Ref.—1 Ann. Mines, 4, 517, 1843. Cf. also Haid., quoted by Brewster, l. c., and Dx., l. c.

588. DICKINSONITE. G. J. Brush and E. S. Dana, Am. J. Sc., 16, 114, 1878.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c} = 1.73205: 1: 1.19806; \beta = *61° 30' = 001 \, \text{A}$ 100 E. S. Dana1.

 $100 \wedge 110 = 56^{\circ} 41\frac{5}{6}', 001 \wedge 101 = 42^{\circ} 13\frac{1}{6}', 001 \wedge 011 = 46^{\circ} 28\frac{1}{6}'.$

Forms: $a(100, i \cdot \bar{i}), c(001, 0); x(301, -3 \cdot \bar{i}); \gamma(\bar{1}03, \frac{1}{4} \cdot \bar{i}), n(051, 5 \cdot \bar{i}), p(\bar{1}11, 1),$ s (221, 2).

Angles: $cy = 12^{\circ} 50'$, $cx = *42^{\circ} 30'$, $cn = 79^{\circ} 15'$, $cp = 61^{\circ} 8\frac{1}{4}'$, $cs = 82^{\circ} 2\frac{1}{4}'$. $pp' = 98^{\circ} 40'$, $ss' = 118^{\circ} 7'$, Angle $a'cp = *60^{\circ}$.

Crystals tabular, pseudo-rhombohedral; triangular striations on c. Commonly foliated to micaceous; also curved

lamellar, radiated or stellated.

Cleavage: c perfect, separable into thin lamellæ. Fracture uneven. H. = 3.5-4. G. = 3.338-Brittle. 3.343. Luster vitreous, on c somewhat pearly. Color olive- to oil-green, grass-green; slightly dichroic. Optically biaxial.

Comp.—3R_sP₂O_s + H₂O with R = Mn, Fe, Na, chiefly, also Ca, K, Li2. The ratio for Mn : Fe(Ca) : Na

(K., Li,) is closely 6:3:2, which requires: Phosphorus pentoxide 39.9, iron protoxide 16.5, manganese protoxide 32.6, soda 9.3, water 1.7 = 100.

Anal:-1, 2, H. L. Wells, Am. J. Sc., 39, 214, 1890, upon material of established purity.

P₂O₅ FeO MnO CaO Na₂O K₂O Li₂O H₂O
1. G. =
$$3\cdot143$$
 39·57 13·25 31·58 2·15 7·46 1·52 0·17 1·65 quartz 2·58 = 99·93
40 89 12·96 31·83 2·09 7·37 1·80 0·22 1·63 quartz 0·82 = 99·61

Earlier analyses, 3, 4, by Penfield (quoted by Brush and Dana, l. c.) were made on much less pure material, they show more lime and water and less alkalies.

3, after deduction of impurities, viz., 3.30 p. c. quartz and 6.89 p. c. eosphorite; 4, after deducting 1.89 p. c. quartz, 6.89 p. c. eosphorite.

	P_2O_5	FeO	MnO	CaO	Li ₂ O	Na ₂ O	K_2O	H_2O
3.	39.36	12.40	25.10	13.36	0.03	5.25	0.89	3.86 = 100.25
4.	39.53	11.90	23.96	[14.98]	0.24	4.78	0.73	3.88 = 100

Pyr., etc.—In the closed tube gives water, the first portions of which are neutral, but the last portions react faintly acid; the residue is magnetic. Fuses in the naked lamp-flame, and B.B. in the forceps colors the flame at first green, then greenish yellow; reacts for iron and manganese with the fluxes. Soluble in acids.

Obs.—Occurs at Branchville, Fairfield Co., Conn., intimately associated with eosphorite, triploidite, and other species in nests in a vein of albitic granite. Often disseminated in minute plates through massive eosphorite, giving it a green color; similarly embedded in lithiophilite. Named after Rev. Wm. Dickinson, formerly of Redding.

Ref.—1 L. c., 1878. 2 Id., ibid., 39, 213, 1890.

589. FILLOWITE. G. J. Brush and E. S. Dana, Am. J. Sc., 17, 363, 1879.

Monoclinic. Axes $\check{a}: \check{b}: \dot{c}=1.7303:1:1.4190;\;\beta=89^{\circ}\;50\frac{2}{5}=001\;\land\;100$ E. S. Dana.

d

p

 $100 \land 110 = 59^{\circ} 581,001 \land \overline{1}01 = 39^{\circ} 25',001 \land 011 = 54^{\circ} 491'$

Forms: c(001, 0); $d(201, -2-\bar{\imath})$, $p(\bar{1}11, 1)$.

Angles: $cd = *58^{\circ} 31'$, $cp = *58^{\circ} 40'$, $pp' = *95^{\circ} 23'$, $dp = 95^{\circ} 18\frac{1}{2}'$.

If d be made 100, the axial ratio becomes somewhat similar to that of dickinsonite, as shown below.

Habit pseudo-rhombohedral. In granular crystalline

Cleavage: c nearly perfect. Fracture uneven. Brittle. H. = 4.5. G. = 3.43. Luster subresinous to greasy. Color wax-yellow, yellowish to reddish brown, colorless. Transparent to translucent. Optically biaxial, bisectrix $\perp c$ approx.

Comp.—A hydrous phosphate of manganese, iron, calcium, and sodium, $3R_sP_2O_s + H_2O$. If $R = Mn : Fe(+Ca) : Na_2 = 6 : 2 : 1$, this requires: Phosphorus pentoxide 39.6, iron protoxide 13.4, manganese protoxide 39.5, soda 5.8, water 1.7 = 100.

Anal.—1, Penfield, Am. J. Sc., 17, 363, 1879. 2, H. L. Wells, ib., 39, 215, 1890.

Pyr.—B.B. fuses at 1.5, with intumescence to a black feebly magnetic mass, coloring the flame momentarily pale green, then intensely yellow. In the closed tube a little neutral water. With the fluxes reactions for manganese and iron. Soluble in acids.

Obs.—Occurs sparingly with other manganesian phosphates, especially reddingite and triploidite, in a vein of albitic granite at Branchville, Conn. Named after Mr. A. N. Fillow, of Branchville.

The formula is apparently the same as for dickinsonite, but the ratio for the bases is somewhat different. In form the two minerals are also related, though widely diverse in physical characters. Both are pseudo-rhombohedral, and further we have:

Dickinsonite.	Fillowite.					
$001 \land 100 = 61^{\circ} 30'$	$001 \wedge 100 = 58^{\circ} 31'$					
$001 \wedge \bar{1}11 = 61^{\circ} 8'$	$001 \wedge \bar{1}11 = 58^{\circ} 40'$					
$001 \land 111 = 61' 8'$	$001 \wedge \bar{1}\bar{1}1 = 58^{\circ} 40'$					

Here d of fillowite is made 100, which gives the axial ratio, compared with that of dickinsonite:

Dickinsonite $d: \dot{b}: \dot{b} = 1.7320: 1: 1.1981$ $\beta = 61^{\circ} 30'$ Fillowite 1.7303: 1: 1.1093 $58^{\circ} 31'$

Roselite Group. Triclinic.

590. ROSELITE. Lévy, Ann. Phil., 8, 439, 1824; Edinburgh J. Sc., 2, 177, 1825.

Triclinic. Axes $\check{\alpha}: \check{b}: \dot{c}=0.45360:1:0.65604; \ \alpha=90^{\circ}\ 34', \ \beta=91^{\circ}, \ \gamma=89^{\circ}\ 20'$ Schrauf'.

 $100 \land 010 = 90^{\circ} 39\frac{1}{2}', 100 \land 001 = 89^{\circ} 0\frac{1}{2}', 010 \land 001 = 89^{\circ} 26\frac{2}{3}'.$

Schrauf's lateral axes are exchanged in the above in order to bring out the close approximation to monoclinic symmetry.

$bm = 66^{\circ} 9'$	$c\eta = 23^{\circ} \ 43'$	$bo = 66^{\circ} 0'$	$cS = 57^{\circ} 26'$
$bM = 65^{\circ} 3\frac{1}{2}$	$e\eta = 47^{\circ} 15'$	$b\Omega = 67^{\circ} 22'$	$co = 73^{\circ} 12\frac{1}{9}'$
$mM = 48^{\circ} 47\frac{1}{2}'$	$b\sigma = 69^{\circ} 53'$	$o\Omega = 46^{\circ} 38'$	$cm = 88^{\circ} 52'$
$cd = 79^{\circ} 14'$	$b'S = 69^{\circ} 30'$	$c\sigma = 56^{\circ} 53'$	$cM = 89^{\circ} 20'$
$ce = 23^{\circ} 32'$	$\sigma S = 40^{\circ} 37'$	$c\Omega = 73^{\circ} 29\frac{1}{2}'$	

Crystals small, often complex and, as explained by Schrauf, combined according to a number of twinning laws with embedded tw. lamellæ. Also in druses of crystals and in spherical aggregates.

Cleavage: macrodiagonal. H. = 3.5. G. = 3.5-3.6. Luster vitreous. light to dark rose-red. Transparent to translucent. Axes of elasticity sensibly

parallel to crystallographic axes.

Comp.—(Ca, Co, Mg), As, O₈.2H, O = Arsenic pentoxide 51.4, lime 28.1, cobalt protoxide 12.5, water 8.0 = 100 (Ca : Co = 3 : 1).

Anal.-Winkler, J. pr. Ch., 16, 86, 1877.

Earlier analyses by Schrauf (on minute quantities), l. c., and Winkler (J. pr. Ch., 10, 191, 1874) gave somewhat different results. The crystals from the Rappold mine are darker in color and contain a little more cobalt with G. = 3.585; G. = 3.506 Daniel, Schrauf.

Pyr.—Heated to 100° becomes dark blue and splits up, but regains the red color on cooling.

Fuses B B. easily and on charcoal gives arsenical fumes; after roasting reacts for cobalt with

the fluxes. Dissolves in acids.

Obs.—Early (1824) found at Schneeberg, Saxony, on quartz; later obtained from the same region at the Daniel and Rappold mines. Also reported from Schapbach, Baden.

Named after Gustav Rose (1798–1873).

Ref.—1 Min. Mitth., 137, 1874; earlier but incomplete observations were made by Lévy and Haidinger, cf. Schrauf.

591. BRANDTITE. A. E. Nordenskiöld, Öfv. Ak. Stockh., 45, 418, 1888. Triclinic. In form near roselite.

Forms1:	$e (023, \frac{2}{3}-\tilde{i}')$	$\phi (0\bar{4}3, \frac{4}{8}-\tilde{i})$	σ (111, 1')	S (111, '1)

c (001. O)	$n(0\bar{2}3.42.2)$			

Approximate measured angles: $bc = 90^{\circ}$ 35', $b\eta = 66^{\circ}$ 55', $b\phi = 49^{\circ}$ 46', $bf = 47^{\circ}$ 2', $be = 65^{\circ} 7', bS = 69^{\circ} 52'.$

In crystals, prismatic by development of the brachydomes, and with c largely

developed. Faces c striated | edge c/η . Twins common with c as tw. pl. Crystals united in radiated groups and in rounded or reniform aggre-

H. = 5-5.5. G. = 3.671-3.672. Luster vitreous.

Colorless to white. Transparent to translucent. Comp.—Ca, MnAs, Os + 2H, O or 2CaO.MnO.As, Os, 2H, O = Arsenic pentoxide 51.3, manganese protoxide 15.8, lime 24.9, water 8.0 = 100.

Anal.-G. Lindström, G. För. Förh., 13, 123, 1891.

$$As_2O_6$$
 P_2O_6 MnO PbO FeO CaO MgO H_2O 50.48 0.05 14.03 0.96 0.05 25.07 0.90 8.09 Cl 0.04, insol. 0.04 = 99.71

Pyr., etc.—Fuses rather easily to a brown bead; in the closed tube gives off water without decrepitation; arsenical fumes on charcoal. Dissolves in hydrochloric and nitric acids.

Obs.—Found at the Harstig mine, near Pajsberg, Wermland, Sweden. Associated with barite, calcite. caryopilite, sarkinite. and also crystallized native lead.

Named after the Master of the Mint, Georg Brandt (d. 1768).

Ref.—1 Nordenskiöld, quoted by Lindström, l. c.

592. FAIRFIELDITE. G. J. Brush and E. S. Dana, Am. J. Sc., 17, 359, 1879. Leucomanganit Sandberger, Jb. Min., 370, 1879; 1, 185, 1885.

Axes $\check{a}: \bar{b}: \dot{c} = 0.2797: 1: 0.1976; \alpha = 102° 8\frac{2}{3}', \beta = 94° 33\frac{1}{3}',$ Triclinic. $\gamma = 77^{\circ} 195' \text{ E. S. Dana.}$ $100 \land 010 = *102^{\circ} 0', 100 \land 001 = *88^{\circ} 0', 010 \land 001 = 78^{\circ} 33$.

Forms:
$$c\ (001,\ 0)$$
 $m\ (110,\ I')$ $M\ (1\bar{1}0,\ I')$ $q\ (112,\ \frac{1}{2}')$ $a\ (100,\ i\cdot\bar{i})$ $g\ (320,\ i\cdot\bar{3}')$ $n\ (230,\ i\cdot\bar{3}')$ $r\ (113,\ \frac{1}{2}')$ $p\ (111,\ 1')$ $s\ (1\bar{4}1,\ '4\cdot4)$

The relation in form between fairfieldite and roselite-brandtite is not clear; the fairfieldite measurements leave much to be desired.

In prismatic crystals with a, b largely developed. Usually in foliated to

lamellar crystalline aggregates; occasionally curved, foliated, or fibrous; in radiating masses.

The planes of light-vibration intersect a in lines making angles of 40° and 50° with the obtuse edge a/b; in the latter, an optic axis is visible toward the edge named. The planes intersect b in lines making angles of 10° and 80° with the edge a/b, the second axis visible in this

Comp.—A hydrous phosphate of calcium and manganese, Ca₂MnP₂O₈ + 2H₂O = Phosphorus pentoxide 39.4, manganese protoxide 19.6, lime 31.0, water 10.0=100. Iron replaces a little of the manganese.

Anal.—1, 2, S. L. Penfield, Am. J. Sc., 17, 359, 1879; 1, clear transparent, filling cavities in reddingite; 2, massive, somewhat friable. 3, H. L. Wells, ib., 39, 212, 1890.

	G.	P2O5	MnO	FeO	CaO	Na ₂ O	K ₂ O	H ₂ O	quartz	
1.		38.39	15.55	5.62	28.85	0.73	0.13	9.98	1.31 =	100.56

3.	3.07	37.69	17.40	3.42	30.02	-	-	9.81	1.66 =	100

Pyr., etc.—B.B. glows, blackens, and fuses at 4.15 to a dark yellowish brown mass, coloring the flame pale green, with faint reddish yellow streaks on the upper edge. Reactions for iron and manganese with the fluxes. In the closed tube gives off neutral water; turns first yellow,

then dark brown, and becomes magnetic. Soluble in acids.

Obs.—Occurs with other manganesian phosphates in a vein of albitic granite at Branchville, Fairfield Co., Conn. Also at Rabenstein, near Zwiesel, Bavaria (leucomanganite). In composi-

tion fairfieldite is analogous to roselite and more closely to brandtite.

593. MESSELITE. W. Muthmann, Zs. Kr., 17, 93, 1889.

Triclinic. In indistinct minute tabular crystals, with $am = 42^{\circ}-43^{\circ}$; often in stellate aggregates.

H = 3-3.5. Colorless to brownish. Transparent to translucent. Extinction

on a inclined 20° to the edge a/m; an optic axis visible through a.

Comp.—(Ca,Fe),P,O, + 2½H,O = Phosphorus pentoxide 38·3, iron protoxide 19·4, lime 30·2, water 12·1 = 100. Here Ca: Fe = 2:1. With 2H,O the composition would correspond to brandtite and fairfieldite.

Anal.-Muthmann, l. c.

P2Os	FeO	MnO	CaO	MgO	H ₂ O
37.72	15.63	tr.	31.11	1.45	12.15 insol. $1.40 = 99.46$

Gives off water when heated and becomes dark brown to black.

Obs.—Found near Messel in Hesse, in a coal mine; the crystals occur in a bituminous clay slate.

594. REDDINGITE. G. J. Brush and E. S. Dana, Am. J. Sc., 16, 120, 1878; ib., 17, 365, 1879.

Orthorhombic. Axes $\ddot{a}: \ddot{b}: \dot{c} = 0.8678:1:0.9486$ E. S. Dana¹ $100 \land 110 = 40^{\circ} 57', 001 \land 101 = 47^{\circ} 32\frac{5}{6}', 001 \land 011 = 43^{\circ} 29\frac{1}{6}'.$ Forms: $b(010, i-\bar{i}), r(112, \frac{1}{2})^2, s(223, \frac{2}{3})^2, p(111, 1), t(221, 2)^2, q(212, 1-\bar{2}).$

	• At 1	100° loss 13 p. c		b Do.	11.6.		

Obs.-From Riechelsdorf and from Freiberg. At Joplin, Mo. The name alludes to the magnesia present, from πικρός, bitter.

596. TRICHALCITE. Trichalcit Herm., J. pr. Ch., 73, 212, 1858.

In radiated groups, columnar; also in dendritic forms.

H. = 2.5. Luster silky. Color verdigris-green.

Comp.—Cu, As, O, + 5H, O = Arsenic pentoxide 41.3, cupric oxide 42.6, water 16.1 = 100.

Anal.—Hermann, l. c.

As2O, 38.73 P2O5 0.67 CuO 44.19 $H_2O 16.41 = 100$

Pyr., etc.—Heated decrepitates, yields much water, and becomes dark brown. B.B. on charcoal fuses in the outer flame to a pearl, and in the inner yields a bead of copper. Dissolves easily in cold hydrochloric acid.

Obs.—From the Turginsk copper mine, or Berezov, on tetrahedrite. Resembles tyrolite.

LAVENDULAN Breithaupt, J. pr. Ch., 10, 505, 1837. Lavendulite.

Amorphous, with a greasy luster, inclining to vitreous. H. = 2·5-3. G. = 3·014 Br. Color lavender-blue. Streak paler. Translucent. Fracture conchoidal.

Contains, according to Plattner, arsenic, cobalt, nickel, and copper. Goldsmith (Proc. Acad. Philad., 192, 1877) obtained on an impure sample from Chili, after deducting impurities (11.6 insol.):

NiO 1.35 As2O. 46.89 CuO 40·10 CoO 2.51 $H_2O 9.13 = 99.98$

The formula arrived at is R₃As₂O_{8.3}H₂O, but the material was too impure to make the conclusion very definite. B.B. fuses easily. Soluble in warm hydrochloric acid. Occurs with cobalt and other ores at Annaberg, Saxony, as the result of their alteration.

Similarly with cobalt ores from Chili.

CHLOROTILE. Chlorotil Frenzel, Min. Mitth., 42, 1875; Jb. Min., 517, 1875.

In minute capillary crystals of prismatic habit (orthorhombic), also fibrous and massive; soft. Color in the mass pale green to emerald-green, microscopic crystals colorless. Transparent. Composition asserted to be Cu₃As₂O₈ + 6H₂O = Arsenic pentoxide 39.9, cupric oxide 41.3, water 18.8 = 100. An approximate analysis gave: As₂O₅ 41, CuO 41, H₂O 18 = 100. Occurs with aragonite and wapplerite, at Schneeberg, and with quartz and scheelite at Zinnwald.

Vivianite Group. Monoclinic.

597. VIVIANITE. Bloa Järnjord, Naturligit Berlinerblätt, Calx Martis phlogisto juncta, etc., Cronst., 182, 1758. Cæruleum Berolinense nativum Born., Lithoph., 1, 136, 1772. Crystals prismatic, sometimes flattened $\parallel a$; prismatic faces vertically striated. Crystals often in stellate groups. Often reniform and globular. Structure divergent, fibrous, or earthy; also in-

crusting.

Cleavage: b highly perfect; a in traces; also fracture fibrous nearly $\pm c$. Flexible in thin laminæ; sectile. H.=1·5-2. G.=2·58-2·68. Luster, b pearly or metallic pearly; other faces vitreous. Colorless when unaltered, blue to green, deepening on exposure. Streak colorless to bluish white, soon changing to indigo-blue; color of the dry powder often liverbrown. Transparent to translucent; becoming opaque on exposure. Pleochroism strong.

Figs. 1, 2, Cornwall, Rath.

Optically +. Ax. pl. and Bx_o \perp b. Bx_{a.r} \wedge b = 61° 22'. Bx_{a.y} \wedge b = 61° 28'. Bx_{a.bl} \wedge b = 61° 36'. Dispersion ρ < v small, also horizontal inconsiderable. Axial angles, Dx.

Comp.—Hydrous ferrous phosphate, Fe, $P_2O_8 + 8H_2O = Phosphorus$ pentoxide 28.3, iron protoxide 43.0, water 28.7 = 100.

Many analyses show the presence of iron sesquioxide due to alteration; see 5th Ed., p. 557. Colorless crystals from Delaware gave Fisher (Am. J. Sc., 9, 84, 1850): P₂O₅ 27·17, FeO 44·10, H₂O 27·95, SiO₂ 0·10 = 99·32.

Pale bluish green crystals from Cornwall (measured by Rath, above) gave Flight 1.13 Fe₂O₃; a dark blue variety contained 9.17 Fe₂O₂ and dark brown crystals 5.08 Fe₂O₃, Ch. News, 22,

260, 1870.

A peculiar variety of vivianite has been described by W. L. Dudley (Am. J. Sc., 40, 120, 1890) forming "blue roots" embedded in clay some two feet below the water surface near Eddyville, Ky. The roots were from ½ to 2 cm. thick and 6 to 12 in length, and the woody fiber had been nearly replaced by the vivianite. An analysis of material purified by washing and decanta tion and dried for twelve hours over sulphuric acid gave:

Pyr., etc.—In the closed tube yields neutral water, whitens, and exfoliates. B.B. fuses at 1.5, coloring the flame bluish green, to a grayish black magnetic globule. With the fluxes reacts for iron. Soluble in hydrochloric acid.

Obs.—Occurs associated with pyrrhotite and pyrite in copper and tin veins; sometimes in narrow veins with gold, traversing gray-wacke; both friable and crystallized in beds of clay, and sometimes associated with limonite, or bog iron ore; often in cavities of fossils or buried

bones.

At St. Agnes in Cornwall transparent indigo crystals have been found, 1 inch in diameter and 2 in. long, in pyrrhotite; at Wheal Falmouth, and near St. Just; in Devonshire, near Tavistock: at Bodenmais and the gold mines of Verespatak in Transylvania, in crystals; on the promontory of Kerch in the Black Sea, in large indistinct crystals in the interior of shells. The earthy variety, sometimes called blue-iron earth or native Prussian blue (Fer azuré), occurs in Greenland, Syria, Carinthia, Cornwall, etc. The friable varieties in bog iron ore in several peat swamps in the Shetland Isles, at Ballagh in the Isle of Man, accompanying sometimes the horns of the elk

and deer, and near an old slaughter-house in Edinburgh. At Cransac, France, in crystals

formed after the burning of a coal mine; at Anglar, a massive form (anglarite).

In N. America, it occurs in N. York, at Harlem, in crystals accompanying stilbite and feld-spar in fissures in gneiss. In New Jersey, at Imleytown, in dark blue crystals; at Allentown, Monmouth Co., in considerable abundance, both crystallized, in nodules, and earthy, embedded in bog iron ore, and associated with clays; at Mullica Hill, Gloucester Co. (mullicite), in considerable accompanying stilbite and feld-spar in fibers or accompanying stilbite and feld-spar in fibers or accompanying and earthy, embedded in bog iron ore, and associated with clays; at Mullica Hill, Gloucester Co. (mullicite), in cylindrical masses, consisting of divergent fibers or acicular crystals; at Franklin, occasionally; it often fills the interior of belemnites and other fossils in the ferruginous sand formation. Also in Delaware, 4 m. W. of Cantwell's Bridge, and near Middletown, in the Green Sand, in fine large crystals which are colorless when first obtained, containing only iron protoxide; near Cape Henlopen, in Sussex Co. In Maryland, in the north part of Somerset and Worcester Cos. In Virginia, with bog ore in Stafford Co., and 8 or 10 m. from Falmouth, with gold and galena. In Kentucky, near Eddyville, embedded in clay (cf. above). In California, an earthy form in cavities in asphaltum in Los Angeles Co.; crystal'ized at Camptonville, Yuba Co. In Canada,

with limonite at Vaudreuil, abundant.

Named by Werner after J. G. Vivian, an English mineralogist who discovered the specimens in Cornwall. Werner was not aware of their identity with the Blaueisenerde when he gave the

Alt.—Becomes altered, as above stated, through the oxidation of the iron. Tschermak obtained (Ber. Ak. Wien, 49 (1), 340, 1864) for an altered vivianite in crystals from a cabinet in Vienna: P₂O₅ 30·5, Fe₂O₅ 55·0, Na₂O 1·5, H₂O 14·0 = 101. G. = 2·95; luster metallic-pearly; color on face of cleavage pinchbeck-brown, elsewhere blackish brown; streak ocher-yellow.

Ref.—¹ Cornwall, Pogg., 136, 405, 1869; earlier angles are incorrect. ⁹ Mlr., Min., p. 500, 1852; Rath, l. c. ⁴ Dx., on French crystals, N. R., 184, 1867. ⁵ Mgg., Jb. Min., 1, 53, 1884.

598. SYMPLESITE. Breithaupt, J. pr. Ch., 10, 501, 1837.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=0.7806:1:0.6812; \beta=72^{\circ}43'=001 \land 100$ Krenner'.

 $100 \land 110 = 36^{\circ} 42', 001 \land 101 = 33^{\circ} 29\frac{1}{2}, 001 \land 011 = 33^{\circ} 2\frac{1}{2}'.$

Forms¹: a (100, i-i), b (010, i-i), c (001, O); m (110, I); r (013, $\frac{1}{3}$ -i).

Angles: $mm''' = *73^{\circ} 24'$, $rr' = 24^{\circ} 28'$, $br = *77^{\circ} 46'$, $mr = *68^{\circ} 56'$.

In small prismatic crystals sometimes tabular ||b|; faces m vertically striated;

in radiated spherical aggregates.

Cleavage: b perfect. Fracture uneven. Brittle. H. = 2.5 nearly. G. = 2.957. Luster of cleavage-face pearly; elsewhere vitreous. Color pale indigo, inclined to celandine-green; sometimes between leek- and mountain-green. Streak bluish white. Subtransparent to translucent.

Pleochroic: r yellowish green to oil-green, | b colorless to greenish yellow, a bluish green to blue. Optically -. Ax. pl. $\perp b$ and inclined to $\ell + 31^{\circ}$ 48'.

 $Bx_a \perp b$. $2H_{a,y} = 107^{\circ} 28'$.

Comp.—Hydrous arsenate of iron, probably Fe, As, $O_s + 8H_2O = Arsenic$ pentoxide 39.0, iron protoxide 36.6, water 24.4 = 100. The analysis gives $9H_2O_s$, which requires: Arsenic pentoxide 37.8, iron protoxide 35.5, water 26.7 = 100.

Anal.—Boricky, Vh. Min. Ges., 3, 98, 1868, deducting 7.7 p. c. quartz.

FeO H₂O As2Os Hüttenberg G. = 2.96437.84 34.73 27.43 = 100

Pyr., etc.—In the closed tube yields much water; at a high temperature some arsenous acid sublimes, imparting an acid reaction to the water, and giving a black magnetic residue. B.B. in the forceps infusible, but colors the outer flame light blue (arsenic), and becomes black and magnetic. On charcoal gives a strong arsenical odor. With the fluxes reacts for iron, and gives also traces of manganese and sulphuric acid (Plattner).

Obs.—Occurs at Lobenstein in Voigtland, with siderite; at Hüttenberg, Carinthia; sparingly with pharmacosiderite at Pisek, Bohemia (Vrba). Also with quartz in cavities in hornstone at Felsöbánya.

Named from $\sigma \dot{\nu} \nu$ and $\pi \lambda \eta \sigma i \dot{\alpha} \xi \epsilon i \nu$, to bring together, in allusion to its relation to other

599. BOBIERRITE. Phosphate de Magnésie tribasique et hydraté Bobierre, Les Mondes, 691, April 1868. Bobierrite Dana, Min., 595, 1868.

Monoclinic; in minute six-sided prismatic crystals, with a (100), b (010), m (110) and a terminal plane c (001)? inclined 77° to a. Forms crystalline agglomerations, looking like white spots in the guano in which it is embedded. Also massive.

Cleavage: clinodiagonal. Colorless to white. Optically +. Ax. pl. \(\perp \)?

Bx_a inclined 34° to a. 2E = 125° approx. Dispersion \(\rho < v\) weak, Lcx.

Comp.—Hydrous magnesium phosphate, Mg₂P₂O₈ + 8H₂O = Phosphorus pentoxide 29.5, magnesia 35.0, water 35.5 = 100.

Anal.-A. Lacroix, C. R., 106, 631, 1888.

P2O 29.97 MgO 34.59 $H_2O 35.38 = 99.94$

Insoluble in water, but easily soluble in acids without effervescence. Obs.—From the guano of Mexillones, on the Chilian coast.

600. HŒRNESITE. Hörnesit Haid., Vh. G. Reichs., 41, 1860; Ber. Ak. Wien, 40, 18, 1860.

Monoclinic. In crystals resembling gypsum in habit, giving the angles: $mm''' = 73^{\circ}$, $zz'(?) = 28^{\circ}$ (cf. vivianite, p. 814). Also columnar; stellar-foliated. Cleavage: clinodiagonal, perfect. H. = 1. G. = 2.474. Luster of cleavage pearly. Color snow-white. Folia transparent, flexible.

Comp.—Hydrous magnesium arsenate, Mg, As, O, +8H, O = Arsenic pentoxide 46 6, magnesia 24.3, water 29.1 = 100.

Anal.-Hauer, quoted by Haidinger, l. c.

As2O5 46.33 · MgO 24.54 $H_2O 29.07 = 99.94$

Pyr., etc.—In a glass tube gives much water. B.B. fuses easily, and on charcoal affords the odor of arsenic. Insoluble in water and easily soluble in acids.

Obs.—First distinguished by Kenngott in minerals from the Banat, Hungary (vicinity either of Cziklowa or Orawitza), in the Imperial Mineral Cabinet at Vienna. Occurs in a coarsely granular calcite, containing also some garnets.

Named after Dr. Hörnes, of the Imperial Cabinet.

601. ERYTHRITE. Kobold-Blüthe Brückmann, Magnalia, 161, etc., 1727. Kobolt Blomma, Flos Cobalti [the cryst.], Koboltbeslag [impure earthy], Cobalti minera colore rubro, etc., Wall., Min., 234, 1747. Rhodoise Huot, 1, 313, 1841.

Monoclinic. Axes $\dot{a}:\dot{b}:\dot{c}=0.75:1:0.70;\ \beta=75^{\circ}$ approx., Brezina.

Forms²: $a(100, i-i), b(010, i-i); m(110, I), w(\bar{1}01, 1-i); r(\bar{1}12, \frac{1}{2}), v(\bar{1}11, 1).$

Angles nearly as with vivianite, measured: $m'v = 45^{\circ} 48'$, $vw = 29^{\circ} 43'$, $rr' = 34^{\circ} 12'$.

Crystals prismatic and vertically striated. Also in globular and reniform shapes, having a drusy surface and a columnar structure; sometimes stellate. Also

pulverulent and earthy, incrusting.

Cleavage: b highly perfect; a, w indistinct. Thin laminæ flexible in a direction $\perp b$ and nearly $\perp c$. Sectile. H. = 1·5-2·5; least on b. G. = 2·948. Luster of b pearly; other faces adamantine, inclining to vitreous; also dull and earthy. Color crimson- and peach-red, sometimes pearl-gray or greenish gray; red tints incline to blue \(\preceq\) b. Streak a little paler than the color; the dry powder deep lavender-blue. Transparent to subtranslucent.

Optically -. Ax. pl. and Bx_a \(\perp b\). Axial angles, Dx. 3:

Var .- 1. Crystallized and foliated. 2. Earthy. The latter is the earthy cobalt bloom (Kobult beschlag Germ., Rhodoise Huot.).

Comp.—Hydrous cobalt arsenate, $Co_*As_*O_* + 8H_*O = Arsenic pentoxide 38.4$, cobalt protoxide 37.5, water 24.1 = 100. The cobalt is sometimes replaced by nickel, iron, and calcium.

Anal.—1-3, Kersten, Pogg., **60**, 251, 1843. **4**, Lindaker, Vogl's Joach., 1857. 5, Petersen, Pogg., **134**, 86, 1868.

	As ₂ O ₅ CoO	NiO	FeO C	aO H ₂ O	
1. Schneeberg	38.43 36.52	tr.	1.01 .	- 24.10	= 100.06

5. Wittichen	38.10 30.36	3.71	3.04 t	r. 24.79	0 = 100

Pyr., etc.—In the closed tube yields water at a gentle heat and turns bluish; at a higher heat gives off arsenic trioxide, which condenses in crystals on the cool glass, and the residue has a dark gray or black color. B.B. in the forceps fuses at 2 to a gray bead, and colors the flame light blue (arsenic). B.B. on charcoal gives an arsenical odor, and fuses to a dark gray arsenide, which with borax gives the deep blue color characteristic of cobalt. Soluble in hydrochloric acid, giving a rose-red solution.

The earthy cobalt bloom, of a peach-blossom color (Kobaltbeschlag), is shown by Kersten to be cobalt bloom, with some free arsenic trioxide. He obtained, ibid., p. 262:

	As ₂ O ₃	As2Os	CoO	FeO	H ₂ O	
 Schneeberg Annaberg 		19·10 20·00	16.60 18.30	2.10		NiO,SO_3 $tr. = 100.70$ NiO,CaO,SO_3 $tr. = 98.53$

Obs.—Occurs at Schneeberg in Saxony, in micaceous scales, stellately aggregated; in brilliant specimens, consisting of minute aggregated crystals, at Saalfeld in Thuringia; also at Riechelsdorf in Hesse; Wolfach and Wittichen in Baden; Auerbach on the Bergstrasse; Modum in Norway. The earthy peach-blossom varieties have been observed at Allemont in Dauphine; in Cornwall, at the Botallack mine, St. Just, etc.; near Alston in Cumberland; near Killarney in Ireland. A perfectly green variety occurs at Platten in Bohemia, and sometimes red and green tinges have been observed on the same crystals.

In the U. S., in Penn., sparingly near Philadelphia. In Nevada, at Lovelock's station. In

California, Los Angeles Co., and at the Kelsey mine, Compton.

Named from epubpos, red.

Ref.—¹ Min. Mitth., 19, 1872. ² Mgg., Jb. Min., 1, 53, 1884. ³ Dx., N. R., 132, 1867, Bull. Soc. Min., 1, 76, 1878.

3. Laurium	$G_{\cdot} = 3.11$	41.40	28.72	tr.	2.01	4.64	23.11	=	99.88

Pyr., etc.—In the closed tube yields water and becomes grayish yellow. B.B. in R.F.

infusible; on charcoal gives arsenical fumes.

Obs.—From the Sierra Cabrera, Spain, in a gangue of brown spar, which is connected with the Mountain Limestone and argillaceous schist; similarly associated at the zinc mines of Laurium, Greece. Results from the alteration of arsenides of nickel and cobalt. Ref.—1 Bull. Soc. Min., 1, 75, 1878.

604. KÖTTIGITE. Zinkarseniat Otto Kõttig, J. pr. Ch., 48, 183, 1849; Naumann, ib., p. 256. Köttigite Dana, Min., 487, 1850.

Monoclinic, isomorphous with vivianite, $bm = 53^{\circ}$, $an(100 \land 101) = 39^{\circ}$ Groth¹.

Massive, or in crusts, with crystalline surface and fibrous structure.

Cleavage: clinodiagonal, perfect. H. = $2\cdot5-3$. G. = $3\cdot1$. Luster of surface of fracture silky. Color light carmine- and peach-blossom-red. Streak reddish white. Translucent to subtranslucent. An axis of elasticity in b inclined 37° to c. Comp.—Hydrous zinc arsenate, Zn,As,O, + 8H,O = Arsenic pentoxide 37.3, zinc oxide 39.4, water 23.3 = 100. Cobalt and nickel replace part of the zinc.

Anal.-Köttig, l. c.

As₂O₅ [37 17] ZnO 30.52 CoO 6.91 NiO 2.00 CaO tr. $H_2O 23.40 = 100$

Pyr., etc.—In the closed tube gives much water, and at a higher temperature a faint crystalline sublimate of arsenic trioxide. B.B. fuses easily, coloring the flame blue; on charcoal in R.F. gives copious fumes of arsenic and coats the coal with zinc oxide; with soda the coating is much more marked, and is yellow while hot and white on cooling; this moistened with cobalt solution and heated in O.F. assumes a green color. With borax and salt of phosphorus gives a cobalt-blue glass.

Obs.—Occurs with smaltite at the cobalt mine Daniel, near Schneeberg. The color is owing

partly to the arsenate of cobalt in the mineral.

Ref.—1 Min.-Samml. Strassb., 166, 1878.

605. RHABDOPHANITE. Rhabdophane Lettsom, Zs. Kr., 3, 191, 1878; Proc. Cryst. Soc., 105, 1882; L. de Boisbaudran, C. R., 86, 1028, 1878. Scovillite G. J. Brush and S. L. Penfield, Am. J. Sc., 25, 459, 1883. Skovillit.

Massive, small mammillary, globular with indistinct fibrous structure. Also as

an incrustation, botryoidal or stalactitic, with radiated fibrous structure.

Fracture uneven. H. = 3.5. G. = 3.94-4.01 scovillite. Luster greasy. Color brown, pinkish or yellowish white. Translucent. Optically uniaxial, positive, Bertrand'. Shows the spectroscopic absorption-bands for didymium and erbium.

Comp.—A hydrous phosphate of metals of the cerium and yttrium groups, RPO, + H₂O or R₂O₃.P₂O₅.2H₂O. Assuming the relation of yttrium to cerium metals as 1:4, the percentage composition is: P.O. 28.4, (Y,Er), O. 11.1, (La,Di), O. 53.3, $H_{\bullet}07.2 = 100.$

Anal.—1, Hartley, J. Ch. Soc., 41, 210, 1882, as recalc. by Brush and Penfield. 2, Brush and Penfield, l. c. and ibid., 27, 200, 1884.

(Y,Er)2O3 (La,Di)2O3 H₂O P2O5 7.99 26.26 = 1001. Rhabdophanite 9.93 53.82 $Fe_2O_3 0.29 = 100$ 2. Scovillite 29.10 6.86

The original analysis of scovillite (Penfield) gave: P₂O₅ 24·94, (Y,Er)₂O₃ 8·51, (La,Di)₂O₅ 55·17, Fe₂O₃ 0·25, combined H₂O 5·88, H₂O lost at 100° 1·49, CO₂ 3·59 = 99·83. The authors conclude that the CO₂ is due to an admixed mineral having the composition R₂O₃.3CO₂.3H₂O, and deducting this the result above given is obtained. Hartley obtained, excluding 5·69 impurities: P₂O₅ 24·64, (Ce,La,Di,Y)₂O₃ 61·69, H₂O combined 7·50, Al₂O₃, Fe₂O₃, CaO, MgO with some P₂O₅ 1·93, SiO₂ 3·76 = 99·52; another determination gave: Ce₂O₂ 23·19, Y₃O₃ 2·09.

Pyr., etc.—B.B. infusible. With salt of phosphorus and borax gives a rose-colored bead in both flames. Soluble in hydrochloric acid.

Obs.—Rhabdophanite is known only in a few specimens obtained from Cornwall prior to 1820; it was taken for brown sphalerite, some varieties of which it resembles rather closely. Named from $\rho\alpha\beta\delta\sigma$, rod, and $\dot{\phi}\alpha i\nu\epsilon\sigma\theta\alpha\iota$, to appear, in allusion to the absorption-bands seen

Scovillite occurs sparingly in thin pinkish or yellowish incrustations on limonite and

pyrolusite at the Scoville ore bed in Salisbury, Conn.

Ref.—1 Bull. Soc. Min., 3, 58, 1880.

606. CHURCHITE. A new British mineral containing cerium, A. H. Church, Ch. News, 12, 121, 1865. Churchite C. G. Williams, ib., 183. Hydrated cerous phosphate Church, J. Ch. Soc., 18, 259, 1865.

Monoclinic? In fan-like aggregations of minute crystals. Also radiated columnar.

Cleavage perfect in one direction. Fracture conchoidal. G .= 3.14 approx. Luster vitreous; pearly on cleavage plane. Color pale smokegray, tinged with flesh-red. Streak white. Transparent to translucent. Doubly refracting.

Comp.—A hydrous phosphate of cerium (didymium) and calcium, RPO₄+2H₂O or R₂P₂O₄ + 4H₂O. If Ce₂O₃: CaO = 5:3, the formula requires: Phosphorus

pentoxide 27.5, cerium oxide 53.2, lime 5.4, water 13.9 = 100.

Anal.-Church, l. c.

Ce2O3 H₂O P2O5 CaO 5.42 14.93 F tr. = 100.7028.48

C. G. Williams (l. c.) has proved churchite to contain didymium.

Pyr., etc.—B.B. in tube yields acid water, becoming opaque. In outer flame becomes reddish, and difficultly fusible With borax in outer flame gives a bead which is orange-yellow and opaline while hot, and colorless or slightly amethystine when cold.

Obs.—Occurs at Cornwall, in a copper lode, as a coating one-tenth of an inch thick on quartz

and argillaceous schist.

Named after Prof. A. H. Church, of Cirencester, England.

Scorodite Group. Orthorhombic.

5. Peru, e	arthy		50.0	35.7	14.5	=	100.3

An Iron-sinter (Eisensinter, Arseniksinter) from Nerchinsk, analyzed by Hermann, l. c., is an amorphous scorodite.

Pyr., etc.—In the closed tube yields neutral water and turns yellow. B.B. fuses easily, coloring the flame blue. B.B. on charcoal gives arsenical fumes, and with soda a black magnetic scoria. With the fluxes reacts for iron. Soluble in hydrochloric acid.

Obs.—Found of brown color in the granitic mountains of Schwarzenberg, in Saxony, associated with arsenopyrite; at Dernbach, Nassau; at Lölling, near Hüttenberg in Carinthia, with löllingite; at Chanteloube, near Limoges; at Nerchinsk, Siberia, in fine crystals; also as an amorphous crust or *iron-sinter* on beryl, topaz, and quartz; leek-green, in the Cornish mines, coating cavities of ferruginous quartz; at the Minas Geraes, in Brazil; in Popayan; Dist. Lucma, Peru, in an earthy form; at the gold mines of Victoria, in Australia, in quartz with arsenopyrite and gold.

Occurs in minute crystals and druses of leek-green and greenish white colors, near Edenville, N. Y., with arsenopyrite, iron-sinter, etc., in white limestone; in Cabarrus Co., N. C., on G. Luderick's farm, in aggregations of greenish white, brownish green and leek-green crystals; coating cavities of quartz and limonite with copper ores and pyrite. In Northern Alabama with arsenopyrite. In Utah, Tintic district, at the Mammoth mine on enargite associated with pharmacosiderite and various copper arsenates; at the Horn Silver mine, Utah. As a thin amorphous incrustation on the siliceous sinter of the geysers and hot springs of the Yellowstone region; thus at the Joseph Coat Springs and elsewhere (Hague, Am. J. Sc., 34, 171, 1887); also at the Steamboat Springs, Nevada.

The cobalt-scorodite of Lippmann (l. c.) occurs in bluish crystals with quartz and hypo-

chlorite, at Schneeberg; it has not been analyzed.

Named from σκοροδον, garlic, alluding to the odor before the blowpipe.

Alt.—Scorodite occurs altered to limonite.

Artif.—Formed in crystals like the natural mineral (G. = 3.28) by the action of arsenic acid on metallic iron in sealed tubes at a high temperature, Verneuil and Bourgeois, Bull. Soc. Min.,

3, 32, 1880.

Ref.—¹ Dernbach, Nassau, Jb. Min., 396, 1876. ² Dx., Ann. Ch., Phys., 10, 402, 1844; cf. Mlr., Min., p. 411, 1852, Kk., Min. Russl., 6, 307, 1874, Rath, l. c. ³ Erem., Ural, Vh. Min. JOGYNAITE N. Nordenskiöld. An earthy mineral, formed from the decomposition of arsenopyrite, and referred to scorodite. Occurs with beryl from the Adun-Chalon Mts., Nerchinsk, Siberia. See v. Koksharov, Bull. Acad. St. Pet., 19, 571, 1873.

608. STRENGITE. A. Nies, Jb. Min., p. 8, 1877.

Orthorhombic. Axes $\check{a}: \dot{b}: \dot{c} = 0.86517:1:0.98272$ Bruhns and Busz'. $100 \land 110 = 40^{\circ} 52', 001 \land 101 = 48^{\circ} 38\frac{1}{3}', 001 \land 011 = 44^{\circ} 30'.$

Forms¹: $a (100, i-\bar{\imath}), k (430, i-\frac{\pi}{3})^2, d (120, i-\bar{2}); f (302, \frac{3}{2}.\bar{\imath})^2; g (805, \frac{8}{5}.\bar{\imath})^2, e (012, \frac{1}{2}.\bar{\imath})^2, p (111, 1),$ π (15·12·10, $\frac{3}{2}$ - $\frac{5}{4}$)²?.

Crystals rare; in habit and angle near scorodite; also prismatic by extension of macrodomes. Generally in spherical and botryoidal forms, aggregates with

d α p

radiated fibrous structure, and drusy surface.

Cleavage: a imperfect. H. = 3-4. G. = 2.87. Luster vitreous, brilliant. Color peach-blossom-red, carmine-red, and various other shades; sometimes nearly colorless. Streak yellowish white. Translucent to transparent. Bx $\perp c$. Ax. angle 60° approx., Bruhns & Busz³.

Eleonore M., Nies. Virginia, Ayres. Comp.—Hydrous ferric phosphate, FePO₄ + 2H₂O or Fe₂O₃. P₂O₅. 4H₂O = Phosphorus pentoxide 38·0, iron sesquioxide 42·7, water 19·3 = 100.

Anal.—1, Nies, l. c. 2, Koenig, Proc. Acad. Philad., 277, 1877.

	P2O5	Fe ₂ O ₃	H_2O	
 Eleonore Mine Rockbridge Co., Va. 	37·82 39·30	43.65 42.30		insol. 0.15 = 101.23 = 101.47

Pyr., etc.—B.B. fuses readily to a black shining bead, coloring the flame bluish green.

Iron reaction with borax. Dissolves easily in warm hydrochloric acid; in nitric acid insoluble.

Obs.—Occurs with cacoxenite, at the Eleonore iron mine on the Dünsberg, near Giessen; also in colorless crystals with eleonorite, at the Rothläufchen mine, near Waldgirmes, in the same region; also the Jakobssegen mine near Bremthal in the Taunus. In distinct crystals, with the distinct crystals, and the distinct crystals, and the distinct crystals. pink to red, in cavities in dufrenite, from Rockbridge Co., Va., sometimes like f. 1 in habit,

pink to red, in cavities in dufrenite, from Rockbridge Co., Va., sometimes like f. 1 in habit, also f. 2. Named after Prof. A. Streng, of Giessen.

Ref.—1 Zs. Kr., 17, 558, 1890. The results of Nies, l. c., were deduced from 111 \wedge $\bar{1}11$ = 77° 46′, 111 \wedge 1 $\bar{1}1$ = 64° 52′, 120 \wedge 1 $\bar{2}0$ = 61° 24′.

³ E. F. Ayres, priv. contr. The crystals examined were in part like f. 1 with also another brachypyramid, s in part (f. 2) prismatic $\|$ axis \bar{b} . The last named are like the crystals figured and imperfectly described by Koenig, and formed the material of anal. 2. The suggestion, therefore, that they belonged to phosphosiderite (cf. f. 1, below) does not seem applicable unless, indeed, the latter is merely a form of strengite. The angles measured by Koenig and Ayres are as follows: bk = 58° K, 57° 52′ A; bd = 30° 29′ A; ff'''' = 62° 35′ K; gg''' = 57° 40′ K, 58° 24′ A, $b\pi$ = 62° 53′ A.

² Cf. phosphosiderite below.

Artif.—Rose-red microscopic crystals having the composition of strengite have been obtained by A. de Schulten by heating a solution of FeCl₃.6H₂O with phosphoric acid solution in a closed tube at 180°-190° C. They are, however, monoclinic, tabular $\parallel b$ (010) with $\beta=65^\circ$. Extinction inclined 38° to edge a/b. Twins a (100) and c (001). Ax. plane $\parallel b$ (010). C. R., 100, 1532, 1908 1885.

609. PHOSPHOSIDERITE. W. Bruhns and K. Busz, Zs. Kr., 17, 555, 1890. Orthorhombic. Axes $\ddot{a}: \ddot{b}: \dot{c}=0.53302:1:0.87723$ Bruhns & Busz¹. $100 \land 110 = 28^{\circ} 3\frac{1}{4}', 001 \land 101 = 58^{\circ} 43', 001 \land 011 = 41^{\circ} 15\frac{1}{4}'.$

Forms:	c (001, O)	n (210, i - $\bar{2}$)	g (034, 3-1)	d (111, 1)
$a (100, i-\bar{\imath})$	p (710, i-7)	m(110, I)	h (011, 1-ĭ)	i (771, 7)
b (010, i-i)	$o(410, i-\bar{4})$	e (101, 1- \bar{i})	t (041, 4-ĭ)	

The form is not far from that of strengite (cf. ref. 1) and the chemical composition differs only in the amount of water, but it does not seem possible to unite the two species.

oo''' = 15° 11'	$ee' = 117^{\circ} 26'$	$tt' = 148^{\circ} 11'$	$dd''' = 48^{\circ} 59'$
$nn''' = 29^{\circ} 51'$	$ce = *58^{\circ} 43'$	$dd' = 102^{\circ} 6'$	$cd = 61^{\circ} 48'$
$mm''' = 56^{\circ} 7'$	$gg' = 66^{\circ} 41'$	$dd'' = 123^{\circ} 36'$	$ci = 85^{\circ} 37'$
$bm = *61^{\circ} 561'$	$hh' = 82^{\circ} 31'$		

In prismatic crystals, with b prominent; faces mostly rough and not allowing of exact measurement.

Cleavage: b perfect. H. = 3.75. G. = 2.76 peach-blossom-red or reddish violet. Transparent. H. = 3.75. G. = 2.76.

Pleochroism distinct: c nearly colorless; b carmine-red; a pale rose. Optically +. Ax. pl. | b. Bx $\perp c$. angle large. Dispersion strong, $\rho > v$.

$$2K_y = 62^{\circ} 55'$$
 $2E_y = 126^{\circ} 26' \text{ Na}$ $\beta_y = 1.7315$ $\therefore 2V_y = 62^{\circ} 4'$

Comp.— $2 \text{FePO}_4 + 3\frac{1}{2} \text{H}_2 \text{O} \text{ or Fe}_2 \text{O}_5. \text{P}_2 \text{O}_5. 3\frac{1}{2} \text{H}_2 \text{O} = \text{Phos-}$ phoric pentoxide 38.9, iron sesquioxide 43.8, water 17.3 = 100.

Anal.—Bruhns & Busz, l. c.

$$\frac{2}{2}$$
 P₂O₅ 38·85 Fe₂O₂ 44·30 H₂O 17·26 = 100·41

Pyr., etc.—In the closed tube becomes yellow and opaque, giving off water without decrepitation. B.B. fuses easily to a black magnetic bead. Soluble completely in hydrochloric acid; nearly insoluble in nitric acid.

Obs.—Found in cavities in an iron ore (Pecheisenstein) from the Kalterborn mine, near Eiserfeld, Siegen mining district, Germany.

Ref.-1 L. c. By making the cleavage face = 001 and m (110) = 021 Bruhns & Busz calculate the axes:

$$\ddot{a}: \ddot{b}: \dot{c} = 0.82285: 1: 0.93805,$$

which are not very far from the axes of strengite. The two minerals differ, however, in optical orientation as well as chemically.

610. BARRANDITE. Barrandit v. Zepharovich, Ber. Ak. Wien, 56 (1), 20, 1867.

In spheroidal concretions, indistinctly radiated fibrous, with the surface crys-

talline angular; concentric in structure.

H. = 4.5. G. = 2.576. Luster between vitreous and greasy. Color pale bluish, reddish, greenish or yellowish gray. Streak yellowish to bluish white. Translucent to opaque.

Comp.—(Al, Fe) $PO_4 + 2H_2O$ or $(Al, Fe)_2O_3 \cdot P_2O_5 \cdot 4H_2O$. If Al: Fe = 3:4 the percentage composition is: Phosphorus pentoxide 40.7, alumina 12.5, iron sesqui-

oxide 26.2, water 20.6 = 100.

Anal.-E. Boricky, l. c.

P2O5 39.68 Al2O3 12.74 Fe₂O₃ 26.58 $H_2O 21.00 = 100$

Pyr., etc.—Yields water with an acid reaction. B.B. splits open and becomes darker in color; moistened with sulphuric acid colors the flame bluish green. Soluble in hot hydro-

Obs.—Occurs at Cerhovic, N.N.W. of Přibram, in Bohemia, in clefts in a Lower Silurian sandstone, with cacoxenite and stilpnosiderite; the translucent globules $\frac{1}{2}$ to $1\frac{1}{2}$ mm. in diameter, and having within some resemblance to opal; the opaque variety without luster; sometimes a grain of limonite at center, and particles of the same as impurity.

Alt.—Stated to give origin by alteration to dufrenite, similar globules and fibrous crusts at

the locality having the composition of the latter mineral.

611. VARISCITE. Variscite Breithaupt, J. pr. Ch., 10, 506, 1837.

Axes $\check{a} : \bar{b} = 0.648 : 1$; 100 \wedge 110 = 32° 57′ Chester¹. Orthorhombic. Observed forms: $a(100, i-\bar{i}), b(010, i-\bar{i}), c(001, 0), m(110, I); mm''' = *65° 54'.$

Crystals prismatic, usually six-sided, but rarely distinct. Commonly in sheaf-

like aggregates and incrustations with reniform surface.

H. = 4. Luster vitreous, brilliant. Color deep emerald-green, bluish green to colorless. Transparent to translucent. Indices $\gamma - \alpha = 0.0173$ Lex. Comp.—AlPO₄ + 2H₂O or Al₂O₅.P₂O₅.4H₂O = Phosphorus pentoxide 44.9, alumina 32.3, water 22.8 = 100.

Anal.—1, Petersen, Jb. Min., 357, 1871. 2, Chester, Am. J. Sc., 13, 295, 1877.

P2O5 Al2O3 H2O

1. Voigtland G. = 2.40844.05 31.25 22.85 Cr₂O₃,Fe₂O₃,FeO 1.21, CaO 0.18, MgO 0.41 2. Arkansas \ \cdot 44.35 \ \ 31.85 \ \ 23.80 = 100 = 99.95

From 2 an insoluble residue of 50-70 p. c. has been deducted.

Pyr., etc.—Yields water in a matrass. B.B. in the forceps infusible, but becomes white; in the outer flame, colors the flame deep bluish green; with borax and salt of phosphorus forms a pale yellowish green glass; with soda fuses with effervescence, but imperfectly; with cobalt solution becomes blue.

Obs.—Occurs in quartz and siliceous slate at Messbach near Plauen in Saxon Voigtland.

In Montgomery Co., Arkansas, on quartz. Named from Variscia (Voigtland). Ref.—1 Arkansas, Am. J. Sc., 15, 207, 1878.

PLANERITE Hermann, Bull Soc. Nat. Mosc., 35 (2), 240, 1862. A mineral from the copper mines of Gumeshevsk, in the Ural. Occurs in thin subcrystalline, botryoidal layers in the cavities of a quartz rock. H. = 5; G. = 2.65. Color on fresh surface verdigris-green, passing to olive-green on exposure to the air. Luster dull. Translucent on the edges. $\gamma - \alpha = 0.0173$, like variscite, Lex. Analysis afforded:

P20. 33.94 Al₂O₃ 37.48 CuO 3.72 FeO 3.52 H₂O 20.93 = 99.59

dermann regards the hydrated oxides of iron and copper as unessential, as in many other aluminous phosphates, turquois, peganite, fischerite, etc.

B.B. in tube decrepitates, yielding much neutral water. Easily soluble in borax, giving copper reaction. Only slightly attacked by acids, but easily decomposed by boiling with caustic soda. Named after Planer, director of the mines.

AMPHITHALITE. Amfithalit Igelström, Öfv. Ak. Stockh., 23, 93, 1866. B. H. Ztg., 25, 309, 1866.

Massive. H. = 6 Color milk white. Subtranslucent. Analysis.-Igelström:

 P_2O_5 30.06 Al₂O₃ 48.50 MgO 1.55 CaO 5.76 H₂O 12.47 FeO, MnO tr. = 98.34

B.B. infusible. Insoluble in acids. Occurs in the quartzyte of Horrsjöberg, Wermland, with lazulite, rutile, and cyanite. Named from αμφιθαλής, becrowned, since it usually occurs surrounded by other beautiful minerals, though unattractive itself. Groth refers this to the doubtful berlinite (AlPO₄ + ½H₂O?) which is mentioned on p. 847.

612. CALLAINITE. ? Callaina Plin., 37, 33. Turquois pt. Callais Damour, C. R., 59, 936, 1864. Callainite Dana.

Texture wax-like. Massive.

H. = 3.5-4. G. = 2.50-2.52.Color apple-green to emerald-green, spotted Translucent. or lined with whitish and bluish.

Comp.—AlPO, $+2\frac{1}{2}$ H₂O or Al₂O₃.P₂O₅.5H₂O = Phosphorus pentoxide 42.6, alumina 30.5, water 26.9 = 100.

Anal.-A. Damour, l. c.

PoOs Al₂O₃ Fe₂O₃ Mn₂O₃ CaO H.O 42.58 29.57 0.70 1.82 tr. 23.62 sand 2.10 = 100.39

Pyr., etc.—When heated yields water, and becomes opaque, chocolate-brown, and friable. B.B. infusible.

Obs.—From a Celtic grave. near Mané-er H'roek in Lockmariaquer, in rounded pieces from the size of a flax-seed to that of a pigeon's egg, and found in the collections of the Polymathic

Society of Morbihan, in western France.

Damour makes this mineral the callais of Pliny, and especially in view of its green color. But the callais was blue, and the green stone really related to it was probably the callaina (see p. 845). Yet, as this identity is not established, the name callainite is better than Pliny's name unmodified.

613. ZEPHAROVICHITE. E. Boricky, Ber. Ak. Wien, 59 (1), 593, 1869. Crystalline to compact, horn-like in aspect. Fracture conchoidal. H. = 5.5. G. = 2.37. Color greenish, yellowish or grayish white. Translucent.

Comp.—AlPO₄.3H₂O = Phosphorus pentoxide 40·3, alumina 29·0, water 30·7 = 100.

Nos. 1 and 2 contained intermingled wavellite, and No. 3 an earthy gibbsite. Boricky thinks the analyses prove the mineral to be essentially an aluminium phosphate with 3 molecules H₂O. It is, however, to be noted that this differs from callainite above only in containing 1 molecule more of water, and analysis 2, after deduction of the 6 04 of quartz, gives: P2Os 40.28, Al₂O₃ 30.57, CaO 0.58, H₂O 28 56, a result which approaches the figures given by Damour in his analysis of callainite. The species, therefore, must be regarded as a doubtful one.

Occurs in sandstone at Trenic in Bohemia.

Named for Prof. V. von Zepharovich (1830-1890).

GIBBSITE. A so-called gibbsite stated to have come from Richmond, Mass., and to occur with the true gibbsite (aluminium hydrate = hydrargillite, p. 254) has given Hermann, J. pr. Ch., 40, 32, 1847; also 47, 1, 1849:

$$P_2O_5 37.62$$
 $Al_2O_3 26.66$ $H_2O 35.72 = 100$

This corresponds nearly to AlPO₄ + 4H₂O. but the occurrence is not above question. The

substance was called richmondite by Kenngott (cf. p. 255).

Genth also mentions a gibbsite of Hermann, occurring in scales on wavellite from Gen. Trimble's farm near White Horse Station, Chester Valley R. R. (locality formerly called 'Steamboat"). He says it is a phosphate corresponding with peganite but containing more water.

614. KONINCKITE. Cesàro, Ann. Soc. G. Belg. Mem., 11, 247, 1883-84.

In small spherical aggregates of radiating needles; in one case terminated by an oblique plane

Cleavage transverse. H. = 3.5. G. = 2.3. Luster vitreous. Color and streak yellow. Extinction parallel.

Comp.—FePO₄ + 3H₂O or Fe₂O₂.P₂O₅.6H₂O = Phosphorus pentoxide 34.6, iron sesquioxide 39.0, water 26.4 = 100.

Anal.—Cesàro, l. c.

Al2O, 4.6 P2O5 34.8 Fe₂O₃ 33.8 $H_2O 26.8 = 100$

Pyr., etc.—B.B. fuses easily. Soluble in strong acids. Obs.—Occurs with richellite at Richelle near Visé, Belgium. Named for the Belgian geologist, L. G. de Koninck (1809–1887).

Hydrous Phosphates, etc.—Acid Division.

Pyr., etc.—Heated in a closed tube whitens, and at an incipient red heat gives off water. B.B. in the platinum forceps fuses easily with intumescence, tingeing the flame green; the button crystalline with brilliant facets on cooling. Dissolves readily in dilute acids.

Obs.—Occurs on the rock guano of Aves Island and Sombrero in the Caribbean Sea, in groups and crusts consisting of delicate and mostly transparent crystals. Named after Prof. G. J. Brush of New Haven.

Ref.—1 Am. J. Sc., 39, 45, 1865; the position is changed to correspond to pharmacolite (q.v.), as suggested by Dufet, Bull. Soc. Min., 11, 187, 1888.

METABRUSHITE. A. A. Julien, Am. J. Sc., 40, 371, 1865. Zeugite Julien, ib., p. 373. Ornithite Julien, ib., p. 377.

Monoclinic. In imperfect crystals with $a(100, i-\overline{i}), b(010, i-\overline{i}), o(101, -1-\overline{i})$. Faces a broad and even, but dull, b, o deeply furrowed and rounding into one

another; crystals sometimes flattened | b. Angle ao = 38°, but varying. Cleavage: b perfect. Brittle. H. = 2.5-3. G. = 2.288, 2.356, 2.362. feeble, sometimes resinous on fracture; on b pearly. Color pale yellow, buff, to nearly white; streak uncolored. Translucent to transparent.

Comp.—2HCaPO, + 3H₂O or 2CaO.P₂O₄.4H₂O = Phosphorus pentoxide

43.6, lime 34.3, water 22.1 = 100.

Anal.-Julien, l. c.

P20 H₂O MgO Al₂O₃, Fe₂O₃ 4 42.72 32.98 21.83 0.52 0.79 0.05 hygr. 1.50 = 100 R

The water included some organic matter.

Pyr., etc.—Same as for brushite.

Obs. From the island of Sombrero, West Indies, coating cavities in guano and the coral rock, the latter altered by filtrations from the overlying guano. The crystals are sometimes 1 inch long and 1 inch broad.

Alt.—The crystals of metabrushite from Sombrero are often hollow from the removal of the

interior, and otherwise altered. Julien describes the following varieties:

1. H. = 3.25. G. = 2.971. The crust of the hollow crystals thin, and surfaces within and without often coated by minute rhombs of calcite; the zeugite of Julien. 2. Crust rather thicker, without a glittering surface of calcite rhombs. 3. G. = 2.988-3.030; in narrow blades sometimes an inch long; the crust thick, the crystals being nearly or quite solid. Zeugite is named from $\zeta \epsilon \nu \gamma i \tau \eta 5$, yoked together, because of its relation to metabrushite and ornithite. Cf. martinite, beyond.

4. Ornithite of Julien, from Sombrero (l. c., p. 377), appears also to be altered metabrushite, its crystals presenting the same forms and habit, but usually quite small and very thin parallel to the orthodiagonal; also sometimes thin parallel to the clinodiagonal, and acute rhombic in section; angle $100 \land 101 = \text{about } 38^\circ$; H = 2.5. The analysis given was made on only one-tenth of a gram, and the results are hence unavoidably doubtful.

Analyses of varieties 1, 3, 4, afforded Julien (the water including some organic matter):

		P2O6	CaO	H20	MgO	Fe ₂ O ₃ , Al ₂ O ₃	SO ₃	CO2	F	NaCl
Var. 1. Zeugite	2	46.55	44.21	3 02	3.59	0.66	0.19	0.24	tr.	1.08 = 99.54
Var 3. "	~	43.24	48.87	3.98	0.56	1.02	0.18	1.74	tr.	? = 99.59
Var. 4. Ornithite		40.14	45.77	9.45	tr.	4.62	_	-	-	-=99.98

In 1, oxygen ratio for P_2O_6 : CaO (impurities excluded) = 2.95: 1.56, and as noted beyond the composition is near that of martinite.

Ornithite corresponds nearly to the formula Ca₃P₂O₈ + 2H₂O.

There occur also, with the above, hemispherical stellated groups of white crystals, as altered ornithite, which Julien has not analyzed, but supposed to be the same compound minus the water. One crystal of the so-called ornithite had on its edges and surface microscopic tufts of acicular crystals.

620. MARTINITE. Kloos [Sammlg. G. Reichsmus. Leiden, 1], Jb. Min., 1, 41 ref., 1888. Rhombohedral. As an aggregation of minute rhombohedrons (0.05 mm.) with plane angles of 75° and 105°, filling cavities in pseudomorphous crystals of gypsum. G. = 2.894. Luster vitreous. Color white or slight yellowish. Transparent.

Comp.—H₂Ca₅(PO₄)₄.½H₂O or 5CaO.P₂O₅.¾H₂O = Phosphorus pentoxide 48·1,

lime 47.3, water 4.6 = 100.

Anal.-Kloos, l. c.

P₂O₅ CaO H₂O 47.67 46.78 4.52 insol. 0.20, organ. 0.75 = 99.92 47.87 47.63 5.46 = 100.96

Pyr., etc.—B.B. burns white and falls to pieces without melting. Dissolves in dilute acid without effervescence.

Obs.—Found in the phosphorite deposits derived from guano on Table Mt., near St. Barbara, on the south shore of the island Curaçoa, West Indies.

Martinite seems to be nearly identical with the zeugite of Julien.

621. NEWBERYITE. G. vom Rath, Ber. nied. Ges., p. 5, Jan. 13, 1879. Orthorhombic. Axes $\check{a}:\check{b}:\dot{c}=0.95482:1:0.93601$ Schmidt'. $100 \wedge 110=43^{\circ}\ 40'\ 34'',\ 001 \wedge 101=44^{\circ}\ 25'\ 48'',\ 001 \wedge 011=43^{\circ}\ 6'\ 25''.$

In small highly modified crystals, with monoclinic symmetry. Also in incrustations sometimes crystalline, or globular, sometimes glassy, with a reniform surface.

Cleavage: b. H = 2-2.5. G. = 2.48. Luster strongly

vitreous. Colorless to white. Transparent to translucent. Ax. pl. in a section ||b| inclined $69\frac{1}{2}$ ° to edge bm, $13\frac{1}{2}$ ° to bp, 15° to bd. Bx normal, or nearly so, to b. 2E = 55°. Dispersion $\rho < v$, also crossed. Comp.—HCaAsO₄ + 3½H₂O or 2CaO.As₂O₆.8H₂O = Arsenic pentoxide 47.4, lime 23.0, water 29.6, = 100. The calcium is replaced in part by magnesium,

Anal.-Frenzel, l. c.

As ₂ O ₅	CaO	MgO	H_2O	
47.70	14.19	8.29	29.40 =	= 99.58
47.69	15:60	7.35	29 49 =	= 100.13

5 equivalents of water (19 p c.) go off at 100°, the remainder at 360°.

Obs.—Found with pharmacolite at Joachimsthal; also at Schneeberg. Named after Herrn

Wappler of the Freiberg Mineralien-Niederlage.

Ref.—1 Jb. Min., 290, 1875, and later Zs. Kr., 4, 281, 1880. It may yet prove that wapplerite belongs to the monoclinic system, from which it deviates but little, if at all. The triclinic axial ratio and angles deduced by Schrauf (l. c., 1880) are as follows:

$$\check{a}:\check{b}:\dot{c}=0.90089:1:0.26159; \quad \alpha=90^{\circ}\ 13'\ 55'', \quad \beta=95^{\circ}\ 20', \quad \gamma=90^{\circ}\ 35''.$$

RÖSSLERITE R. Blum [JB. Wett. Ges. Hanau, 32, 1861], Jb. Min., 334, 1861. Described as occurring with pharmacolite and erythrite in the Kupferschiefer at Bieber, Hesse, in thin crystalline plates with columnar or fibrous structure. One cleavage. H. = 2-3. Luster vitreous or dull. Colorless or white. An analysis by Delffs gave:

This conforms to the formula HMgAsO₄ + 7H₂O. Named after Dr. K. Rössler. A mineral referred here by Tschermak (Ber. Ak. Wien, 56 (1), 828, 1867) occurring in monoclinic crystals at Joachimsthal and Kremnitz is made by Schrauf (Jb. Min., 290, 1875) an altered form of wapplerite. This may be true of the original mineral also. An analysis gave Tschermak: As, 0, 49.1, MgO 17.0, H2O 34.7 = 100.8.

623. HANNAYITE. Ulrich, vom Rath, Ber. nied. Ges., p. 11, Jan. 7, 1878; p. 5, Jan. 18 1879.

Triclinic. Axes $\alpha : b : c = 0.6990 : 1 : 0.9748; \alpha = 122^{\circ} 31\frac{1}{2}', \beta = 126^{\circ} 46\frac{1}{8}'$ $\nu = 54^{\circ} 9'$ Rath.

 $100 \land 010 = 112^{\circ} 58\frac{1}{4}', 100 \land 001 = *65^{\circ} 28', 010 \land 001 = 73^{\circ} 14'.$

Forms: $a (100, i-\bar{i}), c (001, 0); m (110, I'), l (130, i-\bar{3}') cleavage, M (110, I);$ ω (133, 1-3).

Angles: $am = *39^{\circ} 32'$, $mM = *65^{\circ} 26'$, $cm = *50^{\circ} 50'$, $c\omega = 52^{\circ} 20'$, $a\omega = *70^{\circ} 24'$

In small and slender prismatic crystals, vertically striated. Cleavage: c, m, M, l. G. = 1.893. Color yellowish.

Comp.—A hydrous phosphate of magnesium and ammonium, Mg₃P₂O₄.2H₂(NH₄)PO₄+8H₂O or (NH₄)₂O.3MgO.2P₂O₄.10H₂O = Phosphorus pentoxide 44.4, magnesia 18.7, ammon. ox. 5.6, water 22.5 = 100.

Anal.—1, MacIvor, quoted by Rath, l. c. 2, Id., Ch. News, 55, 216, 1887.

After Rath.

	P_2O_5	MgO	(NH ₄) ₂ O	H ₂ O	
1.	₹ 45·70	18.90	8.09	28.20	= 100.89
2	44.71	18.54	8.10	[28.25]	FeO 0.31 , MnO $0.09 = 100$

Heated 36 hours at 100° undergoes no change; between 100° and 110° or 115° loses 21 08 p. c., becoming opaque; heated over a Bunsen flame loses the remainder of the water and the ammonia (36.48 = total loss). The remainder fuses, but dissolves only in part in concentrated hydrochloric acid.

Obs.—Discovered by MacIvor of Melbourne in the bat guano which forms deposits 30 feet deep in the Skipton basaltic caves 30 miles s.w. of Ballarat, Victoria, and recognized as new by Ulrich, as stated in a letter to vom Rath. Occurs with struvite and newberyite. Named after

Prof. J. B. Hannay, of Manchester, England.

624. HUREAULITE. Alluaud, Vauquelin, Ann. Ch. Phys., 30, 302, 1825; Alluaud, Ann. d. Sc. Nat. 8, 349, 1826. Dufrénoy, Ann. Ch. Phys., 41, 338, 1829; Des Cloizeaux and Damour, ibid., 53, 293, 1858.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=1.9192:1:0.5245; \beta=*84° 1'=001 \land 100$ E. S. Dana'.

 $100 \land 110 = *62^{\circ} 21', 001 \land 101 = 14^{\circ} 48' \cdot 2, 001 \land 011 = 27^{\circ} 32' \cdot 9.$

Forms:	c (001, O)	β (501, 5-1)	ϵ ($\bar{2}21, 2$)	z (6 21, 6- 3)
a (100, i-ī)	m(110, I)	$p(223, -\frac{2}{8})$	k (511, 5-5)	l (841, 8-2)
\$ (010, i-i)	α ($\overline{4}01$, $4-\overline{i}$)	δ (111, -1)		

See also below, ref. 1, for planes on figs. 3, 4.

In short prismatic crystals, sometimes tabular $\parallel a$. Faces a, m striated; also $\epsilon \parallel$ edge m/ϵ , and $\delta \parallel$ edge δ/m . In Branchville crystals zone $m \ l \ k \ a$ striated \parallel intersection-edges. Crystals isolated or grouped, the groups sometimes mammillary, or fascicled as in stilbite. Also massive, compact, scaly, or imperfectly fibrous.

Cleavage: a rather perfect. H. = 5. G. = 3.185, yellow, and 3.198, reddish, Damour; 3.149 Branchville. Luster vitreous, somewhat greasy, bright. Color orange-red, brownish orange, rose-violet, and pale rose, grayish, nearly colorless. Streak nearly white. Transparent to translucent.

Optically – Ax./pl. $\perp b$. Bx $\perp b$; Bx₀ $\wedge c = +75^{\circ}$ or $\alpha = 15^{\circ}$ for red; Bx₀ $\wedge c = 76^{\circ}$ or $\alpha = 14^{\circ}$ for blue. Dispersion $\rho < v$ large; crossed distinct (1°).

 $2H_{a,r} = 88^{\circ} 52'$ $\therefore 2E_r = 173^{\circ} 52'$ $2H_v = 86^{\circ} 22'$ Limoges

Other trials gave 2Har = 84° 51', 85° 55', etc. The angle diminishes 6° 34' between 41°.5

Var.—The (a) brownish orange or yellowish, (b) the rose-violet, and (c) the pale rose, are three varieties occurring at Limoges, differing somewhat in their crystalline planes. The orange is the most commou.

Comp.— $H_2Mn_s(PO_4)_4 + 4H_2O$ or $5MnO.2P_2O_5.5H_2O$ = Phosphorus pentoxide 39.0, manganese protoxide 48.6, water 12.4 = 100.

Anal.—1, Dufrénoy, l. c., 1829. 2-4, Damour, l. c., 1858. 5, H. L. Wells, Am. J. Sc., **39**, 210, 1890.

Figs. 1, 2, Branchville. 3, 4, Limoges, Dx.

The street of the street	G.	P2O5	MnO	FeO	CaO	H ₂ O
1. Limoges		38.00	32.85	11.10	-	18.00 = 99.95
2. " yellow	3.185	37.96	41.15	8.10	-	12.35 quartz 0.35 = 99.91
3. "	The Care	38.20	42.04	6.75	_	12.00 " $0.50 = 99.49$
4. " reddish		37 83	41.80	8.73	-	11.60 " $0.30 = 100.26$
5. Branchville	3.149	38.36	42.29	4.56	0.94	12.25 " $1.76 = 100.11$

Pyr., etc.—In the closed tube gives water. B.B. fuses to an orange-yellow or reddish yellow crystalline pearl, brown in the outer flame, then becomes black, and the flame is colored

green. Reactions of manganese and iron. Easily soluble in acids.

Obs.—Found in cavities of triphylite or its altered form heterosite, in granite, at Limoges, commune of Huréaux, France. Probably at Michelsdorf, Silesia, with sarcopside (Websky).

In the U. States, at Branchville, Conn., in a vein of albitic granite, immediately associated

In the U. States, at Branchville, Conn., in a vein of albitic granite, immediately associated with lithiophilite, also fairfieldite, dickinsonite, etc.

Ref.—¹ Branchville, Conn., Am. J. Sc., 39, 207, 1890.

As described by Dx., the Limoges crystals conform to two types: Type I, f. 4, with b (010), p (001), m (110); also g (321), e (011), u ($\overline{3}11$), t ($\overline{3}41$). Again, II, f. 3, with a (100), m (110); also o (105). α ($\overline{15}\cdot 0\cdot 8$), δ ($\overline{435}$), k ($\overline{19}\cdot 5\cdot 8$), x ($\overline{11}\cdot 9\cdot 10$), e ($\overline{9}\cdot 11\cdot 10$).

The axial ratio and calculated angles are: $\hat{a}:\hat{b}:\hat{c}=16977:1:0\cdot 8887$; $\beta=89^\circ$ 27' = 001 \wedge 100. mm'' = 119° 0'; po = 5° 58', pg = 57° 7'; pa = 44° 44', pm = 89° 48', ee' = 83° 15', a\delta=69° 17', a'e = 71° 44', pe = 47° 28', \delta\delta'=52° 13'; ee' = 83° 11', uu' = 51° 14'; pt = 75° 47', tt'=124° 55', bt = 27° 32'.

Referred to the axial ratio above accepted, the forms of Direction the following

Referred to the axial ratio above accepted, the forms of Dx, type I, receive the following probable symbols: b=010, $p=\bar{1}03$, m=110, $e=\bar{1}53$, $u=\bar{1}\bar{2}$, 3, 2?, t=661?. Those of type II become: a=100, m=110, o=001, o=401, o=111, o=511, o=52, o=22. The angles of Dx. differ from those of Branchville chiefly in the prismatic zone. Type II conforms most nearly to the Branchville crystals, and referred to their axial ratio the anomalously complex symbols become simple. The relations of the other type are less certain. The Limoges crystals obviously need further asymmetrical. crystals obviously need further examination.

625. FORBESITE. Hydrous Bibasic Arsenate of Nickel and Cobalt D. Forbes, Phi. Mag., 25, 103, 1863. Forbesit Kenngott, Ueb., 1862-65, 46, 1868.

Structure fibro-crystalline.

H. = 2.5. G. = 3.086. Luster dull to silky or resinous. Color grayish white.

Comp.—H₂(Ni, Co)₂As₂O₈ + 8H₂O = Arsenic pentoxide 42.5, nickel protoxide 18.4, cobalt protoxide 9.2, water 29.9 = 100.

Anal.—Forbes, l. c.

As2O, 44.05

NiO 19.71

CoO 9.24

 $H_2O 26.98 =$ 99.98

Pyr.—B.B. in the closed tube yields water, becoming darker; on charcoal fuses imperfectly, evolves arsenic fumes, leaving metallic globules of an arsenide of nickel and cobalt. With fluxes gives reactions for nickel and cobalt.

Obs.-Occurs in the desert of Atacama in veins in a decomposed dioryte. A few yards below the surface it passes into chloanthite, from which mineral it appears to have been

derived.

626. ISOCLASITE. Isoklas Sandberger, J. pr. Ch., 2, 125, 1870.

Monoclinic? In minute crystals with dull faces. Also columnar.

Cleavage: clinodiagonal, perfect. H. = 1.5. G. = 2.92. Luster vitreous to pearly. Colorless to snow-white.

Comp.—Ca₃P₂O₈.Ca(OH)₂.4H₂O or 4CaO.P₂O₅.5H₂O = Phosphorus pentoxide 31.2, lime 49.1, water 19.7 = 100.

Anal.-Sandberger, l. c.

P2O, 29.90 CaO 49.51 H₂O 18.53 (ign.) $H_2O 2.06 (at 100^\circ) = 100$

Pyr., etc.—In the closed tube gives off neutral water. B.B. the fresh mineral glows and soluble in hydrochloric acid.

Obs.—Found with hornstone and brown-spar on specimens from Joachimsthal, obtained eighty years ago, and now in the Würzburg Museum.

Altered crystals yielded: P₂O₅ 34·00. CaO 1·00, MgO 17·30, Na₂O 9·80, Fe₂O₅, Al₂O₅ 0·36; H₂O 9·22 (ign.), H₂O 24·26 (100°), insol. 0·18 = 96·12.

Named from ioos, equal, and κλάσις, fracture.

627. HEMAFIBRITE. Aimafiorit L. J. Igelström, Öfv. Ak. Stockh., 41, No. 4, 86, 1884. Hämafibrite.

Orthorhombic. Axes $\ddot{a}: \ddot{b}: \dot{c} = 0.5261:1:1.1510$ H. Sjögren'. $100 \land 110 = 27^{\circ} 45', 001 \land 101 = 65^{\circ} 26', 001 \land 011 = 49^{\circ} 1'.$

Forms': b(010, i-i), m(110, I), e(122, 1-i).

Angles: $mm''' = *55^{\circ} 30'$, $ee' = 71^{\circ} 19'$, $ee'' = 115^{\circ} 36'$, $ee''' = *75^{\circ} 40'$, $be = 52^{\circ} 10'$, $me = 36^{\circ} 44'$. The form approximates closely to that of scorodite, strengite, and reddingite.

Crystals prismatic; commonly in spherical radiated groups with fibrous structure.

Cleavage: b distinct; m less so. Fracture uneven. Brittle. H. = 3. G. = 3.50-3.65 A. Sj. Luster vitreous on crystalline faces, greasy on the fracture. Color brownish red to garnet-red, soon becoming brownish black to black. Streak brick-red. Transparent to translucent.

Optically +. Ax. pl. | a. Bx \(\perp c\). 2E = 70° approx. Dis-

persion $\rho > v$.

Comp.—Mn, As, O, 3Mn(OH), + 2H, O or 6MnO. As, O, 5H, O = Arsenic pentoxide 30.93, manganese protoxide 57.0, water 12.1

Anal.-1, A. Sjögren, Zs. Kr., 10, 129, 1885. 2, C. H. Lundström, ibid.

		As_2O_5	MnO	FeO	H_2O	
1.	Nordmark	30·76 30·88	57·94 58·02	0·79 0·25		= 101.50 MgO $0.41 = 101.57$

An earlier but incorrect analysis with somewhat different results is given by Igelström, l. c.

Pyr.—B.B. fuses easily to a black slaggy bead. On charcoal yields arsenical fumes. Gives off water in the closed tube, and becomes black. Soluble in hydrochloric acid.

Obs.—Occurs with other manganese minerals at the Moss mine, Nordmark, Sweden; it is easily decomposed on exposure and goes over into a black foliated mineral. Named from αΐμα, blood, and Latin fibra, fiber, in allusion to its red color and also to the fibrous structure.

Ref.—¹ G. För, Förh., 7, 386, 1884, and Zs. Kr., 10, 126, 1885. Cf. also Btd., Bull. Soc.

Min., 7, 124, 1884.

628. CONICHALCITE. Konichalcit Breithaupt and Fritzsche, Pogg., 77, 139, 1849.

Reniform and massive, resembling malachite.

Fracture splintery. Brittle. H. = 4.5. G. = 4.123. Color pistachio-green, inclining to emerald-green; streak the same. Subtranslucent.

Comp.—Perhaps $(Cu, Ca)_3As_2O_8$. $(Cu, Ca)(OH)_2 + \frac{1}{2}H_2O$ or 4(Cu, Ca)O. As $2O_8$. $1\frac{1}{2}H_2O$ = Arsenic pentoxide 43.6, cupric oxide 30.1, lime 21.2, water 5.1 = 100. Here Cu : Ca = 1 : 1.

The original mineral also contains phosphorus and in small amount vanadium replacing the arsenic. These are absent in the Utah variety, which also contains zinc and further gives the ratio RO: As₂O₅: H₂O = 4:9.44:1.64.

Anal.-1-3, Fritzsche, l. c. 4, Hillebrand, Proc. Col. Sc. Soc., 1, 114, 1884.

	AS2O6	P2Os	V2O5	CuO	CaO	ZnO	H_2O
1. Spain	30.68	[8.81]	1.78	31.76	21.36		5.61 = 100

Pyr., etc.—In the closed tube decrepitates, gives water and turns black. In the forceps fuses, and colors the flame at first emerald-green, but after a time light blue adjacent to the assay. On charcoal fuses with deflagration to a red slag-like mass, which gives an alkaline reaction to test paper, and with soda gives a globule of copper. On charcoal, with salt of phosphorus and metallic lead, the Spanish mineral yields a glass which is dark yellow while hot and chrome-green

on cooling (vanadium).

Obs.—From Hinajosa de Cordova, in Andalusia, Spain. Also from the American Eagle mine, Tintic district, Utah, where it occurs with other copper arsenates, derived from the altera-

tion of enargite.

Named from Kovia, powder, and xalkos, lime.

629. BAYLDONITE. A. H. Church, J. Ch. Soc., 18, 265, 1865.

In minute mammillary concretions, with a drusy surface. Structure often somewhat reticulated.

Fracture subconchoidal, uneven. H.= 4.5. G.= 5.35. Luster strong resinous Color grass-green to blackish green. Streak siskin- to apple-green. Subtranslucent.

Comp.—(Pb,Cu)₃As₂O₄.(Pb,Cu)(OH)₂ + H₂O or 4(Pb,Cu)O.As₂O₅.2H₂O, with Pb: Cu = 1:3 = Arsenic pentoxide 31.7, cupric oxide 32.7, lead protoxide 30.6, water 5.0 = 100.

Anal.-Church, l. c.

3 As2O6 31.76 CuO 30.88 PbO 30.13 H₂O 4.58 Fe₂O₂, CaO, and loss 2.65 = 100

Pyr., etc.-B.B. gives off water and becomes black. On charcoal fuses to a black bead, defingrates, giving off arsenical fumes, and leaves a white metallic bead of lead and copper. With borax in outer flame gives a blue bead. Difficultly soluble in nitric acid.

Obs.—Occurs in Cornwall. Named after Dr. John Bayldon.

630. TAGILITE. Tagilith (fr. N. Tagilsk) Hermann, J. pr. Ch., 37, 184, 1846; (fr. Ullersreuth) Breith., B. H. Ztg., 24, 309, 1865.

Monoclinic, but like liroconite in habit of crystals, Breith. Also in reniform

or spheroidal concretions. Structure fibrous; also earthy.

Cleavage: brachydiagonal, distinct. Fracture uneven. Brittle. H. = 3-4. G. = 4.076 Breith. Luster vitreous. Color verdigris- to emerald-green. Streak verdigris-green. Subtranslucent.

Comp.—Cu₃P₂O₃.Cu(OH)₂ + 2H₂O or4CuO.P₂O₃.3H₂O=Phosphorus pentoxide

27.7, cupric oxide 61.8, water 10.5 = 100.

Anal.-1, Hermann, l. c., including a little limonite. 2, Field, Ch. Gaz., 17, 225, June 15, 1859.

Pyr., etc.—Becomes first green on ignition, and finally fuses to a black glass. Obs.—Occurs as a delicate coating with malachite and calcite at the Wilhelmine mine in the Spessart, Germany.

632. EUCHROITE. Euchroit Breithaupt, Char., 172, 266, 1823.

Orthorhombic. Axes $\ddot{a}: \dot{b}: \dot{c}=0.6088:1:1.0379$ Haidinger. $100 \land 110 = 31^{\circ} 20', 001 \land 101 = 59^{\circ} 36\frac{1}{3}', 001 \land 011 = 46^{\circ} 4'.$

Forms¹: b (010, i-i), c (001, O); m (110, I), s (230, i- $\frac{5}{2}$), l (120, i-i); d (102, $\frac{1}{2}$ -i)², e (101, 1-i)², n (011, 1-i).

Angles: $mm''' = *62^{\circ} 40'$, $ss' = 95^{\circ} 12'$, $ll' = 78^{\circ} 47\frac{1}{2}'$, $dd' = 80^{\circ} 52'$, $ee' = 119^{\circ} 13'$, $nn' = *92^{\circ} 8'$.

Habit prismatic; faces msl striated vertically.

Cleavage: m, n (011) in traces. Fracture small conchoidal to uneven. Rather brittle. H. = 3.5-4. G. = 3.389. Luster vitreous.

bright emerald- or leek-green. Transparent to translucent. Optically +. Ax. pl. $\| a$. Bx $\perp c$. Axial angles:

 $2E = 61^{\circ} 11'$ at 17° C. and $56^{\circ} 8'$ at 86° C., $Dx.^{3}$

Comp.—Cu₃As₂O₈.Cu(OH)₂ + 6H₂O or 4CuO.As₂O₈.7H₂O = Arsenic pentoxide 34.2, cupric oxide 47.1, water 18.7 = 100.

Analyses agree closely, see 5th Ed., p. 566. Wöhler obtained: As₂O₅ 33·22, CuO 48·09, H₂O 18·39 = 99·70, Lieb. Ann., 51, 285, 1844. Pyr., etc.—In the closed tube gives more water, but has otherwise the same reactions as olivenite.

Obs.—Occurs in quartzose mica slate at Libethen in Hungary, in crystals of considerable size, having much resemblance to dioptase. Named from $\epsilon \tilde{v} \chi \rho o \alpha$, beautiful color.

Alt.—Tschermak suggests that olivenite may be euchroite altered by the loss of water, he finding crystals of olivenite projecting from the holes of cavernous euchroite, Ber. Ak. Wien.

Ref.—¹ Ed. J. Sc., 2, 133, 1825, or Pogg., 5, 165, 1825; also Dx., Ann. Ch. Phys., 13, 423, 1845. ² Solly, Proc. Cambridge Phil. Soc., 4, 6, 1883. ³ Propr. Opt., 2, 30, 1859, N. R., 57, 1867.

633. VOLBORTHITE. Hess, Bull. Ac. St. Pet., 4, 1838, and J. pr. Ch., 14, 52, 1838. unfite. Vanadate of Copper. Vanadinsaures Kupfer. Knauffite. Vanadate of Copper.

In small six-sided tables, often aggregated in globular forms.

Cleavage: in one direction very perfect. H. = 3-3.5. G. = 3.55 Credner. Luster pearly to vitreous. Color olive-green, citron-yellow. Streak clear yellowish green, nearly yellow. Thin splinters translucent.

Comp.—A hydrous vanadate of copper, barium, and calcium; perhaps (Cu, Ca, Ba), (OH), VO, +6H₂O = Vanadium pentoxide 19.6, cupric oxide 38.4, lime 6.8, baryta 6.2, water 29.0 = 100.

Anal.-1, 2, Genth, Am. Phil. Soc. Philad., 17, 122, 1877; 1a, 2a, the same, after deduction of impurities (Rg., Min. Ch. Erg., 263, 1886).

	V2Os	CuO	BaO	CaO	MgO	H ₂ O	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃
1.	13.62	34.04	4.29	4.29	3.01	[33.15]	1.38	4.45	1.77 = 100
2.	13.59	38.01	4.30	4.49	1.42	[31.60]	1.36	4.78	0.45 = 100

2a.	14.55	40.70	4.60	4.80	1.52	33.83	-	-	- = 100

The material analyzed consisted of about 85 p. c. of insoluble gangue, the analysis of the remainder is given in 1 and 2; in 1a, 2a, the corresponding results after the deduction of the impurities are given. Calciovolborthite or Kalkvolborthit, p. 790, has a very different

Pyr., etc.—B.B. on charcoal fuses easily to a black bead, which in the inner flame becomes blackish gray. With soda on charcoal yields copper; with borax and salt of phosphorus reactions for copper. Fused with soda in the platinum spoon, the mass yields on treatment with water a solution which, acidulated with hydrochloric acid and boiled, gives an emerald-green solution, and this diluted with water becomes blue; Kbl.

Obs.—From Sisersk and Nizhni Tagilsk in the Ural, where it was found by Dr. A. Volborth, after whom it was named; and from several mines of the Permian formation in the government of Permian generally at the Alexandrey wine in the Motoriikh Districts.

of Perm, especially at the Alexandrov mine in the Motovilich District.

634. CORNWALLITE. Cornwallit Zippe, Abh. Böhm. Ges. Prag, 1846.

Massive.

Fracture conchoidal. H. = 4.5. G. = 4.16-4.17. Color emerald-green to dark verdigris-green.

Comp.—Cu, As, O_s . 2Cu(OH), + H₂O or 5CuO. As, O_s . 3H₂O = Arsenic pentoxide

33.8, cupric oxide 58.2, water 7.9 = 100.

Anal.—Church, J. Ch. Soc., 21, 276, 1868.

$$As_2O_5$$
 P_2O_5 CuO H_2O $G. = 4.17$ 30.47 4 2.71 59.95 7 8.23 $= 101.36$

An earlier analysis by Lerch (5th Ed., p. 569) gave 13 p. c. H₂O. Pyr., etc.—In the matrass yields water. B.B. on charcoal gives arsenical fumes, and a bead of copper enveloped in a brittle crust.

Obs.—From Cornwall, occurring in small botryoidal or disseminated individuals on olivenite. Resembles malachite, but differs from it in not effervescing with acids.

635. TYROLITE. Kupferschaum Wern., Hoffm. Min., 3, 180, 1816, Letzt. Min. Syst., 19, 50, 1817. Kupaphrite Shep., Min., 1, 294, 1835. Tirolit Haid., Handb., 509, 1845.

Orthorhombic. Axes $\check{a}:\bar{b}=0.9325:1$, E. S. Dana'. In thin crystals, tabular $\|c$, and elongated $\|\bar{b}$, the free extremity bounded by the forms: b (010, i-i), m (110, I), l (120, i-i). Angles: $mm'''=*86^{\circ}$, $am=43^{\circ}$, $ll'=56^{\circ}$ 24', $bl = 28^{\circ} 12'$

Distinct crystals rare, usually grouped in fan-shaped forms and closely foliated aggregates. Also reniform, massive; structure radiate foliaceous, surface drusy.

Cleavage: c highly perfect, micaceous. Very sectile. Thin laminæ flexible. H. = 1-1.5. G. = 3.02-3.098. Luster: c pearly; other faces vitreous. Color pale apple-green and verdigris-green, inclining to sky-blue. Streak a little paler. Translucent to subtranslucent. Optically –. Ax. pl. ||b|. Bx $\perp c$. Axial angle large.

Comp.—Perhaps Cu, As, O, 2Cu(OH), + 7H, O or 5CuO. As, O, 9H, O = Arsenic

pentoxide 29.2, cupric oxide 50.2, water 20.6 = 100.

Kobell's analysis, quoted below, gives 13.65 CaCO₃, present apparently as an impurity; it is also stated (N.-Z. Min., 540, 1885) that Frenzel found 13 p. c. CaCO₃ in the Schneeberg mineral. Further, recent careful analyses by Hillebrand on material seemingly faultless show no carbonic acid, but, on the other hand, some sulphuric acid which is not to be explained as due to admixed gypsum; the exact composition is hence complex and as yet uncertain.

Anal.—1, 2, Hillebrand, Am. J. Sc., 35, 300, 1888; from 2, 1.25 p. c. gangue has been deducted. 3, R. Pearce, Proc. Col. Soc., 2, 135, 150, 1886. 4, Kbl., Pogg., 18, 253, 1830. 5, Church, J. Ch. Soc., 26, 108, 1873.

5	Libethen (?)	3.162				[8.73] - 10	

It is not clear that anal. 5 belongs here.

Pyr., etc.—In the closed tube decrepitates and yields much water. B.B. in the forceps fuses to a steel-gray globule. On charcoal gives off arsenical fumes, and fuses quietly without deflagration to a slaggy mass, which in R.F. yields globules of copper. Soluble in nitric acid, in some cases with effervescence. Soluble in ammonia, yielding a blue solution and a white

residue of calcium carbonate.

Obs.—Usually occurs in the cavities of calamine, calcite, or quartz, accompanied by other ores of copper, appearing in small aggregated and diverging fibrous groups of a pale green color, and possessing a delicate silky luster. Has been observed in the Banat, at Posing and Libethen in Hungary; Nerchiusk in Siberia; Falkenstein and Schwatz in Tyrol; Saalfeld in Thuringia; Riechelsdorf in Hesse; Schneeberg in the Erzgebirge; in Zechstein-dolomite near Bieber.

In the U States, in the Tintic district, Utah, at the Mammoth mine with chalcophyllite and

other related species.

Ref.—1 E. S. Dana, Utah, Am. J. Sc., 39, 273, 1890.

637. VESZELYITE. Schrauf, Anz. Akad. Wien, 135, 1874; Zs. Kr., 4, 31, 1879. Monoclinic (or triclinic?). Form as in figure.

Measured angles, Schrauf $mM = 84^{\circ}$ 47, $e\epsilon = 70^{\circ}$ 43'-51', inclination edge e/ϵ to m/M = 76° 10, also $me = 57^{\circ}$ 19' $m\epsilon = 104^{\circ}$ 3', $Me = 104^{\circ}$ 16'.

Incrusting, consisting of a granular aggregate of indistinct crystalline individuals. Occasionally in distinct crystals, combinations of the prism and brachydome.

H. = 3.5-4. G. = 3.531. Color and streak greenish blue.

Comp.—A hydrous phospho-arsenate of copper and zinc; perhaps (Rg.) $7RO.(P,As)_2O_5.9H_3O=(R=Zn:Cu=2:3, As:P=2:3)$, requiring: Arsenic pentoxide 10.2, phosphorus pentoxide 9.5, cupric oxide 37.5, zinc oxide 24.8, water 18.1=100.

Anal.-Schrauf (on 0.1 gr.).

As2Os	P2O5	CuO	ZnÔ	H ₂ O
10.41	9.01	37.34	25.20	17.05 = 99.01

Named after the mining engineer Veszelyi.

Ref.—1 L. c., Schrauf's letters are retained, m=011, e=110, also δ ($\bar{2}01$) and σ ($\bar{1}21$) rare. Schrauf gives a triclinic axial system (with which the angles do not wholly agree), but it obviously makes small claim to exactness.

638. LUDLAMITE. N. S. Maskelyne and F. Field, Phil. Mag. 3, 52, 135, 525, 1877.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=2.2520$. 1:1.9819; $\beta=*79^{\circ}\ 27'=001$ \wedge 100 Maskelyne.

 $100 \land 110 = *65^{\circ} 41\frac{1}{2}', 001 \land \overline{101} = 45^{\circ} 53', 001 \land 011 = 62^{\circ} 49\frac{5}{6}'.$

Forms:
$$m (110, I)$$
 $d (\bar{1}01, 1-\bar{i})$ $l (011, 1-\bar{i})$ $p (111, -1)$ $a (100, i-\bar{i})$ $t (201, -2-\bar{i})$ $k (\bar{2}01, 2-\bar{i})$ $r (112, -\frac{1}{2})$ $q (\bar{1}11, 1)$ $c (001, 0)$

Crystals small, tabular ||c|. Faces c, q striated or furrowed ||edge c/q|.

Cleavage: c highly perfect; a distinct. H. = 3-4. G. = 3·12. Luster vitreous, brilliant. Color bright green. Streak greenish white. Transparent. Optically +. Ax, pl. || b. Bx_a \wedge c = -67° 5'. Dispersion $\rho > v$ small; of bisectrices nearly zero.

