison Company on Holborn Viaduct. The Holborn station was equipped with two Edison dynamo machines, and it is interesting, as giving an inkling of the notions then prevailing, that these machines were described by the then editor of one of our chief engineering papers as "enormous," it being added, evidently as a matter of wonder, that "no less than 1000 full size or 16-candle incandescent electric lamps were maintained constantly in operation from one machine." It may be mentioned that each of these dynamos was driven by a high-pressure Porter engine of 130 horse-power, which shows that even in 1882 ideas had not progressed very far beyond those to which I have already alluded in connection with Liverpool three years earlier. The design of these early Edison machines, with their multiple-magnet limbs each with its separate winding, is also illustrative of the ignorance then prevailing on electromagnetic subjects, it being obvious in the light of modern knowledge that the arrangement was altogether inefficient and absurd. It was the late Dr. John Hopkinson who first put the design of continuous-current dynamos and their magnetic circuits on a sure foundation.

So far from assisting electricity supply, the Electric Lighting Act of 1882 had the immediate effect of crushing enterprise in that direction, the period of seven years for which licences, or the twenty-one years for which provisional orders, were granted to promoters of electric supply undertakings being found quite inadequate to enable money to be raised for such purposes. Between 1883 and 1888, when the Act was amended, only ten licences were applied for, all of which afterwards expired or were revoked, and though in the first year there were a considerable number of applications for provisional orders, not one of these was carried into effect, capitalists refusing to find money for undertakings which had only a tenure of twenty-one years. No doubt, also, this unsatisfactory result was assisted by the severe reaction that had set in from the speculative mania in electric lighting affairs of a few years earlier.

It was not until 1885 that Sir Coutts Lindsay laid down an installation in Bond Street to light the Grosvenor Picture Gallery and the premises of some of the neighbouring tradesmen, which installation in its subsequent development had probably more influence than anything else on the fortunes of electricity supply, not only in London, but in the country generally. Quite a novel system of distribution was employed, the current being alternating and distributed at high pressure by means of overhead wires, and transformers (or secondary generators, as they were called) on the Goulard and Gibbs system being used to reduce the pressure to suit that of the lamps.

To begin with, the system did not work well, and, on the advice of Lord Kelvin, Mr. S. Z. de Ferranti was called in to assist. The station was immediately reorganised and fitted with machinery of much greater capacity, and so successful was the outlook that, early in 1888, the London Electric Supply Corporation, Ltd., was formed with a capital of 1,000,000*l.* sterling, and what were then considered as immense works were started upon as far away as Deptford, six miles from the centre of London, the scheme being to transmit the electricity from where land, coal, labour, and water for condensing could be cheaply obtained, at a pressure of no less than 10,000 volts, with suitable substations where it could be transformed and thence distributed at lower pressures. The great courage shown by those responsible for the venture was deserving of a better fate—but alas for the uncertainty of human endeavours! While the working of the station at Deptford was still in its inception, the plant at the Grosvenor Gallery became ignited by a short circuit and was burnt out; while the London Electric Supply Corporation soon afterwards went into the hands of a receiver, leaving unfinished, and never to be finished, the 10,000 horse-power sets of dynamo and engine which Mr. Ferranti's genius had dared to devise.

Though so very unsuccessful financially at its first start off, there can be no question as to the enormous influence that the Deptford undertaking had on the history of electricity supply, not only in London or in this country, but throughout the world. Here, at length, was an electricity supply proposition on a scale similar to those of the great undertakings that furnish gas to the Metropolis, with generating plant and means of distribution designed for the sale of electricity over a large portion of London. The more cautious procedure adopted by other concerns which sprang up about the same time and later was no doubt more successful from a business point of view, but the impulse given by this ambitious scheme became manifest from the great competition that was shown for provisional orders for different parts of London, leading to the public inquiry that was held by the Board of Trade immediately after the passing of the amended Electric Lighting Act of 1888, in which the period of twenty-one years, after which the undertaking was subject to purchase without any allowance for goodwill, was extended to forty-two years.

[1] From a discourse delivered at the Royal Institution on Friday, April 19, by Alan A. Campbell Swinton.

It is worthy of note that the London Electric Supply Corporation has now some time ago successfully emerged from its period of financial distress, while Mr. Ferranti, though, as has been shown, he was one of the pioneers of electricity supply, still remains with us as one of the most vigorous intellects in the electrical industry, and one who, as president of the Institution of Electrical Engineers, is even now dreaming fresh dreams of higher things and lower costs so far as electricity supply is concerned.

During the period with which we have been dealing, so far as the public were then aware, the chief improvements that had been effected in connection with machinery for electricity supply had reference to the dynamos which generated the current, the batteries that stored it, the cables and switches and other apparatus that distributed it and regulated its performances. True, to some extent, special designs of steam engines had been got out to suit the requirements of driving the fast-running dynamos, as, for instance, the well-known Willan's engine. As yet, however, there had been no departure from the reciprocating engine.

Early in the year 1885 the present speaker had the privilege, for the first time, of seeing running in the works of Messrs. Clark, Chapman and Parsons, Gateshead-on-Tyne, the first true rotary engine that ever gave useful results. The invention had been patented by Sir Charles Parsons in April, 1884, and in the interval this first practical steam turbine had been constructed. I am able to show you the actual machine, which the South Kensington Museum authorities have kindly sent here, withdrawing it for the evening from the congenial company of Watt's beam engine and Stephenson's "Rocket," amongst which it now has its appropriate abode.

As will be seen, it is a very small machine directly coupled to a dynamo giving about six electrical horse-power when running at the great speed of 18,000 revolutions per minute, and it is interesting to compare its parts, as, for instance, its blading, with that of the very large steam turbines on exactly the same principle that have been constructed in recent years, as, for instance, portions of blading such as is used in the turbines of the *Mauretania*, which, through the courtesy of Messrs. C. A. Parsons and Co., I am also able to bring to your notice.

The steam turbine has now come into very general use, being employed to the almost complete exclusion of other heat engines where very large electrical powers are wanted. At its inception, however, its inventor had many difficulties to encounter, together with much prejudice. Since the days of James Watt inventors up to that time had been continually trying to produce a successful rotary engine, and all had failed. It was natural, therefore, for engineers to ask why this new inventor should succeed any more than those who had gone before. They did not realise that the advances that had been made in thermodynamics, and more especially in machine tools and workshop methods, had rendered things practicable which, up till that time, had not been so; nor did they understand that here at last the subject was being tackled on really scientific principles by one exceptionally endowed by nature to grapple with it. Another difficulty that Sir Charles Parsons had to contend with was that, in the nature of things, experiments must usually be conducted, in the first instance, on a small scale. Moreover, at that period, when the steam turbine was only employed for driving dynamos, there was no demand for machines of any but what at the present day would be considered of very small size. Now it is one of the peculiarities of steam turbines that they are much easier to make in large sizes than in small sizes to give reasonable economy. Thus it was by reason of the very small powers that were wanted that in these earlier days turbines earned the opprobrious epithet of "steam-eaters."

The Parsons steam turbine was first chiefly employed for the electric lighting of ships, but in 1887 the whole of the electricity for lighting the Mining, Engineering, and Industrial Exhibition that was held in Newcastle-upon-Tyne was generated by a number of Parsons machines; while a little later the Newcastle and District Electric Lighting Company was formed, the works of which on the banks of the Tyne were the first in which steam turbines were employed to afford a public supply of electricity for general lighting and other purposes. The first machines employed in this station were only of about 100 horse-power, while others of an improved type, which were first employed at Cambridge and at Scarborough, were of about double this power, and were considered as very large. The first steam turbines to be employed in London were used for the lighting of Lincoln's Inn Hall, where they worked for many years, to be followed not long after, in 1891, by three others, each of 50 horse-power, at New Scotland Yard, which still exist, and to-day are providing electricity for lighting, printing, and other purposes, for the Metropolitan Police.

Some fifteen years ago, in evidence that he gave before the Judicial Committee of the Privy Council in connection with Sir Charles Parsons's application for a prolongation of his patent, Lord Kelvin characterised the Parsons turbine as the most important development in steam engines since the days of James Watt. At the time this seemed a somewhat bold assertion, but in the light of experience it has proved to be a fact.

I mentioned just now that it was on the banks of the Tyne that the steam turbine was first applied to the public supply of electricity, and it has also been on the banks of the Tyne, and in the adjacent areas of Northumberland and Durham, that the greatest existing development in this country of electricity supply for industrial purposes has taken place. Not the least of the causes that have led to this is the fact that, apart from London, where the circumstance are very special, in Newcastle-upon-Tyne alone among the great manufacturing cities of Great Britain has electricity supply remained in the hands of private enterprise, and not become municipalised.

The district covered by this vast power-supply undertaking extends as far north as Morpeth, as far west as Consett, is bounded on the east by the sea, and extends right away down through the county of Durham to Stockton-on-Tees, Middlesbrough, and Cleveland. There are seventeen generating stations, of which six are coal-fired stations, and the remainder most interesting waste-heat stations, where steam for making the electricity is obtained either from exhaust steam that has already done work in blowing or other engines, or by steam raised by blast-furnace gas or from the waste heat and gas from coke ovens.

Excepting in the old original power station at Neptune Bank, where power supply was inaugurated by Lord Kelvin in June, 1901, and where there are still some reciprocating engines, the whole of the works are equipped with alternators driven by steam turbines, mostly of the Parsons type, supplying 3-phase 40-cycle current at voltages varying from 3000 to 12,000. The power is supplied to all the leading manufacturers for every kind of purpose, and also to the railway from Newcastle to the sea, which has been electrified. The total horse-power connected amounts to nearly 200,000.

It is obvious that an undertaking of these vast dimensions, covering as it does large portions of two counties and several large towns and industrial centres, could never have been undertaken by a single municipality. It is equally obvious that it could never have succeeded as well as it has had Newcastle itself, which has been from the first the nucleus of the undertaking, been cut out of the area of supply. This explains why other electric power schemes, such as those being worked on the Clyde and in the area round Glasgow, in Yorkshire and in Lancashire, have failed to go ahead anything like so rapidly as the one of which I have just been speaking. Parliament in its wisdom, at the instance of municipal parochialism, cut nearly all the large towns out of the areas supplied by these schemes, with the result that progress has been impeded with real benefit to no one.

As to the future, we have seen from the lessons of the past how very dangerous it is to prophesy, it being frequently the entirely unexpected that turns up. So far as the immediate future of electricity generation on a large scale is concerned, the steam turbine appears likely to hold the field, though in regard to the smaller stations, where units up to 500 or 1000 kilowatts are what are wanted, the internal-combustion engine is undoubtedly gaining ground. Will it, however, ever catch up the steam turbine in the case of the really large power stations? Turbine units up to 25,000 kilowatts are now in actual use or in contemplation, and as electricity becomes more and more employed, not only for power, but for electrochemical and metallurgical purposes and for domestic heating, we may expect units of plant of still larger dimensions. At present about 2000 horse-power, or about 1500 kilowatts, seems to be about the maximum that it is considered can be safely obtained per cylinder from the internal-combustion engine, so that increased powers can only be obtained by a process of multiplication, which leads, in the case of very large units of plant, to great complication. Then again, as the steam turbine, particularly with the employment of superheated steam, tends to increase in fuel economy as the dimensions of the unit of plant are increased at a much greater ratio than does the internal-combustion engine, a point must be reached when, as we enlarge the units of plant, taking all things, such as first cost, lubricating oil, attendance, and upkeep, into account, the steam turbine will be as cheap as, or even cheaper than, its rival.

So far, the internal-combustion or gas turbine has not been alluded to, but some of the difficulties in the way of its successful realisation may be mentioned. All turbines essentially consist of machines by means of which power is obtained by the passage of fluids or hot gases through narrow apertures, and by their impingement on blades, in such a manner that the fluids or gases are in intimate contact with large surfaces of metal Now, as all engineers are aware, the law which limits the efficiency obtainable in any heat engine is expressed by the formula $(T'-T)\div T'$, where T' is the absolute temperature of the working gas and T the absolute temperature of the condenser or the exhaust. From this it is clear that if we are to get maximum efficiencies, the temperature of the working fluid must be as high as possible, and the sole reason for the extra good efficiency of an internal-combustion engine is because in this machine the temperatures that can be successfully dealt with are very high. In the cylinder the combustion takes place when the gas is in considerable mass, and though those portions of it which are in contact with the walls of the cylinder become cooled, still, the interior of the mass keeps very hot, indeed at temperatures which could not possibly be employed in turbines unless we could find the materials of which to construct the blades which would maintain their tenacity while running at a red heat. It is conceivable that the science of metallurgy may be able to provide new metals or alloys with the necessary properties for doing this in the future, but at present no such material exists, and the only way in which the internal-combustion turbine can for the moment be worked is by reducing the temperatures of the gases by the introduction of water, steam, or air to a reasonable amount; indeed, in practice the temperature has to be reduced to that usual with superheated steam, when, of course, according to the formula I have quoted, the maximum efficiencies theoretically obtainable with the internal-combustion engine and the steam turbine become equal. Even then, if other things were equal, the internal-combustion turbine might have some advantage by doing away with boilers; but, unfortunately, there are other difficulties —such as the bad economy of all methods of compressing the gaseous mixture as is necessary to obtain the full advantage of its combustion.

No doubt the future of electricity supply lies with very large stations employing very big units of plant, and combining the generation of electricity with chemical manufacture, the electricity on the one hand and the chemicals on the other being by-products each of the other's manufacture. So far as this country is concerned, for electricity supply at all events, we are not likely to depart from the use of coal so long as that source of energy holds out. For the propulsion of ships oil may present advantages, but on land in Great Britain coal must remain the cheaper. In all probability, however, in the future the coal will not be simply burnt. It will be turned into gas, and the sulphate of ammonia and the tar, with all its interesting constituents, saved. Whether the gas will be burnt under boilers for the raising of steam to supply steam turbines, or whether it will be used in internal-combustion engines, will depend on the progress made by the latter in regard to attaining larger dimensions, and also as regards improvements in the gas firing of boilers, in respect of which, as has recently been shown by Prof. Bone in his interesting lecture on surface combustion, there is still much to be done.

When the coal and oil and also the peat are exhausted, what then? The date may be distant, but come it must, and that within a period short in comparison with our past civilisation.

The water-power existing on the earth, when all harnessed, would only supply a very small percentage of the demand for power, light, and heat. The utilisation of the tides does not appear a very hopeful project, any more than does the utilisation of the internal heat of the earth. There remain the energy dependent on atomic transformation, the availability of which the highest authorities appear to regard as probably impracticable, and the radiant energy that reaches this planet from the sun. The latter, as calculated by Sir J. J. Thomson, amounts on a clear day to no less than 7000 horse-power per acre, or about 4,500,000 horse-power per square mile of the earth's surface.

Here is obviously an ample supply of energy sufficient for all purposes provided it can be converted into work by some reasonably efficient process. This should not prove impossible, and we have therefore here a problem for the physicist of the utmost importance to the race.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LONDON.—At a meeting held on May 7, Convocation received a report from the standing committee, in which is reprinted the statement presented to the Royal Commission on behalf of Convocation. The statement deals exhaustively with the origin of the commission as having reference specifically to the question of the future relations of the Imperial College to the University. Other questions involved in the commission's terms of reference are not mentioned in this statement; but Dr. Senter, one of the witnesses, put in a statement regarding the work of the University on its external side. As a record of the events leading to the establishment of the Imperial College the statement is valuable. Lord Rosebery's letter, dated June 27, 1903, to Lord Monkswell, then chairman of the London County Council, is reprinted, and a detailed account of the proceedings in the Senate in relation to the question is given. It is urged that the only changes necessary in the constitution of the University for the incorporation of the Imperial College are such as were offered by the Senate in December, 1908.

Presentation Day at the University was on May 8, the Vice-Chancellor (Sir William Collins) presiding. The report of the Principal (Sir Henry Miers) showed a decrease in candidates for all examinations as compared with 1910–11 of 12,681 to 12,263, due mainly to a decrease of entries at the matriculation examination. The number of degrees or diplomas granted was 1342, and the number of internal students is 4578. The record of endowments and benefactions given or offered during the year for university purposes amounts to a capital sum of 650,000*l.* Reference was made to the resignation of Sir William Ramsay. Finally, the Principal asserted that the activities of the University had not been checked by the general feeling of uncertainty due to the existence of the Royal Commission. The chief subject for anxiety was the decline of matriculation entries and its financial effect.

A letter from Lord Haldane to Sir Francis Mowatt, dated May 7, has been published, containing an account of the actual position of matters in regard to the proposed new university buildings. The sum of 375,000*l.* asked for the proposed site behind the British Museum was not a settled price. It is stated that the site was regarded as most suitable, because it was ascertained that additional land adjoining might be available for subsequent development. There is a risk, Lord Haldane suggests, that in consequence of the action taken by certain persons connected with the University the offers originally made may not now be available, and in the circumstances it would be idle to take steps to complete the formation of the proposed trust. "If there is to be a hostile attitude within the University itself, the task of those who wish to help in every way they can becomes a very hard one."

IN addition to a studentship in pathology and bacteriology which they endowed some time ago, the Misses Riddell, of Belfast, have now placed 25,000*l.* at the disposal of trustees to provide a hall of residence at Queen's University, Belfast, for young Protestant girl students at the University.

EXETER COLLEGE, Oxford, has appointed Mr. A. M. Hocart, late open scholar of the college, to a senior studentship, tenable for two years, in order that he may conduct anthropological research in Fiji and the adjoining parts of the Pacific region. Mr. Hocart has already had experience of field work under Dr. Rivers in the Solomon Islands, and has since had an opportunity as a teacher of natives in Fiji of mastering the local dialect.

PROF. FILIBERT ROTH, who recently resigned his chair of forestry at the University of Michigan to accept a similar post at Cornell, has reconsidered his decision, and will remain at Ann Arbor. The Michigan regents have agreed to provide the facilities required for the extension of their forestry department. A thousand-acre "school forest" is to be purchased, which, together with the present eighty-acre forest farm, will give ample opportunity for the field work of the students.

MR. GOLDSWORTHY L. DICKINSON, fellow and tutor of King's College, Cambridge, and Mr. Percy M. Roxby, lecturer in the University of Liverpool, have been elected to Albert Kahn Travelling Fellowships. These fellowships, each of the value of 660*l.*, were established to enable the persons appointed to them to travel round the world. The founder's object is to enable men of proved intellectual attainments to enter into personal contact with men and countries they might never have known. The trust is administered at the University of London, and Sir Henry Miers, F.R.S., is the honorary secretary to the trustees, as well as a trustee himself.

THE detailed programme of papers and discussions at the Congress of the Universities of the Empire, to be held in July next, as already announced, is now complete. The congress meets for discussion on six half-days, beginning on July 2 and concluding on July 5. Among numerous other papers, the following may be mentioned:—Sir Alfred Hopkinson, Vice-Chancellor of Manchester University, on the question of the division of work and specialisation among universities; Principal Peterson, McGill University, on inter-university arrangements for post-graduate and research students; Prof. A. Smithells, F.R.S., the relation of universities to technical and professional education and to education for the Public Services; Mr. H. A. Roberts and Miss M. G. Spencer, on the action of universities in relation to the after-careers of their students; and Sir James Donaldson, Vice-Chancellor and Principal of the University of St. Andrews, on the representation of teachers and graduates on the governing body of a university. Many varied entertainments have been arranged for members of the congress. These include a luncheon to delegates by invitation of the Government at the Hotel Cecil, dinners given by several city companies, and many "At Homes."

THE Viceroy of India attended the recent Convocation of the Calcutta University, and in his capacity of chancellor of the University delivered an address. Dealing with the need for further progress in the provision of facilities for higher education, Lord Hardinge said the Government of India has decided to make a solid advance in the direction of teaching and residential universities. A recurring grant of 3 lakhs of rupees a year has been allotted, of which the Calcutta University will receive 65,000 rupees a year for the appointment of University professors and lecturers in special subjects, and for the encouragement in other ways of higher studies and research. Non-recurring grants amounting to 16 lakhs, of which the Calcutta University will receive 4 lakhs, have been allotted for the provision of University buildings, libraries, and equipment. In addition, a special grant of 10 lakhs has been reserved for hostel accommodation in Calcutta, which will be non-collegiate in character. Another sum of 10 lakhs has been allotted for the development of accommodation in Dacca and the buildings required for the new university in that place. Lord Hardinge hopes that the liberality of the Government will be supplemented by private liberality, and that before many years have passed efficient teaching universities will take the place of the examining and federal universities which India has to-day.

The attendance at German universities forms the subject of an article by Mr. R. Tombo, jun., in the issue of *Science* for April 26. Mr. Tombo analyses the statistics given in the Deutscher Universitäts-Kalendar for the summer semester of the present year. There are 57,398 students in German universities, as contrasted with 57,200 for the preceding summer semester. This is, however, exclusive of 5563 auditors, who, if added, would run the grand total to 62,961, as against 61,274 during the summer semester. The University of Berlin continues to lead the list with an enrolment of 9829 matriculated students. The University of Berlin is followed by the University of Munich, with an enrolment of 6797 matriculated students and 782 auditors. The University of Leipzig ranks third with 5170 matriculated students and 925 auditors. Of the remaining universities, Bonn, Breslau, and Halle each have more than 3000 students; Göttingen, Freiburg, Heidelberg, Münster, Strassburg, and Marburg each have more than 2000, and all the other universities, except Rostock with 955, have each more than 1000 students. Of the total number of students in German universities, 52,435 are from Germany, and of the remainder 160 only are from the British Isles.

SOCIETIES AND ACADEMIES.

London.