Pyr., etc.—In the closed tube gives off much water, the last portions of which react acid and color Brazil wood paper yellow (fluorine), and also etch the tube. B.B. in the forceps swells

up and splits frequently into fine acicular particles, which are infusible, but color the flame pale green; moistened with sulphuric acid the green becomes more intense. Gives a blue with cobalt solution. Some varieties react for iron and manganese with the fluxes. Heated with sulphuric acid gives off fumes of hydrofluoric acid, which etch glass. Soluble in hydrochloric acid, and also in caustic potash. Obs.—Wavellite was first discovered in a tender clay slate near Barnstaple, in Devonshire.

by Dr. Wavel. It has since been found at Clonmel and Cork, Ireland; in the Shiant Isles of Scotland; with the amblygonite of Montebras, France; at Zbirow and Zajecov in Bohemia; at Frankenberg and Langenstriegis, Saxony; Dünsberg near Giessen, Hesse Darmstadt; on brown iron ore in the Jura limestone at Amberg in Bavaria (the *lasionite* of Fuchs); in a manganese mine at Weinbach near Weilburg in Nassau (Genth); at Villa Rica, Minas Geraes, Brazil.

Kapnicite is from Kapnik, Hungary.

Kapnicite is from Kapnik, Hungary.

In the United States reported as found near Saxton's River, Bellows Falls, N. H.; also at the slate quarries of York Co., Pa., near the Susquehanna; at Silver Hill mine, Davidson Co., N. C., with actinolite, pyrite, and native silver; at White Horse Station, Chester Valley R. R., Pa., in a bed of limonite, abundant in stalactitic forms, part drusy with rhombic crystals, and often coated with a pearly scaly mineral yet undetermined; at Magnet Cove, Arkansas, in fine stellate radiations of a light green to deep green color.

Named after Dr. Wavel, the discoverer. The species was considered a variety of diaspore by D'Aubuisson, Bournon, Hausmann, and some other early mineralogists, and placed next to diaspore by Werner in 1817; while Jameson arranged it in 1816 among the zeolites.

Pyr., etc.—In the closed tube decrepitates, yields water, and turns brown or black. B.B. in the forceps becomes brown and assumes a glassy appearance, but does not fuse; colors the flame green; moistened with hydrochloric acid the color is at first blue (copper chloride). With the sodium test gives hydrogen phosphide. With borax and salt of phosphorus gives beads in O.F. which are yellowish green while hot and pure green on cooling. With salt of phosphorus and tin on charcoal gives an opaque red bead (copper). Soluble in hydrochloric acid.

Obs.—The highly prized oriental turquois occurs in narrow seams (2 to 4 or even 6 mm. in thickness) or in irregular patches in the brecciated portions of a porphyritic trachyte and the surrounding clay slate in Persia, not far from Nishapur, Khorassan (cf. Schindler, Vh. G. Reichs., 93, 1884, Rec. G. Surv. India. 17, 182, 1884); the exact locality is stated to be on the southern slopes of the Mt. Ali-Mirsa, N.W. of the village Madèn. Also in the Megara Valley, Sinai, with limonite in seams in porphyry; a greenish blue variety comes from the Karkaralinsk (Kirgeshi Steppes), Semipalatinsk, Siberia. Also in the Kara-Tube Mts. in Turkestan, 50 versts from Samarkand with limonite, etc., in seams in a siliceous clay slate; the locality has been worked at some unknown time in the past. An impure variety is found at Steine in

Silesia, and at Oelsnitz in Saxony.

In the U. States, occurs in the Los Cerillos Mts., 20 m. S.E. of Santa Fé, New Mexico, in a trachytic rock, a locality long mined by the Mexicans and in recent years reopened and extensively worked. It has afforded some fine gems. Cf. Blake, Am. J. Sc., 25, 227, 1858; 25, 197, 1883; Silliman, ib., 22, 67, 1881; Clarke and Diller, l. c.; also Kunz, Gems, etc., of the U. S.,

Found also in the Burro Mts., Grant Co., N. M., southwest of Silver City (Snow, Am. J. Sc., 41, 511, 1891); at the Holy Cross Mt., Colorado. A pale green turquois occurs in the Sierra Nevada, five miles north of Columbus, Nevada; a kind pseudomorphous after apatite at Taylor's ranch, Chowchillas river, in Fresno Co., California (Zeph. & Moore, l. c.).

Domeyko (Min., 3d Ed.) refers here an earthy cupriferous aluminium phosphate from San Lorenzo, Chili (5th Ed., p. 587).

On the microscopic structure of turquois, see Bkg., Zs. Kr., 2, 163, 1878, 3, 81, 1879. Natural turquois of inferior color is often artificially treated to give it the tint desired. More-

over, many stones which are of a fine blue when first found retain the color only so long as they are kept moist, and when dry they fade, become a dirty green, and are of little value. Much of the turquois (not artificial) used in jewelry in former centuries, as well as the present, and that described in the early works on minerals, was bone-turquois (called also odontolite, from όδους, tooth), which is fossil-bone, or tooth, colored by a phosphate of iron. Its organic origin becomes manifest under a microscope. Moreover, true turquois, when decomposed by hydrochloric acid, gives a fine blue color with ammonia, which is not true of the odontolite.

The Callais of Pliny is generally regarded as turquois, and probably rightly so. But all he says of it is, "Callais sapphirum imitatur, candidior et litoroso marisimilis," resembling sapphire (that is, lapis-lazuli) in color, but paler, and like the sea toward the shore; indicating a greenish

blue tint and degree of opacity corresponding well enough with much turquois.

The Callaina also of Pliny (to which he devotes a long chapter) is referred to this species, and with even better reason. It was a stone of a pale green color, and was obtained, according to him, amid inaccessible rocks in the countries that lie at the back of India, near Mt. Caucasus, etc. He also states that it was remarkable for its size, and was full of holes and foreign substances, which it is difficult to reconcile with the true turquois. But he speaks in the next sentence of a kind from Carmania (a district of Persia) as of better quality and clearer, and this may have been real turquois. He says that no stones were more easily imitated, which is very true of turquois. He also remarks that the beauty of the Callaina is greatly heightened by a setting of gold, the contrast peculiarly befitting it.

Pliny also speaks of another stone called Callaica (37, 56), and says of it: "Callaicam vocant e turbido callaino; ferunt pluris conjunctis semper inveniri;" it is so called because it is a turbid

callaina, and they are found together. He also remarks that the stone called "Augetis (37, 54) multis non alia videtur quam callaina," by many is thought to be nothing but callaina. (See further Callainite, p. 825).

The Persian smaragdus, or emerald, alluded to by Pliny (37, 18, citing from Democritus). as "without transparency, agreeable and uniform in color, satisfying the vision without allowing it to penetrate it," may have been turquois; yet, as with most of Plicy's descriptions (owing to his mixing different things of similar aspect), when all the other characters given are weighed they leave doubt.

It is probable that the turquois—oriental and occidental—was as commonly used in Persia as a gem in ancient times as now. The name turquois (or turquoise) is French in form, and

means Turkish, a Turkish gem, the gem having come into Europe through Turkey.

W. P. Blake (l. c., and ib., 25, 197. 1883) regards the bluish green turquois of Los Cerillos as the chalchihuitl of the Mexicans; he proposes the mineralogical name chalchuite. By others this Mexican stone is referred to jade (p. 371), also by others to emerald.

643. SPHÆRITE. Sphärit v. Zepharovich, Ber. Ak. Wien, 56 (1), 24, 1867.

In globular concretions with a drusy faceted surface, without a distinct fibrous or concentric structure.

Cleavage distinct in one direction. H. = 4. G. = 2.536. Luster greasyvitreous, glimmering. Color light gray, bluish; also reddish from mixture with hematite. Translucent.

Comp.—Perhaps $4AlPO_{\bullet}.6Al(OH)_{\bullet} + 7H_{\bullet}O$ or $5Al_{\bullet}O_{\bullet}.2P_{\bullet}O_{\bullet}.16H_{\bullet}O$ = Phosphorus pentoxide 26.3, alumina 47.1, water 26.5 = 100.

Anal.-1, Boricky (l. c.); 1a, same, with SiO2, CaO, MgO, and some P2O6 (for these bases) excluded:

		P206	Al ₂ O ₃	MgO	CaO	H ₂ O	SiO:		
1.	2	28.58	42·36 46·71	2.60	1.41	24.03	0.87	=	99 85
10.		26.80	46.71	-	-	26.49	-	=	100

Pyr., etc.--Yields water. B.B. is infusible, and colors the flame bluish green. With cobalt solution a fine blue.

Obs.—Occurs lining cavities or seams in hematite, at Zajecov, north of St. Benigna, Bohemia,

in Lower Silurian schists, along with wavellite.

Alt.—Becomes opaque white, dull, and earthy by alteration.

644. LISKEARDITE. Maskelyne, Nature, 18, 426, Aug. 15, 1878.

Massive; in thin incrusting layers, with uniform fibrous structure. Color white, with a slight blue or greenish blue tint.

Comp.— $(Al, Fe)AsO_4.2(Al, Fe)(OH)_3 + 5H_2O$ or $3(Al, Fe)_2O_3.As_2O_6.16H_2O = Arsenic pent-$

oxide 27.1, alumina 30.9, iron sesquioxide 8.1, water 33.9 = 100.

Obs.—Occurs in crusts one-fourth of an inch thick as a coating of cavities or incrustation on quartz or other minerals; accompanying species are scorodite, arsenopyrite, chalcopyrite, pyrite, earthy chlorite; from Liskeard, Cornwall.

645. EVANSITE. D. Forbes, Phil. Mag., 28, 341, 1864.

Massive; reniferm or botryoidal.

Fracture subconchoidal. H. = 3.5-4. G. = 1.939. Luster vitreous or resinous; internally waxy. Colorless, or milk-white; sometimes tinged with yellow or blue. Streak white. Translucent, subtranslucent.

Comp. -2AlPO_4 . $4\text{Al}(OH)_3 + 12\text{H}_2O$ or 3Al_2O_3 . P_2O_4 . $18\text{H}_2O = \text{Phosphorus pent-}$

oxide 18.4, alumina 39.6, water 42.0 = 100.

Anal.-Forbes, l.c.

$\frac{3}{3}$ P₂O₅ 19.05 Al₂O₂ 39.31 H₂O 39 95 insol. 1.41 = 99.72

Pyr., etc.—B.B. in closed tube yields neutral water, decrepitates, leaving milk-white powder. Infusible. Moistened with sulphuric acid colors the flame green. On charcoal with cobalt solution gives intense blue. With fluxes trace of iron. Soluble in sulphuric, nitric, and hydrochloric acids. Fluorine not detected.

Obs.—Occurs at Zsetcznik, Hungary, as reniform or globular concretions on limonite. Brought in 1855 from Hungary, by Brooke Evans, of Birmingham, England, after whom it was named. It was labeled allophane.

A mineral occurring in a small fissure in the Yoredale Rocks, Ratcliffe Wood, Macclesfield, is referred here by A. S. Woodward. The loss on ignition was 40 p. c. Min. Mag., 5, 333, 1883.

CCERULEOLACTITE. Coeruleolactin T. Petersen, Jb. Min., 353, 4871. Crypto-crystalline to micro-crystalline. Fracture uneven to conchoidal. H. = 5. G. =

2.552-2.593. Color milk-white passing into light copper-blue. Streak white. Composition, perhaps $3Al_2O_3.2P_2O_4.10H_2O$ = Phosphorus pentoxide 36.9, alumina 39.7

water 23.4 = 100.

35.05 21.43 4.45 0.55 4.20 tr. 33.06 Cl 0.46, SO, tr., insol. 0.80 = 100

Of the water 15.46 p.c. is lost at 100°, and 17.60 more at a red heat. B.B. fuses readily. From Sugar Loaves, Taranaki, New Zealand.

BERLINITE C. W. Blomstrand, Öfv. Ak. Stockh., 25, 198, 1868. TROLLEITE, ibid., p. 199. AUGELITE, ibid., p. 199. ATTACOLITE, ibid., p. 201.

These are aluminium phosphates from the iron mine of Westanå, Scania, Sweden. They need further study to show that they are all independent species. The characters given are as follows:

Berlinite. Compact massive, no cleavage, resembles quartz. H=6. G=264. Luster vitreous. Colorless to grayish or pale rose-red. Translucent. Analysis:

 $P_2O_5 54.84$ $Al_2O_3 40.27$ $Fe_2O_3 0.26$ $H_2O 4.14 = 99.51$

This corresponds to $2\Lambda l_2O_3$, $2P_2O_5$, H_2O . B.B. whitens without fusing. Hardly attacked by acids. Named after Prof. N. H. Berlin, of the University of Lund.

TROLLEITE. Compact, with indistinct cleavage. Fracture even to conchoidal. H. = 5.5 G. = 3.10. Luster more or less vitreous. Color pale green. Analysis:

 $\frac{3}{5}$ P₂O₅ 46.72 Al₂O₃ 43.26 Fe₂O₃ 2.75 CaO 0.97 H₂O 6.23 = 99.93

This corresponds to $4Al_2O_3.3P_2O_6.3H_2O$. Scarcely attacked by acids. Named after the Swedish chemist H. G. Trolle-Wachtmeister.

AUGELITE. Massive. Cleavage distinct in three directions. G. = 2.77. Luster of cleavage surface strongly pearly. Pale red, also colorless. Analysis:

 P_2O_5 35·04 Al_2O_3 49·15 Fe_2O_3 0·89 MnO 0·31 CaO 1·09 H_2O 12·85 = 99·33

This corresponds to $2Al_2O_3$, P_2O_5 , $3H_2O$. Yields much water in the glass tube. B.B. infusible. Scarcely affected by acids. Named from $\alpha \mathring{v} \gamma \acute{\eta}$, luster.

ATTACOLITE. Massive, indistinctly crystalline. H. = 5. G. = 3.09. Color pale red. Analysis: [H₂O 6.90 = 98.68

²/₂ P₂O₅ 36·06 Al₂O₅ 29·75 Fe₂O₅ 3·98 MnO 8·02 MgO 0·33 CaO 13·19 Na₂O 0·45

8.6 p. c. SiO_2 has been deducted; the formula is doubtful. B.B. fuses easily, and, when more heated, with intumescence, to a brownish yellow glass. With soda a strong manganese reaction. Very incompletely decomposed by acids. Named from $\alpha \tau \tau \alpha \kappa \epsilon \psi s$, salmon, alluding to the color.

646. PHARMACOSIDERITE. ? Fer minéralisé par l'acide arsenique Proust, Ann. Chem., 1, 195, 1790; Arsenicated Iron Ore Kirwan, 2, 189, 1796. Olivenerz, Arseniksaures Eisen in Würfeln kryst. (f. Carharrack) Klapr., Schrift. Ges. nat. Fr. Berl., 1, 161, 1786, Beitr., 3, 194, 1802; Würfelerz, var. of Olivenerz, Lenz, 2, 18, 151, 1794. Würfelerz Karsten, Tab., 66, 1808. Cube Ore. Pharmakosiderit Hausm., Handb., 1065, 1813.

Isometric: tetrahedral. Observed forms:

a(100, i-i) d(110, i) o(111, +1) $\omega(40.1.1, 40.40)^{1}$

Commonly in cubes with faces sometimes striated \parallel edge a/o, or replaced by the vicinal trapezohedron ω ; also

tetrahedral. Rarely granular.

Cleavage: a imperfect. Fracture uneven. Rather sectile. H. = 2.5. G. = 2.9-3. Luster adamantine to greasy, not very distinct. Color olive-green, passing into yellowish brown, bordering sometimes upon hyacinth-red and blackish brown; also passing into grass-green, emerald-green, and honey-yellow. Streak green to brown, yellow, pale. Subtransparent to subtranslucent. refraction.²

Figs. 1, 2, Utah, Pearce.

Pyroelectric. Shows anomalous double

Comp.—Perhaps $6 \text{FeAsO}_{\bullet}.2 \text{Fe(OH)}_{\bullet} + 12 \text{H}_{\bullet} \text{O} \text{ or } 4 \text{Fe}_{\bullet} \text{O}_{\bullet}.3 \text{As}_{\bullet} \text{O}_{\bullet}.15 \text{H}_{\bullet} \text{O}$ (Rg.) = Arsenic pentoxide 43·1, iron sesquioxide 40·0, water 16.9 = 100.

Anal.—Berzelius, Ak. H. Stockh., 354, 1824.

P2O5 Fe₂O₃ CuO H₂O As₂O, 37.82 2.53 39.20 0.65 18.61 gangue 1.76 = 100.57

Pyr., etc.—Same as for scorodite.

Obs.—Formerly obtained at the mines of Wheal Gorland, Wheal Unity, and Carharrack, in Cornwall, coating cavities in quartz, with ores of copper; found in quartz at Burdle Gill in Cumberland, in small brilliant crystals; in minute tetrahedral crystals at Wheal Jane; also in Australia; at St. Leonard and Garonne, Dept. du Var, in France; at Schneeberg and Schwarzenberg in Saxony; at Königsberg, near Schemnitz, Hungary, and on the Sandberg; in cubic crystals (G. 2.873 Vrba) at Pisek, Bohemia.

In Utah, at the Mammoth mine, Tintic district, in straw-yellow to pale green crystals (f. 1, 2) on a ferruginous quartz with scorodite and various copper arsenates derived from

enargite.

Named from φάρμακον, poison (in allusion to the arsenic present), and σίδηρος, iron.

Proust first announced the existence of an arsenate of iron, from greenish white concretionary specimens found in Spain; but from his meager description its identity with this species cannot be made certain.

Alt.—Has been observed altered to psilomelane, limonite, hematite.

Ref.—¹ Phillips, vicinal to the cube; this approximate symbol is suggested by Naumann,
Lehrb. Kryst., 1, 113, 1829. ² Btd., Bull. Soc. Min., 4, 256, 1881.

647. CACOXENITE. Kakoxen J. Steinmann, Vortr. Böhm. Ges., Prag; 1825. Cacoxene.

Occurs in radiated tufts of a yellow or brownish yellow color.

H. = 3-4. G. = 3.38. Becomes brown on exposure. Comp.—FePO, Fe(OH), + 4½H,O or 2Fe₂O, P₂O, 12H₂O = Phosphorus pentoxide 20.9, iron sesquioxide 47.2, water 31.9 = 100.

The above corresponds to anal 1; anal. 2, 3, give somewhat different results.

Anal.—1, 2, Hauer, Jb. G. Reichs., 5, 67, 1854; after deducting insoluble matter. 3, Nies. Jb. Min., 1, 108, 1881.

	P205	Fe ₂ O ₃	H ₂ O
1. Hrbek mine	19.63	47.64	32.73 = 100
2. "	25.71	41.46	32.83 = 100
3. Eleonore mine $G_1 = 2.4$	26.17	40.35	$30.59 \text{ Al}_2\text{O}_3 2.89 = 100$

Pyr., etc.—Yields water, with trace of fluorine. Fuses on the edges to a black shining flag, and colors the outer flame bluish green. Reactions for iron. Soluble in hydrochloric acid.

Obs.—Occurs at the Hrbek mine, near St. Benigna in Bohemia, along with earthy limonite, dufrenite, etc. Stated by Zepharovich to be sometimes derived from the alteration of barrandite. Also at the Eleonore mine on the Dünsberg, near Giessen.
In the U. States, at Noblis mine, Lancaster Co., Penn., on limonite; reported with the

martite of the Lake Superior mining region.

648. BERAUNITE. Breithaupt, Handb., 156, 1841; B. H. Ztg., 402, 1853. Eleonorite **Nies**, Ber. Oberhess. Ges., 19, 111, 1880; Streng, Jb. Min., 1, 102, 1881.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=2.7538:1:4.0165; \beta=*48°33'=001 \land 100$ Streng.

 $100 \land 110 = 64^{\circ} 9',001 \land 101 = 88^{\circ} 11\frac{1}{2}',001 \land 011 = 71^{\circ} 37\frac{1}{2}'.$

Forms¹: $a(100, i-\bar{i}), c(001, 0); x(h0l, -m-\bar{i}), p(\bar{1}11, 1).$

Angles: $cp = 89^{\circ} 23$, $ap = *75^{\circ} 36'$, $pp' = 140^{\circ} 4'$, $pp''' = *39^{\circ} 56$.

Twins: tw. pl. a; sometimes penetration-twins.

Crystals small, tabular | a, resembling some lazulite; faces a striated \parallel edge c/a. Commonly united in druses and in radiated foliated globules and crusts.

Cleavage: a distinct. Luster vitreous, on a inclining to pearly. Color reddish brown to dark hyacinth-red. Strongly pleochroic; red-brown | axis b, pale yellow in a transverse

direction. Streak yellow. Bisectrix nearly $\perp a$.

Var.-1. Beraunite in small foliated aggregates; also in monoclinic crystals with c, b, m, p (111); cleavage b, c (Boricky).

2. Eleonorite in crystals (cf. fig.) with angles as above. Its identity with beraunite can hardly be questioned, though not absolutely proved. Cf. Bertrand (Bull. Soc. Min., 4, 88, 1881), who states that they are alike in angles, pleochroism, and optical characters.

Comp.—Perhaps 2FePO_4 : $\text{Fe}(OH)_3 + 2\frac{1}{2}H_2O$ or 3Fe_2O_3 . $2P_2O_4$. $8H_2O$ = Phos pnorus pentoxide 31·3, iron sesquioxide 52·8, water 15·9 = 100.

Boricky calculates for the St. Benigna beraunite, 3Fe₂O₃.3P₂O₃.12H₂O = Phosphorus pent-

oxide 29.6, iron sesquioxide 55.4, water 15.0 = 100.

Anal.—1, Tschermak, Ber. Ak. Wien, 49 (1), 341, 1864.

	a Expelled	at 250° C.	

Pyr.—B.B. fuses easily to a black bead metallic in appearance, crystalline on cooling.

Easily soluble in hydrochloric acid.

Obs. - Beraunite is from the Hrhek mine, St. Benigna, near Beraun, in Bohemia; reported also from Wheal Jane, near Truro, England, by Greg, associated with pure and altered vivianite; from Scheibenberg, Saxony.

Eleonorite occurs on limenite at the Eleonore mine on the Dünsberg, near Giessen, and at the Rothläufchen mine near Waldgirmes, in the same region. Also occurs (anal 7) with dufrenite in Sevier Co.. Arkansas, in rosettes of foliated crystals of a blood-red color.

GLOBOSITE Breithaupt, B. H. Ztg., 24, 321, 1865. A mineral occurring at the Arme Hilfe mine near Hirschberg, in small globular concretions. H. = 5-5.5. G. = 2.825-2.827. Luster greasy to adamantine. Color wax-yellow to yellowish gray. Streak white. Brittle. Analysis. Fritzsche:

B.B. in tube yields water; by stronger heat gives the fluorine reaction, depositing a ring of silica, and leaving a red residue not magnetic, but giving with fluxes the reaction for iron. Slowly soluble in hydrochloric acid.

It occurs as above with massive and pulverulent limonite; also in the cobalt mine of Schneeberg in Saxony, with quartz and hypochlorite.

PICITE A. Nies, Ber. Oberhess. Ges., 19, p. 112, 1880. A. Streng, Jb. Min., 1, 116, 1881.

Amorphous; in thin coatings, or in small stalactitic and spherical forms. Fracture subconchoidal. H. = 3-4. G. = 2.83. Color dark brown. Streak yellow. Luster vitreous to greasy. Translucent. Anisotropic. Analysis.—Nies, deducting 2 10 p. c. insol.:

$$P_2O_3$$
 24.47 Fe_2O_3 46.50 Al_2O_3 1.00 H_2O 28.03 = 100

From the Eleonore mine, on the Dünsberg, and the Rothläufchen mine, near Waldgirmes, in the neighborhood of Giessen. Closely related, as shown by Nies, to the *Picites resinaceus* of Breithaupt (Handb. Min., 3, 897, 1847), and to a phosphate mentioned by Boricky (Ber. Ak. Wien, 56 (1), 16, 1867) as occurring at the Hrbck mine, St. Benigna, Bohemia.

Delvauxene Dumont, L'Institut, 121, 1839, Delvaux, Bull. Ac. Belg. 147, DELVAUXITE.

Delvauxit Haid., Handb., 512, 1845.

A hydrated ferric phosphate from Berneau, near Visé, Belgium, with 40 to 50 p. c. water. Color yellowish brown to brownish black or reddish; G. = 185. Anal. -1, 2, Dumont, l. c. 3, Delvaux, l. c.

	P_2O_5	Fe ₂ O ₂	H_2O		
1.	16.04	34 20	49.76	=	100
2.	16.57	36.62	46.81	=	100
3.	18.20	40.44	41.13	=	99.77

Dumont's analyses give 2Fe₂O₃.P₂O₅ 24H₂O. The mineral is characterized as a wet dufrenite by Church, Ch. News. 10, 157, 1864, who found that it lost 20°33 p. c. over sulphuric acid, and

nearly 6 p. c. more on heating to 100° C.; the total percentage of water having been found to be 87.23, whence the essential water is only 10-11 p. c. He detected a trace of line.

Delvauxite sometimes occurs at Visé in the form of gypsum (Cesaro), cf. also Jorissen, Mem. Soc. G. Belg., 6, 38, 1879, who gives the formula 5Fe₂O₂.2P₂O₄.15H₂O or 26H₂O if the water lost at ordinary temperatures is included. A similar hydrated ferric phosphate has been noted at Pisek, Bohemia (G. = 2.789), cf. Vrba, Zs. Kr., 15, 206, 1888.

649, 650. CHILDRENITE—EOSPHORITE.

649. Childrenite. Lévy, Brandes J., 16, 274, 1823.

Orthorhombic. Axes $\ddot{a}: \dot{b}: \dot{c} = 0.77801:1:0.52575$ Miller. $100 \land 110 = 37^{\circ} 53', 001 \land 101 = 34^{\circ} 3', 001 \land 011 = 27^{\circ} 44'.$

Forms: $a(100, i-\bar{i}), b(010, i-\bar{i}); m(110, I); p(111, 1), s(121, 2-\bar{2}), r(151, 3-\bar{3})$

Fig. 1, Tavistock, after Mlr. 2, Hebron, Me., Cooke.

Habit pyramidal, form sometimes a double six sided pyramid, comb. of sm or rsm; also prismatic. Faces r, s striated | edge s/s'"; also m vertically. Only known in crystals.

Cleavage: a imperfect. Fracture uneven. H. = 4.5-5. G. = 3.18-3.24. Luster vitreous to resinous. Color yellowish white, pale yellowish brown, brownish black. Streak white to yellow-Translucent.

Optically —. Ax. pl. $\| \vec{a} \cdot Bx \perp b \cdot Ax$. angles variable, Dx.2:

Anal. 4 was made on pure crystals; 5, on the massive mineral containing 14:41 p. c. impu-

rities, chiefly quartz; 6, on pink massive mineral occurring in nodules in a chloritic mineral.

Pyr., etc.—Childrenite in the closed tube gives off neutral water. B.B. swells up into ramifications, and fuses on the edges to a black mass, coloring the flame pale green. Heated on charcoal turns black and becomes magnetic. With soda gives a reaction for manganese. With

borax and salt of phosphorus reacts for iron and manganese. Soluble in hydrochloric acid.

Eosphorite in the closed tube decrepitates, whitens, gives off abundance of neutral water, and the residue turns first black, then gray, and finally liver-brown with a metallic luster, and becomes magnetic. B.B. in the forceps cracks open, sprouts and whitens, colors the flame pale green, and fuses at about 4 to a black magnetic mass. Reacts strongly for manganese.

Obs.—Childrenite occurs in crystals and crystalline coats, on siderite, pyrite, or quartz, and sometimes with apatite, near Tavistock, and at the George and Charlotte mine, and also at Wheal Crebor, in Devonshire; on slate at Crinnis mine in Cornwall. Crystals 1 in. long have been

In U. States, at Hebron, Me., in minute hair-brown prismatic crystals, with amblygonite. Eosphorite occurs at Branchville, Fairfield Co., Conn., in a vein of pegmatyte associated with rhodochrosite and the manganesian phosphates, lithiophilite, triploidite, dickinsonite. Also as embedded nodules (anal. 6), in a massive green chloritic mineral. The massive mineral (anal.

5, G. = 2·92-3·08) is often impure from the presence of quartz, dickinsonite, and apatite.
 Childrenite was named after Mr. J. G. Children, an English mineralogist (1777-1852).
 Eosphorite from ἐωσφορος (synonym of φωσφορος), which means dawn-bearing, in allusion to

the characteristic pink color.

651. MAZAPILITE. G. A. Koenig, Proc. Acad. Philad., 192, 1888, Zs. Kr., 17, 85, 1889. Orthorhombic. Axes $\check{a}:\bar{b}:\dot{c}=0.8617:1:0.9980$ Koenig. $100 \land 110 = 40^{\circ} 45',001 \land 101 = 49^{\circ} 11\frac{1}{2}',001 \land 011 = 44^{\circ} 56\frac{1}{2}'.$

Forms: $a (100, i-\bar{i}), n (120, i-\bar{2}), r (201, 2-\bar{i}), d (012, \frac{1}{3}-\bar{i}), o (111, 1).$

Angles: $nn''' = *119^{\circ} 45'$, $rr' = 133^{\circ} 18'$, $nr''' = *46^{\circ} 42'$, $dd' = 53^{\circ} 2'$, $no = 66^{\circ} 14'$, $no'' = 113^{\circ} 37'$, $no''' = 78^{\circ} 41'$, $nr = 62^{\circ} 34'$.

Crystals slender prismatic, 3 to 15 mm. in length; often monoclinic in

development of faces.

Cleavage not observed. H. = 4.5. G. = 3.567, 3.582. Luster submetallic, dull on the fracture. Color black, on fracture surfaces deep brownish red; in thin splinters blood-red by transmitted light. ocher-yellow. Subtranslucent.

Comp.—Ca₃Fe₂(AsO₄)₄.2FeO(OH) + 5H₂O or 3CaO.2Fe₂O₃.2As₂O₄. 6H₀O = Arsenic pentoxide 43.6, iron sesquioxide 30.3, lime 15.9, water 10.2 = 100. Anal.-G. A. Koenig, l. c., 1889.

As ₂ O ₅	Sb ₂ O ₅	P2O5	Fe ₂ O ₃	CaO	H_2O
43.60	0.25	0.14	30.53	14.82	9.83 = 99.17

About one molecule of water is expelled up to 360°; the remaining five at a red heat, Pyr., etc.—Yields water in the closed tube, and at a red neat the powder becomes brick-red. B.B. fuses at 3 to a black magnetic globule, on charcoal gives the odor of arsenic and a coating of arsenic trioxide.

Soluble in warm hydrochloric acid.

Obs.—Occurs sparingly at the Jesus-Maria Mine in the mining district of Mazapil, Zacatecas, Mexico. The crystals are embedded in a gaugue of radiated aragonite and granular calcite, with other minerals probably identified as chrysocolla and pharmacolite; also associated with silver ores.

Ref. -1 L. c.; cf. also Dx., Bull. Soc. Min., 12, 441, 1889, who makes n = 110, d = 102, r = 041, o = 121. He gives $110 \wedge 1\bar{1}0 = 60^{\circ}$ and $102 \wedge \bar{1}02 = 52^{\circ}$ 6', whence $\check{a}: \check{b}: \dot{c} =$

0.57735:1:056443.

652. CALCIOFERRITE. Calcoferrit J. R. Blum, Jb. Min., 287, 1858.

Monoclinic? Foliated massive; in nodules.

Cleavage: very perfect, or foliated, in one direction; traces in another at right angles to the perfect one; also in another oblique to the same. Brittle. H. = 2·5. G. = 2·523-2·529 Reissig. Luster of cleavage-face pearly. Color sulphur-yellow, greenish yellow to siskin-green, yellowish, white. Streak sulphur-yellow. Thin laminæ translucent.

Comp.—Ca₃Fe₂(PO₄)₄, Fe(OH)₃.8H₂O or 6CaO.3Fe₂O₃.4P₂O₃.19H₂O = Phosphorus pent-

oxide 32.9, iron sesquioxide 27.8, lime 19.5, water 19.8 = 100.

Obs.—Occurs in bright green crystals, implanted on andrewsite at the West Phœnix mine, Cornwall. Also as a thin crystalline coating on dufrenite at Sayn, Westphalia (Ullmann).

Andrewsite Maskelyne, Chem. News, 24, 99, 1871, J Ch. Soc., 28, 586, 1875. Near chalcosiderite. Occurs in globular disks with radiated structure resembling wavellite. H. = 4. G. = 3.475. Color bluish green. Streak blackish green. Analysis.—Flight, J. Ch. Soc., 28. 586, 1875.

SiO2 P206 Fe₂O_{3.} FeO CuO MnO H.O Al203 CaO 0.08 0.49 = 99.598.79 0.92 26.09 44.64 7.11 10.86 0.60

A little limonite is probably present as impurity. The nucleus of the andrewsite globules afforded: P₂O₅ 12·28, Fe₂O₃ 73·92, CaO 4·31, H₂O 7·85, CuO,MnO tr., SiO₂ 1·48 = 99·84. This corresponds to 5Fe₂O₃.P₂O₅.5H₂O.

Obs.—Occurs in Cornwall on a quartzose veinstone associated with limonite and gothite.

and interpenetrated with a mineral resembling, if not identical with, dufrenite.

657. GOYAZITE. Damour, Bull. Soc. Min., 7, 204, 1884.

Tetragonal or hexagonal. In small rounded grains.

Cleavage: basal. H. = 5. G. = 3.26. Color yellowish white. Semi-transparent. Optically uniaxial, positive, Richard.

Comp.—A highly basic phosphate of aluminium and calcium, Ca₂Al₁₀P₂O₂₂.9H₂O or 3Ca₀.5Al₂O₃.P₂O₆.9H₂O = Phosphorus pentoxide 14.5, alumina 51.9, lime 17.1, water 16.5 = 100.

Anal.—Damour, l. c.

Al2O3 50.66 CaO 17:33 $H_2O 16.67 = 99.53$ P2O5 14.87

Pyr.—B.B. fuses with difficulty on thin edges; becomes blue when ignited and moistened with cobalt solution. Gives off water in the closed tube and turns white and opaque. Not attacked by acids.

Obs.—From the diamond washings of Minas Geraes, Brazil.

Named from the province in which the principal diamond localities occur. A phosphate was described by Damour in 1853 (L'Institut, 78) which may be a related mineral. Compact, of a pale or dark brick-red color. Scratches glass feebly. G. = 3·194. Supposed by Damour to be a hydrous phosphate of aluminium and calcium. B.B. in a tube gives considerable water, and in a platinum crucible at a red heat loses 12.70 p. c. of water. Found in rolled pebbles with the diamond sand of Bahia.

658. PLUMBOGUMMITE. Plomb rouge en stalactites—tantot en globules, de Lisle, Demeste Lettres Min., 2, 399, 1779: Crist., 3, 399, 1783. Sel acide-phosphorique-martial G. de Laumont, J. de Phys., 28, 385, 1786. Plomb-gomme de Laumont. Aluminiate de Plomb avec eau de combinaison Berz., in his Nouv. Min., 283, 1819. Bleigummi, Blei-aluminat, etc., Berz., Schw. J., 27, 65, 1819 (trl. ir. Nouv. Min.). Native Aluminiate of Lead Smithson, Ann. Phil., 14, 31, 1819 (citing Berz., and also a letter by de Laumont, in which S. Tennant (who died in 1815) is coid to be foot a combination of vide of lead 14, 31, 1818 (citting betz., and also a letter by the Landont, in which S. Felhant (who the late in 1815) is said to have first analyzed plombgomme and made it a combination of oxide of lead, alumina, and water). Plomb hydro-alumineux H., Tr., 3, 410, 1822. Gummispath Breith., Char., 56, 1832. Plomgomme Beud., Tr., 2, 1832. Plumbo-gummite, Shep., Min., 2, 113, 1835. Plumbo resinite Dana, Min., 230, 1837. Bleigummi, Gummibleispath. Bleihydro-aluminat, Germ. Hitchcockite Shep., Rep. Canton Mine, Ga., 1856, Min., 401, 1857.

Hexagonal. Reniform, globular, botryoidal, with sometimes a concentric

structure; in thin crusts; compact massive.

H. = 4-5. G. = 4-4.9; 4.88, Nuissière, Dufrénoy; 4.014, hitchcockite, Genth; Breithaupt gives 6.42. Luster resinous or gum-like. Color yellowish gray, reddish brown, greenish; also yellowish white; sometimes grayish white, Streak uncolored. Translucent; subtransparent. Optically uniaxial, bluish. positive, Bertrand'.

Comp.—Uncertain; anal. 4 corresponds nearly to Pb0.2Al, O₃.P₂O₅.9H₂O = Phosphorus pentoxide 19.4, alumina 27.9, lead protoxide 30.5, water 22.2 = 100,

The other analyses vary widely.

Anal.—1-3, Damour, Ann. Mines, 17, 191, 1840. 4, Genth, Am. J. Sc., 23, 424, 1857.

P₂O₅ SO₃ Al₂O₃ PbO H₂O Fe₂O₃ CaO PbCl₂ 8.06 0.30 34.32 35.10 $18.70 \quad 0.20 \quad 0.80 \quad 2.27 = 99.75$ 1. Huelgoet 12.05 0.25 12.05 62.15 6.18 8.24 = 100.9215 18 0.40 2.88 70.85 1.24 9.18 = 99.734. Hitchcockite 18 74 25.54 29.04 20.86 0.90 1.44 CO₂ 1.98, Cl 0.04, insol. 0.48=99.02

Berzelius made the mineral a hydrous aluminate of lead. Damour concluded from his results that in Berzelius's investigation the phosphoric acid was precipitated with the alumina and lead, and so lost sight of. He observes that his own analyses, though so widely different, agree in affording 1: I for the oxygen ratio of water and alumina, and regards the alumina as present in the state of a hydrate.

Pyr., etc.—In the closed tube decrepitates and yields water. B.B. in the forceps swells up like a zeolite, colors the flame azure-blue, but is imperfectly fused. On charcoal gives in addition a faint white coating of lead chloride (Plattner). With soda gives metallic lead. With cobalt

a faint white coating of lead chloride (Flatther). With soda gives metanic lead. With cooling solution gives a blue color. With the sodium test yields a phosphide. Soluble in nitric acid.

Obs.—Occurs in clay-slate at Huelgoet in Brittany, associated with galena, sphalerite, pyrite, and pyromorphite; also in a lead mine at Nuissière, near Beaujeu; at Roughten Gill, Cumberland; at Mine la Motte, Missouri(?); at Canton mine, Ga., with galena, etc. (hitchcockite).

Named from the Latin plumbum, lead, and gummi, gum. The identity of de Lisle's mineral to be a carrelian like in color) with plembumma, though questioned by de Laumont in

(which was carnelian-like in color) with plombgomme, though questioned by de Laumont in his early paper, is admitted in his letter cited in Ann. Phil., 14, 31, 1819.

The mineral looks usually like drops or coatings of gum, also at times somewhat like chalcedony or allophane. It differs from globular pyromorphite or sphalerite in not being fibrous within. The hitchcockite occurs in botryoidal crusts and thin coatings, white, bluish, yellowish, or greenish, allophane-like, sometimes concentric in structure; Shepard gives H. = 2.75-3, and says that it loses 29 p. c. on ignition.

Church finds that there is no loss in vacuo or dry air, at 100° 11.1 p. c. (6H2O), and the rest

Pyr., etc.—In the closed tube yields water. In the forceps fuses at 2.5 to a blackish mass, and colors the flame green. With salt of phosphorus gives a green bead, which with tin on charcoal becomes on cooling opaque red (copper). With soda on charcoal gives a globule of copper. Soluble in nitric acid.

Obs.—Gunnis Lake formerly afforded splendid crystallizations of this species, and also Tincroft and Wheal Buller, near Redruth, and elsewhere in Cornwall. Found also at Johann-georgenstadt, and Eibenstock and Schneeberg, in Saxony; in Bohemia, at Joachimsthal and Zinnwald; in Belgium, at Vielsalm. A variety from Providence in Cornwall is in 8-sided tables with the control of the country of the Cornwall is in 8-sided tables. with a low pyramid, and has a leek green color, with G, = 3.329-3.372 (Breith., B. H. Ztg., 24. 303, 1865)

As noted below, some so-called torbernite belongs to the corresponding arsenate, zeunerite. First named torberite (torbernite) by Werner; after the chemist Torber Bergmann [Lat. Torbernus, as written by Bergmann himself]. Then, this naming after persons having been denounced as an innovation (see Karsten's Werner's Verbess., 43, 1793), Werner substituted Chalcolite (fr. $\chi \alpha \lambda \kappa \delta 5$, copper, signifying, as he says, "ein Kupferhaltender Stein") in allusion to Bergmann's determination in 1780 that the mineral was muriate of copper. When, finally, it was shown by Klaproth to be an ore of uranium instead of copper, Werner, with Karsten and others, threw aside chalcolite, because false in significant, and used Uranglimmer. Chalcolite has since crept back again, but is no more appropriate now than it was sixty years. has since crept back again, but is no more appropriate now than it was sixty years ago. The name torberite was written as it should be torbernite, by some mineralogists of the last century.

Both this species and the autunite have gone under the common name of uranite; the former also as Copper-uranite: the latter Lime-uranite.

Ref.—1 Min. Mitth., 181, 1872. 2 This list contains the forms noted by Lévy, Min. Heul., 200, 1827.

3, 329, 1837, angles quoted by Dufrénoy and repeated by Mir., Min., 517, 1852; Hausm., Min., 2, 1104, 1847; Greg and Lettsom, Min., 384, 1858, whose list as here noted contains several angles not given by Mir; Hbg., Min. Not., 6, 41, 1863; Kk., Min. Russl., 5, 35, 1866. As suggested by Schrauf, some of these observations may have been made on the following species. zeunerite, so that the list of forms is not above doubt.

660. ZEUNERITE. Weisbach, Jb. Min., 207, 1872; 315, 1873; Jb. Berg-Hütt., 1877. Kupferuranite, Kupfer-Uranglimmer, pt.

Tetragonal. Axis c = 2.9125; 001 \wedge 101 = *71° 3' Weisbach'.

Forms¹: c(001, 0); a(100, i-i), $z(107, \frac{1}{2}-i)$, $p(407, \frac{4}{2}-i)$, e(101, 1-i), i(201, 2-i).

Angles: $cz = 22^{\circ} 35\frac{1}{2}$, $cp = 59^{\circ} 0$, $ce = 71^{\circ} 3$, $ci = 80^{\circ} 15\frac{1}{2}$, $ee' = 83^{\circ} 57'$

In tabular crystals resembling torbernite; also acute pyramidal.

Cleavage: c perfect; a distinct. Fracture uneven. Brittle. H. = 2-2.5. G. = 3.2. Luster on c pearly. Color grass-green to emerald- and apple-green.

Comp.—An arsenate of copper and uranium corresponding to the phosphate torbernite, Cu(UO₂), As, O₄ + 8H, O or CuO.2UO₂. As, O₄. 8H, O = Arsenic pentoxide 22.3, uranium trioxide 56.0, cupric oxide 7.7, water 14.0 = 100.

Anal.-Winkler, J. pr. Ch., 7, 8, 1873.

 $H_{\circ}O$ 15.68 = 99.97 As2O5 20.94 UO3 55.86 CuO 7.49

Pyr., etc.—Yields arsenical fumes on charcoal, and with soda gives a globule of copper.

Soluble in nitric acid.

Obs.—First found with other uranium minerals at the mine Weisser Hirsch, near Schneeberg. Saxony; the crystals rest upon quartz or upon iron ocher. Also found at Geisterhalde, near Joachimsthal; Wheal Gorland, Cornwall, on snicky quartz with chalcocite and melaconite; and Zinnwald, Saxony, on quartz.

Named for the Director of the Academy at Freiberg.

Artif.—Winkler (l. c., p. 14) has obtained zeunerite artificially, having the following composition: As₂O₅ 22·11, UO₃ 57·21, CuO 7·01, H₂O 14·65 = 100·98.

Ref.—¹ Schneeberg, l. c. Schrauf gives $ce = 68^{\circ}$ 20′, which varies widely from the allied species; he adds i ($ci = 78^{\circ}$ 46′), Min. Mitth., 182, 1872. Cf. also torbernite, ref. ²; the two species were probably early confounded.

661. AUTUNITE. Var. of Uranglimmer, Urankalk, or Chalcolite, of authors prior to 1819. Sel à base de chaux, du l'oxide d'urane joue le rôle d'acide, Berz., N. Syst. Min., 295, 1819. Uranit Berz., Jahresb., 4. 46, 1823. Kalk-Uranit, Kalk-Uranglimmer, Germ. Lime-Uranite. Autunite B. & M., 519, 1852. Calcouranit Breith., B. H. Ztg., 24, 302, 1865.

4. "	½ 13·40	60.84	5.31	20.33	= 99.88
5. Madagascar	14.93	55.08 .	6.51	22.08	Fe_2O_3 1.36 = 99.96

Church found that the mean loss of water (anals. 2, 3, 4) in dry air, in vacuo and at 100° (or in vacuo alone), was 15.03 p.c., and at a red heat 4.68 p.c. more. He concludes that unaltered crystals contain 10 p.c. H₂O, or if dried in vacuo, 2H₂O.

The early analysis of Berzelius gave 15.48 p. c. H₂O = 8 molecules. Pyr., etc.—Same as for torbernite, but no reaction for copper.

Pyr., etc.—Same as for torbernite, but no reaction for copper.

Obs.—Autunite is found usually with uraninite and other minerals containing uranium; also associated with silver, tin, and iron ores. Occurs in the Siebengebirge, in the hornstone of a trachytic range; at Johanngeorgenstadt and Eibenstock; Falkenstein in Saxon Voigtland; at Lake Onega, Wolf Island, Russia; near Limoges, and at St. Symphorien near Autun; formerly at South Basset, Wheal Edwards, and near St. Day, England

In the U. States, occurs sparingly at the feldspar quarry in Middletown, Conn., associated with columbite and albite, in minute tabular crystals and thin scales, of light green and lemonyellow colors; with uraninite at Branchville, Conn., also in minute crystals at Chesterfield, Mass., on the quartz or albite, and sometimes in the red centers of tourmalines; at Acworth, N. H., straw-yellow and light green; also in a gneiss quarry on the Schuylkill, near Philadelphia, about \(\frac{1}{2}\) m. above the suspension bridge. In N. Carolina, at the Flat Rock and other mica mines in Mitchell Co.; in Alexander Co. Found in the Black Hills, S. Dakota; at Silver Reef, Utah.

Berzelius calls the uranite of Cornwall and that of Autun, respectively, chalcolite and uranite, in his article announcing the composition, in JB., 4, 146, 147, 1823; and the special application

in his article announcing the composition, in JB., 4, 146, 147, 1823; and the special application of uranite to this species dates from that time. Yet, in order to avoid confusion from the double use of the name, it is better to adopt for the species the name of autunite, from one of its noted

localities.

Ref.—1 Ann. Mines, 11, 261, 1854; 14, 339, 1858. Brezina makes the Johanngeorgenstadt mineral monoclinic, with $\dot{a}:\dot{b}:\dot{c}=0.3463:1:0.3525,\ \beta=90^\circ$ 30', Zs. Kr., 3, 273, 1879. An early paper on the crystallization of "Oxyd of Uranium" (probably including both tor-

bernite and autunite), with two plates, is given by Phillips in Trans. G. Soc., 3, 112, 1816 (read Feb. 1815).

662. URANOSPINITE. Weisbach, Jb. Min., 315, 1873; Jb. Berg-Hütt., 1877. Orthorhombic. Axes $\check{a}:\check{b}:\dot{c}=1:1:2.9136$ approx.

Forms: c(001, 0); $q(1.0.10, \frac{1}{10}-\overline{i})$, $y(102, \frac{1}{2}-\overline{i})$, $r(101, 1-\overline{i})$, $x(012, \frac{1}{2}-\overline{i})$.

Angles: $cq = 16^{\circ} 15'$ (meas. 17°), $cy = cx = *55^{\circ} 32'$, $cr = 71^{\circ} 3'$ (meas. $71\frac{1}{2}$ °).

In thin tabular crystals rectangular in outline.

Cleavage: c perfect. H. = 2-3. G. = 3.45. Color siskin-green. Optically biaxial.

Comp.—Probably an arsenate of uranium and calcium corresponding to autun-

ite, Ca(UO,), As, O, + 8H, O or CaO.2UO, As, O, 8H, O = Arsenic pentoxide 22.9, uranium trioxide 57.2, lime 5.6, water 14.3 = 100.

Anal.-Winkler, J. pr. Ch., 7, 11, 1873.

Church urges that the water may correspond to 10 equivalents instead of 8, Min. Mag., 1, 236, 1877.

Obs.—Occurs with uraninite and various secondary uranium minerals at Neustädtel near

Schneeberg, Saxony.

Artif.—Obtained by Winkler (l. c.) by mixing uranium nitrate with a solution of lime in an excess of arsenic acid. The minute yellow crystals gave: As₂O₆ 23·01, UO₃ 59·01, CaO 5·62, $H_2O 14.27 = 101.91.$

663. URANOCIRCITE. Weisbach, Jahrb. Berg-Hütt., 1877, Abhandl., p. 48. Bariumuranite.

Orthorhombic. In crystals similar to autunite.

Cleavage: c perfect; a, b distinct. G. = 3.53. Luster pearly on c. Color yellow-green. Transparent to translucent. Optically biaxial. Bx $\perp c$. 15°-20°

Comp. — A phosphate of barium and uranium analogous to autunite, Ba(UO₂)₄P₂O₈ + 8H₂O or BaO.2UO₂.P₂O₆.8H₂O = Phosphorus pentoxide 14·0, uranium trioxide 56.7, baryta 15.1, water 14.2 = 100.

Anal.-Winkler, quoted by Weisbach.

P2O5 15.06

UO. 56.86

BaO 14.57

 $H_2O 13.99 = 100.48$

Earlier analyses by Georgi, and Uwao Imai, gave confirmatory results. Church (Min. Mag., 1, 234, 1877) finds that in vacuo over H₂SO₄, at 20° C., 6H₂O go off; and the remainder (2H₂O)

Obs.—Occurs in quartz veins near Falkenstein, Saxon Voigtland. Formerly called autunite

(lime-uranite).

664. PHOSPHURANYLITE. F. A. Genth, Am. Ch. J., 1, 92, 1879.

Occurs as a pulverulent incrustation; consisting of microscopic rectangular scales, with pearly luster. Color deep lemon-yellow.

Comp.—Hydrous uranium phosphate, (UO₂), P₂O₈ + 6H₂O or 3UO₃. P₂O₆. 6H₂O = Phosphorus pentoxide 12.7, uranium trioxide 77.6, water 9.7 = 100.

Anal.—1. Genth, l. c.; 1a, same, after deducting the lead oxide, present as impurity.

	P_2O_5	UO_3	H_2O	PbO	
1.	11:30	71.73	10.48	4.40 = 97.9	1
1a.	12.08	76.71	11.21	- = 100	

Pyr.—B.B. in the closed tube yields water, and becomes brownish yellow on cooling. Easily soluble in nitric acid.

Obs.—Occurs with other uranium minerals at the Flat Rock mine, Mitchell Co., N. C.;

incrusts the quartz, feldspar, and mica; also at the Buchanan mine.

665. TROGERITE. Weisbach, Jb. Min., 870, 1871.

Monoclinic. In thin tabular crystals | b, resembling gypsum; crystals united in druses.

Cleavage: b perfect. G. = 3.3. Luster on cleavage face pearly. Color lemon-yellow.

Comp.—A hydrous uranium arsenate, (UO₂), As₂O₃ + 12H₂O or 3UO₃. As₂O₃. $12 \text{H}_{\bullet} \text{O} = \text{Arsenic pentoxide } 17.6$, uranium trioxide 65.9, water 16.5 = 100.

Anal.-Winkler; two other analyses on material less pure gave concordant results, J. pr. Ch., 7, 7, 1873.

> As2O5 19.64 UO: 63.76 $H_2O 14.81 = 98.21$

Obs.—Occurs with walpurgite and other uranium minerals at the Weisser Hirsch mine at Neustädtel, near Schneeberg, Saxony. Named after the mining administrator, R. Tröger.

Reported with uraninite from the Bald Mountain mining district, Black Hills, S. Dakota.

For remarks on the form, cf. Schrauf, Min. Mitth., 185, 1872.

FRITZSCHEITE Breithaupt, B. H. Ztg., 24, 302, 1865. A mineral much resembling autunite in its four-sided quadratic (or nearly so) tables, with a perfect basal cleavage; with H. = 2-2.5; G. = 3.504?; vitreous to pearly in luster; reddish brown to hyacinth-red in color and streak; translucent; affording Fritzsche (l. c.) reactions for uranium, manganese, vanadium, phosphorus, and provide the stream of the s The red color is attributed to the manganese, and it is considered a mangan-uranite containing some vanadium. It occurs with crystals of autunite and torbernite at Neuhammer, near Neudeck in Bohemia, in a hematite mine; at Johanngeorgenstadt, of fine red color, with torbernite. Red crystals in groups, supposed to be this mineral, have been observed on specimens of uranite from Autun, and from Steinig, near Elsterberg, in Saxon Voigtland.

666. WALPURGITE. Walpurgin A. Weisbach, Jb. Min., 870, 1871; 1, 1877; Jb. Berg-Hütt. Sachs., 1877.

Triclinic. In thin scale-like crystals resembling gypsum; usually tabular $\parallel b$

and twins with b as twinning-plane; sometimes a feather-like striation on a.

Measured angles: $m\underline{m} = 62^{\circ} 30'$, $\mu\underline{\mu} = 72^{\circ} 18'$, $bc = 70^{\circ} 52'$, $cm = 80^{\circ} 40'$, $c\mu = 82^{\circ} 59'$, $bm = 59^{\circ} 2'$, $b\mu = 53^{\circ} 50'$. Extinction-angle 8° with vertical axis in plane normal to b, 16° for twin, Weisbach-Groth¹.

Cleavage: b distinct. H. = 3.5. G. = 5.76. Luster adamantine

to greasy. Color pomegranate- and wax-yellow.

Comp.—Probably a basic arsenate of bismuth and uranium, $Bi_{10}(UO_2)_3(OH)_{24}(AsO_4)_4$ or $5Bi_2O_3.3UO_3.2As_2O_5.12H_2O = Arsenic pentoxide 11.9, uranium trioxide 22.4, bismuth trioxide 60.1, water 5.6=100.$ Anal.—Winkler, J. pr. Ch., 7, 6, 1873.

> As2Os UO3 Bi2O3 H₂O 97.92 11.88 20.29 61.43 4.32 13.03 20.54 59.34 97.56

Obs.—Occurs with trögerite and other uranium minerals at the Weisser Hirsch mine at Neustädtel, near Schneeberg, Saxony. Ref.—1 Zs. Kr., 1, 93, 1877. Cf. Schrauf, Min. Mitth., 183, 1872.

667. RHAGITE. Weisbach, Berg-Hütt., Abh.; Jb. Min., 302, 1874.

In crystalline aggregates, spherical or mammillary, smooth on the surface.

Fracture subconchoidal. Brittle. H. = 5. G. = 6.82. Luster resinous to adamantine. Color yellowish green, sometimes wax-yellow. On the edges translucent.

Comp.—Perhaps (Rg.) 2BiAsO₄.3Bi(OH)₃ or 5Bi₂O₂.2As₂O₅.9H₂O = Arsenic pentoxide 15.7, bismuth trioxide 78.8, water 5.5 = 100.

Anal.—Winkler, J. pr. Ch., 10, 190, 1874.

Fe2O3, Al2O3 As,O Bi₂O₃ CaO H_2O gangue 14.20 1.47 4.62 3.26 = 98.430.50

Pyr., etc.—Easily soluble in hydrochloric acid, with difficulty in nitric acid. In the matrass decrepitates, and crumbles to a yellow powder, giving off its water; on charcoal fusible.

Obs.—Occurs on bismutite and quartz, accompanied by walpurgite, at the Weisser Hirsch mine, Neustädtel, near Schneeberg, Saxony.

Named from $\rho \alpha \xi$ ($\rho \alpha \gamma$ os), grape, in allusion to the color and botryoidal grouping.

668. MIXITE. Schrauf, Zs. Kr., 4, 277, 1879.

In very slender acicular crystals, deeply striated vertically; extinction parallel'. Also as an incrustation in irregular particles, granular and rough or spherical, reniform, with partial concentric fibrous structure.

 $H_{\bullet} = 3-4$. $G_{\bullet} = 3.79$. Color emerald-green to bluish green, pale green, or

whitish; streak somewhat lighter. Translucent to transparent in fine fibers.

Comp.—A hydrated basic arsenate of copper and bismuth, but formula doubtful.

861

Schrauf suggests 20CuO.Bi₂O₃.5As₂O₅.22H₂O = Arsenic pentoxide 32·0, bismuth trioxide 12.9, cupric oxide 44.0, water 11.1 = 100.

Anal.—1, Schrauf, l. c. 2, Hillebrand, Am. J. Sc., 35, 305, 1888; also Pearce Proc. Col. Soc., 1, 151, 1886.

G.
$$As_2O_5$$
 P_2O_5 Bi_2O_3 CuO ZnO H_2O

1. as_2O_5 as_2O_5

Pyr., etc.-In dilute nitric acid the mineral is instantly covered with a layer of a brilliant white powder of bismuth arsenate, insoluble in the acid; the copper arsenate goes into solution. On ignition becomes blackish green and gives off water. Roasted on charcoal gives a silverwhite bead of copper and bismuth, with a coating of bismuth trioxide.

Obs.—Occurs with bismuth ocher, bismutite, and torbernite in the Geistergang at Joachimsthal. Also at Wittichen, Baden, in crevices in barite with erythrite. In Utah, Tintic district, at the Mammoth mine in tufts of minute acicular crystals in a loosely coherent gangue.

Named after Bergrath A. Mixa.

Ref.—1 Cross, Am. J. Sc., 35, 306, 1888; cf. Schrauf, l. c., who makes it oblique 6° to 9°.

Antimonates; also Antimonites, Arsenites.

A number of antimonates have been included in the preceding pages among the phosphates, arsenates, etc. Cf. pp. 754, 803, 804.

669. ATOPITE. A. E. Nordenskiöld, G. För. Förh., 3, 376, 1877.

Isometric; in octahedrons, with cube and dodecahedron.

 $H_{\bullet} = 5.5 - 6$. $G_{\bullet} = 5.03$. Luster greasy. Color yellow to resin-brown. lucent.

Comp.—Perhaps calcium pyroantimouate, Ca,Sb,O, or 2CaO.Sb,O,=Antimony pentoxide 74.1, lime 25.9 = 100. Iron, manganese, and the alkali metals are also

Anal.—Nordenskiöld, l. c.

MnO 1.53 \$ Sb2O, 72.61 FeO 2.79 CaO 17.85 K₂O 0.86 $Na_2O 4.40 = 100.04$

Pyr., etc.—B.B. in forceps in O.F. unchanged. On charcoal in R.F. sublimes in part, fuses at first with difficulty, and gives finally, when the antimony pentoxide is all reduced to the metallic state and driven off, a dark infusible slag. In salt of phosphorus dissolves to a clear bead, yellow while hot, and colorless on cooling. Insoluble in acids; decomposed with difficulty by fusion with sodium carbonate. Easily reduced by hydrogen.

Obs.—Occurs sparingly in octahedrons embedded in hedyphane, which in turn forms little veins in rhodonite, at Långban, in Wermland, Sweden. Named from ατοπος, unusual.

Schneebergite A. Brezina. Vh. G. Reichs., 313, 1880.

Isometric; in small (0.5-1 mm.) octahedrons. Fracture conchoidal. Brittle. Cleavage dodecahedral in traces. H. = 6.5. G. = 4.1 Weidel. Luster vitreous to adamantine. Color honey-yellow. Transparent. Consists principally (Weidel) of calcium and antimony, with a little iron, and traces of copper, bismuth, zinc, magnesia, and sulphuric acid. B.B. infusible, becomes slightly brown. Insoluble in acids. Found by Lhotsky, at Schneeberg, Tyrol, near the union of anhydrite (or gypsum) with chalcopyrite and magnetite.

670. BINDHEIMITE. Blei-Niere (fr. Nerchinsk) Karst., Tab., 50, 77, 78, 1800 (citing anal. by Bindheim, Schrift. Ges. Nat. Fr. Berlin, 10, 374, 1792). Antimonate of Lead. Antimonbleispath, Antimonsaures Bleioxyd, Germ. Stibiogalenit Glock., Syn., 257, 1847. Bleinierite Nicol. Min., 383, 1849. Pfaffite Adam, Tabl. Min., 37, 1869.

Amorphous, reniform, or spheroidal; also earthy or incrusting. Structure sometimes curved lamellar.

H. = 4. G. = 4.60-4.76 Siberia, Hermann; 5.05 white, Cornwall, Heddle; 4.707 brown, ib., Heddle. Luster resinous, dull, or earthy. Color white, gray, brownish, yellowish. Streak white to grayish or yellowish. Opaque to translucent.

Comp.—A hydrous antimonate of lead, but analyses vary widely and no general

formula can be given.

Anal. 1 gives nearly Pb₃Sb₂O₈ + 4H₂O = Antimony pentoxide 30°2, lead protoxide 63°0, water 6°8 = 100. Other varieties give 2PbO.Sb₂O₅.3H₂O. Anal. 7, made on apparently very pure material, gives Sb₂O₅: PbO: H₂O = 5: 6°3: 11, and, as noted by Dunnington, most analyses give the molecular ratio PbO + Sb₂O₅: H₂O = 1: 1 or 1: 2.

Anal.—1, Hermann, J. pr. Ch., 34, 179. 1845. 2, C. Stamm, Pogg., 100, 618, 1857. 3, 4, Heddle, Phil. Mag., 12, 126, 1856. 5, Dick, ibid. 6, Mixter, King's Rep. G. Surv. 40th Par., 2, 759, 1877. 7, Dunnington, Proc. Amer. Assoc., 182, 1877. 8, Wait, Trans. Am. Inst. Mng. Eng., 8, 51, 1880. Also W. F. Hillebrand, Proc. Col. Soc., 1, 119, 1884, an impure variety from Secret Cañon, Nevada.

G.	Sb ₂ O ₅ Pb	$O H_2O$
1. Nerchinsk 4.6-4.76	31.71 61	6.46 = 100
2. Horhausen	41.13 48	$5.43 \text{ Fe}_{2}O_{3} 3.35, \text{ CuO } 0.84 = 99.59$

7. Sevier Co., Ark. 4.73	49.67 40.	
8. "	41.72 45	38 5.00 Fe ₂ O ₃ 2.06, Al ₂ O ₃ 4.05, SiO ₂ 1.84, Ag 0.04

Pyr., etc.—In the closed tube gives off water. B.B. on charcoal reduced to a metallic globule of antimony and lead, coating the charcoal white at some distance from the assay, and yellow nearer to it.

Obs.—A result of the decomposition of other antimonial ores; thus at Nerchinsk in Siberia; Horhausen; near Endellion in Cornwall, with jamesonite, from which it is derived, etc. In the U. States, in Sevier county, Arkansas; also Montezuma mine, Humboldt valley, Nevada.

Bleinierite is German for Lead-kidney-ite! and Stibiogalenite implies the presence of galena or lead sulphide; hence the substitute above after the earliest analyst of the species.

671. ROMEITE. Roméine Damour, Ann. Mines, 20, 247, 1841; 3, 179, 1853.

Tetragonal. Axis c = 1.0257; $001 \land 101 = 45^{\circ} 43\frac{1}{2}'$ Damour'. In groups of minute octahedrons o(111). Angles: $oo' = 71^{\circ} 12'$, $oo'' = *110^{\circ} 50'$. Cleavage none. H. above 5.5. G. = 4.713. Color hyacinth- or honey-yellow. Double refraction strong².

Comp.—An antimonite of calcium, perhaps CaSb,O, = Antimony 69.8, oxygen

14.0 (antimony trioxide 83.8), lime 16.2 = 100.

The analysis gives more nearly Ca₂Sb₂O₈ = Antimony 63·4, oxygen 16·9, lime 19·71 = 100. Anal.—Damour, l. c.

0 15.82 Fe 1.31 MnO 1.21 CaO 16.29 SiO₂ sol. 0.96 insol. 1.90=99.67 Sb 62.18 or Sb₂O₅ 40.79 Sb₂O₃ 36.82 FeO 1.70 1.21 16.29 0.96 1.90 = 99.67

Pyr., etc.—B.B. fuses to a blackish slag. With borax affords a colorless glass in the inner flame, a violet in the outer (manganese). With soda on charcoal gives white antimonial fumes and globules of metallic antimony; fused on platinum foil with soda gives a bluish green

manganate. Insoluble in acids.

Obs.—Romeite was found by B. de Lom at St. Marcel in Piedmont, in small nests or veins in the gangue which accompanies manganese, consisting in part of feldspar, epidote, quartz, limonite, and greenovite.

Named by Damour after the crystallographer Romé de Lisle (or Romé de l'Isle, 1736-1790).

Ref.—1 L. c. ² On the anomalous double refraction see Btd., Bull. Soc. Min., 4, 240, 1881.

672. NADORITE. Flajolot, C. R., 71, 237, 406, 1870.

Orthorhombic. Axes $\check{a}: \bar{b}: \dot{c}=0.7490:1:1.0310$ Cesàro¹. $100 \land 110=36^{\circ} 50', 001 \land 101=54^{\circ} 0\frac{1}{6}', 001 \land 011=45^{\circ} 52\frac{1}{2}'.$

Forms 2 : $a (100, i - \bar{i})$ $b (010, i - \bar{i})$	$\pi (430, i-\frac{\pi}{8})$ $q (230, i-\frac{3}{2})$ $r (130, i-3)$	θ (103. $\frac{1}{8}$ - $\bar{\imath}$) ζ (15.0.8, $\frac{1}{8}$ - $\bar{\imath}$) η (101, 1- $\bar{\imath}$)	$e (503, \frac{5}{3} - \bar{i})$ $d (201, 2 - \bar{i})$ $\epsilon (703, \frac{7}{3} - \bar{i})$	δ (11·0·3, $\frac{11}{3}$ - $\bar{\imath}$) l (011, 1- $\bar{\imath}$) tw. pl. p (111, 1)
c (001, O)				7 (555, 5)

Also doubtful x (37.17.12), y (17.5.4).

Twins: tw. pl. l (011), hence crossing at angles of nearly 90 (f. 2), since $ll' = 91^{\circ}$ 45'. Crystals

tabular | a; also prismatic | c

Cleavage a, very perfect. H. = 3·5-4. G. = 7·02. Luster resinous to adamantine. Color smokybrown to brownish yellow. Streak yellow. Translucent.

Optically +. Ax. pl. $\parallel b$. Bx $\perp c$. Ax. angle large. $2H_o = 145^\circ$. Dispersion strong, $\rho > v$. Dx.

Comp.—PbClSbO₂ or PbSb₂O₄. PbCl₂ = Antimony 30.5, lead 52.4, chlorine 9.0, oxygen 8.1 = 100.

Anal.—1, Pisani, C. R., 71, 319, 1870. 2, Flajolot, l. c. and Zs. G. Ges., 24, 47, 1872. 3, Tobler, Zs. G. Ges., 24, 40, 1872.

Fig. 1, 2, Cesàro.

Pisani gives: Sb_2O_3 37·40, PbO 27·60, Pb 26·27, Cl 9·00 = 100·27.

Pyr., etc.—In the closed tube decrepitates and gives a white sublimate. B.B. on charcoal yields an antimony coating and a globule of metallic lead. Added to a bead of salt of phosphorus saturated with copper gives the blue coloration of the flame due to copper chloride. Soluble in hydrochloric acid.

Obs.-From Djebel-Nador, in the province of Constantine, Algiers; it occurs in cavities in a

deposit of zinc in the Nummulitic limestone, cf. Braun, Zs. G. Ges., 24, 30, 1872.

Ref.— Bull. Soc. Min., 11, 44, 1888. Cesaro's position is here accepted, as also his interpretation of the planes and angles of Des Cloizeaux; cf. Dx., ib., 5, 122, 1882, and earlier, C. R., 73, 81, 1871.

673. ECDEMITE. Ekdemit A. E. Nordenskiöld, G. För. Förh., 3, 379, 1877. Heliophyllit G. Flink, Öfv. Ak. Stockh., 45, 574, 1888; Hamberg, G. För. Förh., 11, 229, 1889.

Tetragonal' (?). In acute pyramidal crystals, p, with $cp = 52^{\circ}-54^{\circ}$ approx. Hamberg; faces strongly striated horizontally. Also in crystals tabular $\parallel c$. Commonly massive, coarsely foliated or granular; also as a crystalline incrustation.

Čleavage: basal, nearly perfect. Brittle. H. = 2.5-3. G. = 6.89-7.14. Luster on cleavage plane vitreous, on fracture surfaces greasy. Color bright yellow

Translucent in thin splinters. Optically uniaxial, negative; in part to green. also biaxial.

Hamberg shows that basal (cleavage) sections of heliophyllite are in part normally uniaxial, in part biaxial. In the case of the foliated masses (A) the lamellæ cross at right angles as if twinned about a prism of 90°. There are also acute pyramidal crystals of tetragonal form (B); of these sections $\parallel c$ show an isotropic ground-mass, also systems of doubly-refracting lamellæ as if twinned as above; the lamellæ in part diagonal, also in the direction of a ditetragonal prism (210). Sections of ecdemite showed a structure somewhat similar to that last mentioned. These biaxial, doubly-refracting lamellee are regarded as secondary, the original structure having been normal tetragonal. Cf. below.

Comp.—Perhaps (Flink), Pb₄As₂O₄.2PbCl₂ = Arsenic trioxide 12·1, lead protoxide 81·3, chlorine 8·6 = $102\cdot0$ deduct (0 = 2Cl) = 100.

This composition is analogous to that taken for ochrolite, which, however, is based on the analysis of a very small amount of material. Hamberg shows that analyses 2-4 agree more closely with the complicated formula Pb₁₃Cl₈As₄O₁₅ = Pb₉As₄O₁₆.4PbCl₂. Nordenskiöld gives the formula Pb. As2O8.2PbCl2

Anal.-1, Nordenskiöld, l. c. 2, Flink, l. c. 3, 4, Hamberg, l. c.

As₂O₃ Sb₂O₃ PbO Cl 1. Ecdemite G. = 7.1410.60 83.45 8.00 = 102.058·00 FeO, MnO 0·54 = 100·93 8·05 FeO, MnO 0·07, CaO 0·08 = 100·64 7·96 FeO, MnO 0·16, CaO 0·11 = 101·09 80.70 11.69 2. Heliophyllite G. = 6.8863. 0.56 A 10.85 81.03 1.38 4. \boldsymbol{B} 10.49 80.99

The oxygen equivalent of the chlorine (1.8) is to be deducted.

Pyr., etc.—Fuses easily to a yellow mass, with the loss of lead chloride as a white sublimate; gives a characteristic lead coating on charcoal. Soluble readily in nitric acid or in warm hydrochloric acid.

Obs.-Found at Långban, Wermland, Sweden, in small granular masses, embedded in a yellow manganesian calcite; also as an incrustation. Associated crystals of a similar composition were regarded by Nordenskiöld as orthorhombic (see below).

Also found (heliophyllite) at the Harstig mine, Pajsberg, Sweden; it occurs in crystals in

druses later filled with barite and inesite.

Ecdemite is named from $\epsilon \kappa \delta \eta \mu o \delta$, unusual; heliophyllite from $\eta \lambda i o \delta$, sun, and $\phi \dot{\nu} \lambda \lambda o \nu$,

leaf, in allusion to the color and structure.

Ref.—¹ See observations of Hamberg. **Ref.**—¹ See observations of Hamberg. Nordenskiöld gives the angles on the supposed orthorhombic mineral, dimorphous with ecdemite, $cp = 65^{\circ}$ 24′, $pp' = 78^{\circ}$ 32′. Brögger gives (quoted by Flink) for the same angle, $cp=65^{\circ}$ 36'; the crystals are regarded as twins or fourlings. Flink calculates for heliophyllite the axial ratio $\check{a}:\check{b}:\check{c}=0.9666:1:2.2045$ corresponding to the axial ratio of ochrolite.

674. OCHROLITE. Ochrolith G. Flink, Öfv. Ak. Stockh., 46, 5, 1889. Orthorhombic. Axes $\check{a} : \bar{b} : c = 0.90502 : 1 : 2.01375$ Flink. $100 \wedge 110 = 42^{\circ} 8\frac{3}{4}', 001 \wedge 101 = 65^{\circ} 48', 001 \wedge 011 = 63^{\circ} 35\frac{1}{4}'.$

Forms: c (001, O), d (101, 1-i), e (011, 1-i). Angles: $cd = 65^{\circ} 48'$, $dd''' = *48^{\circ} 24'$, $ce = 63^{\circ} 35\frac{1}{8}'$, $ee''' = *52^{\circ} 49'$, $de = 79^{\circ} 30'$.

In small crystals, thick tabular ||c|, and often elongated ||b| by extension of d. Crystals often united in diverging groups having the macro-axis in common.

Luster adamantine. Color sulphur-yellow, sometimes with tinge of gray. Translucent.

Comp.—Probably Pb₄Sb₂O₄.2PbCl₂ = Antimony trioxide 16.6, lead oxide 77.0, chlorine 8.2 = 101.8, less oxygen 1.8 = 100.

Anal.—Flink on 0.2 gr., after deducting 5 p. c. CaCO₃.

Sb₂O₃ [17.59] Cl 7.72 PbO 76.52

Dissolves in nitric acid, the solution becoming turbid upon dilution; also soluble in caustic potash.

Obs.—Found sparingly in the Harstig mine at Pajsberg, Sweden; occurs in druses with barite, mimetite, hematite. Named in allusion to the bright sulphur-yellow color from \$\tilde{\alpha}\cop 05. bright yellow, and livos, stone.

2

011

u"

675. TRIPPKEITE. Damour and vom Rath, Zs. Kr., 5, 245, 1880, Bull. Soc. Min., 3, 175. Tetragonal. Axis c = 0.9160; 001 \wedge 101 = 42° 29½' Rath.

Forms:
$$m (110, I)$$
 $\epsilon (331, 3)$ $x (312, \frac{3}{2}.3)$ $c (001, 0)$ $u (112, \frac{1}{2})$ $y (314, \frac{3}{4}.3)$ $z (24.5.20, \frac{6}{5}.\frac{2.4}{5})$ $a (100, i \cdot i)$ $o (111, 1)$ $uu' = *45^{\circ} 13'$ $\epsilon \epsilon'' = 151^{\circ} 8'$ $yy' = 30^{\circ} 25'$

Habit octahedral, crystals small, brilliant.

Cleavage: a perfect; m less perfect. Color bluish Optically uniaxial, positive, Dx.

Comp.—According to a qualitative examination by Damour, essentially an

arsenite of copper (nCuO, As, O,).

Pyr., etc.—Easily soluble in acids. B.B. in the closed tube becomes emerald-green on slight heating, then the green disappears and the color becomes brownish; on continued ignition the color becomes yellowish green a second time. Fuses easily to a green slag. In the open tube gives crystals of arsenic trioxide.

Obs.—Occurs with olivenite, as an older formation, in druses in massive cuprite from Copiapo, Chili. Named after the young mineralogist, Dr. Paul Trippke, who died June 16,

1880.

The following are antimonates, or antimonites, of doubtful character.

AMMIOLITE. Antimonite de Mercure Domeyko, Ann. Mines, 6, 183, 1844. Cinabrio subido Domeyko, Min., 168, 1845. Ammiolite Dana, Min., 534, 1850. Antimoniato de cobre con cinabrio terroso Domeyko, Min., 129, 1860.

Earthy powder. Color deep red, scarlet.

Composition doubtful, but regarded as antimonate of copper mixed with cinnabar and with other impurities. Analyses by Domeyko of the material obtained in the earliest part of a process of levigation:

Sb ₂ O ₅	CuO	Hg	S	Fe ₂ O ₃	quartz	H ₂ O and loss.	
24.1	16.9	19.9	3.3	2.2	248	8.8	
29.5	15.6	23.6	3.3	3.1	8.1	16.9	
23.1	18.1	19.8	3.1	1.1			

Rivot has found in a similar substance from Chili (Ann. Mines, 6, 556, 1854): Sb 36.5, Cu 12.2, Hg 22.2, Te 14.8, Fe, S tr., quartz 2.5, O and loss 11.8. He observes that his result indicates the presence of mercury telluride (cf. coloradoite, p. 64) and antimonic acid along with antimonate of copper.

Found in many of the Chilian mines, filling cavities in the quartzose or argillo-ferruginous gangue of the mercurial tetrahedrite, and in the pores of the imperfectly compact tetrahedrite itself, and has proceeded from the decomposition of this mercurial ore.

Named from aumior, vermilion.

F. Field has analyzed a red earthy substance from Tambillos, near Coquimbo, Chili, and made it a compound of antimonite of mercury and sulphantimonite of mercury; but there is much uncertainty over his results. Cf. J. Ch. Soc., 12, 27, 1860, and Min., 5th Ed., p. 548.

Arequipite A. Raimondi, Minéraux du Pérou, Paris, p. 167, 1878.

Compact, wax-like. Fracture conchoidal. H. nearly 6. Color honey-yellow. On the Compact, wax-like. basis of a qualitative analysis, stated to be a silico-antimonate of lead. B.B. on charcoal fuses with difficulty, yielding buttons of lead, and gives off antimonial vapors. Slightly attacked by nitric acid; dissolves slowly in hydrochloric acid to which a little nitric has been added, and leaves a residue of silica. Occurs sparingly in a quartzose gangue, with argentiferous lead carbonate and chrysocolla, at the Victoria mine, Mt. de la Trinité, near Tibaya, Province of Arequipa, Peru.

BARCENITE J. W. Mallet, Am. J. Sc., 16, 306, 1878.

Massive; structure finely granular, compact or porous; also columnar (pseudomorphous), cture tolerably even. Brittle. H. = 5.5. G. = 5.343. Luster dull, earthy, sometimes hilly resinous. Color dark gray, nearly black. Streak ash-gray, with slight green-Fracture tolerably even. slightly resinous. Color darkish tint. Anal.—J. R. Santos:

The sulphur is assumed to exist as HgS, and is accordingly deducted with a corresponding amount of mercury. For the remainder the following atomic ratios are then obtained: $RO: Sb_2O_3: Sb_2O_5 = 4:1:5$, and $Sb_2O_5: H_2O = 1:5$. The antimonic acid $(Sb_2O_5: H_2O)$ is again assumed to exist independently as an impurity, and the formula for the remainder written:

[Sb₂O₃.4(RO)].(Sb₂O₅)₅ corresponding to a normal antimonate RSbO₂. The result reached,

however, must at best be regarded as of very doubtful value.

From Huitzuco, State of Guerrero, Mexico; associated with livingstonite, from the decomposition of which it has been formed. Named after Sr. Mariano Barcena, a Mexican mineralogist.

Coronguite Raimondi, Minéraux du Pérou, pp. 88, 91, 1878.

Amorphous, earthy, pulverulent, sometimes slightly lamellar. H. = 2.5-3. G. = 5.05.

Color, exterior, grayish yellow; interior, blackish, with luster slightly resinous. Intimately mixed with small quantities of sulphur, antimony, silver, and lead. An analysis, after the deduction of impurities, gave:

> $Ag_2O 7.82 Fe_2O_3 0.52 H_2O 11.21 = 100$ Sb₂O₅ 58.97 PbO 21.48

It is hence, if homogeneous, an antimonate of lead and silver. Found at the mines of Mogollon, Huancavelica, and Empalme, in the district of Corongo, province Pallasca, and at Pasacancha, province of Pomabamba, Peru.

Taznite Domeyko, C. R., 85, 977, 1877; Min. Chili, 3d Ed., p. 298, 1879.

Amorphous, more or less fibrous in structure. Earthy. Color yellow. Soluble in hydrochloric acid. Regarded as an arsenio antimonate of bismuth, analogous to bindheimite, but doubtless heterogeneous; believed to have been derived from the alteration of some sulpharsenite or sulphantimonite of bismuth. Very impure, from the admixture of varying quantities of bismuth ocher. An analysis gave: Bi₂O₂ (sol. in HNO₂) 42·00, Bi₂O₂ (united with Sb and As) 29·50, Sb₂O₅ 5·29, As₂O₅ 12·20, Fe₂O₃ 7·00, H₂O 4·90, insol. 1·00 = 101·89. Obtained with other bismuth minerals from the mines of Tazna and of Choroloque, in Bolivia.

Some other related antimony minerals, of doubtful character, are mentioned on pp. 293, 294.

Phosphates or Arsenates with Carbonates. Sulphates. Borates.

676. DAHLLITE. W. C. Brögger and H. Bäckström, Öfv. Ak. Stockh., 45, 493, 1888.

In crusts with fibrous structure normal to the surface.

H. = 5. G. = 3.053. Luster resinous. Color pale yellowish white; colorless in thin section. Optically uniaxial, negative. Double refraction slightly greater than that of apatite.

Comp.—2Ĉa, P, O, CaCO, 14H, O = Phosphorus pentoxide 39.0, carbon dioxide

6.0, lime 53.7, water 1.3 = 100.

Anal.-H. Bäckström, l. c.

CaO K₂O H₂O POOs CO2 FeO Na₂O 6.29 0.79 0.89 0.11 1.37 = 100.8938 44 53.00

Pyr., etc.—Decrepitates B.B., but does not fuse. Dissolves in cold dilute acid with the evolution of carbon dioxide.

Obs.—Occurs as a crust from 6 to 8 mm. in thickness, upon a bright red massive apatite at Ödegaard, Bamle, Norway.

The natural suggestion that the mineral is a mechanical mixture of apatite and calcite is answered by the microscopic examination, showing it to be fresh and homogeneous.

Named for the brothers Dr. Tellef Dahll and Johann Dahll, mineralogists and geologists.

CIPLYTE J. Ortlier [Ann. Soc. G. Nord., 16, 270, 1888-89], Bull. Soc. Min., 13, 160, 1890. Stated to be a silico-phosphate of calcium occurring in the chalk of Ciply and other points in Belgium, associated with phosphorite. Composition, based upon an analysis of impure material: 4CaO.2P₂O₄.SiO₂? It is only feebly soluble in sulphuric acid and hence can be separated from the enclosing mass. No physical description is given.

677. DIADOCHITE. Diadochit Breith., J. pr. Ch., 10, 503, 1837. Phosphoreisensinter Rg. Destinezite Forir & Jorissen, Bull. Soc. G. Belg., 7, 117, 1881.

Monoclinic. In microscopic six-sided tables, perhaps related to gypsum in

form (Cesàro). Reniform or stalactitic; structure curved lamellar.

Fracture conchoidal. Fragile. H. = 3. G. = 2.035. Luster resinous,

inclining to vitreous. Color yellow or yellowish brown. Streak uncolored. Comp.—Formula uncertain. Destinezite, anal. 4, gives 2Fe₂O₃.2SO₃.P₂O₃. 12H_oO (Cesàro) = Phosphorus pentoxide 16·9, sulphur trioxide 19·1, iron sesquioxide 38.2, water 25.8 = 100.

Rammelsberg calculates for anal. 1, 7Fe₂O₃.6SO₃.3P₂O₅.54H₂O.

Anal.—1, Plattner, Rg., Min. Ch., 360, 1860. 2, 3, Carnot, Bull. Soc. Min., 3, 39, 1880; the material in 2 was brown, vitreous, of 3 whitish, earthy. 4, Cesàro, Mem. Soc. G. Belg., 12,

Pyr., etc.—Yields much water in the closed tube, and swells up, becoming lusterless and opaque yellow; when ignited gives off sulphuric acid. B.B. in the forceps swells up and falls to powder, but carefully ignited fuses easily to a grayish black slag, and colors the flame bluish green. On charcoal affords a steel-gray magnetic globule. With soda affords metallic particles, and gives a sulphide which blackens silver. With borax and salt of phosphorus reacts

for iron. Soluble in hydrochloric acid.

Obs.—From alum-slate near Gräfenthal and Saalfeld in Thuringia. Also at the anthracite mine of Peychagnard, Isère, France. Named from διάδοχος, a successor, on the supposition

that it is an iron sinter, in which phosphoric acid has replaced the arsenic acid.

Destinezite occurs in yellowish white nodular masses of an earthy aspect on the surface, but dull on the fracture; it is from the ampelite at Argenteau, Belgium. Named after M. Destinez.

678. PITTICITE. Eisenpecherz Karsten [not Wern.], Tab., 66, 98, 1808. Fer oxydé, resinite Haüy, Tabl., 98, 1809. Pittizit Hausm., Handb., 285, 1813. Eisensinter Wern., Hoffm. Anal. 5 shows almost no sulphuric acid, Genth calculates 4FeAsO_4 . Fe(OH)₃ + $10\text{H}_2\text{O}$. An iron-sinter mentioned on p. 821, from Nerchinsk, analyzed by Hermann had the composition of scorodite.

Pyr., etc.—In the closed tube yields water, and at a high heat gives off sulphur dioxide. In the forceps and on charcoal like scorodite. With soda on charcoal gives arsenical fumes

and a sulphide which blackens silver.

Obs.—Occurs in old mines near Freiberg and Schneeberg in Saxony, and elsewhere; occurs also at Redruth in Cornwall. An ore on Hopkins's farm near Edenville, N. Y., is referred by Beck to this species. The mineral analyzed by Genth (anal. 5) was from the Clarissa mine, Tintic district, Utah.

679. SVANBERGITE. Svanbergit *Igelström*, Öfv. Ak. Stockh., 11, 156, 1854. Rhombohedral. Axis $\dot{c} = 1.2063$; $0001 \land 10\overline{1}1 = 54^{\circ} 19\frac{1}{2}$ Dauber'.

Forms: c (0001, O), r (10 $\overline{1}1$, R), n (40 $\overline{4}1$, 4), V (50 $\overline{5}1$, 5); s (02 $\overline{2}1$, - 2). Angles: $cn = 79^{\circ}$ 49 $\frac{1}{2}$ ', $cV = 81^{\circ}$ 50', $cs = 70^{\circ}$ 15', $rr' = 89^{\circ}$ 25', $nn' = 116^{\circ}$ 57', $VV' = 118^{\circ}$ 1', $ss' = 109^{\circ}$ 12', $rn = 25^{\circ}$ 30'.

In rhombohedral crystals, resembling cubes; also in modified forms.

Cleavage: basal, perfect. H. = 5. G. = 3·30; 2·571 Breith.; 3·29 Blomstrand. Luster vitreous to adamantine. Color honeyyellow to yellowish brown, reddish brown, and rose-red. Streak reddish or colorless. Subtransparent. Optically uniaxial, positive. Double refraction strong.

Seligmann.

Comp.—A hydrated phosphate and sulphate of aluminium and calcium chiefly; formula doubtful.

Anal.—1, Igelström, l. c., and J. pr. Ch., 64, 252, 1855. 2, Blomstrand, Öfv. Ak. Stockh., 25, 204, 1868.

Pyr., etc.—In a tube yields acid water. B.B. on coal fuses only on the thinnest edges; with soda in reducing flame a red hepatic mass, which becomes green with water and yields hydrogen sulphide with dilute acid. With borax, an iron-colored glass. With cobalt solution a fine blue. But little acted upon by acids.

Obs.—From Horrsjöberg in Wermland, Sweden, occurring with lazulite, cyanite, pyrophyllite, damourite, hematite, etc., in gneiss; also from the iron mine at Westanå, Scania. It is

near beudantite in crystallization.

Ref.—¹ Pogg., **100**, 579, 1857; Seligmann obtained $nn^{1\gamma} = 62^{\circ}$ 54' whence c = 1.2389 and $rr' = 90^{\circ}$ 26', but he measures $rr' = 89^{\circ}$ 13'. Zs. Kr., **6**, 227, 1881.

680. BEUDANTITE. Levy, Ann. Phil., 11, 195, 1826. Bieirosite, Corkite, Dernbachite Adam, Tabl. Min., 49, 1869.

Rhombohedral. Axis $\dot{c} = 1.1842$; 0001 \wedge 1011 = 53° 494′ Dauber¹.

Forms: $c (0001, 0)^2$; $r (10\overline{1}1, R)^2$, $V (50\overline{5}1, 5)^3$; $\eta (01\overline{1}1, -1)^3$, $s (02\overline{5}1, -2)^2$, $t (05\overline{5}2, -\frac{5}{2})^3$, $u (-04\overline{4}1, -4)^2$, $v (05\overline{5}1, -5)^2$.

Angles: $cr = 53^{\circ} 49'$, $cs = 69^{\circ} 55'$, $ct = 73^{\circ} 42'$, $cu = 79^{\circ} 38'$, $cv = 81^{\circ} 41'$, $rr' = *88^{\circ} 42'$, $ss' = 108^{\circ} 51'$, $tt' = 112^{\circ} 26\frac{1}{2}'$, $uu' = 116^{\circ} 50'$, $vv' = 117^{\circ} 56\frac{1}{2}'$.

Crystals usually acute rhombohedrons, often modified; also in nearly square rhombohedrons (r), with c, resembling the isometric cube with octahedron. Faces c flat, dull; r bright, curved.

Cleavage: c easy. H. = 3·5-4·5. G. = 4-4·3. Luster vitreous to subadamantine, resinous. Color dark to clear olive-green, yellowish

green, black, brown. Streak greenish gray to yellow. Usually opaque, rarely

transparent. Optically negative.

Comp.—A phosphate or arsenate with sulphate of ferric iron and lead; formula doubtful. Includes (1) the mineral from Cork and Dernbach with little or no arsenic, and (2) that from Horhausen (the original beudantite) with little phosphorus.

The Cork crystals are black, brown, or green and opaque; G.=4.295, green, Rg.; those of Dernbach, olive-green to yellowish green, sometimes transparent, with H.=3.5, G.=4.002Sandberger. These two varieties form Cork and Dernbach have been called by Adam, corkite and dernbachite, respectively, while the name beudantite is given to that from Horhausen.

Beudantite and svanbergite have nearly the same form and may prove also to have analo-

Anal.—I. Sandberger, Pogg., 100, 611, 1857. 2, Rg., ibid., p. 581. 3, 4, Percy, Phil. Mag., 37, 161, 1850. 5, Sandberger, l. c.

690.

Nitroglauberite

APPENDIX TO PHOSPHATES, ARSENATES, ETC.

MIRIQUIDITE Frenzel, Jb. Min., 939, 1872, 673, 1874.

Rhombohedral. In minute crystals with $r(10\overline{11}, R)$ and $e(01\overline{12}, -\frac{1}{2})$; approx. angles $rr'=114^\circ$, $re=57^\circ$ Rath. Faces r often horizontally striated and curved. Also massive. Brittle. H. = 4. Luster vitreous. Color blackish brown to yellowish or reddish brown. Streak ocher-yellow. Translucent to opaque.

Contains As₂O₅ P₂O₅, PbO, Fe₂O₃, H₂O; not analyzed.

B.B., fusible to a globule, coloring the charcoal yellow (PbO). In matrass gives water, and with the fluxes reacts for iron.

Found at Schneeberg with chalcocite, pyromorphite, cuprite, torbernite, etc.

The following arsenates of nickel need confirmation:

Arsenate of Nickel. Nickelerz C. Bergemann, J. pr. Ch., 75, 239, 1858. Ærugite Adam, Tabl. Min., 43, 1869. Crystalline massive or amorphous. H. = 4. G. = 4.838. Color dark grass-green to brownish in spots where amorphous; streak lighter.

Comp.—Perhaps $Ni_5As_2O_{10}$ or $5NiO.As_2O_5$ = Arsenic pentoxide 38.0, nickel protoxide 62.0 = 100. Analysis afforded:

 $As_2O_6 36.57 P_2O_6 0.14 NiO 62.07 CoO 0.54 CuO 0.34 Bi_2O_3 0.24 Fe_2O_3 tr. = 99.90$

Unaltered in the closed tube. B.B. on charcoal affords arsenical fumes; with borax in R.F. gives a gray bead (nickel); with soda on charcoal gives off arsenical fumes and yields a magnetic mass. From Johanngeorgenstadt, along with the normal nickel arsenate below, also nickel oxide and native bismuth.

Arsenate of Nickel. Nickelerz C. Bergemann, J. pr. Ch., 75, 239, 1858. Xanthiosite Adam, Tabl. Min., 42, 1869. Amorphous. H. = 4. G. = 4982. Color sulphur-yellow. Comp.—Perhaps $Ni_3As_2O_8$ or $3NiO.As_2O_8$ = Arsenic pentoxide 50·5, nickel protoxide 49·5 = 100. Analysis by Bergemann, l. c.:

CoO 0.21 CuO 0.57 $Bi_2O_3 \ 0.62 = 100.17$ As₂O, 50.53 P2O, tr. NiO 48.24

Like the preceding in pyrognostic characters. Also occurs at Johanngeorgenstadt.

Rhombohedral. Axis c = 0.8276; $0.001 \land 10\overline{1}1 = 43^{\circ} 42'$, $rr' = *73^{\circ} 30'$ Brooke-Rammelsberg¹.

NITER. 871

Isomorphous with calcite. Usually in massive form, as an incrustation or in

beds.

Cleavage: r perfect. Fracture conchoidal, seldom observable. Rather sectile. H. = 1.5-2. G. = 2.24-2.29; 2.290 Tarapaca, Hayes. Luster vitreous. Color white; also reddish brown, gray, and lemon-yellow. Transparent. Taste cooling. Optically —. Double refraction strong. Refractive indices for yellow (Na):

$$\omega = 1.58739$$
 $\epsilon = 1.33608$ Schrauf²

Comp.—Sodium nitrate, NaNO₃ = Nitrogen pentoxide 63.5, soda 36.5 = 100.

Pyr., etc.—Deflagrates on charcoal with less violence than niter, causing a yellow light, and also deliquesces. Colors the flame intensely yellow. Dissolves in three parts of water at

60° F.

Obs.—In the district of Tarapaca, northern Chili, and also in the neighboring parts of Bolivia, the dry pampa for 40 leagues, at a height of 3,300 feet above the sea, is covered with beds of this salt (caliche) several feet in thickness, along with gypsum, common salt, glauber salt, and remains of recent shells. The azufrado or caliche jaune is a deposit rich in the nitrate and colored yellow by alkaline iodides, cf. V. L'Olivier, Ann. Ch. Phys., 7, 289, 1876. These nitrate deposits are of great commercial value; they formerly belonged to Peru, but passed into the hands of Chili in 1884.

Deposits also occur in Humboldt Co., Nevada, 25 miles east of Lovelock's station; also near Calico, San Bernardino Co., Cal. Reported from southern New Mexico (Min. Res., 1882).

Ref.—' Ann. Phil., 21, 452, 1823; Rg., Kryst. Ch., 348, 1881; Haüy gives 73° 44′, Mohs 73° 27′, Schrauf 74° 10′. An increase of 100° C. causes rr′ to increase about 27′ Mlr. 2 Ber. Ak. Wien, 41, 784, 1860.

684. NITER. Nitrate of Potash. Saltpeter. Salpeter, Salpetersaures Kali, Germ. Kalisalpeter Hausm., Handb., 849, 1813. Potasse nitratée Fr. Salitre Span.

Axes $\ddot{a}: b: \dot{c} = 0.5910: 1: 0.7010$ Miller. Orthorhombic. $100 \land 110 = 30^{\circ} 35', 001 \land 101 = 49^{\circ} 52', 001 \land 011 = 35^{\circ} 1\frac{3}{4}'.$

Forms: $a (100, i-\bar{\imath}), b (010, i-\bar{\imath}), c (001, 0); m (110, I); x (012, \frac{1}{2}-\bar{\imath}), k (011, 1-\bar{\imath}), i (021, 2-\bar{\imath});$ p (111, 1).

Angles: $mm''' = *61^{\circ} \ 10'$, $xx' = 38^{\circ} \ 38'$, $kk' = *70^{\circ} \ 3\frac{1}{2}'$, $ii' = 109^{\circ} \ 0'$, $pp' = 88^{\circ} \ 20'$, $pp'' = 108^{\circ} 3', pp''' = 48^{\circ} 38'.$

Twins: tw. pl. m, pseudohexagonal, resembling aragonite. Generally in thin crusts, silky tufts, and delicate acicular crystallizations.

Cleavage: k (011) perfect; b less so; m imperfect. Fracture subconchoidal to uneven. Brittle. H. = 2. G. = 2.09-2.14. Luster vitreous. Streak and white. Subtransparent. Taste saline and cooling. Streak and color

Optically –. Ax. pl. ||a|. Bx $\perp c$. $2E = 8^{\circ} 40'$,

Comp.—Potassium nitrate, KNO₃ = Nitrogen pentoxide 53.5, potash 46.5 = 100.

After Mlr.

Pyr., etc.—Deflagrates vividly on burning coals, and detonates with combustible substances.

Colors the flame violet. Dissolves easily in water; not altered by exposure.

Obs.—Found generally in minute needle-form crystals, and crusts on the surface of the earth, on walls, rocks, etc. It forms abundantly in certain soils in Spain, Egypt, and Persia, especially during hot weather succeeding rains. Also manufactured from soils where other nitrates (nitrate of calcium or sodium) form in a similar manner, and beds called nitriaries are arranged for this purpose in France, Germany, Sweden, Hungary, and other countries. Refuse animal matter, also, if putrified in calcareous soils, gives rise to the calcium nitrate. Old plaster, lixiviated, affords about 5 p. c. of niter. In India it is obtained in large quantities for the arts.

In Madison Co., Kentucky, it is found scattered through the loose earth covering the bottom

872 NITRATES.

of a large cave. Also in other caverns in the Mississippi valley. Those of Tennessee, along the limestone slopes and in the gorges of the Cumberland table-land, afford it abundantly. Niter, according to Frankenheim, is dimorphous, like calcium carbonate; one form ortho-

rhombic and isomorphous with argonite, the other *rhombohedrat*, like soda niter (q.v.), isomorphous with calcite. The former is the normal one between -10° C. and 300° C.; and between these temperatures the rhombohedral is easily transformed into it. Above 300° the rhombohedral is the normal one, the orthorhombic here changing to it, and retaking again its

form on a diminution of temperature, Pogg., 92, 354, 1854.

Ref.—¹ At 19° C., Phil. Mag., 17, 58, 1840; Min., 601, 1852; an increase of 100° increases kk' about 44', mm' remains about constant, ² Ber. Ak. Wien, 41, 787, 1860. ² Zs. Kr., 2, 102,

685. NITROCALCITE. Kalksalpeter Haus., Handb., 1813. Nitrate of lime. Calcium nitrate. Chaux nitratée. Nitrocalcite Shep., Min., 2, 84, 1835. Calcinitre Huot., Min., 2, 430, 1841.

In efflorescent silken tufts and masses. Color white or gray. Taste sharp and bitter.

Comp.—Hydrous calcium nitrate, $Ca(NO_3)_2 + nH_2O$. The amount of water of crystallization is uncertain.

Pyr., etc.—On burning coals it slowly fuses with a slight detonation, and dries. Very deli-

quescent before, but not after, being desiccated by heat.

Obs.—It occurs in silky efflorescences, in many limestone caverns, as those of Kentucky. The salt forms in covered spots of earth, where the soil is calcareous, and is extensively used in the manufacture of saltpeter. According to Hausmann, a large part of the so-called niter in nature is this salt.

On the crystallization of the artif. salt, Ca(NO₃)₂ + 4H₂O, cf. Rg., Kr. Ch., 358, 1881

(Mgc., etc.).

686. NITROMAGNESITE. Nitrate of Magnesia Beud., Tr., 2, 384, 1832. Nitromagnesite Shep., Min., 2, 85, 1835. Magnesinitre Huot., Min., 2, 431, 1841. Magnésie nitratée. Magnesia salpeter.

In efflorescences. White. Taste bitter.

Comp.—Hydrous magnesium nitrate, $Mg(NO_3)_2 + nH_2O$.

Obs.—From limestone caves, along with nitrocalcite.

The existence of this species as a natural product has not yet been clearly made out. On the artif. salt, $Mg(NO_3)_2 + 6H_2O$, cf. Rg., Kr. Ch., 359, 1881 (Mgc.).

687. NITROBARITE. Barytsalpeter, Salpetersaurer Baryt, Germ. Nitrobarite H. C. Lewis, Amer. Nat., 16, 78, 1882.

Isometric; tetartohedral. In octahedrons made up of the plus and minus tetrahedrons. 111 and 111; also in twins like spinel.

Crystals colorless, in part covered with a thin brownish black coating resembling wad.

Comp.—Barium nitrate, Ba(NO₂)₂ = Nitrogen pentoxide 41.4, baryta 58.6 = 100.

Obs.-From Chili, exact locality unknown.

Artificial crystals are tetartohedral and often highly modified. Cf. Scc., Pogg., 109, 366, 1860; Baumh., Zs. Kr., 1, 51, 1877; Lewis, ib., 2, 64; Wulff, ib., 4, 122, 1879; Henriques, ib., 5, 365, 1881; a summary is given in Rg., Kr. Ch., 354, 1881.