Royal Society, May 9.—Sir Archibald Geikie, K.C.B., president, in the chair. A. Vernon **Harcourt**: The variation with temperature of the rate of a chemical change. In an inquiry into the connection between the conditions of a chemical change and its amount, one of the conditions varied was that of the temperature of the solution in which the change took place (Phil. Trans., vol. clxxxvi., 1895, A, pp. 817–95). A relation was found to exist between this condition and the rate of change, expressed by the equation

$$a_1 = a_{1_0}(T/T_0)^m,$$

where a is the rate of change, or the number of minutes in which a definite portion of chemical change is accomplished, T_0 the absolute temperature 273°, and T any other absolute temperature. Not only do the numbers found from this equation agree very closely with the observed numbers, but the equation expresses a natural law which is nearly related to that upon which all calculations of gaseous volumes have long been based. Several later measurements of the rate of change at different temperatures have been published and compared with numbers calculated from other formulæ. In an appendix to the present paper it is shown, by one of the authors of the previous paper, that the numbers thus calculated are in less close agreement with the actual measurements than numbers calculated from his formula given above, while also the formulæ have no physical interpretation.—Dr. C. **Chree**: Some phenomena of sun-spots and of terrestrial magnetism at Kew Observatory. An investigation made some years ago by the author indicated the probability that a relation existed between the amplitude of the daily range of the magnetic elements and the sun-spot area, not on the same day, but several days previously. The object of the present research was to inquire into the reality of this connection. It was found that there is a well-marked period of about 27·3 days in magnetic phenomena, in this sense, that if a certain day exhibits magnetic disturbance attaining the international standard "2," as interpreted at Kew, a day which follows either 27 or 28 days after has nearly double the chance of attaining standard "2" that the ordinary day has. This 27-28-day period was not so clearly shown in the years of maximum sun-spot frequency of the epoch considered as in the years of minimum frequency, and was most clearly shown in certain intermediate years characterised by the number rather than by the magnitude of magnetic disturbances. The conclusion that a period of about 27·3 days exists in "magnetic storms" had been reached some years ago by Mr. Arthur Harvey and Mr. E. W. Maunder, independently, considering respectively data from Toronto and Greenwich, but their conclusions have not been universally accepted. The present investigation shows that the phenomenon is not confined to the large disturbances usually termed "magnetic storms," but is exhibited in the daily range of the average day.—Sir Walter Noel **Hartley** and H. W. **Moss**: The ultimate lines and the quantities of the elements producing those lines in spectra of the oxyhydrogen flame and spark. In a recent paper by one of the authors (Proc. Roy. Soc., 1911, vol. lxxxv., p. 271, Hartley) on some mineral constituents of a dusty atmosphere as determined both by flame and spark spectra, a brief reference was made to the method employed for ascertaining the weights of matter necessary to give calcium and copper lines in the spark. This work has been extended to about twenty elements. The quantities of the elements which render the ultimate lines in the oxyhydrogen flame spectra had previously been carefully determined. With the alkali metals it is found to vary between 0·0008 milligram in the case of potassium, 0·01 mgrm. rubidium and cæsium, and 0·1 mgrm. lithium. In the alkaline earth group, 0·01 mgrm. strontium, 0·1 mgrm. calcium, and barium 1·0 mgrm. Silver 0·1 mgrm., copper 1·0 mgrm., and gold 50 mgrms. Gallium, iridium, and thallium 0·01 mgrm., manganese 0·001 mgrm., lead 0·1, and tin 100 mgrms. The gold spectrum shows the heads of very strong bands which correspond with lines in the spark spectrum. Tin shows no lines, but the edges of bands or flutings which are enfeebled until scarcely visible.—E. **Marsden** and C. G. **Darwin**: The transformations of the active deposit of thorium. The present paper is concerned with a series of experiments undertaken with the view of discovering the genetic arrangement of the various products in the active deposit of thorium, and more particularly the transformations occurring in the product or products included in thorium C. The results give strong reason for supposing that, of the atoms of thorium C, 35 per cent. emit α particles of range 4·8 cm., and become converted into atoms of thorium D, while the remaining 65 per cent. emit β particles and disintegrate into atoms of a very short-lived α-ray product, thorium C. The experiments also show that although the β rays of thorium C are extremely penetrating ($\mu = 13·5$ cm.$^{-1}$ Al), yet they are practically unaccompanied by γ rays, while the relatively soft β rays of thorium D are accompanied by a very intense penetrating γ radiation containing more than six times the amount of energy of the β rays.—W. **Wilson**: The β particles reflected by sheets of matter of different thicknesses. (1) The radiation reflected when the β particles from uranium (*loc. cit.*) strike a screen can be split up into two parts, one with a very large coefficient of absorption, and the other with absorption coefficient of the same order as that of the primary beam. (2) The absorption coefficient of the more penetrating part of the reflected beam decreases with increasing thickness of the reflector. (3) The final absorption coefficient of the rays reflected from thick sheets of aluminium, copper, and lead are 33·7, 26·6, and 20·2 $cm.^{-1}$ respectively. (4) The coefficient of absorption of the easily absorbed part of the radiation reflected by aluminium is about 235 $cm.^{-1}$. The absorption coefficients of the corresponding rays reflected from copper, lead, and air have not been determined with any degree of accuracy, but are of the same order of magnitude as that of the rays reflected by aluminium. (5) An expression has been obtained for the variation of the amount of reflected radiation with the thickness of the reflector, and has been shown to be in good agreement with the results obtained experimentally by Schmidt.

Geological Society, May 1.—Dr. Aubrey Strahan, F.R.S., president, in the chair.—P. **Lake** and Prof. S. H. **Reynolds**: The geology of Mynydd Gader, Dolgelly; with an account of the petrology of the area between Dolgelly and Cader Idris. Mynydd Gader lies immediately south of the area described by the authors in a previous paper (Q.J.G.S., vol. lii., 1896, pp. 511–21). The Tremadoc beds are here succeeded by a group of rocks which are, for the most part, of volcanic origin. These may be divided into a rhyolitic series below and an ashy series above. The rhyolitic series is formed chiefly of lava-flows; the ashy series consists mainly of volcanic ashes and slates, the ashes predominating below and the slates above. *Didymograptus bifidus* occurs near the base of the ashy series, *D. murchisoni* in the upper part. The rhyolitic series appears to be older than the main mass of volcanic rocks in the Arenig area, but it may be contemporaneous with the Calymene ashes of that district. It is probably of approximately the same age as the volcanic series of Skomer Island, and the fact that in both places the rhyolitic rocks are soda-rhyolites is of considerable interest. H. **Bolton**: Insect-remains from the midland and south-eastern coalfields. The writer describes a series of three insect-wings obtained by Dr. L. Moysey from the Shipley clay-pit near Ilkeston (Derbyshire), and a blattoid wing, and three fragments from the borings of the Kent Coal Concessions Company, Ltd., in East Kent. The first series of insect-wings occur in greyish-brown ironstone nodules, which lie in bands in a yellow clay about 30 or 40 ft. below the top hard coal. The East Kent insect-remains occur in core shales, the horizon of which is not yet determined. The East Kent insect-remains contain one wing, referable to the genus *Soomylacris (Ettoblattina)*, a species of which is already known from the Forest of Dean coalfield. The finding of two species of the same genus in coalfields so widely separated as those of the Forest of Dean and East Kent is not without interest, in view of the generally-accepted belief in the former continuity of the Coal Measures across the south of England.

Linnean Society, May 2.—Dr. D. H. Scott, F.R.S., president, in the chair.—Miss T. L. **Prankerd**: The structure of the Palæozoic seed *Lagenostoma ovoides*, Will.—Dr. Karel **Domin**: Additions to the flora of western and north-western Australia. The account was drawn up from undescribed material in the herbarium of the Royal Botanic Gardens, Kew, consisting chiefly of collections by Dr. E. Clement and Captain A. A. Dorrien-Smith. Beside many new varieties, the author characterises fourteen new plants, one being *Casuarina dorrieni*, eight grasses, three being species of Panicum, and five other Monocotyledons. G. H. **Wailes**: Fresh-water Rhizopoda from the States of New York, New Jersey, and Georgia, with a supplementary account of some species from the Seychelles. The gatherings forming the basis of the present paper were collected in the autumn of 1911; the Rhizopod fauna is summed up as being rich in species and individuals, about 80 per cent. being similar to those found in Europe. The remainder of the paper was devoted to a systematic account of the species found, including three new species of Nebela, one of Euglypha, and many varieties.

Physical Society, April 26.—Mr. A. Campbell, vice-president, in the chair.—The adjourned discussion on Mr. H. Donaldson's paper on the coefficients of expansion of fused silica and mercury was resumed. Prof. H. L. **Callendar** opened the discussion by communicating a paper on the expansion of vitreous silica. The expansion of vitreous silica at ordinary temperatures had acquired special interest recently in connection with mercurial thermometry and standards of length and expansion. The majority of observers had used the Fizeau method with specimens 10 mm. to 15 mm. long. Somewhat different values had been found for different specimens with different standards of comparison. For a cylindrical specimen on a platinum-iridium tripod Chappuis found 50×10^{-6} for the expansion from 0° C. to 100° C., and $0·385\times10^{-6}$ for the coefficient at 0° C. Scheel, for a similar specimen, tested against a quartz-crystal ring, found $45·5\times10^{-6}$ from 0° C. to 100° C., and $0·217\times10^{-6}$ at 0° C. For a ring specimen tested in a vacuum by the absolute method he found values almost identical with Chappuis; but Randall, employing a similar ring specimen, also made by Zeiss, found the mean coefficient from 16° C. to 80° C. (which is nearly the same as that from 0° C. to 100° C.) to be only $0·424\times10^{-6}$. Such differences might be due to accidental errors, or to differences in form and treatment of the specimens employed, or to differences in the standards of comparison. But since the whole expansion of 1 cm. of fused silica between 0° C. and 100° C. was only of the order of one wave-length of light, it was also possible that small constant errors might arise in so delicate an experiment from gas-films or other surface effects variable with temperature. It seemed, therefore, desirable to measure the expansion of the long silica rods at low temperatures by a direct interference method in which such sources of error were excluded. The method used gave a smaller and more rapidly diminishing value for the expansion of the silica rods than that obtained by other observers employing the orthodox Fizeau method with short specimens. With the assistance of Mr. A. Eagle, the author had made some observations on the difference between the radial and axial expansion of a silica tube similar to that from which the bulbs of the mercury weight thermometers employed by Harlow and Eumorfopoulos had been constructed. Three sets of determinations had been made by Mr. Eagle on three different days with closely concordant results. The mean of these showed that the axial coefficient of expansion of the specimen tested exceeded the radial coefficient by $0·20\times10^{-6}$ over the range 18° C. to 90° C. This result agreed as closely as could be expected with the values of the cubical coefficient deduced from the weight thermometer observations of Harlow and Eumorfopoulos when the values of Callendar and Moss for the absolute expansion of mercury were assumed.—R. **Appleyard**: The solution of network problems by determinants. The paper is a practical application of the method described before the Physical Society in 1885 by Dr. J. A. Fleming. Let it be supposed that cyclic currents have been assigned to all the meshes of a given network, and that all capacities (K, in farads), inductances (L, in henries), and leakances (S, in mhos) have been converted into resistances in ohms

$$\left(\frac{1}{Kp}, Lp, \frac{1}{S}, \text{ where } p = 4\pi\sim\right).$$

The general network problem then is to find the current, in amperes, in any given branch, corresponding to the application of an E.M.F. of sine form, between any two fixed points in the network.

MANCHESTER.

Literary and Philosophical Society, April 23.—Prof. F. E. Weiss, president, in the chair. R. L. **Taylor**: The action of bleaching agents on the colouring matter of linen. The author showed that the colouring matter of unbleached linen is quite abnormal with regard to the action of the ordinary bleaching agents upon it, and differs from every other colouring matter with which he is acquainted. Whereas colouring matters, such as indigo, Turkey-red, and the colouring matter of cotton, are bleached much more rapidly by free chlorine or hypochlorous acid than by a hypochlorite, with the colouring matter of linen the exact opposite is the case, this being bleached more rapidly by a solution of a hypochlorite. Apparently the maximum bleaching effect on unbleached linen is produced by a solution of a hypochlorite which contains no free alkali, but rather some free chlorine or hypochlorous acid. Excess of alkali retards the bleaching action, just as it does in the case of other colouring matters. The addition of a chloride to the solution sometimes accelerates and sometimes retards the bleaching action (this depending upon the amount of alkali in the solution), instead of, as is the case with other colouring matters, always accelerating it.

CAPE TOWN.

Royal Society of South Africa, March 20.—Mr. S. S. Hough, F.R.S., president, in the chair.—L. **Peringuey**: Bushman sticks decorated on intaglio and poker-work, a note on the decorative skill of the Bush people and other aborigines. Specimens of sticks, decorated with drawings and carvings, also bust models, &c., were exhibited. On the sticks the intaglios were extremely fine, and represented hunting scenes, in which men in police uniform and on horseback were depicted with most consummate skill; other sticks were ornamented with poker-work and line drawings of very great artistic merit, but representing modern subjects, a railway train among them. Poker-work was, in his opinion, probably of Kafir origin, and it was quite possible that the Bush people had obtained it from the latter, but improved on it through their natural artistic disposition. He had at one time doubted the authorship of rock-graving in connection with the Bush people, but he exhibited a Bush painting in which the back of the animals had been graved. The Bushman thus combined the two arts, graving and painting.—J. R. **Sutton**: Some meteorological conditions controlling nocturnal radiation. According to the results obtained, it appears that after allowance has been made for the state of the sky and the movement of the air, the only factor of real importance determining the radiation temperature gradient is the relative humidity.—T. **Muir**: The resultant of a set of homogeneous lineo-linear equations. Three different methods are given for obtaining the resultant, but the main interest is concentrated on one of them, because of two or three somewhat obscure references made to it by Sylvester when studying the problem in 1863.—W. A. Douglas **Rudge**: The variation in the value of the atmospheric electrical potential with the altitude. This paper gives some account of observations taken at various places in South Africa in order to find the relation which exists between the atmospheric potential gradient and the altitude of the places of observation. Observations were taken between Lourenco Marques and Durban, *via* Johannesburg, passing thus from sea-level to sea-level over a considerable stretch of country in which the altitudes rose to nearly 7000 ft. The general result is that there is a great change in the value of the potential gradient with the altitude, the extreme value at the highest point (6500 ft.) being not more than one-eighth of that at sea-level. Similar differences having been observed on previous occasions at other places, led to the investigations being conducted. The maximum values were about 500 volts per metre at Lourenco Marques and Durban, and 58 volts at Belfast, 6500 ft. above sea-level, and at places in between values were obtained which showed that the greater the altitude the smaller the potential gradient. An exception to this rule was seen at Johannesburg, where the potential gradient was very variable and changed signs at different points in the neighbourhood. These variations were traced to the clouds of steam, and especially of dust, proceeding from the mine heaps. Steam has the effect of increasing the positive gradient, while dust lowers it.—H. A. **Wager**: Respiration and cell energy.

PICTURESQUE SAVOY.

Costumes, Traditions, and Songs of Savoy. By Estella Canziani. Illustrated with fifty reproductions of pictures by the author, and with many line drawings. Pp. xiii + 180. (London: Chatto and Windus, 1911.) Price 21*s.* net.

HERE is a book which should give pleasure to many. It appeals to the general reader who wishes to be told in an entertaining manner of journeyings in little-known places, or to look on charming colour reproductions of picturesque costumes, personal ornaments, and beautiful landscapes. It also appeals to many groups of specialists by its representations of wood carvings, seals, coins, and coats of arms, by its music remembered from olden times, and by its abundance of legends, customs, and folk-songs. We have vivid accounts of mountaineers, laborious, home-loving, honest, and frugal, who generously combine to make up a neighbour's loss by fire or by death in his herd, help him to tile his new house, and divide amongst themselves the outdoor work for his widow. The people fear crowds and towns, though not the loneliness of their mountain solitudes. Their houses are wooden stables with straw-coloured earthen floors, which they share with their animals. Their furniture consists of a few primitive chairs, beds of straw and rags in rough wooden boxes raised on tall legs, and a water tub and a hay box for the cattle. The food is as rude as the hovel. The midday meal at an inn may be boiled cabbage, black bread, and wine, and the staple fare is black bread, milk, and soup, with a little rice. Pigs killed, dried, and salted once a year furnish an occasional and unattractive dish, and mutton (of extraordinary toughness) is an exceptional treat.

In these widely different surroundings we find not a few beliefs and practices familiar in our own British Isles. The pigs must be killed under the waxing, and not under the waning, moon. The saint of Dieublanc village hangs his cloak on the sunbeams, as did St. Brigit of Kildare. The *Bacchu-ber* dance (pp. 74–5) closely resembles the complicated sword-dances which Mr. Cecil Sharp has found still lingering near Flamborough and elsewhere. The homeward way of the newly-married was once barred by a cart or plank until drink-money was paid, just as and why it was barred with a rope in rural England. The future of a bride (whether *elle portera la culotte*) is judged by her success in leaping a stream, as it was once in northern England by jumping the "petting stone." Still more curious is it to meet in Savoy (p. 128) the tale of the cat that, overhearing that "Doldrum is dead," dashes off to claim the succession as King of the Cats.

But most of the beliefs and practices are unlike our own. If the baying of dogs at midnight foretells death, as to ourselves, the hooting of owls is a sign, not of disaster, but of a birth. Mountains, glaciers, torrents, and especially caves, are the homes of evil spirits, but lakes and river sources of good spirits. The damned are confined in desolate places and beneath glaciers, whence they can cut their way up to Paradise by labouring for countless nights till cockcrow with the ineffective aid of a pin, and peasants still cut out steps to aid this labour of the lost. The Mer de Glace and the lake of Aigueblette each cover fertile lands destroyed on account of the inhospitality of their inhabitants. On stormy nights the witches and fays play ball with a baby, which they toss to one another and over the great fire in the midst of their circle, and their victim is ever after distorted and ailing, "and only cares for the company of snakes." The Devil is watchful, and picks off at once the red flowers which bloom on the mountain fern on St. John's Night, and confer invisibility. Sometimes, however, he comes by the worst, as when a saint seized him in the form of a bear, and forced him to draw the materials for a monastery in the place of the oxen previously destroyed by him. The art of making Chartreuse, by the way, is said to have been filched from the Devil by a monk who stole into the secret grotto where the Arch Enemy was making liqueurs. God's lightning warns of the coming of the Devil's thunder, so that one has time to avert evil by signing the cross.

But there is no end to the legends—of hidden treasures, lake serpents, ghosts, and animal-guardians of ruins and ancient castles—and the book contains much other interesting matter. We are present with the author at *festas,* where the "bidder," dressed up in colours, beats his drum and clashes his cymbals, and then turns somersaults, as he leads churchwards the peasants in their most gorgeous garments. We sympathise with her vain attempts to hurry the postcart, and we learn the social customs of the valleys. The lover knows without speech the failure of his courtship if oats are dropped into his pockets, or the burnt ends of the firebrands turned towards him, or if he is invited to sit near the logs piled beside the fire. As a funeral passes all doors and windows are shut to prevent entry of the freed soul of the dead, and the white gloves worn by the bearers are cast upon the coffin in the grave to get rid of the impurity of death. Miss Canziani does not seem to have found, or noted here, charms or folk-medicine, or the evil-eye belief (which is prevalent at least in Rumilly).

We have left ourselves no space to dwell on the characteristic melodies or the songs, but these present less novelty, as MM. A. van Gennep, Tiersot, Ritz, and Servettaz have all published collections from Savoy.

Miss Canziani tells us that the distinctive village costumes which she depicts so brilliantly are gradually disappearing, that the fays are abandoning their mountain homes, and that the old legends are being forgotten. We must therefore congratulate ourselves that the brush and pen of an enthusiastic and painstaking recorder have preserved for us so much of antique beauty, poetry, and custom before they fade away for ever.

A. R. W.

THE GEOLOGY OF SELSEY BILL.

Selsey Bill: Historic and Prehistoric. By Edw. Heron-Allen. Pp. xvi + 404 + maps and plates. (London: Duckworth and Co., 1911.) Price £2 2s. net.

The Recent and Fossil Foraminifera of the Shore-sands at Selsey Bill, Sussex. By Edw. Heron-Allen and Arthur Earland. (Reprinted from the Journal of the Royal Microscopical Society.) (London: Printed by Wm. Clowes and Sons, Ltd., 1908–1911.)

SELSEY BILL, the south-western promontory of Sussex, is classic ground to the geologist on account of the fossiliferous Middle Eocene deposits (or Bracklesham beds) which are exposed along its shores. It is therefore appropriate that any work on this region should devote considerable space to its geology, and Mr. Heron-Allen's sumptuous volume now before us includes no fewer than six chapters dealing with various aspects of the subject. Realising the needs of the general reader, Mr. Heron-Allen does even more than refer to the geological formations which can be actually studied within the area; for he attempts a brief sketch of the successive changes in geography and conditions which have occurred in southern Britain since the beginning of geological time, and alludes to certain hypotheses and general principles which are likely to excite interest. Following this, he gives a most useful description, illustrated by a map, of the series of fossiliferous Bracklesham beds exposed on the beach, based partly on the work of the Geological Survey, partly on his own observations made in association with Mr. Thomas Woodland.

The successive beds dip very gently from the western shore under the peninsula in a north-easterly direction, reappearing on the east side of the Bill; and they are covered partly by patches of Pleistocene deposits, partly by variously moving modern banks of sand and shingle, which render the study of them difficult. Good figures of some of the typical fossils occupy three plates, and will be useful to a beginner; but the nomenclature adopted in these illustrations and in the long lists added to the geological description will not always satisfy the modern worker.

Mr. Heron-Allen's new observations relate to the Pleistocene and other more recent deposits, which he has evidently studied with great diligence. His description of a fresh-water clay from which he obtained the remains of a young mammoth in April, 1909, is especially interesting, and is illustrated by a plate of photographs of the lower molars and some bones. His records of discoveries of flint implements both of Palæolithic and Neolithic types are also important; and the photographs of a "Mesolithic chisel" found beneath the Coombe rock on top of the raised beach are especially noteworthy. It is curious that no relics of the Bronze Age have hitherto been met with, though those of the Iron Age are abundant.