688. GERHARDTITE. H. L. Wells and S. L. Penfield; Am. J. Sc., 30, 50, 1885. Orthorhombic. Axes $\check{a}:\check{b}:\dot{c}=0.92175:1:1.15617$ Penfield. $100 \land 110 = 42^{\circ} 40', 001 \land 101 = 51^{\circ} 261', 001 \land 011 = 49^{\circ} 81'.$

```

In crystals, the pyramidal zone strongly striated and the faces often in

oscillatory combination.

Cleavage: c highly perfect, yielding flexible laminæ; a less perfect. Sectile, fragile. H. = 2. G. = 3.426. Luster vitreous, brilliant. Color deep emerald-green. Streak light green. Transparent.

Pleochroic: $\|\mathfrak{c}(\check{a})\|$ blue, $\|\mathfrak{b}(\bar{b})\|$ and $\|\mathfrak{a}(\check{c})\|$ green.

Optically –. Ax. pl. || b. Bx $\perp c$. Dispersion $\rho < v$. Axial angles: $2K_y = 76^{\circ} 20'$, $2K_{gr} = 80^{\circ} 4'$ $(n_y = 1.703, n_{gr} = 1.722)$.

Comp.—Basic cupric nitrate, Cu(NO₃)₂.3Cu(OH)₂ or 4CuO.N₂O₅.3H₂O = Nitrogen pentoxide 22.5, cupric oxide 66.2, water 11.3 = 100.

Anal.-H. L. Wells, l. c.

N₂O₄ 22·76 [22·25] CuO 66.38 H₂O 11.26 1. 100.40 2. 66.26 11.49

Pyr., etc.—Fuses at 2, coloring the flame green. With soda on charcoal easily reduced to metallic copper with deflagration. In the closed tube gives nitrous fumes and strongly acid water. Soluble in dilute acids; insoluble in water.

Obs.—Occurs with acicular crystals of malachite in cavities in cuprite at the United Verde

copper mines at Jerome, Arizona; only a few specimens have been found.

Named after Charles Gerhardt, the chemist who first established the composition of the corresponding artificial salt, Ann. Ch. Phys., 18, 178, 1846, or C. R., 22, 961, 1846.

Artif.—Obtained by Gerhardt (l. c.) as already noted. Further, the same compound has been formed by Wells by heating a solution of normal nitrate with metallic copper in a sealed been formed by Wells by heating a solution of normal nitrate with metallic copper in a sealed tube to 150° C, for 24 hours or more. The crystals (Pfd.) were tabular $\|c\|$ and elongated $\|b\|$. The form is near that of the natural crystals, but they are referred to the monoclinic system with the axial ratio a:b:c=0.9178:1:1.1402; $\beta=*85^\circ 27'=001 \land 100$. Observed forms: a (100), c (001), m (110), d (101), e (011). Angles: $cd=*48^\circ 25\frac{1}{3}'$, $ee'=*97^\circ 19'$, $mm'''=84^\circ 55'$, $cm=86^\circ 39'$. Twins: tw. pl. a. Cleavage: c perfect. Brittle. Luster brilliant. Color dark green. Transparent. Pleochroic, green and blue. Ax. pl. $\|b\|$. Negative bisectrix in the obtuse axial angle. Dispersion $\rho < v$. $2H_{gr} = 63^\circ 50'$ (section not exactly $\pm b$). Bourgeois, however, has repeated these experiments and obtained orthorhombic crystals; he has also obtained similar results by heating the nitrate of copper in a sealed tube at 130° with

has also obtained similar results by heating the nitrate of copper in a sealed tube at 130° with urea, Bull. Soc. Min., 13, 66, 1890. Michel has also obtained orthorhombic crystals of the same basic nitrate at ordinary temperatures and under the normal atmospheric pressure by the action for several years of a solution of cupric nitrate and fragments of Iceland spar (ibid., p. 139).

689. DARAPSKITE. A. Dietze, Zs. Kr., 19, 445, 1891.

Tetragonal. In square tabular crystals with several undetermined pyramids

on the edges. Colorless. Transparent.

Comp.—NaNO₃.Na₂SO₄ + H₂O = Nitrogen pentoxide 22·0, sulphur trioxide 32.7, soda 38.0, water 7.3 = 100; or, Sodium nitrate 34.7, sodium sulphate 58.0, water 7.3 = 100.

Anal.—Dietze, l.c.

Na₂O 38.27 N2Os 22.26 SO₃ 32.88 $H_2O 7.30 = 100.71$

The water is readily expelled by heat, without decrepitation.

Obs.—From the Pampa del Toro in Atacama, Chili; intimately associated with blödite and soda niter. Named after Dr. L. Darapsky.

690. NITROGLAUBERITE. Schwartzemberg, Domeyko, 3d App., Min. Chili, 46, 1871. From the desert of Atacama, forming a white, homogeneous mass with fibrous crystalline structure. Comp.—6NaNO₃.2Na₂SO₄.3H₂O = Sodium nitrate 60·1, sodium sulphate 33·5, water 6.4 = 100. Analysis:

> NaNO₃ 60.35 Na2SO4 33.90 $H_2O 5.75 = 100$

Dissolves in water. An artificial salt, having the composition 2NaNO₂.2Na₂SO₄.3H₂O₄ has been described, cf. Rg., Kryst. Ch., 468, 1881.

Oxygen Salts.

5. BORATES.

The aluminates, ferrates, etc., allied chemically to the borates, have been already introduced among the oxides. They include the species of the Spinel Group, pp. 220–229, also chrysoberyl, p. 229, etc.

Rhombohedral. Axis $\dot{c} = 0.8221$; 0001 \wedge 1011 = 43° 304′ Brögger.

In tabular crystals with the forms: c (0001, O), a (1120, i-2), r (1011, R). Angles: $cr = *43^{\circ} 30\frac{1}{2}'$, $rr' = 73^{\circ} 12'$, $ar = 53^{\circ} 24'$.

Cleavage: basal, perfect. Fracture conchoidal. Brittle. H. = 5·5-6. G. = 4·200 Cleve. Luster somewhat pearly on c; elsewhere vitreous. Color sulphur-, lemon-, or wine-yellow. Transparent to translucent.

Optically negative. Double refraction strong.

Comp.—A borate of calcium and tin, CaSn(BO₃)₂ or CaO.SnO₂.B₂O₃ = Boron trioxide 25.1, tin dioxide 54.5, lime 20.4 = 100.

Regarded by Groth as a stannate, Ca(BO)₂SnO₄. Brögger points to similarity in axial ratio to proustite, also calcite and soda niter.

Anal.—P. T. Cleve, l. c.

 B_2O_3 [23·18] SnO₂ 53.75 ZrO2(?)0.90 CaO 20.45 ign. $1.72^{\circ} = 100$ a Probably also B2O2.

Pyr., etc.—B.B. on the platinum wire, when strongly heated, sinters but does not fuse, though coloring the flame green, especially after being moistened with sulphuric acid. Gives a colorless glass with salt of phosphorus after long blowing. Only imperfectly decomposed by hydrochloric acid.

Obs.—From the island Arö in the Langesund flord, southern Norway; occurs very sparingly, with meliphanite, homilite, cancrinite, elecolite, etc.

A. F. Nordenskiäld

Named in honor of the Swedish mineralogist and explorer, A. E. Nordenskiöld.

692. JEREMEJEVITE. Jeremeiewit Damour, Bull. Soc. Min., 6, 20, 1883. Eichwaldit Websky, Ber. Ak. Berlin, 671, 1883, Jb. Min., 1, 1, 1884. Jeremejewit Germ., Jeremejeffite, Yeremeyevite.

Hexagonal. Axis $\dot{c} = 0.68358$; 0001 \wedge 1011 = 38° 17′ 6″ Websky.

Forms: a (11 $\overline{20}$, i-2), e (21 $\overline{30}$, i- $\frac{3}{2}$), n (10 $\overline{14}$, $\frac{1}{4}$), f (10 $\overline{13}$, $\frac{1}{3}$), d (10 $\overline{11}$, 1), q (70 $\overline{75}$, $\frac{7}{5}$), g (4153, $\frac{5}{3}$ - $\frac{5}{4}$). Also various vicinal forms, ϵ , μ , etc.

Angles: $nn''' = 22^{\circ} 19\frac{1}{2}'$, $ff''' = 29^{\circ} 29'$, $dd''' = 76^{\circ} 34'$, $gg''' = 95^{\circ} 43'$, $nn' = 11^{\circ} 6\frac{1}{2}'$, $ff'' = 14^{\circ} 37'$, $dd' = 36^{\circ} 5\frac{1}{2}'$, $qg' = 43^{\circ} 31'$, $gg' = 29^{\circ} 11'$, $gg^{xi} = 16^{\circ} 44'$.

In elongated prisms resembling beryl; summits rounded and prismatic faces broken by vicinal planes.

Cleavage none. Fracture uneven. Brittle. H. = 6.5. G. = 3.28. vitreous. Colorless to pale yellow. Transparent. Optically negative.

Figs. 1-3, Websky; 4, Klein.

Websky describes the crystals as consisting, in the first place, of an outer zone which is hexagonal with perhaps pyramidal (or trapezohedral) hemihedrism and optically uniaxial-to

this he limits the original name of Damour. He assumes also a twinning with tw. axis $\pm a$ (1120) with hemimorphic development. Within, more or less irregularly bounded, is a The algorithm and the electrometric development. Within, more or less threghtary bounded, is a core in sectors seeming to form an orthorhombic trilling; to this he gives the name eichwaldite. Optically biaxial. For the former he gives $\dot{c}=0.68368$; for the latter he deduces $\dot{a}:\dot{b}:\dot{c}=0.5523:1:0.5434$, with the forms a (104), a (101), a (136). Optically —. Ax. pl. inclined 30° to the prismatic edges. a (114), a (115), a (116). The terminal planes referred to the eichwaldite project at the extremity beyond the jeremejevite (f. 2, 3). The crystallographic results, based upon the various reflections from the parts of the rounded summits, must be regarded as more or less uncertain, and it is difficult to believe that the two parts of the crystals are

fundamentally distinct.

Klein (Jb Min., 1, 84, 1891) has studied the optical structure more minutely. He finds a section to consist of three and often four parts (f. 4), of which A is uniaxial; B is biaxial with variable angle, 6° to 35° (in air), ax. pl. \bot edge B/C; C, divided into differently orientated sectors, is biaxial with an angle of 52° , ax. pl. in $C_1 \bot$ line bisecting angle B_1B_2 , etc.; finally, D, sometimes but not always observed, is uniaxial and negative like A. Elevation of temperature makes no change in optical relations, but pressure normal to the axis c made A biaxial with ax. pl. \bot pressure; while with both B and C the axial angle could be increased, or diminished to 0° , according as the pressure was normal or parallel to the ax. plane. No difference in density could be detected between the parts A, B, C.

Comp.—An aluminium borate, AlBO, or Al₂O₃.B₂O₃ = Boron trioxide 40.6, alumina 59.4 = 100. A little iron sesquioxide replaces part of the alumina.

Anal.—Damour, l. c.

Fe₂O₃ 4.08 $K_2O 0.70 = 100$ B₂O₃ [40·19] Al₂O₃ 55.03 $G_{\cdot} = 3.28$

Pyr.—B.B. in the forceps loses its transparency, becomes white and tinges the flame green, but does not fuse. Gives a fine blue when moistened with cobalt solution and subsequently ignited. In fine powder dissolves in concentrated caustic potash leaving a faint residue of iron sesquioxide.

Obs.—Collected by the director of the Nerchinsk mines, J. I. Eichwald, at Mt. Soktuj, a northern extension of the Adun-Chalon chain in Dauria, in the Nerchinsk mining region in east-

ern Siberia; the crystals were found loose in a granitic sand beneath the turf.

Jeremejevite is named after Prof. Eremeyev (Germ. Jeremejew), of the School of Mines at St. Petersburg; the name here retains essentially the German form.

On a borate of aluminium, $3Al_2O_3$. B_2O_3 , and other borates prepared by Ebelmen, cf. Ann. Ch. Phys., 33, 63, 1851, also Mallard, Bull. Soc. Min., 11, 308, 1888.

693. SUSSEXITE. G. J. Brush, Am. J. Sc., 46, 140, 240, 1868.

Orthorhombic¹(?). In fibrous seams or veins.

H. = 3. G. = 3.42. Luster silky to pearly. Color white with a tinge of

pink or yellow. Translucent,

Comp.—HRBO, where R = Mn, Zn, and Mg, or 2(Mn, Zn, Mg)O.B, O, H, O = Boron trioxide 34.1, manganese protoxide 41.5, magnesia 15.6, water 8.8 = 100. Here Mn (+ Zn): Mg = 3:2. In anal. 2, the ratio of Mn: Zn: Mg = 0.536: 0.040:0.398.

Pyr., etc.—In the closed tube darkens in color and yields neutral water. If turmeric paper is moistened with this water, and then with dilute hydrochloric acid, it assumes a red color (boric acid). In the forceps fuses in the flame of a candle (F = 2), and B.B. in O.F. yields a black crystalline mass, coloring the flame intensely yellowish green. With the fluxes reacts for manganese. Soluble in hydrochloric acid.

Obs.—Found on Mine Hill, Franklin Furnace, Sussex Co., N. J., associated with franklinite, zincite, willemite, and other manganese and zinc minerals. Named from the county in which the locality is situated.

the locality is situated. Ref.—1 Cf. Dx., Min., 2, 15, 1874.

694. LUDWIGITE. G. Tschermak, Min. Mitth., 59, 1874.

Orthorhombic, Renard. Prismatic angle: mm'''= 89° 20'. Observed forms: 110, 410, 310, 120 Mallard².

In finely fibrous masses; fibers parallel, often radiating; also short and inter-

Extinction parallel.

Tough upon fracture, but easily cut. H. = 5. G. = 3.91-4.02. Luster silky on fresh fracture. Color blackish green to nearly black with a tinge of violet; greenish brown in microscopic splinters. Streak dark. Strongly pleochroic. Axial plane probably \perp prismatic axis. Comp.—Perhaps $3 \text{MgO.B}_2 \text{O}_3 + \text{FeO.Fe}_2 \text{O}_3 = \text{Boron trioxide 16.6, iron sesqui-$

oxide 37.9, iron protoxide 17.0, magnesia 28.5 = 100.

The above formula of Tschermak and Ludwig finds some support in the fact that a corresponding composition is obtained by Flink for pinakiolite, which he characterizes as a manganese-MgO: FeO: Fe₂O₃: B₂O₃: H₂O = 76: 24: 24: 17: 20; the first three terms here agree with Tschermak's formula, the others do not. Further, RO: (B₂O₃ + Fe₂O₃)=3:1, also H₂: Mg: Fe = 1: 3:1 and B: Fe = 2: 3 nearly. The corresponding percentage composition is: Boron trioxide 11:2, iron sesquioxide 38:4, iron protoxide 17:3, magnesia 28:8, water 4:3 = 100.

The formula is then 3(H₂, Mg, Fe)O.(B, Fe)₂O₃ or 3RO.B₂O₃, analogous to that of sussexite.

Anal.—1, 2, Ludwig and Sipöcz; 1 mean of 7 partial analyses. 3, Whitfield, Am. J. Sc.,

34, 284, 1887.

		G.	B_2O_3	Fe ₂ O ₃	FeO	MgO	MnO	H_2O		
1.	Dark green	3.951	16.09	39.92	12.46	31.69	tr.	-	=	100.16
2.	Black	4.016	15.06	39.29	17.67	26.91	tr.	-	=	98.93
3.	66		12.04	37.93	15.78	30.57	0.16	3.62	=	100.10

Pyr., etc.—Heated in the air the mineral becomes red; in fine splinters fusible with difficulty to a black, strongly magnetic, slag. With the fluxes gives the reaction for iron. Dissolved slowly by cold hydrochloric acid when in the state of a fine powder.

Obs.—Occurs embedded in a crystalline limestone, with irregularly situated beds of magnetite, at Morawitza in the Banat, Hungary; the magnetite is embedded in the mineral in the

form of grains or fine thread-like veins.

Named after Ernst Ludwig, Professor of Chemistry at Vienna.

Alt.-F. Berwerth has described (ibid., 247, 1874) ludwigite altered to limonite. An analysis of material, having a brownish red color, and graduating insensibly into pure ludwigite, afforded: Fe₂O₃ 75·34, MnO tr., CaO 0·09, MgO 5·80, CO₂ 1·65, SiO₂ 2·83, H₂O 14·51, B₂O₃ 0·80=101·02. G. = 3·41. Besides the limonite (88·17 p. c.), some talc, brucite, magnesite, and calcite are also present as mechanically mixed impurities.

Artif.—An artificial borate allied to ludwigite has been prepared by Ebelmen, cf. Mld., l.c.;

it is orthorhombic with a prismatic angle of 89° 10′.

Ref.—¹ Bull. Ac. Belg., 9, 547, 1885. ² Bull. Soc. Min., 11, 310, 1888.

695. PINAKIOLITE. Pinakiolith G. Flink, Zs. Kr., 18, 361, 1890.

Orthorhombic. Axes $\check{a} : \check{b} : \dot{c} = 0.83385 : 1 : 0.58807 \text{ Flink}^{1}$. $100 \wedge 110 = 39^{\circ} 49\frac{1}{3}', 001 \wedge 101 = 35^{\circ} 11\frac{2}{3}', 001 \wedge 011 = 30^{\circ} 27\frac{1}{2}'.$

Forms: $b (010, i-\tilde{\imath}), l (310, i-\tilde{3}), e (011, 1-\tilde{\imath})$ as tw. plane.

Angles: $bl = 74^{\circ} 28'$, $ll' = *31^{\circ} 4'$, $ee' = *60^{\circ} 55'$, $le = 82^{\circ} 12'$.

In small rectangular crystals tabular $\|b$, usually thin and often bent or broken. Twins common with e (011) as tw. pl.; in habit cruciform, the axes crossing at angles of nearly 60° and 120°.

Cleavage: b rather perfect. Very brittle. H. = 6. G. = 3.881. Luster

metallic, brilliant on crystalline faces. Color black. Streak brownish gray. Absorption b > a > c. Optically -. Ax. pl. ||c| = c. Bx $\perp b$. Ax. angle about 60°. Dispersion probably $v > \rho$.

Comp.—3MgO.B₂O₃ + MnO.Mn₂O₃ = Boron trioxide 16.7, manganese sesqui-

oxide 37.7, manganese protoxide 16.9, magnesia 28.7 = 100.

Anal.—Flink, l. c. 1a from 1, after deducting SiO2 and H2O.

	B_2O_3	Mn ₃ O ₄	Fe ₃ O ₄	MgO	CaO	PbO	
1. 1a.		49·39 50·63					SiO_2 1·21, H_2O 0·47 = 99·22 = 100

A determination of the oxygen set free gave 4.34 p. c. (required by the formula 3.80).

Pyr., etc.—Fuses with some difficulty to a black non-magnetic glass. With potassium bisulphate and fluorite colors the flame intensely green. Reacts for manganese with the fluxes. Dissolves in warm concentrated hydrochloric acid with the evolution of chlorine.

Obs.—Occurs at Långban, Wermland, Sweden, in bands in granular dolomite with hausmannite. Also associated with tephroite, manganophyllite, berzeliite.

Named from $\pi i \nu \alpha \kappa i \sigma \nu$, a small tablet, and $\lambda i \vartheta o \delta$, stone, in allusion to the form of the

Ref.—1 L.c.; cf. also Brögger, ibid., p. 376, on the morphological relations of pinakiolite to

manganite, etc.

696. HAMBERGITE. W. C. Brögger, Zs. Kr., 16, 65, 1890.

Orthorhombic. Axes $\check{a}:\check{b}:\dot{c}=0.79877:1:0.72676$ Brögger. $100 \land 110 = 38^{\circ} \ 37', \ 001 \land 101 = 42^{\circ} \ 175', \ 001 \land 011 = 36^{\circ} \ 0\frac{1}{2}'.$

Forms: $a (100, i-\bar{\imath}), b (010, i-\bar{\imath}); m (110, I); e (011, 1-\bar{\imath}).$

Angles: $mm''' = 77^{\circ} 14'$, $bm = *51^{\circ} 23'$, $ee' = *72^{\circ} 1'$, $me = 68^{\circ} 28\frac{1}{2}'$.

In prismatic crystals (f. 1), the faces α vertically striated.

Cleavage: b perfect; a less so. Brittle. H. = 7.5. G. = 2.347. Luster vitreous. Color grayish white. Transparent to translucent.

Optically +. Ax. pl. $\parallel b$. Bx $\perp c$. Double refraction very strong. Dispersion small $v > \rho$. Axial angles, Bgr.:

For Li
$$2H_{a,r} = 95^{\circ} 21'$$
 $2H_{o,r} = 102^{\circ} 46'$ $\therefore 2V_{r} = 86^{\circ} 50'$
For Na $2H_{a,y} = 95^{\circ} 42'$ $2H_{o,y} = 102^{\circ} 28'$ $\therefore 2V_{y} = 87^{\circ} 7$
For Tl $2H_{a,gr} = 96^{\circ} 8'$ $2H_{o,gr} = 102^{\circ} 13'$ $\therefore 2V_{gr} = 87^{\circ} 24\frac{1}{2}'$

Refractive indices:

Comp.—Be₂(OH)BO₃ or 4BeO.B₂O₄.H₂O = Boron trioxide 37·1, beryllium oxide 53.3, water 9.6 = 100.

Anal.-Bäckström, quoted by Brögger, l. c.

BeO 53.25 3 $H_2O 10.03 = 100$ B₂O₃ [36.72]

The water goes off only at a strong red heat, and the last fourth requires the blast lamp.

Pyr., etc.—B.B. decrepitates violently, but does not fuse. Insoluble in ordinary acids, but completely dissolved by digestion with hydrofluoric acid over a water bath.

Obs.—Occurs in a small vein near Helgaråen on the mainland near the entrance to the Langesund fiord, southern Norway. The vein consists of feldspar, black mica, barkevikite,

red spreustein, and in traces zircon and fluorite.

Named after the Swedish mineralogist, A. Hamberg.

697. SZAIBELYITE. Szaibelyit K. F. Peters, Ber. Ak. Wien, 44, 143, June 1861. Boromagnesit Groth, Tab. Ueb., 38, 1874.

In small nodules bristled with acicular crystals.

H. = 3-4. G. = 3. Color white outside, yellow within. Streak white. Translucent. Optically biaxial.

Comp. $-2Mg_5B_4O_{11}.3H_2O$ or $5MgO.2B_2O_3.1\frac{1}{2}H_2O$ = Boron trioxide 38·1, magnesia 54.5, water 7.4 = 100.

Anal. - Stromeyer, Ber. Ak. Wien, 47 (1), 347, 1863, after deducting impurities.

A granular form contained more water (12.35 p. c.).

Pyr., etc.—Yields water. B B. splits open, glows, and fuses to a pale, hornlike, brownish gray mass, coloring the flame yellowish red. Dissolves with difficulty in hydrochloric acid.

Obs.—Occurs in kernels embedded in a gray granular limestone at Rezbánya, in Hungary.

Named after Szajbelyi, who collected the limestone containing it.

698. BORACITE. Kubische Quarz-Krystalle (fr. Lüneburg) Lasius, Crell's Ann., 2, 333, 1787. Lüneburger Sedativ-Spath Westrumb, Kl. phys.-ch. Abh., 3, 167, 1789. Borazit Wern. Bergm. J., 393, 1789, 234, 1790. Borate of Magnesia. Magnésie boratée Fr. Parasit O. Volger, Pogg., 92, 77, 1854. Massive Boracite of Stassfurt = Stassfurtit G. Rose, Pogg., 97, 632, 1856.

Isometric and tetrahedral in external form under ordinary conditions, but in molecular structure orthorhombic and pseudo-isometric; the structure becomes isotropic, as required by the form, only when heated to 265°. Observed forms':

a (100, i-i)	η (17·3·0, $i = \frac{17}{3}$)4	e (210, i -2) ³	ρ (441, 4) ⁵	$n_{i}(2\bar{1}1, -2-2)$
d(110, i)	θ (13.3.0, $i - \frac{13}{3}$)4	$l (530, i-\frac{5}{3})^4$	$\sigma_{1}(8\bar{8}1, -8)^{5}$	$u (431, 4-\frac{4}{3})^4$
o (111, 1)	$h (410, i-4)^3$	p (221, 2) ³	τ , $(16.\bar{1}6.1, -16)^5$	$v (531, 5-\frac{5}{3})$
$o_{i}(1\overline{1}1, -1)$	$f (310, i-3)^2$	$\Sigma (552, \frac{5}{2})^2$	$n (211, 2-2)^5$	

Also doubtful 12.1.0 and \$ (116).

Penetration-twins: tw. pl. o. Habit cubic and tetrahedral or octahedral; also dodecahedral. Crystals usually isolated, embedded; less often in groups. Faces o bright and smooth, o, dull or uneven. Also massive.

Cleavage: o, o, in traces. Fracture conchoidal, Brittle. H. = 7 crystals. G. = 2.9-3. Luster Color white, inclining vitreous, inclining to adamantine. to gray, yellow, and green. Streak white. Subtransparent to translucent. Commonly shows double refraction, which, however, disappears upon heating to 265°, when a section becomes isotropic. Refractive indices, Dx.:

$$n_{\rm r} = 1.663$$

$$n_{\star} = 1.667$$

$$n_{\rm bl} = 1.675$$

Also, Mld.:

$$\beta - \alpha = 0.00477$$
 $\gamma - \alpha = 0.01074$ $\gamma - \beta = 0.00597$ $\beta = 1.6622$ $\gamma = 1.6730$

Strongly pyroelectric, the opposite polarity corresponding to the position of the + and - tetrahedral faces. The faces of the dull tetrahedron o, (111) form the analogous pole, those of the polished form o (111) the antilogous pole, Rose.

As very early observed, boracite commonly shows double refraction, at variance with the external form; this has been variously explained, and some authors have attributed it to alteration. Sections show tw. lamellæ which in general may be explained (Mallard) as having the dodecahedral faces as tw. plane; further, a simple dodecahedral crystal has a structure as if made up of twelve biaxial individuals (ax. angle about 90°), with ax. pl. parallel to the longer discovered of the planch of the control of the planch of the control of the planch of the control of the control of the planch of the control of the planch of the control of the control of the planch of the control of the control of the control of the planch of the control o diagonal of the rhombic face to which the bisectrix is normal; other forms, however, show

distinct types of internal structure. Increase of temperature brings about a change in position of the tw. lamellæ, and at 265° (Mallard) they disappear and a section becomes normally isotropic, at the same time the pyroelectricity disappears also; the molecular structure then agrees with the external crystallographic form. No chemical change has taken place, for even at 300° no chlorine is lost (Jannasch). The molecular structure of boracite has been minutely studied optically and by etching especially by Klein and Baumhauer, also pyroelectrically by Mack (cf. references beyond).

Comp.—Mg,Cl₂B₁₆O₃₀ or 6MgO.MgCl₂.8B₂O₃ = Boron trioxide 62·5, magnesia 31·4, chlorine $7\cdot9=101\cdot8$, deduct (O = Cl) $1\cdot9=100$.

A little iron (FeO) is sometimes present (as an impurity?) and the *Eisenstassfurtit* (ironboracite, Huyssenite, Dana, Min., 799, 1868) of Huyssen from Stassfurt is described as having half the Mg replaced by Fe, Jb. Min., 329, 1865. For analyses see 5th Ed., p. 596.

Var.—1. Ordinary. In crystals of varied habit. 2. Massive, with sometimes a subcolumnar structure; Stassfurtite of Rose. It resembles a fine-grained white marble or granular limestone.

Parasite of Volger is the plumose interior of some crystals of boracite.

Pyr., etc.—The massive variety gives water in the closed tube. B.B. both varieties fuse at 2 with intumescence to a white crystalline pearl, coloring the flame green; heated after moistening with cobalt solution assumes a deep pink color. Mixed with oxide of copper and heated on charcoal colors the flame deep azure-blue (copper chloride). Soluble in hydrochloric acid.

Alters very slowly on exposure, owing to the magnesium chloride present, which takes up water. It is the frequent presence of this deliquescent chloride in the massive mineral, thus originating, that led to the view that there was a hydrous boracite (stassfurtite). Parasite of Volger is a result of the same kind of alteration in the interior of crystals of boracite; this alteration

giving it its somewhat plumose character, and introducing water.

Obs.—Observed in beds of anhydrite, gypsum, or salt. In crystals at Kalkberg and Schildstein in Lüneburg. Hannover; at Segeberg, near Kiel, in Holstein; at Luneville. La Meurthe, France; massive, or as part of the rock, also in crystals, at Stassfurt, Prussia. When from the carnallite layer it is fine granular or compact, with conchoidal fracture, white or greenish; from the kainite layer it is white, soft, with earthy fracture and yellowish or reddish in color (Precht and Wittjen). It occurs at Douglashall, Westeregeln, in crystals pseudomorph after quartz (Ochsenius, Jb. Min., 1, 271, 1889).

It has been urged that the original mineral from which the pseudomorphous crystals called

achtaragdite may have been formed was boracite; cf. p. 435 and Zs. Kr., 17. 93, 1889.

Artif.—Obtained by Heintz (Pogg.; 110, 613, 1860) by fusing a mixture of 10 parts boric acid, 100 of sodium chloride, 5 of magnesium borate. Also in the wet way by A. de Gramont, Bull. Soc. Min., 13, 252, 1890.

On the pyroelectricity, Friedel and Curie, Bull. Soc. Min., 6, 191, 1883; Mack, Zs. Kr., 8, 503, 1883. Also earlier Hankel, Riess and Rose, etc. Boracite was first shown to be pyroelec-

tric by Hauy in 1791.

699. RHODIZITE. Rhodizit G. Rose, Pogg., 33, 253, 1834, 39, 321, 1836. Rhodicit Hausm.

Isometric and tetrahedral, like boracite. In dodecahedrons, faces o smooth

and shining, d often uneven.

H. = 8. G. = 3.41 Rose; 3.38 Dmr. Luster vitreous, inclined to adamantine. Color white. Translucent. Pyroelectric, the angles replaced by o, the antilogous pole, Rose. Exhibits the phenomena of double refraction, analogous to boracite, but does not become isotropic with elevation of temperature².

Comp.—A borate of aluminium and potassium, with also cassium and rubidium;

perhaps R₂O.2Al₂O₃.3B₂O₃.

Anal.-Damour, Bull. Soc. Min., 5, 98, 1882.

B2O3 Al₂O₃ Fe₂O₃ K₂O₁Cs₂O₁Rb₂O Na₂O CaO MgO 1.93 12.00 1.62 0.74 0.82 ignition 2.96 = 95.4033.93 41.40

The loss and 2.96 of volatile matter (at a white heat) are referred to boric acid giving 41.49 p. c. There is probably no water present, possibly a little fluorine, Dmr.

Pyr., etc.—B.B. in the platinum forceps fuses with difficulty on the edges to a white opaque glass, tingeing the flame at first green, then green below and red above, and finally red throughout.

With borax and salt of phosphorus fuses to a transparent glass.

Obs.—Found by G. Rose in minute crystals on red tourmalines from near Sarapulsk and Shaitansk in the vicinity of Ekaterinburg in the Ural, and named from $\beta o\delta i\zeta e i\nu$, in allusion to its tingeing the flame red. The largest crystals seen were two lines in diameter.

Ref.—¹ Bull. Soc. Min., 5, 31, 72, 1882. ² Cf. Klein, Jb. Min., 1, 77, 1891.

700. WARWICKITE. Shepard, Am. J. Sc., 34, 313, 1838, 36, 85, 1839. Enceladite T. S. Hunt, ib., 2, 30, 1846, 11, 352, 1851.

Orthorhombic. Axes $\check{a}: \bar{b} = 0.977:1$ Des Cloizeaux¹.

Forms: $a (100, i \cdot \bar{i}), b (010, i \cdot \bar{i}); h (310, i \cdot \bar{3}), m (110, I), g (130, i \cdot \bar{3}).$

Angles: $ma = *44^{\circ} 20'$, $mm''' = 88^{\circ} 40'$, $hh''' = 36^{\circ} 5'$, $gg' = 37^{\circ} 41'$.

Usually in elongated prismatic crystals with rounded terminations.

Cleavage: a perfect. Fracture uneven. Brittle. H. = 3-4. G. = 3.355 Dmr.; 3.362 Smith. Luster of cleavage surface submetallic-pearly to subvitreous; often nearly dull. Color dark hair-brown to dull black, sometimes a copper-red tinge on cleavage surface. Pleochroic. Streak bluish black.

Optically +. Double refraction strong. Ax. pl. ||b|. Bx $\perp a$.

approx., Lex.

Comp.—Perhaps 6MgO.FeO.2TiO, 3B,O, = Boron trioxide 30.7, titanium dioxide 23.5, iron protoxide 10.6, magnesia 35.2 = 100.

Anal.-J. L. Smith, Am. J. Sc., 8, 432, 1874.

Pyr., etc.—Yields water. B.B. infusible, but becomes lighter in water; moistened with sulphuric acid gives a pale green color to the flame. With salt of phosphorus in O.F. a clear bead, yellow while hot and colorless on cooling; in R.F. on charcoal with tin a violet color (titanium). With soda a slight manganese reaction. Decomposed by sulphuric acid; the product, treated with alcohol and ignited, gives a green flame, and boiled with hydrochloric acid and metallic tin gives on evaporation a violet-colored solution.

Obs.—Occurs in granular limestone 2½ m. S.W. of Edenville, N. Y., with spinel, chondro-

dite, serpentine, etc. Crystals usually small and slender; sometimes over 2 in. long and \(\frac{3}{8} \) in. broad. The latter are the enceladite of Hunt.

Ref.—1 Dx., Min., 2, 16, 1874. ² Bull. Soc. Min., 9, 74, 1886.

701. HOWLITE. Silicoborocalcite H. How, Phil. Mag., 35, 32, 1868. Howlite Dana, Min., p. 598, 1868.

Orthorhombic? Penfield. In small rounded embedded nodules consisting of microscopic thin flattened prismatic crystals, sometimes terminated by two domes. Extinction parallel. Ax. pl. 1 to axis of crystals. Texture compact, without cleavage; also chalk-like or earthy.

Fracture nearly even and smooth. H. = 3.5; often less. G. = 2.55; 2.59Pfd. Luster subvitreous, glimmering. Color white. Subtranslucent, or trans-

lucent in thin splinters.

Comp.—A silico-borate of calcium, H₆Ca₂B₅SiO₄ or 4CaO.5B₂O₃.2SiO₂.5H₂O = Silica 15.3, boron trioxide 44.6, lime 28.6, water 11.5 = 100.

Anal.-1, How, l.c. 2, Penfield and Sperry, Am. J. Sc., 34, 220, 1887.

		SiO ₂	B_2O_3	CaO	Na ₂ O	K ₂ O	H_2O	
1.	G 0.00	15.25	[44·22] 44·52	28.69		-	11.84	= 100
2.	$G_{\cdot} = 2.59$	15.33	44.22	27.94	0.23	0.13	11.99	= 100

A small amount of gypsum has been deducted in both cases, 4.3 p. c. for anal. 2. The water does not go off below 360° C.

Pyr.—Ignited in the closed tube, water reacting for boron with turmeric paper is given off Obs.—Occurs in Nova Scotia, in nodules, of the size mostly of filberts, embedded in anhy-

drite or gypsum, at Brookville, about 3 m. S. of Windsor, and associated with ulexite; a harder kind occurs in anhydrite, and a softer in gypsum. Also 30-40 miles N.E. of Brookville and at other points in Hants Co. In aggregates of transparent scales in gypsum at Winkworth in the same region, the nodules sometimes as large as a man's head.

Winkworthite H. How, Phil. Mag., 41, 270, 1871. In embedded nodules, crystalline on fracture. Glistening. H. = 2·3. Colorless to white. Translucent. Analysis.—SiO₂ 4·98, B₂O₃ [14·37], SO₃ 31·51, CaO 31·14, H₂O 18·00 = 100. Found in gypsum at Winkworth, Nova Scotia.

Probably to be regarded as a mixture of howlite and gypsum.

702. LAGONITE. Borate de Fer Omalius d'Halloy, 1833. Lagonite Huot, Min., 1, 290, 1841. Sideroborine Huot, 1, 273, 1841. Lagunit Kenng.
An earthy mineral of an ocherous yellow color, occurring as an incrustation.

Comp.—Fe₂O₃,3B₂O₃,3H₂O = Boron trioxide 49.5, iron sesquioxide 37.8, water 12.7=100. Anal.—Bechi, Am. J. Sc., 17, 129, 1854.

Fe₂O₃ 36.26 H₂O 14·02 MgO, CaO and loss 1.77 = 100B₂O₃ 47.95

Occurs as an incrustation at the Tuscan lagoons. First mentioned by Beudant, Min., 2, **2**50, 1832.

703. LARDERELLITE. Mascagni [Viagg. Tosc., 3, 1806], Achiardi, Min., Tosc., 1, 258, 1872. Larderellite Bechi, Am. J. Sc., 17, 129, 1854.

Monoclinic. Very light, white to yellowish, and tasteless. Appearing under the microscope to be made up of minute tabular crystals with the plane angle of the prism 66° or 67° with sometimes also 100 and 010, Dx. Extinction parallel to the diagonals of the base.

Comp.—A hydrous borate of ammonium (NH₄), 0.4B, 0,.4H, 0 = Boron tri-

oxide 69.2, ammonium oxide 12.9, water 17.9 = 100.

Anal.-Bechi. ib.

B2O3 (8.57 (NH₄)₂O 12.73 $H_2O 18.33 = 99.63$

In Am. J. Sc., 19, 120, 1855 (also Contin. at Georg., 1, 128, 1853, quoted by Achiardi, Min. Tosc., 1, 258, 1872), the results given are: B₂O₃ 69·24, (NH₄)₂O 12·90, H₂O 17·86 = 100. This is obviously an error, for these numbers give the exact theoretical composition.

Pyr., etc.—Gives off ammonia fumes in the glass tube. B.B. fuses easily to a colorless glass which gives a green color to the flame when treated with alcohol.

Dissolves in hot vector and is transformed into a parameter approach to the formula.

Dissolves in hot water, and is transformed into a new salt, represented by the formula $(NH_4)_2O.6B_2O_3.9H_2O$. A salt with the formula $(NH_4)_2O.4B_2O_3.6H_2O$ is also known.

Obs.—Occurs at the Tuscan lagoons.

Named after Sr. Larderel, a proprietor of the Tuscan borax industry.

Ref.—1 Min., 2, 9, 1874.

704. COLEMANITE. Neuschwander, H. G. Hanks, 3d Rep. Min. California, 86, 1883.

Monoclinic. Axes $\hat{a}: \bar{b}: \hat{c} = 0.774843: 1:0.540999; \beta = 69^{\circ} 50' 45'' = 001$ ∧ 100 Jackson¹.

The figures of Evans, Bull. Cal. Acad., p. 59, Feb. 1884, apparently give simply the theoretical composition.

Pyr.—B.B. decrepitates, exfoliates, sinters, and fuses imperfectly, coloring the flame yellow.

ish green. Soluble in hot hydrochloric acid with separation of boric acid on cooling.

Obs.—First discovered (Oct. 1882) in Death Valley, Inyo Co., California; later (1883) in greater abundance in Calico district, San Bernardino county. The beautiful crystals, sometimes 2 or 3 inches in length, line geodes in the massive mineral, associated with quartz crystals as

an earlier deposit, also strontianite, etc. A snow-white massive borate sometimes covers the crystals (see priceite below).

Named after Mr. William T. Coleman of San Francisco.

Ref.—Bull. Cal. Acad., No. 2, January 1885 (read Oct. 1884); the measurements of vom Rath, Vh. Ver. Rheinl., 41, 333, 1884, Zs. Kr., 10, 179, 1884, Hjortdahl, Vid.-Selsk. Christ., Oct. 17, 1884, and Zs. Kr., 10, 25, Arzruni, ib., 10, 272, agree closely with these results.

² Jackson, l. c. ³ Id., ibid., 358, 1886. ⁴ Zs. Kr., 14, 230, 1888, also for B, C, E, etc.

PRICEITE. Cryptomorphite (?), Chase, Am. J. Sc., 5, 287, 1873. Priceite Silliman, ibid., 6, 128, 1873. Pandermite Muck, vom Rath, Ber. nied. Ges., p. 193, July 2, 1877.

Massive, loosely adherent, friable and chalky (priceite), to firm and compact (pandermite).

H. = 3. G. = 2·26-2·30; 2·48. Color snow-white.

Comp.—A hydrous borate of calcium, near colemanite. Whitfield's analyses for both minerals correspond nearly to 5CaO.6B₂O₃.9H₂O. = Boron trioxide 48.7, lime 32·5, water 18.8 = 100. The various analyses are discussed by Kenngott, Jb. Min., 1, 241, 1885.

Analyses.—1, Silliman, l. c. 2. Chase, l. c. 3, Whitfield, ib., 34, 283, 1887. 4, Muck, l. c. 5, Pisani, Min., p. 215, 1875. 6, Whitfield, l. c., p. 284.

5. "	[50.1]	32.0	17.9 = 100
6. "	48.63	32.16	19.40 = 100.19

B.B. gives a green flame, and fuses at a red heat. In the matrass gives off neutral water.

Insoluble in water, but perfectly so in hydrochloric acid.

Priceite is from Curry Co., Oregon, five miles north of Chetko, where it occurs in a hard, compact form in layers, between a bed of slate above, the cavities and fissures of which it fills, and a tough blue steatite below; also occurring in boulders or rounded masses completely embedded in the steatite. Many of these masses weigh 200 lbs. each. Others are smaller, Named after Mr. Thomas Price of from 20 lbs. down to small pellets the size of a pea. San Francisco.

Pandermite occurs in more or less irregular lumps or nodules of varying size up to a ton, in an extensive bed beneath a thick stratum of gypsum, on the Chinar San, a small stream emptying into the Rhyndacus river which flows into the sea of Marmora near the port of

Panderma. Cf. C. G. Warnford Lock, J. Soc. Arts, 28, 767, 1880.

These two minerals are obviously identical, they may represent a massive and not entirely pure variety of colemanite.

705. PINNOITE. Staute, Ber. Chem. Ges., 17, 1584, 1884.

Tetragonal, with pyramidal hemihedrism. Axis c = 0.7609; 001 \wedge 101 = 37° 16', Luedecke'.

Forms: a(100, i-i), e(101, 1-i), o(111, 1), $z(312, \frac{3}{2}-3)$.

Angles: $ee' = 50^{\circ} 42'$, $ee'' = 74^{\circ} 32'$, $oo' = 62^{\circ} 23\frac{1}{2}'$, $oo'' = 94^{\circ} 12'$, $eo = 31^{\circ} 12'$, $ao = *58^{\circ} 48 2'$, $az = 43^{\circ} 9'$, $a'z = 75^{\circ} 55\frac{1}{2}'$.

Rarely in distinct prismatic crystals, showing pyramidal hemihedrism in the form z (312). Usually crystalline and fine granular to faintly fibrous, in nodules with radiated fibrous structure.

Fracture even. H. = 3-4. G. = 3.27 St., 3.373 L. Luster vitreous. Color sulphur- or straw-yellow, sometimes pistachio-Translucent.

Comp.—A hydrous magnesium borate, MgB,O,.3H,O or MgO.B₂O₃.3H₂O = Boron trioxide 42.6, magnesia 24.4, water

Luedecke. 33.0 = 100.

Anal.—1, Staute, l. c. 2, 3, Stromeyer, Zs. Nat. Halle, 58, 646, 1885.

	[42·85]	24·07	32·50	0·21	0.37 = 100

Pyr.—B.B. fuses with some difficulty to a dense white mass. Soluble in acids. Obs.—From the upper kainite layers at Stassfurt, associated with earthy boracite, also with kainite. Named after Oberbergrath Pinno.

Ref.—1 Zs. Ver. Halle, 58, 645, 1885.

Kaliborite W. Feit, Ch. Ztg., 13, 1188, 1889; J. Ch. Soc., 58, 341, 1890.

Massive, resembling pinnoite; separating into microscopic granules, clear and colorless when digested in water. G. = 205. Anal.—W. Feit, after deducting 1-2 p. c. NaCl:

B2O3 57.46 K₂O 6.48 MgO 12-06 $H_2O 24.00 = 100$

B.B. fuses with difficulty to a colorless glass. Slightly soluble in water yielding an alkaline

solution; readily dissolved in warm acids.

Occurs with boracite (and stassfurtite), also pinnoite in the upper kainite layers at Schmidtsmannshall near Aschersleben; it contains a small amount of sodium chloride which probably cements together the minute granules. Regarded as an alteration-product of pinnoite.

706. HEINTZITE. Ein neues Mineral, etc., *Luedecke*, Zs. Nat. Halle, 62, 354, 1889. Heintzit *Id.*, Zs. Kr., 18, 481, 1890. Hintzeite *L. Milch*, ibid., p. 478.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=2.1937:1:1.7338; \ \beta=80^{\circ}\ 12'=001\ \land\ 100$ Milch.

 $100 \land 110 = 65^{\circ} 10\frac{1}{2}', 001 \land 101 = 34^{\circ} 28\frac{1}{6}', 001 \land 011 = 59^{\circ} 39\frac{1}{2}'.$

Forms:
$$c (001, 0)$$
 $x (\overline{1}01, 1-\overline{\imath})$ $o (\overline{1}12, \frac{1}{2})$ $a (100, i-\overline{\imath})$ $m (110, I)$ $n (111, -1)$ $r (311, -3-\overline{3})$ $mm''' = 130^{\circ} 21'$ $cm = 85^{\circ} 54'$ $nn' = 102^{\circ} 18'$ $a'x = *57^{\circ} 49'$ $co = 45^{\circ} 11'$ $nn''' = *77^{\circ} 42'$ $cx = 41^{\circ} 59'$ $m'o = 48^{\circ} 55'$ $oo' = 80^{\circ} 24'$ $cn = 58^{\circ} 51\frac{1}{4}'$ $a'r = 37^{\circ} 49'$ $rr' = 64^{\circ} 10'$ $mn = 27^{\circ} 3'$ $an = 64^{\circ} 2'$ $xn = *81^{\circ} 33'$

n

With Luedecke, the forms lettered as above have the following symbols: $a(100) = a'(\bar{1}00), c(001) = d(\bar{1}02), x(\bar{1}01) = c(001), m(110) = m(120),$ $n(111) = o(\bar{1}11), x(311) = (\bar{2}11).$ He measures $ac = 57^{\circ} 41.4' (a'd = 57^{\circ} 49' \text{ M}),$ $cd = 42^{\circ} 6.5'$ ($xc = 41^{\circ} 59'$ M), $am = 65^{\circ} 23'$ ($am = 65^{\circ} 10\frac{1}{2}'$ M). He gives perfect cleavage d (102) and c (901), also less perfect a (100).

In small crystals, sometimes aggregated together; faces m, c, n, often hemi-

morphically developed. Cleavage: a, c, both perfect. H. = 4-5. G. = 2.13. Luster vitreous. Color-

less to white. Transparent, sometimes clouded.

Optically +. Ax. pl. and $Bx_0 \perp b$. Axial angles, Milch:

$$2H_r = 105^{\circ} 42' \text{ Li}$$
 $2H_v = 104^{\circ} 27' \text{ Na}$ $2H_{gr} = 104^{\circ} 54'$ $(n_v = 1.4678)$

Milch gives $Bx_a \wedge \dot{c} = -7^\circ$ or $c \wedge 100 = 83^\circ$; while Luedecke gives $Bx_a \wedge \dot{c} = -64^\circ$ 44' or c \(\cap \overline{100} = 25\circ 16'\). Obviously there is an error here, probably due to the confounding of the two cleavage-faces.

Comp.—A hydrous borate of magnesium and potassium, but formula doubtful. since the two analyses differ widely.

Anal. 1 gives K₂O.4MgO.9B₂O₃.16H₂O. Anal. 2, K₂O.4MgO.11B₂O₃.14H₂O.

Anal.—1, Baurath, quoted by Milch, l. c. 2, Luedecke, l. c.

The sodium and chlorine in 1 are probably present as NaCl.

Pyr., etc.—Fuses very easily (below 1) coloring the flame intensely green. Easily soluble in hydrocaloric and nitric acids.

Obs.—Occurs at Leopoldshall, Stassfurt, embedded in nodules of pinnoite.

Named Heintzite after the chemist Heintz of Halle, and simultaneously Hintzeite after the German mineralogist, Ch. Hintze. Luedecke's name is taken because he first announced the species, but it is impossible to decide which chemical and optical data should be accepted where they differ.

Comp.—Na₂B₄O₂.10H₂O or Na₂O.2B₂O₃.10H₂O = Boron trioxide 36.6, soda 16.2, water 47.2 = 100.

Pyr., etc.—B.B. puffs up and afterward fuses to a transparent globule, called the glass of borax. Fused with fluorite and potassium bisulphate, it colors the flame around the assay a clear green. Soluble in water, yielding a faintly alkaline solution. Boiling water dissolves double its weight of this salt.

Obs.—Borax has been obtained since very early times from the salt lakes of Tibet, and until the discoveries in California and Nevada this was the most important source; it was brought to

Europe in the crude state under the name of tincal and there purified.

The lakes furnishing the berax or tincal are in Ladák and Great Tibet. The most westerly deposits are in the lake-plain of Pugha on the Rulangchu (a branch of the Indus) at an elevation of 15,000 feet. The deposits of impure borax (sohuga) here occur over an area, 2 miles long by mile broad, covered by a saline efflorescence; successive crops are obtained by the action of moisture (rain or snow) and subsequent evaporation. Deposits also occur to the east of the Pugha district, at the lakes of Rudokh where a purer material (chú tsalé) or water borax is obtained; also farther east at the large lakes of Tengri-Nur, 100 miles north of Lhasa, and further at the lake Bul Cho to the north and Yamdok Cho or Patte to the south. (See further Spon's Encyclopedia, 1, 533, 1882). H. Warth shows that borax is present in the waters of Sambhar

Encyclopedia, 1, 533, 1882). H. Warth shows that borax is present in the waters of Sambhar Lake in Rajputana, India, and also in the saline efflorescence called "reh" (p. 155) from Aligarh (Rec. G. Surv. India, 24, 68, 1891). Borax has also been found at Viquintizoa and Escapa in Peru; at Halberstadt in Transylvania; in Ceylon. It occurs in solution in the mineral springs of Chambly, St. Ours, etc., Quebec, Canada (Hunt, Logan's G. Rep., 1853).

In California, it is abundant in Lake Co., 80 miles north of San Francisco, at Borax Lake and Hachinhama, two small alkaline lakes in the immediate vicinity of Clear Lake;—it is stated to have been discovered here in 1856. It is present in solution in the lake waters and in the case of Borax Lake has been obtained also in large quantities in fine crystals embedded in the lake mud and the surrounding marshy soil. The crystals are sometimes very large, up to 5 or 7 inches in length and weighing a pound each. Nine hundred pounds of crystals have been taken from one cofferdam, four feet square (Ayres). It has also been found in fine large clear crystals at Borax Lake. San Bernardino Co., with hanksite (which it sometimes incloses), thenardite, at Borax Lake, San Bernardino Co., with hanksite (which it sometimes incloses), thenardite, and other soda salts; at Death Valley, Inyo Co. Also occurs with the ulexite of Rhodes Marsh, etc., Esmeralda Co., Nevada. Cf. H. G. Hanks, 3d. Min. Rep. California, 1883.

Named borax from the Arabic buraq, which included also the niter (sodium carbonate) of

ancient writers, the natron of the Egyptians. Borax was called chrysocolla by Agricola because used in soldering gold.

Prof. Bechi has analyzed a borate occurring as an incrustation at the Tuscan lagoons, which afforded: B_2O_3 43·56, Na_2O 19·25, H_2O 37·19 = 100, giving the formula $Na_2O.2B_2O_3.6H_2O.$ Am. J. Sc., 17, 129, 1854. Ref.—¹ Min., 54, 1839, credited to Naumann. ² Mohs-Zippe, l. c. ³ Dx., Min., 2, 7, 1874.

⁴ Dx., ibid. ⁵ Tschermak, Ber. Ak. Wien, 57 (2), 641, 1868.

TINCALCONITE C. U. Shepard. Borax from California, pulverulent and efflorescent, 32, p. c. water. Bull. Soc. Min., 1, 144, 1878.

708. ULEXITE. Boronatrocalcit *Ulex*, Lieb. Ann., 70, 49, 1849 Natronkalk-borat. Ulexite *Dana*, Min., 695, 1850. Natronborocalcite. Tinkalzit (fr. Africa) *Kletzinsky*, Polyt. Centr., 1384, 1859. Tiza S. America.

Usually in rounded masses, loose in texture, consisting of fine fibers, which

are acicular or capillary crystals.

 $H_{1} = 1$, $G_{2} = 1.65$ N. Scotia, How. Luster silky within. Color white. Tasteless.

Comp.—A hydrous borate of sodium and calcium, probably NaCaB,O. 8H,O= Na₂O₂CaO₅B₂O₂.16H₂O = Boron trioxide 43.0, lime 13.8, soda 7.7, water 35.5 = 100.

Some doubt exists as to the quantity of water; analysis 7 gives only 12 H₂O (calc. 29.2 p. c.). Anal.—1, Raimondi, Min. Pérou, 263, 1878. 2, Holtz, Rg., Min. Ch. Impurities have been deducted (gypsum, KCl, NaCl, SiO2, etc.): in 1, 4.07 NaCl, in 3, 7.7

Pyr., etc.—Yields water. B.B. fuses at 1 with intumescence to a clear blebby glass, coloring the flame deep yellow. Moistened with sulphuric acid the color of the flame is momentarily changed to deep green. Not soluble in cold water, and but little so in hot; the solution alkaline in its reactions.

Obs.—Occurs in the dry plains of Iquique, Chili, in the province of Tarapacá (where it is

888 BORATES.

called tiza), in whitish rounded masses, from a hazelnut to a potato in size, which consist of interwoven fibers of the ulexite, with pickeringite, glauberite, halite, gypsum, and other impurities; at Salinas de la Puna, Province of Jujuy, Argentine Repub.; also at the Laguna Blanca, Catanarca, and in Prov. Salta; on the West Africa coast.

In Nevada, in large quantities in the salt marshes of the Columbus Mining District, in the south-eastern part of Esmeralda Co. Thus in the deposits called Teel's Marsh, Rhodes Marsh, Columbus Marsh, and Fish Lake valley-these are oval-shaped alkali flats covering 10,000 to 20,000 acres each. The ulexite occurs here in the saline crusts formed by evaporation; it is mixed with common salt, also gypsum and glauberite; it occurs in part in the form of balls ("cottonballs") 3-4 inches through embedded in the salt. In California, in San Bernardino Co.; also the variety called "sheet cotton" from Death Valley. Inyo Co., and from Desert Springs, also called Cane Springs, in Kern Co. Also in Nova Scotia, at Windsor, Brookville, and Newport Station, filling narrow cavities, or constituting distinct nodules or mammillated masses embedded in white gypsum, and associated at Windsor with glauber salt, the luster internally silky and the color very white.

Named after the German chemist, G. L. Ulex, who gave the first correct analysis of the

mineral.

Alt. - Occurs altered to gypsum.

The following are near ulexite:

Franklandite Reynolds, Phil. Mag., 3, 284, 1877. Massive, with fine fibrous structure. H. = 1. G. = 1.65. Color white. An analysis gave:

H₂O (Na, K)Cl B₂O₃ CaO Na₂O $CaSO_4 + 2 aq.$ 12·10a 12:37 27.92 2.41 1.44 = 100[43.76*] ^a Other independent determinations gave B₂O₃ 41.81, CaO 11.94, H₂O 27.66.

Deducting impurities, the formula deduced is Na₂CaB₆O₁₁.7½H₂O. It is very near ulexite. Slightly soluble in water, readily in dilute hydrochloric and nitric acids. Fuses easily. From Tarapaca, Chili. Named after the English chemist, Frankland.

CRYPTOMORPHITE H. How, Am. J. Sc., 32, 9, 1861: Min. Mag., 1, 257, 1877. In dull white kernels consisting of microscopic rhombic plates. Near ulexite in composition. Analysis.-How, after deducting impurities:

> Na2O 5.61 H₂O 19.72 B₂O₃ 59·10 CaO 15.55

Occurs in white lusterless kernels of the size of a pea or bean lying between crystals of gypsum and glauber salt at Windsor, Nova Scotia. Named from $\kappa\rho\nu\pi\tau$ os, concealed, and μορφή, form, because the structure is only revealed by the microscope.

709. BECHILITE. Borate de Chaux Beud., Tr., 2, 249, 1832. Hayesine? Bechi, Am. J. Sc., 17, 129. 1854. Bechilite Dana. Hydrous Borate of Lime. Borocalcit Groth., Tab. Ueb., Alger-Phillips, Min., 318, 1844. 38, 1874.

In crusts, as a deposit from springs. Comp.—CaB₄O₇.4H₂O or CaO.2B₂O₃.4H₂O=Boron trioxide 52·2, lime 20·9, water 26·9=100. Anal.—Bechi, l. c.

 SiO_2 , Al_2O_3 , MgO 1.75 = 99.99B₂O₃ 51·14 CaO 20.85 H₂O 26.25

Pyr., etc.—Yields water. B.B. fuses easily, coloring the flame reddish yellow; moistened with sulphuric acid the flame is colored green.

Obs. - Found by Bechi (after whom it is named) as an incrustation at the baths of the boric acid lagoons of Tuscany. The borate mentioned by Beudant (1832) was from Monte Rotondo,

The Hayesine of D Forbes (Phil. Mag., 25, 113, 1863), from the waters of the hot springs, Baños del Toro, in the Cordilleras of Coquimbo, may be the above species. It occurs in the waters in the form of snow-white silky or feathery flakes, and also as a flaky sediment at the bottom. Forbes suggests that the mineral is formed by the action of hot vapors, volcanic in source, on the lime of the waters through which they pass.

HAYESINE Hydrous borate of lime A. A. Hayes, Am. J. Sc., 46, 377, 47, 215, 1844. Borocalcite. Hydroborocalcite Hausm., Handb., p. 1429, 1847. Hayesine Dana, Min., 217,

The supposed borate of lime of Hayes (CaB₄O₇ 6H₂O = Boron trioxide 46.0, lime 18.4, water 35.6 = 100) has been shown to be ulexite (cf. 5th Ed., p. 599, and Raimondi, Min. Pérou, 252, 264, 1878. The same is true of the mineral analyzed by Reichardt (JB. Ch., 737, 1858, 760, 1862; these analyses, however, are quoted by Dx., Min., 2, 10, 1874). Two recent analyses par tially sustaining the species have been made. 1, Brun. Zs. Kr., 7, 390, 1882. 2, Darton, Am. J. Sc., 23, 458, 1882.

Isometric. In octahedrons (o), also with dodecahedral planes (d); less often in cubes with o and d. Crystals rare. Usually massive and botryoidal; also in grains; structure sometimes columnar, or curved lamellar.

Fracture conchoidal to uneven. Brittle. H. = 5.5. G. = 9.0 to 9.7 of crystals; of massive altered forms from 6.4 upwards, see below. Luster submetallic, to greasy or pitch-like, and dull. Color grayish, greenish, brownish, velvet-black.

Streak brownish black, grayish, olive-green, a little shining. Opaque.

Comp .- A uranate of uranyl, lead, usually thorium (or zirconium), often the metals of the lanthanum and yttrium groups; also containing nitrogen in varying amounts up to 2.6 p. c. Calcium and water (essential?) are present in small quantities; iron also, but only as an impurity. The relation between the bases varies widely and no definite formula can yet be given. Cf. Hillebrand, ref. below.

When the composition of the minerals here provisionally included together is more thoroughly understood, it may prove that they should be separated, as two or three independent

species.

The ratio of UO3 and UO2 varies widely even in different specimens from the same locality. Thus the oxygen ratio of UO₃ to other bases varies from 1:4.37 (Branchville) to 1:1 in bröggerite; while nivenite gives an acid ratio. This fact, coupled with the behavior of the material when treated with acids, has led Hillebrand to suggest that while the variation may be only due to alteration, it is perhaps more probable that all specimens examined are simply mixtures of two (or more) compounds in varying amounts.

The presence of nitrogen, first shown by Hillebrand, to whom we owe most of our present knowledge of the composition of the species, is a remarkable fact, as being the only case in which this element has been identified in a mineral belonging to the original crust of the earth. The part played by the nitrogen is still uncertain; the amount seems to bear some relation to the UO₂ present. The nitrogen is set free, as nitrogen gas, by a non-oxidizing inorganic acid and by fusion with an alkaline carbonate; probably also by caustic alkalies in a current of CO2.

Var.—The varieties of uraninite include:

1. Crystallized. Uranniobite of Hermann, from Norway. In crystals, usually octahedral, with G. varying for the most part from 9.0 to 9.7; occurs as an original constituent of coarse granites (pegmatyte). The variety from Branchville, which is as free from alteration as any yet examined, contains chiefly UO₂ with a relatively small amount of UO₂. Nitrogen is present in the maximum quantity, as yet observed, 2.6 p. c. Thoria is prominent, while the earths of the lanthanum and yttrium groups are only sparingly represented.

Bröggerite, as analyzed by Hillebrand, gives the oxygen ratio of UO₃ to other bases of about 1:1. It occurs in octahedral crystals, also with d and a. G. = 9.03.

Cleveite and nivenite contain UOs in larger amount than the other varieties mentioned, and are characterized by containing about 10 p. c. of the yttrium earths. Cleveite is a variety from the Arendal region occurring in cubic crystals modified by the dodecahedron and octahedron. G. = 7.49. Nivenite occurs massive, with indistinct crystallization. Color velvet-black. H. = 5.5. G. = 8.01. It is more soluble than other kinds of uraninite, being completely decomposed by the action for one hour of very dilute sulphuric acid at 100°.

2. Massive, probably amorphous. Pitchblende; nasturan of Kobell (from $\nu\alpha\sigma\tau\delta$ 5, dense).

Contains no thoria; the rare earths are also absent, and nitrogen is very sparingly present if at all. Water on the other hand is prominent and the specific gravity is much lower, in some cases not above 6.5. These last differences are doubtless largely due to alteration. Here belong the kinds of pitchblende which occur in metalliferous veins, with sulphides of silver, lead, cobalt, nickel, fron, zinc, copper, as that from Johanngeorgenstadt, Přibrám, etc.; probably also that from Black Hawk, Colorado, (Hillebrand).

Anal.—1-11, 15-21, Hillebrand, Am. J. Sc., 40, 384, 1890; also U. S. G. Surv., Bull. 78. In the latter place the methods, results, and conclusions are stated more minutely. 12-14, 22, Id., Am. J. Sc., 42, 390, 1891. In these analyses the La₂O₃ group includes the earths insoluble in potassium sulphate, the Y₂O₃ group those soluble in it.

Earlier analyses are more or less incomplete or untrustworthy, see 5th Ed., p. 155; also

Branchville, Comstock, Am. J. Sc., 19, 220, 1880 (in which the thorium is overlooked). Further, 23, Blomstrand, l. c. 24, G. Lindström, quoted by Nordenskiöld, l. c. (cf. Blomstrand, l. c., p. 69). 25, Hidden and Mackintosh, l. c. 26, Lorenzen, Nyt Mag., 28, 249, 1884. The absence of thorium in anal. 26, while Hillebrand obtained a considerable amount in material stated to have come from the same locality, is not explained.

For analyses, see p. 891, opposite.

Blomstrand (l.c.), in discussing the composition of the natural uranates, deduces for uraninite

the formula of an ortho-uranate, $\hat{U}_3(\hat{U}O_6)_2$, or $(UO_2)_3(UO_3)_2$; this Hillebrand shows has no

general application.

Pyr., etc.—B.B. infusible, or only slightly rounded on the edges, sometimes coloring the outer flame green (copper). With borax and salt of phosphorus gives a yellow bead in O.F., becoming green in R.F. (uranium). With soda on charcoal gives a coating of lead oxide, and

892 URANATES.

frequently the odor of arsenic. Many specimens give reactions for sulphur and arsenic in the open tube. Soluble in nitric and sulphuric acids; the solubility differs widely in different varieties, being greater in those kinds containing the rare earths. Not attractable by the

Obs.—As noted above, uraninite occurs either as a primary constituent of granitic rocks or as a secondary mineral with ores of silver, lead, copper, etc. Under the latter condition it is Fibram in Bohemia, and Rezbánya in Hungary. It is associated with torbernite at Tincroft and Tolcarn mines near Redruth in Cornwall; also near Adrianople, Turkey. Occurs in Norway in pegmatyte veins at several points near Moss, viz.: Anneröd (bröggerite), Elvestad, Huggenäskilen, Skraatorp; also near Arendal at the Garta feldspar quarry (cleveite), associated with orthite,

fergusonite, thorite, etc.

In the U. States, at the Middletown feldspar quarry, Conn., in large octahedrons, rare; also more abundantly at Hale's quarry in Glastonbury, a few miles N.E. of Middletown. At Branchville, Conn., in a pegmatyte vein, not uncommon as small octahedral crystals, often aggregated together; usually embedded in albite. In N. Carolina, at the Flat Rock mine and other mica mines in Mitchell Co., rather abundant, but usually altered, in part or entirely, to gummite and uranophane; the crystals are sometimes an inch or more across and cubic in habit. In S. Carolina, at Marietta. In Texas, at the gadolinite locality in Llano Co. (nivenite). In large quantities at Black Hawk, near Central City, Colorado. Rather abundant in the Bald Mountain district, Black Hills, S. Dakota.

Also with monazite, etc., at the Villeneuve mica veins, Ottawa Co., Quebec, Canada.
Cleveite is named after the Swedish chemist, P. T. Cleve. Bröggerite after the Swedish mineralogist, W. C. Brögger. Nivenite after Mr. William Niven, of New York City.

Alt.—The hydrous mineral called gummite occurs as a result of the alteration of this species;

also uranic ocher.

Coracite is from about 90 m. above Sault Ste. Marie, on the north side of L. Superior; it appears to be a uraninite partly altered to gummite. Analyses.—1, Whitney, Am. J. Sc., 7, 434, 1849, 5th ed., p. 155. 2, Genth, ibid., 23, 421, 1857. Whitney found 15 92 p. c. CaCO₂, which was separated by Genth before analysis.

712. GUMMITE. Feste Uranokker pt. Wern., Min. Syst., 26, 1817, Hoffm. Min., 4, a, 279. Lichtes Uranpecherz Freiesleben. Uranisches Gummi-Erz, Breith., Uib., 60, 1830, Char., 218, 1832. Urangummi Breith., Handb., 903, 1847. Phosphor-Gummit Herm., J. pr. Ch., 76, 327, 1859.

Uranisches Pittin-Erz, Pittinus inferior, *Breith.*, Handb., 901, 1847. Eliasit *Haid.*, Jb. G. Reichs., 3, No. 4, 124, 1852. Pittinit *Herm.*, J. pr. Ch., **76**, 322, 1859.

Crystalline (Foullon); perhaps in part amorphous. In rounded or flattened pieces, looking much like gum.

H. = 2.5-3. G. = 3.9-4.20 Breith. Luster greasy. Color reddish yellow to orange- or hyacinth-red, reddish brown. Streak yellow. Feebly translucent.

Comp.—An alteration-product of uraninite of doubtful composition.

Foullon calculates the formula (Pb, Ca, Ba)U₃SiO₁₂+6H₂O, for the essential part of gummite

which is associated with uranophane (p. 699) and sometimes intimately mixed with it.

Anal.—1, Kersten, Schw. J., 66, 18, 1832. 2, Ragsky, Pogg., Erg., 4, 348, 1854. 3, Hermann, l. c. 4-10, von Foullon, Jb. G. Reichs., 33, 1, 1883. 11, Genth, Am. Ch. J., 1, 89, 1879.

Genth, discussing anal. 11, arrives at the conclusion that it represents a mixture of uranium hydrate (40 p. c.), uranotile (33 4), lead uranate (22 7), and barium uranate (4 3).

Pyr., etc.—Yields much water and a bituminous odor. With salt of phosphorus in O.F.

gives a yellow bead, becoming green in R.F. (due to uranium), leaving an undissolved skeleton of silica.

Obs.-From Johanngeorgenstadt, with uraninite. Eliasite and pittinite are from Joachimsthal, where they occur with pitchblende. Eliasite is somewhat resin-like in aspect; G. = 4.087-4.237 Zeph. Color dull reddish brown. Pittinite is black in color; streak olive-green; luster

greasy submetallic; G. = 4.8-5.0 Breith.; 5.16 Herm.

Gummite is also abundant at the Flat Rock mine, Mitchell Co., N. C.; crystals examined by Foullon consisted of a lemon-yellow granular or earthy exterior (uranophane) inclosing the orange-red gummite and often in the center a nucleus of uraninite. Also at many other localities with uraninite, as at Branchville, etc. On coracite see p. 892.

YTTROGUMMITE A. E. Nordenskiöld, G. För. Förh., 4, 31, 1878. Occurs with cleveite (p. 890) and is probably a final decomposition-product of it. It has the appearance of orangite. Luster brilliant. Color black to yellow. Translucent fracture conchoidal. Optically anisotropic. H. = 5. A hydrous compound containing yttrium and uranium oxides. Between the black opaque cleveite and the translucent honey-yellow yttrogummite occur many intermediate products.

Thorogummite Hidden and Mackintosh, Am. J. Sc., 38, 480, 1889. Occurs with fergusonite, cyrtolite, and other species at the gadolinite locality in Llano Co., Texas. Usually massive, sometimes in groups of crystals near zircon in form. H. = 4-4.5. G. = 4.43-4.54. Color dull yellowish brown. Easily soluble in nitric acid. After ignition becomes of a dull greenish hue. Anal.:

UO. ThO2 SiO₂ (Ce,Y)₂O₃ PbO Al₂O₃ Fe₂O₃ CaO 22.43 41.44 13.08 6.69a 2.16 0.96 0.85 0.41 7.88 P₂O₅ 1.19, hygr. H₂O 1.23 [=98.32a At. wght. 135.

The formula calculated for the above is UO₃.3ThO₂.3SiO₂.6H₂O.

Chlorothorite Hidden, Trans. N. Y. Acad. Sc., 8, 185, May 27, 1889. A name provisionally suggested for "a tetragonal thorium silico-uranate." Apparently the same as the above, thorogummite. So named because it turns green upon ignition.

713. URANOSPHÆRITE. Weisbach, Jb. Berg-Hütt. Sachs., and Jb. Min., 315, 1873.

In half-globular aggregated forms, sometimes with a dull or a slightly lustrous surface, sometimes rough and drusy, made up of minute acutely-terminated crystals. Structure concentric, also radiated.

H. = 2.3, G. = 6.36. Color orange-yellow, brick-red (Winkler). Luster

greasy. Streak yellow.

Comp.—(BiO), U,O, 3H,O or Bi,O, 2UO, 3H,O = Uranium trioxide 52.7, bismuth trioxide 42.4, water 4.9 = 100.

Anal.—1, 2 Winkler: 1, impurities (11 p. c.) deducted, 2, perfectly pure material, J. pr. Ch., 7, 5, 1873.

1.	50.32	44.12	5.56 =	100
2.	50.88	44.34	4.75 =	99.97

Pyr., etc.—Decrepitates on heating, and falls to pieces to a mass of crystalline needles, with silky luster, homogeneous and of brown color.

Obs.—Occurs with other related uranium minerals at the mine Weisser Hirsch, near Schneeberg, Saxony.

Twins: tw. pl. m, pseudo-hexagonal, like the artificial potassium sulphate.

Usually in mealy crusts and stalactitic forms.

Cleavage: c distinct. H. = 2-2.5. G. = 1.76-1.77. Luster when crystallized, vitreous. Color yellowish gray, lemon-yellow. Translucent. Taste pungent and bitter.

Optically +. Ax. pl. | b. Bx $\perp a$. Dispersion weak, $\rho < v$. Ax. angles: $2E_r = 87^{\circ} 44'$, $2E_{bl} = 88^{\circ} 47'$. The angle is increased by rise of temperature, Dx.

Comp.—Ammonium sulphate, (NH₄) SO₄ = Sulphur trioxide 60.6, ammonium

oxide 39.4 = 100.

Pyr., etc.—In the closed tube yields water and is sublimed; with lime gives off ammonia

vapors. Dissolves readily in water.

Obs.—Occurs about volcanoes, in the fissures of the lava, as at Etna, Vesuvius, and the Lipari Isles, and is also one of the products of the combustion of mineral coal. Also found in the guano of the Guañape Islands, Peru.

Named after Professor Mascagui.

Ref.—1 Artif. cryst., Pogg., 18, 169, 1830; Rg., Kr. Ch., 387, 1871. 2 Propr. Opt., 2, 24, 1859, N. R., 96, 1867.

715. TAYLORITE. Sulphate of Potash and Ammonia W. J. Taylor, Proc. Ac. Philad., 309, 1859. Taylorite Dana, Min., 614, 1868.

Rhombohedral. Axis $\dot{c} = 1.2839$; $0001 \land 1011 = *56^{\circ} 0'$ Mitscherlich.

Forms: c(0001, 0); $m(10\overline{10}, I)$; $a(11\overline{20}, i-2)$, $e(10\overline{12}, \frac{1}{2})$, $r(10\overline{11}, R)$, $d(01\overline{14}, -\frac{1}{4})$, ϵ (0112, $-\frac{1}{2}$), y (0111, -1).

Angles: $ce = 36^{\circ} 33'$, $ry = 48^{\circ} 59'$, $ee' = 62^{\circ} 6'$, $rr' = 91^{\circ} 461'$.

Figs. 1-3, Douglashall, Bücking.

Occurs in rhombohedral crystals, often thin tabular; also in distorted forms which appear to be orthorhombic in symmetry, and again united in groups resembling the pseudohexagonal twins of aragonite (f. 3), but throughout optically uniaxial (Bkg.). Also in blades made up of aggregated crystals; massive, or imperfectly mammillary, and in crusts.

Cleavage: m rather distinct; c imperfect. H. = 3-3.5. G. = 2.63-2.656 Bkg. Luster vitreous, inclined to resinous. Color white, sometimes tinged with blue or green. Transparent to translucent, or opaque. Taste saline and bitter,

disagreeable. Unalterable in the air. Optically +. Indices:

 $\omega = 1.493$ $\epsilon = 1.501$ Senarmont (Dx.). $\epsilon = 1.4993$ Bücking. For Na, $\omega = 1.4907$

Comp.—Sulphate of potassium and sodium, (K,Na)₂SO₄; if K: Na = 3:1, as found by Sec. (l. c.) the percentage composition is: Sulphur trioxide 48.2, potash 42.5, soda 9.3; or, Potassium sulphate 78.6, sodium sulphate 21.4 = 100.

Geserick (quoted by Bücking) found that crystals from Douglashall near Westeregeln, containing 10 to 14 p. c. of sodium chloride as impurity, consisted of K2SO4 and Na2SO4 in the ratio of 5: 2, and 3: 1. An analysis of the Rocalmuto salt gave Rath, Pogg. Ann., Erg.-Bd., 6, 360, 1873:

> SO₃ 49.50 K2O 33.24 $Na_2O [17.26] = 100$

This corresponds nearly to 4K₂SO₄ + 3Na₂SO₄.

Pyr., etc.—Fuses before the blowpipe without intumescence. Soluble in water.

Obs.—Found at Vesuvius, upon lava, in delicate crystallizations, and also in masses an inch or more in thickness. Occurs at Douglashall near Westeregeln in blödite, which with the halite forms a deposit between kainite and halite in the kieserite region. Also at Rocalmuto, Sicily. These crystals were regarded by Rath as orthorhombic, but Strüver shows (Rend. Acc. Linc., 5,

750, 1889) that it is throughout optically uniaxial and identical with aphthitalite of Scacchi. Bücking earlier proved the same for the Westeregeln crystals as above noted.

The artificial salt (K, Na)₂SO₄ is dimorphous. Cf. Mitscherlich, l. c., or Rg., Kr. Ch., 401, 1881. Scc., Mem. Acc. Napoli, 1, read May 12, 1863 (Polisimm. Crist., p. 11 et seq.), also 5, Mch. 181, 1870. 6, Dec. 12, 1872. Poly. Pogg. Fyr., 5, 269, 1872. Mid. Bull. Scc. Min. 5, 200. 12, 1870; 6. Dec. 13, 1873. Rath, Pogg. Erg., 6, 362, 1873. Mld., Bull. Soc. Min., 5, 226,

1882; also arcanite beyond.

Named aphthalose by Beudant, in 1832, from ἀφθιτος, unalterable, and ἄλς, salt; and changed, by Shepard, to the less incorrect form from these Greek words, aphthitalite. Arcanite of Haidinger was derived from one of its alchemistic names, Arcanum duplicatum. Glaserite given by Hausmann in 1847, after the chemist Christoph Glaser (1664), the salt having been early called Sal polychrestum Glaseri.

Ref.—¹ Artif. cryst., Pogg. Ann., 58, 468, 1843. The rhombohedral nature of the Vesuvian mineral was shown by Scacchi. Bücking obtained for the Douglashall crystals, 0001 \(\Lambda \) 1012 =

 $36^{\circ} 38'$, whence c = 1.2879, Zs. Kr., 15, 561, 1889.

The following description is based upon the artificial potassium sulphate, which thus far has not been identified in nature, although formerly supposed to be represented by the mineral from Rocalmuto.

ARCANITE. Orthorhombic. Axes $\check{a}: \bar{b}: \dot{b} = 0.5727: 1: 0.7464$ Mitscherlich. $100 \land 110 = 29^{\circ} 48', 001 \land 101 = 52^{\circ} 30', 001 \land 011 = 36^{\circ} 44\frac{1}{4}'.$

Forms: a (100, i- \bar{i}), b (010, i- \bar{i}), c (001, O); m (110, I), f (130, i- $\bar{3}$); e (102, $\frac{1}{2}$ - \bar{i}); u (011, 1- \bar{i}); v (021, 2- \bar{i}), s (112, $\frac{1}{2}$), o (111, 1).

Angles: $mm''' = *59^{\circ} 36'$, $ff' = 60^{\circ} 24'$, $ee' = 66^{\circ} 11'$, $uu' = 73^{\circ} 28\frac{1}{2}'$, $vv' = *112^{\circ} 22'$, $cs = 36^{\circ} 54'$, $co = 56^{\circ} 21'$, $ss' = 62^{\circ} 49'$, $ss''' = 34^{\circ} 43\frac{1}{2}'$, $oo' = 92^{\circ} 29'$, $oo''' = 48^{\circ} 52'$.

Twins: tw. pl. m, repeated, yielding pseudohexagonal forms, resembling aragonite; also f (130). Crystals prismatic, m, also pyramidal, o. Cleavage: c distinct; also b, m. Fracture uneven to conchoidal. Rather brittle. Optically +. Ax. pl. $\parallel a$. Bx $\pm c$. Dispersion feeble, $\rho > v$ oil, $\rho < v$ in air. Axial angles, Dx.:

The axial angle is increased about 10° C. in passing from 17° to 155°.8 C. Mallard notes that crystals are uniaxial and negative above 650°.

Composition: Potassium sulphate, K₂SO₄ = Sulphur trioxide 46.0, potash 54.0 = 100;

also (K, Na)2SO4.

On artif. cryst., Pogg., 18, 169, 1830; 58, 468, 1843. Rg., Kr. Ch., 389, 401, 1871; also Baumhauer, Zs. Kr., 12, 308, 1886, Tf. vi. Cf. also Scc., etc., references under aphthitalite, Dx., Propr. Opt., 2, 23, 1859; N. R., 98, 1867. See also Mld., on the effect of heat, Bull. Soc. Min., 5, 219, 1882.

718. GLAUBERITE. Glauberite Brongniart, J. Mines, 23, 5, 1808. Brongniartin Leonh., Handb., 270, 1826.

Monoclinic. Axes $\hat{a}: \bar{b}: \dot{c}=1.21998:1:1.02749$; $\beta=67^{\circ}$ 49' 7'' = 001 \wedge 100 Zepharovich¹.

 $100 \stackrel{1}{\wedge} 110 = *48^{\circ} 29' 6'', 001 \stackrel{1}{\wedge} 101 = 30^{\circ} 36' 54'', 001 \stackrel{1}{\wedge} 011 = 43^{\circ} 34' 30''.$

Forms ² :	$z \ (\bar{3}02, \frac{3}{2} - \bar{\imath})$	$\beta (113, -\frac{1}{8})^6$	s (111, - 1)	n ($\bar{1}11, 1$)
a (100, $i-\bar{i}$)	$t \ (\bar{2}01, \ 2-\bar{\imath})$	$\delta (112, -\frac{1}{2})^5$	$\xi (661, -6)^3$	$x (\bar{3}31, 3)$
c (001, O)	$f(023, \frac{2}{3}-i)^5$	$\alpha (334, -\frac{3}{4})^4$	$v(\bar{1}13, \frac{1}{3})$	e (311, 3-3)
m(110, I)	$g (021, 2-i)^5$	$\epsilon \ (445, -\frac{4}{5})^4$	$u(\bar{1}12, \frac{1}{2})^3$	

Fig. 1, Common form. 2, Aranjuez, Laspeyres. 3, Westeregeln, after Zepharovich.

7	nm'"	=	96°	58'	cδ	=	27°	57'		cv	=	24°	3811	$\alpha\alpha'$	=	55°	2'

			124°				*75°						111/2	ee'	=	44	15'	
	R	_	20°	201	ms	_	*32°	28'	45"	88	=	42	31'					

Crystals tabular $\parallel c$, the prism m sometimes wanting; also prismatic by exten-

Cleavage: c perfect. Fracture conchoidal. Brittle. H. = 2·5-3. G. = 2·7-2·85. Luster vitreous. Color pale yellow or gray; sometimes brick-red. Streak white. Taste slightly saline.

Optically –. Ax. pl. $\perp b$; also $\parallel b$. Axial angles very variable with change of temperature. Bx_{a.r} \wedge \dot{c} = - 31° 3′, Bx_{a.y} = - 30° 46′, Bx_{a.bl} \wedge \dot{c} = - 30° 10′.

The optical character (-) and the position of the axes of elasticity remain sensibly constant between 0° and 100°. The ax. pl., however, at first $\pm b$ with horizontal dispersion and $v < \rho$ becomes on rise of temperature $\parallel b$ with inclined dispersion and $v > \rho$. The axial angle accordingly diminishes to 0° at a temperature depending upon the wave-length and then increases in the new plane. In white light, therefore, the interference-figures are abnormal and change with rise in temperature. Axial angles, Laspeyres':

				red	(Li)	yello	w (Na) green	(Tl)	bl	ue

Comp.—Na₂SO₄.CaSO₄ = Sulphur trioxide 57.6, lime 20.1, soda 22.3 = 100; or, Sodium sulphate 51.1, calcium sulphate 48.9 = 100. Analyses agree closely, see 5th Ed., p. 628.

Pyr., etc.—B.B. decrepitates, turns white, and fuses at 1.5 to a white enamel, coloring the flame intensely yellow. On charcoal fuses in O.F. to a clear bead; in R.F. a portion is absorbed

flame intensely yellow. On charcoal fuses in O.F. to a clear bead; in R.F. a portion is absorbed by the charcoal, leaving an infusible hepatic residue. With soda on charcoal gives the reaction for sulphuric acid. Soluble in hydrochloric acid. In water it loses its transparency, is partially dissolved, leaving a residue of calcium sulphate and in a large excess this is completely dissolved. On long exposure absorbs moisture and falls to pieces.

Obs.—In crystals in rock salt at Villa Rubia, near Ocana, in New Castile; also at Aussee, in Upper Austria; Berchtesgaden, in Bavaria; at Douglashall, Westeregeln, also at Leopoldshall, Stassfurt, sometimes in large crystals 3 × 2 inches across; at the salt mines of Vic, in France; at Varengeville, near Nancy, a red variety in salt with polyhalite and anhydrite; with thenardite, hanksite, etc., Province of Tarapacá, Chili, with ulexite; at the Mayo salt mines in Punjab, India. In the volcanic tufa of the hill Rosenegg, Rielasingen, Hegau, crystals changed to calcite.

crystals changed to calcite.

In crystals in the Rio Verde Valley, Arizona, with thenardite, mirabilite, etc.; the crystals in the Rio Verde Valley, Arizona, with thenardite, mirabilite, etc.; the crystals are tabular | c with the prism nearly wanting; they are sometimes altered to calcite, cf. Blake,

l. c. Borax lake. San Bernardino Co., California.

Alt.—Occurs altered to calcite, as above noted.

Twins²⁴: (1) m, only as tw. lamellæ, developed by pressure and producing a structure somewhat similar to that of a triclinic feldspar. (2) (601) also as tw. lamellæ, forming striations on c and m, the latter inclined about 19° to the vertical edge; (3) o (011) as polysynthetic tw. lamellæ, also producing fine striations which

Figs. 1-8, 10, 11, Simple forms. 9, Buckingham Co., Va. 12, De Kalb, N. Y., Chester. 13, Colorado. 14, Cheshire. 15, Vernasca, Sansoni.

on m are inclined about 45° to the basal edge. Crystals commonly tabular $\|c$, and united in diverging groups having the axis \bar{b} in common; also prismatic, most frequently $\|$ axis \bar{b} , d (102) predominating, but also $\|$ axis \dot{c} , m prominent, or again $\|\breve{a}$ with o (011) prominent. Rarely apparently hemimorphic in direction of axes

ă (f. 12) or c, but only as a result of secondary development, not properly a molecular hemimorphism as concluded, after pyroelectrical experiments, by Hankel, and also by Valentin on the ground of the symmetry of the etchingfigures. Also in globular forms, fibrous or lamellar, crested; coarsely laminated, laminæ convergent and often curved; also granular, resembling white marble, and earthy; colors sometimes banded as in stalagmite.

Cleavage: c perfect; m also perfect, fig. 1 the form yielded by cleavage; also b erfect. Fracture uneven. Brittle. H. = 2.5-3.5. G. = 4.3-4.6; 4.486, imperfect. Fracture uneven. Brittle. H. = 2.5-3.5. G. = 4.3-4.6; 4.486, G. Rose, a pure colorless crystal. Luster vitreous, inclining to resinous; sometimes pearly on c, less often on m. Streak white. Color white; also inclining to yellow, gray, blue, red, or brown, dark brown. Transparent to translucent to opaque.

Sometimes fetid, when rubbed.

Optically +. Ax. pl. ||b|. Bx $\perp a$. Refractive indices, etc., Arzruni²⁶:

		α	β	y	2E	2V
For C " D " F	20°	1·63351 1·63609 1·64254	1.63457 1.63712 1.64357	1·64531 1·64795 1·65469	64° 1′	37° 28′
For D	50° 100° 200°	1·63575 1·63512 1·63344	1·63678 1·63612 1·63474	1·64726 1·64643 1·64426	68° 51′ 77° 16′ (204°)	38° 43′ 40° 15′ 44° 18′

Dx. gives $2E_r = 63^{\circ} 5'$ at $12^{\circ} C_{.} = 69^{\circ} 49'$ at $95^{\circ} 5_{.} = 74^{\circ} 42'$ at $195^{\circ} 8^{\circ}$.

Var.—1. Ordinary. (a) Crystals usually broad or stout; sometimes very large, weighing 100 lbs.; again in slender needles. (b) Crested; massive aggregations of tabular crystals, the crystals projecting at surface into crest-like forms. (c) Columnar; the columns often coarse (Stangenspath) and loosely aggregated, and either radiated (Strahlbaryt) or parallel; rarely fine fibrous. Werner's Stangenspath was from Freiberg. (d) In globular or nodular concretions, subfibrous or columnar within. Bologna Stone is here included, being radiated, globular, often reddish gray in color. It is from a bed of clay in Mt. Paterno, near Bologna, and was early a source of wonder because of the phosphorescence it exhibited after heating with charcoal. "Bologna phosphorus" was made from it in the form of sticks, by powdering the mineral and uniting it again with gum. (e) Lamellar, either (α) straight or (β) curved; the latter sometimes as aggregations of curved scale-like plates; the krummschaliger Schwerspath of Werner, from Freiberg, is included here; it contained some lime, and Breithaupt gives $mm''' = 78^{\circ}$ 7' and $G = 4 \cdot 02 - 4 \cdot 29$. (f) Granular. (g) Compact or cryptocrystalline. (h) Earthy. (i) Stalactitic and stalagmitic; similar in structure and origin to calcareous stalactites and stalagmites and of much beauty when polished.

Michel-lévyte from Perkin's Mill, Templeton, Quebec, was described by Lacroix as a monoclinic form of barium sulphate, but shown by the author (Am. J. Sc., 39, 61, 1890) to be simple barite. It is peculiar in showing a strong pearly luster parallel usually to one face of prismatic cleavage (also to both) and in this direction separates easily into thin laminæ. This is the result of pressure from the inclosing crystalline limestone, which has also produced polysynthetic twinning ||m|(110)| and o (011). Cf. Bauer²⁴, who has studied the twinning structure minutely and who shows that crystals standing free in cavities are without these secondary tw. lamellæ

and peculiarities of cleavage.

The barite of Muzsaj, Hungary, and of Betler, near Rosenau, was early called Wolnyn. It

The barte of Bussal, Italigary, and of Beter, hear Rosenard, was early earlied worlds. It is common barite, in crystals, usually oblong in the direction of the vertical axis. See Schrauf, Ber. Ak. Wien, 39, 286, 1860; Schmidt, Zs. Kr., 3, 428, 1879, et al.

Cawk is the ordinary barite of the Derbyshire lead mines. Withering, who first analyzed it, describes it as occurring in roundish forms, consisting of rhomboidal laminæ confusedly aggregated and white or reddish in color, with G. = 4'330; and a second variety as radiated fibrous, somewhat silky in luster, and at times concentric in structure, yellowish white, and opaque, with G. = 4'00. Greg & Lettsom (1858) confine the term to an opaque earthy variety of the Dorbyshire lead mines. of the Derbyshire lead mines.

2. Fetid; so called from the odor given off when struck or when two pieces are rubbed together, which odor may be due to carbonaceous matters present; a highly fetid variety is

obtained in Berks Co., Pennsylvania.

3. Allomorphite Breith., a kind having the form and cleavage of anhydrite, and found at Unterwirbach, near Rudolstadt; G = 4.36-4.48. Probably pseudomorphous; Breithaupt regarded it as a case of dimorphism.

4. Calcareobarite Thomson, Min., 1, 105. A white barite from Strontian in Argyleshire,

containing, probably as mixture, 6.6 p. c. of lime, and some silica and alumina.

5. Celestobarite; the variety containing much strontium sulphate, as that of the Binnenthal, Switzerland, to which von Waltershausen applied the name barytocelestine; also from other localities. See further p. 906.

6. Calstronbarite, from Schoharie, N. Y., has the aspect of a mere mixture. Shepard made

it a compound of carbonates of strontium and calcium, with 65.55 p. c. of sulphate of barium, and says it is partly soluble in hydrochloric acid with effervescence. Von Hauer found a specimen from Schoharie labeled calstronbarite to consist of sulphate alone.

Schoarite Adam, Tabl. Min., 62, is a barite containing some

10 p. c. of silica.

Comp.—Barium sulphate, BaSO₄ = Sulphur trioxide 34.3, baryta 65.7 = 100.

Strontium sulphate is often present, also calcium sulphate and rarely ammonium sulphate (as noted below); further, as impurities, silica, clay, bituminous or carbonaceous substances.

Analyses, see 5th Ed., p. 618.

A barite from Pettis Co., Missouri, has been described by Luedeking & Wheeler (Am. J. Sc., 42, 495, 1891) which showed thin white or yellowish bands parallel to the edges of the tabular crystals (f. 16). These bands consist of a mixture of the sulphates of barium and strontium with small amounts of the sulphates of calcium and ammonium. An analysis of the white barite gave:

Pettis Co., Mo., L. & W.

SrSO₄ 10.9 . CaSO₄ 0.2 BaSO, 87.2 (NH₄)₂SO₄ 0.2 $H_2O 2.4 = 100.9$

The ammonium sulphate is present to somewhat greater extent in the yellow than in the white kinds.

Pyr., etc.—B.B. decrepitates and fuses at 3, coloring the flame yellowish green; the fused mass reacts alkaline with test paper. On charcoal reduced to a sulphide. With soda gives at first a clear pearl, but on continued blowing yields a hepatic mass, which spreads out and soaks into the coal. If a portion of this mass be removed, placed on a clean silver surface, and moistened, it gives a black spot of silver sulphide. Should the barite contain calcium sulphate, this will not be absorbed by the coal when treated in powder with soda. Insoluble in acids,

Obs.—Occurs commonly in connection with beds or veins of metallic ores, especially of lead, also copper, silver, cobalt, manganese, as part of the gangue of the ore; also often accompanies stibnite. Sometimes present in massive forms with hematite deposits. It is met with in secondary limestones and sandstones, sometimes forming distinct veins, and in the former often in crystals along with calcite and celestite; in the latter often with copper ores. Sometimes occupies the cavities of amygdaloid, porphyry, etc.; forms earthy masses in beds of marl. Occurs as the petrifying material of fossils and occupying cavities in them, cf. Roth, Allg. Ch. Geol., 1, 608, 1879.

Barium sulphate as a cement in sandstone occurs near Nottingham. It is deposited by minewater in boxes and pipes at the coal mines of Newcastle-on-Tyne in layers, white and brown, rather soft; they contain 90 p. c. BaSO₄, 8 SrSO₄, 1 CaSO₄, also SiO₂, Al₂O₃, Fe₂O₃; the mine waters contain some BaCl₂. Clowes, Proc. Roy. Soc., 46, 363, 368, 1889.

At the Dufton and Silverband lead mines, in Westmoreland, England, large transparent

crystals occur, sometimes of gigantic dimensions; some were found lying in the mud at the bottom of a cavern, and one weighed 100 lbs. Other English localities are in the Gwennap and Liskeard districts, Cornwall; in Cumberland and Lancashire; in Derbyshire, Staffordshire, etc.—thus beautiful blue crystals come from the Gillfoot hematite mine near Egremont in Cumberland; also Frizington; Cleator Moor; Alston Moor; fine stalactitic at Newhaven; also from Middleton near Matlock, Derbyshire. In Scotland, in Argyleshire, at Strontian; in Perthshire, of a bright yellow color at Ballindean; at the Cumberland lead mine; in Ireland, in thick veins in old red cyndstone at Ballynescreen in Londonderw.

in old red sandstone, at Ballynascreen in Londonderry.

The septaria of Durham, England, which are cut and polished for tables, etc., have the veinings lined with brown heavy spar, adding much to their beauty. Some of the most important of the many European localities are at Felsöbánya, Nagybánya, Schemnitz, and Kremnitz, in Hungary, often with stibuite; Hüttenberg, Carinthia; at Freiberg, Marienberg, in Saxony; Clausthal in the Harz: Přibram, Bohemia; with the manganese ores of Ilefeld, Œhrenstock, etc.; at Royal and Roure in Auvergne.

In the United States, in N. Hamp., at Piermont. In Mass., at Hatfield and Leverett. In Conn., at Cheshire, large crystals, sometimes transparent, intersecting the red sandstone in veins with chalcocite and malachite; at Berlin, Farmington, and Southington. In N. York, at Pillar Point, opposite Sackett's Harbor, massive, 2-3 ft. thick, in compact limestone, affording large slabs, beautiful when polished; at Scoharie, a fibrous variety with calcite, the two often mechanically mingled; in St. Lawrence Co., fine tabular or prismatic crystals at De Kalb, the crystals often opaque and earthy white on the surface; at Fowler with hematite, at the Parish ore bed, and on the farm of J. Morse, in Gouverneur, with calcite and hematite, and on the banks of Laidlaw lake in Rossie; the crested variety at Hammond, with crystals of pyrite; at Wolcott, Wayne Co., near the stratum of lenticular iron ore, and on the S. side of the Mohawk, opposite Little Falls.

In Penn., in crystals at Perkiomen lead mine. In Virginia, at Eldridge's gold mine in Buckingham Co.; 3 m. S. W. from Lexington, in Rockbridge Co.; a beautiful white variety on the plantation of J. Hord, Esq., Fauquier Co. In N. Carolina, a vein of white massive barite occurs at Crowders Mt., Gaston Co.; also another in Madison Co.; in crystals at the Phœnix mine in Cabarrus Co. In Kentucky, near Paris, in a large vein. In Tenn., on Brown's Creek; at Haysboro', near Nashville; in large veins in sandstone on the W. end of I. Royale, L. Superior, and on Spar Id., N. shore, one vein (containing also calcite) 14 ft, wide, sometimes in crystals. In Missouri, not uncommon with the lead ores; a peculiar variety, containing ammonium sulphate, as noted above, occurs at Smithion and Sedalia, Pettis county; also interesting crystals at the Last Chance mine, Morgan Co.; in earthy form near St. Louis; in concretionary forms at Salina, Saline Co., Kansas. In Colorado, at Sterling, Weld Co.; Apishapa Creek; also in El Paso and Fremont Cos. In the Bad Lands of S. Dakota, wine-yellow crystals occupying the cavities of fossils, e.g., the tooth of a Brontotherium. In fine crystals near Fort Wallace, New Mexico. Near Perkin's Mill, Templeton, Quebec (Michel-lévyte, p. 902), embedded in granular lime-

stone which carries apatite in the neighborhood; in a vein cutting Laurentian limestone at Hall, Ottawa Co. In Ontario, in Bathurst, and N. Burgess, Lanark Co.; Galway, Peterborough Co.; as large veins on Jarvis, McKellar's, and Pie islands, in L. Superior, and near Fort William, Thunder Bay. In Nova Scotia, in veins in the slates of East River of the Five Islands,

Colchester Co.

Named from βάρος, weight, or βάρυς, heavy.

Alt.—Occurs altered to calcite, siderite, cerussite, quartz, limonite, hematite, pyrite, psilomelane, göthite.

Artif.—Obtained crystallized by Gorgeu from a solution of the sulphate in the fused chlo-

Bull. Soc. Min., 10, 284, 1887.

Ref.—! Svárov, Denkschr. Ak. Wien, 32, pt. 2, 1, 1872; the variation for crystals of different localities is not inconsiderable. Cf. Dbr., Pogg., 108, 440, 1859; Hkr., l. c.; also Kk., Min. Russl., 7, 25, 58, 1875. This is the common position, which the cleavage makes natural; some authors make the cleavage planes 010 and 101, then d=120, etc.

LEEDSITE Thomson. A mixture of CaSO, 71.9, BaSO, 28.1, from near Leeds.

DREELITE. Dréelite Dufrénoy, Ann. Ch. Phys., 60, 102, 1835. Dreeit Glocker, Syn., 261, 1847.

Supposed to be rhombohedral and in composition between barite and anhydrite, 3BaSO. CaSO₄, with G. = 3.2-3.4. Dufrénoy obtained on analysis:

BaSO,	CaSO ₄	CaCO;	SiO ₂	Al ₂ O ₃	CaO	H_2O
61.73	14.27	8.05	9.71	2.40	1.52	2.31 = 100

Occurs in small unmodified crystals, disseminated on the surface and in the cavities of a quartzose rock, at Beaujeu, France, Dept. of the Rhone; also at Badenweiler, Baden. Named by Dufrénoy after M. de Drée, a liberal patron of science. Shown by Lacroix (Bull. Soc. Min., 8, 435, 1885) to be simply barite, the crystals ortho-

rhombic and not rhombohedral.

Eggonite Schrauf, Zs. Kr., 3, 352, 1879. Described as occurring in minute crystals resembling barite, but assumed to be triclinic by Schrauf. In composition supposed to be essentially a cadmium silicate. Later shown (priv. contr.) to be simply barite. It occurs on and implanted in crystallized calamine at Altenberg (natural association?), which in turn fills cavities in smithsonite; so called from $\check{\epsilon}\gamma\gamma\sigma\nu\sigma$, grandson, as being supposed to be the third generation in the series of zinc-cadmium compounds.

Crystals resembling those of barite (q.v.) in habit; commonly tabular ||c| or prismatic ||axis a| or b; also more rarely pyramidal by the prominence of the forms ψ (133) or χ (144); in the latter the faces often rounded and the crystals

lenticular in shape (f. 3). Also fibrous and radiated; sometimes globular; occasionally granular.

Cleavage: c perfect; m nearly perfect; b less distinct. Fracture uneven. H. = 3-3·5. G. = 3·95-3·97; 3·959, crystals, Beudant; 3.973 Tharand, Breith.; also below. Luster vitreous, sometimes inclining to pearly. Streak white. Color white, often faint bluish, and sometimes reddish. Transparent to subtranslucent.

Optically +. Ax. pl. ||b|. Bx $\perp a$. Axial angles, in-

dices, etc., Arzruni9:

	α	β	y	$2E_v$	2V
For C, 20° " D, " " F, "	1.61954 1.62198 1.62790	1.62120 1.62367 1.62960	1·62843 1·62092 1·63697	89° 13′	51° 12′
For D, 50° '100° '200°	1·62162 1·62107 1·61958	1.62346 1.62297 1.62168	1·63053 1·62976 1·62790	$92^{\circ} 0' \ 95^{\circ} 44' \ 105^{\circ} 26'$	52° 23½′ 54° 19′ 58° 35′

Herrengrund, after Schrauf. Also, Dx. 10:

At 20° C. $2E_r = 88^{\circ} 30'$ $\beta_r = 1.623$ $2E_y = 89^{\circ} 36'$ $\beta_y = 1.625$ $2E_{bl} = 92^{\circ} 49'$ $\beta_{bl} = 1.635$ $2E_r = 89^{\circ} 15'$ at $6^{\circ} \cdot 6$, $92^{\circ} \cdot 4$ at 47° , $93^{\circ} \cdot 42'$ at $76^{\circ} \cdot 5$, $95^{\circ} \cdot 56'$ at $100^{\circ} \cdot 5$.

Also (measured), Arzruni9:

$$2E_{r} = 87^{\circ} \ 2' \ Li$$
 $2E_{y} = 88^{\circ} \ 38' \ Na$ $2E_{gr} = 89^{\circ} \ 55_{\frac{1}{2}}' \ Tl$

Var.—1. Ordinary. (a) In crystals of varied habit as noted above, and giving varying fundamental angles, cf. ref. ¹; a tinge of a delicate blue is very common and sometimes belongs to only a part of a crystal.

The variety from Montmartre, called apotome by Hauy (Min., 2, 33, 1822), was prismatic by extension of o(011) and doubly terminated by the pyramid $\psi(133)$; his dioxynite (p. 35) was

similar with also d (102), from Meudon.

(b) Fibrous, either parallel or radiated. (c) Lamellar; of rare occurrence. (d) Granular. (e) Concretionary. (f) Earthy; impure usually with carbonate of lime or clay.

2. Calciocelestite. Containing much calcium.

3. Barytocelestite. Contains much barium. Cf. below.

Comp.—Strontium sulphate = SrSO₄ = Sulphur trioxide 43.6, strontia 56.4 = 100.

Many celestites are pure strontium sulphate, thus from Lüneburg, G. = 3.975 Hintze, l. c.; Torda, G. = 3.89-3.94 A. & Fr. Koch, Min. Mitth., 9, 416, 1887.

Calcium is, however, often present in small quantities, usually less than 0.5 p. c. Cf. Arzruni, l. c.; also Bärwald, Zs. Kr., 12, 228, 1886, who gives G. = 3.902-3.931.

Barium is less common, though in some varieties present in large amount. A celestite from Greiner gave Ullik 48 9 p. c. BaO, G. = 4·133, Ber. Ak. Wien, 57 (1), 929, 1868; in one from Lairdsville, N. Y., Chester found 7·28 BaO, 2·01 CaO, Am. J. Sc., 33, 286, 1887. Collie found in Clifton barytocelestite varying amounts of BaO, Min. Mag., 2, 220, 1879. The barytocelestite from Werfen, Salzburg, contains BaSO₄ and SrSO₄ in the ratio of 4:1, Hatle and Tauss., Min. Mitth., 9, 227, 1887.

General analyses, besides those noted above, see 5th Ed., p. 620.

Wittstein attributes the blue color of the celestite of Jena to a trace of iron phosphate.

Pyr., etc.—B.B. frequently decrepitates, fuses at 3 to a white pearl, coloring the flame strontia-red; the fused mass reacts alkaline. On charcoal fuses, and in R.F. is converted into a difficultly fusible hepatic mass; this treated with hydrochloric acid and alcohol gives an intensely red flame. With soda on charcoal reacts like barite. Insoluble in acids.

Obs.—Celestite is usually associated with limestone, or sandstone of Silurian, Devonian, Jurassic, and other geological formations; occasionally with metalliferous ores, as with galena and sphalerite at Condorcet, France. Occurs also in beds of gypsum, rock salt, and clay; sometimes fills cavities in fossils, e.g., ammonites; and with sulphur in some volcanic regions, sometimes incloses sulphur in crystals, in one case 14 p. c., Johnston-Lavis. Observed as a recent formation at Bourbonne d'Archambault.

Sicily, at Girgenti and elsewhere, affords splendid groups of crystals along with sulphur and gypsum. Fine specimens are met with at Bex in Switzerland, and Conil in Spain; at Dornburg, near Jena, fibrous and bluish; in the department of the Garonne. France; in the Paris basin at Montmartre and elsewhere; in Tyrol; Rezbánya, Hungary; at Northen, Lüneburg, in Hannover; in rock salt, at Ischl, Austria. Also found at Aust Ferry, near Bristol; in trap rocks near Tantallan, in East Lothian; at the Calton Hill, Edinburgh; near Kuaresborough, in York-

shire; at Popayan, U. S. Colombia.

Specimens, finely crystallized, of a bluish tint, are found in limestone about Lake Huron, particularly on Drummond Island, also on Strontian Is., Put in Bay, L. Erie, and at Kingston in Ontario, Canada; Chaumont Bay, L. Ontario, Schoharie, and Lockport, N. Y., have afforded good specimens; also the Rossie lead mine; Depauville and Stark (farm of James Coill), N. Y. A blue fibrous celestite occurs at Bell's Mills, Blair Co., Penn., associated with pearl spar and anhydrite, and this was the celestite taken to Europe by Schütz, and named by Werner after an analysis by Klaproth.

In Mineral Co., W. Virginia, a few miles south of Cumberland, Md., in pyramidal blue In Mineral Co., W. Virginia, a few limes south of Cumberland, Md., in pyramidal blue crystals up to 3 inches in length, f. 3, also 5-9. They are found in small cavities in an argillaceous limestone used for cement. The cavities apparently represent former concretions, but are now partially empty and in part filled with clay (G. H. Williams, Am. J. Sc., 39, 183, 1890). In cavities in limestone at Nashville, Tenn. In Brown Co., Kansas, a red variety in large crystals. In Texas, at Lampasas, in very large crystals. At Glen Eyrie, Colorado. In fine clear crystals with the colemanite of Death Valley, San Bernardino Co., California.

In Canada, in crystalline masses at Kingston, Frontenac Co.; Lansdowne, Leeds Co.; in radiating fibrous masses in the Laurentian of Renfrew Co.; also a red variety in dolomite at Caledon, Peel Co.

The dark blue fibrous celestite of Jena is peculiarly pleochroic; and its color also varies with the angle between the principal cleavage and the direction of the fibers; the color with the angle 86°, dark blue; 67°, sky-blue; 46°, pale blue (Schmid, Pogg., 120, 637, 1867).

Named from calestis, celestial, in allusion to the faint shade of blue often present.

Alt.—Pseudomorphs of calcite, occurring in acute pyramidal forms (f. 10, 11) from Obersdorf, near Sangerhausen, Thuringia—the so-called barleycorn (Gerstenkörner) pseudomorphs—have been referred to gay-lussite (Breith.), to celestite, Hauy's apotome (Dx.), gypsum (Kenng.), anhydrite (Groth). They occur as complete crystals, often in interpenetrating groups, up to two inches or more in length, embedded in clay. Color pale yellow, the exterior usually smooth and hard; the interior, cavernous with loosely coherent calcite grains. They have been called natrocalcite on the idea that they contained soda.

Similar pseudomorphs, but not all of like origin, have been noted from a number of other localities. For a list of these cf. E. S. D., U. S. G. Surv., Bull. 12, p. 25, 1884; also Blum, Pseudomorphosen, 18, 1843; Roth, Allg. Ch. Geol., 1, 201, 1879.

Figs. 5-9, Celestite, Mineral Co., W. Va., Williams. 10, 11, Pseudomorphs, Sangerhausen.

The recent discovery by G. H. Williams of celestite in pyramidal crystals (f. 3, also 5-9) resembling closely the pseudomorphs and occurring like them embedded in clay makes it almost certain that Des Cloizeaux's explanation was correct. The apparently related forms from the thinolite of Lake Lahontan (p. 271) cannot, however, be explained in this way.

Artif.—Cf. Gorgeu. Bull. Soc. Min., 10, 284, 1887; Bourgeois, ib., p. 323.

Ref.—Bex and Herrengrund, Ber. Ak. Wien, 59 (1), 549, 1869, the axial ratio varies widely for different localities. Cf. Dbr., Pogg., 108, 447, 1859; Kk., Min. Russl., 5, 5, 1866; Arzruni, Zs. G. Ges., 24, 477, 484, 1872.

Sella⁵ adds the following, observed once only and needing confirmation: 520, 10.9.0. 9.10.0, 1.0.22, 1.0.15, 108, 2.0.15; 0.1.16; 11.12.2, 10.11.2, 9.10.2, 782, 671, 562, 792, 236, 126, 131, 143, 295, 168, 1.10.20, 1.11.13. Also vicinal, 1.0.94°.

Figs. 1, 5, 8, Phœnixville. 2, Anglesea, Lang. 3, Felsöbánya, Knr. (b, 010, in front). 4, 7, Siegen, Lang. 6, 9, Müsen.

Lang (l. c.) gives a long list of calculated angles.

Crystals sometimes tabular | c; more often prismatic in habit, and in all the

three axial directions, m, d, o, predominating in the different cases; also thick and stout. Also pyramidal of varied types. Faces m, a often vertically striated; d horizontally. Also massive, granular to compact. Sometimes stalactitic; in nodular forms, often inclosing a nucleus of galena, with concentric structure, being made up of layers of different color.

Cleavage: c, m distinct, but interrupted. Fracture conchoidal. Very brittle. H. = 2.75-3. G. = 6·12-6·39; 6·35 Phenixville, Smith. highly adamantine in some specimens, in others inclining to resinous and vitreous. Color white, tinged yellow, gray, green, and sometimes blue. Anglesea, after Streak uncolored. Transparent to opaque.

Optically +. Ax. pl. || b. Bx \(\preceq\) a. Ax. angles and indices, Dx.

Anglesea, after Lang.

Comp.—Lead sulphate, PbSO₄ = Sulphur trioxide 26.4, lead oxide 73.6 = 100. Analyses, 5th Ed., p. 624.

Pyr., etc.—B.B. decrepitates, fuses in the flame of a candle (F. = 1.5). On charcoal in O.F. fuses to a clear pearl, which on cooling becomes milk-white; in R.F. is reduced with effervescence to metallic lead. With soda on charcoal in R.F. gives metallic lead, and the soda is absorbed by the coal; when the surface of the coal is removed and placed on bright silver and moistened with water it tarnishes the metal black. Difficultly soluble in nitric acid. Soluble in citrate of ammonia (J. L. Smith). Soluble in 22,816 parts of water of 11° C. (Fresenius). Soluble in 30,062 parts of water (Rodwell).

Obs.—First observed by Monnet as a result of the decomposition of galena, and often

found in its cavities; also surrounds a nucleus of galena in concentric layers. At Leadhills it occurs, occupying the cubical cavities of galena, or disposed on the surface of the ore; and this locality, and also that of Wanlockhead, formerly afforded large and beautiful crystals, some transparent and several inches in diameter. First found in England at Pary's mine in Anglesca. Occurs also at Melanoweth in Cornwall; in Derbyshire and in Cumberland in crystals; Clausthal, Zellerfeld, and Giezenbach, in the Harz; near Siegen in Prussia; Schapbach and Badenweiler in

Baden; Schwarzenbach and Mies in Carinthia; Felsőbánya and elsewhere in Hungary; Nerchinsk In Siberia; and at Monte Poni, Sardinia in small but perfect transparent crystals; Fondon in Granada; massive in Siberia, Andalusia, Alston Moor in Cumberland; in Australia, whence it is exported by the ton to England. In the Sierra Mojada, Mexico, in immense quantities, mostly massive.

In the United States it occurs in large crystals at Wheatley's mine, Phenixville, Pa.; less well crystallized in Missouri lead mines; at the lead mine of Southampton, Mass.; at Rossie, N. Y.; with galena at the Walton gold mine, Louisa Co., Va. In fine crystals of varied habit at the Mountain View mine, near Union Bridge, Carroll Co., Maryland, associated with galena, also Mountain View mine, near Union Bridge, Carroll Co., Maryland, associated with galena, also cerussite and native sulphur (G. H. Williams, Johns Hopkins Univ. Bulletin, April, 1891). In Colorado at various points, but less common than cerussite. At the Cerro Gordo mines of California (argentiferous galena), with other lead minerals, also mimetite, chrysocolla, smithsonite, etc. In Arizona, in the mines of the Castle Dome district, Yuma Co., and elsewhere.

Named from the locality, Anglesea, where it was first found by Dr. Withering.

Alt.—Anglesite occurs altered to cerussite (lead carbonate); also to a hydrous anglesite, according to Breith. Cf. ref. also Slg., Vh. Ver. Rheinl., 33, 253, 1876. Pseudomorphs of mimetite (cf. p. 772), perhaps after anglesite from Mexico, are described by Genth and Rath, Proc. Am. Phil. Soc., 24, 33, 1887.

Artif.—Obtained in crystals at a temperature of 300° C. from solution in water (Dr. Sullivan); in lamellar crystals by fusing a mixture of gynsum and common salt, and treating with water:

in lamellar crystals by fusing a mixture of gypsum and common salt, and treating with water;

In lanellar crystals by tusing a mixture of gypsum and common sait, and treating with water; A. Gages. A recent formation at Bourbonnes les-Bains.

Twins: 1, tw. pl. d (012) with $b\underline{b} = 53^{\circ} 10'$ and $kk' = 76^{\circ} 29'$ Hbg.; 2, tw. pl. r (101) occasionally as tw. lamellæ, which may be developed by heat. Crystals

Figs. 1, 2, Stassfurt, Hbg. 3, Aussee, Id. 4, Santorin, Id.

not common, thick tabular, also prismatic | axis b, often terminated by a horizontally striated brachydome, probably d (012) in oscillatory combination 7 with b. Also massive, cleavable, and then somewhat resembling an isometric mineral with cubic cleavage; fibrous, lamellar, granular, and sometimes impalpable. The lamellar and columnar varieties often curved or contorted.

Cleavage: in the three pinacoidal directions yielding rectangular fragments but with varying ease, thus, c very perfect; b also perfect; a somewhat less so. Fracture uneven, sometimes splintery. Brittle. H. = 3-3.5. G. = 2.899-2.985; 2.956 Aussee; 2.985 Stassfurt. Luster: c pearly, especially after heating in a closed tube; a somewhat greasy; b vitreous; in massive varieties,

vitreous inclining to pearly. Color white, sometimes a grayish, bluish, or reddish tinge; also brick-red. Streak grayish white.

Optically +. Ax. pl. | b. Bx \(\perp \alpha\). Axial angles, Grailich 8:

$$2E_{\rm r} = 71^{\circ} \ 24' - 71^{\circ} \ 42' \ {\rm Dx}. \qquad 2E_{\rm r} = 70^{\circ} \ 18' \qquad 2E_{\rm v} = 72^{\circ} \ 42'$$

Indices $\alpha = 1.571 \qquad \beta = 1.576 \qquad \gamma = 1.614 \ {\rm Miller}^{\circ}$

Var.—1. Ordinary. (a) Crystallized; crystals rare, more commonly massive and cleavable in its three rectangular directions (Würfelanhydrit Germ.) as noted above. (b) Fibrous; either parallel, radiated or plumose. (c) Fine granular. (d) Scaly granular. Vulpinite is a scaly granular kind from Vulpino in Lombardy; it is cut and polished for ornamental purposes. It does not ordinarily contain more silica than common anhydrite. A kind in contorted concretionary forms is the tripestone (Gekrösstein or Schlangenalabaster).

2. Pseudomorphous; in cubes after rock-salt.

Comp.—Anhydrous calcium sulphate, CaSO₄ = Sulphur trioxide 58.8, lime

Pyr., etc.—B B. fuses at 3, coloring the flame reddish yellow, and yielding an enamel-like bead which reacts alkaline. On charcoal in R.F. reduced to a sulphide; with soda does not fuse to a clear globule, and is not absorbed by the coal like barite; is, however, decomposed, and yields a mass which blackens silver; with fluorite fuses to a clear pearl, which is enamel-white on cooling, and by long blowing swells up and becomes infusible. Soluble in hydrochloric acid.

One hundred parts of water, at 18.75° C., dissolve 0.2 part of anhydrite. Cf. further under

gypsum, p. 935.

Obs.—Occurs in rocks of various ages, especially in limestone strata, and often the same that contain ordinary gypsum, and also very commonly in beds of rock-salt. It was first discovered at the salt mine near Hall in Tyrol, by Abbé Poda; and next that of Bex, Switzerland. Other localities are at Aussee, both crystallized and massive, the former sometimes in splendid geodes, the latter brick-red; at Sulz on the Neckar, in Würtemberg; Himmelsberg, near Ilefeld; Andreasberg Bleiberg in Carinthia; Lüneburg, Hannover; Lauterberg in the Harz; Kapnik in

Hungary; Wieliczka in Poland; Ischl in Upper Austria; Berchtesgaden in Bavaria; at Rienthal and elsewhere in the Alps, crystals, or other cavities, within quartz crystals; Stassfurt, in fine

rystals, embedded in kieserite. in cavities in lava at Santorin.

In the U. States, at Lockport, N. Y., fine blue, in geodes of black limestone, accompanied by crystals of calcite and gypsum; also at Hillsboro, New Brunswick, etc. In Pennsylvania, at the Darby Tunnel on the Baltimore & Ohio R. R. near Philadelphia; in cavities in limestone at Nashville, Tenn. In Nova Scotia it forms extensive beds at the estuary of the Avon and the St. Croix rivers, also near the Five Islands and elsewhere, associated with gypsum, in the Carboniferous formation.

Alt.—Absorbs moisture and changes to gypsum, cf. Hammerschmidt, Min. Mitth., 5, 245, 1882. Extensive beds are sometimes thus altered in part or throughout, as at Bex, in Switzerland, where, by digging down 60 to 100 ft., the unaltered anhydrite may be found. Sometimes specimens of anhydrite are altered between the folia or over the exterior. Also altered to quartz

and siderite.

Artif.—Obtained from fusion (Mitscherlich), also (Hoppe-Seyler) by heating gypsum in a closed vessel with sodium or calcium chloride; again (Gorgeu) from a solution at a red heat in the chlorides of potassium, sodium, etc. Cf. Rose (Ber. Ak. Berlin, 363, 1871), who describes the transformation of gypsum into anhydrite in a solution of sodium chloride; also Hammer-schmidt, l.c. Spezia (Att. Acc. Torino, 21, 912, 1886) shows that, contrary to earlier statements, pressure alone, even up to 500 atmospheres, is not sufficient to cause the formation of annydrite

instead of gypsum.

Ref.—¹ Min Not., 10, 1, 1871. This is the position of Grailich and von Lang, Ber. Ak. Wien, 27, 25, 1857; with Mir. and Dx., a = 100, b (above) = 001, c = 010, r = 110, f = 113; with Naumann and Schrauf, a = 001, b = 100, c = 010, r = 011, f = 311. The dissimilarity in cleavage makes an attempt to obtain correspondence in angle between this species and barite,

celestite and anglesite quite unsatisfactory.

² Cf. the monograph of Hbg.; he adds as probable 706, 708, 067. ³ Mlr., Phil. Mag., 47, 124, 1874; also doubtful 021, 023. ⁴ Groth, Min.-Samml., 141, 1878. ⁵ Hbg., Santorin, l. c. ⁶ Mgg., Jb.  $nn''' = 36^{\circ} 5'$

Color pale green, brownish or yellowish, also sky-blue.

 $\mu\mu'' = 84^{\circ} 23'$

Translucent. Comp.—Cupric sulphate, CuSO, = Sulphur trioxide 50.3, cupric oxide 49.7 = 100.

Anal.—Scacchi, l. c.

CuO 49.47 = SO₃ 50·30 99.77

Pyr., etc.—Completely soluble in water. Effloresces very readily in contact with the air. When preserved in the matrix untouched the crystals will remain two or three days without sensible alteration, but upon being detached, or even touched, they change color almost imme-

diately. In the alteration the crystals first show a blue color, then split to pieces slowly, and separate into minute granules, which seem to be crystals, though too small to allow of their form being determined. The cause of the efflorescence in this case is the absorption of the water from the atmosphere, not the loss of water, as is generally true. The change when complete results in the production of chalcanthite.

Obs.—Found at Vesuvius, having been produced by sublimation at the time of the eruption

of October, 1868. The name is derived from ΰδωρ, water, κύανος, azure blue, in allusion to

the change of color noted above.

Rei. L. c.; the position here taken is that which brings out the relation in form to barite, etc.

Dauber adds the following as probable: 230, 601, 443, 665, 10 3.4, 16.5.4, 532, 852, 652, 512, 922, \$\bar{1}\cdot 8\cdot 4\$, \$\bar{7}22\$, \$\bar{9}32\$, \$\bar{1}\bar{3}\cdot 5\cdot 2\$, \$\bar{1}\bar{2}\cdot 5\cdot 4\$, \$\bar{1}\bar{5}\cdot 7\cdot 5\$, \$532, \$\bar{1}\bar{3}\cdot 8\cdot 6\$, \$\bar{1}\bar{1}\cdot 10\cdot 10\$, \$\bar{7}83\$, \$\bar{3}\cdot 4\cdot 12\$, \$\bar{3}48\$, \$\bar{5}88\$, \$\bar{1}23\$, \$\bar{3}\cdot 8\cdot 12\$; and the following as doubtful: 530, 450, 340, 380, 501, 803, 702, 085, 554, 332, 11.3.1, 13.5.1, 12.9.4, 13.1.4, 12.1.4, 15.2.3, 713, 21.3.5, 18.3.4, 17.5.4, 416, 12.3.2, 11.5.1, 743, 10.9.10, 11.10.6, 456, 362.

Crystals usually prismatic (m, rarely t (111)), but habit very varied; sometimes resembling acute rhombohedral forms (f. 4). Faces mostly smooth and

brilliant; m vertically striated. Also imperfectly columnar and granular. Cleavage: m rather distinct; c, a less so. Fracture small conchoidal to uneven. Sectile. H. = 2·5-3. G. = 5·9-6·1. Luster adamantine to vitreous. Color various shades of bright hyacinth-red. Streak orange-yellow. Translucent. Optically +. Ax. pl. $\parallel b$. Bx_a $\wedge \dot{c} = +$ 5° 30′. Dispersion inclined, very large (cil). Axial angle large.

large (oil). Axial angle large:

$$2H_r = 97^{\circ} 35$$
 $2H_v = 97^{\circ} 0'$ $n_v = 1.468$ $\therefore 2V_v = 54^{\circ} 3'$ $\beta_v = 2.42 \text{ approx., Dx.}^4$

Comp.—Lead chromate, PbCrO, = Chromium trioxide 31.1, lead protoxide 68.9 = 100.

Anal.—1, Bärwald, Zs. Kr., 7, 170, 1883. Also Pfaff, Berzelius, 5th Ed.

1. Berezov CrO₃ 31.16 PbO 68.82 = 99.98

Vauquelin discovered the metal chromium in this mineral in 1797.

Pyr., etc.—In the closed tube decrepitates, blackens, but recovers its original color on cool-B.B. fuses at 1.5, and on charcoal is reduced to metallic lead with deflagration, leaving a residue of chromium oxide, and giving a lead coating. With salt of phosphorus gives an emerald-

green bead in both flames.

Obs.—First found at Berezov, in crystals in quartz veins, or intersecting gneiss or granite; also occurs at Mursinka and near Nizhni Tagilsk in the Ural, in narrow veins, traversing decomposed gneiss, and associated with gold, pyrite, galena, quartz, and vauquelinite; in Brazil, at Congonhas do Campo, in fine crystals in decomposed granite; at Rezbánya in Hungary, at the mine of St. Anthony; Moldawa in Hungary; on Luzon, one of the Philippines, whence crystals were received by J. D. Dana in 1842, from El Señor Roxas of Manila, and understood to be from the northern peninsula of Luzon; according to Dr. Hochstetter, at the mines of Labo, in the Province of North Camarines, on the southeastern peninsula of Luzon (Dauber). Occurs in limited quantities with vanadinite, wulfenite, etc., in some of the mines of the Vulture district, Maricopa Co., Arizona.

This species was first noticed by Lehmann (l.c.). The name Crocoite is from κρόκος, saffron. Berthier, in 1832, gave the word the bad form Crocoise, which von Kobell altered, in 1838, to Crocoiste, and Breithaupt, in 1841, to Crocoite (Krokoit), and v. Kobell also to this last-mentioned

form in his later works.

Artif.—Formed by Manross (Lieb. Ann., 82, 359, 1852) by the fusion together of potassium chromate and lead chloride; also by Drevermann (ib., 89, 36, 1854) by the diffusion method using potassium chromate and lead nitrate. Also more simply in crystals like the native mineral by Bourgeois, Bull. Soc. Min., 10, 187, 1887.

Ref.—¹ Ural. Dbr., Ber. Ak. Wien, 42, 19, 1860; Pogg., 106, 150, 1859, and Kk., Min. Russl., 7, 97, 1875. See Dbr. for values for other localities.

² See Dbr., l. c.; Mlr., Min., 557; Hbg., Min. Not., 3, 27, 1860, who gives α, β from Berezov.

³ Mir., l. c., not noted by Dbr., but requiring confirmation. ⁴ Bull. Soc. Min., 5, 103, 1882;

Cf. also Bärwald, who makes the refractive index somewhat higher, Zs. Kr., 7, 170, 1882.

A lead chromate from Pretoria, Transvaal, S. Africa, afforded Dawson: CrO₃ 25·24, PbO 74·76 = 100. This corresponding nearly to 4PbO.3CrO₃. Min. Mag., 6, xvIII, 1885.

726. PHŒNICOCHROITE. Melanochroit *Hermann*, Pogg., 28, 162, 1833. Phœnikochroit *Glocker*, Grundr., 612, 1839. Subsesquichromate of Lead *Thom*. Phönicit *Haid.*, Handb., 504, 1845,

Orthorhombic? Crystals usually tabular, and reticularly interwoven. Also massive.

Cleavage in one direction, perfect. H. = 3-3.5. G. = 5.75. Luster resinous or adamantine, glimmering. Color between cochineal- and hyacinth-red; becomes lemon-yellow on exposure. Streak brick-red. Subtranslucent to opaque.

Comp.—A basic lead chromate, 3PbO.2CrO₃ = Chromium trioxide 23.2, lead

protoxide 76.8 = 100.

Anal.-Hermann, l. c.

CrO₃ 23.31

PbO 76.69 = 100

Pyr., etc.—B.B. on charcoal fuses readily to a dark mass, which is crystalline when cold. In R.F. on charcoal gives a coating of lead oxide, with globules of lead and a residue of chromium oxide. Gives the reaction for chromium with fluxes. Dissolves in hydrochloric acid with the separation of lead chloride.

Obs.—Occurs in limestone at Berezov in the Ural, with crocoite, vauquelinite, pyromorphite,

and galena. Named Melanochroite by Hermann, from $\mu \dot{\epsilon} \lambda \alpha s$, black, and $\chi \rho \dot{\epsilon} \alpha$, color. But, as the color is red, and not black, and the name is therefore false to the species, Glocker changed it to $Ph\alpha ni$ cochroite, from ϕ oivikos, deep red, and $\chi \rho o \alpha$; and in this he is followed by Hausmann. The abbreviated form phanicite is bad, because it is too much like the name of another mineral, phenacite.

Artif.—Meunier obtained phænicocroite by the action of a solution of potassium dichromate

on galena, C. R., 87, 656, 1878. Cf. earlier, Drevermann, Lieb. Ann., 89, 36, 1854.

Twins: tw. pl. e (102)3. Crystals usually minute, often wedge-shaped; irregularly aggregated, and in mammillary forms. Also reniform or botryoidal.

and granular; amorphous.

Fracture uneven. Brittle. H. = 2.5-3. G. = 5.8-6.1. Luster adamantine to resinous, often faint. Color green to brown, apple-green, siskin-green, olive-Luster adamantine green, ocher-brown, liver-brown; sometimes nearly black. Streak greenish or Faintly translucent to opaque.

Comp.—A phospho-chromate of lead, perhaps, as suggested by Rammelsberg, 2(Pb,Cu)CrO, (Pb,Cu)_sP₂O_s = Chromium trioxide 15·0, phosphorus pentoxide 10·6,

lead protoxide 69.5, cupric oxide 4.9 = 100.

Anal.—1, 2, Nordenskiöld, l. c. 3, Hermann, l. c. 4, Pisani, Bull. Soc. Min., 3, 196, 1880. 5, Nicolayev, Min. Russl., 8, 353.

Sept. No.		P_2O_5	CrO ₃	PbO	CuO	Fe ₂ O ₃	H_2O
1. Laxmannite	G. = 5.77	8.05	15.26	61.26	12.43	1.09	1.31 = 99.40
2. "		8.57	16.76	61.06	10.85	1.28	0.90 = 99.42
3. Phosphochromite	G. = 5.80	9.94	10.13	68.33	7.36	2.80	1.16 = 99.72
4.		9.78	15.80	70.60	4.57	-	- = 100.75
5. "Vauquelinite"	G. = 6.06	9.23	11.95	62.70	9.58	-	3.00 = 96.46

Berzelius gave for the original vauquelinite: CrO₃ 28·33, PbO 60·87, Cu 10·80 = 100, which correspond to 3(Pb, Cu)O.2CrO₃; he probably overlooked the phosphoric acid, for the observations of Des Cloizeaux and Koksharov make it almost certain that vauquelinite and laxmannite are identical, although Nordenskiöld argues for the presence of a pure chromate, free from phosphoric acid, with his laxmannite. All the crystals examined by Koksharov proved to contain P_2O_5 , but varying somewhat in amount (8 to 10 p. c.) as explained by the associated pyromorphite. authors give the name laxmannite to the above phospho-chromate, the existence of which is suffi.

ciently proved, and retain vauquelinite for the still hypothetical chromate, assumed to have the composition given above. This, by the way, is identical with that of phœnicochroite except in

the presence of copper.

Pyr., etc.—B.B. on charcoal slightly intumesces and fuses to a gray submetalic globule, yielding at the same time small globules of metal. With borax or salt of phosphorus affords a green transparent glass in the outer flame, which in the inner after cooling is red to black, according to the amount of mineral in the assay; the red color is more distinct with tin. Partly soluble in nitric acid.

Obs.—Occurs with crocoite at Berezov in the Ural, generally in mammillated or amorphous masses, or thin crusts; early reported at Pontgibaud in the Puy-de-Dôme (but needs confirma-

tion, Dx.); also with the crocoite of Brazil.

At the lead mine near Sing Sing it has been reported by Dr. Torrey in green and brownish green manifolding concretions, and also nearly pulverulent; and at the Pequa lead mine in Lancaster Co.. Pa., in minute crystals and radiated aggregations on quartz and galena. of siskinto apple-green color, with cerussite. Probably also with crocoite, vanadinite, wulfenite at some of the mines in the Vulture district in Maricopa Co., Arizona. All these American localities require revision.

Named after Vauquelin, the discoverer of the metal chromium, and also the first one to notice the crystals of this species (J. Mines, 6, 737). Laxmannite is for the chemist Prof. E. Laxmann, who early traveled extensively in Siberia, and (Nd.) first called attention to the min-

erals of Berezov.

John describes a greenish or brownish chromo-phosphate of lead and copper (Chrom-Phosphorkupferbleispath) from Berezov, Siberia, as occurring in small crystalline concretions, having the surface covered with capillary prisms; H = 2-3; opaque to subtranslucent; fracture uneven; powder dull greenish. Analysis afforded (Jb. Min., 67, 1845): PbCrO₄ 45·0, PbO 19·0, CuO 11·20, P_2O_5 4·10, CrO_3 7·50, manganese tr., H_2O 1·78, impurities 11·42. To a large extent soluble in nitric or hydrochloric acid. It is probably only an impure vauquelinite.

Ref.—¹ Crystals with the composition given in anal. 5, Min. Russl., 8, 345, 1878. See also Nd., l. c., and Dx., Bull. Soc. Min., 5, 53, 1882, whose angles vary rather widely from these. ² Kk., p. 357, also Dx. ³ Haid.; the specimen supposed to be from Pontgibaud, cf. Dx.,

l. c., p. 56.

Jossaite Breithaupt, B. H. Ztg., 17, 54, 1858. From Berezov, occurring in small orange yellow crystals with vauquelinite. Described as orthorhombic, with a prismatic angle of 62° - 70° , and traces of prismatic cleavage; the luster between vitreous and waxy; streak dull yellowish white; H. = 3.0; G. = 5.2. According to Plattner, it gives the reactions of chromic acid and oxides of lead and zinc.

Tarapacaite Raimondi, Minéraux du Pérou, p. 274, 1878. Occurs in minute fragments of a brilliant yellow color, in the midst of soda niter (the variety called caliche azufrado, p. 871). Essentially a potassium chromate, but mixed with a little sodium chloride, sodium nitrate, and sodium and potassium sulphates. From the province of Tarapacá, Chili; also (Domeyko, Min. Chili, 3d Ed., 447) in the natural salt deposits of the desert of Atacama, Chili. It needs further examination.

Calcium Chromates. On the artificial formation and crystalline form of various calcium chromates, see H. B. v. Foullon, Jb. G. Reichs., 40, 421, 1890. The salts described have the composition: $Ca_2CrO_5 + 3H_2O$, monoclinic; $CaCrO_4 + 2H_2O$, monoclinic and isomorphous with gypsum; $CaCrO_4 + H_2O$, orthorhombic.

SULPHATES OF MERCURY. Seyfriedsberger has described two sulphates of mercury from the mercury furnace at Idria, $\mathrm{Hg_2SO_4}$ and $\mathrm{HgSO_4}$. The former occurs in orthorhombic crystals, with a (100). b (010), c (001), m (110), p (230), f (102), g (203), h (101), d (011), o (111). Axial ratio $\check{a}:\bar{b}:\dot{c}=0.666:1:0.707$. Angles: $mm'''=67^\circ~20'$, $hh'=93^\circ~30'$, $dd'=70^\circ~33'$, etc. Zs. Kr., 17, 433, 1890.

Sulphates with Chlorides, Carbonates, etc.—In part hydrous compounds.

728. Sulphohalite	3Na _o SO ₄ .2NaCl	Isomet	ric $\check{a}:\check{b}:\dot{c}$

Hexagonal $\dot{c} = 1.0140$

à : b : c

734. Leadhillite 4PbO.SO₂.2CO₂.H₂O? Monoclinic 1.7476:1:2.2154 89° 48'

Two double salts, sulphates and nitrates of sodium, are described on p. 873.

728. SULPHOHALITE. W. E. Hidden and J. B. Mackintosh, Am. J. Sc., 36, 463, 1888. Sulfohalit Germ.

Isometric. In dodecahedrons, also with cubic and octahedral faces; an apparent development of the latter according to tetrahedral symmetry has been noted. H. = 3.5. G. = 2.489. Luster vitreous. Color faint greenish yellow. parent.

Comp.—3Na, SO, 2NaCl = Sulphur trioxide 44.2, chlorine 13.0, soda 45.7

= 102.9; or, Sodium sulphate 78.5, sodium chloride 21.5 = 100.

Anal.-Mackintosh, l. c.

SO3 42.48

Cl 13·12

Na2CO3 1.77

This is interpreted as Na₂SO₄ 75·41, NaCl 21·62, Na₂CO₃ 1·77 = 98·80. If the loss is regarded as Na₂SO₄ and the Na₂CO₃ is taken as replacing a small part of the sulphate, the above formula is obtained. Slowly soluble in water.

Obs.—Observed implanted upon crystals of hanksite from Borax lake, San Bernardino
Co., California; obtained from a cavity reached in boring at a depth of 35 feet.

Ref.—1 Cf. Hidden, Am. J. Sc., 41, 438, 1891.

729. CARACOLITE. Websky, Ber. Ak. Berlin, p. 1045, 1886.

Orthorhombic (?) and pseudo-hexagonal by twinning. Axes $\check{\alpha}: \dot{b}: \dot{c} =$ 0.5843:1:0.4213 Websky¹

 $100 \land 110 = 30^{\circ} 17\frac{3}{4}', 001 \land 101 = 35^{\circ} 47\frac{2}{4}', 001 \land 011 = 22^{\circ} 50\frac{1}{4}'.$

Measured angles: $pp''' = *37^{\circ} 44'$, $pp^{iv} = *100^{\circ} 16'$, also $pp' = 67^{\circ} 13'$ (calc.).

As a crystalline incrustation; the crystals have the form of a hexagonal pyramid with base and prism, but are explained as trillings, analogous to aragonite, with the prism as twinning plane, $mm''' = 60^{\circ} 35\frac{1}{3}$.

Cleavage not noted. H. = 4.5. Luster vitreous. Colorless.

Comp.—Perhaps Pb(OH)Cl.Na₂SO₄ = Sulphur trioxide 20.0, lead protoxide 55.5, soda 15.5, chlorine 8.8, water 4.5 = 104.3.

Anal.-Websky, l. c., on impure material.

SO3 Pb Cu FeO

0.29 insol. 1.84 = 82.73 + 2.30 (O = Cl) = 85.0316.70 10.18 50.88 2.51 0.33

Adding 12:46 Na₂O = equiv. of SO₃ (diminished by equiv. of ZnO and FeO), 2:51 p. c. H₂O remains. This is interpreted as consisting of 83.9 p. c. caracolite and 14.26 percylite (with 1.84 residue), but the result is very problematical.

Pyr.—Fuses in the Bunsen flame to a brown glass giving a strong soda flame with a blue spot close to the assay. Partially dissolved by water, the solution evaporated depositing cubes

of sodium chloride, etc.

Obs.—Occurs intimately mixed with blue cubes of percylite as an incrustation and in crevices in a gangue consisting of galena, anglesite, and quartz. From Mina Beatriz, Sierra Gorda, Atacama, some 20 or 30 miles from Caracoles, Chili (cf. Fletcher, l. c., and Sandb., Jb. Min., 2, 75, 1887.

Ref.—1 L. c., it may prove that the crystals belong to the hexagonal system to which they approximate closely; cf. Fletcher, Min. Mag., 8, 172, 1889.

Chlorothionite. Clorotionite A. Scaechi, Att. Accad. Napoli, 6, 1873 (Contrib. Min., II, p. 59).

Occurs in thin crystalline mammillary crusts of a bright blue color. Analysis:

SO, 32.99 Cu 19.56 K 26.29 loss 1.12 = 100Cl 20.04

Crystals obtained by recrystallization from a solution, and thus purer than the original material, gave essentially the same result. Formula K₂SO₄,CuCl₂ = SO₄, 31·2, Cl 23·0, Cu 20.5, K 25.3 = 100, From Vesuvius, as a result of the eruption of April, 1872. The name records the presence of chlorine and sulphur $(\vartheta \epsilon \hat{\imath} o \nu)$.

730. KAINITE. Zincken, B. H. Ztg., 24, 79, 1865.

Monoclinic. Axes $\hat{a}: \hat{b}: \hat{c} = 1.21866: 1:0.58635; \beta = 85^{\circ} 5\frac{2}{3} = 001 \land 100$ Groth'.

In hexagonal crystals with prominent basal plane; sometimes short prismatic with faces a horizontally striated; also flattened with a series of pyramids in oscillatory combination. These pyramids are shown to belong to the second series by the etching-figures.

Cleavage: basal, perfect. Fracture conchoidal. Etching-figures on c rhombohedral in symmetry, and corresponding to various scalenohedrons varying with the kind of acid or its degree of concentration. H. = 2 on c; on pyramidal faces = 3. G. = 3.141. Luster vitreous. Color dark green. Pleochroism not strongly marked, green (ω) and bluish green (e). Optically —. Double refraction strong. Indices: $\omega = 1.694$, $\epsilon =$ 641 for $\lambda = 525$ approx.

Figs. 3-5, Penfield, basal sections showing etching-figures: 3, in dilute sulphuric acid; 4, in very dilute sulphuric acid; 5, in hydrochloric acid.

Comp.—A highly basic sulphate of aluminium and copper, Cu. AlClSO, ... 9H.O which may be written (AlCi)SO₄.6Cu(OH)₂ + 3H₂O = Sulphur trioxide 10.1, alumina 6.3, cupric oxide 59.7, chlorine 4.5, water 20.4 = 101.0, deduct (0 = 201)1.0 = 100.

Anal.—Penfield, l. c.

4 SO3 10.11 Cl 4·11 Al2O3 6.60 CuO 59.51 $H_2O 20.41 = 100.74$

Pyr., etc.—B.B. fuses at 3 to a black slaggy mass, coloring the flame green. On charcoal in the reducing flame yields globules of metallic copper. Yields acid water abundantly in the

closed tube.

ed tube. Insoluble in water, but readily soluble in dilute acids.

Obs.—From the neighborhood of Tombstone, Arizona, but exact locality unknown; perhaps from the Globe district. Only a single specimen has thus far been preserved; this shows a mass of impure cuprite nearly covered with the fine hexagonal crystals of spangolite associated with a few crystals of azurite and a prismatic mineral, perhaps atacamite.

Named after Mr. Norman Spang of Etna, Allegheny Co., Penn.

733. HANKSITE. W. E. Hidden, Am. J. Sc., 30, 133, 1885.

Hexagonal. Axis $\dot{c} = 1.0140$; 0001 \wedge 1011 = *49° 30′ Hidden¹.

Forms: c (9001, O); m (10 $\overline{1}$ 0, I); p (40 $\overline{4}$ 5, $\frac{4}{5}$)², o (10 $\overline{1}$ 1, 1), s (20 $\overline{2}$ 1, 2).

Angles: $cp = 43^{\circ} 8'$, $co = 49^{\circ} 30'$, $cs = 66^{\circ} 52\frac{1}{2}'$, $pp' = 39^{\circ} 58\frac{1}{2}'$, $oo' = 44^{\circ} 41\frac{1}{2}'$, $ss' = 54^{\circ} 45'$.

In hexagonal prisms, usually short prismatic to tabular; often in interpenetrating groups. Faces m striated horizontally. Also in quartzoids.

Cleavage: c distinct. Fracture uneven to subconchoidal. Brittle. = 3-3.5. G. = 2.562. Luster vitreous, rather dull. Color white, inclining to Transparent to translucent. yellow. Optically uniaxial, negative. saline.

Comp.—An anhydrous sulphato-carbonate of sodium, 4Na₂SO₄.Na₂CO₅ = Sulphur trioxide 47.5, carbon dioxide 6.5, soda 46.0=100; or, Sodium sulphate 84.3, sodium carbonate 15.7 = 100.

Anal.—1, J. B. Mackintosh, Am. J. Sc., 30, 134, 1885. 2, S. L. Penfield, ib., p. 137.

	SO ₃	CO_2	Na_2O	Cl	ign.	insol.	
1. 2.	45·89 43·59	5·42 5·42	46·34 40·86	2·36 2·13			= 100.01 K $2.33 = 100.06$

The bases in 1 were calculated as soda. In 2 the insoluble portion is admixed clay which rendered the crystal partially opaque; the chlorine is probably due to impurity (NaCl); inclusions

of cubic crystals were observed microscopically.

Pyr.—Fuses easily with a yellow flame. Readily soluble in water. Effervesces with acids.

Obs.—Found with halite, thenardite, glauberite, trona, borax, etc., at Borax Lake, San Bernardino Co., California; cf. Hanks, Am. J. Sc., 37, 63, 1889. Hanksite is sometimes inclosed in borax crystals. Also known from Death Valley, Inyo Co., and reported from Nevada. The crystal analyzed by Penfield was a low hexagonal prism, 75 mm. across; from California, but expect lecelity, unknown. exact locality unknown.

Named after Henry G Hanks, formerly State Mineralogist of California.

Ref.—¹ L. c. Bodewig measured $oo' = 44^{\circ} 31'$, $co = 49^{\circ} 15\frac{1}{2}'$, Am. J. Sc., 38, 165, 1889.

7.	"			7.3	11.5	81.3	1.8	=	101.9

Pyr., etc.—B.B. intumesces, fuses at 1.5, and turns yellow; but becomes white on cooling. Easily reduced on charcoal. With soda affords the reaction for sulphuric acid. Effervesces briskly in nitric acid, and leaves white lead sulphate undissolved. Yields water in the closed tube.

Obs.—Found at Leadhills, with other ores of lead; also in crystals at Red Gill, Cumberland, and near Taunton in Somersetshire; at Matlock, Derbyshire. From the Mala-Calzetta lead mine near Iglesias, Sardinia (maxite), associated with galena, cerussite, anglesite; it was supposed at first to be an independent species (cf. App. II. 38, III, 67). Grenada is also stated to be a locality of it, and the island of Seriphos, Grecian Archipelago. The crystals seldom exceed an inch in length, and are commonly smaller.

Reported by C. U. Shepard from Newberry District, S. C., but there is some doubt as to the locality; also from the Morgan silver mine, Spartanburg District, S. C. Observed from Arizona, at the Schulz gold mine with wulfenite, vanadinite, cerussite; it is partly altered to cerussite

(Pfd.).

The name maxite was given for the Belgian mining engineer, Max Braun.

Ref.—1 Zs. Kr., 1, 193, 1877; the form was first made monoclinic by Haidinger, later ortho-

rhombic and hemihedral, cf. Haid., Trans. R. Soc. Edinb., 10, 217, 1826 (1824); Mir., 563, 1852. Artini (ref. below) calculates $\dot{a}:\dot{b}:\dot{c}=1.75152:1:2.22608;~\beta=89°31'55'.$ ² Cf. Lasp. and Mir., Min. 563, 1852. ³ Artini, monograph of the Sardinian mineral, Giorn. Min., 1. 1, 1890. ⁴ Dx., Propr. Opt., 2, 38, N. R., 72, 1867. ⁵ Hintze. 735. MISENITE. A. Scacchi, Mem. G. sulla Campania, 98, 1849.

In silky fibers of a white color. Soluble; taste acid and bitter.

Comp.—Probably acid potassium sulphate, HKSO, or K, SO, H, SO, = Sulphur trioxide 58.8, potash 34.6, water 6.6 = 100.

Anal.-Scacchi, l. c.

SO₃ 56.93 $Al_2O_3 0.38 = 100$ K₂O 36.57 H₂O 6·12

Pyr., etc.—Fuses easily in the flame of a Bunsen burner, imparting to it a violet color. Soluble in water.

Obs. - Occurs in a hot tufa cavern at Cape Misene near Naples.

The artificial salt is dimorphous, being obtained ordinarily in orthorhombic crystals, and also in silky fibrous forms and acicular crystals which are monoclinic. Cf. Marignac and Rg., Kr. Ch., 391, 1881. The monoclinic modification has been studied by Wyrouboff, who concludes that misenite belongs to this, the less stable form. It has: $110 \wedge 110 = 68^{\circ}$, $001 \wedge 110 = 80^{\circ}$, $001 \wedge 101 = 62^{\circ}$, $\beta = 77^{\circ}$ 55', G. = 2.245. Bull. Soc. Min., 7, 5, 1884.

736. ALUMIAN. Breith., B. H. Ztg., 17, 53, 1858.
Rhombohedral? Crystals microscopic. Also massive.
Cleavage, traces. H. = 2-3. G. = 2.702-2.781. Luster of small crystals vitreous; of masses weak. Color white. Subtranslucent.

Comp.—Perhaps Al₂O₃.2SO₃ = Sulphur trioxide 61·1, alumina 38·9= 100. Utendörffer's determinations (l. c.), contains 37-38 p. c. of alumina, with sulphuric acid, and no water.

Pyr., etc.—B.B. unaltered; only hygroscopic water given off, but at a high temperature sulphuric acid, which may be detected by litmus paper. With cobalt solution a fine blue.

Obs.—From mines in the Sierra Almagrera, southern Spain. What appears to be the same mineral was earlier mentioned by Goebel as an efflorescence on the north-east side of Mt. Ararat. He found: SO_3 58.58, Al_2O_3 38.75, $FeSO_4$ 2.78 = 100.11, Sehw. J., 60, 401, 1830.

737. LANARKITE. Sulphato-carbonate of Lead Brooke, Ed. Phil. J., 3, 117, 1820. Lanarkite Beud., Tr., 2, 366, 1832. Dioxylith Breith., Char., 1832. Kohlenvitriolbleispath, Halbvitriolblei, Germ.

Monoclinic. Axes $\hat{a}: \bar{b}: \hat{c} = 0.86811:1:1:38363; \beta = 88^{\circ}11' = 001 \land 100$ Schrauf'.

$cn = *65^{\circ}$		ar	=	38°	17'	MM'	=	73°	5

Crystals small, rarely having a diameter of more than two millimeters. Faces brilliant.

Color brown. Powder brownish yellow. Opaque.

Comp.—A basic cupric sulphate, probably corresponding to lanarkite, Cu,SO, or 2CuO.SO, = Sulphur trioxide 33.6, cupric oxide 66.4 = 100.

	SO_3	CuO	insol.		
1.	36.07	62.27	1.22	=	99.56
2.	33.49	65.20	[1.31]	=	100

Pyr., etc.—Kept for some time in water, the crystals dissolve in part, giving a blue solution; they preserve their form, however, though the color changes from brown to bluish. Dissolves easily in nitric acid. B.B. fuses, leaving a black scoriaceous residue. Unaitered at a temper-

ature of 260°. With the fluxes gives reaction for copper.

Obs.—Found at Vesuvius, having been produced by sublimation during the eruption of October, 1868. The name is derived from $\delta o\lambda \epsilon \rho \delta^{\epsilon}$, fallacious, $\phi \alpha i \nu \epsilon \sigma \vartheta \alpha i$, to appear.

739. CALEDONITE. Cupreous Sulphato-carbonate of Lead Brooke, Ed. Phil. J., 3, 117, 1820, Ann. Phil., 4, 117, 1822. Calédonite Beud., Tr., 2, 367, 1832.

Orthorhombic. Axes $\check{a}: \bar{b}: \dot{c}=0.9163:1:1.4032$ Brooke-Miller'. $100 \land 110 = *42^{\circ} 30', 001 \land 101 = 56^{\circ} 51\frac{1}{8}', 001 \land 011 = *54^{\circ} 31\frac{1}{8}'.$

Forms²:
$$x$$
 (201, 2- $\bar{\imath}$) g (018, $\frac{1}{8}$ - $\bar{\imath}$) e (011, 1- $\bar{\imath}$) r (111, 1) b (010, i - $\bar{\imath}$) H (0·1·24, $\frac{1}{24}$ - $\bar{\imath}$) k (016, $\frac{1}{6}$ - $\bar{\imath}$) δ (021, 2- $\bar{\imath}$) v (774, $\frac{7}{4}$) c (001, O) χ (0·1·20, $\frac{1}{20}$ - $\bar{\imath}$) ψ (013, $\frac{1}{8}$ - $\bar{\imath}$) Σ (335, $\frac{3}{6}$) t (221, 2) ψ (0·1·10, $\frac{1}{10}$ - $\bar{\imath}$) f (012, $\frac{1}{2}$ - $\bar{\imath}$) g (223, $\frac{3}{8}$) g (20·20·1, 20)?

Crystals prismatic in the direction of the brachydiagonal axis; usually minute; occasionally in divergent groups.

Cleavage: c perfect; a less so. Fracture uneven. Rather brittle. H.=2.5-3. G. = 6.4. Luster resinous. Color deep verdigris-green or bluish green; inclining to mountain-green if the crystals are delicate. Pleochroic. Streak greenish white. Translucent.

Ax. pl. | a. Bx \(\preceq\) 010. Axial angles, Dx.3 Optically -.

Comp.—A basic sulphate of lead and copper. Perhaps (Pb,Cu)SO4.(Pb,Cu)(OH)3 or 2(Pb,Cu)O.SO, H,O. If Pb: Cu = 2:1 the percentage composition is: Sulphur trioxide 17.9, lead protoxide 66.3, cupric oxide 11.8, water 4.0 = 100.

Anal.—1, W. Flight, J. Ch. Soc., 27, 101, 1874. 2, Collie, ib., 55, 92, 1889.

	SO_3	PbO	CuO	H_2O	
1. Leadhills	17.30	68.42	10.17	4.05	= 99.94
2. "	15.6ª	67.7a	10.7	3.5	$CO_2 \ 1.9 = 99.4$
	a G	iven as PbSO4	59.1, PbO 24.2.		

The analysis of Brooke gave CO2, which according to N. Story-Maskelyne and Flight belongs with the admixed cerussite.

Pyr., etc.—B.B. on charcoal easily reduced. Partially soluble, with a slight effervescence

when impure with lead carbonate, in nitric acid, leaving a residue of lead sulphate.

Obs.—Occurs at Leadhills, Scotland, accompanying other ores of lead, in crystals with linarite; at Red Gill in Cumberland; also at Rezbánya in Hungary; Tanne in the Harz; Mala-Calzetta mine near Iglesias, Sardinia, with leadhillite in a quartzose gangue (Rath). In the Ural at the Preobrayensk mine near Berezov, in gold quartz with cerussite, anglesite, bismite.

Said to occur at Mine la Motte, Missouri, but needs confirmation. In California at the

argentiferous galena mines of Cerro Gordo, with anglesite, mimetite, smithsonite, etc.

Ref.—¹ The early, though not very satisfactory, measurements of Brooke are accepted here, as is done by Koksharov (Min. Russl., 9, 40, 1884). Schrauf refers crystals from Rezbánya to the monoclinic system, the macrodiagonal axis of Miller becoming the clinodiagonal axis; the crystals are regarded as twins with numerous tw. lamellæ; thus e (011) becomes e (101) and η (101), etc. The same conclusion is reached by Eremeyev after the study of Uralian crystals. The axial ratios deduced by these authors are:

$$\vec{a}: \vec{b}: \vec{b} = 1.09134: 1: 1.57860$$
 $\beta = 89^{\circ} 18'$ Schrauf $1.08956: 1: 1.57725$ $\beta = 88^{\circ} 22'$ Erem.

The question cannot be regarded as definitely settled, until the complex structure assumed is confirmed by optical examination. On the crystallization of the species, see: Brooke; Ann. Phil., 4, 117, 1822; Greg and Lettsom, Min., 403, 1858; Mlr., Min., 561, 1852; Peters, Ber. Ak. Wien, 44 (1), 170, 1861; Hbg., Min. Not., 9, 48, 1870; Schrauf, Rezbánya, Ber. Ak. Wien, 64 (1), 179, 1871, Atlas xl., 1873; Erem., Mem. Acad. St. Pet., 31, No. 16, 1883; Rath, Ber. nied. Ges., Feb. 8, 1886.

² Cf. Mlr., Schrauf, Erem., l. c.

³ Dx., N. R., 205, 1867, he finds no proof of the twinning convented of remarks quested by Klr.

assumed, cf. remarks quoted by Kk.

8. Colorado	18.65	68.70	[12.65] = 100

Ludwig found that the water went off above 300°; Church gives H₂O 1.04, below 260°. Var.—I. Ordinary Brochantite. The analyses vary considerably, as shown below. The

crystals are vertically striated.

2. Waringtonite. Essentially brochantite in composition, but occurring in non-striated crystals in form like a doubly curving wedge, of paler green color than ordinary brochantite, with G. = 3·39-3·47, and H. = 3-3·5.

Pyr., etc.—Yields water, and at a higher temperature sulphuric acid, in the closed tube,

and becomes black. B.B. fuses, and on charcoal affords metallic copper. With soda gives the

reaction for sulphuric acid.

Obs.—Occurs in small but well-defined crystals, with malachite and native copper, at Gumeshevsk and Nizhni Tagilsk in the Ural; the königine (or königite) was from Gumeshevsk; in small brilliant crystals with malachite in a quartzose rock near Roughten Gill, in Cumberland; in Cornwall (in part waringtonite), and sometimes with crystals of brochantite on the so-called waringtonite; at Rezbánya; in Nassau, with chalcopyrite; in small beds at Krisuvig in Iceland (krisuvigite); in Mexico (brongnartine); in Chili, at Andacollo, Atacama with atacamite, with which it can easily be confounded; in Australia (brought from Sydney, N. S. W.); Balade mine, New Caledonia.

In the U. States, found at Monarch mine, Chaffee Co., Colorado; Bill Williams Fork,

Arizona. In Utah, Tintic district, at the Mammoth mine; also, near Frisco.

Named after Brochant de Villiers. Waringtonite is for Warington W. Smyth (1817–1890).

Artif.—Formed in a bright green powder by Field (Phil. Mag., 24, 123, 1862) by adding to a strong solution of sulphate of copper a small quantity of caustic potash, boiling, filtering, and washing till all the sulphate of copper is removed; analysis after drying at 100° C. afforded SO₂ 16.98, CuO 67.51, H₂O [15.51] = 100. See further under LANGITE.

Also by Mannier as the result of the action of concentrated sulphate of copper upon galance.

Also by Meunier as the result of the action of concentrated sulphate of copper upon galena for 11 months, C. R., 36, 686, 1878. Atanasesco heated copper sulphate in a closed tube at 200° with (A) oxide of copper and (B) with water. The brochantite obtained had the following com-

position:

SO3 CuO H₂O 23.00 67.46 10.36 =100.82 AB 67.20 10.47 = 22.51 100.18

These correspond to 3CuO.SO₃.2H₂O. Bull. Soc. Ch., 44, 14, 1885.

Ref.—¹ Min. Russl., 3, 260. Compare also Rose, Reis., Ural, 1, 267, 1837; Lévy, Heul. Min., 3, 98, 1837; Schrauf, Ber. Ak. Wien, 67 (1), 275, 1873. Schrauf gives an exhaustive monograph of the species; he makes it isomorphous with malachite, and in crystalline form approximately monoclinic. He distinguishes four types. I. Brochantite from Rezbánya (in two varieties), Redruth, Cornwall, etc., triclinic. II. Waringtonite from Cornwall, and a variety from Rezbánya, monoclinic (?). III. From Nizhni Tagilsk, monoclinic-triclinic. IV. Königine from Russia, also a variety from Rezbánya, monoclinic or orthorhombic.

	* SO.	20:08. PbO 54	80.			STEAR DOOR

Pyr., etc.—In the closed tube yields water and loses its blue color. B.B. on charcoal fuses easily to a pearl, and in R.F. is reduced to a metallic globule which by continued treatment coats the coal with oxide of lead, and if fused boric acid is added yields a pure globule of copper. With soda gives the reaction for sulphuric acid. Decomposed by nitric acid, leaving a white

residue of lead sulphate.

Obs.—Formerly found at Leadhills. Occurs at Roughten Gill, Red Gill, and near Keswick, in Cumberland, in crystals sometimes an inch long; near Schneeberg, rare; in Dillenburg, at the mines Aurora and Thomas; Nassau on the Lahn; at Schapbach, in Baden (Sandberger, l. c.), and from Badenweiler (Liweh, Zs. Kr., 9, 522, 1884); at Rezbánya; at the Kadainski mine, Nerchinsk in E. Siberia; in the vicinity of Berezov in the Ural; supposed formerly to be found at Linares in Spain, whence the name.

From the Ortiz mine in the Sierra Capillitas, Argentine Republic; from Chili (Stelzner, Min. Mitth., 249, 1873; Frenzel, l. c.). Also from the state of Jalisco, Mexico.

In the United States, in fine specimens at the Cerro Gordo mines in Inyo Co., California. Alt.—Linarite occurs altered to cerussite, a change like that of anglesite to cerussite.

Forms: m (110, I), g (120, i- $\tilde{2}$); d (104, $\frac{1}{4}$ - $\tilde{\imath}$).

Angles: $mm'' = 76^{\circ} 15'$, $gg' = *65^{\circ} 0'$, $dd' = *52^{\circ} 0'$.

In prismatic crystals, long or short.

H. = 2-2.5. Luster vitreous. Colorless, when pure, and transparent. saline and rather bitter. Permanent in the air.

Comp.—Hydrous sulphate of sodium, ammonium, and potassium, (Na,NH,K). $SO_4 + 2H_0O_2$

Anal.—Taylor, l. c.

SO3 Na₂O (NH₄)₂O K_2O H_2O

12.94 2.67 44.97 17.56 19.45 residue 2.41, P₂O₅ tr. = 100

Pyr., etc.—Only partially sublimed in the closed tube, but otherwise reacts like mascagnite. Obs.—From the cave of Las Piedras, near Comayagua, Central America, embedded in a black mass made up of the excrement of bats. The crystals often have a coating of organic matter. The cave is worked for the niter, which the earth of the floor near its mouth affords by lixiviation.

Named after Dr. John L. Le Conte.

Guanovulite Wibel, Ber. Ch. Ges., 7, 392, 1874.

Found in crystalline deposits filling the eggs of birds in Peruvian guano. H. = 2. G. = 2·33-2·65. Color yellowish white. Luster silky. A sulphate of potassium and ammonium. Calculated formula, 7K₂O.2(NH₄)₂O.12SO₃.11H₂O. Analysis, after deducting impurities:

SO₃ 49.60

K2O 35.49

(NH₄)₂O 5.09

 $H_2O 9.82 = 130$

In water dissolves, leaving a very small residue, and giving a light yellowish solution, which has a salty taste. Insoluble in ether or alcohol. Heated in a glass tube it first loses water and ammonia, then becomes black, and on stronger heating melts and gives off much sulphuric acid.

Comp.—Hydrous sodium sulphate, Na, SO, + 10H, O = Sulphur trioxide 24.8, soda 19.3, water 55.9 = 100.

Analyses, 5th Ed., p. 636; also Sicily, Zs. Kr., 4, 639, 1880; Peru, Raimondi, Min. Pérou, 288, 1878.

Pyr., etc.—In the closed tube much water; gives an intense yellow to the flame. Very soluble in water. Loses its water on exposure to dry air and falls to powder.

Obs.—Occurs at Ischl, Hallstadt, and Aussee in Upper Austria; also in Hungary, Switzerland, Italy; at Guipuzcoa in Spain, etc.; abundantly at the hot springs at Carlsbad; in considerable beds near Bompensieri Montedoro, Sicily. In beds in the province of Tarapacá, Chili; at Kailua, on Hawaii, Sandwich Islands, abundant in a cavern, and forming from the action of volcanic heat and gases on salt water.

Effloresces with other salts on the limestone below the Genesee Falls, Rochester, N. Y.: at Windsor, Nova Scotia; also near the Sweetwater River, Rocky Mountains. Large quantities of this sodium sulphate are obtained from the Great Salt Lake, Utah. It is present in solution in

the waters of the lakes, and in winter when a temperature falls to a certain point the precipitation begins and the salt accumulates so that it can be gathered from the bottom and is thrown upon the shores by the waves. "Under favorable circumstances the shores become covered to a depth of several feet with crystallized mirabilite. . . . Speaking only of the amount thrown upon the shores and of most ready access, the source is practically inexhaustible. The substance must be gathered, if at all, soon after the deposit first appears; as, if the water once rises above the critical temperature, the whole deposit is taken again into solution. This change is very rapid, a single day being often sufficient to effect the entire disappearance of all the deposits within reach of the waves."—J. E. Talmage, Science, 14, 446, Dec. 27, 1889.

The artificial salt was discovered by Gauber, a German chemist, about the middle of the

seventeenth century, while he was operating with sulphuric acid and common salt; and the

name sal mirabile was his own expression of surprise at its formation.

Ref.—¹ Min. Mohs, 2, 31, 1825. ² See Haid.; also Miller, Min., p. 545, 1852; with him, a is the base and c the orthopinacoid. Cf. also Rg., Kr. Ch., 395, 1881. ³ Aussee, Zeph., Lotos, 1877. ⁴ Propr. Opt., 1, 73, 1857. N. R., 175, 1867.

The so-called Revisin is impure glauber salt, as pronounced by Reuss in 1791, after his early

p

study of it. It occurred as a deposit of crystals and efflorescent crusts in or about the mineral springs of Saidschitz and Sedlitz. The crystals had the form of glauber salt. The analysis by Reuss corresponded to 68 0 of glauber salt, 31 7 of epsomite, and 0 3 of gypsum = 100.

Exanthalose Beudant, Tr., 2, 475, 1832. A white efflorescence, such as results from the exposure to the air of glauber salt. Beudant obtained $Na_2SO_4 + 2H_2O$; analyses:

	SO ₃	Na ₂ O	H_2O	
1. Vesuvius	44.8	35.0	20.2	= 100
2. Hildesheim	42.5	33.4	18.8	gangue 5:3= 100

The Vesuvian mineral was from the lavas of 1813, according to Beudant. It was named from $\dot{\epsilon}\xi\alpha\nu\theta\epsilon\hat{\imath}\nu$, to effloresce, and $\ddot{\alpha}\lambda$ 5, salt.

744. KIESERITE. Kieserit Reichardt, Salzbergwerk Stassfurt, 1860; B. H. Ztg., 20, 39, 1861. Martinsite Kenngott, Ueb., 22, 1856-57; Rammelsberg, Pogg., 98, 262, 1856 (not Martinsite Karsten, 1845).

Monoclinic. Axes $\hat{a}: \hat{b}: \hat{c} = 0.91470: 1: 1.75713; \beta = 89^{\circ} 5\frac{2}{3} = 001 \land 100$ Tschermak1.

 $100 \wedge 110 = 42^{\circ} 26\frac{3}{4}', 001 \wedge \overline{1}01 = 63^{\circ} 12\frac{5}{6}', 001 \wedge 011 = 60^{\circ} 21\frac{1}{6}'.$

Forms: $t(101, -1-\bar{\imath})$ eleavage; $u(012, \frac{1}{2}-\bar{\imath}); x(113, -\frac{1}{8}), p(111, -1); h(\bar{2}29, \frac{9}{8}), v(\bar{1}13, \frac{1}{8}),$ e (111, 1).

Rarely in crystals. Habit pyramidal, resembling lazulite in form and angle.

Faces e, v, brilliant and smooth, p less so; x, u rounded. Twinning lamellæ of undetermined position observed in grains. Usually massive, coarse to fine granular, or compact.

Cleavage: e, v perfect; p, t, u less so. Friable to firm. H. = 3-3.5. G. = 2.569 Tsch.; 2.517 Bischof. Luster vitreous. Color white, grayish white, to yellowish. lucent to opaque. Little soluble.

Optically +. Ax. pl. $\parallel b$. Bx_a $\wedge \dot{c} = 76^{\circ} 25'$. Dispersion inclined distinct (30'), $\rho > v$ also distinct.

 $2E_r = 90^{\circ} 42'$ $2E_v = 90^{\circ} \text{ Na} \qquad 2E_{gr} = 89^{\circ} 38'$

Hallstadt, Tschermak. Comp.—Hydrous magnesium sulphate, MgSO, + H2O

= Sulphur trioxide 58.0, magnesia 29.0, water 13.0 = 100.

The water goes off above 200° (Tschermak), whence the formula H(MgOH)SO4. Analyses agree with formula closely; see 5th Ed., p. 641; also Wieser, Vh. G. Reichs., 130, 1871, and Tschermak, l. c., both of Hallstadt. Also Precht and Wittjen, Ber. Ch. Ges., 14, 2131, 1881, who show that the massive and crystallized varieties have the same composition.

Pyr., etc.—In the closed tube yields water. B.B. fuses easily, and with soda on charcoal gives the sulphuric acid reaction. But little altered at 100° C. Dissolves in nitric acid, leaving a small residue of impurities. Soluble slowly, but completely, in water, 100 of water taking up 40.9 parts; a residue is deposited of microscopic crystals of anhydrite, or of stassfurtite.

Obs.—From the salt mine of Stassfurt, often mixed with carnallite and gypsum. F. Bischof divides the Stassfurt salt beds vertically (Ann. Ch. Phys., 5, 305, 1865, and B. H. Ztg., 24, 1865) into four regions, corresponding, he observes, to the natural order of origin from an evaporating saline: 1, or lower, the anhydrite region; 2, the polyhalite; 3, the kieserite; and 4, the carnallite. The kieserite is in beds, 9 to 12 in. thick, alternating with common salt. The whole deposit is beds 100 feet thick and heat the following in the common salt. about 190 feet thick, and has the following as its mean percentage composition: Common salt 65. kieserite 17, carnallite 13, magnesium chloride (hydrated) 3, anhydrite 2 = 100. At Neu-Stassfurt it forms a mass with halite on the border of the white carnallite; the solution of the halite leaves the kieserite in crystals resembling anhydrite.

Occurs also at the Hallstadt salt beds with blödite, halite, anhydrite, glauberite; at Kalusz

in Galicia. In the Mayo salt mines, Punjab, India.

Named after Mr. Kieser, President of the Academy of Jena. For the martinsite of Karsten, see under Halite, p. 156. Ref.—1 Ber. Ak. Wien, 63 (1), 317, 1871.

ABRAUM SALTS. Abraumsalze Germ. (From the German Abraum, abraumen, i.e., to be removed). The mixed salts overlying the rock-salt deposits at Stassfurt, Prussia; they consist chiefly of carnallite, sylvite, and kieserite.

745. SZMIKITE. J. von Schröckinger, Vh. G. Reichs., 115, 1877.

Amorphous, stalactitie, with botryoidal surface. H. = 1.5, G. = 3.15. Color whitish, on the fracture reddish white to rose-red.

Comp.—MnSO₄ + H₂O = Sulphur trioxide 47.4, manganese protoxide 41.9, water 10.7 = 100.

Anal.-1, Schrauf; 2, Dietrich, both l. c.

	SO ₂	MnO	H ₂ O	
1.	47.43	41.78	10.92 =	100.13
2.	47.11	41.61	11.19 =	99.91

Exposed to damp air in small fragments becomes deeper red, and increases slightly in weight.

Obs.—From Felsőbánya, Hungary. Named after Bergrath Szmik.

746. GYPSUM. Γύψος [= mostly burnt Gypsum] Herodotus, Plato, Theophrastus. Σεληνίτης, Άφροσέληνον, Dioscorides, 5, 152, 159. Lapis specularis (principal part), Gypsum (= burnt gypsum only), Plin. Also doubtful (besides some included above): 11.5.0, 13.23.0, 11.25.0, 7.25.0, 5.23.0, 7.0.11. 225 or 7·7·18, 245 or 5·10·12, 11·21·26.

Figs. 1-5, etc., Common forms. 6, Sicily, Pirsson. 9, Wasenweiler, Kaiserstuhl, Hbg.

Twins: (1) tw. pl. a, and usually contact-twins, very common, often the familiar swallow-tail twins; the reëntrant angle formed by the pyramid l; also as cruciform penetration-twins. (2) d (101), contact-twins and usually bounded by m or n; again in forms represented by f. 9. Crystals usually simple in habit, common form (f. 1) flattened $\|b\|$ or prismatic to account $\|b\|$; again prismatic (f. 3) by

extension of l (111). The faces m, b often vertically striated. Also lenticular by rounding of l (111) and e (103). The form e (103), whose faces are usually rough and convex, is nearly at right angles to the vertical axis (edge m/m'''), hence the apparent hemimorphic character of the twin, f. 6. Simple crystals often with warped as well as curved surfaces. Also foliated massive; lamellar-stellate; often granular massive; and sometimes nearly impalpable.

Cleavage: b eminent, yielding easily thin polished folia; a (100), giving a surface with conchoidal fracture; n (111), with a fibrous fracture ||t| (101); a cleavage fragment has the rhombic form of fig. 11, with plane angles of 66° and 114°. Also cleavage $||\beta|$ (509) and e (103) developed by pressure in thin cleavage fragments. H.

= 1.5-2. G. = 2.314-2.328, when pure crystals. Luster of b pearly and shining,

other faces subvitreous. Massive varieties often glistening, sometimes dull earthy. Color usually white; sometimes gray, flesh-red, honey-yellow, ocher-yellow, blue; impure varieties often black, brown, red, or reddish brown. Streak white. Transparent to opaque.

Optically +. Ax. pl. at ordinary temperatures ||b|, and Bx $\wedge c = +52\frac{1}{2}^{\circ}$ (at 9.4° C.), cf. f. 16. Dispersion $\rho > v$, also inclined strong, $Bx_r \wedge Bx_{bl} = 0^{\circ} 30'$.

Axial angles, Dx.:

 $2E_r = 95^{\circ} 14' \text{ at } 20^{\circ}, 75^{\circ} 58' \text{ at } 47^{\circ}, 59^{\circ} 19' \text{ at } 71\frac{1}{2}^{\circ}, 39^{\circ} 1' \text{ at } 95\frac{1}{2}^{\circ}, 0^{\circ} \text{ at } 116^{\circ}.$

With increase of temperature the axes come together, and at 116° the axial angle is 0° for red rays; at 120° the axes (red) open in a plane \pm b with small horizontal dispersion. Bx₁ changes its position 5° 38' between 20° and 95° , the axial figure in the polariscope showing the more rapid motion for the blue rays than for the red.

Refractive Indices, Lang8:

	α(16·8°)	β (17·7°)	y (16·8°)
For B	1.517427	1.519407	1.527251
C	1.518325	1.520365	1.528142
D	1.520818	1.522870	1.530483
E	1.523695	1.525806	1.533552
\mathbf{F}	1.526269	1.528262	1.535994
G	1.530875	1.532831	1.540736

The values corrected by Cauchy's formula agree closely, e.g.:

For D 1.522772 1.530483

Also axial angles (observed):

 $2V_B = 57^{\circ} 18' \ 2V_C = 57^{\circ} 42' \ 2V_D = 58^{\circ} 8' \ 2V_E = 58^{\circ} 6' \ 2V_F = 57' 28' \ 2V_G = 56^{\circ} 13'$

Further at 19°, Dufet:8

 $\alpha = 1.52046$ $\beta = 1.52260$ $2V_D = 58^{\circ} 1\frac{1}{4}'$ For D $\nu = 1.52962$

Var.-1. Crystallized, or Selenite; either in distinct crystals, or in broad folia, the folia sometimes a yard across and transparent throughout. Usually flexible and yielding a fibrous fracture | t (101), but the variety from Montmartre rather brittle.

An arenaceous variety occurs in Sussex, N. Brunswick, the crystals containing much sand, which is often regularly arranged within (O. C. Marsh).

2. Fibrous; coarse or fine. (a) Satin spar, when fine fibrous, a variety which has the pearly opalescence of mooustone (cf. p. 266); (b) plumose, when radiately arranged.

3. Massive; Alabaster, a fine grained variety, either white or delicately shaded; scaly-granular; earthy or rock gypsum, a dull-colored rock, often impure with clay, calcium carbonate or The Montmartre gypsum contains calcium carbonate, silica, and sometimes with anhydrite. and Delametherie called it Montmartrite.

Also, in caves, curious curved forms, often grouped in rosettes and other shapes.

Comp.—Hydrous calcium sulphate, $CaSO_4 + 2H_2O = Sulphur trioxide 46.6$, lime 32.5, water 20.9 = 100.

Pyr., etc.—In the closed tube gives off water and becomes opaque. Fuses at 2.5-3, coloring the flame reddish yellow. For other reactions, see Anhydrite, p. 911. Ignited at a temperature not exceeding 260° C., it again combines with water when moistened, and becomes firmly solid. Soluble in hydrochloric acid, and also in 400 to 500 parts of water.

Recent experiments on the solubility of gypsum and anhydrite in water have been made by McCaleb, Am. Ch. J., 11, 30, 1889. The specimens employed were as follows: A, gypsum, pink foliated mass, Saltville, Va.; B, do., white massive, Nova Scotia; C, selenite, honey-yellow crystal, Montmartre; D, gray massive anhydrite, impure (81 p. c.) 13 p. c. sand, Salzburg; E, do., grayish massive, pure (97 p. c.), Nova Scotia; F, gypsum and anhydrite mixed, white massive, Nova Scotia. The following figures give the amount of calcium sulphate in grams discolved from each scure centimeter in one week: dissolved from each square centimeter in one week:

A	В	C	D	E	F
0.2388	0.2219	0.1177	0.0666	0.0601	0.2184

The differences in A, B, C, are due to the different amount of surface presented; in C only the face b was exposed.

Obs.—Gypsum often forms extensive beds in connection with various stratified rocks,

especially limestones, and marlytes or clay beds. It occurs occasionally in crystalline rocks. It is also a product of volcanoes, occurring about fumaroles, or where sulphur gases are escaping, being formed from the sulphuric acid generated, and the lime afforded by the decomposing lavas-lime being contained in augite and labradorite. It is also produced by the decomposition of pyrite when lime is present; and often about sulphur springs where hydrogen sulphide is emitted, this gas changing, through reaction with vegetable matter, into sulphuric acid. Gypsum is also deposited on the evaporation of sea-water and brines, in which it exists in solution. Crystals may be seen to form on evaporating a drop of sea-water in the field of a microscope.

Fine specimens are found in the salt mines of Bex in Switzerland; at Hall in Tyrol; in the sulphur mines of Sicily; in the gypsum formation near Oçana in Spain; in the clay of Shotover Hill, near Oxford; and large lenticular crystals have been met with at Montmartre, near Paris. A noted locality of alabaster occurs at Castelino, 35 m. from Leghorn, whence it is

taken to Florence for the manufacture of vases, figures, etc.

This species occurs in extensive beds in several of the United States, and more particularly N. York, Ohio, Illinois, Virginia, Tennessee, and Arkansas, and is usually associated with salt

springs, also with rock salt. Also on a large scale in Nova Scotia, etc.

Handsome selenite and snowy gypsum occur in N. York, near Lockport in limestone along with pearl spar and anhydrite; also near Camillus, Onondaga Co.; occasionally crystals are met with pearl spar and anhydrite; also near Camillus, Onondaga Co.; occasionally crystals are met with in the vicinity of Manlius. In Maryland, large grouped crystals on the St. Mary's in clay; also near the mouth of the Patuxent. In Virginia, large beds of gypsum with rock salt, in Washington Co., 18 m. from Abingdon; also near Lynchburg. In Ohio, large transparent crystals have been found at Ellsworth and Canfield, Trumbull Co. In Tenn., selenite and alabaster in Davidson Co. In Kentucky, in Mammoth Cave, it has the forms of rosettes, or flowers, vines, and shrubbery, often called outopholites (cf. Encyc. Brit., 15, 449). Also common in isolated crystals and masses, in the cretaceous clays in the western U. S.

In N. Scotia, in Sussex, Kings Co., on Capt. McCready's farm, large single and grouped

crystals, which mostly contain much symmetrically disseminated sand.

Named from $\gamma \dot{v} \dot{\psi} o \dot{s}$, the Greek for the mineral, but more especially for the calcined mineral. The derivation ordinarily suggested, from $\gamma \dot{\eta}$, earth, and $\ddot{\epsilon} \dot{\psi} \dot{\epsilon} i \nu$, to cook, corresponds with this, the most common use of the word among the Greeks. Theophrastus, after mentioning localities, speaks of the making of gypsum by burning the proper stones (among which alabaster is included); of making plaster or cement from it by "powdering it, pouring on water, and stirring it with wooden instruments, there being too much heat for the hand;" of the necessity of preparing it "immediately before the use of it, because it soon dries and becomes hard;" of its value for whitening the walls of houses, and of its being an excellent material for making images and ornaments.

The word y v \u00fc v \u00e4 v by the best authorities. The sentences in Herodotus containing it, and the verb γυψόω derived from it meaning to cover or whiten with gypsum, are most intelligible if calcined gypsum, or

preparations from it, are understood.

Powdered chalk is not likely to have been used for a whitewash; and a wash is implied instead of dry chalking. Moreover, true chalk was probably unknown to the Greeks, it being a production of more western countries; and, according to Pliny, even the Romans included under their term Creta (Latin for chalk) principally clays, and prominently the "Cimolian earth" (cimolite, p. 689), true chalk being what Pliny calls "the inferior kind." Theophrastus speaks of a Tymphæan gypsum (so called by the people of Tymphæa) which was a fuller's earth of some The word viwos is, therefore, much more likely to have been applied at times to white

Selenites (= moonstone) of Dioscorides, which he says was also called aphroselenon (moonfroth), "because it was found at night while the moon was on the increase," was probably crystallized gypsum or modern selenite. His description λευκός, διαυγής, κουφος (= white, transparent, light), is good as far as it goes; and the uses of the stone which he mentions also agree better with this view than with that of its being either the modern moonstone or eat's-eye, to which it has been referred. to which it has been referred. The name is from $\sigma \epsilon \lambda \dot{\eta} \nu \eta$, moon, and alludes probably to the peculiar moon-like white reflections. Some aggregated crystallized masses might well have suggested the name aphroselenon. It is doubtful what Pliny had in view under the name selenitis (37, 67); it is probable, from his brevity on the subject, that he did not know the

Lapis specularis (Specular-stone) of Pliny was mostly crystallized gypsum (the rest being

mica): he speaks of it (36, 59) as affording by burning the best of gypsum.

'Αλαβαστρίτης (or alabaster-stone, meaning the stone out of which ointment vases of the kind called alabastra were made) was with Theophrastus and Pliny mainly if not wholly stalagmite, which is now often called oriental alabaster (see under CALCITE, p. 268); and Thebes in Egypt was a famous locality. Such vases were made of other materials, and it is possible that gypsum-alabaster was one; for when polished it often resembles some clouded stalagmites. This opinion is favored—though not placed beyond question—by the statement in Theophrastus,

which Pliny reiterates,* that the gypsum-stone is "very similar to," "not unlike" (meaning in the rough state, of course) alabastrites, which resemblance is not obvious if stalagmite is the only alabastrites. The alabastritis of Pliny, from Syria, said to be white spotted with various tints, may be of this kind, as Syria was noted for its gypsum-stone, according to Theophrastus and

Pliny.

'Αλάβαστρον (alabastron) occurs as the name of alabaster-stone in the writings of the Christ but without description. The alabastrum historian Herodianus about two centuries after Christ, but without description. The alabastrum of Pliny, something white and froth-like, called also, as he says, stimmi, stibi, and larbasis, and coming from silver mines, cannot be alabaster. There is here probably some mistake on the

part of Pliny.

Burnt gypsum is called Plaster-of-Paris, because the Montmartre gypsum quarries, near

Paris, are, and have long been, famous for affording it.

Alt.—Gypsum occurs altered to calcite, malachite, quartz; also to anhydrite; cf. Hammer-

schmidt, Min. Mitth., 5, 245, 1882.

Ref.— Bull. Soc. Min., 9, 175, 1886; cf. also Ann. Ch. Phys., 10, 53, 1844. Trustworthy angles are difficult to obtain; the dimensions change sensibly, with change of temperature; cf. Beckenkamp, Zs. Kr., 6, 450, 1882. Beckenkamp deduces the following:

1	$a \cdot b : c$	$\beta'(=180$	$(\beta - \beta)$
At 0°	0.689724:1:0.413411	98° 56′	17.7"
25°	0.689515:1:0.413251	98° 58′	6.4"
50°	0.689301:1:0.413072	98° 59′	59.0"
75°	0.688998:1:0.412916	99° 1′	32.8"
100°	0.688596:1:0.412661	99° 3′	25.6"
120°	0.688395:1:0.412517	99° 5′	29.6"

See earlier, Neumann, Pogg., 27, 240, 1833. With Dx., m is also the unit prism but $n=011,\,t=001,\,$ etc.; in the 5th Ed. n was the unit prism. $t=100,\,$ etc.

² See Hbg., Min. Not., 4, 1, 1861, and Brezina, Min. Mitth., 17, 1872, for lists of planes and early authorities; also Dx., l. c., Gdt. Index, 2, 121, 1888. CALCIUM CHROMATE. An artificial calcium chromate, isomorphous with gypsum, has been described by Foullon. Cf. p. 916.

747. ILESITE. A. F. Wuensch, Mining Index, Leadville, Colorado, Nov. 5, 1881. M. W. Iles, Am. Ch. J., 3, 420, 1881.

Monoclinic?, in artificial crystals Hillebrand1.

In loosely adherent crystalline aggregates, prismatic. Color clear green, becoming white on exposure in consequence of loss of water. Taste bitter, astringent. Friable. Soluble in water.

Comp.—RSO₄ + $4H_2O$ with R = Mn : Zn : Fe = 5 : 1 : 1. This requires: Sulphur trioxide 35.6, manganese protoxide 22.5, zinc protoxide 5.2, iron protoxide 4.6, water 32.1 = 100.

Anal.—M. W. Iles, mean of several partial analyses, deducting residue (0.63 SiO₂).

SO ₃	MnO	ZnO	FeO	H_2O	
36.07	22.31	5.97	4.18	31.60 =	100.13

^{*} It is not clear that Pliny is here independent authority. He appears to be citing from Theophrastus in the most of what he says about gypsum; and in one or two cases he cites blunderingly. He says, for instance, that plaster after hardening may by pounding be powdered [for use again]; whereas Theophrastus states more correctly that "by burning it may again and again be made fit for use."

The amount of water is in doubt, and in the unaltered mineral is probably larger than in

the material analyzed (Hillebrand).

Obs.—Occurs in a siliceous gangue with the sulphides of iron and zinc (from which it has been formed), in veins 2 to 8 inches wide; found in several mines at the head of Hall Valley, Park Co., Colorado. Named after Dr. M. W. Iles of Denver.

Ref..—1 Proc. Col. Soc., 1, 140, 1884.

748. EPSOMITE. Epsom Salt. Sal nativum catharticum A. Hermann, De Sale nativo cathartico in fodinis Hungariæ recens invento, Posonii, 1721. Sal neutrum acidulare, Sal Anglicanum, Wall., Min., 184, 1747. Id., Sel d'Epsom Fr. Trl. Wall., 1, 339, 1753. Halotrichum Scopoli, De Hydrarg. Idriense Tent., Venet., 1761 (Klapr. Beitr., 3, 104), Princip. Min., 1772. Magnesia vitriolata (Sal Anglicus, Epsomensis, Seidlizensis, Seydschütensis, amarus, etc.) Bergm., Sciagr., 1782. Bittersalz Wern. Gletschersalz. Haarsalz pt. Epsomite Beud., Tr., 445, 1824. Reichardtit Krause [Arch. Pharm., 5, 423, 6, 41], Zs. Nat. Halle, 44, 554, 1874.

Orthorhombic. Axes $\check{a}:\check{b}:\dot{c}=0.9902:1:0.5709$ Miller. $100 \land 110 = 44^{\circ} 43', 001 \land 101 = 29^{\circ} 58', 001 \land 011 = 29^{\circ} 43\frac{1}{3}'.$

Forms:

 $x (201, 2-\bar{\imath})$ $z (111, 1)$ $a (100, i-\bar{\imath})$ $f (120, i-\bar{2})$ $v (011, 1-\bar{\imath})$ $s (211, 2-2)$ $b (010, i-\bar{\imath})$ $n (101, 1-\bar{\imath})$ $r (021, 2-\bar{\imath})$ $t (121, 2-\bar{2})$ $mm''' = *89° 26'$ $rr' = 97° 34\frac{1}{2}'$ $ss'' = 104° 17\frac{1}{2}'$

After Miller.

Crystals prismatic in habit; often hemihedral in the Also in botryoidal masses and delipyramidal planes. cately fibrous crusts.

Cleavage: b very perfect; v (011) less perfect; m in traces. Fracture conchoidal. H. = $2 \cdot 0 - 2 \cdot 5$. G. = $1 \cdot 751$; $1 \cdot 685$, artif., Schiff. Luster vitreous to earthy. Streak and color white. Transparent to translucent. Taste bitter and saline.

Optically –. Ax. pl. $\|c\|$. Bx $\perp b$. Axial angles:

2E, = 77° 59', 78° 5', 78° 11' in three sections, Dx.² $2E_{v} = 77^{\circ} 43', 77^{\circ} 44', 78^{\circ} 3'$ "

Refractive indices for D line, Topsoe and Christiansen²:

 \therefore 2E = 78° 18' 2V = 51° 25' $\beta = 1.4554$ y = 1.4608

Comp.—Hydrous magnesium sulphate, MgSO, + 7H2O = Sulphur trioxide 32.5, magnesia 16.3, water 51.2 = 100.

Pyr., etc.—Liquefies in its water of crystallization. Gives much water in the closed tube at a high temperature; the water is acid. B.B. on charcoal fuses at first, and finally yields an infusible alkaline mass, which, with ccbalt solution, gives a pink color on ignition. Very soluble in water, and has a very bitter taste.

Obs.—Common in mineral waters, and as a delicate fibrous or capillary efflorescence on rocks, in the galleries of mines, and elsewhere. In the former state it exists at Epsom, England, and at Sedlitz and Saidschitz (or Saidschütz) in Bohemia. At Idria in Carniola it occurs in silky fibers, and is hence called *hairsalt* by the workmen. Also obtained at the gypsum quarries of Montmartre, near Paris; in Fitou, Dept. of the Aude, France; at the anthracite mine of Peychagnard, Isère, in large crystals; in Aragon and Catalonia in Spain; in the Cordillera of St. Juan in Chili; and in a grotto in Southern Africa, where it forms a layer 1½ in thick. Also found at Vesuvius, at the eruptions of 1850 and 1855. A massive variety (reichardtite) occurs in thin layers with carnallite at Leopoldshall, Stassfurt.

The floors of the limestone caves of Kentucky, Tennessee, and Indiana, are in many instances covered with epsomite, in minute crystals, mingled with the earth. In the Mammoth Cave, Ky., it adheres to the roof in loose masses like snowballs. At the Alum Cave, in Sevier, Tenn., on the headwaters of the West Fork of Little Pigeon River, masses of nearly pure epsomite, almost a cubic foot in volume, have been obtained (Safford's Rep., 119). It effloresces from the calcareous sandstone, 10 m. from Coeymans, on the east face of the Helderberg, N. Y. Said to occur also over the California plains, east of San Diego (Am. J. Sc., 6, 389, 1848). Also effloresces from a pyritiferous serpentine in Marmora, Ontario; and on dolomites of the Clinton forces of the Country of the Clinton. formation (Silurian) in sheltered places between Niagara Falls and Lake Huron as at Dundas, where layers occur 1 in. thick.

	In 2, six	molecules	of wate	er escape at 1	00°.	tion in the south

Wheeler found 4.9 p. c. FeSO₄ in the ferro-goslarite.

Pyr., etc.—Yields water. On charcoal with soda gives a zinc coating, and a sulphide which

tarnishes silver. Easily soluble in water.

Obs.—This salt is formed by the decomposition of sphalerite, and is found in the passages of mines. It occurs at the Rammelsberg mine near Goslar, in the Harz; at Schemnitz in Hungary; at Falun in Sweden; and at Holywell in Wales; Elba at Capanne Vecchie. It is not of common occurrence.

In Montana at the Gagnon mine, Butte, derived from the alteration of a cupriferous zinc sulphide. Ferro-goslarite occurs associated with sphalerite at Webb City, Jasper Co., Missouri; it is in mammillary or stalactitic incrustations of a light yellow to brown color. Goslarite is common in the drainage of the mines of the region.

f (120, i- \check{z}) x (201, 2- $\bar{\imath}$) r (021, 2- $\check{\imath}$) n (101, 1- $\bar{\imath}$) v (011, 1- $\check{\imath}$) z (111, 1) Forms: 8 (211, 2-2) b (010, i-i) t (121, 2-2) m(110, I)

In acicular crystals and thin prisms. Also fibrous; and as an efflorescence. Cleavage: b. H. = 2-2.25. G. = 2.004, Fulda. Luster vitreous. Color apple-green to greenish white. Streak white, faintly greenish. Soluble; taste metallic astringent.

Optically -. Ax. pl. ||c|. Bx $\perp b$. Dispersion $\rho > v$ large.

$$2E_r = 64^{\circ} 24'$$
 $2E_v = 63^{\circ} 45' Dx.$

Refractive indices for D line, Topsoe and Christiansen2:

$$\alpha = 1.4669$$
 $\beta = 1.4888$ $\gamma = 1.4921$... $2E_y = 64^{\circ} 22'$ $2V_y = 41^{\circ} 56'$

Comp.—Hydrous nickel sulphate, NiSO₄ + 7H₂O = Sulphur trioxide 28.5, nickel protoxide 26.6, water 44.9 = 100.

Pyr., etc.—B.B. in tube gives water, strongly acid, swells up, and hardens, becoming yellow and opaque. On charcoal glows strongly and evolves sulphurous acid. With borax and phosphorus salt gives a distinct nickel reaction. The Riechelsdorf mineral colors the outer flame blue, from the presence of arsenic.

Obs.—A result of the alteration of nickel ores. Occurs near Cape Hortegal, in Galicia,

Spain, on magnetite, with which some millerite is mixed; at Riechelsdorf, in Hesse; as an earthy crust, mountain-green in color, with native bismuth and arsenical nickel, at the Friedens mine near Lichtenberg in Bayreuth (pyromeline). Also in acicular crystals and crusts at Wallace mine, Lake Huron, upon a sulphide of nickel and iron; at the Gap nickel mine, Lancaster Co., Pennsylvania.

Named by Casares after Sr. Moreno, of Spain. A. M. Alcibar states that Prof. Casares sent a communication on this mineral to the Société de Pharmacie of Paris in 1849, which was

not published.

Ref.—¹ Mem. Soc. Genève, 14, 242, 1858. There has also been believed to be a tetragonal form, ³ cf. Haid., Pogg., 6, 196, 1826; Mitsch., ib., 12, 144, 1828, but according to Marignac this contains only 6H₂O.

² Ibid. (epsomite), p. 549. ³ Lang, Ber. Ak. Wien, 31, 99, 1858.

Tecticite Breith. Graulit Glocker, Syn., 1847. A clove-brown mineral, easily soluble in water and attracting moisture readily, occurring in small pyramidal and acicular crystals supposed to be orthorhombic, and also massive. Probably a hydrous sulphate of ferric iron; but composition not ascertained. H. = 1.5-2.

From Graul, near Schwarzenberg, in Saxony, and Bräunsdorf in the Erzgebirge. Named from τηκτικός, in allusion to the deliquescence; but changed to graulite by Glocker, because

the Greek signifies liquefying actively, and not passively as in deliquescence.

FAUSERITE. Fauserit Breith., B. H. Ztg., 24, 301, 1865.
Orthorhombic. Prismatic angle 88° 42′. Cleavage: brachypinacoidal, distinct; prismatic, in traces or none; basal, rather distinct. Crystals grouped in stalactitic forms. H. = 2-2·5. G.=1·888. Luster vitreous. Color reddish and yellowish white to colorless. Translucent to transparent. Taste astringent, bitter.
Comp.—Perhaps (Mn,Mg)SO₄ + 6H₂O, with Mn: Mg = 2:1, requiring: Sulphur trioxide 32·2, manganese protoxide 19·0, magnesia 5·4, water 43·4 = 100. Some authors give 7H₂O.

Anal.-1, 2, Mollnár, quoted by Breithaupt.

	SO ₃	MnO	MgO	$\mathrm{H_2O}$
1.	34.49	19.61	5.12	42.66 Al ₂ O ₃ , Fe ₂ O ₃ trace
2.	33.78	20.05	5.63	40.54

Obs.—Stated to be from Herrengrund in Hungary. Named after Mr. Fauser. A mineral called fauserite by Loczka, from Hodrusbánya, Hungary, was epsomite, MgSO₄ + 7H₂O, with only small quantities of zinc (0.54 ZnO), manganese (0.54 MnO), cobalt (0.08 CoO), iron (0.04 FeO). Ber. aus Ungaru, 8, 108, 1890. This throws doubt over Breithaupt's mineral.

Melanterite or Copperas Group. Monoclinic.

The species here included are the ordinary vitriols. They are identical in general formula with the species of the Epsomite group, and are regarded as the same compound essentially under oblique crystallization. The copper sulphate diverges from the others in crystallization, and contains but 5 of water.

SYNONYMY BEFORE 1750. Χαλκανθον, Χαλκῖτης, Μελαντηρία, Σώρυ, Miσυ, Dioscor., 5, 114-118. [Chalcanthum (from χαλκος, brass, and ανθος, flower) is vitriol of any kind; Spain is given as a locality; Chalcitis, a disintegrating pyrites, iron or copper, impregnated with the same, as a result of its alteration; Melanteria (fr. $\mu \in \lambda \alpha \nu$, ink), a salt-like chalcanthus, or earth containing it; Soru, a black earth or stone impregnated with some vitriol; Misu, a yellowish vitriolic stone, perhaps partly copiapite, and partly yellow ocher impregnated with vitriol of some kind.

Atramentum sutorium = Chalcanthum, Chalcites, Sory, Misy, Plin., 34, 29-32; evidently In part from Dioscorides. [The description of Chalcanthum gives prominence to blue vitriol, while its use as shoemaker's ink (which Atr. sutorium signifies) implies the presence of green (or iron) vitriol, the material still used for blackening leather; *Chalcites* and *sory* are the same as above; *Misy* is yellow and pulverulent, like the mineral now called copiapite.]

Atramentum sutorium = Melanteria = Chalcanthum, Chalcites, Sory, Misy, Agric., Foss., 212-214, 1546; Kupferwasser id., Interpr., 463, 1546. [The first three of these names are synonyms for any vitriol or all; and include (as partly also in Dioscorides) capillary or wool-like, plumose, stalactitic, and salt-like kinds, besides Lapis atramenti; Agricola mentions the varieties Atramentum sutorium candidum (= $\lambda \epsilon \nu \kappa \delta i \nu \nu V$, which is white or zinc vitriol; A. s. viride, which is green vitriol; A. s. cæruleum, which is blue vitriol; Sory, a gray or blackish stone, often nodular (glebæ rotundæ), impregnated with any vitriol; Misy, a yellow efflorescent or mealy vitriol. Goslar in the Harz is the principal locality cited by Agricola. Chalcites is said to be between sory and misy in texture, and rubra et æris colore; perhaps a red ocher (a frequent result of the alteration of pyrites) containing copperas and some unaltered pyrites.

Atramentum viride, a quibusdam Vitreolum vocatur, Albertus Magnus, De Min., Libr. 5, c.

3, 1270. Vitriolum Agric., ib., 213. [So named from vitrium, glass, in allusion to the glassy appearance of the crystals of vitriols; Agricola speaks, in connection with his explanation of the word, of "A. candidum translucidum instar Crystalli."]

Atramentum Gesner, Foss., 13, 1565; divided into A. album durum Goslarianum [or Zinc vitriol], A. viride [or Iron vitriol], A. cœruleum Cyprium pulcherrimum [or Blue vitriol], etc. Melanteria, Sory, Misy, Gesner, ib., 15, 16.

Vitriolum Wallerius, Min., 155, 1747, and Cronstedt, Min., 113, 1758; a genus including the species V. Cupri (= V. Cypri, V. Veneris); 2, V. viride (= V. ferri, V. martis); 3, V. album, vel zinci (from Goslar); besides 4, V. mixtum (a mere mixture); 5, 6, Terra vitriolica and Lapis atramentarius (earth or stone impregnated with vitriol of some kind), and including Lapis atramentarius flavus, or Misy.

751. **MELANTERITE**. Μελαντηρία, Χάλκανθον, etc., Dioscor. Chalcanthum, Atramentum sutorium, etc., Plin. Melanteria, Atramentum sutorium viride, Agric. Vitriolum pt. Albertus Magnus. Comp.—Hydrous ferrous sulphate, FeSO₄ + 7H₂O = Sulphur trioxide 28.8, iron protoxide 25.9, water 45.3 = 100. Manganese and magnesium sometimes replace part of the iron, the former in the variety luckite.

Anal.—1, Janovsky, Ber. Ak. Wien, 79 (1), 187, 1879. 2, Carnot, l. c.

An impure iron-magnesium sulphate from Falun, sold as "botryogen," belongs here, see analyses by Blaas, Ber. Ak. Wien, 88 (1), 1135, 1884; Hockauf, Zs. Kr., 12, 253, 1886.

SO₃ FeO MnO MgO H₂O

1. Idria G. =
$$1.79$$
 $\frac{3}{2}$ 29.80 20.37 4.60 45.07 = 99.84

2. Utah, Luckite 26.3 21.7 1.9 0.2 [42.2] CaO 0.5, insol. 7.2 = 100

Pyr., etc.—In the closed tube yields water, and after a time sulphurous and sulphuric acids. On charcoal turns at first brown, then red, and finally black, becoming magnetic. With the fluxes reacts for iron. Soluble in twice its weight of water, and the solution is blackened by a tincture of nutgalls. Exposed to the air becomes covered with a yellow powder, which is the

ferric sulphate.

Obs. This salt usually proceeds from the decomposition of pyrite or marcasite, which readily afford it, if occasionally moistened while exposed to the atmosphere. Occurs near Goslar in the Harz; Bodenmais in Bavaria; Falun, Sweden; at Hurlet, near Paisley; and in many mines in Europe and elsewhere. Usually accompanies pyrite in the U. States, occurring as an efflorescence; at Copperas Mt., a few miles E. of Bainbridge, Ohio, it is associated with aium and pyrite.

Luckite is from the "Lucky Boy" mine, Butterfield Cañon, Utah.

Ref.—1 Ber. Ak. Wien, 79 (1), 183, 1879, measurements of the pure iron sulphate; the pres-

ence of magnesium in varying amounts makes a sensible change in angle, cf. Zeph., l. c., and Rg., Pogg., 91, 325, 1854; Schrauf, Jb. Min., 1, 236, 1886. Cf. epsomite, p. 938.

² Cf. Brooke, Ann. Phil., 6, 120, 1823; Mlr.. Min., 550, 1852.

Rammelsberg shows that there is a close relation in form between the monoclinic melanterite.

and orthorhombic epsomite, Kr. Ch., 425, 1881. See also Schrauf, Ber. Ak. Wien, 39, 894, 1860; Zeph., l. c. ³ Dx., N. R., 173, 1867.

BOURBOLITE. Lefort, C. R., 55, 919, 1862. An impure sulphate of iron, apparently a mixture of melanterite and a ferric sulphate; from Bourboule, in the Dept. of Puy-de-Dôme, France. Derived apparently from the alteration of marcasite. Lefort's analyses obtained:

SO ₃	Fe_2O_3	FeO	H_2O
38.04	5.08	16.08	40.80 = 100
37.55	8.71	13.83	39.91 = 100
35 22	8.25	12.99	43.54 = 100

It is a friable greenish substance, partly soluble in water and partly in acids.

752. MALLARDITE. Carnot, Bull. Soc. Min., 2, 117, 1879.

Monoclinic, Mld. In crystalline masses with fibrous structure. Colorless. Comp.—Hydrous manganese sulphate, MnSO₄ + 7H₂O = Sulphur trioxide 28.9, manganese protoxide 25.6, water 45.5 = 100.

Analyses by Carnot and Rioult agree closely, l. c. and App. III, p. 72.

Pyr, etc.—Easily soluble in water. Changes rapidly on exposure; effloresces, becomes opaque, and finally pulverulent. Is decomposed by strong heating, losing the sulphuric acid and water, and leaving a reddish brown residue. Carnot obtained from a solution of manganese sulphate at 15° C. the salt $MnSO_4 + 5H_2O$ in triclinic crystals; but at a temperature of 6° C. he obtained monoclinic crystals with the composition $MnSO_4 + 7H_2O$.

Obs.—Occurs in a gray clay-like gangue, with quartz sand and barite. From the silver mine "Lucky Boy," south of Salt Lake, near Butterfield Canon, Utah.

753. PISANITE. F. Pisani, C. R., 48, 807, 1859. Pisanit Kenng., Ueb. 1859, 10, 1860. Cyanoferrite Adam, Tabl. Min., 66, 1865. Cuproferrite Des Cloizeaux, N. R., 157, 1867. Kupfereisenvitriol Germ.

2. Tuscany	28.84	und.	10.07	und.

Pyr., etc.—B.B. gives with the fluxes reactions for copper. Otherwise like melanterite, Obs.—Occurs with chalcopyrite at a copper mine in the interior of Turkey. The interior of the mineral has sometimes druses of minute crystals. Also as a recent formation at the mines of chalcopyrite and pyrite near Massa Marittima, Tuscany.

Ref.—1 N. R., 157, 1867. 2 Zs. Kr., 2, 309, 1878.

754. BIEBERITE. Cobalt Vitriol Sage, J. Phys., 39, 53, 1791. Kobaltvitriol Kopp, Gehlen's J., 6, 157, 1808. Red Vitriol. Sulphate of Cobalt. Rhodhalose Beud., Tr., 2, 481. 1832. Bieberit Haid., Handb., 489, 1845.

Monoclinic. Axes $\hat{a}: \bar{b}: \hat{c} = 1.1815: 1: 1.5325; \beta = 75^{\circ} 19\frac{3}{4}' = 001 \land 100$ Marignac'.

 $100 \land 110 = 48^{\circ} 49', 001 \land 101 = 43^{\circ} 22', 001 \land 011 = 56^{\circ} 0'.$

Forms:
$$m (110, I)$$
 $t (\bar{1}01, 1-\bar{i})$ $o (011, 1-\bar{i})$ $n (121, -2-\hat{2})$ $b (010, i-\hat{i})$ $f (103, -\frac{1}{3}-\bar{i})$ $e (013, \frac{1}{3}-\hat{i})$ $r (111, -1)$ $r (\bar{1}21, 2-\hat{2})$ $c (001, 0)$ $v (101, -1-\bar{i})$

Usually in stalactites and crusts, investing other minerals.

G. = 1.924, artificial crystals, Schiff. Luster vitreous. Color flesh- and rosered. Subtransparent to translucent. Friable. Taste astringent.

Comp.—Hydrous cobalt sulphate, CoSO, + 7H, O = Sulphur trioxide 28.5.

cobalt oxide 26.6, water 44.9 = 100.

Pyr., etc.—In a matrass yields water, and when strongly heated, sulphur dioxide. Gives a blue bead with borax.

Obs.—In the rubbish of old mines at Bieber, in Hesse; at Leogang in Salzburg; at Tres

Puntas, near Copiapo, Chili.

Beudant's name Rhodhalose is not an admissible derivative from ροδόεις, rose-colored, and αλs, salt, and is unmineralogical in its termination; it should have been Rhodohalite. Instead of making it right (in which case it would be no longer Beudant's name), it appears better to adopt the name applied by Haidinger, derived from the longest known locality.

Ref.—¹ Mem. Soc. Phys. Geneve, 14, 245, 1855. See also Rg., Kr. Ch., 1, 419, 1881.

CUPROMAGNESITE. Scacchi, Rend. R. Accad. Sc. Napoli, Oct., 1872; Zs. G. Ges., 24, 506. Found at Vesuvius as a product of the eruption of April, 1872, in bluish green crusts, consisting of copper vitriol and sulphate of magnesium. From the solution crystals are obtained having the composition (Cu, Mg)SO₄ + 7H₂O, and isomorphous with iron vitriol.

Crystals commonly flattened | p. Occurs also massive, stalactitic, reniform, sometimes with fibrous structure.

Cleavage: M, m, p imperfect. G. = 2.12-2.30. Luster vitreous. Fracture conchoidal. Brittle. H. = 2.5. Color Berlin-blue to sky-blue, of different shades; sometimes a little greenish. Streak uncolored. Subtransparent to translucent. Taste metallic and nauseous.

Optically -. Acute bisectrix in the right quadrant behind; a plane, S, normal to it makes the following angles, Pape' (see Introduction, p. xxxiii):

$$mS = 81^{\circ} 31'$$
 $MS' = 43^{\circ} 41'$ $pS = 72^{\circ} 52\frac{1}{2}'$

Refractive indices for the Axial angle, $2V = 56^{\circ} 2'$. Dispersion $\rho < v$. D line, Pape3:

$$\alpha = 1.5156$$
 $\beta = 1.5394$ $\gamma = 1.5464$ $\alpha = 1.5140$ $\beta = 1.5368$ $\gamma = 1.5433$ $\gamma = 1.5433$ $\gamma = 1.5433$ $\gamma = 1.5433$

Comp.—Hydrous cupric sulphate, CuSO, + 5H, O = Sulphur trioxide 32·1, cupric oxide 31.8, water 36.1 = 100.

Pyr., etc.—In the closed tube yields water, and at a higher temperature sulphur trioxide. B.B. with soda on charcoal yields metallic copper. With the fluxes reacts for copper. Soluble

in water; a drop of the solution placed on a surface of iron coats it with metallic copper.

Obs.—Found in waters issuing from mines and in connection with rocks containing chalcopyrite, by the alteration of which it is formed. Some of its foreign localities are the Rammelsberg mine near Goslar in the Harz; Falun in Sweden; at Parys mine, Anglesea; at various mines in Co. of Wicklow; formerly in crystals an inch long at Ting Tang mine in Gwennap; also Rio Tinto mine, Spain. The waters of the Rio Tinto mine have yielded annually 1,800 cwt. of copper, consuming 2,408 cwt, of iron. At Wicklow about 500 tons of iron were laid in the pits at one time, and in about 12 months the bars were dissolved, and each ton of iron yielded 1½ to 2 tons of a rock and roc to 2 tons of a reddish mud which was cement copper (Cementkupfer Germ.) containing for every ton 16 cwt. of pure copper. It has been observed at Vesuvius among the products of the eruption of 1855; at Copiapo, Chili, with stypticite.

Found at the Hiwassee copper mine, also in large quantities at the Isabella and other mines,

round at the Hiwassee copper mine, also in large quantities at the Isabella and other mines, in Polk Co., Tennessee, 30 m. from Cleveland; at the Canton mine, Georgia. In Arizona, at the Yavapai mine near Clifton, Graham Co., and at Jerome, Yavapai Co.

On the ancient chalcanthum, see p. 645. Beudant's name cyanose (with cyanosite derived from it, from κύανος) is rejected like other names in which the terminal s of the Greek is retained. Moreover, chalcanthite, meaning flowers of copper, is old and good.

^a Also in one anal., 1.42 Na,Cl.

Pyr., etc.—In the flame of a Bunsen gas-burner becomes milky, colors the flame violet, and melts easily to a colorless (on cooling white) bead, with a crystalline granular texture. In closed tube gives off water, decrepitating violently. Easily attacked by water, dissolving in part with the separation of calcium sulphate. Vrba found that one part of syngenite dissolved in 400 pts. of water, like gypsum.

Obs.—Found in cavities in halite at Kalusz, East Galicia; it occurs below the level of the

"Abraum Salts" (p. 933), and in gypsum-anhydrite-bearing rock salt. Name derived from $\sigma v \gamma \gamma \epsilon v \eta \delta$ (related), alluding to its close relation to polyhalite.

Artif.—The artificial salt is well known; it was described by Miller⁵ and Lang⁶ as orthorhombic, which has led to the supposition of dimorphism. It is shown, however, by Zepharovich that the natural and artificial salts are identical and both monoclinic, but the latter often twins.

In short prismatic crystals often highly modified. Also massive

granular or compact, also somewhat fibrous.

Cleavage not observed. H. = 2.5. G. = 2.22-2.28. Luster vitreous. Colorless and transparent to bluish green, reddish yellow and translucent; also flesh-red to brick-red. Taste faint, saline and bitter.

Optically—. Ax. pl. || b. $Bx_r \wedge c = -44^{\circ} 48'$, $Bx_{bl} \wedge c = -43^{\circ} 21'$.

angles1:

Var.—The original blödite from Ischl, analyzed by John, was massive, somewhat fibrous, flesh-red to brick-red in color, and splintery in fracture. The astrakanite, from near Astrakhan, was in whitish crystals. Simonyite from Hallstadt was supposed to differ from blödite in not efflorescing in the air, which, however, has been shown not to be true of the characteristic mineral.

Comp.—Hydrous sulphate of magnesium and sodium, MgSO. Na, SO. + 4H, O = Sulphur trioxide 47.9, magnesia 12.0, soda 18.6, water 21.6 = 100; or, Magnesium sulphate 36.4, sodium sulphate 42.0, water 21.6 = 100.

Analyses agree closely with the formula; one by Paul, Stassfurt, gave: SO₃ 48·14, MgO 11·97, Na₂O 18·55, H₂O 21·60 = 100·26, Zs. G. Ges., 23, 671, 1871; see also 5th Ed., p. 659; Tschermak, l. c. (simonyite); Zimmermann, Stassfurt, quoted by Luedecke, l. c. et al. Foullon obtained a somewhat abnormal composition (12.6 MgO, 24 H₂O, etc.) for blödite from Hall in Tyrol (Jb. G. Reichs., 38, 1, 1888).

Pyr., etc.—Heated loses water rapidly; at a red heat fuses quietly to a transparent globule,

which is white on cooling. Somewhat deliquescent in a moderately moist atmosphere.

Obs.—From the salt mines of Ischl; at Hallstadt (simonyite) in thin layers between rock salt; at Stassfurt in crystals, sometimes an inch across, on the massive mineral or on carnallite. Also from salt lakes near Astrakhan, east of the mouth of the Volga; the soil of the country near Mendoza, between San Luis de la Punta and the foot of the Andes, especially east of San Juan. occurring in imperfect crystals at the junction of two layers of common salt, one to two feet below the surface. Also common in northern Chili in the Pampa del Toro, Atacama (Dietze, Zs. Kr., 19, 446, 1891), and at Cerros Pintados, in Tarapacá (Schulze, Vh. Ver. Santiago, 2, 54, 1889).
In India, in rock salt at the Varcha mine, 30 miles from Shahpur, Punjab.
Named after the chemist and mineralogist Blöde. Simonyite from F. Simony, who

discovered the Hallstadt locality.

Ref.— Stassfurt, Zs. G. Ges., 23, 670, 1871; also Rath, Pogg., 144, 586, 1871. See Groth, and Hintze, I. c., and vom Rath. l. c. Brezina noted on simonyite c, n, m, d, p, Ber. Ak. Wien, and thirds, 18.0, and volume and the simple of simple of the simple of th

Kr., 15, 568, 1889.

A sulphate of magnesium and sodium having the formula Na₂SO₄.4MgSO₄ + 7H₂O is mentioned by Domeyko as occurring at Canota, 55 miles from Mendoza, Argentine Republic. An analysis gave:

Pyr., etc.—Loses 11 p. c. water at 100°, and all the rest by heating to 133°, Reichardt.

According to Graham, the artificial salt loses its water wholly at 132°.

Obs.—Found at Vesuvius among the salts produced at the eruption in 1855, in crystals along with crystals of cyanochroite, an isomorphous species in which copper replaces the magnesium. Further as a thin incrustation upon the kainite of Leopoldshall, Stassfurt (schoenite); also at Aschersleben in the kainite region; with kainite at Galuz in East Galicia.

Named from πικρός, bitter, and μέρος, part, in allusion to the magnesium present. Schoenite is for the mining officer Schoene of Leopoldshall.

Ref.—' L. c. The artificial crystals have been measured by Brooke, Murmann and Rotter,

and Rammelsberg with results agreeing for the most part with the above, cf. Rg., Kr. Ch., 1, 448, 1881. Luedecke, Zs. Nat. Halle, 58, 651, 1885. Murmann and Rotter, Ber. Ak. Wien, 34, 142, 1859. 4 Dx., Propr. Opt., 2, 51, 1859.

761. CYANOCHROITE. Cianocroma Scacchi, Mem. Vesuv., 191, 1855.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=0.7477:1:0.5052; \beta=*75^{\circ}30'=001 \land 100$ Scacchi¹.

 $100 \land 110 = *35^{\circ} 54',001 \land 101 = 38^{\circ} 13',001 \land 011 = 26^{\circ} 3\frac{5}{8}'.$

Forms: a (100, $i \cdot \bar{i}$), b (010, $i \cdot \bar{i}$), c (001, 0); m (110, I); η ($\bar{1}01$, $1 \cdot \bar{i}$), e ($\bar{2}01$, $2 \cdot \bar{i}$); $o(011, 1-i); n(\bar{1}11, 1); \mu(\bar{1}21, 2-2).$

Angles: $ce = 63^{\circ} 10'$, $cn = 44^{\circ} 31'$, $nn' = 49^{\circ} 39'$, $\mu\mu' = 85^{\circ} 32'$, $em' = *52^{\circ} 32'$.

In crystalline crusts of a clear blue color, crystals obtained from solution.

Artif. crystals of this salt have been measured by Brooke².

Optically +. Ax. pl. $\parallel b$. $ac = +4^{\circ}23'$ or $a = 18^{\circ}53'$, hence $Bx_a \wedge b = -71^{\circ}7'$. Dispersion $\rho > v$. Axial angles, Murmann and Rotter²:

 $2H = 49^{\circ} 39'$ $2E = 76^{\circ} 12'$ $2V = 48^{\circ} 53'$ $\beta_{r} = 1.489$ $\beta_{v} = 1.491$ $\beta_{bl} = 1.498$

Comp.—Hydrous sulphate of copper and potassium, CuSO₄. K₂SO₄ + 6H₂O = Sulphur trioxide 36:3, cupric oxide, 17:9, potash 21:3, water 24:5 = 100; or, Cupric sulphate 36:1, potassium sulphate 39:4, water 24:5 = 100.

Obs.—From the saline crusts formed on the lavas during the eruption of Vesuvius in 1855. Named in allusion to the color from κυανος, blue, and χρόα, color. Scacchi's name has been changed to the above, in order to secure the termination ite and avoid ambiguity (the mineral containing no chrome).

Ref.—¹ L. c. ² Ann. Phil., 7, 118, 1824. ³ Ber. Ak. Wien, 34, 169, 1859. Cf. Rg., Kr.

Ch., 1, 462, 1881.

762. POLYHALITE. Polyhalites Strom., Comment. Soc. R. Götting., 4, 139. Polyhalit Strom., Unters., 1, 444, 1821.

Probably monoclinic'. Usually in compact fibrous or lamellar masses.

Cleavage easy in one direction. H. = 2.5-3. $G_{\cdot} = 2.769$; 2.784 Pfeiffer. Luster resinous or slightly pearly. Streak red. Color flesh- or brick-red, some-Translucent to opaque. Taste bitter and astringent, but times yellowish. very weak.

Comp.—Hydrous sulphate of calcium, magnesium, and potassium, 2CaSO. $MgSO_4$, $K_2SO_4 + 2H_2O = Sulphur trioxide 53.2, lime 18.6, magnesia 6.6, potash 15.6,$ water 6.0 = 100; or, Calcium sulphate 45.2, magnesium sulphate 19.9, potassium

sulphate 28.9, water 6.0 = 100.

Analyses conform closely to the formula after deduction of impurities (NaCl, Fe₂O₃, etc.); see 5th Ed., p. 641; also Schober, Berchtesgaden. Jb. Min., 578, 1869; v. Lill, Stebnik, Galicia, Min. Mitth, 89, 1874; E. Pfeiffer, Stassfurt [Arch. Pharm., 219, 1881], Zs. Kr., 10, 524,

Pyr., etc.—In the closed tube gives off water. B.B. fuses at 1.5, colors the flame yellow. On charcoal fuses to a reddish globule, which in R.F. becomes white, and on cooling has a saline hepatic taste; with soda like glauberite. With fluorite does not give a clear bead. Partially soluble in water, leaving a residue of calcium sulphate which dissolves in a large amount of water.

Obs.—Occurs at the mines of Ischl, Ebensee, Aussee, Hallstadt, and Hallein in Austria, with common salt, gypsum, and anhydrite; at Berchtesgaden in Bavaria; at Stassfurt, cf. kieserite, p. 932; at Stebnik, Galicia; at Vic in Lorraine.

The name polyhalite is derived from $\pi \circ \lambda \circ S$, many, and $\tilde{\alpha} \lambda S$, salt, in allusion to the number

of salts in the constitution of the mineral.

Ref.—1 Cf. Dx., N. R., 202, 1867, who finds that the Ischl variety is amorphous, inclosing a biaxial mineral whose ax. pl., about the + bisectrix, is strongly inclined to the plane of cleavage and oblique to the direction of fibers.

KRUGITE Precht, Ber. Ch. Ges., 14, 2138, 1881. Near polyhalite. Massive, crystalline.

H. = 3.5. G. = 2.801.

Formula, 4CaSO₄. MgSO₄. K₂SO₄ + 2H₂O = Calcium sulphate 62·3, magnesium sulphate 13·7, potassium sulphate 19.9, water 4.1 = 100. Anal.—Precht:

	CaSO ₄	MgSO ₄	K_2SO_4	H_2O	NaCl		
1.	63.15	13.71	18.60	4.16	0.38	=	100
2.	63.85	13.34	17.85	4.20	0.80	=	100.04

In cold water the magnesium sulphate is dissolved, and gypsum and the double salt K₂SO₄. CaSO₄ + 2H₂O are left insoluble; in hot water the magnesium and potassium sulphates are dissolved out, and only the gypsum is left behind. Named for the Mining Director, D. Krug v. Nidda.

MAMANITE A. Goebel. Bull. Ac. St. Petersb., 9, 16, 1865. Like polyhalite in aspect and characters, but stated to have the CaO, MgO, K₂O in the ratio 3:2:1. Color white; luster silky; structure foliated fibrous. In nodules as large as the fist, at the salt mine of Maman in Persia, with carnallite, and also investing or intersecting nodules of carnallite.

763. WATTEVILLITE. Singer, Inaug. Diss. Würzburg, p. 18, 1879.

In very minute acicular crystals, orthorhombic or monoclinic; in part twins; forms fine fibrous aggregates. G. = 1.81. Color snow-white. Luster silky. Taste first sweet, then astringent.

Comp.—Perhaps CaSO₄. Na₂SO₄ + 4H₂O = Sulphur trioxide 45.7, lime 16.0, soda 20.6,

water 17.7 = 100; or, Calcium sulphate 38.8, sodium sulphate 43.5, water 17.7 = 100.

The calcium is replaced in part by magnesium and about one third of the sodium by potassium. The water corresponds more closely to 4½H2O.

Anal.—Singer, l. c., after deducting 33.69 p. c. hygroscopic water.

SO ₃	Al ₂ O ₃	FeO	NiO	CoO	CaO	MgO	K_2O	Na ₂ O	H_2O
44.01	0.24	0.88	1.05	1.30	16.87	2.49	4.74	10.46	17.73 = 99.77

Pyr., etc.—B.B. swells up and fuses with difficulty to a white blebby enamel. Very soluble in water; from the concentrated solution, crystals of gypsum separate on standing, and still more quickly on warming.

Obs.—Found on lignite, associated with other related sulphates on the Bauersburg, near Bischofsheim vor dem Rhön, in Bavaria. Named after M. v. Watteville, of Paris.

Alum and Halotrichite Groups.

The Alums proper are isometric in crystallization and, chemically, are hydrous sulphates of aluminium with an alkali metal and 12 (i.e., if the formula is doubled, 24) molecules of water. The HALOTRICHITES are oblique in crystallization, commonly fibrous in structure, and are hydrous sulphates of aluminium with magnesium, manganese, etc.; the amount of water in some cases is given as 22 molecules, and in others 24, but it is not always easy to decide between the two.

The species here included are not easily distinguishable by the taste or external characters, and hence early authors on minerals include all under one or two names. The old synonymy and the history of the species are therefore more conveniently given here than under the several

subdivisions of the group.

Στυπτηρία Gr. Alumen Plin. [embracing vitriols as well as the alums]. Σγιστη στυπτηρία Diose. [embracing the fibrous or feathery kinds, $\sum_{l} z_{l} \sigma_{l} \tau_{l}$ being from $\sigma_{l} \zeta_{el} \nu_{l}$, l cut, and alluding to the easy subdivision into fibers]. I ριχίτης Dioser. [fr. θρίξ, hair, it embracing capillary kinds]. Alumen fossile, Germ. Alaun, Gesner, Foss., 1565 [vitriols being excl., and comprising the var. A. candidum Neapolitanum (fr. Naples), A. capillare, ib., A. Placodes (latas crustas habens), ib., etc.]. Alum, Alumen [including var. α solidum, β crystallisatum, γ plumosum, or Fjäder-Alun], Wall., Min., 161, 1747. Alun, Argilla acido vitrioli imbuta, Cronst., 115, 1758. Argilla vitriolata [= Sulphate of Alumina] Bergm., Sciagr., 1782. Alaun, Haarsalz, Federalaun [all as one species, or if two, without right distinctions], Wern., and other Min. before 1800. Alumine sulfatée alkaline H., Tr., 2, 278, 1801 [citing Vauquelin's anal. of potash-alum, but including all alums]. including all alums].

In 1795 Klaproth proved (Beitr., 1, 311), and in 1792 Breislak (Essais Min. sur la Solfatara, etc.), that some alum (that of Miseno and the Solfatara, near Naples) was potash-alum. In 1802 Klaproth showed (Beitr., 3, 102) that the Federalaun of Freyenwald was iron-alum. Beudant ascertained that there was a native alum-like mineral which had the constitution attributed in the last century to true alum—that is, was a simple sulphate of aluminium, without an alkali or other protoxide (Tr., 449, 1824). Grüner, in 1821 (Gilb. Ann., 69, 218), made known a native ammonia-alum; Thomson, in 1828 (Ann. Lyc. N. Y., 3, 19, 1828), a native soda-alum; A. A. Hayes, in 1845 (Am. J. Sc., 47, 360), a magnesia-alum.

Alaun Germ. Alun Fr. Allume Ital. Alumbre Span.

764. KALINITE. Potash Alum. Native Alum. Kalialaun, Kalinischer Alumsulphat, Germ. Alumen Weisbach, Synops. Min., 9, 1875. Kalinite Dana.

Isometric. Usually fibrous or massive, or in mealy or solid crusts. Artif. cryst. commonly octahedral, also cubic and with d (110, i), n (211, 2-2), p (221, 2), and the pyritohedron $e(210, i-2)^{1}$. Twins: tw. pl. o.

H. = 2-2.5. G. = 1.75. Luster vitreous. Color white. Transparent to Often exhibits anomalous double refraction3. Refractive index, translucent.

n = 1.4557 for D, Fock².

The anomalous double refraction was early explained by Biot³ as due to lamellar polarization, but Reusch3 (Pogg., 132, 618, 1867) showed that this hypothesis would not answer, since the more transparent the crystals the more distinctly the phenomena are shown, but that they were probably to be explained by secondary internal tension. The subject has been discussed by Mallard 3, from his standpoint an octahedral crystal being regarded as made up of eight hexagonal pyramids having their bases coincident with the octahedral faces and their vertices at the center. Again by Klocke³, who, after giving the results of detailed observations, shows that Mallard's hypothesis does not explain the facts observed, but they are rather to be referred to secondary disturbances in the normal isotropic molecular structure. The investigations of the same author have extended also to the etching-figures and related points.

Comp.—Hydrous sulphate of aluminium and potassium, K2SO4.Al2(SO4)3 + 24H₂O = Sulphur trioxide 33.7, alumina 10.8, potash 9.9, water 45.6 = 100;

or, Potassium sulphate 18·1, aluminium sulphate 36·3, water 45·6 = 100.

The alum from Vulcano contains traces of cæsium and rubidium, Cossa.

Pyr., etc.—B.B. fuses in its water of crystallization, and froths, forming a spongy mass; with cobalt solution an intense blue; on charcoal gives a hepatic mass. Soluble in from 16 to 20

times its weight of cold water, and in little more than its weight of boiling water.

Obs.—Effloresces on argillaceous minerals, and more particularly alum slate. Whitby in Yorkshire is a noted locality, also Hurlet and Campsie near Glasgow. Also obtained at the volcanoes of the Lipari isles and Sicily. Cape Sable, Maryland, has afforded large quantities of alum. An alum, formerly described from the caves of the Unaka Mts., Eastern Tennessee, in Sevier Co., is mentioned with analysis on p. 955 (= apjohnite); masses a cubic foot in size have been obtained.

765. TSCHERMIGITE. Ammonia Alum. Ammoniakalaun, Ammonalaun, Germ. Ammonalun Beud., 2, 497, 1832. Tschermigit v. Kobell, Tafeln Bestimm., 1853.

In octahedrons and fibrous.

H. = 1-2. G. = 1.50.Color white. Luster vitreous. Transparent to translucent.

Comp.—Hydrous sulphate of aluminium and ammonium, (NH4)2SO4.Al2(SO4)3+ 24H_oO = Sulphur trioxide 35·3, alumina 11·3, ammonium oxide 5·7, water 47·7 = 100; or, Aluminium sulphate 37.7, ammonium sulphate 14.6, water 47.7 = 100:

An analysis of ammonia alum occurring in white fibrous plates near Dux, Bohemia, gave Deichmüller (Isis, p. 33, 1885):

SO₃ 34.99 Al₂O₃ 11.40 $(NH_4)_2O 3.83$ H₂O 49.72 $X^a \ 0.06 = 100$ Alkali sulphate not volatilized.

Pyr., etc.—Iu the closed tube yields water and ammonium sulphate; B.B. sublimes; on charcoal gives a coating of ammonium sulphate, and leaves a residue which gives a fine blue with cobalt solution; with soda gives ammonia fumes, and the reaction for sulphuric acid.

Obs.—From Tschermig, and from the mine near Dux, in Bohemia. This salt is manufactured

from the waste of gas works, and used extensively in place of potash alum.

766. MENDOZITE. Soda Alum. Natronalaun, Natrumalaun, Germ. 1 Huot, 2, 448, 1841. Solfatarite pt. Shep., Min., 2, 187, 1835 (not in Min. of 1857). Dana, Min., 653, 1868. Natronalun

In white fibrous masses.

H. = 3, and G. = 1.88 Thomson. Externally white or pulverulent. Some

resemblance to fibrous gypsum, but harder.

Comp.—Hydrous sulphate of aluminium and sodium, Na2SO4.Al2(SO4)3 + $24H_{\bullet}O = Sulphur trioxide 34.9$, alumina 11.1, soda 6.8, water 47.2 = 100; or, Sodium sulphate 15.5, aluminium sulphate 37.3, water 47.2 = 100.

Some doubt exists as to the amount of water, which is sometimes taken as 22, or even 20, molecules; the theoretical amounts corresponding to these are 45.0 and 42.7 p. c. Thomson's early analysis gave 41.96 p. c. H₂O. The normal amount, however, can hardly differ from that of the other isometric alums. This is confirmed by an analysis by Mori (Ch. News, 44, 218, 1881), of a soda alum from Shimané, Prov. Idzumo, Japan:

> SO₃ 34.73 Al2O3 11.27 Na₂O 7.26 $H_2O 46.74 = 100$

Pyr, etc.—Resembles ordinary alum.

Obs.—Occurs near Mendoza, in the Argentine Republic.

Thomson found for the composition of a soda alum from Southern Peru, which he called Subsesquisulphate of Alumiua (Phil. Mag., 22, 192, 1843): SO₃ 32.95, Al₂O₃ 22.55, Na₂SO₄ 6.50, H₂O 39.20 = 101.20. G. = 1.584.

767. TAMARUGITE. H. Schulze, Vh. Ver. Santiago, 2, 56, 1889. Structure fibrous. H. = 1. G. = $2\cdot03-2\cdot04$. Luster vitreous. Colorless. Composition like mendozite, but contains only half as much water: Na₂SO₄.Al₂(SO₄)₃ + $12H_2O$ = Sulphur trioxide 45.7, alumina 14.6, soda 8.9, water 30.8 = 100. Analysis:

CaO 0.20 CoO tr. H₂O 30.86 $Cl\ 0.12 = 100.36$ Al₂O₃ 14·48 Na₂O 9.04 SO₃ 45 66

From the Cerros Pintados, Tarapacá, Chili. Named from the Pampa del Tamarugal, An alum (alumbre nativo) analyzed by Domeyko (Min., 2d App. to 3d Ed., p. 30, 1883) is near the above and may be the same thing; he obtained:

Al₂O₃ 15.10 Na2O 10.70 CaO 0.89 $H_2O 31.37 = 100$ SO₃ 41.94

768. PICKERINGITE. Hayes, Am. J. Sc., 46, 360, 1844. Magnesia Alum ib. Magnesia-alaun, Talkerde-Alaun, Germ. Alumbre.

Monoclinic? In fine acicular crystals; in long fibrous masses; and in efflorescences.

H. = 1. Luster silky. Color white, yellowish, pale rose-red. pulverulent and white on exposure. Taste bitter to astringent.

Comp.—Hydrous sulphate of aluminium and magnesium, MgSO. Al. (SO.). + $22 \text{H}_{\bullet} O = \text{Sulphur trioxide } 37.3$, alumina 11.9, magnesia 4.7, water 46.1 = 100; or, Aluminium sulphate 39.9, magnesium sulphate 14.0, water 46.1 = 100.

Some authors give 24H₂O, but this is not confirmed by the analyses.

Anal.—1, Hayes, l. c. 2, Schulze, Vh. Ver. Santiago, 2, 58, 1889. 3, Schickendantz, Brackebusch, Min. Argentina, 74, 1879; also other analyses giving similar results. 4, H. How, J. Ch., Soc., 16, 200, 1863. 5, Goldsmith, Proc. Ac. Philad., 333, 1876.

In two other trials How obtained: SO₃ 36·36, 36·59, and H₂O 46·16, 46·07.

Pyr., etc.—In the matrass yields water, and acts like other alums. Tastes like ordinary alum.

Obs.—From the Cerros Pintados, northern Chili, and at other points. From various points in the Argentine Republic (Brackebusch, Min. Argent., 74, 1879). From Colorado City, Colorado (anal. 5). Also from N. Scotia. in Newport, on the bank of the Meander, as an efflorescence on the slate or shale (Silurian) of a sheltered cliff, where it results from the action on the shale of decomposing pyrite—and probably a kind containing traces of cobalt and nickel. Named after the Hon. John Pickering of Boston (d. 1846).

STÜVENITE L. Darapsky, Vh. Ver. Santiago, 107, 1886. Occurs in slender acicular crystals. Apparently intermediate between mendozite and pickeringite, but somewhat doubtful. Composition, $(Na_2.Mg)SO_4.Al_2(SO_4)_3 + 24H_2O$. Analysis:

3 SO3 36.1 Al₂O₃ 11·6 MgO 1·0 Na₂O 2·7 K₂O tr. $H_2O 47.6 = 99.0$

Occurs with other sulphates at the old mine of Alcaparossa, near Copiapo, Chili. Named after the mining engineer Enrique Stüven.

Sesqui-Magnesiaalaun of Darapsky (l. c., Jb. Min., 1, 131, 1887) is an alum near pickeringite from the Cerros Pintados, Chili, for which the formula is calculated 1½MgSO₄. Al₂(SO₄)₂+26½H₂O. The homogeneity of the substance is well questioned by Groth. Analyses:

	SO ₃	Al ₂ O ₃	MgO	H_2O	MgCl ₂	insol.
1. Compact	37.93	7.75	8.18	45.22	0.20	0.73 = 100.11
2. "	35 95	11.60	5.82	45.97	0.24	0.36 = 99.94
3. Fibrous	35.17	10.26	6.90	48.54	0.14	- =

An analysis is also given of an altered kind.

The following are near each other, and related to pickeringite; they require further examination.

SONOMAITE E. Goldsmith, Proc. Ac. Philad., 263, 1876. Crystalline. G. = 1:604. Silky luster. Colorless. Composition, 3MgSO₄.Al₂(SO₄)₃ + 33H₂O. Analysis:

 $Al_2O_3 8.01$ FeO 1.78 MgO 7.33 $H_2O [44.34] = 100$ # SO3 38.54

From the neighborhood of the Geysers, Sonoma Co., California.

PICROALLUMOGENE G. Roster, Boll. Com. Geol., 302, 1876. Stalactitic; in nodular and fibrous radiated masses. Color white, with a rose-red tinge. Streak nearly white. Semi-translucent. Taste acid, bitter. Composition, if homogeneous, 2MgSO₄.Al₂(SO₄)₅ + 28H₂O₄. Analysis:

SO ₃	Al ₂ O ₃	MgO	H_2O
36.39	9.16	8.19	$45.69 \text{ K}_2\text{O } 0.37, \text{ CoO } tr. = 99.80$

Fuses easily in its own water of crystallization, and swells out, becoming opaque and porous. Dissolves in slightly warmed water, forming an acid solution, from which oblique prisms resembling gypsum separate on slow evaporation. Occurs with sulphur and melanterite, in the iron mine of Vigneria, Island of Elba.

Dumreicherite Doelter, Capverd Inseln, 93, 1882.

Monoclinic?. In thin crusts consisting of aggregated columns. Taste astringent. in water. Composition, $4MgSO_4$. $\Lambda l_2(SO_4)_3 + 36H_2O$. Analysis, F. Kertscher: Soluble

SO₃ 36.65 Al₂O₃ 7·14 MgO 11.61 H₂O 45.01 $Na_2O_1Cl\ tr. = 100.41$

From crevices in the lava of the Paule valley, S. Antão, one of the Cape Verde islands. Named after A. von Dumreicher of Lisbon.

Aromite L. Darapsky, Jb. Min., 1, 49, 1890.

Crystalline. Fracture conchoidal.

Resembles epsomite, but B.B. swells up slightly, and is decomposed rapidly on exposure. Composition, 6MgSO₄.Al₂(SO₄)₃.54H₂O. Analysis:

	SO ₃	Al_2O_3	MgO	$\rm H_2O$
1.	33.71	5.00	12.71	48.58 = 100
2.	33.21	1.15	15.90	49.87 = 100.3

From the Pampa de Aroma, in the northern part of Tarapacá, Chili.

A related sulphate from the neighborhood of Copiapo is near aromite. It is in fibrous masses. Color yellowish. Luster vitreous, dull. Analysis:

SO ₃	Al_2O_3	FeO	MgO	Na ₂ O	CuO	H_2O	
34.59	4.68	9.45	2.87	1.03	2.12	45.36	Cl $tr. = 100.10$

The copper belongs to admixed copper sulphate.

769. HALOTRICHITE. Federalaun vom Freyenwalde (with anal. showing it to be an iron alum) Klapr., Beitr., 3, 102, 1802. Eisenalaun Germ. Iron Alum. Halotrichit Glocker, Grundr., 691, 1839. Hversalt Forchhammer, JB. Ch., 23, 263, 1843. Halotrichine Scucchi, Mem. Geol. Camp. Nap., 84, 1849.

Monoclinic or triclinic. Silky fibrous. Yellowish white. Taste inky-

astringent. Becomes dull and pulverulent on exposure.

Comp.—FeSO₄.Al₂(SO₄)₂ + 1 24H₂O = Sulphur trioxide 34·5, alumina 11·0, iron protoxide 7·8, water 46·7 = 100; or, Aluminium sulphate 36·9, ferrous sulphate 16.4, water 46.7 = 100.

The early analyses gave only 22 H₂O; the formula then requires: Sulphur trioxide 35.9,

Anal.—1, Rg., Pogg., 43, 399, 1848. 2, Silliman, Dana Min., 226, 1850. 3, Arppe, Finsk. Min., 1857. 4, Forchhammer, l. c. 5, Scacchi, l. c. 6, Linck, Zs. Kr., 15, 26, 1888. 7, Janovsky, quoted by Zepharovich, Ber. Ak. Wien, 79 (1), 183, 1879, after deducting impurities. 8, F. W. Clarke, Am. J. Sc., 28, 24, 1884.

7. Idria $G_{\cdot} = 2.04$	34.90				$47.11 \text{ Fe}_2\text{O}_3 \ 1.40 = 100$
8. Gila R., N. Mexico G. = 1.89	37.19	7.27 13.59ª	-		40.62 insol. 0.50 = 99.17

a A trace as Fe₂O₃.

Lippitt gives for a sulphate from Tepeji, Mexico: SO₄ 41·59, Al 4·92, Fe 7·81, Ca 0·52, $\rm H_2O$ 43·60 = 98·44, Ch. News. 48, 98, 1883. The name Halotrichite is from $\tilde{\alpha}\lambda \xi$, salt, and $\theta \rho i \xi$, hair.

Berg butter (Beurre de Montagne) is an impure alum or copperas efflorescence, of a butterlike consistence, oozing from some alum slates. A yellowish kind from Wetzelstein, near Saalfeld, afforded R. Brandes (Schw. J., 39, 417, 1823): SO₃ 34·82, Al₂O₃ 7·00, FeO 9·97, MgO 0.80, Na₂O 0.72, (NH₄)₂O 1.75, H₂O 43.50 = 99.00.

Pyr., etc.—Fuses in its own crystallization-water, cracks open, and if strongly heated gives off sulphuric oxide, leaving a brown residue; with the fluxes reacts for iron, and with soda on

charcoal gives an hepatic mass.

Obs.—Occurs at Bodenmais, Bavaria, and at Mörsfeld in Rhenish Bavaria. Urumia, Persia, where the inhabitants use it for making ink of a fine quality; at Hurlet and Campsie near Glasgow; at Björkbakkagård in Finland; at the Solfatara at Pozzuoli (halotrichine). At the Tierra Amarilla near Copiapo, Chili, in white silky fibrous forms with oblique extinction (triclinic?). The Hrersalt of Forchhammer is an allied alum from Iceland.

Probably at Rossville, Richmond Co., N. Y. (Beck). The related sulphate of anal. 8 occurs in white asbestiform fibers at the headwaters of the Gila River, 40 miles north of Silver City, New Mexico; the deposit of aluminous sulphates is said to cover some two thousand acres. The salt analyzed by Lippitt was in fine flexible fibers of a greenish white color, from

Tepeji, State of Mexico, Mexico.

770. APJOHNITE. Manganese Alum Apjohn, Phil. Mag., 12, 103, 1838. Manganalaun. Apjohnit Glocker, Syn., 298, 1847.

Bushmanite. Manganese Alum pt., Mangano-magnesian Alum. Bosjemanite Dana, Min.,

654, 1868. Buschmanite. Boschjesmanite.