Mr. Heron-Allen has also worked industriously at the collection and identification of the Foraminifera which occur in patches on the beach. Altogether he has discovered about four hundred species, of which a large proportion agree closely with forms now common in Torres Straits and on the Great Barrier Reef of Australia. Unfortunately, these Foraminifera are of very different ages—some Cretaceous, some Tertiary, and some recent—all mixed, and it is not easy to separate them into groups; but in association with Mr. Arthur Earland, Mr. Heron-Allen has contributed an interesting series of papers on the collection to the Journal of the Royal Microscopical Society. These papers have now been reprinted and issued as a separate volume, in which there is an appendix on the preparation and study of Foraminifera from the Chalk.

The greater part of Mr. Heron-Allen's work on Selsey Bill deals, of course, with history and statistics, with which we are not concerned, and his natural history notes are necessarily brief. He is, however, to be congratulated on his successful effort to give both an interesting and a trustworthy account of the geology, which should stimulate local observers to devote more attention to the Bracklesham fossils and the Coombe rock than these have received during recent years.

A. S. W.

EXPERIENCES OF A BUTTERFLY-HUNTER.

Butterfly-Hunting in Many Lands. Notes of a Field Naturalist. By Dr. G. B. Longstaff. To which are added translations of papers by Fritz Müller on the scent-organs of butterflies and moths: with a note by Dr. E. B. Poulton, F.R.S. Pp. xviii+728. With 16 plates, 7 coloured. (London: Longmans, Green and Co., 1912.) Price 21*s.* net.

IN the handsome volume before us, Dr. Longstaff has brought together an account of his collecting experiences. The first chapter, "Early Reminiscences," describes his work as a collector from 1858 to 1869, chiefly in Britain, and especially during a visit to Rannoch. About 1869 he relinquished collecting, owing to defective sight after the loss of an eye, but from 1903 onward he has been collecting specimens abroad for the benefit of the Oxford Museum, visiting India, Ceylon, China, Japan, Canada, Algeria, South Africa, West Indies, South America, Egypt and the Sudan, New Zealand, and Australia.

Although chiefly a collector of butterflies, insects of all orders attracted more or less of his attention, while Mrs. Longstaff, who frequently accompanied her husband, paid special attention to land and fresh-water Mollusca. He himself made a point of noting the habits of the insects, especially their position at rest, and the odours which many of them emit. The frontispiece shows us the well-known African butterfly, *Eronia cleodora*, on the wing and at rest, and the other coloured plates illustrate not butterflies alone, but numerous interesting insects of all orders, taken by Dr. Longstaff, many of them previously unfigured, and a large proportion actually new to science.

The last chapter is devoted to "Butterfly Bionomics," and deals with such subjects as coloured juices, tenacity of life, mimicry, flight, altitudes, seasonal forms, &c., and the appendix includes a series of twelve important papers by the late Fritz Müller, from various German and Portuguese periodicals, by no means easy of access, even to those acquainted with the original languages. These are translated by Mr. E. A. Elliott, and are illustrated with nine plates. We wish that Porchinsky's beautifully illustrated papers on the colours of larvæ, &c., could also be republished in English from the Russian Entomological Transactions.

Dr. Longstaff's book is addressed chiefly to entomologists, but there are many interesting notes on various subjects scattered through the book, especially his experiences during the earthquake in Jamaica on January 14, 1907. There are also some amusing travellers' tales, which may be found scattered here and there through the book. It is exceedingly well printed, and, notwithstanding the enormous amount of technical matter, and the scores of scientific names on almost every page, we have noticed scarcely any misprints; and, indeed, the only point which appears to be an error which we have noticed is the statement that the mongoose was introduced into Jamaica to kill *snakes*. We believe that it was really introduced to kill *rats*, for venomous snakes are unknown in Jamaica, and harmless ones are not remarkably abundant.

W. F. K.

SOME TEXT-BOOKS OF CHEMISTRY.

(1) *A Text-book of Inorganic Chemistry.* By Dr. G. Senter. Pp. xi+583. (London: Methuen and Co., Ltd., 1911.) Price 6*s.* 6*d.* (Text-books of Science.)

(2) *Chemistry: an Elementary Text-book.* By Profs. W. C. Morgan and J. A. Lyman. Pp. xvi+429. (New York: the Macmillan Co.; London: Macmillan and Co., Ltd., 1911.) Price 5*s.* 6*d.* net.

(3) *The Chemistry of the Radio-elements.* By F. Soddy, F.R.S. Pp. v+92+chart. (London: Longmans, Green, and Co., 1911.) Price 2*s.* 6*d.* net. (Monographs on Inorganic and Physical Chemistry.)

(4) *A Text-book of Practical Chemistry for Technical Institutes.* By Dr. A. E. Dunstan and F. B. Thole. Pp. x+335. (London: Methuen and Co., Ltd., 1911.) Price 3*s.* 6*d.* (Text-books of Science.)

(5) *Practical Chemistry for Medical Students.* By Dr. A. C. Cumming. With a preface by Prof. James Walker. Pp. 171. (Edinburgh: James Thin, 1911.)

(6) *Elementary Experimental Chemistry.* By F. E. Weston. Pp. vii+140. (London: Longmans, Green, and Co., 1911.) Price 2*s.*

(7) *Chemistry Note-book.* By E. J. Sumner. Pp. 92. (Burnley: the Cooper Printing Co., Ltd., n.d.) Price 2*s.*

(8) *An Experimental Course of Physical Chemistry.* By Dr. J. F. Spencer. Part i., Statical Experiments. Pp. xiv+228. (London: G. Bell and Sons, Ltd., 1911.) Price 3*s.* 6*d.*

(9) *Laboratory Exercises in Physical Chemistry.* By Dr. J. N. Pring. Pp. xiv+163. (Manchester: the University Press, 1911.) Price 4*s.* net.

(1) UNTIL recently the problems which are now discussed under the heading of "Physical Chemistry" were usually relegated to the preliminary chapters of a text-book of general

chemistry, and only very occasionally touched upon in the later chapters of the book. Such a text-book had undoubted advantages from the point of view of the teacher; the text-book supplied the dry bones of chemistry, and in a course of lectures the flesh and blood could be added without any undue risk of duplicating the teaching derived from the book. But for the solitary student it was an obvious disadvantage that such questions as mass-action and reversible changes should be dealt with in an isolated chapter, and their application to the "daily round" of chemical changes forgotten or neglected. It was to remedy this defect that the book now under review was written. The author has not merely professed the policy of stating facts before theories, but, in welcome contrast with some recent writers, has held to this policy, so that atomic weights are not introduced until chapter x., page 115. Criticism of the book is largely limited to points of detail. Thus the adoption of the old convention that one molecular proportion of a gas occupies "two volumes" appears to the writer to introduce unnecessary confusion, and seems to carry with it some lurking suspicion that the oxygen molecule O_2 occupies two volumes because it contains two atoms, although the volume occupied is precisely the same in the case of the monatomic molecule of mercury. More emphasis might have been placed upon the fact that molecular weights are now referred to $O_2=32$ instead of $H_2=2$, the statement on p. 109 that "the molecular weight of a gas is double its vapour density referred to hydrogen as unit" being therefore only an approximation and not an exact definition; we have also not noticed on a first reading any statement of the fact that Avogadro's hypothesis is itself only an approximation which becomes accurate only at zero pressure.

In reference to the illustrations, two points have been noticed. The crystal drawings on p. 302 are for the most part correct, but have been printed in curious positions, the upper part of the figure being on the right in Fig. 60, on the left in Fig. 65, and at the bottom of Fig. 63. In Fig. 24 the author has perpetuated the mistake (so often repeated as almost to have become a dogma of the chemical creed) of representing Dumas's experiments on the composition of water as having been made with a Bunsen burner with U-tubes of the modern pattern some six or eight inches long; a reference to the original paper shows that these tubes were a metre in height, and that the beak of the massive copper oxide bulb was also a metre long; on this scale the retort stands of the figure would be 8 ft. high, and the interpolated Bunsen burner about 2 ft. high!

The periodic classification of the elements given on p. 364 shows the elements praseodymium = 140·5 and neodymium = 143·6 as members of the nitrogen and oxygen groups respectively. In view of the extraordinary similarity of these two elements such a separation is very undesirable, and there is every reason for preferring Prof. Armstrong's arrangement, in which the rare earth elements, from lanthanum = 139 to ytterbium = 173, form a vertical column in the boron or aluminium group; precedents for such an arrangement already exist in the clusters Fe, Co, Ni; Ru, Rh, Pd; and Os, Ir, Pt.

These criticisms deal entirely with matters of detail. Turning to more general considerations, it may be noted that the information given is modern and accurate, and that reference is made to a considerable number of observations published during the year 1911, which appears upon the title-page. The style is clear, the book is attractively printed, and the author has undoubtedly succeeded in his endeavour to introduce something of the spirit of physical chemistry into the routine of descriptive chemistry.

(2) The American text-book is in striking contrast to the serious work of our first author. An endeavour has been made

"to bring out the *humanistic* side of the science, to use as far as possible that material which is laden with intense human interest because of its significance to the race."

In so far as this has led the authors to introduce excellent portraits of Dalton, Lavoisier, Faraday, and Kekulé it is to be commended, although Arrhenius, as shown facing p. 260, would scarcely be recognised by his friends. But they proceed to illustrate chemical energy by a picture of a forest being cleared by dynamite, and an obscure photograph of an automobile, enveloped in dust and steam, travelling at 80 miles an hour; rapid oxidation is illustrated by the burning of San Francisco, and slow oxidation by a picture of a bird nesting in a hollow tree; other illustrations show a primeval forest, a coal mine, hydraulic gold-mining in California, and the granite rocks of the Sierra Nevada mountains. The book has evidently been written for American readers, and is not likely to come into general use in England.

(3) Mr. Soddy's book on "The Chemistry of the Radio-elements" is the first of a series of "Monographs on Inorganic and Physical Chemistry," of which ten numbers are already announced. The idea of the series is excellent, and the monographs should appeal to a wider circle and have an even larger circulation than the biochemical monographs already issued by the publishers. Following a general description of radio-activity and radio-active constants, the three "disintegration

series," starting from uranium, thorium, and actinium, are considered, and a note is added in reference to the slight radio-activity of potassium and rubidium. A concise statement of the present position of radio-chemistry is very opportune, and will be welcomed by many readers who are not in a position to master the original literature of the subject.

(4) Messrs. Dunstan and Thole have included in one volume instructions for qualitative analysis, volumetric and gravimetric analysis, gasometry, organic analysis and identification, and physico-chemical determinations; tables of solubility, reagents, atomic weights, logarithms, melting-points and boiling-points are given as appendices. Qualitative analysis is dealt with largely from the ionic point of view, but exception must be taken to the suggestion on p. 12 that H. C. Jones is the originator of the view that the ion is "associated with a variable amount of solvent"; this author's first statement was that the molecules of a salt, and not the ions, are hydrated, and this erroneous view was not withdrawn until the idea of hydrated ions had become generally familiar from the work of Kohlrausch and others. The book does not contain any detailed series of organic preparations, though general instructions are given for acetylation, nitration, preparation of oximes, &c.; but the chapter on organic identification is unusually complete, and forms one of the most valuable features of the book.

(5) Dr. Cumming has compiled a very attractive practical chemistry for medical students, leading up from exercises on solubility, &c., to the examination of organic compounds. The earlier exercises appear to be almost too simple, and it may be doubted whether the separation of salt from sand and the recrystallation of potassium nitrate mixed with a little permanganate are actually carried out by the medical students in the Edinburgh laboratories. In a later edition it would be well to accord to "bunsen" the dignity of a capital letter.

(6) Mr. Weston's book is intended for the use of beginners, and deals with solution, air, water, acids, alkalis, salts, the common gases, and the laws of chemical combination. A feature of the work is the photographic reproduction of actual apparatus; the reproductions are usually good, but a badly-bored cork which makes its first appearance in Fig. 20 shows itself again in the later pictures with the frequency attributed to the "bad penny"; the face reproduced in Fig. 50 would give the impression that a pipette is a worrying instrument to use. The success of a practical course depends almost entirely upon the teacher in charge of the laboratory, and the incidental notes show that the author has that wider range of knowledge which contributes so much to the interest of the work. Black's work on "fixed air," referred to on p. 83, should be dated 1755 and not 1775.

(7) Historical notes are a feature of the "Chemistry Note-book," whereby Mr. Sumner seeks to supplement the imperfections of a schoolboy's "notes." The book is published locally, and is issued in a form which does not lend itself to any modification of the course which the author has adopted in his own school; but the course is a good one, and it may be that other teachers will be content to follow it so closely as to render possible the use of the printed "note-book." Incidental faults are the occasional use of formulæ as abbreviations, a bad habit that needs no encouragement from the teacher of a class of boys, and the slovenly use of the adjective (?) "bunsen." The eleven pages of historical outline at the end of the book are of more general value, and go far to guarantee the qualifications of the author to devise a successful course of elementary chemistry. The list of elements "discovered" by Berzelius is a curious one: there seems to be some confusion between the discovery and the isolation of an element, and it would be easy to dispute the claims of Berzelius to one or other of the two stages in the "discovery" of barium or silicon.

(8) Dr. Spencer has provided a course of experimental work to run side by side with a lecture-course in physical chemistry; the first part, dealing with "statical experiments," is now issued as a separate volume, to be followed by a volume describing the more difficult dynamical experiments. The methods of measuring the mechanical, optical, and thermal properties of substances are illustrated in an ample series of experiments. The methods to be used in correcting a balance and calibrating the weights are described, together with the correction to vacuum standard. It is to be regretted that the correction for latitude is deliberately excluded, and that the vacuum correction is not used systematically in the later experiments. It is not generally realised by chemists that a boiling point under a given pressure of mercury has no accurate significance until a correction has been made for latitude, for height above sea-level, and for the temperature of the mercury of the barometer; the systematic neglect of such corrections is a source of much inaccuracy, and it should be one of the chief objects of a course of experimental work in physical chemistry to get rid of the slovenly habit of making and publishing uncorrected observations. In a later edition the author will perhaps use his opportunity to develop this important feature in a book that is likely to be widely read and used.

(9) Dr. Pring's "Laboratory Exercises" covers a rather narrow range of experiments in physical chemistry, but the book has the advantage that many of the experiments are well worth doing, and are not included in more conventional text-books. The use of Junker's gas calorimeter, the Mahler-Cook combustion bomb, and the Wanner pyrometer, together with experiments on the charge and discharge of an accumulator and on electrolytic oxidation and reduction, provide a course of real value both as an education in method and as a training in operations of great technical importance. Such a course affords a real inducement to a student to enter the Manchester laboratory, offering as it does exceptional opportunities for technical training on lines widely different from the ordinary course of work in physics or in physical chemistry. T. M. L.

OUR BOOKSHELF.

Prehistoric Thessaly: being some Account of Recent Excavations and Explorations in North-eastern Greece from Lake Kopais to the Borders of Macedonia. By A. J. B. Wace and M. S. Thompson. Pp. xvi+272+vi plates. (Cambridge: University Press, 1912.) Price 18*s.* net.

Messrs. Wace and Thompson have opened a new chapter in the history of early civilisation. They have shown that in northern Greece a Neolithic culture, with a peculiar geometric art of its own, held the field contemporaneously with the Bronze Age "Minoan" and "Ægean" culture of southern Greece until the latter had reached its final phase and was entering upon its decline. Bronze was not used by the prehistoric Thessalians until the "Third Late-Minoan Period" of the Ægean culture, when they finally accepted its use from the southerners, not earlier, probably, than *circa* 1300 B.C., and not very long before iron came into general use. This is a most revolutionary discovery, and its effect upon the supposed history of the development of the use of bronze in the rest of Europe cannot yet be gauged. M. Tsountas, the distinguished Greek archæologist, had already discovered important remains of the Neolithic Thessalian culture, with its remarkable polychrome geometric pottery, at Dimini and Sesklo, but he had failed to detect its remarkably late date. He placed it on the usual *a priori* grounds anterior to the Bronze Age Minoan civilisation merely because it was Neolithic. The discovery of Messrs. Wace and Thompson, for which they give chapter and verse in this book, is a much-needed rebuke to *a priori* arguments in dating prehistoric antiquities.

I regret that considerations of space forbid me to say more of the book, which is a fine one. In it the authors have given us not merely a description of their own work, but a comprehensive monograph upon all the recent excavations in northern Greece, including those of Tsountas and Sotiriadis, which have inaugurated this new knowledge of early European civilisation.

H. R. Hall.

Gem-stones and their Distinctive Characters. By Dr. G. F. Herbert Smith. Pp. xv+312. (London: Methuen and Co., Ltd., 1912.) Price 6*s.* net.

This compact and well-illustrated manual supplies a want which has long been felt. So many minerals have been found, in recent years, to furnish varieties characterised by brilliant colours, with exquisite transparency and lustre, that jewellers have now a much wider choice than formerly in making selections for their artistic productions. It is unfortunately true that the use of these new gem-stones is greatly hindered by popular prejudices in favour of the materials with an old-established reputation, but a work like the present is calculated to bring home, both to the artists in jewellery and the public served by them, the wealth of unexploited material at command for ornamental purposes.

The early chapters of the book, describing the characters of gem-stones and the methods of discriminating between different species, are characterised by simplicity, clearness, and accuracy. Among the chapters on technology, that which is perhaps of greatest interest deals with the *manufacture* of precious stones. The method by which true rubies are now regularly produced for the market is not only fully described, but is illustrated by a photograph of the apparatus actually employed. The author is, however, able to show what means are available for discriminating between the natural and the artificial gems, and he adds: "At the time the manufactured ruby was a novelty, it fetched as much as 6*l.* a carat, but as soon as it was discovered that it could easily be differentiated from the natural stone, a collapse took place, and the price fell abruptly to 30*s.*, and eventually to 5*s.* and even 1*s.* a carat. . . . The prices of the natural stones, which at first had fallen, have now risen to almost their former level." The wise caution is still insisted on, however, of *Caveat emptor.*

In the descriptive part of the book an attempt at classification of gem-stones is made, which will probably not meet with very general acceptance. The title of "precious-stones" is only allowed to the diamond, ruby, sapphire, and emerald. The large group of "semi-precious" stones includes (with the topaz, spinel, peridot, zircon, opal, &c.) many beautiful substances which up to the present have been little used. The remaining classes are the "ornamental stones" and the "organic products"—pearl, coral, and amber.

An important feature of the work is the number of illustrations given in it. Besides those in the text, there are thirty-three plates, three of which are in colour, giving a fair idea of the appearance of the gems in their natural and cut conditions.

A Method for the Detection of the Proximity of Ice at Sea.

THIS method has for its basis the varying alteration in the electro-conductivity of sea water in the neighbourhood of melting ice. The conductivity of such water is materially reduced, and is dependent on two separate factors: first, the fall in temperature, and, secondly, the dilution of sea water of high electro-conductivity with water derived from glacier ice of comparatively negligible conductivity.

With regard to the first factor, the fall in conductivity is approximately 2 per cent. per degree centigrade for every degree below 20° C., and with regard to the second factor, namely, admixture of ice-derived water with sea water, the fall in conductivity, as ascertained by direct reading with appropriate apparatus, is as follows:—

(Temperature of experiment throughout $=17{\cdot}8°$ C.)

Specific conductivity of sea water, as shown by the scale of the apparatus used, $=42,000$ reciprocal megohms.

With a dilution of 1 part of ice-derived water with 80 parts of sea water, decrease in conductivity is 1 per cent.; dilution of 1 in 50, decrease $=3$ per cent.; dilution of 1 in 25, decrease $=7$ per cent.; dilution of 1 in 10, decrease $=12$ per cent.

It is obvious that the presence of ice-derived water in increasing proportion in sea water will, with a continuous self-recording apparatus, show a continuous fall in the electro-conductivity readings, and will so furnish presumptive evidence of the approach of ice. It is possible, and even probable, that changes in the composition of the water would be more trustworthy than changes in the temperature. In any case, if the two effects were observed side by side, the results of each method would tend to eliminate any disturbing factor peculiar to the other, such as the presence of fresh estuarial water on the one hand, or, on the other, changes in the temperature due to other causes than the proximity of icebergs.

Pinhole Images.

IN the last paragraph of his letter in NATURE of May 2, Mr. Edser alludes to several ways in which "pinhole" images of the sun's disc may be observed. It is not perhaps so generally known that such images are often produced in great numbers by the reflection of direct sunlight from a glass surface, or by its transmission through a glass plate.

My attention was directed to these images during the recent solar eclipse by observing that direct sunlight, reflected on to the ceiling of a room from a plate of ordinary unsilvered window glass, contained numerous overlapping, but well-defined, crescent-shaped images of the uneclipsed part of the sun's disc. Similar overlapping images could also be traced in the sunlight coming directly through a window pane and falling on the floor, but here the best results were obtained by first using a mirror to reflect the light, after having traversed the window pane, on to the ceiling. The mirror, it should be said, played no part in the production of the images.

These phenomena are not observable with perfectly flat glass, but only with the common kind of window glass, which has a noticeably irregular surface, and appreciably distorts the details of objects seen through it. For the most part a plate of this glass scatters the transmitted light, but here and there, distributed over its surface, are small isolated patches which can be regarded as truly plane-parallel. In the transmission of light these isolated patches act as "holes" relatively to the surrounding and light-scattering parts of the plate, and thus give rise to "pinhole" images. The images noted in the reflected light are obviously produced in a similar manner by regular reflection from any perfectly flat small patches scattered over a surface otherwise irregular. The uniformity in size of the images and their measured dimensions are in accordance with this explanation of their origin.

Meteor-showers towards the End of May.

THE following meteor-showers become due during the last week in May:—

Epoch May 23, 16h. 30m. (G.M.T.), twenty-first order of magnitude. Principal maxima, May 24, 23h. 15m., and May 26, 20h. 5m.; secondary maximum, May 24, 7h. 20m.

Epoch May 27, 6h., third order of magnitude. Principal maximum, May 25, 10h. 30m.; secondary maximum, May 26, 4h. 5m.

Epoch May 29, 23h. 30m., twenty-fourth order of magnitude. Principal maxima, May 26, 4h. 5m., and May 28, 0h. 50m.; secondary maxima, May 27, 3h. 10m., and May 29, 13h. 50m.