Monoclinie? In fibrous or asbestiform masses; also as crusts and efflorescences. H. = 1.5. G. = 1.782 (anal. 3). Luster silky. Color white or with faint tinge of rose, green, or yellow. Taste like that of ordinary alum, but less strong.

Comp., Var.—Hydrous sulphate of aluminium and manganese, MnSO4. Al2(SO4)3 + 24H₂O = Sulphur trioxide 34·6, alumina 11·0, manganese protoxide 7·7, water 46.7 = 100; or, Manganese sulphate 16.3, aluminium sulphate 37.0, water 46.7 = 100.

Bushmanite is intermediate between pickeringite and apjohnite; formula, (Mn, Mg)SO4.

Al₂(SO₄)₃+22 (or 24) H₂O.

Anal.—1, Apjohn, l. c. 2, Ludwig [Arch. Pharm., 143, 97], Rg., Min. Ch., 273, 1875.

3, W. G. Brown, Am. Ch. J., 6, 97, 1884.

4, Stromeyer, Pogg., 31, 137, 1834.

5, J. L. Smith, Am. J. Sc., 18, 379, 1854. 6, E. Schweizer, Kenng. Ueb., 12, 1859.

Apjohnite.

	SO_3	Al_2O_3	MnO	H_2O

						1111801. 1 12 = 100

In the last there was some ammonia with the water.

Brown (1 c.) shows that anals. 1, 2, 4 agree with the general formula given above, while the others agree with $R_3Al_4(SO_4)_9 + 51H_2O$.

Pyr.—Nearly the same as for ordinary alum, but gives with fluxes a reaction for manganese.

Obs.—Apjohnite is from Lagoa Bay in South Africa.

The mineral of anal. 3 is from Alum Cave, Sevier Co., Tenn.; it had been earlier called kalinite. The cave is situated at the headwaters of the Little Pigeon, a tributary of the Tennessee river; it is properly an overhanging cliff 80 or 100 feet high and 300 feet long under which the alum has collected. It occurs in masses, showing in the cavities fine transparent needles with a silky luster; extinction oblique; color of the mass white, with faint tinge of rose, pale green or yellow: H = 1.5; G. = 1.782. Epsomite and melanterite also occur with it.

Bushmanite covers the floor of a cave near the Boschjesman (Bosjesman = Bushman) river in South Africa, to a depth of six inches; the roof is a reddish quartzose conglomerate, containing magnesia and pyrites; it rests on a bed of epsomite, 1½ inches thick. Also, a related alum is found in the Maderanerthal in Canton Uri. Switzerland (called keramohalite by Schweizer) and at Alum Point near Salt Lake, in Utah. This Utah mineral was made a manganesian alum by

Dr. Gale, Am. J. Sc., 15, 434, 1853.

771. DIETRICHITE. Von Schröckinger, Vh. G. Reichs., 189, 1878. Arzruni, Zs. Kr..

Monoclinic (?), Arzruni.

In fine fibrous, tufted forms, as an efflorescence or incrusting.

H. = 2. Luster silky. Color dirty white to brownish yellow. Easily soluble in water; taste like vitriol. B.B. fusible.

Comp.—(Zn,Fe,Mn)SO₄.Al₂(SO₄)₃ + 22H₂O. Anal.—Dietrich, quoted by Von Schröckinger.

SO ₃	Al ₂ O ₃	ZnO	FeO	MnO	MgO	H_2O
	10.92					44.38 = 100.12

A recent formation (within 14 years) in an abandoned working at Felsöbánya, Hungary.

772. COQUIMBITE. Neutrales schwefelsaures Eisenoxyd H. Rose, Pogg., 27, 310, 1833. White Copperas. Coquimbit Breith., Handb., 100, 1841. Blakeite, Dana, Min., 447, 1850. Rhombohedral. Axis $\dot{c} = 1.5613$; 0001 \wedge 1011 = 60° 59' Linck¹.

Twins: Tw. pl. c, the faces a coinciding and often showing a reversed striation \parallel edge o/a. Commonly in hexagonal prisms, f. 1, also in rhombohedral forms;

again in forms simulating a regular octahedron, f. 2. Also granular massive. Cleavage imperfect: m, r, η . H. = 2-2.5. G. = 2.092 Breith.; 2.105 Linck. Color white, yellowish, brownish, greenish, sometimes with a violet or amethystine Taste astringent. Optically +. Refractive indices:

Comp.—Fe₂(SO₄)₂ + 9H₂O = Sulphur trioxide = 42.7, iron sesquioxide 28.5, water 28.8 = 100. The iron may be partly replaced by aluminium.

Anal.—1, 2, Bamberger, Zs. Kr., 3, 522, 1879. 3, Linck, Zs. K., 15, 10, 1888. 4-6, J. B. Mackintosh, Am. J. Sc., 38, 242, 1889.

6.	**		42.32	28.10	[28.67]	$0.91^{\circ} = 100$
					a Incl. Sie	0,

From 1 and 2 some admixed epsomite and silica, and from 3, 1.3 p. c. silica, have been deducted. Water expelled at 110° in anals. 4, 5, 6 = 5, 6, $5\frac{1}{3}$ molecules respectively. The material of anal. 4 was amethystine in color, crystalline, transparent; of 5, amethystine, massive, translucent; of 6, white, massive, opaque.

Earlier analyses by H. Rose (l. c. and 5th Ed., p. 650) established the composition.

Pyr., etc.—B.B. resembles melanterite. Wholly soluble in cold water; if the solution be

heated, iron sesquioxide is copiously precipitated. Soluble in dilute hydrochloric acid.

Obs.—Forms a bed in a feldspathic or trachytic rock, Tierra Amarilla near Copiapo, in the province of Atacama, Chili. The bed of salt is on the increase, and is probably derived from decomposing sulphides. Pits 20 ft. deep have been formed in it by the people of the country. Also north of Sierra Gorda near Caracoles. The mineral does not occur in Coquimbo, from which it takes its name.

A mineral referred here by Scacchi was observed by him about fumaroles after the eruption of Vesuvius in 1855, partly in a brownish friable crust, which, by solution and evaporation,

of vestivities in 1893, partly in a brownish frame critist, which, by solution and evaporation, afforded yellow hexagonal crystals; also as a yellowish crust, in many parts tinged green, compact in texture, with the luster of a surface of fracture very bright.

Ref.—1 Zs. Kr., 15, 5, 1888; Arzruni gave & = 1.5645, ibid., 3, 516, 1879; Rose gave & = 1.562, Pogg., 27, 309, 1833. 2 Cf. authors quoted.

The name blakeite (Dana, Min., 447, 1850) was given to a mineral "from Coquimbo," analyzed by Blake and having the composition of coquimbite but supposed to occur in regular octahedrons. It is deathless identical with accomplishing as remarked by Lindy, who notes that the combination. It is doubtless identical with coquimbite, as remarked by Linck, who notes that the combination e, o (f. 2) has nearly the form of an octahedron $eo = 69^{\circ}$ 42′, $eo''' = 71^{\circ}$ 22′.

773. QUENSTEDTITE. G. Linck, Jb. Min., 1, 213, 1888, Zs. Kr., 15, 11, 1888.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c} = 0.39397: 1: 0.40584; \beta = 78^{\circ} 74'$ Linck. $100 \land 110 = 21^{\circ} 5',001 \land 101 = 39^{\circ} 45\frac{1}{6}',001 \land 011 = 21^{\circ} 39\frac{2}{3}'.$

Forms:
$$p$$
 (350, $i\frac{5}{8}$) r (0·11·10, $\frac{1}{10}$ - i) t (074, $\frac{7}{4}$ - i) v (094, $\frac{9}{4}$ - i) b (010, i - i) q (011, 1- i) s (085, $\frac{9}{6}$ - i) u (0·15·8, $\frac{1}{8}$ - i) w (052, $\frac{5}{2}$ - i) m (110, I)

$$mm^{\prime\prime\prime}=42^{\circ}\ 10^{\prime} \qquad pp^{\prime}=114^{\circ}\ 33^{\prime} \qquad tt^{\prime}=69^{\circ}\ 36^{\prime} \qquad ww^{\prime}=89^{\circ}\ 35\frac{1}{2}^{\prime} \ bm=*68^{\circ}\ 55^{\prime} \qquad qq^{\prime}=43^{\circ}\ 19^{\prime} \qquad bt=*55^{\circ}\ 12^{\prime} \qquad m^{\prime}q=*92^{\circ}\ 37^{\prime}$$

Crystals tabular | b and elongated | à, resembling gypsum; clinodome faces

striated | à.

Cleavage: b perfect; a 100 (or a prism) less perfect, yielding a fibrous fracture. H. = 2.5. G. = 2.116. Luster vitreous. Color reddish violet. Transparent. Optically –. Ax. pl. $\parallel b$. Bx \wedge $\dot{c} = +21^{\circ}$.

Comp.—Fe₂(SO₄)₃ + $10H_2O$ or Fe₂O₃. $3SO_3.10H_2O$ = Sulphur trioxide 41.4, iron sesquioxide 27.6, water 31.0 = 100.

Anal.-Linck, l. c.

4 SO₃ 39·83 Fe₂O₃ 27·66 H₂O 31·35 CaO 0.40 Al₂O₃, MgO tr. = 99.24

Also SO₃ 41.40, Fe₂O₃ 27.59. Of the water 20.84 p. c. goes off at 100°, 3.60 at 140°, 4.68 at 180°, 1.01 at 240°, 1.61 above. It is readily soluble in water.

Obs.—Occurs with coquimbite and other sulphates of the Tierra Amarilla near Copiapo,

Chili.

Named after the German mineralogist, Prof. F. A. von Quenstedt (1809-1889).

Ref.—¹ L. c.; Linck give as a fundamental angle 110 \wedge 011 = 87° 23′; this, however, gives $\beta = 84^{\circ}$ 14′, while the value of β measured on b was found to be 78° approx., the supplement of 87° 23′ or 92° 37′ gives results agreeing approximately with his (he gives a:b:c=0.3942:1:0.4060, $\beta = 77^{\circ}$ 58′).

774. IHLEITE. Schrauf, Jb. Min., 252, 1877

An efflorescence on graphite, having a botryoidal or small reniform structure. G. = 1.812. Color orange-yellow, becoming pale yellow in dry air.

Comp.—An iron sulphate near coquimbite, probably Fe₂(SO₄)₃ + 12H₂O = Sulphur trioxide 39.0, iron sesquioxide 25.9, water 35.1 = 100.

Anal.—Schrauf.

SO3 38.2 Fe₂O₃(Al₂O₃) 24.5 FeO 2.1 $H_2O 35.5 = 100.3$

Soluble in cold water.

Occurs at the graphite deposits at Mugrau, Bohemia, owing its origin to the decomposition of embedded crystals of pyrite. Named for Mr. Ihle, superintendent of mines in Mugrau.

Kornelite Krenner, abstract in Ch. Ztg., 861, 1888, from the Hungarian Academy. Stated to be a hydrous ferric sulphate Fe₂(SO₄)₃ + 7½H₂O = Sulphur trioxide 44.9, iron sesquioxide 29.9, water 25.2 = 100.

775. ALUNOGEN. Hydro-trisulfate d'alumine Beud., Tr., 449, 1824. Davite (?) Mill, Quart. J., 25, 382, 1828. Alunogène Beud., Tr., 2, 488, 1832. Solfatarite pt. Shep., Min., 188, 1835. Keramohalit Glocker, Grundr., 689, 1839. Saldanite Huot, Min., 2, 451, 1841. Stypterit Glocker, Syn., 297, 1847. Halotrichit pt. Hausm., Handb., 2, 1174, 1847 (not Halotrichit Glocker). Schwefelsaures Thouerde. Haarsalz Rg.

Monoclinic, Jurasky. Usually in delicate fibrous masses or crusts; also massive. H. = 1.5-2. G. = 1.6-1.8. Luster vitreous to silky. Color white, or tinged with yellow or red. Subtranslucent to subtransparent. Taste like that of common alum.

Comp.—Hydrous aluminium sulphate, Al₂(SO₄), + 18H₂O = Sulphur trioxide 36.0, alumina 15.3, water 48.7 = 100.

Analyses agree, for the most part, closely, except for impurities; see 5th Ed., p. 649, also references as in App. III; Jb. Min., 2, 254, 1882; Clarke, Am. J. Sc., 28, 24, 1884; Hof, Teneriffe, Min. Mitth., 12, 39, 1891. Marguerite-Delacharlonny has obtained an artificial sulphate with only 16H₂O, which requires 45.7 p.c.; an analysis of the mineral from Bolivia confirms this, giving 45.38 p.c. H₂O, C. R., 111, 229, 1890.

Pyr., etc.—Yields water, and at a higher temperature sulphuric acid, in the closed tube.

Gives a fine blue with cobalt solution. Soluble in water.

Obs.—This species results both from volcanic action, and the decomposition of pyrite in coal districts and alum shales, and occurs at numerous localities; as at Kolosoruk near Bilin. Bohemia; Bodenmais; Pusterthal, Tyrol. The Pasto mineral was from the crater of a volcano. It has been observed by Scacchi at Vesuvius; at Königsberg, Hungary, it occurs in thick druses with iron vitrol. At various points in Peru and Bolivia; the Argentine Republic; Wallewarang, New South Wales; Teneriffe, Canary Islands.

It is found as an efflorescence in numerous places in the United States. A white fibrous alunogen (?) occurs abundantly at Smoky Mtn., Jackson Co., N. C., where, it is said, tons may be obtained. Extensive deposits occur on the Gila river, 40 miles north of Silver City, N. Mexico.

Davite was obtained from a hot spring at Chiwachi, a day's journey from Bogota. Mill obtained: SO_3 28.8, Al_2O_3 15.0, H_2O 51.8, Fe_2O_3 1.2, earthy matters 3.2 = 100.

776. KRÖHNKITE. Krönnkite I. Domeyko, 5th Appendix, Min. Chili, p. 33, 1876; also 3d Ed., Min. Chili, 250, 1879. Krönkite.

Monoclinic. Axes $\hat{a}: \hat{b}: \hat{c} = 0.44625: 1: 0.43521, \beta = 72^{\circ} 41' = 001 \land 100$ Darapsky'.

 $100 \land 110 = 23^{\circ} 4\frac{1}{2}', 001 \land 101 = 35^{\circ} 49\frac{1}{2}', 001 \land 011 = 22^{\circ} 34'.$

Forms: b(010, i-1), m(110, I), e(011, 1-1), p(111, -1).

Angles: $mm''' = 46^{\circ} 9'$, $ee' = 45^{\circ} 8'$, $me = 66^{\circ} 13'$, $m'e = 95^{\circ} 53'$.

In irregular prismatic crystalline masses with coarsely fibrous structure.

Cleavage: m, b, distinct. Fracture conchoidal. H. = 2.5. G. = 1.98. Luster

Color azure-blue, changing somewhat on exposure to the air.

Comp.—A hydrous sulphate of copper and sodium, CuSO₄. Na₂SO₄ + 2H₂O = Sulphur trioxide 47.5, cupric oxide 23.5, soda 18.4, water 10.7 = 100; or, Cupric sulphate 47.2, sodium sulphate 42.1, water 10.7 = 100.

Anal.-1, 2, Darapsky, Jb. Min., 1, 192, 1889.

	SO_3	CuO	Na ₂ O	H_2O	Cl	
1. White	47.02	22.34	[19.24]	11.40	tr. = 100	
2. Green cryst.	46.64	21.38	$[19.24] \\ 19.52$	12.58	tr. = 100.10	

The analysis of Kröhnke, quoted by Domeyko (who writes Krönke and Krönnke), gave.

CuSO₄ 46.28 Na2SO4 42.95 $H_2O 10.77 = 100$

Another analysis by Domeyko gave: SO_3 46 56, CuO 23 20, Na_2O 18 04, H_2O [11 08], Al_2O_3 0 22, $CuSO_4$ 0 90 = 100.

Pyr., etc.—B.B. decrepitates and fuses to a green mass. Easily soluble in water, giving an acid solution.

Obs.—Found in the copper mines near Calama, on the road from Cabija to Potosi, Atacama: from the mining district of Incahuase with sideronatrite. Named for B. Kröhnke.

An artificial salt of this composition is known.

Ref. -! L. c.; his calculations do not entirely agree with the above.

PHILLIPITE I. Domeyko, 5th Appendix, Min. Chili, p. 38, 1876; 3d Ed., Min. Chili, p. 248,

Compact, granular, or with fibrous structure, transverse to veins in the chalcopyrite. Luster cous. Color azure-blue. Translucent, astringent. Composition approximately given by vitreous.

whiteous. Color azute-blue. Haistucent, astringent. Composition approximately given by the formula, CuSO₄, Fe₂(SO₄)₃ + nH₂O. Analysis gave:
SO₃ 28.96, Fe₂O₃ 9 80 (iron subsulphate 2.28), CuO 14.39, MgO 0.85, H₂O 43.72, Al₂O₂ tr.
= 100. Soluble in water, but unaffected by exposure to the air. Found at the copper mines in the Cordilleras of Condes, province of Santiago, Chili. Produced from the decomposition of chalcopyrite, and found in small irregular masses and bands with it in an argillaceous ocher.

777. FERRONATRITE. J. B. Mackintosh, Am. J. Sc., 38, 244, 1889. Gordait Frenzel, Min. Mitth., 11, 218, 1890.

Axis $\dot{c} = 0.55278$; 0001 \wedge 1011 = *32° 33′ Arzruni¹. Rhombohedral.

Forms: c(0001, 0), $m(10\bar{1}0, I)$ cleavage, $a(11\bar{2}0, i-2)$, $s(10\bar{1}2, \frac{1}{2})$, $r(10\bar{1}1, R)$, $\eta(01\bar{1}1, -1)$. Angles: $cs = 17^{\circ} 42'$, $cr = 32^{\circ} 33'$, $ss' = 30^{\circ} 32'$, $rr' = 55^{\circ} 33'$, $rn = 31^{\circ} 13'$, $ar = 62^{\circ} 14'$,

Rarely in distinct accordance crystals, combination of a and r; usually in spheri-

cal forms having a lamellar-stellate structure, often resembling wavellite.

Cleavage: m perfect; a less so. H. = 2. G. = 2.547-2.578 Genth & Penfield. Color pale greenish white, grayish white, white. Optically uniaxial, positive. Indices: $\omega_y = 1.558$, $\epsilon_y = 1.613$ Pfd.²

Comp.— $3\text{Na}_2\text{SO}_4$. Fe₂(SO₄)₃ + 6H₂O or $3\text{Na}_2\text{O.Fe}_2\text{O}_3$. 6SO₃. 6H₂O = Sulphur trioxide 51.4, iron sesquioxide 17.1, soda 19.9, water 11.6 = 100; or, Sodium

sulphate 45.6, ferric sulphate 42.8, water 11.6 = 100.

Anal.-1, Mackintosh, l. c. 2, F. A. Genth, Am. J. Sc., 40, 202, 1890. 3, Frenzel, Zs. Kr., 18, 595, 1891.

	SO ₃	Fe ₂ O ₃	Al_2O_3	Na ₂ O	K_2O	H_2O
1.	50.25	17.23	0.43	18.34	0.40	11.14 insol. 2.00 = 99.79
2.	51.30	17.30	-	19:	95a	11.89 = 100.44
3.	50.85	17.69		20.22	-	11.90 = 100.66

Of the H₂O, 5½ molecules are lost at 110° C., the remainder is easily soluble in water. In anal. 2, the loss at 100° was 0.28 p. c. after two hours.

Obs.—Occurs with other sulphates at Sierra Gorda near Caracoles, Chili.

Ref.— Zs. Kr., 18, 595, 1891. Am. J. Sc., 40, 202, 1890.

778. RÖMERITE. Grailich, Ber. Ak. Wien, 28, 272, 1858. Bückingit G. Linck, Jb. Min., 1, 213, 1888. Roemerite.

Triclinic. Axes $\alpha : \bar{b} : \dot{c} = 0.96840 : 1 : 2.64250; \alpha = 116^{\circ} 31', \beta = 94^{\circ} 401'$ $\gamma = 80^{\circ} 7_{3}^{\prime} \text{ Linck}^{1}$. $100 \land 010 = *98^{\circ} 43^{\prime}$, $100 \land 001 = *89^{\circ} 36^{\prime}$, $010 \land 001 = *64^{\circ} 20^{\prime}$.

Forms:
$$c\ (001,\ O)$$
 $y\ (508,\frac{5}{8}\bar{\imath}')$ $l\ (0\bar{1}4,\frac{1}{4}\bar{\imath})$ $n\ (0\bar{1}2,\frac{1}{2}\bar{\imath})$ $a\ (100,\ i\cdot\bar{\imath})$ $m\ (110,\ I')$ $x\ (\bar{1}01,\ 1-\bar{\imath}_i)$ $t\ (0^*\bar{5}\cdot18,\frac{5}{18}\bar{\imath})$ $q\ (0\bar{1}1,\frac{1}{1}\bar{\imath})$ $b\ (010,\ i\cdot\bar{\imath})$ $\mu\ (3\bar{2}0,\frac{1}{8}\bar{\imath})$ $e\ (011,\ 1-\bar{\imath}')$ $s\ (0\bar{1}3,\frac{1}{3}\bar{\imath})$ $e\ (0\bar{1}3,\frac{1}{3}\bar{\imath})$ $e\ (0\bar{1}1,\frac{1}{1}\bar{\imath})$ $e\ (0\bar{1}3,\frac{1}{3}\bar{\imath})$ $e\ (0\bar{1}3,\frac{1}{3}\bar{\imath})$

Crystals tabular | c, often monoclinic in habit; faces a, c striated | their intersection-edge, brachydome faces vertically striated. Also coarsely granular,

crystalline.

Cleavage: b perfect. Fracture uneven. Brittle. H. = 3-3.5. G. = 2.174Gl.; 2.102 Linck. Luster vitreous. Color light to dark chestnut-brown, violetbrown, rust-brown to yellow. Pleochroic. Transparent to translucent. saline, astringent.

Optically —; double refraction weak. Ax. pl. on c bisects obtuse angle of edges a/c and b/c. Bisectrix inclined about 30° to c. $2H_a = 57^{\circ} 45'$.

798.

799.

Botryogen -

Sideronatrite

Comp.—Perhaps FeSO₄.Fe₂(SO₄)₃ + 12H₂O = Sulphur trioxide 41.7, iron sesquioxide 20.8, iron protoxide 9.4, water 28.1 = 100.

Some analyses give more water, 15H₂O call for 32·9 p. c. Mackintosh calculates 13·7 p. c., Anal.—1, L. Tschermak, Ber. Ak. Wien, 28, 277, 1858. 2, Linck, l. c. 3, J. B. Mackintosh Am. J. Sc., 38, 243, 1889.

The simple empirical formulas are given for most of the basic hydrous sulphates above, since the data in most cases are not sufficient to determine the rational formula.

779. LANGITE. A new British mineral N. S. Maskelyne, Phil. Mag., 27, 316 1864. Langite Maskelyne, Pisani, C. R., 59, 633, 1864, Maskelyne Phil. Mag., 29, 473, 1865. Devilline Pisani, C. R., 59, 813, 1864 = Lyellite Maskelyne, Ch. News, 10, 263, 1864.

Axes $\check{a} : \check{b} : \dot{c} = 0.5347 : 1 : 0.6346 \text{ Maskelyne}^{1}$. $100 \land 110 = 28^{\circ} 8', 001 \land 101 = 49^{\circ} 53', 001 \land 011 = 32^{\circ} 24'.$

Forms: $a(100, i - \bar{i}), b(010, i - \bar{i}), c(001, 0); m(110, I); f(021, 2 - \bar{i}).$ Angles: $mm''' = *56^{\circ}$ $16', cf = *51^{\circ} 46'.$

Twins: tw. pl. m, in forms resembling aragonite. Crystals small and short; simple forms not observed. Also in fibro-lamellar and concretionary crusts, with earthy surface.

Cleavage: c, b. H. = 2.5-3. G. = 3.48-3.50. Luster of crystals vitreous; of crusts somewhat silky. Color fine blue to greenish blue; pleochroic. Translucent. Optically —. Ax. pl. $\parallel b$. Bx $\perp c$.

Comp.—Near brochantite, but contains one molecule of water of crystallization, formula CuSO₄.3Cu(OH)₂ + H₂O or 4CuO.SO₃.4H₂O = Sulphur trioxide 17.0, cupric oxide 67.6, water 15.3 = 100.

Anal.—1, Church, J. Ch. Soc., 18, 87, 1865. 2, 3, Warington, ibid. 4, Pisani, l. c. Also Tschermak, Ber. Ak. Wien, 51 (1), 127, 1865.

5.	Devilline	23.65	51.01	16.60 CaO 7.90.	FeO 2.77 = 101.93

Anals. 1, 2 on material dried in vacuo; 3, do. at 100°.

Maskelyne's early analysis (l. c.) gave 18 p. c. H₂O.

The devilline (or lyellite), which includes the incrusting variety, is, as Tschermak has shown, langite mixed with gypsum, which is apparent in scales. His analysis (ref. above) was made on the devilline containing 18 p. c. of gypsum; and he states that Pisani's analysis of the same (5) indicates the presence of 24 p. c. For an analysis of the lyellite by Church, see J. Ch. Soc., 18,

Pyr., etc.—B.B. on charcoal yields water, acid fumes, and metallic copper. Heated it passes through (1) a bright green color, losing 1 equivalent of water, and then having the ratio of some brochantite; (2) various tints of olive-green; and (3) becomes black. It has finally a strongly acid reaction.

Obs.—Found in argillaceous schist (killas) in Cornwall, in minute twinned crystals; also as

a blue crust, partly earthy. It is associated sometimes with connellite.

Named langite after Dr. Victor v. Lang, formerly of the British Museum, later Professor of Physics at Vienna.

The analyses of so-called brochantite by Berthier of a Mexican specimen, and Field of a Chilian, as well as of the artificial mineral, have the same composition assigned by Pisani and Church to the langite; and there is yet some uncertainty as to the true limits between the two species. The specimens had the green color of brochantite.

Ref.—1 Phil. Mag., 29, 473, 1865; cf. Brezina, Zs. Kr., 3, 374, 1879.

Woodwardite Church, Ch. News, 13, 85, 113, 1866, J. Chem. Soc., 19, 130, 1866.

A complex sulphate of aluminium and copper, perhaps allied to cyanotrichite (lettsomite), or perhaps only an impure uncrystallized variety of langite, mixed with aluminium hydrate. Occurs in Cornwall, in minute botryoidal concretions, of a rich turquois-blue to greenish blue color, translucent to almost transparent. G. = 2·38. Anal.—1, Church, l. c. 2, 3, Warington, ibid. 4, Pisani, C. R., 65, 1142, 1867.

		SO ₃ Al ₂ C	CuO	H_2O	
1.	Cornwall	13.95 77.9	7 48.34	18.48 =	98.74
2.	"	13.04 . 18.6	4 48 67	[19.65] =	100
3.	"	12.54 17.9	3 46.80	[22.73] =	100
4.	"	11.7 13.4	46.8	[26·9] Si	$O_2 \ 1.2 = 100$

The material of 1, 2 was dried at 100°, of 3 in vacuo over H₂SO₄.

Church and Warington also found traces of silica, lime, magnesia, and phosphoric acid, which were undetermined. Pisani makes the mineral impure langite. He analyzed (l. c.) another similar material from Cornwall (received from Mr. Talling), of a clear green color, and obtained: SO₃ 4.7, Al₂O₃ 33.8, CuO 17.4, H₂O 38.7, SiO₂ 6.7 = 100.5; showing a mixture of the copper sulphate with a hydrous silicate of aluminium as well as hydrate; and this he considers as proving that woodwardite is only a mixture. Analyses by Maskelyne & Flight (J. Ch. Soc.,

24, 1, 1871), confirm this view.

The mineral is soluble with scarcely any residue in diluted acids. Named after Dr. S. P.

Woodward.

780. HERRENGRUNDITE. Brezina, Zs. Kr., 3, 359, 1879. Urvölgyite Szabó, Min. Mitth., 2, 311, 1879, and Lit. Ber. Ungarn, 3, 510, 1879.

Monoclinic. Axes $\dot{a}: \bar{b}: \dot{c} = 1.8161:1:2.8004; \ \beta = 88^{\circ} \ 50\frac{1}{6}' = 001 \ \land \ 100$ Brezina'.

Twins: tw. pl. c (001); perhaps also n (750). In thin six-sided tabular crys

tals with c striated $\parallel a$. Usually in spherical groups.

Cleavage: c perfect; γ (or m) rather distinct; also e or ϵ . Rather brittle.

H. = 2.5. G. = 3.132. Luster vitreous; on c sometimes pearly. Color emerald-green, verdigris-green, and bluish green. Pleochroic: $\parallel \mathbf{r}$ yellowish green, $\parallel \mathbf{b}$ bluish green. Streak light green. Transparent. Optically —. Ax. pl. $\perp b$ and sensibly $\parallel a$. Bx $\perp c$. Axial angles, Brezina:

$$2E_r = 59^{\circ} 2' \text{ Li}$$
 $2E_r = 65^{\circ} 18' \text{ to } 66^{\circ} 53' \text{ Na}$ $2E_{gr} = 68^{\circ} 39' \text{ Tl}$

Comp.—2(CuOH), SO₄.Cu(OH), + 3H₂O with one-fifth of the copper replaced by calcium, or CaO.4CuO.2SO₃.6H₂O = Sulphur trioxide 25.0, cupric oxide 49.4, lime 8.7, water 16.9 = 100.

Anal.-1, Berwerth, Zs. Kr., 3, 373, 1879. 2, Schenek, Min. Mitth., 2, 315, 1879. 3, Winkler, Jb. Berg-Hütt., Sachs., 1886.

SO₃ CuO CaO H₂O
1. 24 62 54 16 2 05 19 61 = 100 44
2. 24 62 49 52 8 59 16 73 S₂O₂ 0 33, FeO 0 14, MnO, MgO
$$tr. = 99 \cdot 93$$

3. G. = 2 \cdot 906 24 \cdot 59 49 \cdot 96 8 \cdot 17 17 \cdot 76 = 100 \cdot 48

Brezina regards the CaO as present in the form of gypsum as an impurity; deducting this the result obtained is: SO₃ 23.04, CuO 57.52, H₂O 19.44 = 100. Szabó, on the contrary,

regards the CaO as essential, which is confirmed by Winkler, and also indirectly by Weisbach

(cf. arnimite, following).

Pyr., etc.—On charcoal, loses its green color, becomes black and fuses; with soda a copper bead. Soluble in nitric acid in hydrochloric acid and in ammonia with a residue of calcium sulphate.

Obs.—Occurs with malachite and calcite in a quartz-conglomerate at Herrengrund in Hungary. Related to langite, brochantite, etc. Also on the Sandberg, between Altgebirg and Herrengrund. Named from the locality Herrengrund = Urvölgy in the Hungarian language.

Ref.—1 L. c.; these forms are not all certain. Cf. Gdt., Index, 2, 149, 1890.

780A. Arnimite. Weisbach, Jb. Berg-Hütt., Sachs., 1886.

Forms a bright green incrustation, consisting of short acicular or scaly crystals.

Comp.—2(CuOH)₂SO₄.Cu(OH)₂ + 3H₂O or 5CuO.2SO₃.6H₂O = Sulphur trioxide 24·1, cupric oxide 59·6, water 16·3 = 100. Corresponds to the preceding species, but differs in containing no lime.

Anal.-1, 2, Winkler; 2 containing gypsum.

	SO_3	CuO	Fe_2O_3 , Al_2O_3	CaO	H_2O
1.	24.43	56.81	0.35	0.56	[17.85] = 100
2.	2 28.73	46.38	0.84	6.89	$ \begin{bmatrix} 17.85 \\ 17.16 \end{bmatrix} = 100 $

Deducting impurities and recalculating, the result obtained is: SO₃ 24·07, CuO 59·69, H₂O 16.24 = 100. This corresponds, as noted above, to herrengrundite.

Obs.—Occurs on porcelain-jasper in the coal region at Planitz near Zwickau. Named for the family von Arnim.

781. CYANOTRICHITE or LETTSOMITE. Kupfersammeterz, Kupfersammterz, Wern., Karsten's Tab., 62, 1808. Velvet Copper Ore Jameson, Min., 3, 153, 1816. Sammeterz Breith., Char., 168, 1823, 320, 1832. Cuivre velouté Fr. Cyanotrichit Glocker, Grundr., 587, 1839. Lettsomite Percy, Phil. Mag., 36, 100, 1850.

Orthorhombic. Occurs in velvet-like druses of short capillary crystals; some-

times in spherical globules.

Color clear smalt-blue, sometimes passing into sky-blue; strongly pleochroic. Luster pearly. Optically biaxial, negative. Ax. pl. | and Bxa \(\pm\$ to the direction of elongation of the crystals. Dispersion $\rho < v$ large Btd.

Comp.—Perhaps 4CuO.Al₂O₃.SO₃.SH₂O (Genth) = Sulphur trioxide 12.4,

alumina 15.9, cupric oxide 49.3, water 22.4 = 100.

Percy calculated 6CuO.Al₂O₃.2SO₃.12H₂O, which requires: Sulphur trioxide 16.8, alumina

10·7, cupric oxide 49·8, water 22·7 = 100.

Anal.—1, 2, Percy, l. c. 3, Pisani, C. R., 86, 1418, 1878. 4, 5, Genth, Am. J. Sc., 40, 118, 1890.

5. Utah	12.60 15.	45 0.91 49.54	[21.50] = 100

Obs.—Occurs sparingly at Moldawa in the Banat, coating the cavities of an earthy hydrated iron oxide, along with a white amorphous aluminium sulphate. Also at the copper mines of Cap Garonne, Dept. du Var, France.

In Utah, at Copperopolis, formerly the American Eagle mine, Tintic district; also in Arizona, at the Copper Mountain mine near Morenci, Graham Co.

Named Cyanotrichite from κύανος, blue, and θρίξ, hair; and Lettsomite after the English mineralogist, W. G. Lettsom.

Ref.—1 Bull. Soc. Min., 4, 11, 1881.

782. SERPIERITE. Des Cloizeaux, Bull. Soc. Min., 4, 89, 1881.

Orthorhombic. Axes $\ddot{a}: \ddot{b}: \dot{c} = 0.8586:1:1.3637$ Des Cloizeaux. $100 \land 110 = 40^{\circ} 39', 001 \land 101 = 57^{\circ} 48\frac{1}{3}', 001 \land 011 = 53^{\circ} 44\frac{6}{3}'.$

Forms: e (001, 0); m (110, I); p (111, 1); also probable, η (034, $\frac{3}{4}$ - $\tilde{\imath}$), e (011, 1- $\tilde{\imath}$); and uncertain, α (203, $\frac{2}{3}$ - $\bar{\imath}$), x (043, $\frac{4}{3}$ - $\bar{\imath}$), y (053, $\frac{5}{3}$ - $\bar{\imath}$), z (081, 8- $\bar{\imath}$), perhaps a (100, i- $\bar{\imath}$).

Angles: $mm''' = *81^{\circ} 18'$, $\alpha \alpha' = 93^{\circ} 16\frac{1}{2}'$, $\eta \eta' = 91^{\circ} 18'$, $ee' = 107^{\circ} 30'$, $xx' = 122^{\circ} 23'$, $yy' = 132^{\circ} 30', cp = *64^{\circ} 28', pp' = 86^{\circ} 25', pp''' = 72^{\circ} 0'.$

Crystals minute, tabular $\| c$, and elongated $\|$ axis $\check{\alpha}$; faces c striated $\| \check{\alpha}$; often grouped in light tufts.

Color bluish green. Transparent. Optically negative. Ax. pl. $\parallel a$. Bx $\perp c$. Dispersion $\rho > v$ strong. Axial angles, Dx.:

 $2H_{a,r} = 43^{\circ} 40' \therefore 2E_{r} = 66^{\circ} 5'; \ 2H_{a,r} = 44^{\circ} 20' \therefore 2E_{r} = 67^{\circ} 10'; \ 2H_{a,r} = 43^{\circ} 35' \therefore 2E_{r} = 65^{\circ} 57'$

Comp.—Stated by Damour to be a basic sulphate of copper and zinc.

This may prove to belong near brochantite. Obs.—Occurs on smithsonite at the zinc mines of Laurium, Greece. The probable existence of two other undetermined basic sulphates of copper at the same locality is also mentioned.

783. CASTANITE. L. Darapsky, Jb. Min., 2, 267, 1890.

Monoclinic, with a prismatic angle of 82°, and terminated by one or two oblique planes. Usually in prismatic crystals, perhaps twins; they seldom show distinct faces, which are then dull and rounded. United in massive aggregates; also in minute crystals lining cavities.

H. = 3. G. = 2·118. Luster vitreous, brilliant. Color chestnut-brown. Powder

orange-vellow.

Comp.—Fe₂O₃,2SO₃,8H₂O = Sulphur trioxide 34.5, iron sesquioxide 34.5, water 31.0 = 100.

Differs from amarantite, p. 967, only in containing one molecule more of water. Anal. - Darapsky, l. c.; 1a after deducting impurities.

	SO ₃	$\mathrm{Fe_2O_3}$	H_2O			
1.	33.80	33.92	30.76	Al2O3 tr,	barite $1.15 = 99.63$	
1a.	34.32	34.45	31.23 =	= 100		

Loss of water at 50°, 1.0 p. c.; 80°, 9.5; 100°, 11.8; 145°, 15.5; 170°, 20.5.
Only very slightly soluble in water, but dissolves in warm hydrochloric acid. Remains unchanged on exposure to the air and also in the desiccator over calcium chloride.

Obs.—From Sierra Gorda, Chili; occurs implanted upon olive-green crystalline copiapite and

associated with minute barite crystals.

Named in illusion to its chestnut-brown color. RUBRITE L. Darapsky, Jb. Min., 1, 65, 1890.

In indistinct lamellar crystals of a deep red color, penetrated by white nodules and clear zones, which are present even in the purest portions and hence make the physical characters and composition of the remainder more or less doubtful. Iron sesquioxide is separated by cold water. Analyses:

SO₃ 41·15 Fe₂O₃ 18·22 Al2O3 3.01 MgO 5.62 CaO 4.10 $H_2O 27.64 = 99.84$

For this the formula calculated is: 2½CaO.4½MgO.Al₂O₃.4Fe₂O₃.17SO₃.51H₂O. Deducting gypsum and epsomite, the result is: Fe₂O₃.2SO₃.3H₂O = Sulphur trioxide 42.8, iron sesquioxide 42.7, water 14.5 = 100.

From the neighborhood of the Rio Loa, Chili.

784. COPIAPITE. Miov Diosc. Misy (fr. Cyprus, etc.) Plin., 34, 31. Misy, Germ. Gelb Atrament (fr. Harz, etc.) Agric., Nat. Foss., 213, 457, Interpr., 466, 1546. Misy, Gul Atrament Sten, Lapis atramentarius flavus, Wall., Min., 159, 1747. Misy (fr. Harz) Hausm., Handb., 1061, 1813, 1203, 1847. Gelbeisenerz Breith., Char., 97, 238, 1823, 223, 1832. 				[insol. $0.75 = 100$]

Loss of water in anal. 1. 12.73 p. c. at 110°; in 2, two-thirds (12 molecules) at 110°; in 3, 1 molecule at 75°, 2½ at 100°, 4 at 140°, 6 at 150°, 7 at 190°.

Melville calculates for anal. 4, the formula: RO.2R₂O₃.6SO₃.20H₂O, but in other analyses protoxides are nearly or quite wanting. Darapsky writes the formula: Fe₂O₃.2½SO₃.8H₂O for the mineral analyzed by him, or intermediate between coquimbite and amarantite. He proposes, moreover, to drop the name coquimbite and to use copiapite broadly for ferric sulphates soluble

moreover, to drop the name cogulimate, and to use copiapite broadly for terric surpliates soluble in water, which have one equivalent of iron sesquioxide to more than two of sulphur trioxide. The individual minerals he would call, violite, flaveite, elite, niveite, etc.

Misy is an old term, which has been somewhat vaguely applied. It seems to belong in part here and in part also to other related species (cf. metavoltine, p. 972). The description of Dioscorides is unsatisfactory, but that of Pliny, not over 25 years later, is good, and may represent the true μίσυ of the Greeks; also that of Agricola, which was taken from specimens from the Ranmelsberg mine near Goslar in the Harz, to which the name has been particularly applied. It is the result there of the decomposition of pyrite.

Analyses by List (Lieb Ann. 74, 239, 1850) of this mineral there of the decomposition of pyrite. Analyses by List (Lieb. Ann., 74, 239, 1850) of this mineral

gave:

	SO_3	Fe_2O_3	ZnO	MgO	K_2O	H_2O
1. Goslar	42.92	30.07	2.49	2.81	0.32	21.39 = 100
2. "	43.21	30.37	-	-	-	undet.

Rammelsberg deducts magnesium sulphate 17.25, zinc sulphate 8.83, potassium sulphate 0.57, and obtains:

> SO₃ 47·15 $\text{Fe}_2\text{O}_3 41.00$ $\text{H}_2\text{O} 11.85 = 100$

For this he calculates 4Fe₂O₃.9SO₃.11H₂O; but the result is doubtful. Pyr., etc.—Yields water, and at a higher temperature sulphuric acid. On charcoal becomes magnetic, and with soda affords the reaction for sulphuric acid. With the fluxes reacts for

iron. Soluble in water, and decomposed by boiling water.

Obs.—The original copiapite described by Rose was from Copiapo. It is well represented at the Tierra Amarilla, near Copiapo, Chili, as an incrustation on coquimbite, or alone with copper

and iron vitriols; also near Caracoles, in crystalline masses.

Occurs in soft masses of sulphur-yellow scales at the Redington mine, Knoxville, Cal.; the crystals are described as orthorhombic with prism of 78°, ax. pl. $\parallel b$ (010), Bx_o $\perp c$. Also at Sulphur Bank, Lake Co., California, as a result of the decomposition of marcasite, on cinnabar.

A ferric sulphate, containing 38 p. c. SO₃ (Hillebrand) has been noted from the neighborhood of Las Vegas, N. Mexico (Pearce, Proc. Col. Soc., 3, 228, 1889).

Ref.—¹ Zs. Kr., 15, 14, 1888; a number of doubtful planes are added.

785. KNOXVILLITE. G. F. Becker, U. S. G. Surv., Mon., 13, 279, 389, 1888 (issued 1889). W. H. Melville and W. Lindgrén U. S. G. Surv., Bull. 61, 24, 1890.

Orthorhombic? In rhombic plates with angles of 78° and 102°, and inferred to be isomorphous

with copiapite.

Cleavage: basal, perfect; prismatic and orthodiagonal, also good. Color greenish yellow. Pleochroic. Optically biaxial. Of the axes of elasticity in the basal plane, the greater is parallel to the brachydiagonal axis.

Comp.—A hydrous basic sulphate of chromium, ferric iron, and aluminium, probably related

to copiapite.

The calculated ratio gives the complex formula 54RO.70R₂O₃.165SO₃.540H₂O, which is not very far from 3RO.4R₂O₃.9SO₃.30H₂O.

Anal.—Melville and Lindgren, l. c., on 0.148 grams.

H₂O above 100° SO₃ Cr2O3 Al2O3 Fe2O3 FeO MgO NiO H₂O (100°) gangue 7.41 4.84 15.36 3.81 3.22 0.83 17.60 9.30 1.73 = 10035.90

Obs.—Occurs with redingtonite at the Redington mercury mine, Knoxville, California.

REDINGTONITE. G. F. Becker, U. S. G. Surv., Mon., 13, 279, 1888. W. H. Melville and W. Lindgren, U. S. G. Surv., Bull. 61, 23, 1890.

A hydrous chromium sulphate, occurring in finely fibrous masses of a pale purple color, in part white with silky luster and only purple on a surface perpendicular to the fibers. Also massive with crystalline structure. G. = 1.761. Extinction oblique (13° to 38°). Double refraction feeble. Soluble in water. When heated turns green without losing all its water.

In composition, a hydrous sulphate of chromium, aluminium, iron, etc. The calculated formula is 9RO.8R₂O₃.33SO₃.171H₂O. The sample analyzed was moist and part of the water

may hence be simply hygroscopic.

Anal.—Melville and Lindgren, l. c.

MgO H₂O (above 100°) H₂O (100°) gangue SO3 Cr₂O₃ Al₂O₃ Fe₂O₃ FeO NiO 35.35 7.51 3.14 0.19 4.58 1.00 1.85 14.34 27.09 3.46 = 100.51

Occurs at the Redington mercury mine, Knoxville, California, where (Becker) it results from the action of solfataric gases on chromite.

786. UTAHITE. A. Arzruni, Zs. Kr., 9, 558, 1884; Bull. Soc. Min., 4, 126, 1884.

Rhombohedral. Axis c = 1.1389; 0001 \land 1011 = *52° 45' Arzruni. aggregates of fine scales resolved under the microscope into tabular hexagonal crystals (c, m) with rhombohedral faces (r).

Color orange-vellow. Luster silky.

Comp.—3Fe,0,.3SO,.4H,0 = Sulphur trioxide 30.3, iron sesquioxide 60.6, water = 9.1 = 100.

Anal.—Damour, Bull. Soc. Min., 7, 128, 1884.

H₂O 9.35 $As_2O_6 3.19 = 99.81$ SO₃ 28.45 Fe₂O₃ 58.82

Pyr., etc.—Gives off acid water in the closed tube and turns red. On charcoal becomes black and fuses with some difficulty to a black magnetic scoria.

Obs.-Occurs as an incrustation on quartz at the Eureka Hill mine, in the Tintic district,

Utah. Genth & Penfield mention a ferric sulphate occurring in minute brownish white, apparently hexagonal, scales at the Mimbres mine near Georgetown, N. Mexico, with vanadinite, descloizite, quartz. It seemed to contain no water, and the results of an incomplete analysis led to the ratio of Fe_2O_3 : $SO_3 = 1:1$, with, however, 17 or 18 p. c. unaccounted for.

2.

787. AMARANTITE. Frenzel, Min. Mitth., 9, 398, 1887. Hohmannite A. Frenzel, Min. Mitth., 9, 397, 1887.

Cf. also Frenzel, l. c., and Min. Mitth., 11, 21, 223.

Obs.—From a vein of argentiferous lead ores with sphalerite, chalcopyrite, atacamite, etc., near Caracoles, Chili, some leagues north of Sierra Gorda; it occurs in copiapite; also from the Sierra de la Caparrosa between Calama and Sierra Gorda.

Named amarantite in allusion to the red color; hohmannite after the discoverer, mining engineer Th. Hohmann of Valparaiso.

Ref.—1 Am. J. Sc., 40, 199, 1890. The optical determinations of Wülfing (Min. Mitth., 9, 403, 1887) agree substantially with those of Penfield.

PAPOSITE L. Darapsky [Bol. Soc. Min., Santiago, 735, 1887], Jb. Min., 1, 23 ref., 1889. In crystals and in radiate-fibrous masses. Cleavage distinct. Brittle. Color dark red. Composition calculated by Darapsky, 2FeO₃.3SO₃.10H₂O = Sulphur trioxide 32.5, iron sesquioxide 43.2, water 24.3 = 100.

Anal.—1, Darapsky, l. c. 2, Gräbner, quoted by Frenzel, Min. Mitth., 11, 223, 1890.

1. SO	24.72	Fe ₂ O ₃ 30·00	H ₂ O 16·43	Chalcanthite 28.85 = 100
1a.	34.74	42.17	23.09 = 1	00
2.	36.18	35.92	28.13 = 1	00.23

The analysis of Gräbner as shown by Frenzel makes paposite identical with hohmannite and amarantite; this assumes that essentially the same minerals were analyzed in the case of

Occurs at the Union mine, Reventon district, near Paposa in Atacama, embedded in massive copper vitriol.

Ferric Sulphates. Mackintosh has analyzed (Am. J. Sc., 38, 243, 245, 1889) several ferric sulphates from Chili, which cannot be classed with known species, and yet which are not sufficiently known to deserve independent position.

A. Occurs with copiapite and amarantite in pulverulent orange flakes arranged in parallel It may be a result of the alteration of amarantite; the calculated formula is

Fe₂O₃.2SO₃.4H₂O. Loss of water at 110°, 0.304 molecules; cf. also rubrite, p. 964.

B. White, pulverulent; calculated formula, 4FeO.Fe₂O₃.6SO₃.19H₂O. Loses 9.6 molecules of water (or one half) at 110°

C, D. Both white powders. For C, the approximate formula belongs: 12Na₂O.7FeO. 6Fe₂O₃.Al₂O₃.10SO₃.10H₂O. For D, 1½Na₂O.12FeO.8FeO.14SO₃.19H₂O. Analyses:

	SO ₃	Fe ₂ O ₃	Al ₂ O ₂	FeO	Na ₂ O	H_2O

Pyr., etc.—Same as for copiapite.

Obs.—From the Tierra Amarilla near Copiapo, Chili, in delicately fibrous masses, associated with coquimbite; also from the mines of Paillières, Dept. du Gard, France (cf. pastreite below). An iron sulphate of similar appearance (anal. 8) occurs at the Black Iron mine, Red Cliff, Colorado.

The name alludes to the fibrous structure. There is no reason to doubt the identity of Pri-

deaux's fibroferrite of 1841 with the mineral analyzed by Rose, Smith, and others, and which Hausmann named stypticite in 1847.

789. RAIMONDITE. Raimondit Breith., B. H. Ztg., 25, 149, 1866.

Hexagonal or rhombohedral. In thin six-sided tables with replaced basal

edges, scale-like.

Cleavage: basal, perfect. H. = 3-3.25. G. = 3.190-3.222. Luster pearly. Color between honey- and ocher-yellow. Streak ocher-yellow. Opaque. Optically uniaxial, negative.

Comp.—2Fe, O, 3SO, 7H, O = Sulphur trioxide 35.0, iron sesquioxide 46.6,

water 18.4 = 100.

Anal.-Rube, l. c.

Bolivia SO, 36.08 Fe₂O₃ 46.52 $H_2O 17.40 = 100$

Rg. refers here the mineral from Greenland analyzed by Pisani; this analysis is given under carphosiderite below.

Pyr., etc.—Probably the same as for copiapite, but in water insoluble.

Obs.—From the tin mines of Ehrenfriedersdorf, in scales on cassiterite; also from the tin mines of Bolivia (unless the two localities have been confounded), cf. Raimondi, Min. Pérou, 231, 1878.

PASTREITE Norman, Bergemann, Vh. Ver. Rheinl., 17, 1866. This may be the above species, if part of the iron is present as limonite. According to Bergemann, it occurs amorphous or reniform, of a yellow color, at Paillières, near Alais, Dept. du Gard, with cerussite, limonite, calcite, gypsum, fibroferrite (cf. anal. 7, above); B.B. infusible, in hydrochloric acid easily soluble. The analyses gave :

SO₃ SiO₂ As₂O₅ Fe₂O₃ PbO H₂O 1.86 46.50 1.25 1. Yellow 30.47 2.40 $16.04 \text{ Al}_2\text{O}_3$, MnO, CaO 0.89 = 99.412. Yellowish brown 30.55 2.05 52.80 $13.95 \text{ Al}_2\text{O}_3$, CaO, sand 0.63 = 99.98

Received by Dr. Bergemann from Dr. Normann, of Marseilles, who named it after President Pastré, of that city. It approaches jarosite except in the absence of alkalies.

APATELITE Meillet, Ann. Mines, 3, 808, 1841.

In small friable nodules or balls. Color clear yellow. Resembles copiapite. Composition, perhaps, $4\text{Fe}_2\text{O}_3.6\text{SO}_3.3\text{H}_2\text{O} = \text{Sulphur trioxide }40.9$, iron sesquioxide 54.5, water 4.6 = 100. Anal.-Meillet.

> Fe₂O₃ 53·30 $H_2O 3.96 = 100.16$ SO₃ 42.90

Occurs at Meudon and Auteuil, disseminated in an argillaceous bed connected with the plastic clay.

790. CARPHOSIDERITE. Karphosiderit Breith., Schw. J., 50, 314, 1827.

Rhombohedral? In reniform masses, and incrustations; also in lamellæ

grouped as in mica.

Cleavage: basal, easy. H. = 4-4.5. G. = 2.49-2.50 Breith.; 2.728 Pisani, Luster resinous. Color pale and deep straw-yellow. Streak yellowish. greasy. Optically uniaxial, positive. Double refraction strong.

Comp.—A basic ferric sulphate, perhaps 3Fe₂O₃.4SO₃.10H₂O = Sulphur tri-

oxide 32.7, iron sesquioxide 48.9, water 18.4 = 100.

The P2O5 is regarded (Lcx.) as partly replacing the SO3.

Anal.—1, Pisani, C. R., 58, 242, 1864, after deducting 15 p. c. sand, 9 p. c. gypsum. 2, Lacroix, Bull. Soc. Min., 10, 142, 1887.

SO₃ Fe₂O₃ H₂O 49.88 1. Greenland G. = 2.72831.82 18.30 = 10030.18 48.52 18.48 P₂O₅ 2.72 = 99.90 2. St. Léger

Supposed by Harkort after blowpipe trials to be a hydrous phosphate; but shown by Pisani's analysis of an original specimen to be a sulphate.

Pyr., etc.—B.B. nearly like copiapite, but insoluble in water. Readily soluble in hydro-

chloric acid.

Obs.—Occurs in fissures in mica slate, and was first distinguished by Breithaupt among some specimens which he says were from Labrador. Pisani's specimens were from the Kölburg collection in Paris, and were labeled Greenland, most probably the true locality. In the sandstone quarries at Saint-Léger near Mâcon, France.

The name alludes to the color, and is from $\kappa \alpha \rho \phi o s$, straw, $\sigma i \delta \eta \rho o s$, iron.

791. ALUMINITE. Reine Thonerde (fr. Halle) Wern., Ueb. Cronstedt, 176, 1780. Native Argill Kirwan, Min., 1, 175. Aluminit C. C. Haberle, Das Mineralreich, etc., 1807; Karst., Tab., 48, 1808. Hallite Delameth., Min., 2, 1812. Websterite Levy, in Brooke, 1823. Hydrosulphate d'alumine, Websterite, Beud., Tr., 449, 1824.

Usually in compact, reniform masses.

Fracture earthy. H. = 1-2. G. = 1.66. Luster dull, earthy. Color white. Opaque. Adheres to the tongue; meager to the touch.

Comp.—A hydrous aluminium sulphate, AI, O, SO, 9H, O = Sulphur trioxide

23.3, alumina 29.6, water 47.1 = 100.

Analyses agree closely, see 5th Ed., p. 658; also App. II, III.

Pyr., etc.—In the closed tube gives much water, which, at a high temperature, becomes acid from the evolution of sulphurous and sulphuric acids. B.B. infusible. With cobalt solution a fine blue color. With soda on charcoal a hepatic mass. Soluble in acids.

Obs.—Occurs in connection with beds of clay in the Tertiary and Post-tertiary formations. First found in 1730 in the Garden of the Pædagogium at Halle; afterward suspected to be an artificial product from a manufactory near by; subsequently found elsewhere in the plastic clay of the region, and proved to be native. Since discovered by Mr. Webster at Newhaven, Sussex, in reniform and botryoidal concretions, embedded in ferruginous clay, which rests on the Chalk strata; under similar circumstances at Epernay, in Lunel Vieil, and Auteuil, in France; also at Mühlhausen near Kralup; at Kuchelbad in Bohemia.

WERTHEMANITE Raimondi, Min. Pérou, p. 244, 1878; Domeyko, 5th Append., Min. Chili, 1876.

Massive, easily reduced to powder. G. = 2.80. Color white. Gives an argillaceous odor, and adheres to the tongue. Composition, Al₂O₃.SO₃.3H₂O = Sulphur trioxide 33.9, alumina 43.2, water 22.9 = 100. Analysis:

Al2O2 45.00 SO₃ 34.50 Fe₂O₃ 1.25 $H_2O 19.25 = 100$

B.B. infusible. Soluble in acids. B.B. infusible; after ignition gives a blue color with cobalt solution. Insoluble in acids. Found in a bed of clay near the city of Chachapoyas, Peru. It differs from aluminite only in containing less water.

Winebergite Gümbel [Ostbayer, Grenzgeb., 260] Roth, Allg. Ch. G., 1, 239, 1879. A basic sulphate of aluminium occurring with pissophanite at the Löwmühl near Passau; also at Bodenmais. Analysis:

Al₂O₃ 40.80 FeO 2.60 MgO 0.78 $H_2O 40.21 = 100$ SO₃ 15.61

792. GLOCKERITE. Vitriolocker Berz., Afh., 5, 157, 1816. Fer sous-sulfaté terreux Berz., N. Min. Syst., 1819. Vitriol Ocher. Pittizite Beud., Tr., 447, 1824. Glockerit Naum., Min., 254, 1855.

Massive, sparry or earthy. Stalactitic.

Luster resinous or earthy. Color brown to ocher-yellow, also brownish black to pitch-black;

dull green. Strenk ocher-yellow to brown. Opaque to subtranslucent. Comp., Var.—2Fe₂O₃.SO₃.6H₂O = Sulphur trioxide 15.7, iron sesquioxide 63.0, water 21.3 = 100. This formula was given by Berzelius for a brown to ocher-yellow variety, occurring

with botryogen at Falun, containing according to him: SO₃ 15.9, Fe₂O₃ 62.4, H₂O 21.7 = 100.

The same for a stalactitic variety from Obergrund, near Zuckmantel, the stalactites of which are sometimes 2 feet long, brown to pitch-black, yellowish brown, and dark green in color, with yellowish brown to ocher-yellow streak, shining luster to earthy, and insoluble in water. It is the *Glockerite* of Naumann, who cites Hochstetter's analysis: SO₃ 15·19, Fe₂O₃ 64·34, H₂O 20·7, agreeing closely with that by Berzelius.

Jordan obtained for a compact and earthy vitriol ocher from the Rammelsberg mine near Goslar (J. pr. Ch., 9, 95, 1836), and Scheerer for another from Modum, Norway (Pogg., 45, 188, 1838):

SO3 Fe₂O₃ H₂O 1. Goslar, compact 13.59 63.85 18.46 ZnO 1.23, CuO 0.87, gangue 2.00 = 10068.75 80.73 15.52 ZnO 1.29, CuO 0.50, gangue 4.14 = 100 earthy 9.80 3. Modum, brown 6.00 13.57 = 100.30

Obs.—A result of the alteration of pyrite or marcasite. Glockerite was named after the mineralogist E. F. Glocker. Pitticite is the name of pitch ore (p. 867).

793. FELSÖBANYITE. Felsöbanyt Kenng., Ber. Ak. Wien, 10, 294, 1853; Haid., ib., 12, 183, 1854.

Orthorhombic. Massive, and in concretions, grouped or single, consisting of scales, which are hexagonal, and have two angles of 112°. Cleavage perfect. Optically biaxial.

H. = 1.5. G. = 2.33. Luster of cleavage-face pearly. Color snow-white,

surface often yellowish. Translucent to subtransparent.

Comp.—2Al, O., SO, 10H, O = Sulphur trioxide 17.2, alumina 44.0, water 38.8 = 100.

Anal.-Hauer, Ber. Ak. Wien, 12, 188, 1854.

 $H_2O 37.27 = 99.27$ 3 SO₃ 16.47 Al₂O₃ 45.53

Pyr., etc.—Nearly as for aluminite. Obs.—From Kapnik near Felsöbánya in Hungary, the concretions sometimes grouped on barite

794. PARALUMINITE. Paraluminit Steinberg, J. pr. Ch., 32, 495, 1844.

Massive, and like aluminite. White to pale yellow.

Comp.—Near aluminite, but supposed to be 2Al₂O₃.SO₂.15H₂O = Sulphur trioxide 14·5, alumina 36.8, water 48.7 = 100.

Anal.—Schmid, l. c.

 $H_2O 49.03 = 99.74$. SO₃ 14.54 Al2O3 36.17

Other analyses (5th Ed., p. 661) correspond more or less closely. The species cannot be regarded as well established.

Obs.—Similar in its modes of occurrence to aluminite. Found in Pressler's Mountain and elsewhere, near Halle, and at Huelgoat in Brittany.

PISSOPHANITE. Pissophan Breith., Char., 101, 1832. Garnsdorfite.

Amorphous or stalactitic, somewhat pitch-like in appearance. Fracture conchoidal. Very fragile. H. = 1.5. G. = 1.93-1.98. Luster vitreous. Color pistachio-, asparagus-, or olive green. Transparent. Analyses.—Erdmann, Schw. J., 62, 104, 1831.

			SO_3	Al ₂ O ₃	Fe_2O_3	H_2O	
1.	Green	2	12.59	35.23	9.77	41.69	0.72 = 100
2.	Yellow ocherous		11.90	6.80	40.06	40.13	1.11 = 100

For the most part insoluble in water. Easily soluble in hydrochloric acid. B.B. becomes black. In a glass tube gives off alkaline water.

Occurs at Garnsdorf, near Saalfeld, and at Reichenbach, Saxony, on alum slate. Named

from $\pi i \sigma \sigma \alpha$, pitch, and $\phi \alpha i \nu \epsilon \sigma \vartheta \alpha i$, to appear. Probably not a simple mineral.

795. CYPRUSITE. P. F. Reinsch, Proc. Roy. Soc., 33, 119, 1881. J. Deby, J. R. Micr. Soc., 4, 186, 1884.

Hexagonal? An aggregation of microscopic crystals with hexagonal crosssections.

Soft, chalk-like. H. = 2. G. = 1.7-1.8. Color yellowish; in powder intense sulphur-yellow.

Comp.—A hydrous ferric sulphate, perhaps 7Fe₂O₃.Al₂O₃.10SO₃.14H₂O = Sulphur trioxide 35.2, iron sesquioxide 49.2, alumina 4.5, water 11.1 = 100.

Anal.—H. Fulton, after deducting insoluble portion, J. R. Micr. Soc., 4, 187, 1884.

SO₃ 35.34 Fe₂O₃ 49.68 Al₂O₃ 3.89 $H_2O 11.06 = 99.97$

The amount of alumina is variable. An earlier approximate analysis was made by Reinsch.

Insoluble or but slightly soluble in water. Soluble in acids, leaving a residue. Obs.—Forms veins of considerable magnitude in a doleryte on the island of Cyprus, in the district of Chrysophone, especially on the right bank of the Balahussa. The veins are marked on the surface by a series of ridges several hundred meters long and 25 to 90 broad, having a yellow or vermilion color. The mineral incloses great quantities of the siliceous shells of Radiolaria.

ERUSIBITE Shepard, Rep. Mt. Pisgah Copper Mine, N. Haven, 1859; Am. J. Sc., 28, 129, 1859. A "rusty insoluble ferric sulphate" of undetermined nature. His copperasine (ib.) is announced as a "hydrous cuprous and ferric sulphate," from the same place. His leucanterite (ib.) is an efflorescence on the copperasine. These are names without descriptions.

796. VOLTAITE. Voltaite A. Scacchi, Accad. Sci. Nap., 1840. Zs. G. Ges., 4, 163, 1852. Isometric? In octahedrons, cubes, and dodecahedrons, and combinations of these forms'.

Fracture conchoidal. H. = 3-4. G. = 2.79. Luster resinous. oil-green, greenish black, brown, or black. Streak grayish green. Opaque.

Comp.—Perhaps 5RO.2R₂O₃.10SO₃.15H₂O Blaas. Tschermak calculates for

anal. 1, $K_0O : FeO : Fe_0O_3 : SO_3 : H_2O = 1:5.5:3.4:15.6:22.6$.

Anal.—1, Tschermak, Ber. Ak. Wien, 56 (1), 831, 1867. 2, Blaas, ibid., 87 (1), 143, 1883. An early incorrect analysis was made by Dufrénoy, and another on artificial crystals by Abich (5th Ed., p. 652).

SO₃ Al₂O₃ Fe₂O₃ FeO MgO K₂O Na₂O H₂O G. 2.79 48.0 5.1 12.9 15.6 3.6 tr. 1. Kremnitz 2.6 49.12 3.72 13.85 5.24 7.35 2.37 1.62 16.60 = 99.872. Persia

Pyr., etc.—Soluble in water with difficulty, and at the same time decomposes.

Obs.—This species was first observed at the solfatara near Naples, by Breislak (1792). It has been found by F. Ulrich at the Rammelsberg mine near Goslar in the Harz. The last contains manganese protoxide as well as iron. From Kremnitz in melanterite.

In a pyritiferous trachyte from the region of Madeni Zakh, Persia; the crystals (anal. 2) are

described by Blaas, l. c., as tetragonal, having $\dot{c} = \text{nearly 1}$ and with the forms: 111, 100, 101, and 102. Complex twins, fourlings resembling hausmannite, as inferred from the optical examination. Optically uniaxial. Color greenish black.

Ref.—1 On the form see Blaas, above, and Ber. Ak. Wien, 87 (1), 143, 1883; but cf. Streng, Jb. Min., 2, 164 ref., 1884. Tschermak describes the crystals examined by him as isometric, and, in habit, octahedral with cubic and dodecahedral faces. Both the form and composition are hence somewhat uncertain; it is possible that analyses 1, 2, were made on different minerals.

Pettkoite. A. Paulinyi, Jb. Min., 457, 1867. Described as isometric, in cubes. H. = 2.5. Luster bright. Color pure black. Streak dirty greenish. Taste sweetish. Anal.—A. Paulinyi:

SO₃ 45.32 Fe₂O₃ 44.92 FeO 6.66 $H_2O 1.51 = 98.41$

From Kremnitz, in a breccia, along with iron-vitriol (melanterite), in crystals from the size of peas to millets, and in grains. Named after Bergrath v. Pettko.

Tschermak has shown that pettkoite is only voltaite, the analysis being incorrect. Ber. Ak. Wien, 58 (1), 831, 1867.

797. METAVOLTINE. J. Blaas, Ber. Ak. Wien, 87 (1), 155, 1883.

Hexagonal. In aggregates of minute six-sided scales. $H_{\cdot} = 2.5$. $G_{\cdot} = 2.53$. Color yellow. Dichroic: ω yellow, ϵ green.

Comp.—Perhaps 5(K₂, Na₂, Fe)O.3Fe₂O₃.12SO₃.18H₂O. Analysis.—Blaas, l. c.

FeO 2.92 K2O 9.87 Na₂O 4.65 SO₃ 46.90 Fe₂O₃ 21.20 $H_2O 14.58 = 100.12$

Dissolves slowly and imperfectly in cold water; upon heating a red powder separates. Slowly soluble in hydrochloric acid.

Obs.—Occurs with voltaite in a pyritiferous trachyte from Madeni Zakh in Persia. The

author states that much so-called misy belongs here.

The above is very near the compound sometimes named Maus's salt (Maus, Pogg., 11, 78, 1827) (the mausite of Haidinger, Ber. Ak. Wien, 11, 393, 1853).

798. BOTRYOGEN. Rother Eisen-Vitriol Berz., Afh., 4, 307, 1815. Red Iron Vitriol. Fer sulfaté rouge Fr. Botryogen Haid., Pogg., 12, 491, 1828. Neoplase pt. Beud., Tr., 2, 483, 1832. Botryt Glock., Syn., 300, 1847.

Monoclinic. Axes $\hat{a}: \hat{b}: \hat{c} = 0.65215: 1:0.5992; \beta = 62^{\circ} 26\frac{1}{5} = 001 \land 100$ Marainger'.

 $100 \land 110 = 30^{\circ} 2',001 \land 101 = 54^{\circ} 474',001 \land 011 = 27^{\circ} 58\frac{2}{3}'.$

Forms: $b\ (010,\ i\cdot\dot{i}),\ c\ (001,\ 0);\ m\ (110,\ I),\ f\ (120,\ i\cdot\dot{2});\ x\ (\bar{1}01,\ 1\cdot\bar{i});\ v\ (023,\ \frac{\pi}{2}\cdot\dot{i});\ n\ (\bar{1}11,\ 1).$

Angles: $mm''' = *60^{\circ} 4'$, $ff' = 81^{\circ} 42'$, $a'x = 62^{\circ} 46\frac{1}{4}'$, $vv' = *39^{\circ} 0'$, $cm = *66^{\circ} 23'$, $cn = *60^{\circ} 42'$ $59^{\circ} 24\frac{1}{2}$, $nn' = 56^{\circ} 6'$.

Crystals short prismatic, small; faces m, f vertically striated. Usually in reni-

form and botryoidal shapes, consisting of globules with a crystalline surface.

Cleavage: m rather distinct; f(120) in traces. H. = 2-2.5. G. = 2.04-2.14. Luster vitreous. Color deep hyacinth-red; massive varieties sometimes ocher-yellow. Streak ocher-yellow, a little shining. Translucent. Taste slightly astringent. Pleochroic: vibrations $\parallel c$ orange, $\perp c$ orange-gray. Comp.—Perhaps MgO.FeO.Fe₂O₃.4SO₃.18H₂O (Hockauf) = Sulphur trioxide

34.9, iron sesquioxide 17.4, iron protoxide 7.9, magnesia 4.4, water 35.4 = 100.

Some manganese protoxide is also present.

Anal.—1, Hockauf, l. c., 0·3 p. c. insol. residue deducted. 2. Blaas, Ber. Ak. Wien, 87 (1), 161, 1883. Cf. also ibid., 88 (1), 1134.

1. Falun	£ 36·94	16.38	2.23	1.93	7.63	0.90	33.99 = 100
2. Persia G. = 2·138	40.95	20.50	4.12	-	3.59	-	30.82 = 99.98

For the early results of Berzelius, see 5th Ed., p. 657.

Pyr., etc.—B.B. intumesces and gives off water, producing a reddish-yellow earth. On charcoal becomes magnetic; with soda gives a hepatic mass. Remains unaltered if kept dry, but in a moist atmosphere it becomes covered with a dirty yellowish powder. Partly soluble in boiling water, leaving an ocherous residue.

Obs.—Occurs at the copper mine of Falun, in Sweden, coating gypsum or pyrite. Much of the so-called botryogen is not this mineral, but a mixture of other sulphates, cf. Blaas, Hockauf, l. c. From the region of Madeni Zakh. Persia, where it incloses crystals of voltaite. Also noted by Raimondi (called alcaparossa amarilla) as occurring in Peru (and Chili).

Named from $\beta \acute{o} r \rho \upsilon \delta$, a bunch of grapes, and $-\gamma \acute{e} \nu \eta \delta$, producing (from $\gamma \acute{i} \gamma \nu \epsilon \sigma \vartheta \alpha \imath$, to become). This last part of the name is bad and is well thrown aside by Glocker, who makes it botryte; botryite would be more correct.

Ref.—1 L. c.; this is Miller's position. There is some uncertainty about the true symbol of n, cf. Hockauf, Zs. Kr., 12, 240, 1886, who also calls attention to the resemblance in angle to anorthite and the possible asymmetry of the crystals, based upon an extended series of measurements.

799. SIDERONATRITE. Raimondi, Minéraux du Pérou. 212, 233, 1878. Domeyko, 3d Ed. Min. Chili, p. 158, 1879. Urusit Frenzel, Min. Mitth., 2, 133, 359, 1879.

Orthorhombic Pfd. In crystalline masses of fine fibrous structure, separating

into thin splinters.

Cleavage: probably pinacoidal. H. = 2-2.5. G. = 2.153; 2.355 G. & P. Color orange-yellow to straw-yellow. Streak pale yellow to yellowish white. Optically +. c (= Bx_a) | fibers, Pfd.

Comp.—2Na, O.Fe, O,. 4SO,. 7H, O (Genth) = Sulphur trioxide 43.8, iron sesqui-

oxide 21.9, soda 17.0, water 17.3 = 100.

The above description applies to sideronatrite. Urusite, which seems to be the same mineral, occurs in pulverulent, earthy forms; also in lumps, consisting of minute prismatic crystals. $G_{\cdot} = 2.22.$ Color lemon- to orange-yellow. Streak ocher-yellow. Transparent in Soft. minute crystals.

Anal.—1, Raimondi, l. c. 2, Frenzel, Min. Mitth., 11, 214, 1890. 3, Genth, Am. J. Sc., **40**, 201, 1890. 4, Frenzel, Min. Mitth., **2**, 133, 1879. 5, Id., ib., p. 359.

4. Urusite	42.08	21.28	16.50	19.80 = 99.66
5. "	41.64	22.00	17.24	[19.12] = 100
	a At 110°	loses 4 1	molecules	H ₂ O, Genth.

Both sulphates are insoluble in cold water, but decomposed by boiling water with separation of fron sesquioxide; soluble in acids.

Obs.—Sideronatrite is from the mine San Simon, Huantajava, province of Tarapacá, Chili. Urusite is found underlying deposits of iron vitriol (melanterite) on the Urus plateau, near Sarakaya, on the naphtha island, Cheleken, in the Caspian Sea. Ref.—1 Am. J. Sc., 40, 201, 1890.

300. ALUNITE. Alumen de Tolpha, quod primum fossum est in Italia, Pii 2di Pontificis temporibus (Piccolomini, 1458-1464). Gesner, Foss., 13, 1565. Romersk Alunsten Wall., Min., 163, 1747. Alaunstein (fr. Tolfa) Wern., Bergm. J., 376, 1789. Alunstone. Aluminilite Delameth., T. T., 2, 113, 1797. Alun de Rome pt. H., Tr., 1801. Pierre alumineuse de la Tolfa Fr. Alunite Beud., 449, 1824. Alaun-Spath Breith., Char., 1823.

Rhombohedral. Axis c = 1.2520; 0001 \wedge 1011 = 55° 193′ Breithaupt¹.

In rhombohedrons, resembling cubes $(rr' = 90^{\circ} 50')$; often terminated by the vicinal rhombohedron p. Faces r often s a fibrous, granular, or impalpable texture. Faces r often striated \parallel edge c/r. Also massive, having

Cleavage: c distinct; r in traces. Fracture flat conchoidal, uneven; of massive varieties splintery; and sometimes earthy. Brittle. H. = 3.5-4. G. = 2.58-2.752; 2.594 Erem. Luster of r vitreous, basal plane somewhat pearly. Color white, sometimes grayish or reddish. Streak white. Transparent to subtranslucent. Optically positive.

Comp.—Hydrous sulphate of aluminium and potassium, K.O.3Al.O.4SO.6H.O

= Sulphur trioxide 38.6, alumina 37.0, potash 11.4, water 13.0 = 100.

The formula may be written $K(A1O)_3(SO_4)_2 + 3H_2O$.

Analyses agree closely, cf. 5th Ed., p. 659; also Rev. Geol., 13, 38, 1877; Lsx., Jb. Min.,

142, 1875.

Pyr., etc.—B.B. decrepitates, and is infusible. In the closed tube yields water, sometimes also ammonium sulphate, and at a higher temperature sulphurous and sulphuric oxides. Heated with cobalt solution affords a fine blue color. With soda and charcoal infusible, but yields a hepatic mass. Soluble in sulphuric acid.

Obs.—Forms seams in trachytic and allied rocks, where it has been formed as a result of the

alteration of the rock by means of sulphurous vapors.

Met with at Tolfa, near Civita Vecchie, in the neighborhood of Rome, in crystals; at Montioni in Tuscany; at Musaz and Bereghszasz in Hungary; on Milo, Argentiera, and Nevis, Grecian Archipelago, and with opal on Santorin; at Mt. Dore, France; near Hadji-Khan, Buchará;

with the hyalite and opal of Queretaro, Mexico.

In the U. S., occurs, associated with diaspore, in rhombohedral crystals, tabular through the presence of c (0001) at the Rosita Hills, Custer Co., Colorado, particularly Democrat Hill and Mt. Robinson. The crystals are dull and opaque with rough faces and consist of alumite but with a granular structure, they being pseudomorphs after an earlier formation of alunite. formation of the alumite is explained by the action of sulphurous gases upon the highly aluminous

The compact varieties from Hungary are so hard as to admit of being used for millstones. Alum is obtained from it by repeatedly roasting and lixiviating, and finally crystallizing by

evaporation.

This species was first observed at Tolfa, near Rome, in the 15th century, by J. de Castro, a Genoese who had been engaged in the manufacture of alum, from an alumstone or "Rock-alum" found near Edessa in Syria. It was named Aluminilite by Delametherie in 1797, a long name well changed to *Alunite* by Beudant in 1824.

Ref.—¹ Vh. G. Reichs., 4, 25, 1852. ² Breith., l. c. ³ Eremeyev, Buchará, Vh. Min. Ges.,

18, 221, 1883.

801. JAROSITE. Gelbeisenerz Rg., Pogg., 43, 132, 1838. Misy Haid., Handb., 512, 1845. Vitriolgelb, Gelbeisenerz, Hausm., Handb., 1205, 1847 [not Gelbeisenerz fr. Harz Breith., Char., 1832] Jarosit Breith., B. H. Ztg., 6, 68, 1852. Moronolite Shep., Suppl. Append. Min., p. 4, 1857.

Rhombohedral. Axis $\dot{c} = 1.2492$; 0001 \wedge 1011 = 55° 16′, Koenig¹.

Forms²: c (0001, 0), r (1011, R), s (0221, -2)². Angles: $rr' = *90^{\circ} 45'$, $cs = 70^{\circ} 53'$, $ss' = 109^{\circ} 49'$.

Often in druses of minute indistinct crystals; less often crystals rhombohedral

in habit, or with c, and then somewhat resembling cubes with tetrahedrat planes. Also fibrous, and granular massive. Also in nodules, or as an incrustation with a tuberose or coralloidal surface.

Cleavage: c distinct. Fracture uneven. Brittle. H. = 2.5-3.5. G. = 3.15-3.26 cryst. Luster vitreous to subadamantine; brilliant, also dull. Color ocher-

yellow, yellowish brown, clove-brown. Streak yellow, shining.

Var.—(1) Crystallized; Jarosite, which occurs also fibrous and granular: G. = 3.256, Spain; 3.244, Maryland, Breith.; 3.144 Arizona; 3.163 Utah. (2) Concretionary, the ordinary form of the Norway and Bohemian mineral, and the moronolite of Orange Co., N. Y.; G. = 2.62 (moronolite)-2.79.

Comp.—K₂O.3Fe₂O₃.4SO₃.6H₂O = Sulphur trioxide 31.9, iron sesquioxide 47.9, potash 9.4, water 10.8 = 100.

The formula may be written $K(FeO)_2(SO_4)_2 + 3H_2O$. Anal.—1, Ferber, B. H. Ztg., 23, 10, 1864. 2, Penfield, Am. J. Sc., 21, 160, 1881. 3, Koenig, l. c. 4, 5, Genth, Am. J. Sc., 39, 73, 1890. See also 5th Ed., p. 660.

	The last of	G.	SO ₃	Fe ₂ O ₃	K ₂ O	Na ₂ O	H_2O	SiO ₂
1.	Spain		31.76	49.24	5.90	0.80	11.35	- Al ₂ O ₃ 1·25=100·30
	Vulture M., Arizona	3.09	30.42	48.27	8.53	0.28	[11.42]	1.08 = 100
3.	Arrow M., Colorado	3.144	29.33	52.36	7.30	0.90	10.55	-=100.44
4.	Tintic distr., Utah	3.163	29.60	50.41	9:	23	10.68	0.08 = 100
5.	"		28.93	51.16	9.05	0.33	10.24	0.29 = 100

The water determined in 2, viz., 12:91, was too high; the result obtained by difference is more nearly correct. In 3, the silica has been deducted, and 8.8 p. c. of turgite remains to be rejected.

For the Gelbeisenerz from near Bilin, Rammelsberg calculates K₂O.4Fe₂O₃.5SO₃.9H₂O, and for that from Modum Na₂O.4Fe₂O₃.5SO₃.9H₂O. Analyses.—1, Rg., l. c. 2, Scheerer, Pogg.,

45, 188, 1838.

	SO ₃	Fe_2O_3	K_2O	Na ₂ O	$\mathrm{H}_2\mathrm{O}$
1. Bilin	32.11	46.74	7.88		13.56 CaO $0.64 = 100.93$
2. Modum	§ 32·45	49.63		5.20	13.11 = 100.39

Both of the above come very near jarosite. Weisbach has used the name kolosorukite for the above, Synops. Min., 42, 1875.

Pyr., etc.—Nearly as for coquimbite, p. 956.

Obs.—The original Gelbeisenerz (cf. above) was from Luschitz, between Kolosoruk and

Bilin, Bohemia, in brown coal; and later from Modum, Norway, in alum slate.

The jarosite was from Barranco Jaroso, in the Sierra Almagrera, Spain, on limonite; also, according to Breithaupt (B. H. Ztg., 25, 149, 1866), from Maryland, of granular form, with quartz and a magnetite altered to hematite; Mexico; Saxony, Thekla mine, near Hauptmanngrün in Voigtland, in small crystals on turgite (hydrohematite) and limonite; Erzgebirge, near Schwarzenberg, at the Frisch Glück mine. In the Ural near Berezov, 15 versts from Ekaterinburg. Also from the province of Cajamarca, Peru.

In the U. S., occurs on quartz at the Vulture mine, Arizona; at the Arrow mine, Chaffee County, Col.; at the Mammoth mine, Tintic district, Utah, lining cavities in a siliceous

limonite.

Moronolite is from Monroe, N. Y., where it occurs on gneiss. It contains less alkali (viz 3:31 p.c. Tyler) than is required for the formula. Named moronolite from μώρον, mulberry,

Ref.—¹ Am. Ch. J., 2, 375, 1880; cf. Kk., Min. Russl., 6, 227, 1874, 8, 242. Breithaupt gives $rr' = 91^{\circ} 2'$, and Koksharov $90^{\circ} 49\frac{1}{2}'$. ² Pfd., Utah, Am. J. Sc., 39, 73, 1890, he obtained $rr' = 91^{\circ} 33'$.

Bartholomite Cleve, Ak. H. Stockholm, 9, Nov. 1870; Geol. W. I. Islands, p. 31. A hydrous sulphate of ferric iron and sodium of uncertain nature. An analysis on impure mate rial, after deducting 2.88 NaCl (halite), 3.87 MgSO₄ + 7H₂O (epsomite), 3.56 insol. yielded:

> Na₂O 19·11 $H_2O 6.82 = 100$ Fe₂O₃ 25.41 SO₃ 48.66

Occurs with mendozite in yellow nodules composed of small needles, an alteration-product of pyrite, at St. Bartholomew, West Indies.

Plagiocitrite Sandberger; Singer, Inaug. Diss., p. 13, Würzburg, 1879.

Monoclinic or triclinic. In microscopic prismatic crystals. G. = 1.881. Color lemonyellow. Translucent. Taste astringent.

Composition, perhaps (K,Na)₂O.2FeO.3(Al,Fe)₂O₃.6SO₃.27H₂O. Analysis, after deducting 9.85 p. c. hygroscopic water:

SO₃ Al₂O₃ Fe₂O₃ FeO NiO CoO MgO CaO Na₂O K₂O H₂O
$$35.44$$
 14.37 7.95 1.64 0.97 0.58 1.19 0.43 4.04 4.23 $29.42 = 100.26$

Easily soluble in water, the solution giving an acid reaction; by boiling, Fe2O3 separates out free from SO₂. Decomposes on exposure, becoming orange-yellow. B.B. swells up, fuses in its own water of crystallization, and leaves a reddish brown spongy residue.

Occurs with other related sulphates at the Bauersberg near Bischofsheim vor dem Rhön;

derived from the decomposition of pyrite."

CLINOPHÆITE. Klinophaeit Sandberger; Singer, Inaug. Diss., Würzburg, p. 16, 1879. In microscopic crystals, probably monoclinic, with planes c (001), m (110), d (101); prismatic angles 85° and 95°. G. = 2.979. Color blackish green. Streak light grayish green. Luster vitreous. Translucent to opaque. Taste astringent.

Composition, perhaps 4(K, Na)2O. FeO. (Fe, Al)2O3.5SO3.8H2O. Analysis, after deducting

7.88 p. c. hygroscopic water:

$$SO_3$$
 Fe_2O_3 Al_2O_3 FeO $NiO(CoO)$ MgO CaO Na_2O K_2O H_2O 37.01 9.48 4.04 6.06 0.76 1.88 0.77 6.35 21.79 $14.72 = 102.86$

Difficultly soluble in water; on boiling, iron sesquioxide separates from the aqueous solution. B.B. fuses with intumescence, leaving finally a black magnetic residue. Occurs with other sulphates at the Bauersberg, near Bischofsheim, as a result of the decomposition of pyrite.

CLINOCROCITE. Klinocrocit Sandberger; Singer, Inaug. Diss., Würzburg, p. 9, 1879.

A mineral of a deep saffron-yellow, occurring in microscopic crystals, probably monoclinic. According to a qualitative examination, a hydrous sulphate of aluminium, ferric iron, sodium, and potassium (lime in traces). From the Bauersberg, near Bischofsheim, formed by the decomposition of pyrite in basalt tufa. Related to the more clearly defined mineral, clinophæite.

802. LÖWIGITE. Alaunstein Römer, Zs. G. Ges., 8, 246, 1856. Löwigit A. Mitscherlich, J. pr. Ch., 83, 474, 1861. Loewigite.

In rounded masses, similar to compact alunite.

H. = 3-4. G. = 2.58. Luster feeble. Color pale straw-yellow. Slightly subtranslucent. Fracture perfectly conchoidal.

Comp.—Perhaps $K_2O.3Al_2O_3.4SO_3.9H_2O$ (Rg.) = Sulphur trioxide 36·3, alumina 34·7, potash 10·7, water 18·4 = 100.

This is like alunite except in the presence of more water.

Anal.—1, Löwig, Zs. G. Ges., 8, 246, 1856. 2, Mitscherlich, J. pr. Ch., 83, 474, 1861.

	SO_3	Al_2O_3	$\mathrm{Fe_2O_3}$	K ₂ O	Na ₂ O	$\mathrm{H}_2\mathrm{O}$
1.	34.84	33.37		10.10	-	18.32 SiO_2 , etc., $3.37 = 100$
2.	34.81	34.95	0.68	9.30	0.39	17.87 SiO_2 , etc., $2.00 = 100$

Pyr., etc.—B.B. nearly like alunite. The water is expelled at a lower temperature than in alunite; and the compound resulting after heating, instead of containing a mixture affording alum and insoluble hydrated alumina, affords to water sulphate of potassium and subsulphate of aluminium. Partially soluble in hydrochloric acid, while alumite is not at all so.

Obs.—Found in a coal bed at Tabrze in Upper Silesia, in compact lumps, having the luster, color, and texture of the Solenhofen lithographic stone, but blackish externally from a coaly

crust; also with alunite at Tolfa,

IGNATIEVITE. Ignatiewit K. K. Klug, Vh. Min. Ges., 23, 116, 1887. Occurs in nodules and reniform masses, having a fibrous structure in white sand in the district of Bakhmut, Ekaterinoslav, South Russia. An impure hydrous sulphate of aluminium and potassium.

803. ETTRINGITE. Lehmann, Jb. Min., 273, 1874.

Hexagonal. Axis $\dot{c} = 0.94345$; 0001 \wedge 1011 = 47° 27' Lehmann.

Forms: c(0001, 0); $m(10\overline{10}, I)$; $o(10\overline{12}, \frac{1}{2})$, $p(10\overline{11}, 1)$.

Angles: $co = 28^{\circ} 35'$, $oo' = 30^{\circ} 53'$, $cp = 47^{\circ} 27'$, $pp' = 43^{\circ} 14'$, $mp = *42^{\circ} 33'$.

In minute needle-like prismatic crystals, seldom more than 3 mm. in length, thickness 10 to 1 mm.

Cleavage: m perfect. H. = 2-2.5. G. = 1.75. Colorless. uniaxial, negative, Btd. Transparent. Optically

Comp.—Perhaps 6CaO.Al₂O₃.3SO₃.3SH₂O (Rg.) = Sulphur trioxide 18.9, alumina 8.0,

lime 26.4, water 46.7 = 100. The small quantity analyzed makes the complex formula doubtful.

Anal.—Lehmann, l./c, on 0.36 gr.

SO ₃	Al_2O_3	CaO	H_2O	loss (SO ₃ ?)
16.64	7.76	27.27	45.82	2.51 = 100

Pyr.—B.B. swells up but does not fuse. Soluble in acids, also to a considerable extent in water, giving an alkaline solution.

Occurs in cavities in the limestone-inclusions in lava of the Bellenberg at Ettringen and Mayen, in the district of Laach.

804. QUETENITE. A. Frenzel, Min. Mitth., 11, 217, 1890.

Monoclinic or triclinic? Massive and in indistinct prismatic crystals embedded in chalcanthite.

Cleavage: prismatic, rather perfect. H. = 3. G. = 2.08-2.14. Luster greasy, feeble. Color reddish brown. Translucent to opaque. Taste slightly astringent.

Comp. - MgO. Fe₂O₃. 3SO₃. 13H₂O = Sulphur trioxide 35.6, iron sesquioxide 23.7, magnesia 6.0, water 34.7 = 100.

Anal.—Frenzel, l. c., after deducting admixed chalcanthite.

Fe₂O₃ 22.70 SO_s 37.37 MgO 5.92 $H_2O 34.01 = 100$

Decomposed by water with the separation of iron sesquioxide.

Obs.—From the Salvador mine in Quetena, eight kilometers west of Calama, Chili; intimately associated with chalcanthite.

805. ZINCALUMINITE. Bertrand and Damour, Bull. Soc. Min., 4, 135, 136, 1881.

In minute crystals, forming very thin hexagonal plates. Optically uniaxial, negative, and hence hexagonal, or possibly orthorhombic with a prismatic angle of about 60° (Bertrand).

G. = 2.26. Color white, or slightly bluish. H. = 2.5-3.

Comp. -2ZnSO_4 . $4\text{Zn}(OH)_2$. $6\text{Al}(OH)_3 + 5\text{H}_2O_5$, or $6\text{ZnO}.3\text{Al}_2O_3$. $2\text{SO}_3.18\text{H}_2O_4$ Sulphur trioxide 12.5, alumina 24.0, zinc protoxide 38.1, water 25.4 = 100.

Anal.—Damour, after deducting a little clay.

SO_3	Al_2O_3	ZnO	CuO	H_2O
12.94	25.48	34.69	1.85	25.04 = 100

Pyr., etc.—B.B. in the closed tube gives off abundance of water, Slightly alkaline, With cobalt solution on strong ignition gives a greenish gray mass with blue at some points. On charcoal a zinc coating. Soluble in nitric acid, leaving 5 to 7 p. c. clay.

Obs.—From the zinc mines of Laurium, Greece, associated with smithsonite, serpicrite, etc.

Enysite Collins, Min, Mag., 1, 14, 1876; C. Le Neve Foster, ibid., p. 9.

Forms a bluish green stalagmitic crust. H. = 2-2.5. G. = 1.59. An analysis gave:

SO₂ 8.12, Al₂O₃ 29.85, CuO 16.91, CaO 1.35, SiO₂ 3.40, CoO₂ 1.05 H₂O (over H₂SO₄ after 3 days)

14.04, at 150° C. 18.21, at a red heat 7.17, Fe₂O₃,Cl,Na₂O tr. = 100.10. Compare analyses of woodwardite by Flight, J. Ch. Soc., 24, 1, Jan., 1871; and Pisani, Phil. Mag., 35, 320, 1868.

Found at St. Agnes, Cornwall, in one of the caves at the old quay. Named after John S. Enys, F.G.S. Probably a mechanical mixture. Cf. Groth, Zs. Kr., 1, 75, 1877.

LAMPROPHANITE. Lamprophan *Igelström*, Öfv. Ak. Stockh., 23, 93, 1866. In thin cleavable folia. H. = 3. G. = 3.07. Luster pearly. Color and streak white. An analysis afforded Igelström:

SO_3	PbO	MnO	MgO	CaO	Na ₂ O, K ₂ O	H_2O
11.17	28.00	7.90a	5.26	24.65	14.02	8.35 = 99.35
			* FeO	tr.		

Yields water. With soda on charcoal yields metallic lead and a hepatic mass. Not wholly soluble in acids.

From Långban in Wermland, Sweden. Named in allusion to the luster from λαμπρός, shining.

806. JOHANNITE. Uranvitriol John, Ch. Unters., 5, 254, 1821. Johannit Haid., Abhandl., Böhm. Ges. Prag, 1830. Sulphate of Uranium. Sulfate vert d'urane Beud. Monoclinic. Prismatic angle 111° and 69°, $\beta=85^{\circ}$ 40′. Crystals flattened, resembling those of trona, and from one to three lines in length; arranged in concentric druses or reniform

 $H.=2-2\cdot 5$. $G.=3\cdot 19$. Luster vitreous. Color beautiful emerald-green, sometimes passing into apple-green. Streak paler, Transparent to translucent; sometimes opaque. Solrible in water. Taste bitter, rather than astringent.

Comp.—A hydrous sulphate of uranium and copper, formula uncertain.

Anal.-Lindacker, Vogl. Min. Joach., 1857.

UO: 67.72 CuO 5.99 FeO 0.20 SO₃ 20.02 $H_2O 5.59 = 99.52$

Pyr., etc.—In a glass tube at a low heat does not change; highly heated gives off water and sulphur dioxide, and becomes brown and finally black. B.B. on charcoal gives sulphurous fumes and a scoria of black color and dull green streak. With salt of phosphorus reacts for copper and uranium. Somewhat soluble in water.

Obs.—Discovered by John near Joachimsthal in Bohemia. Found also at Johanngeorgen-

stadt. Reported from the Middletown feldspar quarry by Shepard.

Named after the Archduke Johann of Austria.

807. URANOPILITE. Weisbach, Jb. Min., 2, 258, 1882. Uranocher pt.

A velvety incrustation on uraninite or mica schist at Johanngeorgenstadt; a similar substance occurs at Joachimsthal. Crystals minute flattened, acicular and terminated obliquely (79½°); extinction oblique (9°). G. = 3.75-3.97. Color yellow.

Comp.—Perhaps CaU₈S₂O_{31.25}H₂O or CaO.8UO₅.2SO₃.25H₂O = Sulphur trioxide 5.4,

uranium trioxide 77.6, lime 1.9, water 15.1 = 100.

Anal.-H. Schulze, l. c.

	SO ₃	UO_3	CaO	H_2O	insol.	
1.	3.18	77.17	2.08	16.59	0.39 =	99.41
2.	4.56	77.46	1.96	14.69	1.33 =	100

A basisches Uransulphat from Joachimsthal, like the above, gave Dauber: SO₃ 4·0, UO₃ 79·9. H_2O 14.3 = 98.2. In microscopic lemon-yellow crystals, Pogg., 92, 251, 1854.

MEDJIDITE J. L. Smith, Am. J. Sc., 5, 337, 1848. Sulphate of Uranium and Lime. Massive, with an imperfectly crystalline structure. H. = 2.5. Luster vitreous in the fracture. Color dark amber. Transparent. A hydrous sulphate of uranium and calcium according to some qualitative trials by Smith.

Occurs near Adrianople, Turkey, on pitchblende, associated with liebigite, in some places with crystals of gypsum; also at Joachimsthal, with liebigite on uranium ore. Externally often dull from loss of water. Named after the Turkish sultan Abdul Medjid.

The following are uncertain uranium sulphates from Joachimsthal, Bohemia, derived from the alteration of uraninite.

URANOCHALCITE. Urangrun Hartmann. Uranochalzit Breith., Handb., 173, 1841. In small nodular crusts and velvety druses, consisting of acicular crystals. H. = 2-2.5. Color fine grass-green to apple-green; streak apple-green.

ZIPPEITE. Basisches schwefelsaures Uranoxyd (verwitterter Uran-Vitriol) J. F. John, Unters., 5, 1821, Jb. Min., 299, 1845. Uranblüthe Zippe. Vh. Ges. Böhm., 1824. Zippeit Haid., Handb., 510, 1845. Dauberite Adam. Tabl. Min., 64, 1869.

In delicate needles; acicular rosettes; warty crusts. H. = 3. Color fine sulphur-yellow,

lemon-yellow, orange-yellow.

Voglianite. Basic Sulphate of Uranium Vogl, Min. Joach., 1857. Voglianite Dana. In soft globular, and nodular, earthy coatings. Color pistachio- to verdigris-green; streak pale green or apple-green.

? Uraconise Beud., Tr., 2, 672, 1832. Uranocker Vogl, Min. Joach. URACONITE. Amorphous, earthy, or scaly, and of a fine lemon-yellow color, or orange. Uraconite Dana. Uraconise of Beudant was described as a yellow pulverulent ore; its composition is unknown. Analyses of these substances, Lindacker, Vogl, Min. Joach., 1857, 5th Ed., pp. 667, 668.

811. Chalcomenite CuSeO₃ + 2H₂O Monoclinic Molybdomenite Cobaltomenite

808. MONTANITE. F. A. Genth, Dana Min., 668, 1868; Am. J. Sc., 45, 318, 1868.

Incrusting; without distinct crystalline structure.

Soft and earthy. Luster dull to waxy. Color yellowish, greenish to white; also brownish red. Opaque.

Comp.—Bi₂O₃.TeO₃.2H₂O = Tellurium trioxide 25.7, bismuth trioxide 68.9,

water 5.4 = 100.

Anal.-1-3, Genth, l. c. 4, Mingaye, Rec. G. Surv., N. S. W., 1, 28.

	TeO ₃	Bi_2O_3	Fe_2O_3	H_2O

4. Norongo, N. S. W.	27.65	50.68	14.38	6.16	gangue $1.00 = 99.87$

Pyr., etc.—Yields water in a tube when heated. B.B. gives the reactions of bismuth and

tellurium. Soluble in dilute hydrochloric acid.

Obs.—Incrusts tetradymite, from whose alteration it has been formed, at Highland, in Montana. The waxy luster is observed when the incrustation has separated from the scales of tetradymite; also with the tetradymite of Davidson Co., N. C. Occurs with tetradymite at Norongo near Captain's Flat, New South Wales; it has in part a pale yellow color, also brownish red color with G. = 3789. The former incrusts tetradymite; the latter (anal. 4) is in small cubical forms, and is regarded (T. W. E. David) as a pseudomorph after pyrite.

809. EMMONSITE. W. F. Hillebrand, Proc. Col. Soc., 2, pt. 1, 20, 1885.

. Monoclinic (?) In thin scales, formed by perfect cleavage ||b| (010), whose outlines are formed by two unequal cleavages giving the plane angles 85° and 95°.

Hardness about 5. Color of scales clear yellow-green. Extinction on b in obtuse angle (95°) inclined 13° to the better cleavage direction and 82° to the other, E. S. D.

Comp.—Probably a hydrated ferric tellurite, but exact composition undetermined.

Anal.—1, 2, Hillebrand, l. c.: 1, of the brown substance; 2, of green portions. From 3-5 p. c. quartz have been deducted.

	Te(Se)	Fe	ZnO	CaO	H_2O

Pyr.—In a closed tube fuses to a deep red globule, water collects in the upper part, a faint sublimate of selenium and a stronger one of selenous oxide, lower down one of tellurous oxide fusible to colorless drops. Readily dissolved in strong acids.

fusible to colorless drops. Readily dissolved in strong acids.

Obs.—Obtained from Arizona, near Tombstone, exact locality unknown. The yellowish green scales are in part embedded in a hard brown gangue consisting of lead carbonate, quartz, and a brown substance containing iron and tellurium.

Named after S. F. Emmons of the U. S. Geological Survey.

810. DURDENITE. E. S. Dana and H. L. Wells, Am. J. Sc., 40, 80, 1890.

Massive; in small mammillary forms showing but little structure and exerting almost no action on polarized light.

H. = 2-2.5. Friable. Luster vitreous, dull. Color greenish yellow. Trans-

lucent to nearly opaque.

Comp.—Hydrous ferric tellurite, Fe₂(TeO₃)₃ + 4H₂O or Fe₂O₃.3TeO₂.4H₂O = Tellurium dioxide 67·1, iron sesquioxide 22·7, water 10·2 = 100. Selenium replaces a small part of the tellurium.

Anal.—1, H. L. Wells, l. c.; 1a, same after deducting insoluble matter (quartz).

	TeO ₂	SeO_2	Fe_2O_3	H_2O	insol.
1.	47.20	1.60	19.24	7 67	23.89 = 99.60
1a.	64.41	2.28	22.97	10.34	- = 100

Pyr., etc.—Gives the usual reaction for tellurium in the open tube; fuses on charcoal and

leaves a magnetic residue. Soluble in hydrochloric acid.

Obs.—From the El Plomo mine, Ojojoma district, Dept. Tegucigalpa, Honduras. It occurs disseminated in grains and narrow veins in a quartzose conglomerate containing much nearly pure metallic tellurium. The same locality affords the selen-tellurium noted on p. 11.

Named after Henry S. Durden of the State Mining Bureau of San Francisco.

FERROTELLURITE F. A. Genth, Am. Phil. Soc., 17, 119, 1877. Described as occurring in delicate radiating tufts, also in very minute prismatic crystals, as a coating on quartz associated with native tellurium and tellurite, at the Keystone mine, Magnolia District, Colorado. Color between straw- and lemon-yellow, inclining to greenish yellow. Insoluble in ammonia; soluble in HCl. A qualitative examination showed the presence of iron and tellurium, and the composition FeTeO₄ is suggested; the quantity, however, was too minute to allow of a satisfactory examination, and Dr. Genth states (priv. contr.) that it is not impossible that the crystals were tellurous oxide colored yellow by a salt of ferric oxide.

MAGNOLITE F. A. Genth, Am. Phil. Soc., 17, 118, 1877.

In radiating tufts of very minute accular or capillary crystals. Color white. Luster silky. Contains mercury and tellurium, and composition inferred to be Hg₂TeO₄. Blackened by ammonia. A decomposition-product of coloradoite, found in the upper part of the Keystone mine, Magnolia District, Colorado.

811. CHALCOMENITE. Des Cloizeaux and Damour, Bull. Soc. Min., 4, 51, 164, 1881.

Monoclinic. Axes $\dot{a}: \bar{b}: \dot{c} = 0.72219:1:0.24604$; $\beta = 89^{\circ} 9' = 001 \land 100$ Des Cloizeaux.

 $100 \land 110 = *35^{\circ} 50', 001 \land 101 = *18^{\circ} 54', 001 \land 011 = 13^{\circ} 49\frac{1}{4}'.$

Crystals small; faces c, g often horizontally striated.

G. = 3.76. Luster vitreous. Color bright blue. Transparent. Optically -.

Ax. pl. \perp and $\text{Bx}_a \parallel b$ (010). Angle small. Dispersion strong, $\rho < v$. Comp.—Hydrous cupric selenite, $\text{CuSeO}_s + 2\text{H}_2\text{O}$ or $\text{CuO.SeO}_2\text{2H}_2\text{O} = \text{Sele-}$ nium dioxide 49.1, cupric oxide 35.0, water 15.9 = 100.

Anal.-Damour, l. c.

SeO₂ 48·12 CuO 35.40 $H_2O 15.30 = 98.82$

Pyr., etc.—B.B. on charcoal fuses to a black slag, giving off selenium fumes, and coloring the flame deep blue. In the closed tube yields a little water and a sublimate of SeO₂ in white needles. In salt of phosphorus gives in O.F. a greenish blue glass, which becomes blood red when reduced with the addition of metallic tin. Soluble in acids.

Obs.—Occurs in minute crystals with the various selenides of silver, copper, and lead, which are found in small veins in the Cerro de Cacheuta, Mendoza, Argentine Republic. Often intimately mixed with azurite, iron oxide, and lead carbonate, which have been formed by the alteration of the selenides and of the pyrites which forms the gangue.

Named from $\chi \alpha \lambda \kappa \dot{\phi} \dot{\phi}$, copper, and $\mu \dot{\eta} \nu \eta$, moon, in allusion to selenium, derived from the more common $\sigma \epsilon \lambda \eta \nu \eta$, moon.

Artif.—MM. Friedel and Sarasin have made artificially (Bull. Soc. Min., 4, 176, 225, 1881, Zs. Kr., 6, 302 1881) a copper selenite having the same form and composition as chalcomenite, and another differing in crystalline form (orthorhombic).

MOLYBDOMENITE. Selenite de plomb Bertrand, Bull. Soc. Min., 5, 90, 1882.

Orthorhombic. In very thin, frigile scales. Cleavage in two directions; easy | large face of the scales. Luster pearly. Color white. Transparent to translucent. Optically +. Ax. pl. normal to intersection of two cleavages, and obtuse bisectrix normal to easy cleavage

Contains lead and selenium, and regarded as a lead selenite; some varieties also contain copper. Occurs associated with chalcomenite and various selenides at Cacheuta, Mendoza,

Argentine Republic. Named from μόλυβδος, lead, and μήνη, moon.

COBALTOMENITE Bertrand, ibid. Associated with molybdomenite. In minute rose-red monoclinic crystals, resembling erythrite. Optically -. Ax. pl. parallel to direction of elongation of crystals, and acute bisectrix normal to it, but strongly inclined to the cleavage direction. Contains cobalt and perhaps a cobalt selenite. There also occur with the lead selenide at the same locality minute white acicular crystals, entirely volatile and apparently consisting only of selenous oxide (p. 201).

Kerstenite Dana. Selenichtsaures 1 Kerstenite Dana. Bleiselenit Germ. Selenichtsaures Bleioxyd Kersten, Pogg., 46, 277, 1839. Selenbleispath.

In small spheres and botryoidal masses. Cleavage distinct in one direction. H. = 3-4. Luster greasy to vitreous. Color sulphur-yellow. Streak uncolored. Brittle. Fracture fibrous. According to Kersten, it consists of selenous oxide and lead oxide, with a small proportion of copper. On coal it fuses readily to a black slag, giving off a strong selenium odor, and is finally reduced to a metallic globule. With borax it fuses and forms a yellowish-green pearl, which is of the same color on cooling. With soda on charcoal metallic lead is obtained. Occurs with selenide of antimony and lead, malachite, etc., at the Friedrichsglück mine, near Hildburg-burger on the west side of the Thirting represented. hausen, on the west side of the Thüringerwald.

Onofrite Köhler, Abhandlung, etc. (Programm zur Prüfung der Zöglinge der Gewerbeschule am 23 März, 1853), Berlin 1853; also Pogg., 89, 146, 1853. Köhlerite Adam, Tabl. Min.,

71, 1865. Selenigsaures Quecksilberoxydul, Quecksilberselenit, Germ.

An earthy yellow mineral from S. Onofre, Mexico, intimately mixed with calomel; regarded

as probably mercurous selenite, but very doubtful.

Oxygen Salts.

Figs. 1-3, Wolframite, 1, 2, Zinnwald. 3, Zinnwald, Rose. 4, Hübnerite, Silverton, Col. (anal. 20), Pfd.

For hübnerite from Silverton, Colorado (f. 4 and anal. 20) Penfield calculates (priv. contr.):

$$\hat{a}: \hat{b}: \hat{c} = 0.83623:1:0.86684; \qquad \beta = 89^{\circ} 7\frac{1}{2}.$$

Angles: $mm' = *100^{\circ} 12'$, $bf = *49^{\circ} 5'$, $bm' = *65^{\circ} 43'$.

Twins: (1) tw. axis \dot{c} with a as comp.-face; (2) tw. pl. k (023) Rose, f. 3. Crystals commonly tabular $\| a \|$; also prismatic with a b d, or b c. Faces in prismatic zone vertically striated. Often in bladed crystals; also irregular lamellar; coarse divergent columnar; massive granular, the particles strongly coherent.

Cleavage: b very perfect; also parting sometimes observed ||a|, and ||t| (102) (Dx.). Fracture uneven. Brittle. H. = 5-5.5. G. = 7.2-7.5. Luster submetallic; metallic-adamantine; resinous. Color dark grayish or brownish black, brownish red, hair-brown. Streak nearly black to dark reddish brown; yellowish brown; greenish gray. Opaque or sometimes translucent. Sometimes weakly magnetic.

For hübnerite, ax. pl. and $Bx_0 \perp b$. $Bx_{ay} \wedge c = 17^{\circ} 39\frac{1}{2}$ Na. Measure-

ments (approx.) on artif. cryst.:

$$2H_{a,r} = 93^{\circ}$$
 $2H_{o,r} = 141^{\circ}$ $2V_r = 75^{\circ}$ (Li) Groth & Arzruni 8

Hübnerite from Colorado, with extinction-angle = 17°, is pleochroic (Pfd.*) with t green, by yellowish brown. The color varies in the same section presumably from variation in amount of FeO.

Comp., Var.—Tungstate of iron and manganese (Fe,Mn)WO₄. In WOLFRAMITE Fe: Mn = chiefly 4:1 and 2:3, but varying from 9:1 to 2:3. HÜBNERITE is nearly pure MnWO₄.

The percentage composition for the pure tungstates, and the compounds in various ratios between them, is as follows:

WO3 FeO: MnO FeO MnO 76.3 23.7 1:0 100 5:1 76.4 19.7 3.9 100 4:1 76.4 18.9 4.7 100 = 76.4 11.9 1:1 11.7 100 2:3 76.5 9.5 14.0 100 76.6 23.4 100

WOLFRAMITE. Often in crystals as above described. Color and streak nearly black. Opaque Chiefly ferrous tungstate.

HÜBNERITE. Usually in bladed forms, rarely in distinct terminated crystals. Color brownish red to hair-brown to nearly black. Streak yellowish brown, greenish gray. Often translucent. Optical characters as above. Chiefly manganese tungstate.

Megabasite, supposed to have a different composition, was later shown (Rg.) to belong here.

Megabasite, supposed to have a different composition, was later shown (Rg.) to belong here. Crystals from Schlackenwald gave Groth and Azzruni the forms: a, b, c, n, m, γ, δ, λ, ω, d.
Anal.—1, Beck & Teich, Vh., Min. Ges., 4, 314, 1869. 2, Liversidge, Min. N. S. W., 85, 1888. 3–6, Kerndt, J. pr. Ch., 42, 81, 102, 105, 1847. 7, Genth, Am. J. Sc., 28, 253, 1857. 8. Pyr., etc.—Wolframite fuses B.B. easily (F. = 2.5-3) to a globule, which has a crystalline surface and is magnetic. With salt of phosphorus gives a clear reddish yellow glass while hot, which is paler on cooling; in R.F. becomes dark red; on charcoal with tin, if not too saturated, the bead assumes on cooling a green color, which continued treatment in R.F. changes to reddish yellow. With soda and niter on platinum foil fuses to a bluish green manganate. Decomposed by aqua regia with separation of tungstic acid as a yellow powder, which, when treated B.B., reacts as under tungstite (p. 202). Wolframite is sufficiently decomposed by concentrated sulphuric acid, or even hydrochloric acid, to give a colorless solution, which, treated with metallic zinc, becomes intensely blue, but soon bleaches on dilution.

Hübnerite is less fusible than wolframite and gives a strong manganese reaction.

Obs.—Wolframite is often associated with tin ores; also in quartz, with native bismuth, scheelite, pyrite, galena, sphalerite, etc. It occurs in fine crystals at Schlackenwald, Schneeberg, Geyer, Freiberg, Altenberg. Ehrenfriedersdorf, Zinnwald, and Nerchinsk, and other places mentioned above; at Chanteloup, near Limoges, in France; near Redruth and elsewhere in Cornwall with tin ores; in Cumberland (the ratio 2: 3 at Lochfells, that of 4: 1 at Godolphin's Ball); on the Island of Rona, one of the Hebrides; in the auriferous sand of the Wicklow rivers, Ireland, with tin. Also in S. America, at Oruro in Bolivia. With tin stone at various points in New England, New South Wales; in quartz veins at Inverell and elsewhere in Gough Co.

In the U. States it occurs at Lane's mine, Monroe, Conn., in quartz, associated with native

bismuth and the other minerals above mentioned, often pseudomorphous after scheelite; in small quantities at Trumbull, Conn., at the topaz vein; massive and in crystals on Camdage farm, near Blue Hill Bay, Me.; at the Flowe mine, Mecklenburg Co., N. C., with scheelite; in Missouri, near Mine la Motte, and in St. Francis Co., 1½ m. from St. Francis River; in a gneiss boulder on the W. shore of Chicf Island, L. Couchiching, Ontario.

The original hübnerite was from the Eric and Enterprise veins, in Mammoth dist., Nevada,

in a vein 3-4 feet wide in argillyte, with scheelite, fluorite, and apatite. Occurs also in quartz of the Royal Albert vein, Uncompanier district, Ouray County, Col.; at the North Star mine, Sultan Mt., and Cement Creek, Bonita Mt., both near Silverton, San Juan Co. At Phillipsburg, Montana; at the Comstock mine, Black Hills, S. Dakota; Bonita Mt., near White Oaks, Lincoln Co., New Mexico.

Also found in Peru, Morococha, province of Tarma, and in rhodochrosite with friedelite and alabandite at Adervielle in the Pyrenees. The original megabasite was from Schlackenwald.

Alt.—Wolframite occurs altered to scheelite by a substitution of calcium for iron; the opposite exchange is more common, and wolframite pseudomorphs after scheelite are often

Ref.—'Ann. Ch. Phys., **19**, 168, 1870. Krenner gives for Ehrenfriedersdorf 0.82447:1:0.86041, $\beta=89^{\circ}$ 39' 38'', Min. Mitth., p. 9, 1875. Seligmann, for Sierra Almagrera (FeO 19.95, MnO 3.15 Doelter) 0.82144:1:0.87111, $\beta=89^{\circ}$ 34', Zs. Kr., **11**, 347, 1886. The species was formerly regarded as orthorhombic; its monoclinic character was first suggested in 1850, Dx., ib., 28, 163. See also Rose, Pogg., 64, 171, 1845 (relation to columbite), Kerndt, l. c., and Groth and Arzruni for measurements of artif. FeWO₄, MnWO₄, etc., Pogg., 149, 237, 1873.

FERBERITE. Ferberit K. L. T. Liebe, Jb. Min., 641, 1863, attributing the name to Breithaupt. Ferrowolframit Weisb., Synops. Min., 43, 1875.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=0.8229:1:0.8462$, assuming $\beta=89^{\circ}22'$ as with wolframite Forms on artif. cryst. (FeWO₄): $a(100, i-\bar{i}), b(010, i-\bar{i}); m(110, I), g(120, i-\bar{i}); d(102, -\frac{1}{2},\bar{i})$ e (011, 1-i); π (111, 1). Angles: $mm''' = 78^{\circ} 53'$, $gg' = 62^{\circ} 34'$, $cd = 27^{\circ} 5'$, $ce = 40^{\circ} 14'$. See Groth and Arzruni, Pogg., 149, 237, 1873.

The original "ferberite" was massive, granular, with some imperfect planes of crystallization. Cleavage: b perfect. H. = 4-4.5. G. = 6.801 Breith.; 7.109 Rg. Luster imperfectly vitreous, a little submetallic-adamantine. Color black. Streak brownish black to blackish brown. Opaque.

Composition of artif. cryst., ferrous tungstate, FeWO4 = Tungsten trioxide 76.3, iron prot-

oxide 23.7 = 100. A little manganese is also present.

Analyses of "ferberite" from Spain: 1. Liebe, l. c., deducting 1.39 limonite (Rg.).
2, Rg., Ber. Ak. Berlin, 175, 1864, and J. pr. Ch., 92, 263, 1864.

1. Spain 2
$$\frac{WO_3}{70\cdot11}$$
 $\frac{SnO_2}{0\cdot14}$ $\frac{FeO}{23\cdot29}$ $\frac{MnO}{3}$ $\frac{MgO}{2}$ $\frac{CaO}{1\cdot75}$ $\frac{Al_2O_3}{1\cdot17} = 99\cdot90$ 2 $\frac{69\cdot27}{1}$ $\frac{69\cdot27}{1}$ $\frac{69\cdot27}{1}$ $\frac{69\cdot27}{1}$ $\frac{69\cdot49-69\cdot88}{1}$ $\frac{69\cdot49-69\cdot88}{1}$

These analyses do not conform to FeWO₄, rather to 2FeWO₄ + FeO or 3FeWO₄ + FeO;

further note that a "ferberite" stated to come from Sierra Almagrera proved (as described by Seligmann, ref., above) to be wolframite with Fe: Mn = 5:1. The existence of the pure FeWO₄ in nature is hence not proved, though made artificially. The original ferberite was from the Sierra Almagrera in southern Spain, in argillaceous schist, with quartz. Named after R Ferber of Gera.

Scheelite Group. Tetragonal.

Twins: (1) tw. pl. a, both contact- and penetration-twins; the comp.-face usually a, also c. Habit octahedral, e predominating, also with p; again tabular ||c|. Faces c rough; e striated ||e| edge e/s,; in the twins a feather-like striation meeting in a medial line. Also reniform with columnar structure; and massive granular.

Cleavage: p (111) most distinct; e (101) interrupted. Fracture uneven. Brittle. H. = 4·5-5. G. = 5·9-6·1; 6·059 Beauce Co., Quebec, Ferrier. Luster vitreous, inclining to adamantine. Color white, yellowish white, pale yellow,

brownish, greenish, reddish; sometimes almost orange-yellow. Streak white. Transparent to translucent. Optically +. Indices:

$$\omega = 1.918 - 1.919$$
 $\epsilon = 1.934 - 1.935$ red, Dx.

Comp.—Calcium tungstate, CaWO, = Tungsten trioxide 80.6, lime 19.4 = 100.

Molybdenum is usually present and may replace a considerable part of the tungsten (cf. below). Copper replaces calcium, see cuproscheelite (p. 988). Didymium (Ce, La) may be present, a section of the mineral showing strong absorption bands (Cossa). Carnot found 0.4 p. c. Ta₂O₅ in scheelite from Meymac, Corrèze, C. R., 79, 637, 1874.

Analyses, 5th Ed., p. 505. R. A. A. Johnston obtained for the crystallized scheelite of

Beauce Co., Quebec:

G. = 6.059 Ferrier WO₃ 79.90 CaO 19.37 SiO₂ 0.29 $Fe_2O_3 0:70 = 100.26$

Traube (Jb. Min., Beil. Bd., 7, 232, 1890) has shown that molybdenum is usually present in scheelite, and sometimes replaces a considerable part of the tungsten. The white and light yellow varieties contain the least, and the dark colored the most; the amount varies widely even in crystals from the same locality. The presence of the molybdenum probably exerts an important influence upon the angles of the species, cf. ref. ¹.

The following are Traube's analyses:

		G.	WO ₃	MoO ₃	CaO

Molybdenum is also present in the scheelite of Yxsjö, Igelström, G. För. Förh., 13,

Pyr., etc.—B.B. in the forceps fuses at 5 to a semi-transparent glass. Soluble with borax to a transparent glass, which afterward becomes opaque and crystalline. With salt of phosphorus forms a glass, colorless in outer flame, in inner green when hot, and fine blue when cold; varieties containing iron require to be treated on charcoal with tin before the blue color appears. In hydrochloric or nitric acid decomposed, leaving a yellow powder soluble in ammonia.

Obs.—Scheelite is usually associated with crystalline rocks, and is commonly found in

connection with cassiterite, topaz, fluorite, apatite, molybdenite, or wolframite, in quartz; also

associated with gold.

Occurs at Schlackenwald and Zinnwald in Bohemia, Altenberg in Saxony, and Fürstenberg near Schwarzenberg: from Riesengrund in the Riesengebirge; the Knappenwand in the Untersulzbachthal, Tyrol, and the Krimlerthal; the Kammegg near Gutannen in the Bernese Oberland; in fine crystals at Carrock Fells in Cumberland, with apatite, molybdenite, and wolframite. Also at Schellgaden in Salzburg; from the Meiseberg near Neudorf in the Harz; Ehrenfriedersdorf in Saxony; Pösing in Hungary; Traversella in Piedmont, in fine crystals, sometimes transparent, also very large (1 pound); and in the Val Toppa gold-mine, near Domo d'Ossola. Piedmont; Meymac, Corrèze, France (containing Ta₂O₃); Dalecarlia and Bitsberg in Sweden; Pitkäranta in Finland at the tin mines (G. = 6.084): Framont in the Vosges, with pyrite in polished crystals, often twins; at the copper mines of Llamuco, near Chuapa in Chili, of a reddish-gray color, mixed with green, due to chrysocolla.

In New South Wales, at Adelong, from a gold mine. New Zealand, massive; Mt. Ramsay,

Tasmania, with cassiterite; at the Pot mine, in south-western Africa.

In the U. States, crystallized and massive at Lane's Mine, Monroe, and at Huntington, Conn., with wolframite, pyrite, rutile, and native bismuth, in quartz; at Trumbull, sometimes in large

crystals an inch or more in length, often partly altered to wolframite; the crystals are embedded in quartz. Also at Chesterfield, Mass, in albite, with tourmaline; at Bangle mine, in Cabarrus Co., N. C.; and Flowe mine, Mecklenburg Co., some crystals at the latter locality having a nucleus of wolframite; in the Mammoth mining district, Nevada; with gold at the Charity mine, Warren's, Idaho; at Murray, Idaho, on the west slope of Cœur d'Alène Mts.; also at the Golden Queen mine, Lake Co., Colorado.

Fine crystals of scheelite, some over two inches long, occur, with pulverulent tungstite, in quartz veins cutting the slates and sandstones of the lower Cambrian or gold-bearing series in the townships of Risborough and Marlow, Beauce County, Quebec; the associated minerals are argentiferous galena, sphalerite, pyrite, chalcopyrite, etc. (Ferrier).

Tungstic acid was discovered in this species by the Swedish chemist Scheele, in 1781. The

word tungsten, first used by Cronstedt, is Swedish for heavy stone.

Alt.—Occurs altered to wolframite, tungstate of iron and manganese, by the action of a

Art.—Occurs aftered to wolframite, thingstate of from and manganese, by the action of a solution of bicarbonate of iron and manganese, or perhaps mainly through sulphate of iron arising from the decomposition of pyrite; crystals more or less altered to wolframite are common at many localities. Also to kaolinite (Ehrenfriedersdorf).

Ref.—1 Pogg., 107, 272, 1859; confirmed by Rg., Zs. G. Ges., 19, 493, 1867, also by Bauer. Traube (l. c.), in discussing the presence of molybdenum in scheelite, obtains the value $ee' = 72^{\circ}$ 36½ and e' = 1.5315, for pure scheelite from Schwarzenberg and Riesengrund, containing only trace of MoO. He also gives the following table propoducing the results of the authors permed. a trace of MoO3. He also gives the following table, reproducing the results of the authors named; to these the value for powellite (p. 989) is added.

4. "	75.75	3.30	$18.05 \mathrm{SiO}_2 0.75 = 97.85$

Pyr., etc.—In the closed tube blackens, and gives off water. B.B. fuses to a black glass, and colors the flame an intense green. On charcoal blackens, fuses with a little intumescence, forming finally a slag containing minute particles of metallic copper. With fluxes gives reactions for tungsten and copper. Easily soluble in hydrochloric acid, tungsten trioxide being separated from the solution.

Obs.—Cuprotungstite is from the copper mines of Llamuco, near Santiago, Chili, and is stated to envelop kernels of cuproscheelite. Ordinary scheelite is said to occur also, and the cupreous varieties may be the result of alteration. The original cuproscheelite was from the vicinity of La Paz, Lower California, in a red metamorphic rock, associated with black tourmaline. Also mentioned by Traube (l. c., p. 241) as enveloping the scheelite from the Pot mine, southwestern Africa.

816. POWELLITE. W. H. Melville, Am. J. Sc., 41, 138, 1891.

Tetragonal. Axis c = 1.5445; 001 \wedge 101 = 57° 43′ Melville.

In minute octahedral crystals with c(001, 0), e(101, 1-i), p(111, 1).

Angles: $ee' = 72^{\circ} 49'$, $ee'' = 114^{\circ} 9'$, $pp' = 80^{\circ} 1'$, $pp'' = 130^{\circ} 48'$, $pp^{\dagger v} = *49^{\circ} 12'$.

No distinct cleavage. Fracture uneven. Brittle. H. = 3.5. G. = 4.526. Luster resinous. Color yellow with marked greenish tinge. Subtransparent.

Comp.—Essentially calcium molybdate, CaMoO, = Molybdenum trioxide 72.0, lime 28.0 = 100. Calcium tungstate is also present.

Anal.-Melville, l. c.

MoO3 58.58 WO3 10.28 CaO 25.55 SiO₂ 3.25 MgO 0.16 Fe_2O_3 1.65 = 99.47

Pyr., etc.—Fuses about 5 to a gray mass. Reacts for molybdenum with salt of phosphorus, cf. scheelite. Decomposed by nitric and by hydrochloric acid.

Obs.—Found at the Peacock lode in the "Seven Devils" mining district in western Idaho.

It is associated with an argentiferous bornite and dark brown garnet. Cf. ref., p. 988. Named for Major J. W. Powell, Director of the U. S. Geological Survey.

817. STOLZITE. Scheel-Bleispath Breith., Char., 14, 1820. Tungstate of Lead. Bleischeelat, Wolframbleierz, Scheelsaures Blei, Germ. Scheelitine Beud., Tr., 2, 662, 1832. Stolzit Haid., Handb., 504, 1845.

Tetragonal; with pyramidal hemihedrism. Axis $\dot{c} = 1.5667$; 001 \wedge 101 = 57° 27' Kerndt'.

Forms: c(001, 0); m(110, I); e(101, 1-i); $v(112, \frac{1}{2})$, n(111, 1), o(221, 2).

Angles: $ee'=73^\circ$ 10′, $vv'=63^\circ$ 19′, $ee''=114^\circ$ 54′, $vv''=95^\circ$ 51′, $nn'=80^\circ$ 15′, $nn''=131^\circ$ 25′, $nn^{\rm i}v=*48^\circ$ 35′, $oo'=87^\circ$ 13′, $oo''=154^\circ$ 34′.

Habit acute octahedral. Crystals often

indistinctly aggregated.

Cleavage: c imperfect; n more so. Fracture conchoidal to uneven. Brittle. H. = 2.75- $G_{\cdot} = 7.87 - 8.13$. Luster resinous, subadamantine. Color green, yellowish gray, brown, and red. Streak uncolored. Faintly translucent.

Comp.—Lead tungstate, PbWO, = Tungsten trioxide 51.0, lead oxide 49.0 = 100. Analyses, 5th Ed., p. 607.

Pyr., etc.—B.B. decrepitates and fuses at 2 to a crystalline, lustrous, metallic pearl. With soda on charcoal yields metallic lead. With salt of phosphorus gives in O.F. a colorless glass, which in R.F. becomes

Fig. 1, Des Cloizeaux. Fig. 2, Lévy.

blue on cooling. Decomposed by nitric acid, leaving a yellow residue of tungsten trioxide. Obs.—Stolzite occurs at Zinnwald in Bohemia, with quartz and mica; in Chili, province of Coquimbo; at Southampton, Mass.

This species was first made known, according to Breithaupt, by Dr. Stolz, of Teplitz. Ref.—1 J. pr. Ch., 42, 113, 1847, he gives $nn^{1v} = 48^{\circ}$ 35' 14', but the seconds are of no value as the crystals did not admit of exact measurement. Lévy, Pogg. Ann., 8, 513, 1826.

818. WULFENITE. Plumbum spatosum flavo-rubrum, ex Annaberg Austr. v. Born, Lithoph., 1, 90, 1772. Kärntherischer Bleispath v. Jacquin, Miscell. Austr., 2, 1781, Vienna; Wulfen, Abhandl. K. Bleisp., Wien, 1785, fol. Plomb jaune de Liste, 3, 387, 1783. Gelbbleierz Wern., Bergm. J., 384, 1789. Yellow Lead-spar, Molybdenated Lead Ore, Kirwan, Min., 2, 212, 1796. Plomb molybdaté H., Tr., 3, 353, 1801. Molybdate of Lead. Molybdänbleispath, Bleimolybdat, Germ. Melinose Beud., Handb., 2, 664, 1832. Wulfenit Haid., Handb., 504, 1841. Chromowulfenite Schrauf, Ber. Ak. Wien, 63 (1), 184, 1871.

Tetragonal, with pyramidal hemihedrism. Axis c = 1.57710; 001 \wedge 101 = 57° 371' Dauber'.

Figs. 1-5, Goodenough: 1, Phenixville; 2, 3, Red Cloud mine, Yuma Co., Arizona; 4, Phenixville; 5, Utah. 6, After Dx. 7, Bleiberg, after Haid.

		57° 37′ 0° 41′		= 134° 10′		65° 51′ 15° 52′	dd'' =	154° 44′

Crystals commonly square tabular, sometimes extremely thin, with a vicinal pyramid replacing the basal plane; less frequently octahedral in habit; also prismatic, the prismatic faces showing the hemihedrism characteristic of the species.

Also granularly massive, coarse or fine, firmly cohesive.

Cleavage: n (111) very smooth; c, s (113) less distinct. Fracture subconchoidal. Brittle. H. = 2.75-3. G. = $6.7-7\cdot0$. Luster resinous or adamantine. Color wax-yellow, passing into orange-yellow; also siskin- and olive-green, yellowish gray, grayish white to nearly colorless, brown; also orange to bright red. Streak white. Subtransparent to subtranslucent. Optically negative. Indices:

$$\omega = 2.402$$
 $\epsilon = 2.304$, red, Dx.⁵

Comp.—Lead molybdate, PbMoO₄ = Molybdenum trioxide 39·3, lead oxide 60·7 = 100. Calcium sometimes replaces the lead.

Chromium is sometimes present, but according to Groth as an impurity, and not causing the occasional red color noted, though Schrauf gave the name *chromowulfenite* on this ground; vanadium was found by Smith in Phenixville crystals (cf. Groth); also by Wöhler (and Rg., cf. Min. Ch.), Lieb. Ann., 102, 383, 1857.

Anal.—1, 3, F. Jost, Zs. Kr., 7, 592, 1883. 2, J. L. Smith, Am. J. Sc., 20, 245, 1855. 4, 5, Reinitzer, Zs. Kr., 8, 587, 1884. 6, C. L. Allen, Ch. News, 44, 203, 1881. Also 5th Ed., p. 608.

Eureka Co., Nev. $G_{\cdot} = 6.701$ 39.33 61.11 $1.04 \text{ Fe}_2\text{O}_2 = 0.38 = 101.86$

Domeyko gives 6.88 p. c. CaO in a Chili variety.

Pyr., etc.—B.B. decrepitates and fuses below 2; with borax in O.F. gives a colorless glass, in R.F. it becomes opaque black or dirty green with black flocks. With salt of phosphorus in O.F. gives a yellowish green glass, which in R.F. becomes dark green. With soda on charcoal yields metallic lead. Decomposed on evaporation with hydrochloric acid, with the formation of lead chloride and molybdic oxide; on moistening the residue with water and adding metallic zinc, it gives an intense blue color, which does not fade on dilution of the liquid.

Obs.—This species occurs in veins with other ores of lead. Found first at Bleiberg, Schwarzenbach, in Carinthia; also at Ruskitza in Austria; at Rezbánya and Szaska in Hungary; at Přibram; at Moldawa in the Banat, where its crystals are red, and have considerable resemblance to crocoite; in the Kirghiz Steppes in Siberia; at Annaberg, Schneeberg, Johanngeorgenstadt, and Berggieshübel in Saxony; at Badenweiler in Baden; sparingly at Chalanches, Dept. of Isère, and at the abandoned mines of Beaujolais in France; in the gold sands of Rio Chico in Antioquia, Colombia, S. A.; in Lackentyre, Kirkcudbrightshire, Scotland; Zacatecas in Mexico.

In the U. States, it is found in small quantities at the Southampton lead mine, Mass.; sparingly near Sing Sing, N. Y., in tabular crystals associated with vanadinite, pyromorphite, etc., upon crystalline limestone; in fine yellow and reddish orange to red crystals (fig. 4, and also in thin tables) at Wheatley's mine, near Phenixville, Pa.; at the Comstock lode in Nevada; in large thin tables of an orange-yellow color at the Tecomah mine, Utah. In New Mexico, pale yellow crystals at the Organ Mts. In Arizona in fine large deep red crystals at the Hamburg and other mines, Yuma Co., often with red vanadinite; also at the Castle Dome district, 30 miles distant; at the Vulture mine, Maricopa Co.; at the Mammoth gold mine near Oracle, Pinal Co., with vanadinite and descloizite; at the Empire mine, Inyo Co., California.

Named in honor of the Austrian mineralogist Wülfen (1728–1805), who wrote a monograph

on the Carinthia lead ores in 1785.

Ref.—1 Bleiberg, Pogg., 107, 267, 1859; crystals from different localities vary rather widely, and make a mean axial ratio unsatisfactory; cf. Dbr., Koch, Zs. Kr., 6, 389, 1882, Kk., Min Russl., 8, 408, Zeph., Zs. Kr., 8, 583, 1884; Goodenough (priv. contr.) obtained on faultless red crystals from Yuma Co., $ss'' = 73^{\circ}$ 16½, ... b = 1.57759. The Ca variety (anal. 4, 5) has c = 1.5744 Zeph., Zs. Kr., 8, 583, 1884.

² See Koch (l. c.) for literature, list of planes with authorities, etc. ⁴ Goodenough. ⁵ Dx., Propr. Opt., 2, 18, 1859. ³ Koch, l. c.

819. REINITE. K. v. Fritsch, Zs. Nat. Halle, 3, 864, 1878; Luedecke, Jb. Min. 286, 1879. In tetragonal pyramids, p(111, 1), with $e(101, 1\cdot i)$. Axis $c=1\cdot 279$; $pp'=76^\circ$ 28'. Cleavage: prismatic (110), indistinct. H. = 4. G. = 6.640. Luster dull, submetallic. Color blackish brown. Streak brown. Opaque, except in the thinnest splinters. Comp.—FeWO₄ = Tungsten trioxide 76.3, iron protoxide 23.7 = 100.

Anal.-E. Schmidt, quoted by Luedecke, l. c.

CaO, MgO tr. = 99.80FeO 24.33

Obs.—Occurs with large quartz crystals, from Kimbosan, in Kei, Japan. Named for Prof.

Rein, of Marburg, who brought the mineral from Japan.

Reinite may prove to be only a pseudomorph after scheelite; such pseudomorphs are common at Trumbull and Monroe, Connecticut, and their angles vary somewhat widely from the original mineral.

PATERAITE. Paterait Haidinger, Jb. G. Reichs., 7, 196, 1856.

An impure massive mineral of black color, supposed to be a molybdate of cobar. Analysis.—Laube, ib., 14, 303, 1864.

 Bi_2O_3 2.0 Fe_2O_3 16.6 CoO 27.0 H_2O 8.6 S 12.0 insol. 3.8 = 100

It was so intimately mixed with pyrite and bismuthinite that, even with the greatest care, it could not be completely separated. Subtracting the bismuth, iron, and sulphur in the above analysis, molybdate of cobalt remains, which, according to Laube, is the true mineral.

Discovered by Vogl, in the Elias mine, Joachimsthal, with uranium ores. Named from A. Patera, who first examined it.

Eosite A. Schrauf, Ber. Ak. Wien, 63 (1), 176, Feb. 1871.

Tetragonal, in minute square octahedrons. Axis c = 1.378; $cp = *62^{\circ} 50'$, $pp' = 77^{\circ} 58'$. Color deep aurora-red, between that of crocoite and realgar. Streak brownish H. = 3-4.

orange-yellow.

Heated in the closed tube darkens, but regains its color on cooling. Fused with potassium oisulphate gives a mass which s'ight yellow while hot, becomes, on cooling, first reddish brown and finally brownish orange-yellow. This dissolved in water and boiled with tin-foil colors the solution faint greenish blue. Not so rapidly acted upon by hydrochloric acid as crocoite or wulfenite. When a splinter of eosite is placed on a glass plate, and treated with hydrochloric acid, with subsequent addition of alcohol, and then gently evaporated, it affords a blue to bluish green coating, with a green precipitate on the edges. From these reactions, and a series of comparative tests made with crocoite, wulfenite, and vanadinite, Schrauf concludes that eosite is vanadomolybdate of lead.

Found implanted in very minute crystals on pyromorphite and cerussite at Leadhills,

Scotland.

ACHREMATITE J. W. Mallet, J. Ch. Soc., 28, 1141, 1875.

Massive, crypto-crystalline. Fracture uneven to subconchoidal. Massive, crypto-crystalline. Fracture uneven to subconchoidal. Brittle. H. =3-4. G. =5.965; in powder, 6.178. Color pale sulphur-yellow to orange and red, in the mass liverbrown, from admixed limonite. Streak pale cinnamon-brown. Luster resinous to adamantine. Translucent on thin edges.

Analysis after deducting limonite, 10 to 15 p. c.

Pb(for Cl) 6.28 3 As₂O₃ 18.25 MoOs 5.01 PbO 68.31 $C1\ 2.15 = 100$

The formula calculated is 3[\$Pb₈As₂O₈.PbCl₂].4[Pb₂MoO₅]. That the mineral is homogeneous is considered by the author as sufficiently proved. B.B. decrepitates slightly, turns dark brick-red, and fuses easily to a nearly black globule, which shows indistinct crystalline facets on cooling. On charcoal yields arsenical odors, a lead coating, and finally globules of lead. With the fluxes, reacts for iron, which, however, is only present as an impurity.

From the mines of Guanaceré, Chihuahua, Mexico. Named from ἀχρήματος, useless, in

allusion to the fact that it was received as a silver ore, while, in fact, of no intrinsic value.

820. BELONESITE. Belonesia A. Scacchi, Mem. Acc. Napoli, 1, No. 5, announced Sept. 8, 1883, published 1886.

Tetragonal. Axis c = 0.66054; 001 $\wedge 101 = 33^{\circ} 26\frac{3}{4}$ Scacchi.

In minute account crystals with a (100, i-i) small, m (110, I), p (111, 1). Angles: pp' =57° $43\frac{1}{2}$ ', pp'' = 86° 6', mp = *46° 57'. Color white. Transparent.

Comp.-A qualitative analysis proved the presence of magnesium and molybdic acid. Regarded as probably magnesium molybdate, MgMoO4 = Molybdenum trioxide 78.3, magnesia 21.7 = 100.

Pyr.—B.B. fuses with difficulty. Dissolves readily in salt of phosphorus, less easily in the

borax bead. Insoluble in acids.

Obs.—From a fragment of an ancient rock enveloped in the lava of 1872 at Vesuvius. It is near in angle to the species of the rutile group.

Named from Belovn, needle.

SALTS OF ORGANIC ACIDS.

Oxalates, Mellates.

821. Whewellite CaC₂O₄ + H₂O₅ Monoclinic 0.8696:1:1.3695 $(NH_4)_{0}C_{0}O_{4} + 2H_{0}O$ 822. **O**xammite

Oxalates.

821. WHEWELLITE. Oxalate of Lime H. T. Brooke, Phil. Mag., 16, 449, 1840. Oxacalcite Shepard, Min., 111, 1844. Whewellite B. & M., Min., 623, 1852. Kohlenspath, Frenzel, Min. Mitth., 11, 83, 1889.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c} = 0.8696: 1: 1.3695; \beta = 72^{\circ} 41\frac{1}{2}' = 001 \land 100$ Miller1.

 $100 \land 110 = 39^{\circ} 42', 001 \land 101 = 45^{\circ} 401', 001 \land 011 = 52^{\circ} 351'.$

Twins common; tw. pl. e (101) often 1, After Miller. 2, Burgk, Weisbach.

heart-shaped. Prismatic faces vertically striated; also $f(112) \parallel \text{edge } f/f$. Only in crystals.

Cleavage: c, b, m; also e Weisbach. Very brittle. Fracture conchoidal. = 2.5. Luster vitreous to greasy; on b somewhat pearly. Colorless. Transparent to opaque.

Comp—Calcium oxalate, CaC₂O₄ + H₂O (E. E. Schmid) = C₂O₄49·4, CaO 38·3,

 $H_{\circ}O 12.3 = 100.$

The related salt, CaC₂O₄ + 3H₂O occurs in tetragonal crystals in the cells of certain plants (Cacti), Lieb. Ann.. 97, 225, 1856, and Pogg., 142, 111, 1871.

Obs.—The original crystals described by Brooke were from an unknown locality; in size they were from $\frac{1}{10}$ to $\frac{1}{4}$ inch broad and occurred implanted upon calcite. Large crystals, 2 inches in thickness, have been found, associated with calcite, in a crevice of the foot-wall of a coal bed at Burgk near Dresden (Weisbach); also found with the coal of Zwickau in Saxony (Frenzel) associated with brown spar and chalcopyrite.

Ref.—1 Miller, Phil. Mag., 16 450, 1840, and Min., p. 623. 2 Weisbach, Burgk near Dresden, Jb. Min., 2, 48, 1884.

THIERSCHITE Liebig, Lieb. Ann., 86, 113, 1853. A calcium oxalate, occurring as a grayish, warty, and somewhat opaline incrustation, about a line thick, on the marble of the Parthenon, Athens. Not analyzed. Its origin is attributed to the action of some kind of vegetation on the marble. It is probably identical with whewellite. Named after Fried. v. Thiersch, the discoverer.

822. OXAMMITE. C. U. Shepard, Rural Carolinian, p. 471, May, 1870. Guañapite Raimondi, Min. Pérou, 30, 33, 1878.

Rarely in small distinct prismatic crystals (orthorhombic); usually in small flattened grains, and pulverulent. Luster silky. Color yellowish white. Trans-Inodorous. parent.

Comp.—Ammonium oxalate, $(NH_4)_2C_2O_4 + 2H_2O = C_2O_455\cdot 0$, $NH_422\cdot 5$, $H_2O_22\cdot 5 = 100$; or, $C_2O_345\cdot 0$, $(NH_4)_2O_32\cdot 5$, $H_2O_22\cdot 5 = 100$.

Pyr., etc.—Whitens in the flame of a candle, but does not take fire. Dissolves in nitric acid;

decomposed by boiling water. In a matrass yields water.

Obs.—Occurs in brown coal at Arten in Thuringia; at Luschitz near Bilin in Bohemia; near Walchow in Moravia; in the Govt. of Tula, Russia in Europe; Nerchinsk, in Transbaikal, E. Siberia.

Artif.—An artificial crystal of mellite, see Friedel & Crafts, Bull. Soc. Min., 3, 189, 1880;

Friedel & Balsohn, ibid., 4, 26, 1881.

Ref.—¹ Pogg., 94, 410, 1855; Kupffer obtained oo' = 61° 46½', oo'' = 93° 5′, 93° 6′, Preisschrift, 121, 1825; Koksharov gives oo'' = 92° 48′, Min. Russl., 3, 217, 1858. ¹² Dx., N. R., 15, 1867; Schrauf, Ber. Ak. Wien, 41, 777, 1860. On the pyroelectricity, see Hankel, Wied., 18, 422, 1883.

PIGOTITE Johnston, Phil. Mag., 17, 382, 1840. A salt of alumina and an organic acid called mudescous acid by Johnston. Composition, $4Al_2O_3$, $C_{12}H_{10}O_8 + 27H_2O$. Formed on granite, in Cornwall, from the action of wet vegetation. Reported also from Wicklow, Ch. Gaz.,

Organic Salts of Iron. Native compounds of iron and organic acids have been indicated by Berzelius and other chemists as common in marshes. But none of them has yet been properly investigated, the kinds of acids, as well as the proportions of acid to bases, being undetermined.

HYDROCARBON COMPOUNDS.

The Hydrocarbon Compounds are divided into two classes: (1) the Hydrocarbons proper, and (2) the Oxygenated Hydrocarbons. As an appendix to the chapter are introduced the highly complex substance Petroleum, and the different kinds of Bitumen, Asphaltum, and Coal.

The Hydrocarbons proper, including the various kinds of mineral wax, also mineral tallow, etc., for the most part belong to the Paraffin Series, having the general formula $C_n H_{2n+2}$. To the paraffins also belong the chief part of the many compounds present in crude petroleum; the American oil particularly consists almost exclusively of paraffins, gaseous, liquid and solid, varying widely in boiling point. With these are present also some of the olefines with the general formula C_nH_{2n} , and further in some cases the benzenes, C_nH_{2n-6} . Some kinds of coal also yield large quantities of paraffin. The compounds of the series C_nH_{2n} , C_nH_{2n-6} , with perhaps others of the series C_nH_{2n-4} ,

etc., may be also represented independently in nature, but the exact composition of the native substances is often in doubt, since in many cases analysis alone is hardly conclusive, as the difference in amounts of carbon required by the formulas of members of different series, or even of the same series, may be less than the errors of analysis. Further, members of two series in some cases

have the same percentage composition.

The Oxygenated Hydrocarbons include chiefly the numerous kinds of native fossil resins, many of which are included under the generic term amber, also other more or less closely related substances. In general, in these compounds weak acids (succinic acid, formic acid, butyric

acid, cinnamic acid, etc.) or acid anhydrides, are prominent.

The Hydrocarbon compounds in general, with perhaps a few exceptions, are not homogeneous substances, but mixtures, which by the action of solvents or by fractional distillation may be separated into two or more component parts. They are hence not definite mineral species and do not strictly belong to pure Mineralogy, rather, with the recent gums and resins, to Chemistry or, so far as they are of practical value, to Economic Geology. In the following pages they are treated with some fullness, though not accorded the rank of species. It may be added here that the original acounts given of these substances, in many cases leave much to be desired in the way of minuteness and accuracy of statement.

For a fuller discussion, more particularly of the economic products, petroleum, bitumen, asphaltum, and coal in its various forms, reference must be made to more technical works.

The microscopic and optical characters of various hydrocarbons, resins and coals have been investigated by H. Fischer & D. Rüst, Zs. Kr., 7, 209, 1882.

Simple Hydrocarbons.

Chiefly members of the Paraffin Series $C_n H_{2n+2}$

Scheererite. Scheererit *Stromeyer*, Kastn. Arch., **10**, 113, 1827; Napthaline résineuse prismatique *Könlein*, Bibl. Univ., **36**, 316, 1827; Pogg., **12**, 336, 1828. Macaire-Prinsep, Bibl. Univ., **40**, 68, 1829, Pogg., **15**, 294, 1829. Schérerite.

In monoclinic crystals, usually thin tabular (\parallel 010), sometimes acicular. Also in loosely aggregated crystalline grains and folia. Soft. G. = 1-1.2. Luster pearly or resinous; feebly shining. Color whitish, gray, yellow, green, pale reddish. More or less translucent to transparent. Easily frangible. Tasteless. Inodorous. Feel not greasy.

Comp., etc.—According to an imperfect analysis by Prinsep contains: Carbon 73, hydrogen 24 = 97. This corresponds nearly to the ratio for H = 1:4, or the composition of marsh-gas = Carbon 75, hydrogen 25 = 100; whence, if the results may be trusted, it is a polymer of

marsh-gas.

Soluble easily in alcohol, and also in ether. Melts at 44°, and then resembles a fatty oil, and like it penetrates paper; these spots, however, may be removed by heat. On cooling, the mineral crystallizes in accular crystals. May be distilled without decomposition; boiling point near 100° (92°, Prinsep).

996

Soluble in sulphuric or nitric acid, and not in alkalies. Takes fire easily and burns without

residue, giving out much smoke and a feeble aromatic odor.

Obs.—Found by Capt. Scheerer, in the year 1822, in the coal of a bed of brown coal in the Tertiary, at Uznach, near St. Gallen, in Switzerland. The bed of coal is two to three feet thick, and the pine stems in it are almost unchanged. Among the species of pine, there is the \overrightarrow{P} . sylvestris; and the birches and firs are those of modern species. The age is the same with that of the peat beds of Redwitz. Besides scheererite it affords also fichtelite and könlite. On cryst., Kenng., Ber. Ak. Wien, 14, 272, 1854, and Min. Schweiz, 418, Leipzig, 1866.

Hatchettite. Hatchetine (fr. Merthyr-Tydvil) Conybeare, Ann. Phil., 1, 136, 1822. Mineral Adipocire, Mountain Tallow (fr. Loch Fyne). Brande, Ed. Phil. J., 11, 1824. Adipocerite. Hatchetine (fr. Glamorganshire) J. F. W. Johnston, Phil. Mag., 12, 338, 1838.

In thin plates, or massive. Reported as sometimes occurring as large crystals in fresh specimens. H. like that of soft wax. Feel greasy. G. = 0.916 Johnston; 0.983 Loch Fyne, after melting and excluding air-bubbles, Brande; 0.608, same before melting id. Luster slightly glistening and pearly. Color yellowish white, wax-yellow, greenish yellow; blackens on exposure. Subtransparent to translucent; but opaque on exposure. Without odor. Melting point 46° Merthyr-Tydvil, Johnston; 47° Loch Fyne, Brande.

Comp., etc.—Ratio of C to H = nearly 1:1, from Johnston's analysis, = Carbon 85.55, hydrogen 14.45 = 100. Anal.—Johnston, l.c.

Glamorganshire Carbon 85.91 Hydrogen 14.62 = 100.53

Very sparingly soluble in boiling alcohol, and precipitated from the solution on cooling. Also soluble sparingly in cold ether, and more largely in boiling; and from the latter deposited in a mass of minute fibers or prisms. After repeated boiling with ether there remains only a minute portion undissolved, mixed with particles of charcoal derived from the blackened surface of the specimen. Charred and decomposed by concentrated and boiling sulphuric acid. No

apparent change in boiling nitric acid.

Obs.—From the crevices of iron-stone septaria, and often in geodes containing also quartz crystals, in the Coal-measures near Merthyr-Tydvil in Glamorganshire (and, Johnston adds, in some of the Midland Counties of England); also in a bog on the borders of Loch Fyne in Argyleshire, Scotland. The latter has not yet been analyzed. Also reported from Rossitz in Moravia (Jb. G. Reichs., 5, 898, 1854), in the Segen-Gottes mine, with spherosiderite as a thin coating on calcite, having H. = 1, G. = 0.892 Patera.

Cesaro has found some hatchettite made up of thin laminæ which are optically biaxial and

positive; a less distinct axial figure was obtained from ozocerite, but it was also positive and like the hatchettite was referred to the orthorhombic system. Ann. Soc. G. Belg., 18, 1891; cf. also Dx., Min., 2, 38, 1874.
Named after C. Hatchett, an English chemist (1765–1847).

This species (or at least the bog variety from Loch Fyne) is probably identical with the kind of paraffin that fuses at 45°-47°; and which has been obtained by the destructive distillation of Boghead coal and peat, and from other sources. Anderson obtained in his analyses of this paraffin:

		C	H	Melting T.
1. From Boghead coal, cryst.		85.1	15.1-15.3	45.5°
2. " " granular		85.0-85.3	15.4	52
3. From peat	2	85.09	15.10	46.7

The Boghead coal (from Boghead and Torbane Hill, near Bathgate in Linlithgowshire) affords on destructive distillation a very large amount of different oils and paraffin, 70 p. c. of the dried mass being volatile. See BATHVILLITE beyond.

PARAFFIN. A native crystallized paraffin, like the above, is described by O. Silvestri as occurring in cavities in basaltic lava near Paterno, Sicily. It is in yellowish white, wax-like, transparent crystalline plates. Melts at 56°, volatilizes at about 300°. Nearly insoluble in cold alcohol, but readily dissolves in boiling ether. An analysis gave: \(\frac{3}{2}\) Carbon 84·00, hydrogen 15·85 = 99·85. Boll. Com. G., 12, 578, 1881; also earlier [Gazz. Ch. Ital., 1877].

CHRISMATITE. Chrismatin (fr. Wattin) Germar, Zs. G. Ges., 1, 40, 1849. Ozokerit (fr. ib.) Breslau, Karst. u. Dech. Arch., 23, 749, 1850. Hatchettin (fr. ib.) Wagner, Jb. Min., 687, 1864; H. Fleck, Steinkohlen Deutschl., 1, 37, 4to, München, 1865.

Butter-like, or of semi-fluid consistence. Soft at 55° to 60°. G. below 1. Luster greasy to silky. Color greenish yellow to wax-yellow. Slightly translucent. Tasteless. Melts at a very low temperature to an oil, which is dark red by transmitted light, and apple-green by reflected.

H. Fleck obtained, 34 p. c. of ash having been removed: Carbon 78 51, hydrogen 19 19,

oxygen 2.30 = 100. Excluding the oxygen as water, as done by Fleck, it leaves C 80.51, H 19.49 =100, corresponding to $C_2H_6=$ Carbon 80, hydrogen 20; making it thus a polymer of C_2H_6 , or the second member of the Marsh-gas series. Fleck adopted the formula $C_{13}H_{38}$. If the oxygen is an essential constituent, either view of the constitution is wholly at fault. Burns with a flame. without smell.

Occurs in cavities of calcite and quartz crystals in an argillaceous sandstone of the Carboniferous formation at Wettin, Saxony.

Named from $\chi \rho i \sigma \mu \alpha$, ointment.

Ozocerite. Part of Native Paraffin. Ozokerit (brought by v. Meyer fr. Slanik, Moldavia) Glocker, Schw. J., 69, 215, 1833; Magnus, Ann. Ch. Phys., 55, 217, 1833. Circ fossile Fr. Mineral wax pt. Erdwachs Germ.

Like wax or spermaceti in appearance and consistency. G. = 0.85-0.90. Colorless to white when pure; often leek-green, yellowish, brownish yellow, brown; and when brown sometimes greenish by transmitted light. Often having a greenish opalescence. Translucent. Greasy to the touch. Fusing point 56° to 63°.

Comp., etc.—Essentially a paraffin, and consisting chiefly of one of the higher members of the series. The original ozocerite, from Slanik in Moldavia, as described by Glocker was wholly called in other and respectively a secondary and transmission of the property and pr

soluble in ether, and gave a yellow solution; also soluble in oil of turpentine and naphtha; and a little soluble in boiling alcohol. G. of the mass, 0.955 Glocker; 0.953 Schrötter. Melting point 62° Schrötter.

The mineral wax of Urpeth Colliery, after the separation of what was soluble in cold ether (see URPETHITE, p. 999), afforded Johnston another portion through its solubility in boiling ether; and this is apparently identical with true ozocerite. While soluble in boiling ether it is sparingly so in boiling alcohol. As obtained from the other solution it was yellow, and had the consistence

of soft wax.

A kind from Boryslaw in Galicia, examined by Hofstädter (Lieb. Ann., 91, 326, 1854), resembled the preceding in its appearance, but was darker colored, being blackish brown, in thin pieces reddish brown to leek-green by transmitted light; G. = 0.944; melting point 60°. By fractional crystallization it was separated into parts varying in fusibility from 60° to 65.5°. That from Truscawitz, Galicia, examined by Walter (J. pr. Ch., 22, 181, 1841) appears to be similar.

Anal.—1, Schrötter, Baumg. Zs., 4, 2, 1836, Bibl. Univ., 3, 184, 1836. 2, Johnston, l. c. 3, Walter, l. c. 4, 5, Hofstädter, l. c. 6, 7, Seal, J. Frankl. Inst., 130, 402, 1890.

	G. (с н	I	Melting T.	Boiling T.
1. Slanik	0.953 84		= 98.12	62°-63°	210°
2. Urpeth C.	86	80 14.06 :	= 100.86	58°	3
3. Truscawitz, crude	84	62 14.29 :	= 98.91	59°	ov. 300°
4. Boryslaw, A. () 944 84	94 14.87 :	= 99.81	61°	
5. "· B.	85	78 14.29 =	= 100.07	65.5°	
6. Utah	0.971 85	44 14.45 =	= 99.89		
7. "		47 14.57 :	= 100.04		

The A of Hofstädter was the portion separated by fractional crystallization which had 61° as the melting point, and the B that which had for this point 65.5°. The material analyzed by

Seal was the white paraffin extracted from the crude material by alcohol, cf. below.

Hermann has described a wax-like mixture from seams in a rock in the vicinity of Lake Baikal, which he calls Baikerite (J. pr. Ch., 73, 230, 1858). About 60 18 p. c. of it was soluble in boiling alcohol, 100 parts dissolving 1; and this portion appears to be ozocerite. It was tasteless and inodorous; melting point 59°; G. = 0.90. The rest (29.82 p. c.) of the baikerite consisted as follows: 7.02 wax-like substance insoluble in alcohol: 32.41 viscid resin; 0.39 earthy impurities.

The same compound has been obtained from mineral coal, peat, petroleum, mineral tar, etc., by destructive distillation. The following are examples. 1, Anderson, Rep. Brit. Assoc., p. 50,

1856, and J. pr. Ch., 72, 379, 1857. 2, Hofstädter, 1. c.

	C	H	Melting Point.
1. Rangoon Tar	85.15	15.29 = 100.44	61°
2. From bitum, shale, Bonn.	86.16	14.36 = 100.52	61°

Obs.—Ozocerite occurs at the localities mentioned, in beds of coal, or associated bituminous deposits: that of Slanik, Moldavia, beneath a bed of bituminous clay shale; in masses of sometimes 80 to 100 lbs., at the foot of the Carpathians, not far from beds of coal and salt; that of Boryslaw in a bituminous clay associated with calciferous beds in the formation of the Carpathians in masses. Reported also from near Gaming in Austria; in Transylvania, near Moldavia, in the Carpathian sandstone: at Uphall in Linlithgowshire.

Ozocerite also occurs in southern Utah on a large scale, where it has been mined to some extent for technical purposes. The deposits are in the form of veins usually a few inches in thickness and extend over a wide area in Emery and Uintah counties; it is associated with fibrous

The crude material has a dark-brown color, is of wax-like consistency and has a foliated structure. G. = 0.9285 Seal. It has a melting point of 51°-55° Seal; 61.5° Newberry; it is

completely soluble in boiling ether, carbon disulphide and benzene; the dilute solution is highly fluorescent. Boiling alcohol extracts from it twenty per cent of a white wax-like substance (S. B. Newberry, Am. J. Sc., 17, 341, 1879). Seal (l. c.) obtained 60 p. c. of this white solid after chilling the solution from the extractor, filtering and drying. This melts and becomes of a yellow-colored waxy consistency and has a specific gravity of 0.9708. It showed marked resistance to the action of a strong acid, agreeing with its character as a paraffin, one of the

higher members of the series. Its composition is shown to be between $C_{18}H_{38}$ and $C_{29}H_{42}$.

Ozocerite has also been found in the clay fields of South Amboy, N. J. F. S. Smith obtained for a sample not purified: Carbon 86.46, hydrogen 12.83 = 99.29. This corresponds to C_nH_{2n} .

Am. Ch. J., 6, 247, 1884.

Named from δζειν, to smell, and κηρός, wax, in allusion to the odor.

On the occurrence and characters of ozocerite in general, see Rateau, Ann. Mines, 11, 147, 1887

Woehler has noted the existence in meteorites of a hydrocarbon (Kabaite) near ozocerite or scheererite, and Meunier has recently repeated the observation (C. R., 109, 977, 1889). The composition of the substance is not yet determined.

ZIETRISIKITE. Cire fossile de Moldavie Magnus, Ann. Ch. Phys., 55, 217, 1833. Ozokerite (fr. Zietrisika) Malaguti, C. R., 4, 410, 1837, Ann. Ch. Phys., 63, 390, 1836, Pogg., 43, 147.

Zietrisikite Dana.

A mineral like ozocerite in most physical characters and in composition, but distinguished by almost complete insolubility in ether and higher melting point. Hardness like that of beeswax, or harder. G. = 0.9; 0.946 Malaguti. Color brown. Melting point 90°; 82°-84° in the crude or impure mineral. Insoluble in ether.

1. Magnus, who made the first examination of the fossil wax brought by Meyer from Slanik, Moldavia, appears to have had a different substance in hand from that examined by Glocker (by whom ozocerite was named) and by Schrötter, as he states that only a very little of it was dissolved by alcohol or ether, and the rest, after the action of these solvents, was eroded with holes, showing the presence of insoluble and soluble constituents. The insoluble was soluble in oil of

turpentine, and of this part the melting point was 82°, and the composition as given below.

2. The wax from Zietrisika, Moldavia, examined by Malaguti, is regarded by him as identical with that of Magnus. It was foliated, conchoidal in fracture, pearly in luster, deep red-brown in color with a greenish reflection, but in very thin pieces brown, and a little harder than beeswax. It was very slightly soluble in alcohol or boiling ether, and very soluble in oil of turpentine and naphtha, with no action from alkalies or cold sulphuric acid. It melts at 84°, and boils at above 300°. On subjecting it to boiling alcohol, a small portion was dissolved, whose melting point was 75°; by a second treatment another portion was obtained, having for the melting point 78°; and at the fourth, the portion dissolved was found to have the same melting point as that of the undissolved mass, which was 90°. This then, which he calls brown ozocerite, appears to be the point of fusion of the true zietrisikite, and this alone was analyzed; as the rest, his yellow ozocerite, he says, "est un mélange, j'ai jugé inutile d'en faire l'analyse."

Anal.—1, Magnus; 2, 3, Malaguti, l.c., and Rg., Min. Ch., 964, 1860.

	C	H	Melting T.	Boiling T.
1. Moldavia	84.61	15.30 = 99.91	82°	
2. Zietrisika, Mold.	84.53	14.22 = 98.75	90°	Above 300°
3. "	84.78	14.37 = 99.15	90°	"

The wax from Zictrisika, in Moldavia, occurs in large masses, and under similar circumstances with that of Slanik.

URPETHITE. Part of Ozocerite (fr. Urpeth Collicry) J. F. W. Johnston, Phil. Mag., 12, 389, Urpethite Dana.

Consistence of soft tallow. G. = 0.885. Color yellowish brown to brown. Adheres to the

fingers, and stains paper.

Analysis.—Johnston: Carbon 85.83, Hydrogen 14.17 = 100. Soluble readily in cold ether. Ethereal solution brown by transmitted light, but with a greenish opalescence by reflected; deposits the wax in brown flocks. Melts at 39° to a yellow-brown liquid.

Constitutes about four-fifths of the Urpeth Colliery ozocerite, and is separated from the latter through its solubility in cold ether. The crude wax, as found, was soft enough to be kneaded in the fingers; had a greasy feel, and gave a greasy stain to paper; was subtransparent; of a brownish yellow color by transmitted light, but yellowish green and opalescent by reflected; and had an odor slightly fatty, which was stronger when melted. It occurred in cavities near a foult in the Colon passages and part in the solid sandstone. a fault in the Coal-measures, and part in the solid sandstone.

BAIKERINITE. Part of Baikerit, Dickflüssiges Harz, Hermann (see p. 998). A thick tarlike fluid at 15°, and a crystalline granular deposit in a viscid honey-like mass at 10°. Color brown. Translucent. Odor balsamic. Taste like that of wood-tar. Easily and perfectly soluble in alcohol and ether. The alcoholic solution becomes milky when diluted with water. Constitutes 32.61 p. c. of the baikerite. No analysis yet made.

Neft-Gil. Naphtdachil, Nephatil, Jb. Min., 84, 1846. Naphthadil Kenng., Ueb., 254, 1844–1849. Neftdegil Herm., J. pr. Ch., 73, 220, 1858. Neft-gil Fritzsche, ib., 321. A very abundant

material in the naphtha region on Cheleken I., in the Caspian. It is a mixture of paraffins and a resin, but appears to be most nearly related to zietrisikite. G. = 0.956; color chocolate-brown; melting point 75°. Hermann found 66 p. c. of a wax-like substance insoluble in alcohol, and 18 p. c. of another soluble in alcohol, besides 13°33 p. c. of a resin. In ether a large part was insoluble; and this portion may be identical with the zietrisikite (see above), or with the insoluble paraffin from the Urpeth wax, called urpethite.

Pyropissite Kenng., Ueb., 148, 1850-51. Kenngott has thus named an earthy, friable, coaly substance, of grayish brown color, and without luster, and having G. = 0.493-0.523, which forms a layer 6 to 9 in. thick in brown coal at Weissenfels, near Halle. A small part is soluble in alcohol, especially in boiling, and this, precipitated by adding water, is a wax-like substance, paraffin-like in aspect. But whether true paraffin, or whether an oxygenated wax, substance, paralini-like in aspect. But whether true paralini, or whether an oxygenated wax, related to geocerite, has not been ascertained. It melts easily to a pitch-like mass, and hence the name from $\pi \partial \rho$, fire, and $\pi i \sigma \sigma \alpha$, pitch. It affords 62 p. c. of paraffin on dry distillation. Coals affording paraffin on distillation are sometimes called Paraffin coal, and in German Wachskohle. Kenngott refers here also an earthy brown substance from Mettenheim, which melts similarly to an asphalt-like substance. It occurs incrusting massive limestone.

HELENITE A. Nawratil, Dingl. Pol. J., 248, 513, 1883. Fossiles Kautschuk. A wax near ozocerite, forming lamellæ 10 to 15 cm. long and 4 to 5 cm. broad. Elastic like caoutchouc. G.=0.915. Color light to dirty yellow. Soluble in chloroform and carbon disulphide, but not in 94 p. c. alcohol. Anal.:

Carbon	85.13	Hydrogen	15.70 = 100.83
	84.62	The state of the	16.43 = 101.05
	85.30		15.29 = 100.59

Formed in the Helena shaft of the petroleum region at Ropa in Galicia.

Fichtelite. Tekoretin Forchh., Vid. Selsk. Afh. Copenh., 1840, J. pr. Ch., 20, 459, 1840. Fichtelit Bromeis, Lieb. Ann., 37, 304, 1841; T. E. Clark, ibid., 103, 236, 1857, Am. J. Sc., 25, 164, 1858.

Monoclinic. Crystals tabular $\parallel c$ or elongated $\parallel \dot{b}$. Forms: a (100, $i \cdot \bar{i}$), c (001, 0), m (110, I), i (101, 1- \bar{i}). Angles (measured): $mm''' = 97^{\circ}$, $ac = 53^{\circ}$, $ai = 52^{\circ}$, $ci = 75^{\circ}$ Clark. Twins: tw. pl. c. H. = 1. Luster somewhat greasy. Color white. Translucent. Brittle. Without taste or smell. Distils over without decomposition. Solidifying temperature 36°

Easily soluble in ether; less so in alcohol. Ax. pl. | 010.

Comp., etc.—Formula doubtful; Rg. gives C_bH₆ = Carbon 88.4, hydrogen 11.6 = 100; Clark deduced C₄H₇ = Carbon 87.3, hydrogen 12.7 = 100. The latest analyses give from

C15H26 to C15H28, see below.

Anal.—I, Bromeis, I. c. (Clark, recalc.). 2, Clark, I. c. 3, Forchhammer, I. c. 4, J. W. Mallet, Proc. Brit. Assoc., p. 79, 1872. 5, 6, Macadam, Min. Mag., 8, 137, 1889.

		C	H	Melting T.	Boiling T.
1.	Redwitz	87.95	10.70 = 98.65	46°	
2.	66	3 87·13	12.86 = 99.99	46°	above 320°
3.	Tecoretin	85.89	12.81 = 98.70	45°	360°
	Alabama	87.82	11.91 = 99.73		
	Handforth	86.78	12·18 O 1·04 =		
6.	Shielding	87.14	12.08 O 0.78 =	= 100	

Hell has investigated (Ber. Ch. Ges. 22, 498, 1889) fichtelite from a peat swamp near Redwitz. where it has been derived from Pinus uliginosa. Dissolves in a mixture of alcohol and ether, where it has been derived from *Prima uniquiosa*. Dissolves in a linkture of alcohol and ether, from which it is deposited as prismatic crystals upon the slow evaporation of the ether. The purified crystals thus obtained melt at 46° and gave on analysis:

Carbon 86·7-87·0, hydrogen 13·2-13·5.

Density of the vapor at 440°, 7·37-7·77, corresponding to the formula C₁₅H₂₈ to C₁₅H₂₆, perhaps C₁₅H₂₇; the last (= doubled, C₃₀H₅₄) requires: Carbon 87·0, hydrogen 13·0 = 100.

Bamberger (ibid., p. 635) confirms the above conclusion. He notes the occurrence at the Kelberger Perenties in Lipson Paragraphs.

Kolbermoor near Rosenheim in Upper Bavaria. Spiegel (ibid., p. 3369) gives the formula $C_{18}H_{32} = \text{Carbon } 87\cdot1$, hydrogen $12\cdot9 = 100$.

Decomposed by anhydrous sulphuric acid; also by heated fuming nitric acid; soluble in

cold nitric acid.

Clark, after a revision of the investigations on fichtelite and the related resins, concludes that there is no doubt of the identity of the substance analyzed by him with Bromeis's fichtelite.

for which is deduced the empirical formula C_5H_8 .

Obs.—The mineral occurs in shining scales, flat crystals, and thin layers between the rings of growth and throughout the texture of pine wood (in part identical in species with the modern

Pinus sylvestris) from peat beds in the vicinity of Redwitz, in the Fichtelgebirge, North Bavaria. The crystals described by Clark were obtained artificially by means of ether and alcohol.

An oily substance was extracted by Schrötter by means of ether from wood of the same peat bed which afforded the fichtelite; and this solution yielded two substances, one of which was an oil, regarded by him as identical with fichtelite in ratio; it gave on analysis: Carbon 88 58, hydrogen 11:34 = 99:42. The other substance was crystallized and contained oxygen.

Fichtelite also occurs in crystals in peat beds at Salzendeich, Elsfleth, Oldenburg; near Sobeslau in peat. In England found in pine logs in a moss at Handforth in Cheshire, and in peat moss at Shielding in Ross-shire. Also from Alabama, in recent pine logs (Pinus Australis).

Tecoretin was obtained from pine trees of the same species in marshes near Holtegaard in Denmark. The resin from the wood, first observed by Steenstrup, was found by Forchhammer, after dissolving it in boiling alcohol, to contain two substances crystallizing from the solution at different temperatures. The *tecoretin* was the least soluble of the two, or that which crystallized out first (the other was his *phylloretin*, see p. 1002); its crystallization was *monoclinic*, and its fusing point 45°. From the analysis Clark writes the empirical formula CH₂; but states that the mineral resembles fichtelite in every other respect. Ref.—1 L. c.; cf. Schuster, Min. Mitth., 7, 88, 1885.

Hartite. Hartit Haid., Pogg., 54, 261, 1841. Branchite Savi, N. Cimento, 1, 342, Jb. Min.,

459, 1842.

Triclinic or monoclinic. Resembling fichtelite in crystalline form, luster, color, translucency, and the reactions with alcohol, ether, and the acids. But melts at 74°-75° C. Boiling temperature very high.

Comp., etc.—Ratio of C to H = 12 : 20 = Carbon 87.8, hydrogen 12.2. Anal.—1, Schrötter,

Pogg., 59, 43, 1843. 2, Piria, JB. Ch., 984, 1855.

	C	H
1. Hartite	87.47	12.05 = 99.52
2. Branchite	87.0	13.4 = 100.4

Piria's analysis corresponds nearly with the ratio 9:16.

Obs.—Hartite is found in a kind of pine, like fichtelite, but of a different species, the Pouce acerosa Unger, belonging to an earlier geological epoch. It is from the brown-coal beds of Oberhart, near Gloggnitz. not far from Vienna. Reported also from Rosenthal near Köflach in Styria, and Pravali in Carinthia. It occurs among the layers or tissues of the wood, and also in clefts in the coal or lignite.

Branchite is colorless and translucent, with G. = 1.044, and comes from the brown coal of

Mt. Vaso in Tuscany. It is soluble in alcohol, like hartite.

Hartite is also found at Obersdorf near Voigtsberg in Styria (cf. Rumpf, who makes the crystals triclinic, Ber. Ak. Wien, 60 (2), 91, 1869).

DINITE Meneghini, Gaz. Med. Italiana, Firenze, Toscana, July, 1852. Occurs as an aggregation or druse of crystals; cleavage none; with the appearance of ice, but with a yellow tinge due to a foreign substance. Inodorous; tasteless; fragile, and easily reduced to powder.

Insoluble in water; little soluble in alcohol, very soluble in ether and in carbon disul-

phide. The ethereal solution on standing deposits large crystals of the dinite. Fuses with the warmth of the hand; heated in a close vessel distills over without undergoing any sensible decomposition. When melted it looks like a yellowish oil; crystallizes in large transparent crystals on cooling.

From a lignite deposit at Lunigiana, Tuscany, where it was found by Prof. Dini.

IXOLYTE. Ixolyt Haid., Pogg., 56, 345, 1842. Amorphous. Fracture imperfect conchoidal in the purer varieties. H. = 1. G. = 1 008. Luster greasy. Color hyacinth-red. Pulverized in the fingers, it becomes ocher-yellow and yellowish brown. Thin fragments subtranslucent. Softens at 76°, but is still tenacious at 100°, whence the name, from 'ιξός, gluey, like birdlime, and λύειν, to dissolve.

This species is said to resemble hartite, though differing in the temperature of fusion and other characters. It occurs in a coal bed at Oberhart, near Gloggnitz; pieces sometimes half an

inch thick, associated with hartite.

NAPALITE G. F. Becker, U. S. G. Surv., Monograph 13, 372, 1888.

A yellow bituminous substance of the consistency of shoemaker's wax. It is dark reddish brown and shows green fluorescence, which, however, disappears on exposure to the air; garnet-red by transmitted light. Brittle, but easily molded when warmed by the hand. Not elastic; fracture conchoidal. H. = 2. Begins to fuse at 42° and becomes liquid at 46°; boils above 300°, and at 130° a heavy colorless oil distills over with an aromatic odor. Separated into various products by fractional distillation. Composition expressed by the formula, CoH4. Analyses, Melville:

Carbon	89.84	Hydrogen	10.17	=	100.01
	89.54		10.36	=	99.90
	89.35		10.11	=	99.46

Könlite. (Fr. Uznach) Kraus, Pogg., 43, 141, 1838. Könlit (fr. ib.) Schrötter, ib., 59, 37, 1843; (fr. Redwitz) v. Trommsdorff, Ann. d. Pharm., 21, 126. Könleinit Hausm., Handb., 1487, 1847; Kenngott, Ber. Ak. Wien, 14, 272, 1854, Min. Schweiz, 419, Leipzig, 1866.

In folia and grains; amorphous; stalactitic. Soft. G. = 0.88, Trommsdorff. Color reddish brown to yellow. Melting point 114°, Kraus; 1074°, Trommsdorff. Distills at 200°, undergoing decomposition at the same time, and leaving a brown residue. Very slightly soluble in cold and hot alcohol; much more soluble in ether; the latter solution affording wax-like

Comp.—Ratio of C, H = 1:1; $n(C_6H_6)$ or a polymer of benzene. Anal.—1, Kraus, l. c.

2, v. Trommsdorff, l. c.

	C	H
1. Uznach, Switz.	92.49	7.42 = 99.91
2. Redwitz, Bavaria	90.90	7.58 = 98.48

The Redwitz mineral may be a different species. Könlite, unlike scheererite, is changed by distillation, yielding a substance which melts by the warmth of the hand. For this product

Kraus proposed the name pyroscheererite.

Obs.—In brown coal at Uznach, at the same locality with scheererite; near Redwitz, Bavaria, in the Fichtelgebirge with fichtelite; reported by Kenngott from the brown coal of Fossa in the Eger valley (Ueb., 147, 1850-51). Named after Könlein, formerly superintendent of the coal works at Uznach.

Phylloretin Forchhammer, J. pr. Ch., 20, 459, 1840. Near the above, and made identical with it by Fritzsche. It was obtained from an alcoholic solution of a resin from the marshes near Holtegaard in Denmark; the more soluble of the two resins obtained (see p. 1001) being the phylloretin. Fusing point 86°-87°. Dissolves easily in alcohol. Forchhammer obtained: Carbon 90°22, 90°12, hydrogen 9°22, 9°26; he deduces for the ratio of C to H. = 8:10.

Naphhalene, Naphhalin. Commonly, as artificially prepared, in rhombic tables of 122° and 78° with the acute angles truncated, or hexagonal tables. Luster brilliant. Color white. G. = 1·153 at 18°; 0·9778 at 79·2°, Kopp.; at which temperature it melts. Boiling point 218°. Dissolves readily in alcohol, ether. oil of turpentine, fatty oils, etc.

Comp.—C₁₀ H₈ = Carbon 93·75, hydrogen 6·25 = 100. The first of the Napthalene series,

the general formula for which is $C_n H_{2n-12}$. Burns with a dense smoking flame. Found sparingly in Rangoon tar, by De la Rue and Müller, and by Warren and Storer. Formed easily from petroleum, coal-naphtha, essential oils, on passing them through red-hot tubes.

2. Oxygenated Hydrocarbons.

Succinite. "Ηλεκτρον Homer, etc. ? Λυγγύριον Theophr., Demostr. Λυγγούριον Diosc., etc. Succinum, Electrum, Lyncurium, Plin., 37, 11, 12, 13. Amber pt. Succin, Ambre, Fr. Bernstein, Agstein, Germ. Succinite pt. Breith., Char., 75, 1820, 140, 1823.

In irregular masses, without cleavage; fracture conchoidal. Optically anisotropic, showing

bright interference-colors in polarized light.

H = 2-2.5. G = 1.050-1.096 Helm; the lowest values for kinds with numerous minute cavities. Luster resinous. Color yellow, sometimes reddish, brownish, and whitish, often clouded, sometimes fluorescent. Streak white. Transparent to translucent. Tasteless. Nega-

tively electrified on friction. Heated to 150° begins to soften and finally melts at 250°-300°.

Comp.—Ratio for C, H, O = 40: 64: 4 = Carbon 78:94, hydrogen 10:53, oxygen 10:53 = 100.

Anal.—1, Schrötter, Pogg., 59, 64, 1843. 2, O. Helm, Schriften Ges. Danzig, 7, No. 4, 192, 1891.

1. C 78·824 H 10.229 0.10.947 = 10078.63 10.48 10.47 $S \cdot 0.42 = 100$

Sulphur, in the form of an organic compound, is present in amounts varying from 0.26 to

0.48 p. c. Helm.

Amber was early found to be not a simple resin. According to Berzelius (Pogg., 12, 419, 1828), it consists mainly (85 to 90 p. c.) of a resin which resists all solvents along with two other resins soluble in alcohol and ether, an oil, and 2½ to 6 p. c. of succinic acid. Schrötter and Forchhammer state that after removing these soluble ingredients, true succinite has the ratio 40:64:4, which is the ratio deduced from the analyses of the whole mass.

The properties of succinite or amber in the narrow sense are given minutely by Helm, l. c.,

1891, as follows:

Heated in the open air, it melts at from 250° to 300° without previously swelling up, boils quietly after the fusion, at the same time giving off dense white fumes which have a peculiar aromatic odor irritating to the respiratory organs. Heated in a glass retort, connected with a cooled receiver, the products of distillation, formed in the neck of the retort, are a reddish brown oil and a crystalline solid (succinic acid), while a watery fluid goes over into the receiver, leaving a blackish brown coke-like substance behind. This residue is easily rubbed to powder and is soluble in oil of turpentine (this is the so-called colophony of amber or Bernstein colophonium Germ.). The oil noted above is thick, of a reddish brown color with greenish fluorescence and peculiar odor; it contains in solution a little sulphur and succinic acid. The watery liquid is a solution of succinic acid in water, and is also said to contain acetic acid and butyric acid.

In regard to the action of solvents, Helm notes that in alcohol 20 to 25 p. c. are dissolved; in In regard to the action of solvents, Helm notes that in alcohol 20 to 25 p. c. are dissolved; in ether 18-23 p. c.; in oil of turpentine 25 p. c.; in chloroform 20 6 p. c.; in amyl alcohol 20 p. c.; in carbon disulphide 24 p. c.; in methyl alcohol 13 p. c.: in benzol 9 8 p. c.; in petroleum ether 2 2 p. c.; in alcoholic solution of potash 40 to 55 p. c. The evaporation of the solution in alcohol or ether gives a brittle resin having the peculiar aromatic odor of succinite and melting at 146°. The amount of succinic acid present is usually from 5 to 6 p. c., or in some cases up to 8 p. c. The presence of this considerable quantity is taken as characteristic of true succinite or when in the new regression. amber in the narrow sense. On the characters of amber and its occurrence in general see Helm, Schriften Ges. Danzig, 7, No. 4, 189, 1891, and also several earlier papers in the same publication; also Conwenz, ibid., 7, No. 3, 165, 1890.

Obs.—Amber occurs abundantly on the Prussian coast of the Baltic; occurring from Dantzig to Memel, especially between Pillau and Dorf Gross-Hubnicken. It occurs in England, near London, and on the coasts of Norfolk, Essex, and Suffolk; also on the coast of Denmark, Sweden, and the Russian Baltic provinces; also in western Russia and in Westphalia. I mined extensively, and is also found on the shores cast up by the waves after a heavy storm.

Further, resins resembling amber in appearance and in many of their characters and of like use occur at many other points, but according to Helm they are to be distinguished from true succinite, or amber in the strict sense, chiefly by their containing very little or no succinic acid. Some of these other localities (see further special kinds described beyond) are: in Galicia, near Lemberg, and at Miszau; in Poland; in Moravia, at Boskowitz, etc.; in the Ural; near Christiania, Noiway; in Switzerland, near Bâle; in France, near Paris, in clay, in the department of the Lower Alps, with bituminous coal; also in the department of l'Aisne, de la Loire, du Gard, du Bas Rhin. It also occurs in various parts of Asia, as in Upper Burma. Also near Catania, on the Sicilian coast, sometimes of a peculiar opalescent blue or green tinge (see simetite, beyond); of a rich golden yellow in southern Mexico.

Amber-like resins have been found in various parts of the Green-sand formation of the United States, either loosely embedded in the soil, or engaged in marl or lignite, as at Gay Head or Martha's Vineyard; near Trenton and also at Camden and elsewhere in New Jersey, and at Cape Sable, near Magothy river, in Maryland. A mass found in the marl pits near Harrison-ville, Gloucester Co., N. J., was $20 \times 6 \times 1$ in. and weighed 64 oz. G. = 1.061 Kunz (this contains no succinic acid, Helm).

In the royal museum at Berlin there is a mass of amber weighing 18 lbs. Another in the kingdom of Ava, Iudia, is nearly as large as a child's head, and weighs 2½ lbs.; it is intersected

by veins of calcium carbonate, from the thickness of paper to one-twentieth of an inch.

It is now fully ascertained that amber and the similar fossil resins are of vegetable origin, altered by fossilization. This is inferred both from its native situation with coal, or fossil wood, and from the occurrence of insects incased in it. Of these insects, some appear evidently to have struggled after being entangled in the then viscous fluid; and occasionally a leg or wing is found some distance from the body, which had been detached in the effort to escape. Göppert has shown (Ber. Ak. Berlin, 450, 1853, Am. J. Sc., 18, 287, 1854) that at least 8 species of plants besides the *Pinites succinifer* have afforded these fossilized resins, and he enumerates 163 species as represented by remains in them. Besides pines, species of the family Abietinea and Cupressinea have probably contributed to them. True succinite, however, is shown by H. Conwentz (Monograph der Baltischen Bernsteinbäume, Danzig, 1890, quoted by Helm) to have been derived from the Pinus succinifer.

Amber was early known to the ancients, and called ἤλεκτρον, electrum, whence, on account of its electrical susceptibilities, has been derived the word electricity. It was named by some lyncurium, though this name was applied by Theophrastus also to a stone, probably to zircon or

tourmaline, both minerals of remarkable electrical properties.

Pliny mentions, as one proposed derivation of electrum, the fable, as he regards it, that the sisters of Phaethon, changed into poplars, shed their tears on the banks of the Eridanus (or Padus), and that these tears were called electrum, from the fact that the sun was usually called elector; as another, that it comes from Electrides, the name of certain islands in the Adriatic; or another, electrides, the name of certain stones in Britannia, from which it exudes. He gives it as his opinion that "amber is an exudation from trees of the pine family, like gum from the cherry, and resin from the ordinary pine"; and, as proof that it was once liquid, alludes to the gnats, etc. in it. He observes that it had been long called *succinum*, because of this origin, "quod arboris succum prisci nostri credidere." He says that in his time it was "in request among women only." But "it had been so highly valued as an object of luxury that a very diminutive human efligy, made of amber, had been known to sell at a higher price than living men, even in stout and vigorous health."

Succinellite. Succinic acid obtained in orthorhombic crystals from amber; cf. Rg, Kr. Ch., 2, 209, 1882. H. = 1. G. = 1.55. Luster vitreous, Colorless or white. An aromatic odor. Soluble in water. Composition corresponds to $C_4H_6O_4$ = Carbon 40.7, hydrogen 5.1, oxygen 54.2 = 100. Evaporates at a low temperature, and on cooling condenses in crystals.

Exists in amber, constituting 2½ to 6 p. c. of the mass (cf. p. 1003), and easily obtained from it by distillation. Its presence ready formed in this resin is shown by the fact that it may be separated either by water, ether, or alkalies, the amber being left after the treatment without its succinic acid.

The mineral resins immediately following are for the most part near succinite or amber. Other resins less closely related are appended to them.

Retinite. Amber pt. A general name applied to various resins, particularly those from beds of brown coal, which are near amber in appearance, but contain little or no succinic acid. It may conveniently serve as a generic name, since no two independent occurrences prove to be alike, and the indefinite multiplication of names, no one of them properly specific, is not to be desired.

A. A retinite from Halle afforded Bucholz (Schw. J., 1, 290, 1811) 91 parts soluble in absolute alcohol, and 9 parts insoluble. The former gives a yellowish brown deposit on dilution, and is more soluble in boiling dilute alcohol than in cold; and it is insoluble in pure ether and turpentine. The latter is also insoluble in ether. Both are soluble in alkalies. The resin fuses with more difficulty than most resins, blackens in the heat, and gives out a strong aromatic odor. By distillation yields a brown thick oil, some water containing a little acetic acid, besides carbonic acid and carburetted hydrogen.

B. Another retinite from the lignite at Walchow (Pogg., 59, 61, 18—) has been called Wal-

сномите (р. 1005).

C. A resin described by Dietrich (Vh. G. Reichs, No. 8, 1875). It occurs at Skuc in Bohemia in a coal-bearing sandstone. Hard, $G_{\rm c}=1.092$. Color dark honey-yellow. Slightly soluble in alcohol, better in benzene and chloroform. Melts to a compact mass and gives off a little suc-

cinic acid. Analysis: C 76·47, H 7·84, O 15·68, S 0·025, N tr.

D. Bronner (Jahr. Ver. Württ., p. 81, 1878) found in a resin from Lebanon a small amount of succinic acid, also formic acid. Analysis gave: C 74·8, H 12·3, O 12·9. 8 p. c. were dis-

solved in alcohol. Cf. Schraufite, p. 1006, also Heim, l. c., 1891, p. 199.

E. A resin from Japan called Japanese amber, analyzed by J. F. Eykmann in Tokio (quoted

by Helm, l. c., 1891, p. 200) gave: C 83 48, H 10 45, O 6 12.

F. A resin from Greenland, analyzed by Chydenius (G. För. Förh., 2, 549, 1878) gave: C 73 47, H 10 20, O 16 33 = 100; empirical formula deduced C₆H₁₀O. Helm found a small amount of succinic acid in this resin, though Chydenius obtained none.

Some other related resins, which have not received special names, are mentioned by Helm,

GEDANITE Otto Helm, Schriften Ges. Danzig, 4, No. 3, 214, 1878. A resin resembling amber, but not containing succinic acid, and less rich in oxygen. Fracture conchoidal. Fragile. H. = 1.5-2. G. = 1.058-1.068. Color wine-yellow, more or less clear. Transparent. Analysis:

> H 11.41 0 7.33 $S \ 0.25 = 100 \ (ash \ 0.06)$ C 81.01

Becomes opaque upon heating, finally milky, and at 140°-180° bubbles up and melts. Warm alcohol dissolves 18-25 p. c., and warm ether 40-52 p. c. Found with succinite on the shores of the Baltic. Named from Gedanum, Latin name of Danzig.

GLESSITE O. Helm, Schriften Ges. Danzig, 5, No. 1-2, 291, 1881. A resin occurring, like gedanite, with succinite on the shores of the Baltic. It is peculiar in the presence of minute spherical cell-like forms, discerned by the microscope. Fracture conchoidal. H. = 2. G. = 1.015-1.027. Luster greasy. Color red-brown and translucent to brown or brownish black and opaque. Analysis:

> C 79.36 H 9.48 0 10.72 S 0.44 = 100

Behaves nearly like succinite with solvents. When heated, begins to swell up at 120°, giving off white fumes, and at 200° melts to a thick liquid. Contains no succinic acid, but probably formic acid. Named glessite from glessum or glæsum, a name applied, as noted by Tacitus, to the amber.

RUMÄNITE O. Helm, Schrift. Ges. Danzig, 7, No. 4, 186, 1891. Rumänischer Bernstein. A yellow amber-like resin obtained from different points in Rumania, as in sandstone in the Buseo district, at Telage in the Bohosa district, etc. Color brownish yellow to brown, seldom yellow. Transparent to translucent. Occurs in brittle masses, with flat conchoidal fracture. H. = 2.5-3. G. = 1.048-1.105. Analysis:

> C 81.64 H 9.65 0 7.56 $S \cdot 1.15 = 100$

In alcohol 6.6 p. c. dissolves; in ether 14.4 p. c.; in chloroform 11.8; in benzene 14.2. Not acted upon by nitric acid in the cold, but when warmed oxidized to a yellow crumbling substance. Melts without previous swelling up at 300°. In a glass retort, a watery fluid is distilled over with evolution of hydrogen sulphide and carbon dioxide; then follows a thick reddish brown oil, while white fine crystals form in the neck which consist of succinic acid; the amount of the last varies in different samples, in four cases 0.3, 0.9, 1.35, 3.2 p. c.

SIMETITE O. Helm & H. Conwentz, Schriften Ges. Danzig, 5, No. 1-2, 293 et al., 1881, [Malpighia, 1, 49, 1886;] Helm, Schriften Ges. Danzig, 7, No. 4, 198, 1891. A resin near amber from near Mt. Etna, Sicily. Remarkable for its deep red color and often showing a beautiful fluorescence. It is usually garnet-red to dark red in color and by reflected light appears nearly black; sometimes lighter yellowish red. G. = 1.052-1.068. Analysis gave Helm:

> C 69.48 H 9.24 0 20.76 $S \cdot 0.52 = 100$

It contains only 0.4 p. c. succinic acid, but more sulphur in the form of an organic acid than succinite; Helm found 0.52 in a light colored kind, 0.67 in a dark red, and 2.4 p. c. in the black varieties. Ether dissolves 27 p. c., alcohol dissolves 21 p. c., and an alcoholic solution of potash 32 p. c.

Conwentz mentions a resin resembling amber from Yucatan, near simetite.

Krantzite (Fossiles Harz fr. Nienburg. Krantzit C. Bergemann, J. pr. Ch., 76, 65, 1859). Near succinite. Occurs in small grains and masses of a light yellow or greenish yellow color, but reddish or brownish externally. G. = 0.968. Rather tender. Sectile and somewhat elastic. The exterior has $G_{\cdot} = 1.002$. Anal.—Landolt:

> C 79.25 H 10.41 $O\ 10.34 = 100$

Corresponding nearly to the formula C40H64O4.

Only 4 p. c. soluble in alcohol, and 6 p. c. in ether; and only softens in turpentine. In sulphuric acid gives a brown solution. Fuses at 225°, and becomes perfectly fluid at 288°; and at a higher temperature yields gas and products of distillation. The ether solution affords a brownish amorphous substance, which is elastic like caoutchouc at 12°, and fuses at 150°.

SIEGBURGITE A. Lasaulx, Jb. Min., 128, 1875.

A resin from the brown-coal formation in the neighborhood of Troisdorf and Siegburg in the region of the Lower Rhine. Occurs in concretionary masses in which the resin is mixed with some 50 p. c. or more of quartz sand, which, in the form of small granules, it cements together. H. = 2-25. Color gold-yellow to brownish red or hyacinth-red. Analyses, Lasaulx, of two samples after deducting sand:

> C 85·14 H 7.90 0.6.96 = 10081.37 5.26 13.37 = 100

Partially soluble in alcohol; also partially in ether, which is colored yellow and after evaporation yields a yellow oil without separation of crystals. Melts and burns readily with a yellow, smutty flame giving an aromatic odor; yields a light greenish yellow oil on distillation, but no succinic acid.

Later investigated by Klinger and Pitschki (Ber. Ch. Ges., 17, 2742, 1884). They obtained from 600 grams of the crude substance, 113 c.c. of a light oily liquid and 10 c.c. of an acid watery liquid; in the distillation styrol (25 gr.) and cinnamic acid (4 gr.) were deducted; benzene and toluene were present in small quantity only.

Walchowite. Bergpech pt. (fr. Walchow) Estner. Min., 3, 1te Abth., 114, 1800. Retinit von Walchow Schrötter, 59, 37, 1843. Walchowit Haid., Ueb., 99, 1843, Handb., 574,

In yellow translucent masses, often striped with brown. Luster resinous. Fracture conchoidal. Translucent to opaque. H. = 1.5-2. G. = 1.0-1.069; an opaque variety 1.035. Ratio for C, H, O = 40:64:3\frac{1}{3}. Anal.—Schrötter, Pogg., 59, 61, 1843.

H 10.66 0 8.93 3 C 80·41

Fuses to a yellow oil at 250° and burns readily; becomes transparent and elastic at 140°. But it is a mixture, as alcohol takes up 1.5 p. c., and ether 7.5 p. c. Forms a dark brown solution in sulphuric acid.

Occurs in brown coal at Walchow, in Moravia, and formerly called Retinite. Estner also mentions a honey-yellow resin from Uttigshof in Moravia (called Bernstein in the Abh. Böhm. Ges., 3, 8), and another of a similar color, but a little greenish, from Litezko in Moravia.

CHEMAWINITE B. J. Harrington, Am. J. Sc., 42, 332, 1891.

A resin related to amber occurring in small fragments, from the size of a pea to that of a robin's egg or larger, on a low beach on Cedar Lake near the mouth of the north Saskatchewan. It forms from five to ten per cent by volume of the sand and vegetable débris, and along a mile of the beach it was estimated to be found in a band thirty feet wide with a minimum depth of two feet (Tyrrell).

Fracture conchoidal. H. = 2.5. G. = 1.055. Color pale yellow to dark brown. Becomes

electric on friction. Ratio for C: H: O = 40: 62.79: 3.56, or not far from recent copals from India. Analysis of material dried in vacuo over sulphuric acid:

> C 79.96 H 10.46 0 9.49 Ash 0.09 = 100

In absolute alcohol, after 3½ hours, 21 01 p. c. were dissolved; in absolute ether, after 2 hours, 24.84 p. c. Heated in a closed tube, begins to soften at 150°, and at 180°-190° could be pressed into a single mass; at 300° became soft and elastic, but did not melt into a flowing liquid and had darkened somewhat from partial decomposition. Yielded no crystals of succinic acid in a retort.

Named Chemawinite from Chemahawin or Chemayin, the Indian name of a Hudson Bay post not far from where the resin occurs. Probably derived from one of the Tertiary or Cretaceous lignites occurring on the Saskatchewan. Some of these are known to contain resins, one of which was found by Harrington to be near the above, with H. = 2, G. = 1.066, and dis solved in absolute alcohol to 29.30 p. c.

Duxite Doeller, Vh. G. Reichs., 145, 1874. A resin from the lignite of Dux, Bohemia. Opaque. Color dark brown. G. = 1.133. Melts at 246°. Fischer obtained, besides 2.72 water and 1.94 ash: C 78.25, H 8.14, O 13.19, S 0.42 = 100. Near walchowite.

Muckite J. von Schröckinger, Vh. G. Reichs., 387, 1878. A resin from the coal beds at Neudorf, Moravia, disseminated in minute particles, and in small bands. Color opaque yellow, or light brownish yellow, and transparent to translucent. H. = 1-2. G. = 1.0025. Anal.— Dietrich:

> C 79.22 H 9.57 O 11.21, corresponding to C₂₀H₂₈O₂

Fuses between 290° and 310°. In alcohol, 14 p. c. dissolve; in ether, 40 p. c., both !caving a yellowish brown residue.

NEUDORFITE J. von Schröckinger, Vh. G. Reichs., 387, 1878. A resin occurring in a coal bed at Neudorf, Moravia. Color pale yellow. Luster waxy. Fracture conchoidal G. = 1.045-1.060. Anal.—Dietrich:

C 78.04, H 9.84, O 11.98, N 0.14, corresponding to $C_{18}H_{28}O_2 = C$ 78.26, H 10.14, O 11.60 = 100.

Fuses at 280°. Dissolves in ether, leaving a whitish yellow resinous powder.

Schraufite J. von Schröckinger, Vh. G. Reichs., 134, 1875. Occurs in small masses and in layers, in the schistose sandstone (Carpathian sandstone), near Wamma, in Bukowina. Fracture semi-conchoidal to splintery. H. = 2-3. G. = 1.0-1.12. Color hyacinth- to blood-red. Translucent. Melting point 326°, when decomposition goes on. Partially soluble in alcohol, benzene, and chloroform; completely soluble in sulphuric acid, the larger portion of the resin separating as a grayish yellow slimy mass, upon dilution with weter. Formula: $C_{11}H_{10}O_2$, requiring: C 73°33, H 8°89, O 17°78 = 100. Anal.—Dietrich:

> H 8.82 0 17:37

With this resin correspond also a resin from Mizun and Höflein, and less closely others from the neighborhood of Lemberg. Schröckinger proposes to include the several occurrences under the name Schraufte, after Prof. A. Schrauf, of Vienna.

This is near the resin from Lebanon, see p. 1004; cf. also John, Vh. G. Reichs., 255, 1876, and Bronner, Jahr. Ver. Württ., 34, 86, 1878.

A resin near schraufite is mentioned by J. Stuart Thomson as found with the coal at Fauldhouse, Midlothian, Scotland, Min. Mag., 7, 215, 1887.

Jaulingite Zepharovich, Ber. Ak. Wien, 16, 366, 1855. A resin occurring in the Jauling, near St. Viet, in Lower Austria. It somewhat resembles A resin occurring in the Jauling, near St. viet, in Lower Austria. It somewhat resembles aber, is hyacinth-red, translucent in thin splinters, may be rubbed to a yellow powder between the fingers, and has $H_{\cdot} = 2.5$, $G_{\cdot} = 1.098-1.111$. By the action of carbon disulphide a resinlike substance was obtained from this which was brownish yellow in color; brittle; at 50° softens, at 70° liquid. Easily soluble in alcohol and ether. Aromatic odor when heated. Ratio for C_{\cdot} , C_{\cdot}

A Beta-jaulingite was obtained from the residue, after the treatment with carbon disulphide, by the action of ether. Color brownish yellow. Softens at 135°, and becomes liquid at 160°. Dissolves easily in alcohol and ether, but not in carbonated alkali or carbon disulphide. Ratio for C, H, O = 40:53\frac{1}{3}:8\frac{3}{3}:0 r 18:24:4, Ragsky, who obtained: \frac{2}{3}:C 70.90, H 7.93, O 21.17 = 100. It contains double the oxygen of the preceding, with less, proportionally, of hydrogen.

Refikite La Cava [J. connais. médicale. Paris, 1852], Dx, Min., 2, 58, 1874.

A resin found in the lignite of Montorio, near Feramo, Abruzzes. It is amorphous, in Very soft. Fragile. Color white. Composition, $C_{20}H_{16}O_2 = Carbon 79.0$, small scales. hydrogen 10.5, oxygen 10.5 = 100. Analysis:

> $0 \ 11.05 = 100$ C 77.77 H 11.18

Soluble in ether and in absolute alcohol, and on boiling separates in masses or small crystals. Also soluble in boiling caustic potash.

Köflachite Doelter, Mitth. Ver. Steiermark, p. 93, 1878.

A resin from Laukowitz near Köflach in Styria, where it occurs in the Tertiary brown coal. Fracture conchoidal. G. = 1.2-1.25. Color dark brown, but reddish brown in fine splinters. Becomes electric with friction. Composition, $C_{29}H_{43}O_2 = Carbon 82.3$, hydrogen 10.2, oxygen 7.5 = 100. Analysis, Andreasch:

$$C 82.23$$
 $H 10.28$ $O 7.49 = 100$

Melting point 98°, but becomes soft at a lower temperature. Easily soluble in ether: soluble in carbon disulphide, but insoluble in alcohol and caustic potash.

AMBRITE. Ambrit (fr. N. Zealand) Hochstetter, v. Hauer, Vh. G. Reichs., 4, 1861. Amberite.

Amorphous; in large masses. H = 2. G. = 1.034. Luster greasy. Color yellowish gray. Subtransparent. Strong electric on friction. Fracture conchoidal.

Ratio deduced for C, H, O = 40:66:5 = Carbon 76.88, hydrogen 10.54, oxygen 12.77.

Von Hauer makes the ratio 32:26:4, which is not nearer the analysis than the above. Anal.-R. Maly, l. c.:

H 10.58 O 12.70 • 8 C 76.53 Ash 0.19

Wholly insoluble in alcohol, ether, oil of turpentine, benzene, chloroform, and dilute acid.

Burns with yellow smoking flame. The ash contains iron, lime, and soda.

Occurs in masses as large as the head in the province of Auckland, N. Zealand, at the Hawakawa colliery, Bay of Islands, at Waikato and at Uhangarei. It much resembles the resin of the *Dammara Australis*, or Kauri gum, which abounds on the island, and is often exported with it.

Bucaramangite. Resine de Bucaramanga Boussingault, Ann. Ch. Phys., 6, 507, 1842.

Resembles amber in its pale yellow color. G. above 1.

Ratio for C, H; O = 42:66:2\frac{1}{2} = Carbon 82.7, hydrogen 10.8, oxygen 6.5 = 100. Insoluble in alcohol. In ether softens and becomes opaque. Fuses easily, and burns with a little smoky flame, leaving no residue. Yields no succinic acid.

An analysis gave Boussingault: C 82.7, H 10.8, O 6.5, N tr. = 100. C. R., 96, 1452, 1883.

ROSTHORNITE H. Höfer, Jb. Min., p. 561, 1871. In lenticular masses in coal. G. = 1.076. Luster greasy. Color brown, with garnet-red reflections; in thin splinters wine-yellow. Composition, C24H40O. Anal.—Mitteregger, l. c.:

& C 84·42 H 11.01 0.4.57 = 100

At 96° commences to melt to a viscous brownish red mass, which at 160° gives off bubbles and at 205° white fumes; heated to 225° the evolution of gas ceases, leaving a thin dark purplish red fluid. Insoluble in dilute nitric acid, as also in potash or alcohol. Slightly soluble in warm ether and entirely so in warm oil of turpentine. Completely soluble in benzene at ordinary temperatures. From Sounberge, Carinthia.

COPALITE. Fossil Copal, Highgate Resin, Aikin, Min., 64, 1815. Retinite pt. Glock., Min., 372, 1831, Haid., Handb., 574, 1845. Fossil Copal J. F. W. Johnston, Phil. Mag., 14, 87, 1839. Copaline Hausm., Handb., 1500, 1847.

Like the resin copal in hardness, color, luster, transparency, and difficult solubility in alcohol. Color clear pale yellow to dirty gray and dirty brown. Emits a resinous aromatic odor when broken. G. = 1°610 Johnston; 1°05 Bastock; 1°053 E. Indies, Kenngott.

Ratio for C, H, O = 40: 64: 1 = Carbon 85°7, hydrogen 11°4, oxygen 2°9 = 100. Anal.—1, 2, Johnston. 3, Duflos [Min. Unters., 2, 1831], Min., 5th Ed., p. 739.

	C	Н	. 0	Ash
1. Yellow trp.	85.677	11.476	2.847	- = 100
2. Gray	85.408	11.787	2.669	0.136 = 100
3. E. Indies	85.73	11:50	2.77	- = 100

Volatilizes in the air by a gentle heat. Burns easily with a yellow flame and much smoke, and hardly any perceptible ash. Slightly acted upon by alcohol. Kenngott's mineral closely resembles the Highgate copalite in its honey-yellow color, and its action with heat and alcohol. From the blue clay (London clay) of Highgate Hill, near London, from whence it is called

Highgate resin. It occurs in irregular pieces of a pale honey-yellow color.

Ambrosine C. U. Shepard, Rural Carolinian, 1, p. 311. In rounded masses. Color yellowish to clove-brown. Fracture conchoidal. Luster resinous. Becomes electric on friction. Melts at about 250° to a clear yellowish liquid; softens at a lower temperature. Gives off "suc-

cinic acid before melting"; on fusion gives an agreeable balsam-like color, unlike that from the resins of ordinary pines, and a dark brown non-volatile fluid remains as long as the melting heat is kept up. Combustible, leaves no ash. Soluble for the most part in oil of turpentine, alcohol, ether, and chloroform, as also in potash. Stated to have been found in the phosphatic beds near Charleston, S. C. (It has been suggested that this may be only a modern resin which has been subjected to the action of salt water.)

AJKITE. A resin near amber, Ajka, Hungary (Bull. Soc. Min., 1, 126, 1878).

WHEELERITE O. Loew, Am. J. Sc., 7, 571, 1874.

A resin, yellowish in color, found in the Cretaceous beds of northern New Mexico, filling the fissures of the lignite, or interstratified in thin layers in it. Most abundantly observed in the vicinity of Nacimiento. Two analyses gave Loew:

> H 7.95 C 73.07 O undet. 2.

These agree closely with the formula $n(C_bH_6O)$, where n is probably 5 or 6. Soluble in ether, less so in carbon disulphide. In concentrated sulphuric acid dissolves producing a dark brown solution, from which it is precipitated by water. In alcohol the principal portion is readily dissolved, while a small part remains insoluble. The hot alcoholic extract of the resin deposits, on cooling, a few yellow flocculi. The solution, on evaporation, gives a yellowish resin very brittle, and becoming strongly electric on friction; it melts at 154°. Named for Lieut. G. M. Wheeler, U. S. Army.

IONITE S. Purnell, Am. J. Sc., 16, 153, 1878. A fossil hydrocarbon found in a more or less impure condition in the lignite of Ione Valley, Amador County, California. Structure firm, earthy. Color brownish yellow. Partially soluble in cold alcohol, largely soluble in ether, completely so in chloroform. A brown tarry oil containing a small quantity of paraffin is separated by dry distillation. Exact chemical nature unknown.

EUOSMITE. Erdharz, Kampferharz, Euosmit, C. W. Gumbel, Jb. Min., 10, 1864.

Amorphous, in masses of a brownish yellow color, or like that of cherry gum, and looking like common pitch. H. = 1.5. G. = 1.2-1.5. Brittle. In thin pieces transparent. Fracture conchoidal. Strongly electric on friction. Has an odor between that of resin and that of

camphor. Dissolves easily in cold alcohol or ether, and hot oil of turpentine.

Ratio of C, H, O = 17:29:1 = Carbon 81.9, hydrogen 11.7, oxygen 6.4 = 100. Afforded 0.84 of ash. The ratio is almost identical with that of leucopetrite. Melts at 77°, and burns with a bright flame and very aromatic odor. Solutions of the alkalies dissolve only a little of it,

after long action.

From clefts in brown coal, at Baiershof, near Thumsenreuth, in the Fichtelgebirge, and derived probably from a kind of Conifer, and one resembling the Cupressinoxylon suaquale Göppert.

Bathvillite. Bathvillite C. Gr. Williams, Ch. News, 7, 133, 1863. Torbanite pt.

Amorphous. Dull, and of a fawn-brown color, looking somewhat like wood in the last stage of decay. Opaque. G., after removing air of pores by air-pump, about 1.01. Very friable, but this characteristic may not be essential to the species. Insoluble in benzene. Torbanite has H. = 2.25; G. = 1.18 Heddle; color clove-brown; powder yellowish; tough.

Comp.—Ratio for C, H, O, from the analyses, 40:68:4, or near that of succinite, = Carbon

78.43, hydrogen 11.11, oxygen 10.46 = 100. The ratio 40:66:4 is less near, giving the percentage: Carbon 78.7, hydrogen 10.5, oxygen 10.8 = 100. Anal.—1, Williams, l. c.; 1a, same with ash excluded.

2, Miller; 2a, same with ash excluded.

	· C	H	0	Ash
1. Bathvillite	58.89	8.56	1.25	25.32 = 100
1a. "	78.86	11.46	9.68	- = 100
2. Torbanite	63.10	8.91	8.21	19.78 = 100
2a. "	78.67	11.11	10.22	- = 100

Williams refers here the torbanite analyzed by Miller. Other analyses of torbanite give less oxygen. The oxygen includes a little nitrogen and sulphur. Williams makes the formula C30 H30O3 = Carbon 78.60, hydrogen 10.92, oxygen 10.48, agreeing hardly as well with the analyses as the above.

Does not melt when heated. In a platinum crucible affords a fatty odor, and burns with a dense smoky flame. No action with moderately dilute nitric acid; completely carbonized by

concentrated sulphuric acid.

Obs.—Bathvillite occurs in the torbanite or Boghead coal (of the Carboniferous formation), adjoining the lands of Torbane Hill, in the grounds of Bathville, Scotland. It forms lumps which fill cavities in the torbanite. Other cavities are occupied by calcite, pyrite, etc. It may be an altered lump of resin; or else material which has filtrated into the cavity from the surrounding torbanite.

The analysis of Miller shows that some of the torbanite has the same composition. As proof of the absolute purity of the substances analyzed could not be had, the results are open to

some doubt, as Williams observes.

TORBANITE. Torbanite, although related to cannel coal, has a very nearly uniform composition, according to all analyses thus far made, excepting that of Miller, and this composition is like that of bathvillite, excepting less oxygen. It corresponds very nearly with the formula $C_{40}H_{68}O_{2\cdot26} = \text{Carbon }82\cdot19$, hydrogen $11\cdot64$, oxygen $6\cdot17$. The mean of five analyses (see 5th Ed., p. 757) is, Carbon $81\cdot15$, hydrogen $11\cdot48$, with oxygen about $6\cdot0$, nitrogen $1\cdot37 = 100$; excluding the nitrogen, C $82\cdot28$, H $11\cdot54$, O $6\cdot08 = 100$. Less than $1\frac{1}{2}$ p. c. of torbanite is soluble in naphtha (Fyfe).

RETINELLITE. Part of Bright Yellow Loam (fr. Bovey) so saturated with petroleum that it burns like sealing-wax, J. Milles, Phil. Trans., 51, 536, 1760; Bitumen from Bovey, Retin asphaltum. Hatchett, ib., 402, 1804; Retinite. Resin of Retin Asphalt, Retinic Acid, J. F. W. Johnston, Phil. Mag., 12, 560, 1838. Retinellite Dana.

Resin-like. Light brown. Begins to melt at 121°, is perfectly fluid at 160°, and gives off a resin-like odor at 100°. Soluble in alcohol, still more freely in ether. Ratio for C, H, O

= 21:28:3 = Carbon 76.8, hydrogen 8.6, oxygen 14.6 = 100. Analysis: Johnston, l. c.

H 8.75 C 76.86 $0 \ 14.39 = 100$

Johnston describes salts of retinic acid with silver, lead, and lime.

The retinasphalt of Hatchett, from the Tertiary coal of Bovey in Devonshire, from which alcohol separates the above species, occurs in roundish masses, having H. = 1-2.5; G. = 1.135 Hatchett; luster slightly resinous in the fracture, often earthy externally; color light yellowish brown, sometimes green, yellow, reddish, or striped; and is subtransparent to opaque; often flexible and elastic when first dug up, though brittle on drying. Johnston, after drying the retinasphalt at 300°, obtained 53 92 p. c. of resin soluble in alcohol, 27 45 of insoluble organic matter, and 13:23 of ash = 100. The insoluble portion has not been investigated.

XYLORETINITE. Xyloretin *Forchhammer*, J. pr. Ch., **20**, 459, 1840. Pogg., **59**, 45, 1843. Psathyrit *Glocker*, Syn., 8, 1847. Hartin Schrötter,

Massive, but crystallizes from a naphtha solution in needles of the orthorhombic system. G. = 1.115 hartine. Color white. Pulve izes in the fingers. Without taste or smell. Soluble in ether.

Ratio (Rg.) for C, H, O = 42:58:5 = Carbon 78:51, hydrogen 9:05, oxygen 12:44. $C_{20}H_{54}O_{2}$, deduced by Schrötter, corresponds better with the analyses. Anal.—1-3, Schrötter, l. c. 4, 5, Forchhammer, l. c.

	C	Н	0	Fusing T.
1. Hartine	78.26	10.92	10.82 = 100	210°
2. "	78.46	11.00	10.54 = 100	
3. "	78.33	10.85	10.82 = 100	
4. Xyloretinite	79.09	10.93	9.98 = 100	165°
5. "	78.57	10.81	10.62 = 100	

The hartine is a white resin separated by ether from a resin obtained from the brown coal of Oberhart. No. 1 is hartine as separated in an amorphous condition by means of naphtha; and 2, 3, crystallized from an ether solution. (Besides the hartine, two amorphous brown resins were also obtained from the solution.) Xyloretinite was derived by Forchhammer through the action of alcohol on fossil pine-wood from the marshes of Holtegaard in Denmark.

Scleretinite J. W. Mallet, Phil. Mag., 4, 261, 1852.
In small drops or tears, from the size of a pea to that of a hazel-nut. H. = 3. G. = 1.136.
Translucent in thin splinters. Color black, but by transmitted light reddish brown, strake cinnamon-brown. Luster between vitreous and resinous, rather brilliant. Brittle; fracture conchoidal. Insoluble in alcohol, ether, alkalies, and dilute acids.

Ratio for C, H, O = 40:56:4 = Carbon 80.0, hydrogen 8.0, oxygen 9.3 = 100. Anal.—J

W. Mallet:

1.	C 76.74	H 8.86	O 10.72	Ash $3.68 = 100$
2.	77.15	9.05	10.12	3.68 = 100

Heated on platinum foil it swells up, burns like pitch, with a disagreeable empyreumatic smell and a smoky flame, leaving a coal rather difficult to burn, and final : !!ttle gray ash.

In a glass tube yields a yellowish brown oily product of a nauseous empyreumatic odor. Even strong nitric acid acts slowly upon it. From the Coal-measures of Wigan, England.

Guyaquillite J. F. W. Johnston, Phil. Mag., 13, 329, 1838.

Amorphous. In large masses or layers. Yields easily to the knife, and may be rubbed to powder. G. = 1.092. Color pale yellow. Luster not resinous, or imperfectly so. Slightly soluble in water, and largely in alcohol, forming a yellow solution which is intensely bitter.

Ratio for C, H, O = 40:52:6 = Carbon 76.67, hydrogen 8.17, oxygen 15.16 = 100

Johnston. Begins to melt at 69½°, but does not flow easily till near 100°. As it cools becomes viscid, and may be drawn into fine tenacious threads. Soluble in cold sulphuric acid, forming a dark reddish brown solution.

A few drops of ammonia put into the alcoholic solution darken. a dark reddish brown solution. A few drops of ammonia put into the alcoholic solution darken the color, and finally change it to a dark brownish red.

Stated to form an extensive deposit near Guyaquil in South America.

MIDDLETONITE J. F. W. Johnston, Phil. Mag., 12, 261, 1838.

In rounded masses, seldom larger than a pea, or in layers a sixteenth of an inch or less in thickness, between layers of coal. Brittle. G. = 1.6. Luster resinous. Color reddish brown by reflected light, and deep red by transmitted; powder light brown. Transparent in small fragments. No taste or smell. Blackens on exposure. Only a trace dissolved by boiling alcohol, ether, or oil of turpentine. Not altered at 210°.

Ratio for C, H, O = 40:44:2 = Carbon 86:33, hydrogen 7:92, oxygen 5:75 = 100. Johnston obtained: § Carbon 86 21, hydrogen 8 03, oxygen 5 76 = 100. On a red cinder burns like resin.

Softens and melts in boiling nitric acid, with the emission of red fumes; a brown flocky precipitate falls on cooling. Soluble in cold concentrated sulphuric acid.

Occurs between layers of coal about the middle of the Main coal or Haigh Moor seam, at

the Middleton collieries, near Leeds, in thin layers and masses, rarely thicker than 18 in., and little rounded masses seldom larger than a pea; also at Newcastle.

Tasmanite. Resiniferous Shale (fr. Tasmania), Catal. Internat. Exhib., 1862. A. H. Church, Phil. Mag., 28, 465, 1864.

In disks or scales thickly disseminated through a laminated shale; average diameter of scales about 0 03 in. Fracture conchoidal. H.=2. G.=118. Luster resinous. Color reddish brown. Translucent. Not dissolved at all by alcohol, ether, benzene, turpentine, or carbon

disulphide, even when heated.

Comp., etc.—No action with hydrochloric acid; slowly oxidized by nitric acid. Readily carbonized by sulphuric acid, with evolution of hydrogen sulphide. Alkalies in solution without action. Burns readily with a smoky flame and offensive odor; fuses partially, yielding oily and solid products having a disagreeable smell. Ratio of C, H, O, S = 40:62:2:1 = Carbon 79.2, hydrogen 10:2, oxygen 5:28, sulphur 5:28 = 100. Anal.—Church, after rejecting 8:14 p. c.

> C 79.34 H 10.41 0 4.93 S 5.32

Obs.—From the river Mersey, north side of Tasmania. The rock is called combustible shale.

TRINKERITE G. Tschermak, J. pr. Ch., 2, 258, 1870, and Jb. G. Reichs., 20, 279, 1870.

Compact and amorphous. H. = 1.5-2. G. = 1.025. Luster greasy. Color hyacinth-red to chestnut-brown. Transparent to translucent. Anal.—1, Hlasiwetz, l. c. 2, Niedzwiedzki, Vh. G. Reichs., 132, 1871.

	C	H	O	S	Ash
1. Carpano	81.1	11.2	3.0	4.7	None $= 100$
2. Gams $G_{\cdot} = 1.032$	81.9		3.1	4.1	- = 99.0

Fuses at 168°-180°, at a higher temperature gives off choking fumes. Insoluble in water, and only slightly in alcohol and ether. Soluble in hot benzene.

Occurs in large compact masses in brown coal at Carpano near Albona in Istria; also found at Gams near Hieflau in Styria. Resembles in composition the tasmanite of Church.

Dysodile. (Fr. Melili, Sicily.) Paulo Boccone, Recherches et Obs. Nouv., etc., Amsterd., 1674. Dysodile Cordier, J. Mines, 23. 275, 1808. Merda di Diavolo Ital. Stinkkohle Germ. Houille papyracée, Tourbe papyracée, Fr.

In very thin leaves or folia, flexible, slightly elastic. G. = 1.14-1.25. Color yellow or

greenish gray. Streak shining.

Very inflammable, burning with a bright flame and an odor like that of asafætida, leaving an ash in the form of laminæ, consisting largely, as shown by Ehrenberg, of the siliceous shells of infusoria, especially of Naviculæ. Delesse found (Thèse anal. Chim., 50, 1843) a variety from Glimbach, near Giessen, to afford water and volatile matters 49.1, carbon 5.5, ash, 45.4; of the last, 17.4 were soluble silica, 11.0 iron sesquioxide, and 10.0 clay.

Church, Ch. News, 34, 155, 1876, has obtained for dysodile from Rotl near Bonn, after deducting ash:

> C 69.01 H 10.04 S 2.35 0 16.90 $N \cdot 1.70 = 100$

It is not certain that the sulphur may not be present as pyrite.

Originally from Melili, Sicily, forming a coaly deposit, made up of very thin paper-like leaves, which had evidently been derived from the joint decomposition and alteration of vegetable and animal matter. Reported also from the lignite deposits of Westerwald near Rolt; of Siegberg to the north of the Siebengebirge; of Saint Armand in Auvergne; Glimbach near Giessen; but the real nature of only the first of these substances has been investigated.

Pyroretinite. Part of Pyroretin of A. E. Reuss, Ber. Ak. Wien, 12, 551, 1854; J. Stanek, ib., p. 554. Pyroretinite Dana.

Resin-like. Deposited in powder from a hot alcoholic solution of pyroretin as it cools. Ratio of C, H, O = 40:56:4 = Carbon 80:00, hydrogen 9:33, oxygen 10:67 = 100. Analysis. -Stanek, l. c.:

> H 9.42 O[10.56] = 100C 80·02

Approaches, as Stanek states, the beta-resin of the resin of *Pinus abies* (Johnston) = $C_{40}H_{58}O_{5}$, and also copaivic acid (fr. Copaiba balsam), $C_{40}H_{60}O_{4}$, and other related compounds,

showing that it is probably from coniferous trees.

Pyroretin of Reuss, the resin which affords the above, occurs in the brown coal, between Salesl and Proboscht, near Aussig in Bohemia. It occurs in masses from the size of a nut to that of a man's head, and also in plates an inch thick. It is brittle; of brownish black color; greasy-resinous luster; wood-brown powder; H. = 2.5; G. = 1.05-1.18; and resembles much brown coal. It burns with a reddish yellow flame, and a strong odor like that of burning amber, and leaves a black coal. It melts easily, decomposing and giving off white fumes, and leaves an asphalt-like mass. Reuss states evidence showing that it has probably been formed by the action of the heat of a basaltic dike on a bed of brown coal.

STANEKITE is separated from the pyroretin of Reuss by boiling alcohol, which leaves it behind. Not soluble in any fluid without decomposition, and not at all in a solution of potash. Anal.-Stanek:

> 0.15.99 = 100€ C 76.71 H 7.30

Corresponding to C: H: O = 39:44:6, or perhaps 40:44:6. When heated gives off the odor of succinic acid.

REUSSINITE. Resin-like. Color fine reddish brown. Soluble in boiling alcohol and in ether, and not deposited from the alcoholic solution on its cooling. Stanek (l. c.) found for the composition of the resin thus obtained: C 81.09, H 9.47, O 9.44 = 100; corresponding to C40 H56O3.5; and he regards the substance as a mixture of the above pyroretinite, C40 H56O4, with another resin (here designated reussinite) of the formula C40H56O3.

Leucopetrite. Leucopetrin L. Brückner, J. pr. Ch., 57, 1, 1852, in art. entitled Ueber einige eigenthümliche wachshaltige Braunkohlen.

Between a resin and wax in characters. Crystallizable in needles from solution. Color of crystals white. Melting point above 100°; and after fusion brown and partly decomposed, and hence the exact melting point not easily determinable. Soluble in ether; also 1 part in 268 of boiling absolute alcohol; but not at all in alcohol of 80 p. c.

Comp.—C₅₀H₆₄O₂, Brückner, = Carbon 81 97, hydrogen 11 47, oxygen 6 56 = 100; very nearly C₄₀H₆₇O₂. Not at all acted upon by a hot solution of potash, or cold nitric acid.

Obs.—From a layer ½ 2 ft. thick, in an earthy *yellowish brown* brown coal, at Gesterwitz, near Weissenfels. The material of the layer is of loam-like aspect, but gives a shining wax-like streak, has G. = 1 297 Wackenroder, and loses 22 p. c. of water at 100°. The dried mass is nearly half sand and other earthy materials. The leucopetrite is associated in the coaly layer, coording to Privilence, with other correspondence of the layer is a localed in the coaly layer, according to Brückner, with other organic compounds, soluble in alcohol of 80 p. c., including two resins, two wax-like substances (p. 1012), and an acid which Brückner calls Georetinic acid (Brücknerellite Dana). By a distillation of the mass of the brown coal, 28 p. c. of the whole passes over as a butter-like mass, which is related to the paraffins, but, according to Brückner, contains 2 p. c. of oxygen. It afforded: 2 Carbon 84.04, hydrogen 14.10, oxygen [1.86], and he writes the formula $C_{68}H_{110}O$. It dissolves easily in hot absolute alcohol and ether, and very sparingly in alcohol of 80 p. c.; crystals in pearly hexagonal plates from the alcoholic solution; melts at 50°.

Named after the locality, Weissenfels (= white rock), from $\lambda \epsilon \nu \kappa \delta s$, white, and $\pi \epsilon \tau \rho \delta s$, stone.

BRÜCKNERELLITE (see above) has the following characters: Crystallizable in white needley from alcoholic solution. Dissolves easily in boiling alcohol; and, if the solution is a concentrate one, crystallizes out more or less completely on cooling. Composition C24H44O8, Brückner,

Carbon 62.61, hydrogen 9.56, oxygen 27.83 = 100. The lead salt afforded: Carbon 43.36, hydrogen 10.56, hydroge gen 6.59, lead oxide 34.58, oxygen [15.47] = 100.

Anthracoxenite. Part of Anthracoxen (fr. Brandeisl) Reuss, T. Laurenz, Ber. Ak. Wien, 21, 271, 1856, J. pr. Ch., 69, 428, 1856. Anthracoxenite Dana.

Obtained as a black powder from a resin, by separating the remainder by means of ether, the anthracoxenite being insoluble in ether. Ratio of C, H, O = 40:38:7½. Anal.—Laurenz:

§ C 75.274 H 6.187

11 p c. of ash were separated. Not soluble in menstrua without decomposition.

From a resin-like material, constituting layers $2\frac{1}{2}$ in thick between layers of coal, in the coal beds of Brandeisl, near Schlan in Bohemia; the mass is amorphous, and has H. = 2.5; G. = 1.181; luster externally weak adamantine; color brownish black, hyacinth-red in thin splinters by transmitted light; streak dull, yellowish brown; fracture small-conchoidal; easily rubbed to a fine powder; fuses easily; burns with a yellow smoking flame, and an odor not disagreeable. This substance was named anthracoxene by Reuss. The name is here appropriated to the part insoluble in ether.

The soluble part, which has been named schlanite, is a dark or light brown powder. Ratio for C, H, O = $40:52:3\frac{1}{2}$ = Carbon 81.63, hydrogen 8.85, oxygen 9.52 = 100. Laurenz, l. c.: $\frac{2}{3}$ C 81.47, H 8.71, O 9.82 = 100.

Geomyricite. Geomyricin L. Brückner, J. pr. Ch., 57, 10, 1852.

apparent under a microscope) of acicular crystals. Color white. Melting point 80° -83°. After fusion has the aspect of a yellowish brittle wax. No action in a solution of potash. Soluble easily in hot absolute alcohol and ether, but slightly in alcohol of 80 p. c. Comp., etc.— $C_{34}H_{68}O_2=$ Carbon 80·59, hydrogen 13·42, oxygen 5·99 = 100. Anal.—Brückner, l. c.

			C	H	0
1.	Melt. T.	$= 83^{\circ}$	80.33	13.50	[6.17]
2.	6.	= 83	79.97	12.85	$\begin{bmatrix} 6.17 \\ 7.18 \end{bmatrix}$ $\begin{bmatrix} 6.55 \end{bmatrix}$
3.	"	= 80	80.21	13.24	[6.55]

Burns with a bright flame. Brückner observes that the composition is very near that of the Chinese wax, Palm wax (from the S. A. palm, *Ceroxylon andicola*), Carnauba wax (from the S. A. palm, *Corypha cerifera*), for which Lewy obtained $C_{36}H_{72}O_2 = Carbon 80.59$, hydrogen

13.42, oxygen 5.99 = 100.

Obs.—Occurs at the Gesterwitz brown-coal deposit, in a dark brown layer, similar in most respects to the yellowish brown which afforded the leucopetrite. Its very slight insolubility in alcohol of 80 p. c. enabled Brückner to separate resins and other soluble ingredients present in the mass. L. Lesquereux states (priv. contr.) that the brown-coal beds of the basin in which Gesterwitz lies has afforded the palms Flabelaria latania and Phænicites Giebelianus, and perhaps others, though none has yet been reported from the particular bed at Gesterwitz.

Geocerite. Geocerain L. Brückner, J. pr.Ch., 57, 14, 1852.

Wax-like. Color white. Not observed to crystallize from its solution in alcohol. Melting point near 80°; after fusion solidifies as a yellowish wax, hard but not very brittle. Soluble in alcohol at 80 p. c. Not acted upon by a hot solution of potash. Comp.— $C_{28}H_{56}O_2$ = Carbon 79·24, hydrogen 13·21, oxygen 7·55 = 100. Anal.—Brückner.

$$\begin{array}{cccccc} \text{C } 79.06 & \text{H } 13.13 & \text{O } [7.81] = 100 \\ 79.16 & 13.01 & [7.83] = 100 \end{array}$$

Obs.—From the same dark-brown brown coal of Gesterwitz that afforded the geomyricite, and from the same solution. The solution, after yielding the geomyricite, and next, on adding a hot solution of acetate of lead, a precipitate of a salt of lead and "geocerinsaure" (geocerellite Dana), finally afforded, on filtering the hot solution, the geocerite in the state of a jelly, which on drying became a white foliated mass. Named from γή, earth, and κηρός, wax.

Geographic has the following characters: Color white. Brittle, and easily pulverized. No crystallization observed. Soluble freely in hot alcohol, and deposited from the solution as a jelly on cooling, with nothing crystalline under the microscope. Melting point 82°. Analysis Brückner (l. c.): § Carbon 78.61, hydrogen 12.70, oxygen 18.69 = 100. This corresponds to C28H56O4.

Bombiccite. Bechi, Achiardi, Min. Toscana, 1, 358, 1873. Bombicci, Mem. Accad. Bologna, Guareschi, Boll. Com. G., 2, 70, 1871. Schrauf, Atlas, xxxv, 1873. 9, 1869

H. = 0.5-1. G. = 1.06. Transparent. Colorless. Analysis, Bechi (after Triclinic. deducting impurities), l. c.

This corresponds to the empirical formula C7HO13. Softens with heat, and fuses at 75°, and at a higher temperature it volatilizes. Insoluble in water, but extremely soluble in carbon disulphide; also soluble in ether and in alcohol.

Found in lignite at Castelnuovo d'Avane, in the upper valley of the Arno, Tuscany. Achiardi refers to this species a fossil resin, described by Guareschi (l. c.) as found in the upper valley of the Arno. It occurs in irregular whitish-yellow masses, soft. It fuses easily, and burns with a smoky flame. Two analyses gave:

1.	C 72.72	H 9·41	0.17.87 = 100
2.	76.94	9.12	13.94 = 100

Hofmannite Bechi, Acc. Linc. Trans., 2, 135, 1878. Occurs in rhomb-shaped tabular crystals; colorless, tasteless, odorless. G. = $1^{\circ}0565$. Soluble in alcohol (5 pts. in 1000 pts. alcohol at 14°) more readily than in ether. Melts at 71° to a fluid resembling olive oil, burns with a bright flame. Composition $C_{20}H_{36}O$. Analysis gave: C 82·23, H 12·20, O 5·57. Forms a white crystalline efflorescence on lignite in the neighborhood of Siena. Named after Prof. A. W. Hofmann, of Berlin.

Idrialite. Quecksilberbranderz pt. Idrialine (fr. Idria) Dumas, Ann. Ch. Phys., 50, 360,

1832. Idrialite Schrötter, Baumg. Zs., 3, 245, 4, 5.
In the pure state crystalline in structure. Color white. In nature found only impure, being mixed with cinnabar, clay, and some pyrite and gypsum in a brownish-black earthy material, called, from its combustibility and the presence of mercury, inflammable cinnabar (Quecksilberbranderz).

Dumas separated the idrialite by treatment with oil of turpentine and obtained: C 94.9, H 5.1 = 100, which corresponds to C: H = 3:2; cf. Schrötter, l. c.

Insoluble in water, and little so in alcohol or ether. Fuses at 205°. Schrötter found in one specimen of the crude mineral: 77.32 idrialite, 17.85 cinnabar, and 2.75 of other impurities.

Bödecker, Lieb. Ann., 52, 100, 1844, obtained for the composition of a substance he derived from the goal of the county and 2.75. from the crude material: $\frac{4}{4}$ Carbon 91.83, hydrogen 5.30, oxygen 2.87 = 100, corresponding to $C_{42}H_{14}O$. He derived it from the ore by sublimation in an atmosphere of carbon dioxide. Bödecker states that a black material obtained from the condensation-chambers at Idria afforded a substance which has the composition of Dumas's idrialite; and this he calls Idryl, supposing it to be the radical of his own idrialite.

Goldschmiedt (Ber. Ak. Wien, 80 (2), 290, 1880) has investigated a pistachio-green mineral resin of Idria occurring in nodules and as an incrustation at the mercury mines, which according to him is the substance which impregnates the hepatic cinnabar, and has been called idrialite. G. = 1.85 Composition, $C_{80}H_{56}O_2 = Carbon 91.6$, hydrogen 5.3, oxygen 3.1 = 100.

C 91.71, H 5.32, to which the formula C₈₀ H₅₄ O₂ agrees more closely.

Zepharovich (Zs. Kr., 13, 140, 1887) has found some of the scales to be anistropic and biaxial with $2H = 101^{\circ} 20'$. The extinction on the tabular face is oblique and it hence probably corresponds to the clinopinacoid, the system being monoclinic.

ARAGOTITE Durand, Proc. Acad. Cal., 4, p. 218, 1872. A volatile hydrocarbon supposed to be related to idrialite. Occurs at the New Almaden Mine, California, in bright yellow scales, A volatile hydrocarbon supposed impregnating a crystalline siliceous dolomite; also on cinnabar at the Redington mine. Insoluble in oil of turpentine, alcohol, and ether.

Bertrand found the scales to be optically biaxial, the bisectrix (+) sensibly normal to the

tabular face, axial angle large, dispersion $\rho < v$. Bull. Soc. Min., 4, 87, 1881.

Posepnyte J. von Schröckinger, Vh. G. Reichs., 128, 1877.

In plates and nodules, sometimes brittle, sometimes hard. Color generally dirty light green. G = 0.85-0.95. Separated by ether into two parts. Anal.-1, 2, Dietrich: 1, of the portion soluble in ether, 2, the insoluble portion. 3, Melville, quoted by Becker, U. S. G. Surv., Mon., 13, 361, 1888.

		C	Н	0
1.	Sol.	71.84	9.95	18.21 = 100
2.	Insol.	84.27	11.74	3.99 = 100
3.		85.60	10.71	3.22 Ash 0.47 = 100

The insoluble portion is regarded as being ozocerite, and for the rest (anal. 1) the formula $C_{22}H_{36}O_4$ is calculated, requiring: C 72.52, H 9.89, O 17.59 = 100. From the Great Western

mercury mine, Lake Co., California.

The substance examined by Melville (anal. 3) is regarded as doubtless posepnyte, though the characters differ somewhat from those given above. It is soft, elastic, with G. = 0.985; color reddish brown. On platinum foil, volatilizes partially at a low temperature with a suffocating, aromatic odor; at a high temperature, becomes black, fuses and boils like rubber. In a retort, a brownish yellow liquid distills over considerably below red heat; at a low red heat a dark brown liquid is obtained, leaving a black residue. Partially dissolved in alcohol; ether removes an olive-colored oil, the substance not dissolving.

Rochlederite. Part of Substanz Bituminose Rochleder, Ber. Ak. Wien, 6, 53, 1851; = Melanchym Haid., Lotos, 1, 85, 216, 6, 86, 8, Heft 3; Kenng., Ueb., 147, 1850, 134, 1853. Rochlederite Dana.

Resin-like. Color reddish brown. Transparent or translucent. Melting point 100°. Soluble in alcohol.

Comp.—Ratio of C, H, O = 40:56:6. Analysis.—Rochleder, l. c.

C 76.79 H 9.06 0.14.15 = 100

Burns with a yellow smoking flame, something like amber.

Obs. - The part soluble in alcohol of a bituminous substance called melanchyme by Haidinger, and found in masses as large as the head in the brown coal of Zweifelsruth, near Neukirchen in Eger, Bohemia. A similar substance, of somewhat lighter color, occurs at Cehnitz, near Strako-

nitz, in Bohemia.

The rest of the substance insoluble in alcohol has been called melanellite. It is black and

Capacitad from rechlederite, or the resinous ingredient gelatinous, as obtained by Rochleder. Separated from rochlederite, or the resinous ingredient of melanchyme, by dissolving the latter out by means of alcohol. The jelly-like mass gave: Carbon 67·14, hydrogen 4·79, oxygen 28·07 = 100, corresponding to the ratio 48: 40: 15 or 48: 40: 16 = 12: 10: 4. Regarded by Rochleder as an acid related to ulmic acid, but, as it was not combined with a base before analysis, there is no proof of its purity.

NATIVE HUMUS ACID. C. v. John, Vh. G. Reichs., 64, Feb. 3, 1891. Native humus acid has been observed at the coal-basin at Falkenau, Bohemia. It was found as a black, crumbling coaly mass leaving an ash of 5.25 p. c., and losing 59.25 p. c. water at 100°. Soluble in ammonia and in sodium carbonate, leaving only a slight residue of clay and a trace of organic matter; hydrochloric acid precipitated the entire organic substance from the solution. Analysis, of material dried at 100°:

> ₹ C 54.98 H 4.64 O 39.98 Ash 0.40 = 100

Calculated formula C46H46O25. This substance agrees closely with a humus acid obtained by Herz (1861) from the brown coal of southern Bavaria, for which he derived the formula C40H36O14.

HIRCITE. Hircine *Piddington*, Arch. Pharm., **74**, 318, Kenng., Ueb., 134, 1853. Amorphous. Fracture conchoidal. G. = 1·10. Color exteriorly brown, within yellowish brown. Subtranslucent to opaque. Softens in boiling water, and then has the odor of a resin. In cold alcohol a little soluble; in boiling about one-half, and the solution, which is gold-yellow, affords white flocks on cooling.

In the flame of a candle fuses and burns with a yellowish flame, like a bituminous coal, and leaves a tough coaly globule of a peculiarly strong animal odor (whence the name, from hircus, After complete combustion, leaves an ash. In sulphuric acid soluble, and color of

solution blood-red.

Dopplerite. Dopplerit Haid., Ber. Ak. Wien, 2, 287, 1849, 52 (1), 281, 1865.

Amorphous. In elastic or partly jelly-like masses. When fresh, brownish black, with a dull brown streak and greasy subvitreous luster; and when in thin plates reddish brown by transmitted light.

H = 0.5. G = 1.089 Fötterle. After drying, H = 2-2.5, G = 1.465, and luster somewhat adamantine. Becomes elastic on drying from exposure to the air. Tasteless. Insoluble

in alcohol or ether.

An acid substance, or mixture of different acids, related to humic acid. Ratio for C, H, O, nearly 10: 12: 5, from analyses 2, 3. Anal.—1, Schrötter, Ber. Ak. Wien, 2, 287, 1849. 2, 3, F. Mühlberg, Jb. G. Reichs., 13, 283, 1865.

	C	H	0	N
1. Aussee	51.09	5.29	42.59	1.03 = 100
2. "	55.94	5.20	38.8	= 100
3. Obbürgen	3 56·63	5.28	37.	79 = 100

From No. 1, 5.86 of ash are excluded; from No. 2, 5.18; from 3, 5 to 14.2 p. c. All were dried. Schrötter found the loss of water 78.5 p. c.; and Mühlberg, at 110°, for No. 2, 20.04 p. c. for an air-dried specimen; for 3, 81.8 p. c. for a jelly-like specimen, and 19.7 for an air-dried. In caustic potash soluble, with a residue of earthy matters. The Aussee dopplerite has also been analyzed by Demel (Ber. Ch. Ges., 15, 2961, 1882), who obtained the composition C₁₂H₁₄O₅, and showed that the ash (5.1 p. c.) consisted largely of line, 72.67 p. c., with Al₂O₅, Fe₂O₅ 12.02 p. c. From the alkaline solutions acids gave a precipitate having the composition C₂₄H₂₂CaO₁₂; this dopplerite is accordingly regarded as a line salt of a humus acid.

Obs.—Found in peat beds, near Aussee in Styria; and at Bad Gonten in Appenzell, and Obbürgen, near Stansstad in Unterwalden, Switzerland.

Named after Bergrath Doppler (1803-1854), who was the first to bring the substance to notice. C. W. Gümbel has referred here (Jb. Min., 278, 1858) a substance from a peat bed near Berchtesgaden. It is soft, plastic, elastic, black, of waxy luster, tasteless; on drying in the air it resembles compact coal, is brittle and velvet-black, and has H. = 2.5, G. = 1.439, luster vitreous, with powder brownish black. The air-dried material loses, at 80°, 12 p. c. of water. Unlike dopplerite, it burns with a bright yellow flame, is partially soluble in alcohol, and the alcoholic solution affords a resin (Kenugt, Ueb., 142, 1858).

A pitch-black coal-like substance from the above mentioned peat beds at Kolbenmoor, near Berchtesgaden, related to dopplerite in composition, and in not burning with a flame when inserted in fragments in the flame of a candle, has been analyzed by C. Gilbert Wheeler (priv. contr., dated Nuremberg, Jan. 23, 1866). It afforded him: C 50 98, H 5 36, N 3 74, O 36 14, ash 3.78 = 100. It appears to be the same substance that is here partially described by Gümbel. It is found embedded in, and entirely surrounded by, the peat; and specimens show well the

transition from peat to the coal-like substance.

Phytocollite H. C. Lewis, Am. Phil. Soc. Philad., Dec. 2, 1881. A black gelatinous hydrocarbon, related to dopplerite, described by T. Cooper (Eng. Mng. J., Aug. 13, 1881) as found in a stratum of muck below a peat bed at Scranton, Penn. When first found it was jelly-like in consistency, but on exposure to the air it became tougher and elastic, somewhat like india-rubber, and finally when quite dry it was brittle and nearly as hard as coal. Only partially dissolved in hot alcohol, but completely in caustic potash. When dry burns with a yellow flame. Analysis by J. M. Stinson, of material dried at 100°, gave: C 28.99, H 5.17, N 2.46, O 56.98, ash 6.40 = 100; whence the empirical formula $C_{10}H_{22}O_{16} = Carbon 30.2$, hydrogen 5.5, oxygen 64.3 = 100. Named from $\phi v r \delta r$ and $\kappa \delta \lambda \lambda \alpha$, plant-jelly.

DOPPLERITE of J. C. Deicke, B. H. Ztg., 17, 383. (Not Dopplerite according to Kenng., Ueb., 141, 1858.) Grayish, earthy, plastic in the fingers when fresh; becoming dark reddish brown to black on drying. Yields after drying: Combustible substance 83.25, water 12.5, ash 4.25. Burns with a bright flame and intense heat, and differ from dopplerite in this respect, and also in containing much less water. From a peat bed at Finkenbach in the Canton of St. Gall, Switzerland.