Epoch May 29, 19h. 30m., thirteenth order of magnitude. Principal maximum, May 31, 10h. 35m.; secondary maxima, May 20, 21h. 35m., and May 31, 18h. 20m.

May 20. JOHN R. HENRY.

THE BRITISH SCIENCE GUILD.

THE sixth annual meeting of the British Science Guild was held at the Institution of Electrical Engineers on Friday last, May 17; and was followed in the evening by a banquet, which was attended by a large and distinguished company, in the Galleries of the Royal Institute of Painters in Water Colours, with the Right Hon. Sir William Mather in the chair. Sir Norman Lockyer, chairman of committees of the Guild, was unfortunately prevented by ill-health from being present at either function. His absence from the banquet was exceptionally disappointing, as the day was his seventy-sixth birthday, and arrangements had been made to mark the appreciation of the members of the Guild of his services to science in general and the Guild in particular by a presentation of plate to him, and a separate token to Lady Lockyer in recognition of her energetic work for the Guild as honorary assistant treasurer and in other ways.

The commemorative gift to Sir Norman consisted of three silver bowls, on the largest of which was inscribed:—"Presented to Sir Norman Lockyer, K.C.B., LL.D., D.Sc., F.R.S., by members of the British Science Guild, on his seventy-sixth birthday, May 17, 1912, as a token of their esteem and as a recognition of his patriotic labours to promote the application of scientific principles to industrial and general purposes." This gift and that of a chatelaine satchel to her personally, was received by Lady Lockyer, who expressed, on behalf of Sir Norman and herself, their sincere appreciation of these marks of regard. In making the presentation, Sir William Mather referred particularly to the importance in national life of the objects of the Guild founded six years ago, and the influence the Guild has exerted, and can continue to exercise. He was followed by Sir David Gill, who paid a tribute to Sir Norman's work in astronomy and astrophysics, and compared the Royal Palace provided by the French Government for Janssen with the tumble-down huts in which like researches in astrophysics have had to be carried on at South Kensington.

The aims and objects of the Guild were referred to incidentally or specifically by several speakers in the course of the evening. Prof. J. Perry, in proposing the toast of "The Peace Organisation of the Empire," expressed the view that organisation from above is unlikely to produce such a condition of permanent stability as organisation from below. Establish a satisfactory system of practical elementary instruction and you will obtain a broad and substantial base for the educational pyramid to be built upon it. In seconding the toast, Dr. W. N. Shaw referred to the fact that organisation is the essential factor of a satisfactory weather service. Mr. Dugald Clerk and Mr. W. Phipson Beale, to whom was entrusted the toast of "The British Science Guild," pointed out that men of science and men of business and affairs are complementary to one another, and it is always an advantage when their qualities can be combined to achieve a common purpose. The toast of "The Guests" was proposed by Sir Boverton Redwood in appropriate terms, and was responded to by Prof. Percival Lowell.

At the annual meeting Sir William Ramsay took the chair; and, in the course of his remarks upon the substance of the report, he referred to the desirability of impressing upon the Government the need for the establishment of works for the utilisation of atmospheric nitrogen in the preparation of nitric acid required in the manufacture of explosives. In the event of war, our supplies of nitrate would no doubt be intercepted, so that when those in the country had been exhausted, we should be at the mercy of the foreign enemy. For the sake of self-preservation, and to render us independent of such a contingency, plants for the production of nitric acid from the atmosphere should be laid down near the coalfields and in other districts, even though the nitrate obtained cost much more than its market value. Alluding to the appointment, by the Government, of committees to inquire into, and report upon, the subject of forestry and silviculture in England and Scotland, Sir William remarked that the subject is of great national importance; at present we spend almost nothing to secure our own supplies, whereas France and Germany spend two millions a year on their forests, and reap a revenue of six millions annually from them.

The adoption of the report was moved by Sir William Mather and seconded by a Canadian member, Dr. Henry Ami. Sir William Mather referred particularly to the sections relating to education, and suggested that one or two of the committees concerned with this subject should combine to prepare a report which would represent the views of the Guild as to the nature and contents of a course of primary education. Such a report, he considered, would be of great value in helping to determine the character of the Elementary Education Bill which may be introduced next year. Dr. Ami summarised the activities of the Canadian section of the Guild, described in an appendix to the annual report; the chief subjects with which the section has been concerned are elementary science teaching, technical education, municipal ice houses, ice conditions on the St. Lawrence, loss by fire—amounting in Canada last year to about £8 a minute—and university development in the West.

On the proposition of Sir Boverton Redwood, supported by Colonel Sir John Young, the meeting elected as vice-presidents the Lord Mayor, Dr. Ferranti, president of the Institution of Electrical Engineers, and Sir Gilbert Parker; and the following new members were added to the executive committee of the Guild: Sir Ernest Shackleton, Sir David Ferrier, Sir John Gorst, Major O'Meara, and Dr. R. M. Walmsley.

The wide scope of the Guild's interests is shown by the many subjects surveyed in the report. No other organisation exists to bring together authoritative opinion upon questions of national importance, and none has exerted greater influence in promoting progress in the right direction. In addition to the appendix mentioned already, there are several others dealing with the endowment and position of science and education, coordination of charitable effort, problems in technical education, synchronisation of clocks and the importance of correct time, disinfectants, coal, and tuberculosis. We must be content now with the mere mention of these subjects, but there may be an opportunity of dealing with some of them adequately in another issue. When the value of the work done by the Guild, as indicated in its annual report, is rightly and widely understood, the present membership of about nine hundred should be increased a hundredfold.

R. A. G.

NATURE AND MAN IN EASTERN AFRICA.[1]

(1) MR. KITCHING is already favourably known to students of Africa as the author of an outline grammar of the Gang language, the Gang, or Gañ, being one of the Nilotic tribes of central Uganda known previously by the Luganda name of Bakedi—"the naked ones." One might at first classify the work under review as a study of the Nilotic peoples of the northern and central parts of the Uganda Protectorate; but as it includes passages dealing with the Bantu races of the same region, especially in regard to the Banyoro, the more general descriptive title is the better. Still, the most valuable part of the book is the study of the Teso and Gañ peoples. (In regard to this last, I have fault to find with the author in that, instead of following well-established systems of orthography for dealing with African languages, such as were good enough for Barth and other African philologists of the first rank, he starts a variant of his own, in which *ñ* is used in the Spanish acceptation, and not, as it should be, to express the nasal consonant in words like "ringing" and "bang." This he expresses by another symbol, the *n'*—most confusing and misleading to the reader, the more so as apparently in some passages by an oversight *ñ* is to be taken as representing the nasal after all.)

For the rest, there is good material in this book for the ethnologist. The only other criticism one might raise is that the book is plastered with Mr. Rudyard Kipling's rhymes to an extent which is, to say the least, unusual. No doubt in dealing with backward races in Asia especially, and in Africa, an occasional line or couplet from Mr. Kipling is much to the point; but a more or less serious work dealing with ethnology has no need for such copious quotations, and quotations which do not always show the poet at his best.

Fig. 1.—Mwenge woman grinding millet. Tobacco is seen growing beside the house on the left. From "On the Backwaters of the Nile."

In one of the appendices there is an excellent selection of fifty proverbs in the Lunyoro language, in which the original version is given as well as the translation. These have every appearance of being authentic, and represent very fairly the wit and wisdom of a most interesting Bantu tribe. One becomes very weary of seeing in books and newspapers dealing with Africa a host of bogus proverbs expressed in English and attributed to the African merely because the writer of the book or newspaper thinks that is what the African ought to say. But this contribution to the stock of the negro's wit and wisdom on the part of Mr. Kitching is quite otherwise; it is genuine.

[1] (1) "On the Backwaters of the Nile." Studies of Some Child Races of Central Africa. By the Rev. A. L. Kitching. With a preface by Dr. Peter Giles. Pp. xxiv+295. (London: T. Fisher Unwin, 1912.) Price 12s. 6d. net.
(2) "Animal Life in Africa." By Major J. Stevenson-Hamilton. With a Foreword by Theodore Roosevelt. Pp. xvii+539. (London: William Heinemann, 1912.) Price 18s. net.

(2) The work by Major J. Stevenson-Hamilton, warden of the Transvaal Government game reserves, deals with the big game, and to some extent the small mammals and birds, of the north-

FIG. 2.—African hunting dog from the north-eastern Transvaal. From "Animal Life in Africa."

eastern Tranvaal, and to a lesser extent of East Africa, Uganda, and the Upper Nile. There is an interesting picture of the white rhinoceros of Zululand from a specimen just killed—for, alas! the care over this wonderful creature exercised by the authorities of Natal seems to take the form chiefly of killing it as specimens for museums. There are many striking photographs of gnus, impala, and lycaon hunting-dogs in the open, and of leopards, zebra, and eland in captivity—more or less; and there is much interesting and novel information regarding the life-history of lions, leopards, antelopes, and elephants.

There is one defect in the work which irritates the eye, and that is commencing the italicised Latin name of a genus or family with a small letter (examples, *bovidae, equus zebra*). Some authors annoy the reader by spelling the specific name with an initial capital in addition to that of the genus. This is confusing. But the practice adopted by Major Stevenson-Hamilton of giving generic and family names without a capital letter is more vexatious.

With regard to the first chapter on the great game of Africa, it is vitiated by a lack of sufficient acquaintance with the fauna of Western and West Central Africa. The author's survey of this question leaves out many important features, and states others incorrectly. His maps illustrating gaps in the distribution of species are not altogether correct. For example, the oryxes extend far into Senegambia and almost to the Atlantic coast of the Sahara. In common with the gazelles, they are also probably found immediately to the south of the Upper Niger. In the map of the Ethiopian region the West African faunal area is quite wrongly delineated. This area covers no very wide belt of territory along the west coast of Africa, and certainly does not extend so far north as the great bend of the Niger. On the other hand, it stretches across Central Africa to the kingdom of Buganda, to the west coast of Tanganyika, and down to the shores of Lake Mweru, besides covering much of northern Angola.

In his treatment of the distribution of mammals the author—like so many other writers on questions of zoography—omits any reference to the limited range of the zebra and the African wild ass. So far as extant information goes, no form of zebra has ever been met with *near the Nile* to the *north* of the 10th degree of N. latitude, or *west of the Mountain Nile*. Zebras are found to the

FIG. 3.—A waterbuck bull in the act of rising. From "Animal Life in Africa."

south-west of Tanganyika, and thence right across southern Congoland into Angola, but have never been heard of elsewhere in West Africa. The ordinary black rhinoceros extends its range *west* *of the Nile* not only to Lake Chad, but to the Upper Niger, and is found within the Niger bend. But in all that vast region of the western Sudan no form of wild horse is met with.

There are persistent stories from Arabs to the effect that there is a wild ass like that of Ethiopia in the western Sahara, and Mungo Park mentions seeing wild asses in northern Senegambia, but so far no proof has come to hand in the shape of skulls and skins. Amongst the fossils of Algeria are equine skulls very like that of the zebra. It is possible, therefore, that in late Pliocene or early Pleistocene times there was a zebra type existing in Northern Africa, but why the striped horses have since restricted their range to the easternmost and southern portion of Africa, and do not, like so many of the antelopes and the rhinoceros, extend their range westward of the Nile, is an unsolved problem.

H. H. Johnston.

NEW AUTOMATIC TELEPHONE EXCHANGE.

A VERY interesting experiment has just been started in the new telephone exchange at Epsom. This exchange is the first in the United Kingdom to be installed on the automatic plan. In this system the subscriber, by means of an attachment to his telephone, himself selects and calls up the desired number, instead of communicating his wants to the exchange operator and being "put through" by her. The exchange operator is thus dispensed with.

The mechanism at the subscriber's telephone simply consists of a means by which a set of contacts are closed or separated a certain number of times—determined by the actual figures of the number required. These operations result in a series of impulses (or of breaks in an otherwise permanent current) over the telephone line and through the mechanism of the exchange. The movement of this mechanism puts the two lines into electrical connection. If the required subscriber be already engaged, the caller's apparatus returns to zero and gives him the well-known signal. Under the system the meter does not record a charge against the person telephoning until the required subscriber has answered. The whole system was described in detail in our issue of October 12 last year.

The system is complete as regards its own exchange, but when a subscriber on another exchange is required, a little more complication is introduced. At present such calls are dealt with by an operator. A slight extension of the principle is to allot a certain number of lines to the main exchanges and to number these with the subscribers. A caller then simply gets through to the required exchange automatically, and then asks for the number required in the usual way.

The working and development of the exchange will be watched with great interest by all telephone users.

MAJOR-GENERAL E. R. FESTING, C.B., F.R.S.

A LARGE circle of friends, both amongst his late colleagues and followers of science and and art, will be grieved to hear of the death of Major-General E. R. Festing (late R.E.) on Thursday last, May 16, from heart failure. Festing was born in 1839, and was educated at Carshalton during the headmastership of Prichett. He was transferred to the Royal Military Academy at Woolwich, and from there was gazetted as a lieutenant in the Royal Engineers when he was only fifteen years of age. His teachers often held up Festing as a worthy example to follow. He learnt thoroughly all he had to learn whilst under tuition, and he had the reputation of being "a calculating boy" from his early youth. The present writer has often had opportunities of knowing that in Festing's later years this power of mental arithmetic had not deserted him. In 1857 the young lieutenant of seventeen was sent to India as one of the officers of a company of sappers and miners, in which capacity he served under Sir Hugh Rose until 1859. On his return from India he was selected by Sir Henry Cole as deputy general superintendent at South Kensington. On the reorganisation of the museum he was appointed assistant director of the Science Museum, with charge of the Works Department under Sir Philip Owen. On this officer's retirement he was appointed director of the Science Museum, which office he held until his own retirement in 1904. For his services to the Department he was created a C.B. in 1900.

Festing was one who was universally beloved by his colleagues and by the subordinates who served under him. He was strict, but absolutely just, and was no self-seeker. He was always ready to further the welfare of his men, or to assist in aiding the science teaching or research with which he daily came in contact at the Royal College of Science. He himself was a man of science, and carried out many investigations, the gist of which is to be found in the pages of the Transactions and Proceedings of the Royal Society, of which he was elected a Fellow in 1886. Electrical science was perhaps what he loved best, though other departments of physics generally attracted him.

Brought into contact, by his position, with inventors, men of science, and artists, when they had gauged Festing's worth they soon became his friends instead of mere acquaintances, and many such will miss him. He was a general favourite of those brother officers with whom he had served in India or elsewhere, as he was with those younger ones of his corps who, when in London or its neighbourhood, found a warm welcome at his home.

Festing leaves a widow, two sons, and a daughter. The elder son is in the Ceylon Civil Service, and the other in the Artillery, whilst the daughter is well known as an author.

NOTES.

The long-promised Government Bill to deal with the subject of the feeble-minded has appeared at last. A Royal Commission, which was appointed in 1904, reported in 1908, but the Government has taken four years before moving in what is admittedly an urgent matter. It would perhaps be ungrateful to inquire whether even this tardy appearance be due in part to the fact that a private Bill on the same subject was brought before the House of Commons on Friday last. The private Bill, which is due to the National Association for the Care of the Feeble-minded and the Eugenics Education Society jointly, gave rise to an interesting discussion, in which an all but general consensus of opinion was manifested in favour of the permanent care and control of those suffering from mental defect and unable to secure adequate protection in their own homes. The private Bill was read a second time without a division, but whether it will be carried further remains to be seen. It is to be hoped that the Government Bill, which is broader in scope, and grants some, though not adequate, financial provision, may be pressed forward in such a way as to make the more limited private Bill unnecessary. Fear of expense would appear to be groundless, for it is certain that each year's delay involves a prospective charge on the community for the support of hereditary defectives born therein far greater than the annual cost of the full scheme of the commissioners. From the wider points of view of the good of the race and the welfare of the existing sufferers the case is overwhelming.

In a speech at the anniversary dinner of the Royal Geographical Society on Monday, May 20, Lord Curzon of Kedleston, president of the society, referred to the cosmopolitan character of geographical science. It is, he said, the handmaiden of history, the sister science to economics and to politics, and surrounded by the frontiers of geology, zoology, chemistry, physics, astronomy, and other sciences, while the literature of travel is appreciated by all. It will be remembered that Colonel Close, in his address as president of the Geographical Section of the British Association last year, contended that geography, apart from cartography, cannot be considered as a science in itself, but only as a common meeting-place and popularising medium for other sciences. The fact is that geography is a branch of science when it is studied and developed by scientific methods. Lord Curzon has no sympathy with the dull and pedantic school geography of former days, which meant, in the main, lists of the names and populations of great cities, the heights of mountains, the principal capes and promontories, number of square miles in a certain territory, and so on. More scientific methods of teaching geography are now followed, and the subject has justified the higher place it has gained as an educational factor, both in the school and outside. These are not the days to say that every branch of science must have its boundaries clearly defined. Astronomy long ago entered the domains of physics and chemistry, while these two sciences are scarcely distinguishable as separate departments of knowledge. So it is with biology, which becomes a branch of mathematics in biometric studies and of chemistry in other aspects. So long as geography is concerned with the advancement of knowledge of the earth and its relations to the needs of man it may claim to have a field of inquiry in which valuable work can be carried on for education and science.

The programme for the educational section of the International Congress of Mathematicians at Cambridge (August 22–28) is now arranged. As already announced, the International Commission on Mathematical Teaching will meet at the same time and place, and in addition to the proceedings of the commission there will be further educational papers in the didactic subsection of the congress. At the first general meeting of the congress, Prof. Klein, president of the commission, will give an account of the work of the commission. The question of prolonging the mandate of the commission until the next congress (four years) will be raised. The commission will then hold three meetings in common with the didactic subsection of the congress, namely:—first meeting, presentation of the reports of the national subcommissions; second meeting, intuition and experiment in mathematical teaching at secondary schools; third meeting, mathematics as needed in the teaching of physics. In addition, the following papers will be read before the didactic subsection:—(1) Prof. J. Perry, the teaching of practical mathematics to evening classes; (2) Prof. M. J. M. Hill, the teaching of the theory of proportion; (3) Dr. T. P. Nunn, the proper scope and method of instruction in the calculus in schools; (4) Dr. A. N. Whitehead, the principles of mathematics in relation to elementary teaching (joint meeting of the didactic and philosophical subsections). Membership of the congress is secured by the payment of £1, which entitles the subscriber to attend the congress and to receive a copy of the Proceedings. The treasurer is Sir J. Larmor, F.R.S., St. John's College, Cambridge.

The new building of the Royal Society of Medicine, in Wimpole Street, was visited by the King and Queen on Tuesday, May 21, and formally opened by his Majesty. In the course of a reply to an address presented by the society, the King said:—"It gives me great pleasure to open the fine building which will henceforth be the home of the society, and which will provide adequately for the increase in your membership and for the extension of your duties since a new and enlarged charter was granted to you by my father, King Edward. The importance of the society's work is now universally appreciated, and it is a matter of satisfaction that the needs of the society have been generously provided for, and that its varied functions can now be carried on unhampered by lack of space. The health and well-being of the community are safeguarded by the energies of the medical profession. We look to you to fight sickness and disease, and we claim from you an untiring vigilance in this contest and unceasing efforts to find, by the investigation of the laws of nature, new means of combating these enemies. Medical science has revealed by experiment and trained observation new securities for life and health during recent years, and none can doubt that the improved public health is mainly due to the discoveries made by the medical profession in this and other countries, to the guidance given by that profession to civil authorities, and to the sanitary precautions against the spread of disease which they have enforced."

Sir David Bruce, C.B., F.R.S., has been approved by the King for special promotion to the rank of Surgeon-General, in consideration of his eminent services to science by his work on Malta fever, malaria, sleeping sickness, and other diseases.

Dr. D. H. Scott, F.R.S., president of the Linnean Society, has been elected a foreign member of the Royal Danish Academy of Sciences and Letters (class of sciences), and foreign member of the Royal Society of Sciences, Upsala.

The Berlin correspondent of *The Times* reports that on May 20 the Reichstag passed the first and second readings of the supplementary estimates for the promotion of aëronautics by means of the financial support of the recently founded "German Experimental Institute for Aëronautics." The estimates provide for a vote of 10,000*l*. as a contribution towards the founding of the institute and a vote of 2500*l*. towards the cost of maintenance for the financial year 1912.

The President of the Board of Trade has appointed a technical committee to advise him, in the interests of safety of life at sea, with regard to the internal subdivision of vessels of all classes by watertight bulkheads and other means. The committee is constituted as follows:—Dr. Archibald Denny (chairman), Mr. James Bain, Mr. H. R. Champness, M.V.O., Dr. G. B. Hunter, Mr. Summers Hunter, Mr. J. Foster King, Mr. Andrew Laing, Mr. W. J. Luke, Dr. S. J. P. Thearle, and Prof. J. J. Welch. The secretary to the committee is Mr. Walter Carter, of the Board of Trade, 7 Whitehall Gardens, London, S.W., to whom communications relating to the work of the committee should be addressed.

On Tuesday next, May 28, Prof. W. M. Flinders Petrie will give the first of two lectures at the Royal Institution on "The Formation of the Alphabet"; on Thursday, May 30, Prof. C. G. Barkla will begin a course of two lectures on "X-rays and Matter"; and on Saturday, June 1, Mr. Willis L. Moore, chief of the United States Weather Bureau, will deliver the first of two lectures on "The Development and Utilities of Meteorological Science." The Friday evening discourse on May 31 will be delivered by Prof. Howard T. Barnes on "Icebergs and their Location in Navigation," and on June 7 by Sir William Macewen on "Lord Lister." An extra Friday evening discourse will be given on June 14 by Mr. A. Henry Savage Landor on "Unknown Parts of South America."

We learn from *The Times* of May 20 that under the will of the late Lord Wandsworth a sum of 10,000*l*. was bequeathed to Sir William Bennett, to be applied by him at his discretion for the promotion of medical research. Sir William Bennett has decided to entrust the administration of the legacy to the London School of Tropical Medicine, under conditions which include the establishment of a research scholarship, tenable for two or three years, and to be given preferably to a British subject. The committee of management of the Seamen's Hospital has been appointed by Sir William Bennett to be the trustee of the fund, and the research scholar will be appointed by that body on the recommendation of the committee of the London School of Tropical Medicine. It is probable that the first Wandsworth scholar will make human blood parasites the first objects of his study, and that he will proceed to the West Coast of Africa for this purpose.

Among the many interesting papers to be presented to the eighteenth International Congress of Americanists, which will be held in London next week, the account of the expedition of the Imperial Russian Geographical Society to Kamchatka and the Aleutian Islands, by Dr. Waldemar Jochelson, is specially worthy of note. The expedition, of which Dr. Jochelson was in charge of the ethnological section, was fitted out in 1908 at the expense of a Russian banker, M. F. P. Riobanschinsky. The expedition excavated thirteen ancient village sites and three burial caves, and explored shell-heaps and other kitchen-midden deposits of the Aleutian Islands. The collections brought back by the expedition included skeletons and skulls, and many prehistoric objects of stone and bone. In addition, much information as to the Aleutian language, folklore, and religion was secured. In 1910 the party crossed to Kamchatka, where old underground dwellings and fortifications were explored, and ancient pottery, the existence of which has been denied by former travellers, was found. The discoveries throw much light on the early relations of Kamchatka and Japan. Dr. Jochelson will also discuss the morphological relations of the language of Kamchatka and of the American Indians, and the identities which he has discovered in their mythology and that of the Indians of the north-west. The paper will be illustrated by a number of lantern-slides and kinematograph films.

We regret to see the announcement of the death, on Tuesday, May 21, at sixty-two years of age, of Sir Julius Wernher, Bart., whose benefactions to education and science are gratefully remembered. He was greatly interested in education, and in many ways promoted the extension of knowledge, as will be seen in the following extract from an obituary notice in *The Times*:—He was a member of Lord Haldane's Committee on the Royal College of Science and Royal School of Mines, which reported in 1905, and the report of which led to the establishment by Royal Charter of the Imperial College of Science and Technology. In February of last year he was awarded the gold medal of the Institution of Mining and Metallurgy in recognition of his "great personal services to the advancement of technological education." A short time before he had given 10,000*l*. to the National Physical Laboratory for the extension of its metallurgical department. But the greatest monument of his munificence will be the new South African University, if its benefactors' wishes are realised. Inspired by Rhodes's example, Beit had bequeathed property which has realised nearly a quarter of a million for the foundation of a university in the Transvaal; and when after the establishment of the South African Union it was decided to divert this money to the creation of a new teaching university for the whole of South Africa on the Groote Schuur estate at Cape Town, Wernher added a sum to his partner's bequest sufficient to bring up the endowment to 500,000*l*.

A PROVINCIAL meeting of the Royal Meteorological Society was held, on the invitation of the Mayor and Corporation, at Southport on Monday, May 13. After assembling at the Town Hall in the morning, the Fellows were driven to the anemograph station at Marshside, where they saw the pressure-tube anemometers and the anemoscope at work. After luncheon a visit was paid to the Fernley Observatory in Hesketh Park to see the large collection of self-recording and other instruments which are in use at this unique observatory. At the same time a demonstration was given of the method of filling and sending up a *ballon-sonde* with meteorograph attached for ascertaining the temperature in the upper atmosphere. Observations of the track of the balloon were made by means of a theodolite. Later, a meeting of the society was held in the Science and Art School, Dr. H. N. Dickson, president, in the chair. Mr. W. Marriott read a paper on the results of hourly wind and rainfall records at Southport, 1902–11, based upon data supplied by Mr. J. Baxendell, the borough meteorologist. When the hourly results are grouped according to summer and winter seasons, a great contrast in the figures is at once apparent. A most marked diurnal variation in the direction of the wind is shown in the summer, which is due to an extreme local development of land and sea breezes. Mr. J. S. Dines also read a paper on the south-east trade wind at St. Helena, in which he showed that observations tend to confirm the hypothesis of a long-period oscillation in the wind direction at St. Helena.

As it covers two years (1910, 1911), the recently issued report of the Felsted School Scientific Society is more bulky than usual; it is, at the same time, rendered much more attractive by containing reproductions of some of the prize competition photographs taken by members of the society last year. These represent ornithological subjects, including sedge-warblers' nests with eggs of cuckoos. Attention is directed to the interest attaching to a brickfield in the neighbourhood of the school, the clay of which is a plateau deposit containing Palæolithic implements.

THE *Aarsberetning* of the Bergen Museum for 1911 opens with a portrait and memoir of the late Prof. G. H. A. Hansen. Extensive additions are in progress or contemplation to the buildings, among which an illustration is given of one connected with the laboratory. Among the additions to the zoological department special interest attaches to a model of a cave with three newly born bears, of which an illustration is given in the report. Bear cubs, it may be mentioned, are remarkable for their extraordinarily small size at the time of birth.

IN its report for the past year the council of the Royal Zoological Society of Ireland announces the gift of 500*l*. by Lord Iveagh and the receipt of a legacy of 100*l*. from the late Mr. L. O. Hutton. The former sum has been devoted to building a hospital for the animals. Mr. Hutton's legacy, on the other hand, is allocated to the construction of a breeding establishment for salmon and trout, towards the cost of which contributions have also been promised from the Irish Fisheries Office and other bodies interested in the subjects. Experiments have been made in keeping apes and monkeys in the open air with satisfactory results. The collection of lions included twenty-two animals at the close of the year, two of these being presented by H.M. the King. One litter of five lion cubs was produced in the gardens during the year. By the courtesy of the society we are able to give an illustration of this litter from the report.

Lion cubs four days old at the Dublin gardens.

SIR ARCHIBALD GEIKIE has sent to *The Times* a letter just received by him from Dr. E. A. Wilson, the chief of the scientific staff of the British Antarctic Expedition. The letter is dated October 31, 1911, at McMurdo Sound, and we extract a few points of interest from it: The self-registering meteorological instruments have given a continuous record of pressure, temperature, wind velocity, and direction, and these records have been checked every four hours by eye observations. A pressure-tube anemometer has given interesting records which will throw light on the character of Antarctic winds. The upper atmosphere has been investigated by means of small balloons, which have shown the direction of upper currents to a height of 6 miles and the temperature up to $1\frac{3}{4}$ miles. An almost unbroken record of the magnetic elements has been obtained, and absolute magnetic observations have been made every week. All through the winter the aurora was observed every hour, but very few brilliant displays occurred. Atmospheric electricity has also been studied. Ice work and physiography have afforded much field work. Land forms now appearing in fresh state with receding glaciation are being studied in relation to similar time- and weather-worn structures of other parts of the world. The discovery of evidences of interglacial period of vulcanicity gives additional interest to the study of this volcanic region. Pendulum observations for value of gravity have been carried out. A tide gauge has given a continuous record. Marine biological work has been carried on throughout the winter at a hole kept open in the sea ice for nets, water samples, and sea temperatures. Quantitative and qualitative observations of minute organisms at various seasons give interesting results. The parasitology of all the seals, penguins, other birds, and fish available has already given good results, and some new protozoa have been found.

The period of Etnean activity which culminated in the eruption of last September began with the opening on May 27, 1911, of a new vent to the north-east of the central crater. This vent is at a height of 3160 metres, or about 80 metres below the north-east rim of the central crater. As seen on June 9 by Prof. A. Riccò, it is triangular in form, the sides being from 80 to 100 metres in length, and though the floor was obscured, its depth was evidently great. That it communicates in some way with the central crater is clear from its position and from the correspondence in the periods of their eruptive action.

We have received from the Cardiff Naturalists' Society a report of the meteorological observations made in that district for 1911, prepared by Dr. E. Walford. The society is doing very useful work in collecting and discussing the rainfall at forty-seven stations, at heights above sea-level varying from 20 ft. at Barry to 2350 ft. at the summit of Tyle Brith (Brecon). The base of the coast-line extends from Neath to Chepstow. The mean annual rainfall for the whole district was 50·95 in.; July, 0·39 in.; December, 12·35 in. The greatest mean during the last ten years was 67·9 in. in 1903, and the least 39·98 in. in 1905. A complete meteorological station is established at Penylan, Cardiff. The rainfall for 1911, 37·63 in., was 1·38 in. below the average; the mean temperature, 50·5°, was 1·5° above the average. Readings above 80° were recorded on seventeen days, and above 90° on two days. At another station actually in Cardiff, Dr. Vachell recorded shade temperatures above 80° on thirty-eight days, and on three days above 90°; 1911 will be remembered as a record year in this respect.

In December, 1910, we directed our readers' attention to the preliminary results obtained by Miss Jacob, of the University of Königsberg, in a research on the friction of solids on each other. The work is now completed, and the results are to be found in the May number of the *Annalen der Physik*. At ordinary temperatures perfectly clean, well-polished solids without lubrication will move over each other on the application of forces far below those generally regarded as the least necessary to start the motion. For these small forces the motion generated is uniform, but for larger forces it becomes an accelerated motion. This means that the friction of clean solids on each other is dependent on the velocity. It is independent of the area of contact and of the force pressing the surfaces together, but varies with the temperature. From ordinary temperatures up to 180° C. it decreases to about one-third its initial value, but resumes that value when the bodies are cooled. If they are heated above 180° C. the friction rises rapidly, and retains an abnormally high value after cooling.

In the *Comptes rendus* for May 6 M. G. Darzens describes the preparation of a new compound of carbon and nitrogen. He names it carbon pernitride, and prepares it by the interaction of cyanogen bromide and sodium hydrazoate, NaN_3. The nitride, $N_3—CN$, can be separated from the aqueous solution in which it is prepared by ether, and forms colourless needles without smell melting at about 36° C. At a few degrees above its melting point the compound can be sublimed in a high vacuum, but it commences to decompose at 70° C., and detonates with extreme violence at 180° C. It is also very sensitive to shock, and, like all substances containing the N_3 group, must be handled in small quantities only and with suitable precautions against the results of explosion. In aqueous solution the nitride undergoes hydrolysis, giving azocarbonic acid, and ultimately hydrazoic acid and carbon dioxide. Measurements of its heat of decomposition were carried out in a calorimetric bomb; its heat of formation was found to be −92·6 calories. From these experiments, which were carried out with some difficulty on account of the destructive effect of each combustion on the calorimeter fittings, the author concludes that this pernitride of carbon is the most endothermic substance known.

In spite of their commercial importance and their wide distribution in plants, the chemical structure of the tannins has so far eluded research. Since the discovery by Strecker, in 1852, that they contained glucose in their molecule, they have been frequently regarded as glucosides of gallic acid. Others, however, have disputed the presence of glucose in the molecule, and tannin is frequently described as digallic acid, a view which is not in agreement with the optical activity. Nierenstein has supposed tannin to be a mixture of digallic acid and optically active leucotannin; this does not agree with the slight acidity of tannin. The recently published researches of Emil Fischer in conjunction with Freudenberg throw a new light on the question. The authors show that carefully purified tannin contains about 8 per cent. of glucose in its molecule. They do not regard tannin as a glucoside of gallic acid, but consider that it is an acyl compound of glucose analogous to the penta-acetyl and penta-benzoyl derivatives of this sugar, in which the alcohol groups form esters with the acid. This novel conception of tannin as a penta-digalloyl glucose is in agreement with its chemical behaviour, but, as is his custom, Fischer has had recourse to synthesis to confirm his views. Digallic acid was not available, but a synthetic penta-galloyl glucose could be obtained without great difficulty, it sufficing to combine glucose with tricarbomethoxygalloyl chloride in presence of quinoline and remove the tricarbomethoxy-groups by cautious hydrolysis with alkali. The new compound has all the properties of the tannins, and there can be little doubt that the new conception is the correct one, and that synthetic tannin will shortly be added to the achievements of the organic chemist.

SUCCESSFUL trials have just been concluded of the first Clyde-built motor ship, *Jutlandia*. An illustrated article in *The Engineer* for May 17 gives some particulars of this ship, which is a sister ship to the *Selandia*. The builders, Messrs. Barclay, Curle and Co., Ltd., Whiteinch, have fitted Diesel engines of the four-cycle type. On the measured mile at Skelmorlie the vessel attained a mean speed of 12 knots, the engines developing 2700 indicated horse-power at 135 revolutions per minute. The fuel used on the trials was oil of specific gravity 0·855, but the engines are capable of using heavier oil, such as is obtainable from the Roumanian or American oil fields. The builders estimate that in regular service the quantity of fuel necessary will be about 10 tons per day of twenty-four hours' continuous running.

Engineering for May 17 gives an account of the system of ozone production and distributing plant installed for air purification and ventilation on the Central London Railway by the firm of Ozonair, Ltd. The system is a plenum one, and consists of Sirocco fans placed at each of the underground stations, excepting that at Shepherd's Bush. The total air supplied to the tubes is about 80,000,000 cubic feet per day. Each fan draws its air through a filter screen, and works in conjunction with an ozone-generating plant. The latter consists of mica sheets with metallic gauze on each side, stacked side by side, and energised by alternating current at about 5000 volts, in such connection that a silent discharge passes between the various plates, so that air flowing between them is ozonised. The ozone generator is supplied from a small transformer, which in turn is supplied with 380 volts alternating current from a small rotary converter. The converter is connected on its direct-current side to the 550-volt lighting circuit of the railway.

OUR ASTRONOMICAL COLUMN.

THE RECENT SOLAR ECLIPSE.—Many preliminary accounts of the solar eclipse of April 17 are given in the May number of *L'Astronomie*; the June number is to be devoted to a fuller discussion.

M. Flammarion—who is to receive the Cross of the Legion of Honour—gives, *inter alia*, a map on which he has drawn the central line derived from numerous observations. Going from south-west to north-east, it passes very slightly to the north of St. Nom-la-Bretèche, rather further north of St. Germain-en-Laye, south of Maisons-Laffite, north of Sartrouville, over Franconville and Moisselles, north of Villiers-la-Sec and south of Luzarches.

Analysing the observations made from a dirigible near the last-named place, Comte de la Baume Pluvinel finds that the line is 1·8 km. north of that given by the *Connaissance des Temps*, and that the central phase occurred at the time given by the "American Ephemeris"; this was from fifteen to twenty-five seconds earlier than the times given by other ephemerides. The shadow of the moon, as seen from the dirigible, appeared as a greyish circle 3·5 km. in diameter travelling over the ground at about 800 metres per second. This shadow passed over the villages Belloy and Villiers-la-Sec at the same moment, the former lying near its northern limit.

At Sartrouville, M. Tramblay determined the interval between the appearance and disappearance of the cusps as four seconds. M. G. Renaudot, at Paris, made some very definite and interesting observations ot the effects on birds and certain plants, which in every case behaved as they usually do at nightfall. As the eclipse was neither total nor annular, M. Flammarion suggests the designation *d'éclipse perlée*, which would describe the appearance of a collar of irregular pearls seen at maximum phase.

M. Simonin asks that observers will forward to him, at the Paris Observatory, the results of their observations of this eclipse.

SOLAR PROMINENCES IN 1910.—We have received amended tables of Prof. Riccò's summary of the prominences observed during 1910 at Catania, in which some of the values are essentially different from those previously given, which we briefly noted in these columns on May 9. The mean frequencies for the four trimestres should read:—N. hemisphere, 1·9, 1·5, 1·1, and 0·3; S. hemisphere, 1·7, 1·3, 1·2, and 1·4, the mean frequencies for the year being N. 1·2 and S. 1·4. Compared with 1909, the year showed a decrease in the frequency and the size of the prominences. Considering their distribution, there were two principal maxima at 25°–29° and 55°–59°, respectively, in the northern, and two at 15°–19° and 50°–54°, respectively, in the southern, hemisphere.

THE UNITED STATES NAVAL OBSERVATORY.—The superintendent's report of the work performed at the U.S. Naval Observatory for the year ending June 30, 1911, contains, among many other items, several interesting results of investigations of instrumental errors. A wide difference of opinion among the staff concerning the performance of the 6-in. transit circle has been settled, as the result of an investigation lasting over three years, by a declaration that the instrument is fit for the fundamental observations for which it is now to be employed. Another investigation was carried out to determine the cause of a periodic error of exactly four minutes, having a range of more than 5 seconds of arc, in the driving-clock of the 26-in. equatorial. No single cause could be found, so it was decided to correct the error by introducing one of opposite sign and having the same amplitude. This was done by scraping the driving side of the bevel gears at those parts which were in mesh at the moment the error occurred, and the error was thereby reduced to about eight-tenths of a second.

The sun was photographed on 148 days, and showed spots on 88 days. In future, the "Nautical Almanac" publications are to be stored and distributed by the Naval Observatory librarian.

EPHEMERIS FOR BORRELLY'S COMET, 1911*e*.—To No. 4572 of the *Astronomische Nachrichten*, M. Schaumasse contributes an ephemeris for comet 1911*e*, which is at present about a degree north of 36 Lyncis, and is travelling in the direction of β Leonis Minoris. This comet is extremely faint, but an observation by M. Schaumasse, with the Nice equatorial *coudé* on April 19, showed that the error of the ephemeris was only −3s., 0′.

THE TEACHING OF MATHEMATICS.[1]

The Content of the School Course in Mathematics.

A SYSTEM of education designed on broad lines to prepare pupils for some particular occupation is not only the best training for that particular occupation, but it is better as a "general education" than a system which has been designed simply as a general education, and not as a preparation for any particular calling. For a boy willingly undertakes work which clearly leads up to the solution of a real and interesting problem, even if that problem is one that belongs to his neighbour's after-life and not to his own. But the course designed for "general education" tends to become a "mental discipline" lacking in interest, and such discipline deadens the mind and makes the boy a machine.

In Papers Nos. 15 and 16 of this series, Mr. Carson and Mr. Durell advocate the inclusion in a school course of certain methods of great beauty, which to a few boys will be a source of delight. But the authors of those papers have no criterion of the suitability of these subjects beyond their own love of them. To a certain point that is a true criterion; what has given pleasure to one person has a good chance of giving pleasure to another; and all the subjects which they advocate deserve a place in a system of recreations for the mathematician's leisure hour. But to determine which of these methods and subjects are to be thrust upon every boy of an ordinary degree of mathematical ability, some better criterion is necessary. I do not say that I would exclude any of these methods, but only that they have not yet been judged on a suitable criterion.

That suitable criterion must be a consideration of the needs in after-life of certain groups of boys. In many cases mathematics is a form of technical knowledge required for the after-career, *e.g.*, for the careers of engineer, mathematical schoolmaster, professor of mathematics. In such cases the content of the subject will be determined by a wide interpretation of the requirements of the career, the treatment of the subject being of the broadest and every problem viewed from many points of view. The boy to whom mathematics is merely a part of his general education will, so far as he goes, study along with the technical group with which he has most in common. It is not necessary that each boy's future career should be planned in advance; all boys, technical, semi-technical, and non-technical, will study together for a time; then gradually the non-technical boys will drop out, and the remainder will bifurcate according to their varying intellectual powers and their varying technical needs.

These are the views to which observation, experiment and reflection are leading students of education. Many a doubter will be converted by a study of Mr. Mercer's admirable account of the teaching at the naval colleges (Paper 17). It is a document which every mathematical master should have by him. Some small portions of the course are special to the requirements of the Navy, but the course as a whole makes an excellent starting point from which to lay out a scheme for any school.

In Paper No. 12 Mr. Usherwood provides further evidence in favour of our principles. The close correlation of mathematics with engineering has given his boys a breadth of mathematical knowledge and a real grasp such as would have been incredible a generation ago. Mr. Usherwood justifies his procedure by quoting Mr. Branford's classification of the impulses which urge towards mathematical study, a classification also held by Dr. Nunn. Of these impulses, the utilitarian is the chief one at the school stage, and every central truth should be made to arise in response to some demand arising from a practical problem. Mr. Usherwood holds that manual as well as mental dexterity should be involved in the practical problem from which an investigation sets out, and he petitions for a greater place in the curriculum for suitable manual training.

Further support to the principles enunciated above is given by Mr. Palmer's historical account of the teaching of arithmetic. It is an excellent account of the changes which have been made in the last quarter-century. A generation ago "general education" was the cry, and if any method had a "bread-and-butter" value that was sufficient reason for its exclusion. The course consequently contained such monstrosities as "true discount." The true criterion has now been adopted; in part, half unconsciously. More conscious application of the criterion will in time recognise that most fractions should be dealt with in decimal form, and will greatly reduce the time spent on vulgar fractions, greatest common factor, and least common multiple. We learn from Mr. Palmer how far removed the school treatment of stocks and shares is from business practice. The whole subject seems to us unsuited to the school. The difficulty lies in the realisation of the circumstances of the problem; the circumstances are far removed from a boy's experience, and the explanation of them profits him nothing. The circumstances once realised, the arithmetic is child's play.

The Methods of Mathematical Study.

The various methods of mathematical investigation have been added one by one at various times to our available stock of tools. On the historical principle that the development of the individual should copy the history of the race, it is appropriate that these various tools should be put in the pupil's hand in the order of their discovery. It is, however, the practice to follow the development of the race too closely, and to discuss by the more primitive method all the problems for which our ancestors used it, regardless of the fact that a later method is a more suitable weapon with which to attack many of these problems. Such exactness of recapitulation cannot be justified; it is the haphazard result of the successive

[1] Papers on the Teaching of Mathematics in the United Kingdom, published by the Board of Education:—

Earlier papers were noticed in NATURE of March 14.

origins of the various methods; the physiologist from whom education has borrowed the historical principle says that "the history of the individual is a *blurred* recapitulation of the history of the race."

Too exact a recapitulation is wasteful of time and deadens the intellect. The recapitulation must be a blurred one; the barriers between the various branches of mathematics must be broken down, and the pupil given freedom to select for any problem whatever tool he finds most appropriate.

In Paper 16 Mr. Durell drives home this principle. The freedom to treat a problem by Euclid's method, by Descartes', or by Monge's, by the principle of duality or by that of continuity, gives to the pupil a breadth of view and to the subject a unity otherwise unattainable. It reduces the multitude of properties of geometrical figures to a small number of greater generalisations which the mind can carry without effort. And it effects a saving of time, which makes possible a much further advance in mathematics than is now customary.

Mr. Durell rightly reduces to small compass the Euclidean treatment of conics, but he retains conics as the chief material to which the various methods are to be applied. His course might be further improved by the substitution in some cases of other material, such as an occasional higher algebraic curve, a transcendental curve, or a surface.

The Postulates of Geometry.

Mr. Carson (Paper 15) pleads for more system in the treatment of elementary geometry, in order that the pupil may gain a better grasp of the subject and have time to pursue his studies further. Mr. Carson would assume as postulates all the geometrical properties which can be looked upon as "intuitive," and build a system of reasoned geometry upon these; a suggestion which deserves serious consideration. The elaboration of this idea must involve some preliminary discussion of the nature of intuition. Intuition varies greatly from individual to individual; that "things equal to the same thing are equal to one another" is not an intuition to every child (see Branford's "Principles of Mathematical Education"); and, on the other hand, to an occasional genius results are intuitive which involve prolonged investigation for the average mathematician. Intuitions depend upon experience, and differ according to the experience of the individual.

It will clearly be necessary to give precision to each particular property which is to be assumed as an intuition. One valuable method of giving such precision is strangely repugnant to Mr. Carson, I mean that of numerical illustration. This method has real value, not only for these intuitions, but also for ensuring the comprehension of a property of which the proof is to follow. Nevertheless, when worked out Mr. Carson's scheme would probably differ little from some courses now in use.

Mr. Carson's main thesis is that if the inclusion of mathematics in the school curriculum is to be upheld, its study must be justified as an end in itself, and not by any consideration of utility. This view is best judged by the conclusions to which it leads him. One such conclusion is that the study is essential for girls as well as for boys; perhaps if Miss Burstall's excellent discussion of that topic in a recent number of *The Mathematical Gazette* had been available at the time when Mr. Carson wrote this paper, he might have modified his views.

We have already referred to Mr. Carson's criterion of the content of the mathematical course—"mathematics for its own sake." To most of us beauty is closely connected with utility; there are on the high road of progress just as many and as lovely views to be seen as in Mr. Carson's bypaths. For many of us, also, the high road provides bread and butter along with beauty; at the present day the view is all too prevalent that real work and beauty are incompatible.

But really Mr. Carson is barely half in earnest. He is constantly falling into some utilitarian justification for his teaching, and then pulling himself up short. And the programme he sketches is excellent, chiefly because he keeps so close to the concrete and to utility.

Examinations.

In recent years there has been much discussion of the value of literary examinations, some holding them to be the only true criterion of a pupil's ability, others holding them entirely harmful. The truth would appear to lie between these extremes. On the one hand, no literary examination can tell us much of the character of a boy, and there are subjects in which training is the great element, and knowledge so small an element that any attempt to examine would spoil the value of the subject. There are, on the other hand, many subjects in which examination has real value—provided it is properly conducted.

An examining body cannot escape the responsibility of influencing schools, whether for good or ill. If the examiner is ignorant of the schools his influence will be bad; he must in some way be put in close touch with the school. He must also not be a mere hack, but have a fresh interest in the subject and some knowledge of educational principles. With that granted, there is ground for hope that his influence on the schools will be good. Another thing of much value is difficult to get, namely, the criticism of the business man who has no expert knowledge of the subject but a real knowledge of the kind of boy he wants in his business. I remember Prof. Henrici's modest account of his early mathematical development as teacher in a technical college. The business committee wanted certain things done which seemed impossible to the young professor with his academic views. But he agreed to try, and speedily he concluded that the business men had been perfectly right.

Messrs. Macaulay and Greenstreet (Paper 14) discuss the scholarship examinations on which the universities select entrance scholars. The discussion concerns Cambridge chiefly, and the authors make a strong case for their view that the universities are not sufficiently acquainted with the conditions of the schools, and that more weight should be attached to the opinions of the schoolmasters who prepare the boys for the examinations. The authors deserve all sympathy in their desire that pupils should not waste time in exploring bypaths and in the acquisition of excessive skill in manipulation, but should push on along the main road. Some of their suggestions, however, scarcely carry conviction. Consider, for instance, their disapproval of the graphical method in statics, a method of such value for giving a grasp of principle. Take, again, their view that a boy should sit still and watch his master draw algebraic graphs without drawing them himself.

David Beveridge Mair.

BIOLOGICAL PAPERS FROM PRAGUE.

PROF. HLAVA (Bull. Internat. Acad. Sci., Prague, xv. Ann.) has found, in the blood of children infected with measles, oval or rod-like bodies, which he regards as probably of protozoan nature. In a blood-smear from another infected child (who also exhibited severe anæmia due to the presence of numerous whip-worms in the intestine), sickle-shaped bodies were present in the red corpuscles. These bodies could not be found in the blood of this child on the following day, but there occurred, in the plasma, ovoid bodies, which, according to Prof. Hlava, were similar to Leishmania. In the accompanying figure, however, only a single nucleus is shown in each cell, whereas two nuclei are present in Leishmania.

J. Hořejší (Bull. Internat. Acad. Sci., Prague, xv. Ann.) records observations on the symbiotic union of a cyanophycean alga (Anabæna) with the roots of *Cycas revoluta*. The alga, which enters a root through the lenticel-system, passes into the meristematic apical tissue, retarding the activity of the latter, inducing dichotomy and the eventual production upon the root of a coral-like outgrowth. The advantages to the two organisms concerned are probably mutual; the root derives from the alga its nitrogenous products, whereas the alga takes up from the root a certain part of its host's products of assimilation. In the same bulletin Dr. B. Němec traces the stages of degeneration of the nuclei in the cells which form the sieve-tubes in Euphorbia, Ricinus, &c.

The biology and physiology of a species of dodder (*Cuscuta gronowii*), parasitic on willows, have been investigated by Dr. K. Spisar (Bull. Internat. Acad. Sci., Prague, xv. Ann.). He found that seedlings would wind round organic or inorganic supports of varying thickness, the contact-stimulus being very strong, contact with a suspended thread being sufficient to bring about the reaction. The zone in which the response reaches its maximum is in or near the growing zone. During the formation of haustoria, which is not dependent either on light or on the want of food, growth ceases, and the circumnutation movements are lost, but reappear in two or three days. This dodder is not very fastidious in regard to its host, and may even be "parasitic" on itself. The tissues remaining in the haustorial zone, when the rest of the dodder has been torn off its host, give rise to adventitious buds, and thus regenerate the parasite. The purple-red colour depends on the influence of light; at any rate, it was soon lost in the dark. In the absence of a suitable food-plant the axis of the dodder (which is green in the seedling) does not assume the usual purple colour.

PALÆOLITHIC MAN IN NEW JERSEY.[1]

SINCE Dr. C. C. Abbott's discovery of Palæolithic implements in the river-deposits of Trenton, New Jersey, nearly forty years ago, the valley of the Delaware has continually attracted the attention of students of early man in North America. This region lies immediately south of the southern limit of the ice-sheet which extended over the greater part of the continent during the Glacial epoch, and it is covered by a thick stratum of boulder clay, with associated gravels, through which the existing rivers have cut their channels. The Trenton gravels occupy the valley excavated by the Delaware, and therefore represent a period later than that of the maximum glaciation, though their constitution suggests that they date back to a time before glacial conditions had completely passed away. Over the Trenton gravels are spread yellow sands and loam, which Dr. J. B. Woodworth regards as Post-glacial; and there is also a thin superficial covering of black soil. All these three deposits yield evidence of man, and for more than twenty years they have been systematically searched and studied by Mr. Ernest Volk. His work has been done under the general direction of Prof. F. W. Putnam, for the Peabody Museum of Harvard University, and an exhaustive, well-illustrated report of his results has now been published by the Museum.

From Mr. Volk's researches, it appears that all the remains found in the surface soil and the pits and graves dug through it are those of the Indians who were displaced by the first European settlers. Numerous human skeletons were obtained, most of them buried in a crouching posture, with the knees drawn up towards the body, as well shown in several photographs.

Traces of man in the underlying yellow sand and loam are rarer than in the black soil. Charcoal and pebbles broken by fire are found, but there is no pottery, and all the stone implements are of argillite. Some of the latter are obviously spear-heads, others are borers, and some are rudely made with a jagged cutting edge. Mr. Volk was fortunate enough to discover a few human skeletons undoubtedly of the same age, but the bones were too much decomposed for preservation, and merely showed that the people were strongly built.

Discoveries in the Trenton gravel, with its intercalated clays and sands, are still rarer. Mr. Volk notes chipped pieces of quartz and certain quartzite pebbles, which he regards as having been artificially broken. He also records fragments of a human cranium, and part of a human femur, which both he and Dr. A. Hrdlička consider to have been cut and worked by man. In the same deposits were found identifiable bones of the musk-ox and the elk.

Both Mr. Volk and the Peabody Museum are to be congratulated on the painstaking thoroughness of this interesting investigation, which it is to be hoped may be continued. In these days of overcrowded libraries, however, we must add a word of protest as to the undigested state in which the report is issued. It may be of moment to the Peabody Museum to know that Mr. Volk did not work on Sundays or Washington's birthday, and was continually interrupted by rain, snow, ill-health, and "errands in town"; but these and innumerable other trivialities lengthen the text to an inordinate extent, while a large proportion of the 125 plates might well have been omitted without detracting from the value of the volume.

A. S. W.

RHEINBERG'S MICRO-SPECTRA METHOD OF COLOUR PHOTOGRAPHY.

THE special features of the micro-spectra method of colour photography are, first, that by its means pictures absolutely faithful in colour, tone, and texture are obtainable by means purely optical without the intervention of any artificial colouring matter whatsoever, and, secondly, that it is a one-plate process involving nothing more than everyday black and white photography. A single negative is taken on a panchromatic plate, a lantern slide is made from it and placed in the position of the negative, white light is projected through the apparatus, and the picture, after slight adjustment, flashes out in its true colours.

The theory of the process is a simple one. It consists in producing by optical means a surface composed of hundreds of complete but very narrow spectra, lying next to one another, the spectra being so close together as to render the individual colours indistinguishable to the unaided eye, so that the surface appears to be white. The photographic positive is used as a mask to block out or weaken those colours which are not wanted, the remainder combining to form the picture.

The surface, composed of these contiguous narrow spectra, is produced by allowing white light to fall upon a fine line screen, of which the opaque lines are three times as wide as the clear interspaces, and forming an image on this screen by means of a lens with a prism just in front of it. The prism spreads each white line into a complete spectrum, and is so calculated that the spectra lie next each other on the focussing screen without interspace. If instead of white light falling upon the line screen we allow coloured light to fall upon it, only those spectrum colours of which the line in question is composed appear on the focussing screen, the colours which are wholly or partially missing from the spectrum of

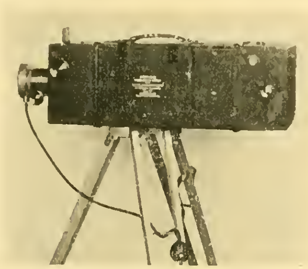

FIG. 1.—Micro-spectra camera on stand.
(Made to instructions by Alfred B. Allen, 20, Endell Street, London, W.C.)

white light being represented by spaces wholly or partially dark.

In taking the photograph, the image of the coloured object is projected by means of any ordinary objective lens on to the line screen, the image of which is in turn projected by the second lens with the prism in front of it on to the photographic plate placed in the position of the focussing screen (Fig. 2 shows diagrammatically the general optical arrangement). The plate must be approximately equally sensitive to all colours, so that the resulting negative is completely darkened when acted upon by any colour in its full intensity, and partially darkened where the incident colour is weakened. A lantern slide positive from this negative

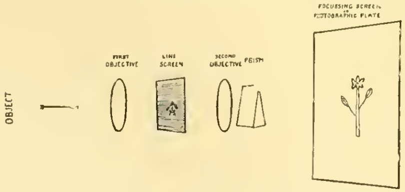

FIG. 2.—General optical arrangement shown diagrammatically.

will, of course, show the reverse effect, being completely transparent where the colour has acted with full intensity, of partial transparency where the colour has acted less strongly, and opaque where the colours were missing, *i.e.* in those parts coincident in position with the spectrum colours of white light that were not present in the object photographed. When therefore this positive is placed in the exact position of the negative, and white light is projected through the apparatus, it acts as the desired mask to block out those colours that are not wanted, and the picture is reproduced in the original colours.

Like so many other scientific problems, however, whilst the theory was simple, in practice difficulties in the way of the construction of the necessary apparatus (Figs. 3 and 4) arose at every turn, and matters were further complicated by the necessity of keeping the camera within portable limits. To indicate one of the main sources of difficulty, an ordinary glass prism produces a spectrum widely extended in the violet and blue region and crowded up at the yellow and red end, an effect very detrimental to the proper rendering of the latter colours. This was overcome by the use of a compound prism specially computed to give a spectrum in which the colours are evenly distributed, as in a grating spectrum. The introduction, however, of a thick prism of this kind introduced aberrations of all kinds, both in the images of the object and of the spectra, which had to be

Sectional plan of micro-spectra camera viewed from above (optical system).

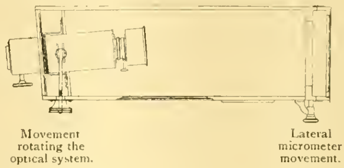

FIG. 3.—Section of micro-spectra camera.

successively overcome. It was, for example, found necessary to place the line screen (which has 372 lines per inch) at a slant to bring the spectra all over the field sharply into focus, a cylindrical lens is used in front of the prism to correct for astigmatism, the front of the camera is placed at the proper angle to prevent wedge distortion, a narrow prism behind the first objective brings the object sharply into focus, and so on. The objectives used in the camera are two 75 mm. Zeiss micro-planars. A field lens is interposed between the first objective and the line screen to direct the light towards the second objective. The whole optical system can be slightly rotated by means of a milled head on the left-hand side of the camera in front; at the back is another milled head securing slight lateral movement, and a lever above the viewing screen (not shown in Fig. 1), permits of

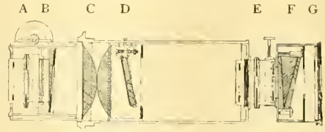

FIG. 4.—Section of optical system.

A, Zeiss 75 mm., micro-planar objective on focussing mount; B, spectacle prism; C, field lens; D, line screen or grating in adjustable frame; E, 75 mm. micro-planar objective; F, compound prism; G, cylinder spectacle lens, 120" focus.

a slight backward or forward movement of $\frac{1}{2}$ mm. These three movements are necessary to enable the lantern plate to be brought to the exact position of the negative, but correct registration is easily secured in a few seconds—the readings can, moreover, be noted on the positive.

Besides the method of viewing the picture on the focussing screen of the camera, which requires a strong artificial light source, the pictures may also be viewed direct on the line screen by means of a magnifying eyepiece, for which purpose ordinary daylight or a weak illuminant suffices. This method in practice does not, however, yield *quite* such good results. The pictures may also be projected in a size of 3 4 ft. diameter on a lantern screen.

Until the advent of a really rapid and satisfactory bleach-out paper, there is no possibility of recording the photograph on paper in colours, and since they can only be viewed in or by means of the camera itself, and the latter (which costs somewhere about 60*l.* at present) will always be a somewhat expensive apparatus, even if the optical and mechanical parts can be further simplified, the process is scarcely one that is likely to become general. That indeed was recognised from the start of the experiments. Nevertheless, given the camera, the process is undoubtedly a simple method of colour photography to work, and this, together with its true colour rendering and the many interesting and quite novel effects to which it lends itself, will, it may be hoped, encourage plenty of other workers to take it up, besides those who may be disposed to experiment with it from the point of view of its scientific interest.

THE FORTHCOMING OPTICAL CONVENTION.

THE issue of a programme of business by the committee of the Optical Convention, which is to meet in London on June 19-26 next, marks the entrance of this undertaking upon a new stage in its development. The idea of an optical convention is not new—in fact a meeting, the first of the kind, was held in London in 1905, and it is out of that gathering that the present proposal has grown. The committee has secured support of a substantial kind in the form of a guarantee fund, which puts the undertaking on a secure financial basis and will enable the catalogue and volume of Proceedings to be produced.

Underlying the whole scheme of the Optical Convention is the fact that optical appliances in one form or another are familiar, at least as tools, to everybody. This circumstance, and the interest of the scientific problems which present themselves for solution in the manufacture of optical instruments, give to optical manufacture its special place in the view of scientific men at large and of those leaders of thought who occupy themselves with the realities of the public weal. It is therefore by no means so surprising as it is pleasant to find that the Board of Education on one side and the scientific societies on the other are furthering the scheme and assisting to bring the plan of an optical convention to a successful issue.

Another aspect of optical work is its national importance. It is probably not realised, even by men who are fairly familiar with the developments of applied physics, how the progress of manufacture is dependent on the provision of the special optical and scientific instruments required at each stage of its development. Field-glasses, gun-sights, range-finders, and numerous other purely optical instruments are absolutely essential in the equipment of any fighting force at the present day, and it is vital to our national interests that we should have, within our own borders, the means of producing such instruments in sufficient quantity for the use of our sailors and soldiers.

The experiment of holding the exhibition in connection with this Convention in the buildings of the Science Museum at South Kensington will be observed with considerable interest, no doubt, by the officers of the Education Board, and certainly by the scientific public. Some years ago, when the Science Museum was much less completely organised than at present, a departmental committee was appointed to consider its organisation and to report upon the improvements that might be made. Among the proposals which commended themselves to that committee was a suggestion that an empty hall should be built, as part of a reconstructed museum, which might be available for purposes of this kind. That proposal is, no doubt, receiving the attention of the authorities at the present time in connection with their rebuilding plans, and it will be of value to them to be able by this experiment to make themselves practically acquainted with the working of such an arrangement. The Art Department at South Kensington already possesses accommodation of this kind in the unoccupied North Court of the Victoria and Albert Museum. If such a building is provided in connection with the Science Museum, with suitable equipment and under proper regulation, it may, we think, prove to be of very great value in establishing and developing a fruitful connection between scientific work and the practical aims of the industrial and manufacturing community.

Attention may also be directed to the very interesting loan collection of optical instruments which is to be exhibited. This loan collection cannot but be full of interest, not only to the student who desires to see how any particular instrument has grown by successive developments to its present stage of efficiency or otherwise, but also, as is often the case, it may contain the germs of still further discoveries which may yet have to be worked out by the efficiently trained minds of our men of science and manufacturers.

The committee of the Optical Convention has, as we are glad to see, realised that the establishment of such relations in their particular departments ought to be a principal object of their undertaking. From the provisional programme, it appears that the scientific societies in their corporate capacity will take a prominent part in this Convention. We observe that the Physical Society, the Royal Astronomical Society, the Royal Photographic Society, and the Optical Society have all arranged for joint meetings with the members of the Convention, and that their several presidents will be presiding at these meetings in the character of vice-presidents of the Convention.

This close connection of the leading scientific societies, having special interests in optical science, with the Convention is not the only way in which the interest of the scientific public is to be manifested and utilised. The scheme of operations comprises a somewhat elaborate plan for making the work of the Convention subservient to the practical aim of improving the design and construction of optical instruments. With this object, a highly qualified committee, announced under the name of the cooperation committee, has been organised. Its members are all very distinguished men, but it is not to their initiative that the Convention trusts for suggestions of the lines along which improvement ought to move. A schedule of inquiries, which has been very extensively circulated during the last few weeks, will, through one or other of the learned societies of London and the Provinces, have come into the hands of most of our readers. It is intended to elicit the expression of private and personal opinion by all users of optical instruments. That is substantially equivalent to saying of all who are engaged in exact scientific work.

These inquiries are intended to produce not so much suggestions for improvement as suggestions of existing defects and desiderata. The committee is to be informed what it is that the users of optical instruments desire. From the material so supplied it will draw up a report in which it may be presumed that the matter of value communicated in answer to this widespread inquiry will appear in a refined and systematic form. How far the demands of the public in this direction can be satisfied remains to be seen, but probably the committee will not consider itself responsible for supplying the requirements of its public. It will be a great matter if these requirements are expressed articulately and stated in such a scientific form that the attention of inventors and manufacturers may be concentrated upon the lines of useful and necessary advance.

The undertaking is one the development of which will be watched with considerable interest. If it should prove that the requirements of the professional man, with whom some optical instrument is part of his equipment, can in this way find useful exposition, the idea is one for which there may prove to be a great future, since it opens up a new line of cooperation between the scientific world and the world of industry, and one which, if it brings them together successfully, will bring them together on a very satisfactory footing.

Among the attractions of the exhibition is one, we observe, which caters for the taste, so much developed in recent years, for the realistic representation of bygone days. An "Isaac Newton" room is to be fitted up in which the leading experiments described by Newton in his "Opticks" will be reproduced by means of apparatus constructed in accordance with Newton's description of the appliances which he himself employed. An arc lamp will make Newton's successor independent of the sunshine, but in all other respects he will follow closely in Newton's footsteps. Another room will, in like manner, be devoted to the demonstration of Fresnel's crucial experiments. That these demonstrations will be among the most popular features of the exhibition cannot be doubted, but the popular appeal should be the smallest part of their merit. There is nothing more stimulating to the modern student than to realise with what slender resources and imperfect appliances some of the great scientific discoverers have accomplished their greatest work.

THE USE OF PEDIGREES.[1]

INFORMATION about family history can be presented most clearly by the use of tabulated pedigrees. Until recently, genealogy has shown a tendency to lay principal stress on the single line of paternal descent, as is shown by early heraldic rolls and other records. Nevertheless, the heralds' visitations were founded on the sound idea of a complete genealogical survey of one section of the nation.

The hereditary descent of physical and mental qualities may often be traced in pedigrees prepared for general purposes, but is better shown in diagrams where the character to be traced is indicated in symbolic form. Instances may be given of the transmission of scientific, administrative, and legal ability, of good and bad character, of mental defect, or of special liability to tuberculosis. Almost any physical or mental character may be traced, and shown to be definitely hereditary. It is impossible to explain the facts by the influence of environment alone.

In some cases, such as in eye colour and certain diseases and physical defects, the laws of inheritance have been shown to be definitely Mendelian in character, and it then becomes possible to predict the average result of any given marriage.

Regarding the nation from the point of view of its innate qualities, the question of selection becomes of supreme importance. In present conditions, what qualities tend to be preserved and what tend to be bred out of the race? There is evidence to show that, on the average, in England the people of the towns are shorter and darker than country dwellers. This fact seems to suggest a gradual increase of the Mediterranean elements in our urban population at the expense of those of northern or Teutonic origin. Again, the modern phenomenon of the limitation of families is most marked among the careful and thrifty in all ranks of life; the careless and casual tend relatively to increase. It seems probable that the nation may tend to become shorter, darker, more emotional, and less rational and self-controlled. Until lately, no attention has been paid to racial considerations; but a genealogical survey of the people is at least as important as a geological survey of the land, for the character of the race is the greatest of national possessions.

[1] Abstract of a discourse delivered at the Royal Institution on Friday, May 3, by W. C. Dampier Whetham, F.R.S.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—Dr. Shipley (Master of Christ's College), Prof. Punnett, Mr. C. Warburton, and Mr. H. Scott have been nominated to represent the University at an International Congress of Entomology to be held at Oxford in August next.

Dr. John Satterly has been appointed lecturer in physics at the University of Toronto.

Mr. J. Hendrick, lecturer in chemistry at Aberdeen College of Agriculture, has been appointed professor of agriculture in the University of Aberdeen.

The annual dinner of the Royal School of Mines Old Students will be held on Wednesday, June 12, at the Imperial College Union, South Kensington. Several distinguished guests have already accepted invitations to be present, including the Right Hon. A. H. D. Acland (chairman of the Education Committee of the Imperial College), Sir Alfred Keogh (Rector of the Imperial College), Mr. F. G. Ogilvie (Board of Education), and Mr. Edward Hooper (president of the Institution of Mining and Metallurgy). Mr. W. Frecheville, who has just been elected to the chair of mining in succession to Prof. Herbert Cox, will preside at the dinner.

A correspondent in *The Electrical Review* for May 3 directs attention to the serious inconvenience to students caused by the City and Guilds of London Institute examinations being held at the end of the Easter holidays, three or four weeks after the teaching has come to an end. The question whether there should be an interval between the teaching and the examination is an important one, and it would be well to have the opinions of the best students on the matter. Those who advocate an interval claim that it is in the interest of the student, who by its means has an opportunity of digesting the information he has received. The University of London, for example, ceases its courses for the degree examination at the end of June, although the examinations do not take place until October or November.

The London County Council proposes to award in July next a certain number of free places at the Imperial College of Science and Technology, South Kensington, for the session beginning in the following October. The instruction will be of an advanced nature, suitable for students qualified to enter on the fourth year of the college course. There is no restriction as to income, but intending candidates must be ordinarily resident within the area of the administrative County of London, and must be students who have attended appropriate courses of instruction for at least two sessions. The studentships cover all ordinary tuition fees, and will be awarded solely on consideration of the past records of the candidates, the recommendations of their teachers, the course of study they intend to follow, and generally upon their fitness for advanced study in science applied to industry. In special cases the free places may be extended to two or more years. Application forms may be obtained from the Education Officer, L.C.C. Education Offices, Victoria Embankment, London, W.C., and must be returned not later than Saturday, May 25.

The latest number of the Journal of the Royal Agricultural Society of England contains an article on rural education in our village schools, by Mr. K. J. J. Mackenzie, of the School of Agriculture, Cambridge. It discusses an important question in an interesting manner. Some of our practical agriculturists, the article points out, hold that the "atmosphere" of the schoolrooms rather stimulates a desire on the part of our country lads to become messenger-boys, shop assistants, or junior clerks, and that the training they there receive is much more likely to make them successful in such avocations than to help them on to become good cowmen, waggoners, shepherds, or skilled labourers. To arrive at some conclusion as to what improvements the agricultural employers of labour desire, Mr. Mackenzie circulated a series of questions, to which he invited replies. His paper summarises the expressions of opinion received, but on the whole it cannot be said that the answers are very helpful or unanimous. The bulk of the suggestions seem to be in the direction of introducing definite instruction in rural subjects, with the view of interesting and instructing the children in the work they will do if they remain in the country. Mr. Mackenzie is right when he urges that what is wanted, and what is becoming more imperative every day, is true education which trains the pupil's intelligence to the best advantage.

The new Harrison-Hughes Engineering Laboraties at Liverpool University were opened on May 18 by Lord Haldane. The laboratories are the outcome of a gift of some 40,000*l*. by Mr. T. F. Harrison, Mr. J. W. Hughes, and Mr. Heath Harrison, of the Harrison line of steamships. During the course of an address, Lord Haldane said it is difficult to underrate the importance of a movement such as that for the development of the engineering side of Liverpool University or the value of such gifts as those which have made the new laboratories possible. It is not merely the bigness of the equipment with which the new laboratories are furnished. The chance is given to the student of getting that expansion of mind which only a university training can give in another branch of applied learning and on a scale which raises its level to the best that can be attained. The functions of a university are quite different from the functions of an elementary or even a secondary school. The teacher in an elementary school delivers certain facts and certain principles to a pupil too young to question them and not expected to inquire into their scope and truth. The mind of the pupil is receptive; he has started learning. But when we come to the university, professor and student are alike in the unknown. They are on a voyage of discovery, in which the professor is more equipped and more thoroughly experienced in the difficult road along which both are advancing in quest of new learning. It is a voyage of discovery which the student and the professor are taking in common, and unless the professor is a man of capacity who can stimulate and develop the imagination of the student and infuse in him the spirit of research and develop a new atmosphere, the work will fail. Later Lord Haldane went on to say Liverpool University has been developing year by year in a fashion which shows that the great and wealthy citizens appreciate what the public life of their city requires, what part the University may play, and how it is their privilege, as well as their pleasure, to make additions which mark a further stage in the life of the city as a whole. It is a very great pleasure to see the University growing and making itself more and more worthy of the great city of Liverpool.

SOCIETIES AND ACADEMIES.

London.

Royal Society, May 16.—Sir Archibald Geikie, K.C.B., president, in the chair.—W. B. **Hardy**: The general theory of colloidal solutions. The physical properties of colloidal solutions prove them to be heterogeneous fluids. If the colloid particles are regarded as a stage in the appearance of a second fluid phase the variations of the energy of the particles with the radius are of predominant importance. If we could assume, for instance, that the tension of the interface varied with the radius as the tension of a free film of fluid was found to vary with the thickness of the film by Renold and Rücker, globules of certain dimensions would alone be stable. It is pointed out, however, that at present there is no adequate basis in experiment or theory for regarding the peculiarities of soap films, themselves a colloidal form of matter, as the property of films or minute spheres of matter in general.—W. B. **Hardy**: The tension of composite fluid surfaces and the mechanical stability of films of fluid. In order to gain further information as to the variations of surface energy with variations in the thickness of a film, the tension and mechanical stability of the surface of water on which a known impurity was allowed to spread has been investigated. It was found that the effect of the impurity depended upon its chemical nature. Substances of great chemical stability, such as the higher paraffins, refuse to spread at all, and only slightly lower the tension of water. Esters—such as glycerides—produce a great fall of tension, and an exceedingly thin film of the order of 2 $\mu\mu$ thick suffices. It is suggested that the great activity of esters is due to their being partly decomposed at the interface with the production of a contact difference of potential between the film and the water.—W. B. **Hardy**: The Formation of a heat-reversible gel. In the course of his study of the cyclo-pentanes, Dr. Ruhemann has synthesised a substance which forms gels with apparently any solvent (alcohol, ether, carbon tetrachloride, carbon bisulphide, aldehyde, glacial acetic acid, &c.). A remarkable feature is that gelation occurs as readily in associating as in non-associating solvents. The gels have a peculiar structure owing to the fact that gelation starts from nuclei and only gradually involves the whole mass.—H. E. **Armstrong**, E. F. **Armstrong**, and E. **Horton**: Studies on enzyme action. XVI. The enzymes of emulsin (II): Prunase, the correlate of prunasin. Evidence has been adduced in previous studies of the series that the diglucoside amygdalin is resolved into glucose, benzaldehyde and hydrogen cyanide by two distinct enzymes present in the emulsin prepared from the almond fruit, one (amygdalase) serving to resolve it into glucose and δ-mandelonitrile glucoside or prunasin, the other to convert this latter compound into glucose, benzaldehyde, &c. Amygdalase is known to occur in certain yeasts unaccompanied by the second enzyme. It is now shown that the second enzyme occurs in the leaf of the almond and of other species of Prunus from which prunasin, but not amygdalin, may be separated; it is proposed to term this enzyme *prunase*. Apparently, the two enzymes are always present in the fruit in association with amygdalin, but amygdalin is not known to occur in the leaf, and the leaf enzyme, as a rule, has little action on amygdalin.—H. E. **Armstrong**, E. F. **Armstrong**, and E. **Horton**: Studies on enzyme action. XVII.—Enzymes of the emulsin type (II): The distribution of β-enzymes in plants. A method of general application is described by which the enzymic activity of plant materials may be determined. It has been applied to the study of the distribution in plants of enzymes capable of acting on the glucosides linamarin, prunasin, salicin, arbutin and amygdalin.—H. E. **Armstrong** and J. Vargas **Eyre**: Studies on enzyme action. XVIII.—Enzymes of the emulsin type (III): Linase and other enzymes in Linaceæ. The method developed in the previous communication has been applied to various species of Linaceæ. The family is found to be divisible into two groups—one of these, which apparently includes all species similar in habit to *L. usitatissimum*, having blue, white, or red flowers, contains the cyanophoric glucoside linamarin and the corresponding enzyme linase. The second group, which comprises the yellow-flowered species of arboreal habit (*L. arboreum*, *L. flavum*, &c.), apparently contains neither glucoside nor enzyme. One important outcome of the inquiry is the proof that whereas the enzyme extracted from *Phaseolus lunatus* is about equally active towards linamarin and prunasin, that present in Linum is much less active towards the latter. It is therefore not improbable that linase is usually accompanied by prunase, and itself without action on prunasin.—A. **Forbes**: Reflex rhythm induced by concurrent excitation and inhibition.—T. Graham **Brown**: The factors in rhythmic functions of the nervous system. In a previous communication it was shown that the act of rhythmic progression is intrinsically conditioned centrally and not peripherally. At the same time, it was suggested that the phenomenon of rhythmic movement in the act is conditioned during a balance of equal and opposite activities.

Zoological Society, May 7.—Prof. E. A. Minchin, F.R.S., vice-president, in the chair.—G. A. **Boulenger**: A collection of fishes made by Mr. A. Blayney Percival in British East Africa to the east of Lake Baringo. This collection was of special importance as coming from a district the fishes of which had not been collected before, and contained examples of five new species.—Dr. F. E. **Beddard**: A new genus of the Cestoidea, founded on some specimens of tapeworms which the author had discovered in the small intestine of an example of the Tasmanian devil (*Dasyurus ursinus*). In briefly describing the most salient points of anatomical interest in this form, which formed the type of a new family, the author remarked that in view of the very considerable peculiarities of structure observed, it was remarkable that the generative organs did not show any marked features of interest as compared with those of other tapeworms.—R. E. **Turner**: Studies in the fossorial wasps of the family Scoliidæ, subfamilies Elidinæ and Anthoboscinæ. Several new species of Elidinæ from South Africa were described, including a new genus in which the female was wingless, and the genus Anthobosca was monographed. The geographical distribution of Anthobosca, which was almost entirely confined to the southern hemisphere, was discussed, and the conclusion was reached that the distribution was due to survival from a wider range in the past, and not to a southern origin.—A. **Chapman**: Notes on the Spanish ibex, with reference to Prof. Angel Cabrera's recent paper on this species.

Royal Astronomical Society, May 10.—Dr. Dyson, F.R.S., president, in the chair.—F. W. **Dyson** and E. W. **Maunder**: The position of the sun's axis as determined from photographs from 1874 to 1911, measured at the Royal Observatory, Greenwich. It was concluded that the final mean value for the position of the sun's axis agrees very closely with Carrington's, and that there is no sufficient evidence of any change during the period covered by the photographs measured.—S. **Chapman** and T. **Lewis**: The effect of magnetism on the rate of chronometers and watches. The chronometers are placed in magnetic fields of different strengths; the balance arm becomes magnetised, and the magnetic field pulls it towards its own position, causing the watch to gain or lose according to its position with regard to the magnetic field. Owing to the smaller size of its balance a watch is more affected than a chronometer.—Prof. **Lowell** spoke on the spectroscopic discovery of the rotation of Uranus, made at the Lowell Observatory, Arizona. The photographs showed the inclination of the lines in the spectra of the limbs of the planet, from which a rotation period of between 10 and 11 hours was deduced.—Dr. J. W. **Nicholson**: The constitution of the solar corona, second paper. The subject was dealt with from the point of view of the movements of the electrons within the atoms.—H. C. **Plummer**: The motions and distances of certain stars of the types B8 and B9. The paper was a continuation of one read in January, certain other classes of stars being examined, the motions of which appeared to be in the plane of the Milky Way.—J. H. **Reynolds**: Preliminary observations of spiral nebulæ in polarised light. The assumption was made that some of the luminosity of a nebula might be due to light reflected from the stars involved in it. From the photographs shown there appeared some evidence of polarisation, and the author proposed to continue the investigation.—Prof. H. F. **Newall**: The spectrum of the sun's limb during the partial eclipse of 1912, April 16–17.

CAMBRIDGE.

Philosophical Society, May 6.—Sir George Darwin, K.C.B., president, in the chair.—Sir J. J. **Thomson**: The unit theory of radiation.—Dr. G. F. C. **Searle**: A simple viscometer for very viscous liquids. If the space between two coaxal cylinders of radii a, b, and of length h, be filled with viscous liquid, the viscosity μ is given in terms of the couple G, which maintains the inner cylinder in motion about its axis with angular velocity ω relative to the outer fixed cylinder, by the equation

$$\mu = \frac{G(a^2 - b^2)}{4\pi\omega h a^2 b^2} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The apparatus exhibited is adapted for finding the viscosity of treacle. At 12° C. the viscosity of treacle is about 400 in C.G.S. units, that of water at the same temperature being 0·0146.—W. A. D. **Rudge**: The action of sunlight and of radium salts on glass. The author has studied the action of sunlight and of radium salts on glass tubing, and exhibited specimens showing the results of the action on the two cases. Glass tubing is affected by sunlight differently, some specimens acquiring a deep amethyst tint, others being merely darkened or bleached, and others, again, being after six months' exposure to a tropical sun practically unaffected. Radium salts produce the same effect, but the coloration with identical glass is much deeper than is the case with sunlight. The change in colour in both instances is probably due to some oxidation of the manganese oxide usually present in small quantity in glass, either as an accidental impurity or deliberately added to destroy the greenish colour due to iron salts.—R. D. **Kleeman**: The different internal energies of a substance. II. In this paper it is further tested to what extent an agreement of a number of formulæ with the facts is obtained on the assumption that (ϕ) in the law of molecular attraction is a function of the temperature only. The coefficients of viscosity and diffusion of gases can be approximately calculated on this assumption. It is found that the more complex the molecule the greater the variation of (ϕ) with the temperature. The value of (ϕ) always decreases with increase of temperature. Evidence is brought forward that the change in the value of (ϕ) and of the internal energy of a molecule with temperature is due to a change in the configuration of the atoms.—A. E. **Oxley**: The detection of small amounts of polarisation in light from a dull sky. The paper describes an arrangement of a bitrapezoid polariser and a Babinet's compensator by the aid of which the existence of polarisation in light from a dull sky can be detected when that light is insufficient in quantity and of an azimuth too indefinite to produce visible complementary tints in crystalline plates.—J. C. **Chapman**: An attempt to refract Röntgen radiation. In this experiment an attempt was made to refract X-rays, under exceptional conditions, by a prism of ethyl bromide vapour. That is when the radiation which it was attempted to refract (1) stimulated the bromine characteristic radiation, (2) was selectively absorbed by the vapour. In neither case could appreciable refraction be detected.—Major P. A. **MacMahon**: (1) The problem of derangement in the theory of permutations; (2) Compound denumeration.

DUBLIN.

Royal Irish Academy, May 13.—Dr. F. A. Tarleton, and subsequently Sir John Ross of Bladensburg, in the chair.—H. **Ryan** and T. **Nolan**: Higher ketones and secondary alcohols derived from amides of palmitic and stearic acids. The higher amides, such as those of palmitic and stearic acids, give good yields of ketones by interaction with alkyl magnesium halides. In this way the authors obtained methyl-, phenyl-, *p*-tolyl-, and α-naphthyl-pentadecyl ketones from palmitamide and ethyl-, phenyl-, and α-naphthyl-heptadecyl ketones from stearamide. The ketones formed crystalline oximes, semicarbazones, and phenylhydrazones. By reduction of the ketones secondary alcohols were obtained, which formed acetyl derivatives and phenyl urethanes.—R. J. **Ussher**: Birds (Clare Island Survey). This report deals with the west coast of Connaught. On the islands land-birds that breed are few, and comprise the chough, raven, peregrine, and rock-dove, while the golden eagle nested within the last twenty years, though now but one survives in Mayo and one in Donegal. The district contains great colonies of cliff-birds; on the Bills many great black-backed gulls nest. Petrels and shearwaters also breed on the islands. The influence of the Atlantic with its west winds produces a moderate temperature in winter, when there is a regular movement to the islands of song thrushes, finches, starlings, rooks, and larks, that do not breed there.—A. R. **Nichols**: (1) Polyzoa, and (2) Echinodermata (Clare Island Survey). (1) Seventy-five species of marine Polyzoa, chiefly encrusting forms belonging to the suborder Cheilostomata, were collected in the Clare Island district. A single species (*Plumatella repens*) of fresh-water Polyzoa was found in a small lake at Clare Island and also at Inishbofin; four other species were found in lakes in the western part of the mainland of Co. Mayo. (2) Thirty-two species of echinoderms are enumerated from the Clare Island district, nine of which belong to the group Holothurioidea.

PARIS.

Academy of Sciences, May 6.—M. Lippmann in the chair.—MM. **de Vanssay, Cot,** and **Courtier**: Observation of the solar eclipse of April 17, 1912. These observations were carried out at three stations near Luzarches, on a line perpendicular to the central line of the eclipse. Details are given of the times of contact and the duration of the annular phase.—P. **Salet**: The character of the solar eclipse of April 17, 1912, in Portugal. The eclipse was not total on the line of centrality in Portugal.—L. **Picart**: Observations of the solar eclipse made at the Observatory of Bordeaux. Times for the first and second contacts are given. The presence of clouds interfered with the observations.—E. **Rabioulle**: The latitude of the Observatory of Toulouse. A comparison of measurements made since 1844. The result for 1911 was $43^\circ\ 36'\ 43{\cdot}5''$.—René **Garnier**: The limits of the substitutions of the group of a linear equation of the second order.—Zoárd **de Geöcze**: The quadrature of curved surfaces.—Louis **Roy**: The dynamical adiabatic law in the motion of flexible membranes.—L. **Riéty**: The electromotive force produced by the flow of saline solutions in capillary tubes.—G. **Berlemont**: A method of joining platinum and quartz. A sound joint can be made directly between quartz and an alloy of platinum and iridium.—Samuel **Lifchitz**: The range of the particles in the Brownian motion. An ultramicroscopic study of smoke particles under the influence of sound waves.—L. **Houllevigue**: The kathode rays with low velocity produced by incandescent lamps.—Ch. **Fabry** and H. **Buisson**: The size of the lines of the spectrum and the production of interference with large differences of path. The theory of Lord Rayleigh, completed by Schönrock, gives a relation between the width of a line in the spectrum, the wave-length, the absolute temperature, and the mass of the vibrating particle. From this follows that in interference there is an order N above which the fringes cannot be observed. N has been determined for helium, neon, and krypton, and the values are in close agreement with the figures predicted by the theory. The increase in the value of N which should result if the temperature is lowered has also been confirmed experimentally. The experiments as a whole confirm the principles of the kinetic theory of gases.—G. D. **Hinrichs**: The systematic errors in the chemical operations used in the determination of the atomic weights.—F. **Bourion**: The separation of iron and titanium. A mixture of the two oxides is heated in hydrochloric acid gas containing a small proportion of chloride of sulphur (S_2Cl_2). The iron is volatilised as chloride, the titanium dioxide remaining unattacked.—G. **Darzens**: A carbon pernitride (see p. 303).—Ed. **Chauvenet**: The oxychlorides of zirconium.—A. **Wahl** and M. **Doll**: The preparation of the αβ-diketonic esters. The authors have extended the method of preparing the diketonic esters by the action of nitrous fumes on the acylacetic esters to the propionyl-, butyryl-, and heptylacetic esters. The properties and chief chemical reactions of the new diketones are given.—Alph. **Mailhe**: Some new colouring matters derived from phenyloxyaniline.—Jean **Escard**: A new densivolumometer applicable to the rapid determination of the density of solids.—Paul **Desroche**: The influence of temperature on the zoospores of Chlamydomonas.—L. **Lutz**: A comparison of the total nitrogen and the nitric nitrogen in parasitic and saprophytic plants.—H. **Hérissey**: The presence of amygdonitrileglucoside in *Photinia serrulata*.—L. **Bull**: An optical illusion perceived at the moment of shutting the eyes. W. Broughton **Alcock**: Attempts at antityphoid vaccination in man by means of a sensitised living vaccine. J. **Bridré** and A. **Boquet**:

Anticlavelous vaccination with sensitised virus.—M. **Fabre-Domergue**: Some new experiments on the bacteriological purification of oysters in filtered water. After four days' circulation of the filtered water the oysters were free from *B. coli*.—Em. **Bourquelot**: The action of emulsin on gentiopicrin in solution in various neutral organic liquids.—Victor **Henri** and Albert **Ranc**: The decomposition of glycerol by the ultra-violet rays. Formaldehyde and other aldehydes and acids are formed when glycerol is exposed to the light from a powerful quartz mercury lamp.—D. **Eginitis**: The recent earthquakes in Cephalonia and Zante.

Registered as a Newspaper at the General Post Office.]

THURSDAY, MAY 30, 1912.

THE PRACTICAL AND SCIENTIFIC METALLURGY OF STEEL.

The Metallurgy of Steel. By F. W. Harbord and J. W. Hall. Fourth edition, enlarged and revised. Volume i., Metallurgy. By F. W. Harbord. Pp. xvi+522+xxix. Volume ii., Mechanical Treatment. By J. W. Hall. Pp. xviii+523–933+xxix. (London: Charles Griffin and Co., Ltd., 1911.) Price 36*s*. net, two volumes.

IT is not surprising that the fourth edition of this valuable and painstaking work should be called for. It is without doubt the best compilation of its kind in metallurgical literature.

In reviewing the fourth edition the critic should, as a matter of fairness, make the preliminary admission that an absence of up-to-dateness is not necessarily due to lack of knowledge on the part of the authors, but possibly to revision rules imposed upon them by the publishers. The plan adopted by the authors of dividing their bulky work into two volumes will be fully appreciated by readers as a much more convenient arrangement.

Mr. Harbord in volume i. deals in his introduction with the definition of steel in perhaps rather unnecessary detail. There is, in the reviewer's opinion, only one true and comprehensive definition of steel, and that is quite brief, namely, "Steel is an alloy of iron and carbon with other elements, which is capable of being hot-worked from commercial ingots or castings into merchant sizes." Mr. Harbord states on p. 3 that "metal containing over 2·3 per cent. carbon may reasonably be classified as cast-iron." Therefore, according to Mr. Harbord, Sheffield crucible cast-steel wortle plates, costing 6d. per lb., are cast-iron. Mr. Harbord is evidently not aware that under specially favourable conditions crucible steel ingots containing nearly 3 per cent. of carbon have been forged, and cast-iron will not forge. Mr. Harbord's treatment of the Bessemer process as to matter, diagrams, and tables is as a whole admirable, but his appreciation of the vital part played by Mushet in this process is rather inadequate. As a matter of justice, the method should be called the Bessemer-Mushet process. Bessemer's blown metal was commercially worthless, and it was brought into the region of practical metallurgy only by what Mr. Harbord calls the "suggested addition" of manganese in Mushet's patent. In the useful article on ingot moulds there is on plate ii. an unfortunate misprint; the drawing is headed "the Thomas Turner patent system of cutting small ingots," instead of "*casting* small ingots."

The practice and chemistry of the crucible process are, as a whole, dealt with in an excellent manner, but the statement that in coke melting the absorption of sulphur is "generally very slight" will be news to Sheffield crucible steelmakers too good to be true. With the best coke now obtainable the average increase is from, say, 0·01 to 0·02 per cent., whilst with impure coke steel is occasionally discarded because it has absorbed up to 0·04 per cent. sulphur. Gas crucible melting, in spite of Mr. Harbord's commendation, has not made very much headway. It has certainly many good points, but the fact remains that the highest qualities of steel are still melted by the Huntsman process.

The electric melting of steel is naturally most ably handled by Mr. Harbord, but in the reviewer's opinion his statement that electrically refined steel is equal to the best crucible steel is contradicted by the ruling market prices, which are based on practical experience. The figure 765 units per ton of steel made in the arc furnace will not appeal to those who, like the reviewer, have personally investigated this matter, and have found 1200 units to be nearer the mark when starting with cold and common scrap. Repairs and renewals are put down at 3*s*. 6*d*. to 5*s*. 6*d*. per ton. This is the cost of electrode waste alone.

In dealing with the thermal phenomena of recalescence and absorption, there is an unhappy slip on p. 353, where Prof. le Chatelier is saddled with the statement that the point A_{r_2} is accompanied by "a slight absorption of heat." The word "absorption" should, of course, read "evolution." The theories of the rival Carbonist and Allotropic schools are fairly stated by Mr. Harbord, but he is obviously unaware that in the discussion on a paper by Sir Robert Hadfield and Prof. Hopkinson on "The Magnetic Properties of Steel," Mr. Osmond withdrew the B iron theory of hardening (Journal of Institution of Electrical Engineers, April, 1911, No. 206, p. 293).

The micrographic section cannot be deemed up-to-date. It is stated that "martensite" is a series of interlacing crystalline fibres, the real composition of which is unknown. It would seem that the composition of an imaginary constituent must necessarily remain unknown. Hardenite, the true constituent of hardened steel, discovered by Sorby and named by Howe, is not mentioned. The constituent "sorbite" is somewhat unkindly disinterred from its grave. Mr. Harbord has evidently not seen the recent work of Dr. Benedicks at Upsala University, which has fully confirmed

O

the observations made years ago at Sheffield University that sorbite is merely pearlite containing its Fe_3C in a fine state of division. Mr. Harbord has also ignored the researches recently published by the Iron and Steel Institute, where the so-called troostite yielded practically the whole of its carbon as carbide.

Turning to vol. ii., for which Mr. Hall is responsible, this naturally deals with metallurgy from an engineer's point of view, and so treats it in an able manner. But in connection with coal-fired reheating furnaces Mr. Hall is disturbed at what he considers their wastefulness in the loss of fuel as smoke. As a metallurgist the reviewer, speaking from personal research data, would re-assure Mr. Hall on this point. The use of smoke in reheating fine steel is an art, and without smoke there would be no fine steel. Mr. Hall deals with hammers, rolling mills, and presses, illustrating his text with many excellent figures. He also describes the fluid compression of steel, wire-drawing, and tube-making. This second volume thus forms a valuable engineering supplement to the metallurgical matter dealt with by Mr. Harbord in vol. i.

These books should be on the shelf of everyone interested in steel metallurgy, and the steel world is much indebted to the authors for their able and laborious work. It is, however, certain that owing to the rapid progress of scientific research the portions of vol. i. dealing with the physical chemistry of steel will for a further edition require drastic revision, or even re-writing, to render them of practical value to the student.

J. O. ARNOLD.

EXPERIMENTAL PSYCHOLOGY.

A Text-book of Experimental Psychology, with Laboratory Exercises. By Dr. C. S. Myers. Second edition. Part i., Text-book. Pp. xiv + 344. Part ii., Laboratory Exercises. Pp. iv + 107. (Cambridge: University Press, 1911.) Price, two vols., 10*s*. 6*d*. net.

THE first edition of Dr. C. S. Myers's book was reviewed in the pages of this journal three years ago. The present edition is issued by a different publisher, viz., by the Cambridge University Press in the place of Mr. Edward Arnold, and the laboratory exercises now appear in a separate volume. The revision of the work has been very thorough, and in many parts important and extensive additions have been made. Certain psychological results appearing in Dr. Henry Head's "Croonian Lectures" of last year have been incorporated in the text, and a most important concluding chapter on the experimental investigation of thought and volition has been added.

The publication of the first edition marked an epoch in the history of the teaching of psychology. The edition just issued is probably the most complete text-book of experimental psychology in this or any other language. Every page is loaded with trustworthy statements of verified fact, yet the argumentation is so well ordered and the style so concise and clear that the book can be read with ease and pleasure. A bibliography of all the important monographs and articles upon the subject under discussion is appended to each chapter; in the text conflicting views are carefully weighed and balanced one against another, and no conclusions are stated without sound justifications of this kind.

The wide scope of the book may be indicated by an enumeration of the headings of the various chapters. These are:—"The Standpoint of Experimental Psychology," "Cutaneous and Visceral Sensations," "Auditory Sensations" (two chapters), "Labyrinthine and Motor Sensations," "Visual Sensations" (two chapters), "Gustatory and Olfactory Sensations," "Specific Energy of Sensations," "Statistical Methods," "Reaction Times," "Memory" (two chapters), "Muscular and Mental Work," "The Psychophysical Methods," "Muscular Effort," "Local Signature," "Sensibility and Sensory Acuity," "Experiences of Identity and Difference," "Binocular Experience," "Binaural Experience," "Visual Perception of Size and Direction," "Time and Rhythm," "Feeling," "Attention," "Thought and Volition."

Addition chapters on the experimental investigation of the psychology of young children and animals would have made the treatment of representative topics more complete, but the author is probably well advised in leaving these rather outlying subjects to books specially devoted to their treatment.

A standard text-book is notoriously difficult to review, and in a case like the present, where the book stands alone, this difficulty is especially great. There are one or two slips, however, that may be pointed out. At the end of the chapter on "Statistical Methods," on p. 124, in the mediate term showing the reduction of the ordinary product-moment formula to the corresponding rank-formula for the correlation coefficient, the term $\Sigma(xy)$ is not identical with the term $\Sigma(xy)$ of the product-moment formula, and should have been written $\Sigma(ab)$, where a and b are corresponding ranks in the two series correlated. In this chapter, too, mention might usefully have been made of the conception of "partial" correlation, which promises to be so important in the analysis of correlation results. In the discussion of the psycho-physical method of constant stimuli, it is unfortunate that a reference is still made to a method for doing without Gauss's formula in which the mean of a frequency-distribution is "corrected" or "adjusted." It has been known for some years that the mean of a frequency-distribution needs no adjustment. One must hasten to add, however, that the text of this chapter on the psycho-physical methods is exceptionally clear and sound, and is undoubtedly the best elementary account we have of a rather difficult part of psychology.

A JOURNEY TO CANADIAN BARRENS.

The Arctic Prairies: a Canoe Journey of 2000 *Miles in Search of the Caribou; being the Account of a Voyage to the Region north of Aylmer Lake.* By Ernest Thompson Seton. Pp. xvi+415. (London: Constable and Co., Ltd., 1912.) Price 12*s*. 6*d*. net.

IT need scarcely be said that Mr. E. Thompson Seton's book makes wholesome and exhilarating reading, instinct throughout with its author's sympathy and enthusiasm for wild life. The æsthetic embroidery, while enjoyably present, is kept subordinate to the sincerity and accuracy required of the true naturalist. A six months' canoe-journey was made by the author in the open season of 1907 down the Athabaska River and through the forested country of its lake and river continuations to Lakes Clinton-Colden and Aylmer of the Barren Lands, in lat. N. 64°, a distance, there and back, of some 2000 miles or so; and this is the record of it.

Geographically, the journey was not of high consequence, though Mr. Seton was able to make some additions and corrections to the previous maps, particularly in respect to Lake Aylmer. Nor is there any startling incident of travel to relate, for the adventures and misadventures were just those of every voyageur into the northern wilderness; indeed, the author's capability is best shown by the relative ease with which his task was accomplished. Neither is this a hunter's book; the sportsman-reader will be fretted with the same sense of wasted opportunity that was expressed by Mr. Seton's Indian and half-breed companions, who found it unaccountable that a man should follow the chase so laboriously for the thin satisfaction of seeing animals. Because of these unusual features—and of the author's ever-artistic touch—the narrative is more entertaining than most of its type.

In a highly interesting chapter on the ebb and flow of animal life, the author discusses a series of graphs which he has compiled from the records of the Hudson Bay Company for the years 1821 to 1908, showing the number of pelts of fifteen different fur-animals that have been dealt with annually during this long period. From these statistics certain deductions are drawn, notably that "the high points for each species are with fair regularity ten years apart" (p. 109). In another chapter Mr. Seton deals categorically with the interdependence of the rabbit (*Lepus americanus*) and the lynx, stating that the former increases rapidly to a maximum in spite of its many voracious enemies, and is then suddenly thinned out nearly to vanishing point by epidemic diseases known collectively as "plague," with secondary consequences almost equally disastrous to the lynx population.

Most commendable is the author's ingenious way of treating a recurrent subject that would make "painful and dreary reading" if oft repeated. He asks the reader to allow him, once and for all, a chapter on that terror of the northern wilds, the mosquito; and later allusions to it take the form of a simple "see chap. ix." The idea might profitably be extended by the introduction of standing references of this kind for use in travel-literature in general.

Some vigorous drawings, as well as photographs, of animal life are reproduced as plates, and the book is further illustrated by 125 sketches in the text, which have the live touch that no photograph can convey.

The appendices include full lists (with notes) of the mammals, birds, and plants that were collected or seen; a short list of insects; a "buffalo summary," from which it appears that more of these animals survive in the wild state than had been supposed; and a (reprinted) plea for the introduction of the yak as a range-beast for the north-west.

ELEMENTARY PRACTICAL PHYSICS.

A Laboratory Note-book of Physics. By S. A. McDowall. Part i., pp. viii+166. Part ii., pp. viii+126. (London: J. M. Dent and Sons, Ltd., n.d.) Price 2*s*. 6*d*. net each part.

THOSE who have to deal with large classes in practical physics know how difficult it is for the demonstrator to set and maintain the class going without some aid in the form of printed instructions, such as note-books or separate slips relating to each experiment. This plan is, however, looked upon with suspicion by many owing to the obvious danger that the work degenerates into mere mechanical operations, without any intelligent appreciation on the part of the pupil of what he is doing, and of the physical principles underlying the experiment. This danger seems to be almost entirely avoided in the volume before us.

At Winchester College, as the author explains in the preface,

"Each student is given a printed slip describing the experiment to be performed and containing questions designed to test whether the experiment had been understood. These slips were then pasted into a note-book, and full supplementary descriptions, with diagrams, graphs, and answers to the questions, are entered by the student as well as the actual experimental results."

The present note-book is a development of this system, the underlying plan being that when the experiments have been worked through, the student should have a text-book of elementary practical physics, largely written by himself, to which he can refer when preparing for any definite examination. The experiments are briefly described on the left-hand pages, the right-hand pages being blank, to receive descriptions, by the student, of important experimental details and calculations. Sketches and diagrams are to be drawn in the blank spaces on the left-hand page. Volume i. contains the simpler experiments on measurement, hydrostatics, heat, light, magnetism, electrostatics and current electricity; while in the second volume are to be found more advanced experiments on the same subjects. This volume includes in addition some experiments on surface tension. It is greatly to be regretted that experiments on dynamics, statics, and sound are omitted entirely. The experiments are numerous and well chosen, and (except for the omissions mentioned) cover the whole range of elementary physics. There is no doubt that a student who had worked through these two volumes, and had filled in the supplementary descriptions and diagrams, would be very well equipped for a higher course.

One of the most valuable features of the book is the large number of short questions ("Why?" "Why not?" "How?" "What do you notice?" "Why ether rather than water?" "Why use the high-resistance coil?" and so on) which are found in brackets among the printed directions. The student is required to answer these questions when writing up an experiment. He is thus encouraged all along to think things out for himself. This feature will be a valuable corrective against the experiments being performed mechanically.

The book contains a few blank pages for additional experiments, and is well supplied with graph paper.

We heartily commend this book to the notice of those who have to deal with large classes in elementary practical physics. G. O.

LOGARITHMIC TABLES.

Tables of Logarithms and Anti-logarithms to Five Places. By E. Erskine Scott. Students' edition. Pp. 383. (London: C. and E. Layton, n.d.) Price 5*s.* net.

Table of Logarithms and Anti-logarithms (Four Figures), 1 to 10,000. Arranged by Major-Gen. J. C. Hannyngton. Pp. iv+41. (London: C. and E. Layton, n.d.). Price 1*s.* 6*d.* net.

Four Place Tables of Logarithms and Trigonometric Functions. Unabridged edition. Compiled by Prof. E. V. Huntington. Pp. 33. (Cambridge, Mass., U.S.A.: the Harvard Co-operative Society; London: E. and F. N. Spon, Ltd., n.d.) Price 3*s.* net (60 cents).

THE old French saying,

> Dans la gendarmerie
> Quand un gendarme rit
> Tous les gendarmes rient
> Dans la gendarmerie,

applies with considerable force to writers of mathematical text-books. For some time past the market has been inundated by a flood of books of logarithmic tables. In these circumstances it is impossible for a reviewer to say that any single book of the collection supplies a long-felt want, and all that can be done is to give as precise a description as possible of the contents and arrangement of the different tables so that a reader can select that one which most closely meets his actual requirements.

Now Hannyngton's and Erskine Scott's tables are exactly similar in character, and only differ in the fact that Hannyngton's are four-figure and Erskine Scott's are five-figure tables. Both books contain logarithms and anti-logarithms, and nothing else, and in each case *all* numbers are tabulated separately so that the use of interpolation is obviated, every logarithm or anti-logarithm being entered separately. This, of course, makes the tables ten times as long, and provides compensating advantages in the matter of convenience. Those whose work is facilitated by this arrangement, and is limited to the use of logarithms, will appreciate the efforts that have been made to supply what they prefer. In Erskine Scott's book the anti-logarithms are printed on green paper.

Huntington's four-figure tables, on the other hand, cover a wider ground, including conversion of degrees into minutes and seconds, squares and cubes and corresponding roots, reciprocals, circumferences and areas of circles, natural functions, logarithms, logarithmic sines, cosines, tangents, cotangents, logarithms of radians, exponential and natural logarithms, radian tables, and constants. Each table occupies two pages only, but "special tables" are given for those parts of the logarithmic and trigonometric scales where the differences are large. The book is well suited for use in the laboratory or examination-room. The author wisely does not follow the usual fashion of introducing unnecessary and superfluous tables of anti-logarithms as well as logarithms. The edges of the pages are cut after the fashion of a "Where is it?" thus facilitating reference. In the trigonometrical logarithms, negative characteristics are used, the functions being thus referred to an arc of unit radius instead of radius 10^{10}, as in the earlier tables.

OUR BOOKSHELF.

Complete Yield Tables for British Woodlands and the Finance of British Forestry. By P. Trentham Maw. Pp. xii+108. (London: Crosby Lockwood and Son, 1912.) Price 7*s.* 6*d.* net.

SIR W. SCHLICH has stated that the most urgent need of British forestry is the collection of statistics by means of which the financial results of the industry can be estimated. These statistics are usually embodied in so-called yield tables, which give for an acre covered with a certain species of tree, and treated in the best manner, the volume of timber, number of trees, their average height and diameter, &c., corresponding to different ages. As the productivity of timber varies with the nature of the soil, a number of qualities of soil must be admitted. Usually three are sufficient—good, medium, and bad soils—and, corresponding to these, three different tables for each species are made. The tables are constructed from a graphic analysis of the data obtained by measuring a large number of sample plots of the given species on all classes of soil and of all ages.

Yield tables are either general, applicable to a whole country, or local, restricted to a small district where climatic conditions are uniform. It is usually admitted that general tables are not trustworthy, and we cannot, therefore, use with safety the German yield tables.

The present volume is an attempt to furnish the necessary yield tables for British practice. His tables, meant to be applicable to all Britain, can only be approximative. They have been constructed by a method which Mr. Maw claims to be new, and explains as follows: "The growth of timber is characterised by certain girth indices and density factors, both of which are interdependent, and which are dependent also on the height growth; and if these and the height growth at different ages are taken into account, the preparation of yield tables is a comparatively easy matter, and results can be obtained which are approximately correct for all practical purposes."

This theoretical method requires to be tested by comparison of actual woods with Mr. Maw's figures. It is also to be noted that his ideal woods are more heavily thinned from the beginning than the ideal woods of most German tables. This is financially sound if the quality of the timber is not thereby affected; but herein lies great danger. Mr. Maw's tables are ingenious and original, and deserve consideration at the hands of practical foresters.

Forme, Puissance et Stabilité des Poissons. By Prof. Frédéric Houssay. (Collection de Morphologie Dynamique. Directeur: Prof. F. Houssay. IV.) Pp. 372. (Paris: A. Hermann et Fils, 1912.) Price 12.50 francs.

THE question of the best form which a body should have so that its resistance shall be a minimum is one which will always attract the scientific mind, and one is naturally inclined to think that in fishes the form that has survived is best for propulsion in water. Prof. Houssay in this new work gives a very complete account of the experiments which he has been making during the last few years on the resistance of fish-shaped forms, partly from this point of view. Curves of power of various forms with and without elastic fins have been obtained by towing them from their leading end. The marked effect of the fins upon the stability and relative resistance to the motion of the forms has been investigated very exhaustively, and some interesting results have been obtained.

By a very ingenious method the author has succeeded in tracing out the stream lines of several fishes, and a very good beginning has been made with the experimental investigation of the power which various fishes are capable of exerting. The author has successfully examined the case of fishes kept almost stationary, and it is hoped that the further experiments which it is proposed to undertake will include some with the fishes moving at different speeds relative to the water.

Quite a large part of the work is devoted to the question of the means of propulsion which the fish possesses, and in particular seeks to differentiate between the action of the main body of the fish, its tail and the fins, and the part which the necessity of these actions has played in giving the fish its form.

G. S. B.

Heat and Steam. By Engineer-Lieut. S. G. Wheeler, R.N. Pp. vii+224. (London: Edward Arnold, 1911.) Price 4*s.* 6*d.* net.

THE original design of the author of this book was to provide material covering the more theoretical parts of the subject required by naval cadets up to the time of their leaving the training cruisers. While this object has been kept in view, sufficient additional matter has been included to render the book useful to other classes of students. The method of treatment of the thermodynamic principles is good, and will be readily comprehended by any reader who has but slight knowledge of higher mathematics.

The earlier chapters deal with heat, temperature, energy, the first law of thermodynamics, and the formation and expansion of steam. These lead to very useful chapters on the theory of reciprocating engines and on their thermal performances in practice. Sufficient is included on valve gears and indicator diagrams to enable the student to understand the ordinary gears and to detect any defects in practical working. A considerable section of the book is devoted to the steam turbine, and this portion is excellent, both as regards the treatment of the laws of expansion in nozzles, and also the explanations given of the action of the more common types of turbines. Some notes on propulsion, coal consumption, internal combustion engines, and refrigerators are also given.

As the book is rather a collection of expanded notes than a comprehensive text-book, the author has wisely omitted any elaborate descriptive drawings. Such drawings as appear give all the information required to enable the principles discussed in the text to be understood readily. Within its scope the book can be recommended as supplying a useful supplement to lecture courses dealing with the subject.

Gardens in their Seasons: a Nature Book for Boys and Girls. By C. von Wyss. Pp. 64. Illustrated. (London: A. and C. Black, 1912.) Price 1*s*. 6*d*.

Wonders of Plant Life. By S. Leonard Bastin. Pp. x+136. Illustrated. (London: Cassell and Co., Ltd., 1912.) Price 3*s*. 6*d*. net.