APPENDIX TO HYDROCARBONS.

The substances included here are: 1, Petroleum, passing into the viscid bitumen, maltha or mineral tar; 2, the solid bitumen Asphaltum; 3, Mineral Coal. These are in general more complex substances than those included in the preceding pages and have still less claim to be regarded as definite mineral species (though it may be a matter of convenience in many cases to have the different kinds provided with names). It is hence not unnatural to separate them from the somewhat more definite substances previously described in this chapter, although no line can be drawn between them, and the division must be made somewhat arbitrarily. In fact it may be noted that even some of the substances ordinarily classed as coals, in behavior toward solvents and in composition, approach closely to hydrocarbons already mentioned (cf. torbanite, pp. 1009, 1022.

With petroleum is to be included also another substance of the first economic importance, Natural Gas; the description of native gaseous compounds, however, does not fall within the

scope of this work.

Petroleum. Naphtha and Petroleum. Nα φθα, Strabo, 16, i. § 15, Dioscor., 1, 101. Naphtha, Bitumen liquidum candidum, Plin., 2, 109, 35, 51. Naphtha flos bituminis Agric., Ort. Caus. Subt., 45, 1544. Liquidum bitumen, nunc vocatur Petroleum, Agric., Nat. Foss., 222, 1546. Erdöl, Bergöl, Steinöl, Germ. Mineral Oil. Kerosene. Bitume liquide Fr. Petrtasphatt. Πετασφάλτος Dioscor., 1, 100. Pissasphaltus Plin., 24, 25, 35, 51. Multhe Plin., 24, 26, 26, 50, 51.

Maltha Plin., 2, 108. Bergtheer Germ. Bitume visqueux, Bitume glutineux, Poix minerale, Mineral graisse, Fr. Petroleum pt. Mineral Tar. Brea Span.

Liquids or oils, in the crude state, of disagreeable odor; varying widely in color, from colorless to dark yellow or brown and nearly black, the greenish brown color the most common; also in consistency from thin flowing kinds to those that are thick and viscous; and in specific gravity from 0.6 to 0.9.

Petroleum passes by insensible gradations into pittasphalt or maltha (viscid bitumen); and

the latter as insensibly into asphalt or solid bitumen.

Comp.—Chemically, petroleum consists for the most part of members of the paraffin series, C_nH_{2n+2} , varying from Marsh Gas, CH_4 , to the solid forms. The olefines, C_nH_{2n} , are also present in smaller amount. The above is especially true of the American oils. Those of the Caucasus have a higher density, the volatile constituents are less prominent, they distill at about 150° and contain the benzenes, C_nH_{2n-6} , in considerable amount. There are present also members of the series $I_{1}H_{2n-8}$. The German petroleum is intermediate between the American and the Caucasian The Canadian petroleum is especially rich in the colid near I_{2n-8} . The Canadian petroleum is especially rich in the solid paraffins.

Obs.—Petroleum occurs in rocks or deposits of nearly all geological ages, from the Lower Silurian to the present epoch. It is associated most abundantly with argillaceous shales, sands, and sandstones, but is found also permeating limestones, giving them a bituminous odor, and rendering them sometimes a considerable source of oil. From these oleiferous shales, sands, and limestones the oil often exudes, and appears floating on the streams or lakes of the region, or rises in oil springs. It also exists collected in subterranean cavities in certain rocks, whence it issues in jets or fountains whenever an outlet is made by boring. These cavities are situated mostly along the course of gentle anticlinals in the rocks of the region; and it is therefore probable, as has been suggested, that they originated for the most part in the displacements of the strata caused by the slight uplift. The oil which fills the cavities has ordinarily been derived from the subjacent rocks; for the strata in which the cavities exist are frequently barren sandstones. The conditions required for the production of such subterranean accumulations would be therefore a bituminous oil-bearing, or else oil-producing, stratum at a greater or less depth below; cavities to receive the oil; an overlying stratum of close-grained shale or limestone, not allowing of the easy escape of the naphtha vapors.

The two regions which now furnish the chief part of the petroleum are, first in importance, western Pennsylvania, with parts of New York and Ohio, and, second, the Baku region on the Caspian Sea, at the eastern end of the Caucasus. The oil has been known to exist at the latter locality since early times, but only recently has its economic importance been recognized.

locality since early times, but only recently has its economic importance been recognized.

In the United States liquid oil occurs in the Lower Silurian, in the "Bird's-eye" limestone of Rivière à la Rose (Montmorency), Canada, and of Watertown, N. Y., in drops in fossil coral; and in the Trenton limestone at Pakenham, Canada, the cavities of large Orthocerata sometimes hold several ounces (T. S. Hunt, Am. J. Sc., 35, 166, 1863); on Grand Manitoulin Id., where a spring affording it rises from the Utica shale, the source possibly the subjacent limestones; at Guilderland, near Albany, from the Hudson River group, as observed in a spring by Beck; quite freely in limestone and shale near Chicago; far more so in Kentucky, in the Cumberland oil region, the wells descend 200 ft. into the Blue Limestone, in which there are bituminous shaly strata overlaid by sheets of thin-bedded compact limestone; these features prevail from Lincoln and Casey Cos., through Adair and Russell, Cumberland and Clinton Cos., Ky., and Overton and Jackson Cos., Tenn.

In the *Upper Silurian* traces have been observed in the Niagara limestone and the Medina red shales; at Gaspé, Canada, in a Lower Helderberg limestone, on Silver Brook, etc.; near Chicago, so abundant in a limestone as to ooze out, and the rock may be made to burn, owing

to its presence.

In the Lower Devonian, the Corniferous limestone is regarded by Hunt as the source of the oil of Enniskillen, Canada, where there are large areas covered by the half-inspissated bitumen. Hunt states (l. c.) that at Rainham, Canada, on L. Erie, shells of Pentamerus aratus are sometimes filled with petroleum; and that in other places in the region embedded corals, Heliophyllum and Favosites, have, in certain of the layers, their cells full of oil (while in other layers it is absent from the corals), and in quarrying, the oil flows out and collects on the water of the quarry; and at Gaspé, Lower Devonian sandstones afford oil springs and give rise to beds of thickened petroleum, and the chalcedonic geodes of a trap dike, intersecting the sandstone, sometimes contain petroleum. In the Middle Devonian, the Black shale, or Genesee slate, is supposed by many geologists to be the principal source of the oil of Pennsylvania, the Kenawha valley, and other parts of eastern Virginia, and of Ohio and Michigan; but J. P. Lesley attributes much of the oil of western Pennsylvania to the Subcarboniferous. Near Fredonia, Chautauqua Co., and at Rockville, Alleghany Co., oil is found in connection with Chemung rocks, or the Upper Devonian (Hall).

A little oil has been observed in connection with Triassic shales at Southbury, Conn.

The oil of southern California proceeds from Tertiary shales. On Trinidad, a thick oil, with asphalt, occurs in connection with lignite and other vegetable remains in the shales constituting

the upper part of the Tertiary.

The oil spring of Cuba, Alleghany Co., N. Y., called the Seneca Oil Spring, long known, was described by Prof. Silliman in 1833 (Am. J. Sc., 23, 97) as a dirty pool, about 18 ft. across, covered with a film of oil, which was skimmed off from time to time for medicinal purposes. The so called "Seneca oil," sold at the time in the shops (and from which he often distilled naphtha for preserving potassium), he observes was not from this spring (around which the Seneca Indians then had a reserve of a square mile), but, as he was told, from Oil Creek, Venango Co., Pa., about 100 m. from Pittsburg. Seneca Lake has oil on its surface in some parts, and it is said to have given the name to the oil; but whether this is the true source, or whether it came from its being collected and sold by the Seneca Indians, is not clear. Hildreth in 1833 (ib., 24, 63), and later in 1836 (ib., 29, 86, 121, 129), gave an account of the salt wells of the Little Kenawha valley, which then afforded, he says, 50 to 100 gallons a year. He also speaks in 1833, of a well 475 ft. deep, 30 m. N. of Marietta, Olio, which, when first opened, discharged at intervals of 2 to 4 days, for 3 to 6 hours each time, throwing out 30 to 60 gallons of oil at each "eruption," but was then yielding only a barrel a week. In 1840 a spouting well of oil at Burksville, Kentucky, was described (ib., 39, 195); the well was bored for salt, and 200 ft. down a "fountain of pure oil was struck, which was thrown up more than 12 ft. above the surface of the earth," emitting, according to the estimate, 75 gallons a minute; it "continued to flow for several days successively," but then failed; and efforts to bring it into action again, or find another, were not successful. The petroleum of Enniskillen, Canada, was

mentioned in 1844 by Mr. Murray, in the Canada Geological Report for 1846; and in 1857 wells were sunk for the collection of it. In 1859, on Oil Creek, Venango Co., Pa., a boring for salt, but 75 feet deep, let out the first fountain of oil of that now famous oil region. For many weeks it discharged 1,000 gallons per day. Since that time the development in western Pennsylvania has been wonderfully rapid, and at the present time the production of this oil. region amounts to 30,000,000 barrels annually. See further the volumes of the Pennsylvania Geol. Survey, also Min. Res. U. S., 1883 et seq., for description of localities, statements of production; also, Petroleum and Natural Gas in New York State, C. A. Ashburner, Am. Inst.

Mng. Eng., read July, 1887.

Noted foreign localities are 3 miles from Ye-nan-gyoung (Fetid-water-rivulet), Upper Burma (and exported from Rangoon), where there are about 100 wells, from 180 to 306 feet deep, each lined with horizontal timber, but not now much worked; also Pegu, Arakan, Upper Assam, and several parts of Punjah, Baluchistán, and Afghanistán (cf. Ball., Geol. India, 3, 124, 1881). Further on the peninsula of Apcheron on the western shore of the Caspian, at Baku, alluded to above, where naphtha exudes from argillaceous and calcareous beds, especially the former, of the Middle Tertiary (Abich), and where it has long been used for burning in lamps and for cooking; near the center of the region the light and pure naphtha oil is obtained, while along tits borders the oil is a thicker petroleum, or passes into an asphalt, and solid masses of this asphalt are often seen floating in the Caspian; on the island of Cheleken, near the eastern coast of the Caspian, in Balkan Bay; on the banks of the Kuban, promontory of Taman, east side of the straits between the Azov and Black Sea; near the river Betchora, in the government of Archangel, Russia; near the village of Amiano, in Parma, Italy, whence enough was formerly obtained to light the streets of Genoa; at Zante, one of the Ionian islands (ancient Zacynthus), which has furnished oil for more than 2,000 years, its petroleum spring having been mentioned by Herodotus. Also obtained in some quantity in Galicia; in Brunswick, Hannover, Alsace, etc. Pliny mentions the oil of a spring at Agrigentum, Sicily, and states that it was collected and used for burning in lamps, as a substitute for oil. He distinguishes this oil from naphtha, which he says was too light and inflammable for such a use. Of naphtha, he mentions a locality in "Parthia" (about the sources of the Indus). Oil is found also near the city of Mexico, and on the river Lagun.

Also in Venezuela, in New Zealand, Japan, China, etc.

The Baku oil fields at Balakhani, 8 miles north of Baku on the Caspian, have come into prominence especially since 1876, and they now rank as a prominent source of the commercial

supply of the world. Some of the wells in the region have given phenomenal outflows (see further Min. Res. U. S., p. 463 et seq., 1886).

The word naphtha is from the Persian nafata, signifying to exude; and petroleum from πέτρος, rock, and oleum, oil (the latter from the Greek ἐλαιον, oil), dating only from the middle ages (see Syn., p. 1015.

The name pittolium is from πίττα, pitch, and oleum, oil, analogous to petroleum; and pittasphaltum, from the Greek for pitch and asphalt.

The word maltha is from the Greek $\mu\alpha\lambda\theta\eta$, soft wax; it was also used sometimes for a mixture of wax and pitch, employed for making the surface of writing tablets, and for some kinds of cements. But Pliny (2, 108) describes under this name an inflammable mud flowing from a pool at Samosata in North Syria on the Euphrates, which he says (ib., 109) was similar

in nature to naphtha; and this use of the word has led to its later application to viscid bitumens.

Petroleum in cavities in crystals. Davy, in his examinations of the fluids in crystals (Phil. Trans., 367, and postscript, 1822), found only water, except in the case of quartz from Dauphiny. The liquid in this case was about as viscid as linseed oil; brownish in color; became solid and opaque at 13°; had a smell resembling naphtha; acted like a fixed oil when heated, the temperature of ebullition being high; and burned with flame, producing a white smoke. The cavity was $\frac{1}{3}$ in across, but only a sixth of it was occupied by the fluid. Davy made his investigations of the fluids in crystals by having the crystals bored through to the cavity by a lapidary, and was the first to use this method.

Petrolene. Boussingault obtained from the viscid bitumen and asphalt of Bechelbronn an oil which he called *Petrolene*, and announced it as the *liquid* ingredient of all asphalt, the solid one being named by him Asphaltene. It was separated by heating in an oil bath to a temperature of 300°. None of it passed over at a temperature below 100°. He obtained for its composition, Ann. Ch. Phys., 64, 141, 1837; 73, 442, 1840:

Carbon	87.36	86.78	87.45	86.98	\$ 88.4
Hydrogen	11.90	12.20	12:30	12.70	12.5

He writes for it the formula $C_{10}H_{16}$, making it of the camphene series C_nH_{2n-4} . It boiled at 280°. The vapor density is stated at 9.415, or "double that of oil of turpentine." There can be no doubt that the petrolene was a mixture of oils. See further, 5th Ed., pp. 729, 730.

The Bechelbronn tar and that similar from Lobsann (both in the Dept. du Bas-Rhin, France)

are called also Minéral Graisse and Graisse de Strasbourg.

Asphaltum. *Λσφαλτος Aristot., Strabo, Diosc., etc. Bitumen Plin., 35, 51. Asphalt, eral Pitch. Asphalt, Bergpech, Erdpech, Germ. Asphalte, Bitume, Fr. [For syn. of Pittasphalt or Mineral Tar (Bergtheer Germ.), see p. 1015.]

Asphaltum, or mineral pitch, is a mixture of different hydrocarbons, part of which are

oxygenated. Its ordinary characters are as follows:

Amorphous. G. = $\tilde{1}$ -1.8; sometimes higher from impurities. Luster like that of black pitch. Color brownish black and black. Odor bituminous. Melts ordinarily at 90° to 100°, and burns with a bright flame. Soluble mostly or wholly in oil of turpentine, and partly or wholly in ether; commonly partly in alcohol.

The more solid kinds graduate into the pittasphalts or mineral tar, and through these there is a gradation to petroleum. The fluid kinds change into the solid by the loss of a vaporizable portion on exposure, and also by a process of oxidation, which consists first in a loss of hydrogen,

and finally in the oxygenation of a portion of the mass.

Comp.—The action of heat, alcohol, ether, naphtha, and oil of turpentine, as well as direct analyses, show that the so called asphaltum from different localities is very various in composition. The following are the classes of ingredients present:

A. Oils vaporizable at about 100°, or below; sparingly present, if at all.

B. Heavy oils, probably of the Pittolium or Petrolene groups (see above); vaporizable between 100° and 250°; constituting sometimes 85 p. c. of the mass.

C. Resins soluble in alcohol.

D. Solid asphalt-like substance or substances, soluble in ether and not in alcohol; black,

pitch-like, lustrous in fracture; 15 to 85 p. c.

E. Black or brownish black substance or substances not soluble either in alcohol or ether; similar to D in color and appearance, Kersten; brown and ulmin-like, Völckel; 1 to 75 p. c. F. nitrogenous substances; often as much as corresponds to 1 or 2 p. c. of nitrogen.

Obs.—Asphaltum belongs to rocks of no particular age. The most abundant deposits are superficial. But these are generally, if not always, connected with rock deposits containing some kind of bituminous material or vegetable remains.

Some of the noted localities of asphaltum are the region of the Dead Sea, or Lake Asphaltites, whence the most of the asphaltum of ancient writers; a lake on Trinidad, 11 m. in circuit, which is hot at the center, but is solid and cold toward the shores, and has its borders over a breadth of 3 m. covered with the hardened pitch with trees flourishing over it; and about Point La Braye, of # m. covered with the hardened pitch with trees hourishing over it, and about 10th La Blaye, the masses of pitch look like black rocks among the foliage; at various places in S. America, similar lakes, as at Caxitambo (not Coxitambo), Peru, which is used at Payta, on the coast (under the equator), for pitching boats, etc.; at Berengela, Peru, not far from Arica (S.), where it is put to the same use; in California, near the coast of St. Barbara, an area of some acres; in a large bed, near Avlona in Albania (G. = 1.205). Also in smaller quantities, sometimes disseminated through shale and sandstone rocks, and occasionally limestones, or collected in certifical research in these rocks. cavities or seams in these rocks; near Matlock, Derbyshire, in stalactitic masses; Poldice mine in Cornwall; Haughmond Hill in Shropshire; at Bastennes and Dax, Dept. of Landes, constituting 6 p. c. of a sandy deposit; Val de Travers, Neuchâtel, impregnating a bed in the Cretaceous formation, and serving as a cement to the rock, which is used for building; impregnating dolomite on the island of Brazza in Dalmatia; in the Caucasus; in gneiss and mica schist in Sweden.

Elaterite. Subterranean Fungus (fr. Derbyshire) Lister, Phil. Trans., 1673. Elastic Bitumen. Mineral Caoutchouc. Bitume élastique Delaméth., J. Phys., 31, 31, 1787. Elastic Bitumen Hatchett, Linn. Trans., 4, 146, 1797. Elastisches Erdpech Klapr., Beitr., 3, 107, 1802. Elastisches Erdharz Germ. Elaterit, Fossiles Erdharz, Hausm., Handb., 1, 87, 1813.

Masssive, amorphous. G. = 0.905-1.233 Derbyshire. Soft, elastic, sometimes adhering to the fingers (a); also moderately soft and elastic; much like india-rubber (b); and occasionally hard and brittle (c), embedded in the softer kinds. Color brown, usually dark brown. Subtranslucent; sometimes dark orange-red by transmitted light.

Johnston analyzed the three kinds, A, B, C, separately (Phil. Mag., 13, 22, 1838). He mentions the action of ether only on the B, from which it separated but 18 p. c. of the mass;

and the two analyses given are those of the undissolved material. Analyses:

		C	- H	
1.	A	85.47	13.28 =	98.75
2.	B	84.38	12.58 =	96.96
3.	B	83.67	12.54 =	96.21
4.	C	85.96	12.34 =	98.30
5.	C	86.18	12.42 =	98.60

He states that the loss in A and C may be partly or wholly oxygen, and that in the case of C, of the insoluble residue, 3-3.8 p. c. is oxygen. He thus leaves the constitution of elaterite in doubt. It appears to be partly a carbohydrogen near ozocerite, and partly an oxygenated

insoluble material.

It is found at Castleton in Derbyshire, in the lead mine of Odin, along with lead ore and calcite, in compact reniform or fungoid masses, and is abundant. Also reported from St. Bernard's Well near Edinburgh; Chapel quarries in Fifeshire; a coal mine at Montrelais, at the depth of 230 feet; and, according to Hausmann (Handbuch, 3, 273), at Neuchâtel, and on the island of Zante. A similar material in external characters has been met with at Woodbury, Ct.

A mineral tar from the Old Red Sandstone at Craig Well, near Dingwall, R. shire, is described by W. Morrison (Trans. Ed. G. Soc., 5, 500, 1888, and Min. Mag., 8, 133, 1889). It is black, lustrous, sticky, of the consistence of tar, and occurs associated with albertite. Insoluble in acids, alkalies, alcohol, but soluble in paraffin oil, and partially soluble in ether, leaving an inflammable residue. Melts at about 140°. On dry distillation yields an inflammable oil, a gas and water. A similar tar occurs in the Carboniferous limestone of Derbyshire.

Analyses, Macadam, Min. Mag., 8, 136, 1889: 1, 2, of elaterite; 3, of mineral pitch.

	C	H	O, etc.	N	S
1. Derbyshire	83.62	11.19	4.78	0.17	0.24 = 100
2. "	82.80	11:92	4.92	0.11	0.25 = 100
3. Dingwall	81.19	13.37	4.45	0.13 .	0.86 = 100

Coorongite is a kind of mineral caoutchouc from the Coorong district, South Australia; analysis gave: C 64.73, C (fixed) 1.00, H 11.63, O 20.38, H₂O 0.47, ash 1.79 = 100. Cf. G. C. Morris, Proc. Acad. Philad., 131, 1877.

New Mineral Resin fr. Settling Stones, J. F. W. Johnston, SETTLING STONES RESIN. Edinb. J. Sc., 4, 122, 1831, Phil. Mag., 14, 88, 1839. Settlingite Dx., Min., 2, 42, 1874. the form of drops, more or less rounded, or flattened, as if once fluid or soft, and found incrusting the rocky walls of a vein at an old lead mine in Northumberland, known by the name of Settling Stones, resting on and occasionally covered by calcite and pearl spar; the rock is the Mountain limestone (Subcarboniferous). The resin is hard, brittle under the hammer, but difficult to reduce to powder; G. = 1·16-1·54; color from pale yellow to deep red; a pale green opalescence; does not melt at 205°. Burns in the flame of a candle. Very slightly acted upon by alcohol. An analysis afforded Johnston:

> C 85·133 H 10.853 Ash 3.256 = 99.242

But Johnston adds: "It is therefore doubtful whether this resinoid substance contains oxygen or not. It may be only an impure carbo-hydrogen." It is very slightly acted upon by alcohol. Gives empyreumatic products when fused in a closed tube. It has close relations to elaterite.

BERENGELITE Johnston, Phil. Mag., 13, 329, 1838. Asphaltum-like. Color dark brown, with a tinge of green. Powder yellow. Luster of surface of fracture resinous. Anal.—Johnston: C 72 47, H 9 20, O 18 33 = 100, corresponding to the ratio for C, H, O = 40:62:8. Forms a solution with cold alzohol, which is bitter to the taste. On evaporation the resin obtained has a clear red color, and remains soft and viscid at the ordinary temperature. Nearly insoluble in caustic potash. Odor resinous, disagreeable; but after fusion for some time at 100°, this odor is succeeded by an agreeable one; on cooling it regains the original odor. It is said to form a lake like that of Trinidad, in the province of St. Juan de Berengela, about 100 m. from Arica, Peru, and is used at Arica for paying boats and vessels.

BIELZITE G. Benkō and K. Jahn, Zs. Kr., 13, 68, 1887.

Massive. Fracture subconchoidal. Brittle. H. = 1-2. 'G. = 1.249. Luster resinous. Color brownish black. Opaque. Analysis: \(\frac{2}{3}\) C 79.74, H 6.34 = 86.08. Melts easily and burns with smoky flame; at 175° becomes soft and at 330° swells up and becomes dry, leaving on cooling a black shining coal. Dissolves in considerable part in chloroform and carbon disulphide; much less soluble in alcohol, ether, and benzene. From Zsil-Vajdej, Transylvania. Named after E. A. Bielz.

PIAUZITE. Retinit von Piauze, Piauzit, Haid., Pogg., 62, 275, 1844. An asphalt-like substance, remarkable for its high melting-point, 315. It occurs slaty massive; color brownish or greenish black; thin splinters colophonite-brown by transmitted light; streak light brown, amber-brown; H. = 1.5; G. = 1.220; 1.186 Kenngott. After melting, it burns with an aromatic odor and much smoke, leaving 5.96 per cent of ash. Soluble in ether and caustic potash, also largely in absolute alcohol. Heated in a glass tube a yellowish oily fluid is distilled, having an acid reaction.

Obtained from a bed of brown coal at Piauze, near Neustadt in Carniola; on Mt. Chum, near Tüffer in Styria, where thousands of pounds have been obtained. It much resembles a

black lamellar coal (cf. Kenngott, Jb. G. Reichs., 7, 91, 1856).

WURTZILITE W. P. Blake, Eng. Mng. J., 48, 542, Dec. 21, 1889; Trans. Am. Inst. Mng. Engineers, Feb. 1890. Henry Wurtz, Mng. Eng. J., 49, 106, 1890.

From the Uinta Mountains, in Wasatch Co., Utah, between Salt Lake and the valley of

Green River, not far from the source of uintahite, or "gilsonite" (see p. 1020).

It is a firm, black solid, and breaks with a brilliant conchoidal fracture, and has a general resemblance to jet or some of the cannel coals. Sectile, the shavings having a degree of elasticity, but if bent too far, or suddenly, snap like glass; when slowly pressed and warmed a flake may be bent nearly double. In very thin plates, deep red. The color by reflected light jet-black. H. = 2-3. G. = 1.030. Does not fuse in boiling water, but becomes softer and tougher, and is more plastic. Melts in the flame of a candle, takes fire, and burns with a bright, luminous flame, with little smoke, giving off a strong bituminous odor. Fused in a glass tube it gives off a dense cloud of white and yellow smoke and distills over a thick, brown tarry oil

with a strong odor, and leaves a small residue of fixed carbon. Fragments warmed in the hand emit a strong odor like that of some of the crude petroleums, which is rather offensive. It resists the usual solvents of bitumen.

Named Wurtzilite after Dr. Henry Wurtz, of New York.

On the relations of uintahite, albertite, grahamite, and asphaltum in general, see W. P. Blake, Trans. Am. Inst. Mng. Eng., read Feb., 1890. Further on the occurrence of various bituminous substances and coals, in Utah and Colorado, with a discussion as to their origin, see Stone, Am. J. Sc., 42, 148, 1891.

The following are related to asphaltum.

ALBERTITE Robb. Melan-Asphalt Wetherill, Trans. Am. Phil. Soc. Philad., 353, 1852. Differs from ordinary asphaltum in being only partially soluble in oil of turpentine, and in its very imperfect fusion when heated. It has H. = 1-2; G. = 1.097; luster brilliant, pitch-like; color jet-black. Softens a little in boiling water; in the flame of a candle shows incipient fusion. According to imperfect determinations, only a trace soluble in alcohol; 4 p. c. in ether; 30 in oil of turpentine. Wetherill obtained in an ultimate analysis: Carbon 86 04, hydrogen 8 96, oxygen 1 97, nitrogen 2 93, S tr., ash 0 10 = 100.

Occurs filling an irregular fissure in rocks of the Subcarboniferous age (or Lewer Carbon-

iferous) in Albert Co., New Brunswick.

This and the related substances have been usually regarded as inspissated and oxygenated petroleum. Peckham, however, takes a different view, cf. Am. J. Sc., 48, 362, 1869. For an article on its mode of occurrence, see Hitchcock, Am. J. Sc., 39, 267, 1865.

An albertite from the Old Red Sandstone at Kiltearn (Strathpeffer), Ross-shire, has been

described by W. Morrison, Min. Mag., 6, 101, 1884; Honeyman, ibid., 7, 77, 1886.

CLOUSTONITE Heddle, Min. Mag., 3, 222, 1879. Occurs in patches in blue limestone and in blue flags at Inganess, Orkney. Brittle. H. = 3. Luster brilliant like obsidian. Color jetblack. Soluble in benzene. At a red heat it gave: 47.8 p. c. of illuminating gas, 51.8 carbon, 0.24 ash; 0.1 p. c. volatile below 210°. Named after Dr. Clouston, who in 1839 wrote an account of the geology and mineralogy of Orkney.

Grahamite Wurtz. Coal or Asphalt Lesley, Proc. Am. Phil Soc. Philad., 9, 183, 1863; Grahamite Wurtz. Rep. Min. Format. in W. Virginia, 1865, Am. J. Sc., 42, 420, 1866. Proc. Am. Assoc., 18, 124, 1869. See also Wurtz, Gas Light Journal, Oct. 2, 1869; S. F. Peckham, ib., Dec. 2, 1869.

Resembles albertite in its pitch-black, lustrous appearance; H. = 2; G. = 1.145. Soluble mostly in oil of turpentine; partly in ether, naphtha, or benzene; not at all in alcohol; wholly in chloroform and carbon disulphide. No action with alkalies or hot nitric or hydrochloric acid. Melts only imperfectly, and with a decomposition of the surface; but in this state the

interior may be drawn into long threads.

Occurs in W. Virginia, about 20 m. in an air line S. of Parkersburg, filling a fissure (shrinkage fissure) in a sandstone of the Carboniferous formation; and supposed to be, like the albertite, an inspissated and oxygenated petroleum. Jenney has manufactured grahamite from petroleum (Am. Chemist, 5, 359). The material is partly columnar from a fracturing as a result of contraction in the material, the structure being vertical to the sides of the vein. Named after J. Lorimer Graham of New York and Col. Graham of Baltimore.

A similar deposit occurs in Huasteca, Mexico (J. P. Kimball, Am. J. Sc., 12, 277, 1876). That from the Cristo mine (cristo-grahamite) has been analyzed by W. Wallace. G. = 1.156.

> Volatile matter...... Illum. gas 61.32 S 0.46 $H_2O 0.36 = 62.14$ 31.63 0.37 Ash 5.86 = 37.86Coke Carbon..... 100.00

UINTAHITE or Unitaite W. P. Blake, Eng. Mng. J., Dec. 26, 1885. Gilsonite. A variety of asphalt from the Uinta (or Uintah) valley. near Fort Duchesne, Utah. Occurs in masses several inches in diameter, with conchoidal fracture; very brittle. H. = 2-2.5; G. = 1.065-1.070. Color black, brilliant, and lustrous; streak and powder a rich brown. A non-conductor of electricity;

electrically excited by friction.

It fuses easily in the flame of a candle and burns with a brilliant flame, much like sealing wax; and like sealing-wax, it will give a clean sharp impression from a seal. Unless the melted mineral is very hot, it does not adhere to cold paper. It has considerable plasticity while warm, and is not sticky, but retains after melting its lustrous black and smooth surface. By distillation a very small quantity of a clear white and dense oil is given off, and a little gas or vapor. It is much more readily dissolved by the heavy oils and fats than by the lighter and more volatile menstrua. Thus it dissolves and incorporates quickly in heavy lubricating petroleum, while the white distillates from petroleum have little or no effect upon it at ordinary temperatures. So also it freely dissolves in oil of turpentine when warmed, but it does not readily dissolve in cold spirits of turpentine. Ether apparently does not attack fragments, but the powder is slowly dissolved. Soluble in ordinary alcohol.

Also called gilsonite after Mr. S. H. Gilson of Salt Lake City.

Mineral Coal. 'Ανθρακευτὰ δ'όσα τῶν τοιούτων γῆς πλέον ἔχει ἢ καπνοῦ [= Coallike substances which have in them more of earth than of smoke or fire] Aristot., Μετεωρολογ., like substances which have in them more of earth than of smoke or fire] Aristot., Μετεωρολογ., 4, 9. Εν & (river Pontus in Thrace) τινας λίθους οι καίονται [= Certain stones which burn] Aristot., Περὶ Θαυμ' Ακουσμ., c. 115. Οὖς δὲ καλοῦσιν εὐθυς αιθρακας τῶν θρυπτομένων (? ὀρυπτομένων) διὰ τὴν χρείας εἰσι γεώδεις, etc. [= Those (of minerals) dug for use, which are called simple coals, are earthy, but will kindle and burn like charcoal] (fr. Liguria). Τheophr., 16 (in Sehneider's edit.), 315 B.C. Ενιοι δὲ τῶν θραυστῶν ἀνθρακοῦνται τῆ και σει και δίαμένουσι πλείω χρόνον [= Some brittle stones become by burning like glowing coals, and remain so a long time] (fr. Compact massive, without crystalline structure or cleavage: sometimes breaking with a

Compact massive, without crystalline structure or cleavage; sometimes breaking with a degree of regularity, but from a jointed rather than a cleavage structure. Sometimes laminated;

often faintly and delicately banded, successive layers differing slightly in luster.

Fracture conchoidal to uneven. Brittle; rarely somewhat sectile. H. = 0.5-2.5. G. = 1-1.80. Luster dull to brilliant, and either earthy, resinous, or submetallic. Color black, grayish black, brownish black, and occasionally iridescent; also sometimes dark brown. Opaque. Without taste, except from impurities present. Insoluble in alcohol, ether, naphtha, and benzene, excepting at the most 2 or 3 p. c. (rarely 10?); usually less than 1 p. c. Insoluble in a solution of potash. Infusible to subfusible; but often becoming a soft, pliant, or paste-like mass when heated. On distillation most kinds afford more or less of oily and tarry substances, which are mixtures of hydrocarbons and paraffin.

Var.—The variations depend partly (1) on the amount of the volatile ingredients afforded on destructive distillation; or (2) on the nature of these volatile compounds, for ingredients of similar composition may differ widely in volatility, etc.; (3) on structure, luster, and other physical

characters.

Coal is in general the result of the gradual change which has taken place in geological history in organic deposits, chiefly vegetable, and its form and composition depend upon the extent to which this change has gone on. Thus it passes from forms which still retain the original structure of the wood (peat, lignite) and through those with less of volatile or bituminous matter to anthracite and further to kinds which approach graphite, like the coal of Rhode Island. Cf. schungite, p. 8.)

1. Anthracite. Anthracit Karst., Tab., 58, 96, 1808. Glanzkohle Germ. H. = 2-2.5. G. = 1.32-1.7, Pennsylvania; 1.81, Rhode Island; 1.26-1.36, South Wales. Luster bright, often submetallic, iron-black, and frequently iridescent. Fracture conchoidal. Volatile matter after drying 3-6 p. c. Burns with a feeble flame of a pale color.

The anthracites of Pennsylvania contain ordinarily 85-93 per cent. of carbon; those of South Wales, 88-95; of France, 80-83; of Saxony, 81; of southern Russia, sometimes 94 per

Anthracite graduates through semi-anthracite into bituminous coal, becoming less hard and containing more volatile matter; and an intermediate variety is called free-burning anthracite.

Native Coke. Carbonite. More compact than artificial coke, and some varieties afford considerable bitumen. From the Edgehill mines, near Richmond, Va., according to Genth, who attributes its origin to the action of a trap eruption on bituminous coal. (Cf. Wurtz, Trans. Am. Inst. Mng. Eng., 3, 457, 1875.)

2. BITUMINOUS COAL. Schwarzkohle Hausm., Handb., 73, 1813. Steinkohle pt. Germ. Under the head of Bituminous Coals, a number of kinds are included which differ strikingly in the action of heat, and which therefore are of unlike constitution. They have the common characteristic of burning in the fire with a yellow, smoky flame, and giving out on distillation hydrocarbon oils or tar, and hence the name bituminous. The ordinary bituminous coals contain from 5-15 p. c. (rarely 16 or 17) of oxygen (ash excluded); while the so-called brown coal or lignite contains from 20-36 p. c., after the expulsion, at 100°, of 15-36 p. c. of water. The amount of hydrogen in each is from 4-7 p. c. Both have usually a bright, pitchy, greasy luster (whence often called *Pechkohle* in German), a firm compact texture, are rather fragile compared with anthracite, and have G. = 1·14-1·40. The *brown* coals have often a brownish-black color, whence the name, and more oxygen, but in these respects and others they shade into ordinary bituminous coals.

The ordinary bituminous coal of Pennsylvania has G. = 1.26-1.37; of Newcastle, England. 1.27; of Scotland, 1.27-1.32; of France, 1.2-1.33; of Belgium, 1.27-1.3. The most prominent

kinds are the following:

(a) Caking or Coking Coal. A bituminous coal which softens and becomes pasty or semiviscid in the fire. This softening takes place at the temperature of incipient decomposition, and is attended with the escape of bubbles of gas. On increasing the heat, the volatile products which result from the ultimate decomposition of the softened mass are driven off, and a coherent, grayish-black, cellular, or fritted mass (coke) is left. Amount of coke left (or part not volatile) varies from 50-85 p. c. A caking coal will lose its caking quality if kept heated for 2 or 3 hours at 300°, and sometimes on mere exposure for a time to the air.

(b) Non-Caking Coal. Like the preceding in all external characters, and often in ultimate

composition; but burning freely without softening or any appearance of incipient fusion.

Percentage of volatile matter same as for caking coal, but the coke is not a proper coke, being

in powder, or of the form of the original coal.

There are all gradations between caking and non-caking bituminous coals. In external characters the two kinds are alike. They often break into layers; and there is besides a horizontal banding arising from a succession of very thin non-separable layers, slightly differing in luster or shade of color. Cherry coal or soft coal (of England) is a non-caking coal igniting well and burning rapidly, while splint or hard coal ignites less readily, burns less rapidly, owing to the smaller amount of volatile matter. Coals which do not cake on burning are called freeburning coals, while the caking are called binding coals.

(c) Cannel Coal (Parrot Coal). A variety of bituminous coal, and often caking; but differing from the preceding in texture, and to some extent in composition, as shown by its products It is compact, with little or no luster, and without any appearance of a banded on distillation. structure; and it breaks with a conchoidal fracture and smooth surface; color dull black or grayish black. On distillation it affords, after drying, 40 to 66 of volatile matter, and the material volatilized includes a large proportion of burning and lubricating oils, much larger than the above kinds of bituminous coal; whence it is extensively used for the manufacture of such It graduates into oil-producing coaly shales, the more compact of which it much resem-The original Parrot coal is a cannel from near Edinburgh, which burns with a crackling noise, whence the name (Percy); and Horn coal, a kind from South Wales, which emits when burning something of the odor of burning horn.

Torbanite. A variety of cannel coal of a dark brown color, yellowish streak, without luster, having a subconchoidal fracture; H. = 2.25; G. = 1.17-1.2. Yields over 60 p. c. of volatile matter, and is used for the production of burning and lubricating oils, paraffin, illuminating gas. Named from the locality at Torbane Hill, near Bathgate in Linlithgowshire, Scotland.

Also called Boghead Cannel (see pp. 1008, 1009).

(d) Brown Coal (Braunkohle Germ., Pechkohle pt. Germ., Lignite). The prominent characteristics of brown coal have already been mentioned. They are non-caking, but afford a large proportion of volatile matter. They are sometimes pitch-black (whence Pechkohle pt. Germ.), but often rather dull and brownish black. G. = 1.15-1.3; sometimes higher from impurities. It is occasionally somewhat lamellar in structure.

Brown coal is often called lignite. But this term is sometimes restricted to masses of coal which still retain the form of the original wood. Jet (Jaïet Fr., Gagath Germ.) is a black variety of brown coal, compact in texture, and taking a good polish, whence its use in jewelry.

Earthy Brown Coal (Erdige Braunkohle) is a brown friable material, sometimes forming

layers in beds of brown coal. But it is in general not a true coal, a considerable part of it being soluble in ether and benzene, and often even in alcohol; besides affording largely of oils and paraffin on distillation. For a notice of "coal" of this kind see under Leucopetrite, p. 1011. Such a coal is sometimes called wax coal and paraffin coal (Wachskohle, Paraffinkohle, Germ.). See also Bathvillite, p. 1008.

Mineral Charcoal. Fibrous charcoal-like substance often found covering the surfaces

between layers of coal, and observed in coal of all ages. It is soft, and soils the fingers like

charcoal. One variety of it is a dry powder.

Comp.—Most mineral coal consists mainly of oxygenated hydrocarbons. On p. 1008 it is shown that the kind of cannel coal called torbanite and the substance bathvillite are closely related in composition, as well as insolubility, to succinite; and it is probable that other cannel coals contain this or some related compound; and that oil-producing (not oil-bearing) shales include a similar kind of hydrocarbon. The ordinary bituminous coals often have 10 to 15 p. c. of oxygen, and may be of analogous composition; though differing much in the precise constitution of these hydrocarbons, some containing such as produce a pasty fusion or incipient decomposition when heated (caking), and others such as undergo no semi-fusion (non-caking). The brown coals, in which there are 20 to 35 p. c. of oxygen, must include other kinds of oxygenated hydrocarbons, of the insoluble kinds. But microscopic examinations appear to show that woody fiber is present in it in various stages of alteration.

Besides oxygenated hydrocarbons, there may also be present simple hydrocarbons (that is, aining no oxygen). This would seem to follow from the small percentage of oxygen containing no oxygen). (2-3 p. c.) in the Tyneside cannel, while the hydrogen is as large in amount as in any cannel or bituminous coals. And there are various bituminous coals, low in oxygen, that suggest the same conclusion. At present, however, chemistry knows of no simple hydrocarbons that are

insoluble in naphtha and benzene.

The presence of *free carbon* is naturally inferred from the composition of coals like the anthracites, which afford very little volatile matter. But even these coals contain ordinarily 1.5 to 2.5 p. c. of each oxygen and hydrogen; and Berthelot holds that they are hydrocarbon

compounds like other coals.

The portion of coal soluble in naphtha or benzene, although small in amount, indicates the presence of other hydrocarbons—simple or oxygenated—oils or resins. Their nature remains to be ascertained. Fyfe obtained by means of naphtha, from the Torbane mineral, 1.2 and 1.4 p. c.; from cannel coal, 2-4 p. c.; and from Newcastle caking, in three experiments, 4.2, 5.8, 9.8 p. c. of soluble material. These results do not accord with the ordinary statements with regard to the insolubility of coal, and the subject needs more extended study.

Coals often contain resins disseminated in visible points through the mass, which may or may

not be of soluble kinds.

Sulphur is present in nearly all coals. It is supposed to be usually combined with iron,

and when the coal affords a red ash on burning, there is reason for believing this true. But Percy mentions a coal from New Zealand which gave a peculiarly white ash, although containing 2 to 3 p. c. of sulphur, a fact showing that it is present not as a sulphide of iron, but as a constituent of an organic compound. The discovery by Church of a resin containing sulphur (see Tasmanite, Trinkerite, etc., p. 1010) gives reason for inferring that it may exist in this coal in that state, although its presence as a constituent of other organic compounds is quite Sulphur is also present as an organic compound in succinite (Helm, p. 1002).

The presence of nitrogen, sometimes 2 p. c., proves the presence of nitrogenous hydro-

carbons; but of what nature is unknown.

The impurities present, which constitute the ash of the coal, consist of silica or quartz, oxide of iron, clay, and other aluminous silicates, or such ingredients as make up the mud and clay of fine soil or alluvium; also some silica, potash, and soda, derived from the original vegetation. The ash in the purest mineral coal amounts to but 0.25 to 1 p. c.; but in that which passes for the

best there are ordinarily 5 to 8 p. c.; and in most that is used for fuel there are 8 to 15 p. c.

Coal occurs in beds, interstratified with shales, sandstones, and conglomerates, and sometimes limestones, forming distinct layers, which vary from a fraction of an inch to 30 feet or more in thickness. In the United States, the anthracites occur east of the Alleghany range, in rocks that have undergone great contortions and fracturings, while the bituminous are found farther west, in rocks that have been less disturbed; and this fact and other observations have led geologists to the view that the anthracites have lost their bitumen by the action of heat. For observations on the geological relations of coal beds, reference may be made to

geological treatises.

The origin of coal is mainly vegetable, though animal life has contributed somewhat to the The beds were once beds of vegetation, analogous, in most respects, in mode of formaresult. tion to the peat beds of modern times, yet in mode of burial often of a very different character. This vegetable origin is proved not only by the occurrence of the leaves, stems, and logs of plants in the coal, but also by the presence throughout its texture, in many cases, of the forms of the original fibers; also by the direct observation that peat is a transition state between unaltered vegetable débris and brown coal, being sometimes found passing completely into true brown coal. Peat differs from true coal in want of homogeneity, it visibly containing vegetable fibers only partially altered; and wherever changed to a fine-textured homogeneous material, even though hardly consolidated, it may be true brown coal

Extensive beds of mineral coal occur in Great Britain; in France, Spain, Belgium; in Netherlands, Prussia, Bavaria, Austria, northern Italy, Silesia, Russia on the south near the Azov, and also in the Altai. It is found in Asia, abundantly in China, in Persia in the Cabul territory, and in the Khorassan or northern Persia, in Hindostan, north of the Gulf of Cutch, in the province of Bengal (the Burdwan coal-field) and Upper Assam, in Borneo, Labuan, Sumatra, several of the Philippines, Formosa, Japan, New South Wales and other parts of Australia, New Zealand, Kerguelen Land; in America, besides the United States, in Chili, at the Straits of Magellan, at Nanaimo on Vancouver's Island, at Melville Island in the Arctic seas,

the Strats of Magellan, at Nanaimo on Vancouver's Island, at Melville Island in the Arctic seas, and in the British Provinces of Nova Scotia, New Brunswick, and Newfoundland.

In England, the principal coal fields are the Manchester of Lancashire and Cheshire; the Great Central of South Yorkshire, Nottingham, and Derby; that of South Wales, Glamorganshire, etc.; the Newcastle field of northern England. In Scotland, a range of beds extends across from the Firth of Forth to the Firth of Clyde; whole area 1650 sq. m. In Ireland, the three are the Limerick fields about the mouth of the Shannon, the Kilkenny fields to the eastward, and that of Ulster on the north. Cannel coal occurs in Great Britain at Lesmahago in Lancashire, about 20 m. from Glasgow; also near Wigan in Lancashire, and West Wemyss in Evre

Mineral coal occurs in France, in small basins, 88 in number, and covering in all, according to Taylor, $\frac{1}{17}$ of the whole surface. The most important are the basin of the Loire between the Loire and the Rhone, and that of Valenciennes on the north, adjoining Belgium. In Belgium, it occupies a western and eastern division, the western in the provinces of Namur and

Hainault, and the eastern extending over Liege.

In the United States there are several separate coal areas; of these that of eastern Pennsylvania produces practically all the anthracite of the country, while the others yield bituminous One of these areas, the Appalachian coal field, commences on the north, in Pennsylvania and southeastern Ohio, and sweeping south over western Virginia and eastern Kentucky and Tennessee to the west of the Appalachians, or partly involved in their ridges, it continues to Alabama near Tuscaloosa, where a bed of coal has been opened. It embraces several isolated patches in the eastern half of Pennsylvania. The whole surface in Pennsylvania has been estimated at 15,437 sq. m., or \(\frac{1}{3}\) the whole area of the state. A second coal area (the Illinois) lies adjoining the Mississippi, and covers the larger part of Illinois, though much broken into patches, and a small northwest part of Kentucky; it is continued westward over a portion of lowa, Missouri, Kansas, Arkansas, and northern Texas west of the Mississippi. The latter area is divided along the Mississippi by a narrow belt of Silurian rock, the whole area is about the same with that of the Appalachian coal field. Another area covers the central portion of Michigan, not far from 5000 sq. m. in area. Besides these, there is a smaller coal region in Rhode Island, which crops out across the north end of the island of Rhode Island, and appears to the northward as far as Mansfield, Massachusetts; the coal from this region is chiefly a graphitic carbon not useful for ordinary combustion. There is also coal (Triassic) in N. Carolina. There are further extensive coal fields in the Rocky Mountains, chiefly bituminous or semi-bituminous, and of more recent geological time than the Carboniferous; much of it belongs to the Laramie epoch; thus at Carbon, Hallville, Wyoming; Evanston and Coalville in Utah; at many points in Colorado, abundant. Further, in Dakota, Montana, Idaho, Utah; also on the Pacific coast, as at Carbonado near Tacoma, at Bellingham Bay, and other points in Washington; in Oregon, California. There are also said to be useful coal deposits in Alaska.

For a general account of the coal fields in the United States, see Min. Res. U. S., 1886, p. 224 et seq. (Ashburner); also the other volumes of Min. Res. U. S.; further the geol. reports of

Pennsylvania, Ohio, etc.
Out of the borders of the United States, on the northeast, commences a fifth coal area, that of Nova Scotia and New Brunswick, which covers, in connection with that of Newfoundland,

18,000 sq. m., or ²/₃ the whole area of these provinces.

The mines of western Pennsylvania, commencing with those of the Blossburg basin, Tioga Co., those of the States west, and those of Cumberland or Frostburg, Maryland, Richmond or Chesterfield, Va., and other mines south, are bituminous. Those of eastern Pennsylvania constituting several detached areas—one, the Schuylkill coal field, on the south, worked principally at Mauch Chunk on the Lehigh, and at Pottsville on the Schuylkill-another, the Wyoming coal field, worked at Carbondale, in the Lackawanna region, and near Wyoming, besides others intermediate—those of Rhode Island and Massachusetts, and some patches in Virginia, are anthracites. Cannel coal is found near Greensburg, Beaver Co., Pa., in Kenawha Co., Va., at Peytona, etc.; also in Kentucky, Ohio, Illinois, Missouri, and Indiana; but part of the so-called cannel is a coaly shale.

Brown coal comes from coal beds more recent than those of the carboniferous age. But much of this more recent coal is not distinguishable from other bituminous coals. The coal of Richmond, Virginia, is supposed to be of the Liassic or Triassic era. Coal of Cretaceous or Tertiary age occurs on the Pacific coast, and in many places over the eastern slopes of the Rocky

Mountains, where a "Lignitic formation" is very widely distributed as noted above.

The coal known to the Greeks and Romans was probably brown coal. The first sentence, The coal known to the Greeks and Romans was probably brown coal. The first sentence, in the synonymy, from Aristotle evidently alludes to mineral coal of some kind; and the first of the two cited from Theophrastus (a favorite pupil of Aristotle) refers to a similar substance, and perhaps the same specimens. The locality of the latter, Liguria (or northwestern Italy along the Mediterranean), where, he adds, there also is amber, may be taken with some freedom, as articles brought by vessels trading with Ligurian ports, even though coming from French ports beyond, might be referred to Liguria. Elis, on the way to Olympias, is given as another locality. The sentence ends with the statement that "these coals are used by the smiths," showing that the value of the substance as fuel was well understood at the time (4th century B.C.). Theophrastus says further, that it will continue to burn as long as any one blows it, but on stopping it deadens, but may be made to burn again; and that it burns with a strong disagreeable odor. The second citation from each, Aristotle and Theophrastus, relates to a similar coal. The locality, in Thrace, identifies it with the Thracian stone of Dioscorides and Pliny, the locality of which, according to the former (from Aristotle), was at Sintia, on the river Pontus (on the Macedonian border of Thracia, to the west of the present Constantinople). According to Dioscorides and Pliny (quoting further in part from Aristotle's "Wonderful Things heard of"), water would make the Thracian stone to burn, and oil extinguish it; which is either altogether a fable, or a partial truth based on somebody's observation that masses or piles of impure pyritiferous coal will become hot, and sometimes ignited, in consequence of being wet. Aristotle mentions its bituminous odor when burning.

The Gagates (whence our word jet) occurred, according to Dioscorides and Pliny, at Gagas

or Gages, a place in Lycia (Asia Minor). The former describes it as black, smooth, and combustible, to which Pliny adds that it was light, and looked much like wood, and that it emitted a disagreeable odor when rubbed, and burned with the smell of sulphur. It was, in part at least, true lignite. Some of the best known localities of jet are the Yorkshire coast in England, near Whitby (Whitby Jet), Aude in France; also Spain, Bohemia, etc.

BYERITE Mallet, Am. J. Sc., 9, 146, 1875. A mineral coal from Middle Park, Colorado. It belongs to the class caking-bituminous, and gave on analysis: 39.95 p. c. volatile matter (gas and tarry oil), 54.03 p. c. fixed residue (coke and ash), and 6.02 p. c. water. G. = 1.323. Color jet-black. Powder brown. Resembles albertite in the large amount of gas and tarry oil yielded by it, but differs in being heavier and in yielding no soluble products with carbon disulphide, ether, etc. Also resembles torbanite, but is heavier, does not crackle in the fire, and melts and intumesces when heated.

A hydrocarbon from Östmark, in Wermland, Sweden, which, according to Ekman (Öfv. Ak. Stockh., 25, 138, 1868), has the composition (ash free): C 67·15, O 29·83, H $2\cdot55$, N $0\cdot47$, S $[0\cdot40]=100$. A similar coal from Grythytte, Finberget, Sweden, has, according to Helland (G. För. Förh., 2, 521, 1875), the composition (ash free): C 67·67, O 28·11, H 3.89, N tr., S 0.33 = 100.

Anthraxolite E. J. Chapman. A black combustible coal-like substance of varying composition, found in Quebec and Ontario.

Wollongongite B. Silliman, Am. J. Sc., 48, 85, 1869.
This name was given provisionally to a supposed hydrocarbon from Wollongong, New South Wales, l. c., occurring in cubical blocks, without lamination; fracture broad conchoidal. It is shown by Liversidge to be simply a carbonaceous shale or kerosene-shale.

SUPPLEMENT.

This supplementary chapter includes: First, descriptions of certain species, fairly well established, but as yet of unknown composition. Second, a summary of recent additions to min eralogical literature, which have appeared during the eighteen months in which the preceding pages have been passing through the press, but too late to find their proper place. This is intended to make the work as complete as practicable to near the close of 1891. Third, brief accounts of many doubtful species, having little or no claim to recognition. This last portion of the chapter contains for the most part references of recent date. The list might be almost indefinitely extended, but the author does not believe that it would be a real service to mineralogical science to attempt to call to life the many bad or doubtful species, which have been once referred to in the literature, but most of them long since forgotten.

AERINITE Lasaulx, Jb. Min., 352, 1876, 60, 1877. A compact, earthy mineral substance, of a bright blue color, from the Pyrenees. H. = 3-4. G. = 3018. Shown by Des Cloizeaux to be a heterogeneous mass, consisting of a blue paste, inclosing different minerals, perhaps owing its color to artificial means. See Rg., Zs. G. Ges., 27, 234, 1876; also Macpherson, Jb. Min., 2, 98, 1882. Analyses are quoted in App. III, p. 2, 1882.

Aguilarite F. A. Genth, Am. J. Sc., 41, 401, 1891.

Isometric. In skeleton dodecahedrons, often elongated in the direction of a cubic or octahedral axis.

No cleavage. Fracture hackly. Sectile. H. = 2.5. G. = 7.586. Luster metallic, bril-

liant. Color iron black. Opaque.

Comp.—Sulpho-selenide of silver, Ag₂S.Ag₂Se = Selenium 14.6, sulphur 5.9, silver 79.5 = 100.

Anal.-F. A. Genth, l. c.

Se 14.82

S 5.86

Ag 79.07 = 99.75

Another determination gave Ag 79.13.

Pyr., etc.—In the open tube heated slowly, yields metallic silver, a slight sublimate of selenium, silky needles of selenium dioxide and sulphur dioxide, the latter forming a small quantity of silver sulphate.

Obs.—From the San Carlos mine at Guanajuato, Mexico; very rare. Named after the

superintendent of the mine, Señor Aguilar.

Alt.—Aguilarite is altered on the surface; the crystals losing their sharp edges and sometimes becoming penetrated by holes showing metallic silver and a coating of microscopic iron-black crystals, sometimes in hexagonal scales. An analysis of the brittle iron-black alteration-product gave:

S Sb As Ag Cu Fe 13.62 10.82 1.29 67.08 6.44 0.82 = 100.07

This corresponds to 5(Ag,Cu)₂S.(Sb,As)₂S₃, or a cupriferous stephanite.

ALBITE, p. 327. Glinka has given a monograph on Russian albite from the localities Kerebinsk in Govt. Orenburg, Kasbek, Kyshtimsk, Mursinka, and Shishimsk. The albite from Kerebinsk and Kasbek proved to be the purest, and of these the former gave the author:

 $\ddot{a}: b: \dot{c} = 0.6330: 1: 0.5573; \alpha = 94^{\circ} 5', \beta = 116^{\circ} 27', \gamma = 88^{\circ} 7'.$

Angle of rhombic section on b (010), 27° 30'. [Russ. Bergjournal, 1889.] Jb. Min., 1 218 ref., 1891.

Münzing has investigated the Pfitschthal pericline and finds that the crystals consist essentially of an oligoclase, rich in soda, upon which albite has been deposited in parallel position, especially in the cavities of the original crystals; this albite follows the same twinning laws. This conclusion, based upon an optical examination, is confirmed by analysis. Jb. Min., 2, 1,

AMPHIBOLE, p. 385 et seq.

The chemical constitution of the amphiboles is discussed by Haefke in an inaug. dissertation (Berlin, 1890). He gives the following analyses, 1-8:

	G.	SiO ₂	TiO2	Al ₂ O ₃	Fe ₂ O ₃	FeO	MgO	CaO	Na.O	K-O	H ₂ O F

Schneider has also given a series of analyses, 9-14, of basaltic hornblende, showing a considerable degree of constancy in composition, except in the Fe₂O₂ and FeO. Zs. Kr., 18, 579, 1891.

	G.	SiO_2	TiO_2	Al ₂ O ₃	Fe_2O_3	FeO	MgO	CaO	Na ₂ O K ₂ O
9. Ortenberg	3.249								1.59 1.77 = 100.49

Lane and Sharpless have described an iron-magnesium amphibole, called by them grünerite, which occurs with the iron ores of L. Superior. It resembles actinolite, but corresponds chemically to the variety cummingtonite (p. 390). Shows polysynthetic twinning $\|a\|$, and also strictions $\|a\|$. It is colorless or slightly greenish or brownish; faintly pleochroic. Extinctions tion-angle 20°. Analysis of pure material from the Champion mine, Am. J. Sc., 42, 505, 1891:

SiO ₂	Al_2O_2	Fe_2O_3	FeO	MgO	Alk.	H_2O
76.32	0.56	0.99	6.96	12.47	tr.	2.80 = 100.20

Nephrite has been extensively mined in the mountains of Nan Chan, China, Martin, C. R.,

112, 1153, 1891. Anals., B. Columbia, see Harrington, Trans. R. Soc. Canada, 61, 1890. Khrushchov has accomplished the difficult task of obtaining amphibole in artificial crystals by a hydrothermal method. A mixture of the following substances was taken: 3 per cent aqueous solution of colloidal silica; an aqueous solution of alumina, and also of ferric and ferrous hydrate; lime-water; freshly prepared magnesium hydrate suspended in water, and finally some drops of caustic soda and potash. This mixture, forming a rather stiff gelatinous mass, was heated in a sealed glass vessel to 550° for three months, with, however, some interruptions.

At the end of this time the mass had been converted into a greenish brown pulp in which were dark-colored shining prismatic crystals, showing the forms: b (010), m (110), r (011), with 011 \wedge 011 = 31° 32′: c'eavage not distinct. Pleochroism not strong. Optically —. Extinction

angle 17° 56'. Absorption c = b > a. Axial angle $2V = 82^{\circ}$. An analysis gave:

SiO₂ Al₂O₃ Fe₂O₃ FeO MgO CaO Na₂O K₂O ign. G. = 3 245 42.35 8.11 7.91 10.11 14.33 13 21 2.18 1.87 0.91 = 100.98

In addition to these crystals, obviously a kind of hornblende (cf. anals, above and on p. 396), there were obtained at the same time crystals referred to a pyroxene near diopside; also isotropic crystals and grains referred with a question to analcite; quartz crystals; adularia in tabular crystals. Jb. Min., 2, 86, 1891; C. R., 112, 677, 1891.

See ASTOCHITE below.

Anomalite G. A. Koenig, Am. Inst. Mng. Eng., Philadelphia meeting, 1876.

A name provisionally given to what appears to be a last stage of alteration of jeffersonite. The form of the original mineral is preserved perfectly, even the strong basal parting. Light, like pumice; color in thin section blood-red. Called anomalite, because it does not give B.B. with salt of phosphorus the manganese bead, although containing some 30 per cent of Mn₂O₃, on account of the presence of cobalt and nickel, whose combined color is green, and this extinguishes the red of the manganese.

Anorthite, p. 337. Lévy and Lacroix have determined the principal indices of refraction for crystals from Saint-Clément. Their values, together with the analysis, are:

The plane $S \perp c$ intersects the (real) obtuse angle cb and makes the (real) angles $cS = 132^{\circ}$, $bS = 120^{\circ}$. C. R., 111, 846, 1890.

APATITE, p. 762. Described as probably occurring in the Thomas slags, with also certain compounds of calcium sulphate and calcium silicate, by Stead and Ridsdale, J. Ch. Soc., 51, 601, 1887; also Miers, ibid., p. 608. Cf. also Hutchings, Nature, 36, 460, 1887.

A work on the occurrence of apatite and phosphates in general has been published recently

by F. Wyatt (The Phosphates of America, New York, 1891).

Aragonite, p. 281. Buchrucker has described crystals from Leogang in Salzburg, showing the new form (850, $i\frac{25}{5}$). The axial angles obtained are: $2E_r = 30^\circ 38'$ Li, $2E_y = 30^\circ 43\frac{1}{2}'$ Na, $2E_{gr} = 30^\circ 57'$ Tl. Zs. Kr., 19, 140, 1891.

ASTOCHITE Sjögren, G. För. Förh., 13, 604, November, 1891. A new kind of amphibole from Långban in Wermland, Sweden. It forms a rather coarse crystalline, short columnar, aggregate together with rhodonite, and has been locally known as "blue rhodonite." Crystallization monoclinic, cleavage-angle 56° 27', crystals not observed. Color varying from blue to grayish violet; for the former the extinction-angle (with c) is 15° 40', for the latter 17° 15'. Optically negative; axial plane | b. Analyses by R. Mauzelius gave:

		G.	SiO ₂	FeO	MnO	MgO	CaO	Na ₂ O	K ₂ O	H_2O	F	
1.	Blue	3.05	56.25	0.15	6.49	21.89	5.44	6.17	1.60	1.56	0.15 =	99.70
2.	Grviolet	3.10	54.76	0.21	12.71	17.82	5.83	4.02	1.65	2.77	0.09 =	99.86

The above correspond to the composition of a normal metasilicate, consisting of (Mg, Mn, Ca)SiO₃ and (Na, K, H)₂SiO₃. Named from αστοχος, missing the mark, aiming badly, in allusion to the fact that it was at first regarded as a pyroxene. It does not seem to be very far from richterite, p. 391.

AUERLITE, p. 489. Lemon-yellow crystals from Price's Land, Henderson Co., N. C., have been analyzed by Hidden and Mackintosh, Am. J. Sc., 41, 438, 1891. The crystals are in part twins, similar to those of rutile, zircon, etc. Analysis:

$$SiO_2$$
 P_2O_5 ThO_2 Fe_2O_5 H_2O $G. = 4.051-4.075$ 6.84 8.58 $[72.16]$ 1.78 $10.64 = 100$

Babingtonite, p. 381. Artificial crystals have been measured by Buchrucker, Zs. Kr., 18, 626, 1891. He calculates the axial ratio:

$$\bar{a}: \bar{b}: \dot{c} = 1.08066: 1: 0.62370; \ \alpha = 77^{\circ} \ 33', \ \beta = 108^{\circ} \ 34', \ \gamma = 97^{\circ} \ 7'$$

Barite, p. 899. On crystals from the Puy-de-Dôme, see Gonnard, Bull. Soc. Min., 14, 174, 1891.

Beaumontite C. T. Jackson, Am. J. Sc., 37, 398, 1839. A supposed "native crenated hydro-silicate of copper" from Chessy, France. Named after Prof. L. Elie de Beaumont.

Bernardinite J. M. Stillman. Described as a new fossil resin from San Bernardino, Cal., Am. J. Sc., 18, 57, 1879; later regarded as an exudation from a species of conifer, which had received its particular characters from exposure to the atmosphere (ib., 20, 93, 1880). It is finally shown by J. Stanley-Brown to be a fungous growth on Polyporus officinalis, impregnated by resinous material. Ibid., 42, 49, 1891.

BERTRANDITE, p. 545. Observed at La Mercerie near the bridge of the Verrière, La Chapelle-sur-Erdre, Lacroix and Baret, Bull. Soc. Min., 14, 189, 1891.

Also noted in cavities in the beryl of Limoges, Haute Vienne, Michel, Bull. Soc. Min., 14,

76, 1891.

BERYL, p. 405. Investigation of the optical anomalies, by A. N. Karnozhitsky, Vh. Min. Ges., 27, 1, 1891, and Zs. Kr., 19, 209, 1891.

Analysis of white crystals occurring at the tin mine of Winslow, Me., gave Hillebrand, U. S. G. Surv., Bull. 55, 53, 1889:

BINDHEIMITE, p. 862. Analyzed by Tscherne from Litica in Bosnia, where it occurs as an alteration-product of bournonite, Vh. G. Reichs., 211, June 30, 1891:

Sb₂O₅ 37.48 PbO 50.12 Fe₂O₃ 5.60 H₂O 7.39 = 100.59

BISMUTHINITE, p. 38. A seleniferous variety from Guanajuato, Mexico, in prismatic crystals, has been analyzed by Genth:

G. = 6.306 $\frac{2}{2}$ S 14.06 Bi 77.54 Se 8.80 = 100.40

Formula: 4Bi₂S₃.Bi₂Se₃. Am. J. Sc., 41, 402, 1891.

Boléite Mallard and Cumenge, C. R., 113, 519, Oct. 26, 1891.

In cubes, sometimes 2 cm. in diameter; also rarely with o (111), d (110), and e (210). Cleavage: cubic, perfect; octahedral, less easy. H. = 3-3·25. G. = 5·08. Color indigo-blue. Refractive index, n=2·07. Sections of the cubic crystals show in polarized light an isotropic center bordered by doubly refracting bands; the latter are regarded as belonging to three crystals uniaxial and negative.

There are also octahedral crystals, regarded as tetragonal, with the forms a (100), c (001),

e (101); the measured angles are:

 $ee' = 74^{\circ} \, 16'$ and $ee'' = *117^{\circ} \, 27'$ c' = 1.646

G. = 5.0 approx. The crystals are optically uniaxial, negative, and are regarded as corresponding to the pseudo-isometric cubic crystals.

The composition deduced is that tentatively given to percylite on p. 172, viz. PbCuCl₂(OH)₂,

with the addition of AgCl. Anal.:

	Cl	Pb	Cu	Ag	H_2O	0		
1. Cubic cryst.	19.98	48.45	13.95	8.85	4·77 4·00	[4.00]	=	100
2. " 3. Octahedral cryst.	19·00 19·7	49.75	14·50 15·0	8·70 9·4	undet.	[4.05]	=	100

From the copper mines at Boleo, near Santa Rosalia, Lower California. The copper deposits here consist of beds interstratified in the tufas and conglomerates resulting from the destruction of the volcanic rocks of the region. The copper is present as malachite, azurite, melaconite, cuprite, atacamite, also as silicates and rarely as the sulphide. Both the cubic and octahedral crystals of boléite are present in an argillacous gangue, and immediately associated with anglesite, cerussite, phosgenite, and atacamite.

The authors consider the two minerals, respectively in cubic and in tetragonal pyramidal crystals, as essentially identical, a pseudo-cubic "réseau" belonging to each; from the ordinary mineralogical standpoint, however, it seems more natural to regard them provisionally (until a more complete examination of percylite) as dimorphous forms of the same compound; in that case the name boléite would naturally belong to the tetragonal substance, while the isometric

mineral would be united with percylite.

Bombite De Bournon; Dufrénoy, Min., 4, 289, 1859. An amorphous, dark blackish gray mineral "from near Bombay"; resembles Lydian stone. Compact with conchoidal fracture. H. = 7. G. = 2·210. B B. fuses easily; insoluble in acids. An analysis by Laugier gave: SiO₂ 50·0, Al₂O₃ 10·5, Fe₂O₃ 25·0, MgO 3·5, CaO 8·5, C 3·0, S 0·3 = 100 8. May be simply a kind of tachylyte.

Braunite, p. 232. Crystals from Långban, described by Flink, show the new forms: $o(304, \frac{3}{4}-i), l(401, 4-i), t_{0}^{-}(524, \frac{5}{4}-\frac{5}{2}), i(212, 1-2), s(645, \frac{6}{5}-\frac{3}{2}).$ The axial ratio obtained is $\dot{c} = 0.99218$, from 111 \wedge 111 = 70° 19′. Anal.:

Mn. O. 84.77 SiO. 9.89 Fe, O, 4.23 CaO 0.34 MgO 0.15 = 99.38

Oxygen (determined by Cl set free with hydrochloric acid) 7.35 p. c.; formula RO.RO2. Ak. H. Stockh., Bihang, 16 (2), No. 4, 1, 1891.

Breithauptite, p. 72. Sarrabus, Sardinia, analysis by E. Mattirolo, Rend. Accad. Linc., 7 (2), 98, 1891.

 $G_{\cdot} = 8.42$ Sb 65.07 As 0.20 Ni 32.94 Co 0.29 S, Ag, Pb tr. = 98.50

BREWSTERLINITE. A new fluid in the cavities of minerals *D. Brewster*, Ed. Phil. J., 9, 1823; Trans. R. Soc. Edinb., 10, 1, 407, 1826; Am. J. Sc., 7, 186, 1824, 12, 214 (with a plate), 1827; Phil. Mag., 25, 174, 1863. Brewsterline *Dana*, Min., 559, 1850; Brewstoline, ib., 471,

A colorless transparent fluid, occurring in cavities of topaz crystals from Brazil, Scotland, and Australia, of chrysoberyl, of quartz crystals from Quebec, amethyst from Siberia, and first described by Sir David Brewster. The cavities are mostly microscopic, but occasionally $\frac{1}{3}$ in across, or even larger. They are generally arranged in layers, and are sometimes counted by thousands in a single crystal. Index of refraction 1.2106, for the fluid from an amethyst from Siberia; 1·1311 for a kind from a topaz; boiling point in a vacuum from 23°-29°, the fluid filling the cavities with the warmth of the hand or mouth; highly expansible, between 10° and 27° more so than water. Volatilized by heat.

Composition not definitely known. The effect of moisture on the dry grains was regarded

as showing that the substance was not one of the hydrocarbon oils, or a resin.

Nordenskiöld has recently investigated this substance (earlier, Sorby, Vogelsang & Geissler, etc.) and concludes that it is a hydrocarbon probably belonging to the naphtha group. Min., 1, 242, 1886.

Cryptolinite or Cryptoline Dana, Min., 559, 1850, is another liquid with a refractive index

of 1.2946 occurring with the above

See further on the above, 5th Ed., pp. 761, 762.

Brookite, p. 241. Occurs in fine crystals at Ville-es-Martin, near St. Nazaire, Loire Inférieure. Lacroix, Bull. Soc. Min., 14, 192, 1891.

BUTYRELLITE. Bog Butter Williamson, Lieb. Ann., 54, 125, 1845. Butyrit Glocker, Syn., 9, 1847. Butyro-limnodic Acid Brazier, Chem. Gaz., 375, 1852. Butyrellite Dana, Min., 747. 1868.

A butter-like substance from the peat bogs of Ireland. Supposed to be a native hydrocar. bon, but, after a thorough chemical examination, Macadam has proved that it is of animal not mineral origin, and is simply butter; all of the ten samples analyzed showed the presence of hairs, microscopically like those of a cow! In one case the same bog which had furnished "bog-butter" also yielded heads of cattle. Min. Mag., 6, 175, 1885.

CALCITE, p. 262. Sansoni, in continuation of an earlier memoir, has given a monograph of

the forms of calcite observed from various localities in Baden. Zs. Kr., 19, 321, 1891. Etching by acids as affected by the concentration of the solvent, Hamberg, G. För. Förh., 12, 617, 1891.

Cancrinite, p. 427. By heating 14 gr. of mica with 7 gr. soda, 14 gr. sodium carbonate, and a certain quantity of water for two days at 500°, Ch. & G. Friedel have obtained a mineral in small hexagonal crystals, resembling hydronosean, p. 1043, with $pp'=23^{\circ}$ 49′ to 25° 1′, optically negative, $\omega-\epsilon=0.010$. G. = 2.357. Analyses gave:

SiO2 K₂O H₂O CO Al₂O₃ Na₂O 35.77 4.42 30.59 22.05 2.34 4.14 = 99.49

Formula calculated: 3(Na₂O.Al₂O₃.2SiO₂).Na₂O.CO₂ + 2H₂O, Bull. Soc. Min., 14, 74 1891.

Cassiterite, p. 234. Crystals from Cornwall described by Solly show the forms: n (661, 6), p (12·12·1, 12), q (18·18·1, 18), ψ (120·120·1, 120), d (432, 2- $\frac{4}{3}$), ϑ (13·11·2, $\frac{13}{2}$, $\frac{13}{1}$). A hemimorphic development in some crystals is noted. He gives also: $\omega_{\rm r} = 1.9793$, $\epsilon_{\rm r} = 2.079$. G. = 6·92 Dolcoath, black crystals. Min. Mag., 9, 199, 1891.

Occurs as a pseudomorph after hematite, also filling cellular crystals, at the Mine del Diablo, Durango, Mexico. Cf. Genth and Rath, Proc. Am. Phil. Soc., 24, 23, 1887, also Pirsson, Am. J. Sc., 42, 407, 1891.

Noted in crystals in slag from the bronze melting. Bourgeois, Bull. Soc. Min., 11, 58,

The locality of cassiterite in San Bernardino Co., briefly alluded to on p. 235, has recently come into prominence and may prove to be of considerable economic importance. is informed (Dec. 10, 1891, priv. contr.) as follows in regard to it: The Temescal tin mines are situated near the northern end of the San Jacinto Estate in San Bernardino Co. The principal vein now being worked has been opened up to a depth of 180 and a length of 300 feet, and varies from a few inches to 8 feet in width. About 40 tons of ore per diem are being crushed and concentrated, yielding 5 p. c. of oxide (cassiterite) which is smelted into pig tin. This vein is evidently a true fissure vein, and shows no sign of weakening. There are also a large number of small veins of a ferruginous mineral similar to that being worked, but which do not appear to contain much tin.

CELESTIALITE J. Lawrence Smith, C. R., 81, 1055, 1875. On treating the graphite from the interior of the meteoric iron of Sevier, Tenn., with ether, Smith obtained small quantities of acicular crystals having a peculiar odor, mixed with some small rounded points. These he regards as identical with crystals obtained from the iron of Alais, France (Mar. 15, 1806), by Roscoe (Proc. Lit. Phil. Soc. Manchester, 3, 57, 1863). Smith has obtained the same crystals from the Alais meteorite. In the closed tube he finds that they fuse at 115°-120°, and at a higher temperature the sulphur is sublimed, and a black residue left behind. He regards these crystals as proof of the presence of a sulpho-hydrocarbon, for which he proposes the name celestablite. Roscoe (l. c.) found that 1.94 p. c. of the meteorite dissolved in ether, and from the solution he obtained crystals melting at 114°, and in two forms: acicular, which he considered as near to könlite (see p. 1002), and rhombic, which he identified as free sulphur.

CERUSSITE, p. 286. Crystals, in part twins with r (130) as tw. pl., are described by G. H. Williams from the Mountain View mine, near Union Bridge, Carroll Co., Md. Johns Hopkins Univ. Circ., No. 87, April 1891. Similar twins, sometimes abnormally developed by extension of the tw. plane r(130), are figured by Pirsson (f. 1-3) from the Red Cloud mine, Yuma Co., Arizona. Am. J. Sc., 42, 405, 1881.

Yuma Co., Arizona, Pirsson.

Chalcopyrite, p. 80. Crystals from Cuba, similar to those described by Penfield from the French Creek mines, Pennsylvania (p. 81), have been described by Des Cloizeaux. The crystal figured resembles f. 12, p. 81, and to the forms he assigns the symbols (538, $\frac{5}{8}$, $\frac{5}{3}$) for the tetragonal scalenohedron and to the sphenoid (401, 4-i); these correspond respectively to χ and ϕ of f. 12.

Chalcostibite (Wolfsbergite), p. 113. Crystals from Wolfsberg, studied by Laspeyres, gave the mean axial ratio: $\check{a}:\check{b}:\check{c}=0.52830:1:0.62339$, approximating to that of sartorite. The forms present are:

 $c(001, 0), e(307, \frac{3}{7}-\bar{\imath}),$

Angles: $100 \land 110 = 27^{\circ} 50\frac{5}{6}', 001 \land 101 = cd = 49^{\circ} 43\frac{1}{6}', 001 \land 011 = cf = 31^{\circ} 56\frac{1}{3}', ce = 26^{\circ} 49\frac{1}{2}', cg = 67^{\circ} 2'.$ In the above d = 011 (d) of p. 113, g = 041 (h), etc. The

habit is shown in the figure.

The above axial ratio is that deduced by Laspeyres. The results, however, though increas-

ing our knowledge of the crystallization of the species, make little claim to exactness. Thus the calculated value of $cd=49^{\circ}$ 43', while he measures 51° 20'; again, $cf=31^{\circ}$ 56' calc., and 29° 14' meas. In view of this the abnormal symbols of the pyramids lose part of their significance; thus p may be 121 instead of 7·14·8, etc. Zs. Kr., 19, 428, 1891.

CHANTONNITE. A supposed black silicate forming veins in certain meteorites, as those of Chantonnay, Charsonville. This is shown by Meunier not to be a definite species, but simply a structure developed by heat. C. R., 52, 339, 1861, and Météorites, 81, 1884.

Chloritoid, p. 640. Lane and Keller have studied the chloritoid occurring with the iron ores of northern Michigan. It occurs in green plates, several centimeters across and up to 4 mm. in thickness, thus at the Champion mine. It is distinctly triclinic as shown in the extinctionangles and the want of symmetry of the lateral cleavages, thus confirming the results of Des Cloizeaux upon sismondine (p. 641). An analysis gave:

The formula deduced is $8H_2O.7FeO.8Al_2O_3.8SiO_2$. The presence of alkalies is noteworthy; the same authors show that the so-called masonite of Natick, R. I., contains about 2 p. c., chiefly soda. Am. J. Sc., 42, 499, Dec., 1891, also Zs. Kr., 19, 383, 1891.

Chromite, p. 228. A variety from the Pick and Shovel mine, S. Fork of Chorro Creek, California, has been analyzed by H. Pemberton, Jr., Ch. News, 63, 241, 1891.

	Cr_2O_3	Al ₂ O ₃	Fe ₂ O ₃	FeO	MgO	MnO	SiO ₂	H_2O
1a.	52.68	11.40	3.52	11.77	16.23	0.15	3.40	0.94 = 100.09
16.	56.96	12.32	3.81	12.73	14.02	0.16	-	- = 100

1b after deducting 3.26 p. c. serpentine.

On the decomposition of chromite by electric current, see E. F. Smith, Am. Ch. J., 13, 414, 1891.

Chrysoberyl, p. 229. Has been recently found (Foote) in twin crystals at Greenwood, Oxford Co., Maine.

Chrysolite, p. 451. Analysis of clear pebbles from Fort Wingate, New Mexico, by Clarke & Schneider, Am. J. Sc., 40, 305, 1890, gave:

SiO ₂	FeO	NiO	MnO	MgO	Fe ₂ O ₃	H_2O
41.98	5.71	0.42	0.10	51.11	0.51	0.28 = 100.11

It was found that at 383°-412° the mineral was hardly attacked by dry hydrochloric acid, though readily decomposed by the aqueous acid.

On the chrysolite of the Kiowa Co., Kansas, pallasite, see Huntington, Proc Am. Acad., 26, April 8, 1891.

CINNABAR. p. 66. Melville and Lindgren have described crystals from the New Idria mercury mines. California. They are very small, from 0.05 mm. to 0.6 in diameter, and 0.02 to 0.2 mm. in thickness; thin tabular in habit and show the forms c (0001, O), h, (02 $\overline{2}3$, $-\frac{2}{3}$), g, (01 $\overline{1}2$, $-\frac{1}{2}$); also various tetartohedral forms, chiefly in the zone c/h, and having for the most part highly complex symbols. U. S. G. Surv., Bull. 61, 1, 1890.

CORUNDUM, p. 210. Crystals obtained artificially by Fremy (see below) gave the new form (11 $\bar{2}3$, $\frac{2}{3}$ -2). Dx. C. R., 106, 567, 1888.

Friedel has described the production of crystals of corundum and diaspore by the wet way by the action of a solution of soda on amorphous alumina at an elevated temperature. At 450° to 500°, both corundum and diaspore were obtained, at 530° to 535° only corundum, and at 400° only diaspore. Bull. Soc. Min., 14, 8, 1891.

The artificial formation of rubies is described in detail with many colored plates by M.

The artificial formation of rubies is described in detail with many colored plates by M. Fremy in Synthèse du Rubis (30 pp. 4to, Paris, 1891). In the most successful method the rubies were obtained in an earthen crucible by the reaction at a very high temperature of a mixture of alumina (with more or less potash) upon barium fluoride, with bichromate of potassium as coloring matter. They are well crystallized, clear, of brilliant color.

F. Noetling describes the Namsèka ruby mine in the valley of the Nampai, Mainglôn state, where the rubies have been found in isolated pockets in secondary deposits of river gravel and sand, probably washed down by the Mogôk stream which joins the Nampai near the Namsèka mine. Rec. G. Surv. India, 24, 119, 1891.

CORONITE. A name proposed by T. S. Hunt for the common brown magnesian variety of tourmaline, Min. Physiology, pp. 162, 350, 1886; Syst. Min., 299, 1891. The name is taken from the locality, Crown Point, N. Y. A number of other variety names proposed by Dr. Hunt will be found in the same volumes; also a system of dual Latin names, after the method of Natural Histories. History, e.g., coronite = "Turmalinus magneseus."

CORYNITE, p. 91. A specimen from a siderite mine near Gosenbach in the Siegen region has been analyzed by Laspeyres:

S Sb As Bi Ni Fe Co 10.28 $G_{\cdot} = 6.488$ 16.22 42.93 0.68 28.91 0.40 1.13 = 100.56

This corresponds to Ni(Sb, As)S. Zs. Kr., 19, 8, 1891.

Covellite, p. 68. On crystals from Leogang, Salzburg, Buchrucker has measured, cp =*79° 18′, and $pp' = 59^{\circ}$ 22, yielding c' = 4.5833. Zs. Kr., 19, 135, 1891.

Craigtonite Heddle, Min. Mag., 5, 30, 1882. A name given to a blue-black substance forming dendritic stains on red granite, in the quarry of Craigton, Hill of Fare, Aberdeenshire, Scotland. An analysis gave alumina, iron sesquioxide, manganese protoxide, magnesia, and alkalies. It is not a mineral species.

CRYOCONITE. Kryokonit, *Nordenskiöld*, Öfv. Ak. Stockholm, 28, 293, 1871; 32, 3, 1874. Geol. Mag., 9, 355, 1872.

A name given by Nordenskiöld to the powder found by him in Greenland covering the surface of land ice, as also at a distance of thirty miles from the coast. It formed a layer of gray powder, sometimes several millimeters in thickness, and often agglomerated into small round balls of loose consistency. It was supposed to be cosmical in origin, but this is not confirmed by later investigators. Cf. Lasaulx, Min. Mitth., 3, 521, 1881, and Wülfing, Jb. Min., Beil.-Bd., 7, 152, 1890; the latter shows that the cosmical element is comparatively insignificant.

CRYOLITE, p. 166. The methods of twinning are described by Baumhauer, Zs. Kr., 18, 355, 1890.

CRYSTALLITES. A name given by Vogelsang to the forms, often observed especially in igneous rocks, which show a regular arrangement of grouping, but have not the properties of crystals, particularly not their regular exterior form. They seem to form an intermediate step between amorphous matter and true crystals. See Vogelsang,—Die Krystalliten, Bonn, 1875. To the crystallites Vogelsang has given a variety of names, according to their form or appearance: Globulites (Vogelsang, p. 13), margarites (p. 19), longulites (p. 21, 112), sphärolites (p. 131), cumulites (p. 134), globosphärites (p. 134), belonosphärites (p. 135), felsosphärites (p. 135), granosphärites (p. 135).

CUPROCALCITE Raimondi, Domeyko, 5th Append., Min. Chili, 1876; Min. Pérou, p. 135, 1878. In small masses and in bands intimately mixed with a ferruginous calcite. H. = 3. G. = 3.90. Color bright vermilion-red. Analysis gave: Cu₂O 50.45, CaO 20.16, CO₂ 24.00, H₂O 3.20, Fe₂O₃ 0.60, Al₂O₃ 0.20, MgO 0.97. SiO₂ 0.30 = 99.88. Formula deduced (Cu₂O)₂, CO₂ + 2CaO.CO₂ + H₂O₃ vo, H₂O₃ vo, H₃O₃ vo, H₃O 1, 130, 1878.

Danalite, p. 435. Found in El Paso Co., Colorado, at West Cheyenne Cañon. It is thus

described by Genth (priv. contr.):

Only part of one crystal, 15×17 mm., is thus far known, and one somewhat larger fragment discolored by oxides of iron and manganese. The crystal shows the forms (Penfield): plus tetrahedron o (111), minus tetrahedron o, (111) with narrow planes of the dodecahedron o (110) truncating their edges. No cleavage observed; fracture uneven, splintery to subconstitutions of the constant of th choidal. Color in some portions pale rose-red to brownish, owing to slight oxidation; also massive. G = 2.626-2.661. Associated with quartz and astrophyllite, a crystal of which is implanted in the crystal. The purest material, of a fine pale rose-color, gave on analysis:

SiO₂ ZnO FeO MnO CuO BeO S ign. $G_{-}=2.661$ \$ 30.26 46.20 6.81 1.22 0.30 12.70 5.49 0.21=103.19 less 2.78 (O=S)=100.41

This agrees closely with the empirical formula given on p. 435, $(Be,Zn,Fe,Mn)_7Si_8O_{12}S_5$ it differs, however, from that analyzed by Cooke in containing much more zinc and but little iron and manganese. A second analysis made upon material somewhat less pure gave nearly identical results.

DATOLITE, p. 502. On crystals from Andreasberg, see Busz, Zs. Kr., 19, 21, 1891. Obtained artificially by A. de Gramont, by the action of a solution of sodium borate upon calcium silicate at a high temperature under pressure, in crystalline forms conforming in physical properties and composition to the natural mineral. C. R., 113, 83, 1891.

DAUBRÉELITE, p. 79. Obtained artificially by Meunier by treating at a red heat an alloy of iron and chromium with hydrogen sulphide. Analysis gave: S 45.01, Fe 19.99, Cr 35.00 = 100. C. R., 112, 818, 1891.

Diamond, p. 3. Walter (Wied. Ann., 42, 505, 1891) has observed a characteristic absorption-band between the Fraunhofer lines G and h in the spectrum given by a diamond prism; this was noted in numerous colorless diamonds, and is ascribed to the presence of some foreign substance at present undetermined. The mean values of the refractive indices for the Fraunhofer lines are:

Α 2.40245 2.40735 2.41000 2.41734 2.42694 2.45141 2.46476

A few diamonds, up to $\frac{25}{35}$ carat, have been found in the gold gravels of Plum Creek, Rock Elm township, Pearce Co., Wisconsin, Kunz, Am. J. Sc., 41, 252, 1891.

Reported as occurring in the meteoric iron of Cañon Diable, Arizona. Cf. A. E. Foote,

Am. J. Sc., 42, 413, 1891.

On the history of the Kohinoor, cf. N. Story Maskelyne, Nature, 44, 555, 1891.

DIASPORE, p. 246. Observed by Cross forming, with alunite, a rock-mass at Mt. Robinson, Rosita Hills, Colorado (cf. also alunite, p. 974). Crystals, of the ordinary habit, are described by Melville, Am. J. Sc., 41, 466, 475, 1891.

On the artificial formation, see corundum, p. 1031.

DIOPTASE, p. 463. Basal sections showing abnormal optical characters have been described by Karnozhitsky. Six sectors were noted with quasi-twinning bands, in part biaxial, normal to the prism; a normal uniaxial central portion was not observed. Zs. Kr., 19, 593, 1891.

DIPYRE, p. 471. On the transformation of dipyre into feldspar, or "werneritization," see Lacroix, Bull. Soc. Min., 14, 16, 1891.

Dolomite, p. 271. On the true orientation of the forms shown by crystals from the Gebroulaz glacier, described by A. Sella, see Becke, Min. Mitth., 11, 536, 1890; $\phi = \bar{8} \cdot 20 \cdot \bar{12} \cdot 5$.

EKMANNITE, p. 662. Investigated optically by Hamberg; uniaxial, positive, the ordinary ray (ω) grass-green, the extraordinary ray (ϵ) nearly colorless. -G. För. Förh., 11, 25, 1889.

ELLONITE *Heddle*, Min. Mag., **5**, 30, 1882. A pale yellow unctuous powder from the gneiss of Ellon, Aberdeenshire, Scotland. It is an impure hydrous silicate of magnesium.

ELROQUITE C. U. Shepard, Min. Contr., 1877. An apple-green to gray, massive substance. Regarded as a hydro-silicate of Al₂O₃ and Fe₂O₃, mixed with opaline silica and a supposed chromium phosphate, to which "the green color was found to be due." To the chromium phosphate the name PHOSPHOCHROMITE is given. From the island of Elroque, Caribbean Sea.

ENARGITE, p. 147. Occurs in the Cerro Blanco mines. Atacama; angle of cleavage prism 82° 2'. Analysis gave R. de Neufville: G. = 4·51, S 32·21, As 18·16, Cu 47·96, Fe 1·22, $Zn\ 0.57 = 100.12$. Zs. Kr., 19, 75, 1891.

ERILITE H. C. Lewis, Proc. Ac. Nat. Sc. Philad., 292, 1880. Minute acicular crystals, looking like tufts of white wool, observed in a cavity in quartz from Herkimer Co., N. Y.; chemical nature unknown. The cavity also contained a liquid of undetermined character.

EUCAIRITE, p. 53. Analyses of a fine granular, perhaps cleavable, variety from the Sierra de Umango, province of La Rioja, Argentine Republic. 1, Fromme, J. pr. Ch., 42, 57, 1890. 2, 3, Bodländer, quoted by Klochmann, Zs. Kr., 19, 265, 1891.

	Se	Ag	Cu
1.	31.53	42.71	25.47 = 99.71
2.	32·54ª	43.14	26.42 = 102.10
3.	32.32	42.20	25.41 = 99.93

^{*} A second determination of the material of anal. 3.

EUDIALYTE, p. 409. Crystals from Magnet Cove, Ark., (see fig.), gave Penfield: ce = 50° 44′, $cr = 67^{\circ} 35'$. Am. J. Sc., 41, 397, 1891.

FALKENHAYNITE R. Scharizer, Vh. G. Reichs., 433, 1890. Massive, somewhat resembling galena. G. = 4.83 corrected. Color gray-black. Analysis of very impure material, after deducting 13.16 p. c. quartz and 12.77 siderite:

S	Sb	As	Bi	Cu	Fe	Zn
26.21	23.10	4.77	0.33	39.51	4.20	1.89 = 100

Assuming further that 3.66~p. c. chalcopyrite are admixed, the formula $\mathrm{Cu_3SbS_3}$ or $3\mathrm{Cu_2S.Sb_2S_3}$ is obtained, or an antimony mem-Magnet Cove, Pfd. ber of the Bournonite Group, p. 126; it is not far, apparently, from stylotypite, p. 130. The result, however, is not very conclusive, considering the nature of the material. From the Fiedler vein at Joachimsthal; named after Count J. Falkenhayn, Minister of Agriculture.

FAYALITE, p. 456. Analysis of a massive variety from Cheyenne Mt., Colorado, by Hidden & Mackintosh, Am. J. Sc., 41, 439, 1891:

 $G_{\cdot} = 4.35$ SiO. 27.66 FeO 65.79 MnO 4.17 $CaO\ 0.47 = 98.09$

Lacroix has noted the occurrence of favalite in the trachytes of the Capucin, Mont Dore.

Feldspar Group, 314 et seq. Joly has made the following approximate determinations of the melting points of the various feldspars by the use of the instrument devised by him called the meldometer, Proc. R. Irish Acad., 2, 38, 1891 (read May 11); and Nature, 33, 15, 1885:

Adularia 1175° C. 1175° C. Albite Sanidine 1140° Oligoclase 1220° Microcline 1175° Labradorite 1230°

These results do not entirely agree with the experience of some pottery makers, who have found that albite melts to a glass at a temperature at which orthoclase is only partially fused.

The same author gives the following as the (approximate) melting points of the minerals in von Kobell's scale of fusibility:

525° C. Stibnite

2. Natrolite 965° Almandite 1265° Actinolite (green) 1296° Orthoclase

1175° 5. 6. Bronzite (Diallage) 1300°

Quartz 1430°

FERRITE. A name proposed by Vogelsang (Zs. G. Ges., 24, p. 529, 1872) for the amorphous hydroxide of iron, which in red or yellow particles plays an important part in many rocks, and whose composition is as yet undetermined.

Ferrosilicite Shepard. A supposed ferrous silicate present in certain meteorites.

FLUOCERITE, p. 175. Crystals from Österby in Dalarne, Sweden, are found by Weibull to be hexagonal, with m (1010) and p (1122) and $mp = 51^{\circ}$ approx., hence c = 1.06. G. För. Förh., 12, 535, 1890.

FLUORITE, p. 161. On etching-figures, see Becke, Min. Mitth., 11, 349, 1890. Becquerel has investigated the phosphorescence of fluorite, C. R., 112, 557, 1891. The remarkable adaptivity of fluorite to the construction of lenses (apochromatic) in consequence chiefly of its low refractive and dispersive powers, is developed by Abbe. Thus for the three hydrogen lines H_{α_1} , H_{β_1} , H_{γ_2} , the differences in the refractive indices are, $n_{\beta}-n_{\alpha}=0.00455$, and $n_{\gamma}-n_{\beta}=0.00255$. Zs. Inst., 10, 1, 1890; cf. Thompson, Phil. Mag., Feb., 1891.

FOOTEITE G. A. Koenig, Proc. Acad. Philad., 289, 1891. Monoclinic. In minute prismatic crystals, tabular $\parallel b$, and in part twins, with tw. pl. a (100). Forms: b (010. i-i), m (110, I), d (h0l, -m-i), n (0kl, m-i), p (111, -1), o ($\overline{1}11, 1$). Approximate measured angles: $mm'''=49^\circ$, edge $mm'''/pp'''=143\frac{1}{2}^\circ$. edge $pp'/oo'=33^\circ$. Color deep blue. Composition deduced, $8\mathrm{Cu}(\mathrm{OH})_2.\mathrm{CuCl}_2+4\mathrm{H}_2\mathrm{O}$. Approximate analysis on 9.0165 gr.

Occurs with paramelaconite and malachite on limonite at the Copper Queen mine, Bisbee, Arizona. Not very far from tallingite. p. 174, but contains only about half as much chlorine. Named after A. E. Foote of Philadelphia.

FOUQUÉITE Lacroix, Bull. Soc. Min., 12, 327, 1889.

Monoclinic. In elongated crystals, usually with rounded outlines. Sometimes polysynthetic twins, with a (100) as tw. pl. Cleavage oblique to the direction of elongation and making an angle of 90° to 108° with this in sections. Color yellow or white; pleochroism extremely feeble. Optically +. Ax. pl. | cleavage (001). Ax. angle about 90°. Dispersion $\rho < v$. $-\alpha = 0.020.$

Composition like zoisite, from which it differs in form; it appears to be an epidote

essentially, containing but little iron (cf. anal. 18, p. 519). Anal.—

	G.	· SiO ₂	Al_2O_3	FeO	CaO	ign.
White	3.24	38.6ª	32.5	1.9	23.9	2.7 = 99.6
Yellow	3.31	38.3	31.9	4.4	23.5	2.7 = 100.8

a Given as 36.6, which makes the total 97.6.

B.B. infusible.

Occurs in anorthite-gneiss at Salem, and less often at Kandy, Ceylon. The rock also contains ordinary epidote (but not immediately associated with fouqueite), scapolite, garnet, amphibole, pyroxene. Named for M. Fouqué.

FRIEDELITE, p. 465. Crystals have been described by Lindström (G. För. Förh., 18, 127, 1891) from the Harstig mine, near Pajsberg, Wermland, Sweden.

They occur in six-sided tables with granular galena and greenish gray augite in calcite. Also the same occurrence by Flink (Ak. H. Stockh., Bihang, 16 (2), No. 4, 20, 1891). He measures $cr = 31^{\circ}$ 33', whence c = 0.5317; he also notes the steep rhombohedron s (15.0.15.1, 15) with faces striated horizontally, $cs = 83^{\circ}$ 43' meas.

Pajsberg, Flink.

	G.	SiO_2	MnO	FeO	CaO	MgO	Cl	H_2O
1.		33.36	49.08	3.83	0.74	1.31	4.19	$8.45 P_2 O_5 tr. = 100.96$
2.	3.058	34.66	47.70	_	0.53	2.27	3.13	8.47 = 99.66

Gadolinite, p. 509. Nordenskiöld discusses again the molecular weight of the gadoliniteearths present in many rare species, and obtains values ranging from 275.8 in orthite from Sandöna to 247 9 in gadolinite from Gamla, Kårarfvet. Ak. H. Stockh., Bihang 17 (2), No. 1,

Gahnite, p. 223. Oebbeke has analyzed the kreittonite of Silberberg near Bodenmais, as follows (Jb. Min., 1, 17 ref., 1891).

Al ₂ O ₃	$\mathrm{Fe_2O_3}$	ZnO	FeO	MnO	MgO
48.40	7.47	27.44	14.79	2.64	tr. = 100.74

GANOMATITE Breith., Char., 106, 1832. (Gänseköthigerz Germ., Goose-dung Ore, Chenocoprolite Dana, Min., 1st Ed., 216, 1837). The material thus named is in part an impure ironsinter, containing some oxide of cobalt, etc. That of Joachimsthal is a yellowish incrustation, occurring with smaltite. That of Andreasberg is a mixture of oxides of antimony, arsenic, and iron, with a little arsenous oxide (Rg., Min. Ch., 993, 1860).

GARNET. p. 437 et seq. The following are recent analyses: 1. Beautiful rose-pink grossularite in large dodecahedrons from Xalostoc, Distr. Cuautla, State of Morelos, Mexico. Occurs embedded in crystalline limestone with honey-yellow vesuvianite, etc. Described by C. F. de Landero, Am. J. Sc., 41, 321, 1891, anal. 1 (cf. anal. 8 by Damour, p. 440).

2. From Kedabék in Caucasus. wine-yellow to honey-yellow crystals in trapezohedrons; described by Müller, Jb. Min., 1. 272, 1891.
3. Cinnamon-garnet from Ottawa Co., Quebec, Canada; described by B. J. Harrington, Can. Rec. Sc., 4, 93, 1890.

4. Rose-red garnets from Laurentian gneiss of Murray Bay. Quebec, Harrington, l. c. 5. Clear light brownish red spessartite from Amelia Co., Virginia; analyzed by F. W. Clarke, U. S. G. Surv., Bull. 60, 129, 1890.

6. Melanite from Oberrothweil in the Kaiserstuhl, analyzed by Soltmann, Zs. Kr., 18, 628, 1891. Cf. anals. 22-31, p. 444.

Grängesite, p. 654. Cf. Lacroix, Bull. Soc. Min., 10, 142, 1887.

Graphite, p. 7. On the formation by contact-metamorphism, see Beck & Luzi, Jb. Min., 2, 28, 1891.

GORTHITE, p. 247. Occurs with hematite, pyrolusite, calcite, barite, etc., in the Lower Carboniferous limestone of Clifton, Nova Scotia. An analysis by Shuttleworth (quoted by Harrington, Can. Rec. Sc., 4, 93, 1890) gave

 $G_{1} = 4.217$ $Fe_{2}O_{3} 88.92$ $Mn_{2}O_{3} 0.14$ $H_{2}O 10.20$ $SiO_{2} 0.32 = 99.58$

GREENOCKITE, p. 69. On artificial crystals, see troilite, p. 1051.

GUANAJUATITE, p. 38. An analysis of an original specimen gave Genth:

G. = 6.977 Se 25.50 S 4.68 Bi 68.86 = 99.04

Formula hence Bi₂Se₂S or 2Bi₂Se₃. Bi₂S₃ analogous to common tetradymite. Am. J. Sc., 41, 403, 1891.

Halite, p. 154. On the double refraction called out by pressure, see Pockels, Wied. Ann., 39, 440, 1890.

On indices of refraction, see Dufet, Bull Soc. Min., 14, 139, 1891.

G. Freda has analyzed some of the chlorides from Vesuvius, like those earlier noted by Scacchi (p. 157) [Gazz. Ch. Ital., 16, 1889], Jb. Min., 2, 374 ref., 1890. The materials analyzed are as follows: 1, stalactitic salt of the 1884 crater; 2, nodular crusts of 1875 crater; 3, cubic crystals, 1881; 4, thick white stalactites, 1886; 5, white nodular crusts from the Mauro lava of 1887; 6, white crusts from the 1888 Mauro lava.

KCl CaCl₂ CaSO₄ NaCl LiCl MgCl2 1.22 insol. 3.08, H_2O and loss [1.23] = 1001. 33.06 58.67 0.07 1.78 0.8932.11 2. 66.38 = 98.49

5. 54.20 43.71 = 97.916. 73.89 24.18 = 98.07

Hausmannite, p. 230. Crystals from Jakobsberg show the new forms:

 $z (5.5.11, \frac{5}{11})?$ m (110, I) $v (335, \frac{3}{5})$ $u (223, \frac{2}{3})$ t (414, 1-4)

Axial ratio assumed, $\dot{c}=1.1573$, $001\wedge101=49^{\circ}$ 10'. G. Flink, Ak. H. Stockh., Bihang, 16 (2), No. 4, 10, 1891.

Heldburgite Luedecke, Zs. Nat. Halle, 4, 291, 884, 1879. Tetragonal. Axis $\dot{c}=0.7500$. In minute (3 mm. long, $\frac{1}{2}$ to $\frac{1}{3}$ mm. thick) prismatic crystals. Forms: a (100, i-i), m (110, I), p (111, 1). Angles: $mp=43^\circ$ 19', $pp''=*93^\circ$ 22½', $pp'=61^\circ$ 56'. It is near zircon in form. In habit resembles guarinite. H. less than that of steel. Luster adamantine. Color yellow. Streak white. Transparent. B. B. infusible. Composition unknown (TiO₂ absent). Occurs in the feldspar of the phonolyte of the Heldburg near Coburg.

HEMATITE, p. 213. Crystals altered to or inclosing cassiterite occur at the Mina del Diabio Durango, Mexico. Cf. Genth & Rath, Proc. Am. Phil. Soc., 24,

23, 1887, and Pirsson, Am. J. Sc., 42, 407, 1891. The crystals described by Pirsson (fig. 1) are in part cellular, and are filled with cassiterite. The planes of the hematite brilliant in luster, but are distinct only at the edges; the forms observed are: c (0001), a (11 $\overline{2}$ 0), d (10 $\overline{1}$ 2), r (10 $\overline{1}$ 1), Θ (20 $\overline{2}$ 1), η (01 $\overline{1}$ 1), s (02 $\overline{2}$ 1), η (22 $\overline{4}$ 3). The cassiterite shows no definite orientation, but forms an intimate crystalline aggregation. Pirsson regards it as a case of simultaneous crystallization in which the form was determined by the hematite.

Hessenbergite Kenng., Ber. Ak. München, 2, 230, 1863. Sideroxen Hessenberg, Min. Not., 7, 4, 1866.

Monoclinic. Axis $\hat{a}:\hat{b}:\hat{c}=1.7514:1:1.0480$; $\hat{\beta}=*89^{\circ}53'=001 \land 100$ Hessenberg¹. $100 \land 110=60^{\circ}16\frac{1}{2}',\ 001 \land 101=30^{\circ}52',\ 001 \land 011=46^{\circ}20\frac{1}{2}'.$ Forms: $c\ (001,\ 0),\ a\ (100\ i-1),\ b\ (010,\ i-2),\ i\ (910,\ i-3),\ f\ (310,\ i-3),\ m\ (110,\ I),\ y\ (101,\ -1-1),\ p\ (501,\ -5-1,\ g\ (504,\ \frac{\pi}{4}-1),\ n\ (301,\ 3-1),\ e\ (012,\ \frac{1}{2}-1),\ o\ (315,\ \frac{3}{2}-3).$ Angles: $)ff'''=60^{\circ}33',\ mm'''=*120^{\circ}33',\ cy=*30^{\circ}52',\ cp=30^{\circ}55\frac{1}{2}',\ cg=36^{\circ}50',\ cn=60^{\circ}58',\ ee'=55^{\circ}18\frac{1}{2}',\ co=22^{\circ}35',\ oo'=22^{\circ}20'.$ Twins: tw. pl. $y\ (101)$ common. Crystals tabular $\|c\|$ C. H. = 7-7·5. Luster adamantine. Colorless, bluish. Transparent.

Comp.—A silicate of undetermined constituents. It has been suggested that it may be

danburite (Groth), but fails to find correspondence in the forms. Cf. Hintze, Zs. Kr., 7, 303, 1882. Pyr., etc.—In a closed tube yields no water, and is unchanged. In the platinum forceps whitens, but does not fuse. In borax melts without intumescence. Heated with cobalt solution becomes gray. No action from hydrochloric acid.

Obs.—Occurs implanted on crystals of hematite (Eisenrosen) at Mt. Fibia, west of the Hospice

of St. Gothard.

Ref.—Min. Not., 7, 4, 1866. Cf. also Kenngott, Jb. Min., 232, 1864.

HESSITE, p. 47. An analysis of tabular crystals from Botes, Transylvania, by Loczka, gives the formula $Ag(Au)_2$ Te. Anal.: Te 37.77, Ag 61.52, Au 1.01, Fe tr. = 100.30. Ber. aus Ungarn, 8, 103, 1891.

HOWARDITE Shepard. A supposed silicate of iron and magnesium, present in certain meteorites.

Hydroniccite C. U. Shepard, Min. Contr., 1877. A name suggested for a doubtful substance conjectured to be a hydrated oxide of nickel, from Texas, Penn.

HYDROBUCHOLZITE Thomson. Thomson obtained (Min., 1, 237, 1836) SiO₂ 41:35, Al₂O₂ 49.55, H₂O 4.85, gypsum 3.12 = 98.87. Probably from Sardinia.

Hydrosamarskite. A. E. Nordenskiöld, Ak. H. Stockh., Bihang, 17 (2), No. 1, 8, 1891. A samarskite from the Nothamnsgrufra, Väddö, containing 10.5 p. c. water and 4 p. c. of "gadolinite-earths" of a molecular weight of 274.1.

Hypoxanthite Rowney, Ed. N. Phil. J., 2, 308, 1855; Sienna Earth. A brownish yellow ferruginous clay or ocher, probably only clayey yellow ocher.

ILVAITE, p. 541. Occurs with calcite, tremolite, andradite, forming irregular crystalline masses in a large vein near the head of Barclay Sound, Vancouver Island, B. C. An analysis gave Hoffmann, Am. J. Sc., 42, 432, 1891:

Iron, p. 28. J. M. Davison has analyzed the kamacite, tænite, and plessite from the Welland meteoric iron (cf. anals. p. 30). He found the plessite to consist of two parts, A and B, corresponding in composition to the other alloys named, and the same may be true in general. Am. J. Sc., 42, 64, 1891.

		Fe	Ni	Co	C
1.	Kamacite	93.09	6.69	0.25	0.02 = 100.05
2.	Plessite A (kamacite)	92.81	6.97	0.19	0.19 = 100.16
3.	" B (tænite)	72.98	25.87	0.83	0.91 = 100.59
4.	Tænite	74.78	24.32	0.33	0.50 = 99.93

Cohen and Weinschenk (Ann. Mus. Wien, 6, 181, 1891) have investigated chemically a series of meteoric irons. They conclude that the cubic irons have a constant percentage of nickel and cobalt; thus they find Fe 92.90, Ni + Co 7.10 in Coahuila, and Fe 93.82, Ni + Co 6.18 in Braunau, while a series of others lie between these limits. In the Magura and Wichita Co. irons they find large crystals (arranged parallel to an octahedral face) of an iron carbide (Kohlenstoffeisen) with 6.4 and 5.1 p. c. carbon and yielding the formulas (Fe,Ni,Co)₃C and (Fe,Ni,Co)₄C; the former has been called cohenite (p. 31). In the octahedral irons they find two kinds of tænite: A, tin-white, flexible, rich in cobalt and nickel, with small amount of carbon; B, grayish, feebler luster, less flexible to brittle, lower in nickel and carbon and higher in carbon. Analyses:

A	Fe	Ni	Co	Cu
Toluca	65.17	34.29	0.40	0.14 = 100
Wichita Co.	65.54	32.87	1.59	- = 100
Glorieta Mt.	63.04	35.53	1.43	- = 100
В	Fe	Ni	Co	C
Staunton	73 10	23.63	2.10	1.17 = 100

The authors also remark that cohenite, (Fe, Ni, Co), C, corresponds to the compound, Fe, C,

which separates from cast iron in crystals when slowly cooled, between 600° and 700°.

The discovery, mode of occurrence, and distribution of the native nickel-iron alloy, called awaruite, on the west coast of the South Island of New Zealand, is minutely discussed by Ulrich in Q. J. G. Soc., 46, 619, 1890. It is shown to be somewhat widely distributed in a highly basic peridotyte or the serpentine which has resulted from its decomposition.

Found in the Berezovsk mining region near Ekaterinburg, Ural; the special locality is the gold placers of Prikanavny in the valley of the Pyshma which empties into the Tura, a branch of the Tobol. The fragments have a peculiar foliated structure. It is magnetic; G. = 7.59, chrysolite, pyroxene, serpentine, chromite, triclinic feldspar, etc. Daubrée and Meunier, C. R., 113, 172, 1891.

Observed as forming part of a thin coating with oolitic structure on quartzyte on the north shore of St. Joseph Is., Lake Huron, Ontario. Analysis of the coating gave: Metallic grains 58.85, limonite 39.73, siliceous matter 1.42 = 100. The spherical metallic grains varied from a microscopic size up to 0.37 mm. in diameter; an analysis of them yielded:

Fe	Mn	Ni	Co	Cu	S	P	C	insol.
88.00	0.51	0.10	0.21	0.09	0.12	0.96	?	9.76 = 99.75

The insoluble portion formed a nucleus of rounded form and coated with a yellowish brown humus-like substance, which disappeared on ignition, leaving the snow-white spherules consisting of 94 p. c. SiO2. G. Ch. Hoffmann, Trans. R. Soc. Canada, 8 (3), 39, 1890.

Hussak has noted the occurrence of undoubted native iron in the gold gravels of the Ribeira

in S. Brazil (ref. ottrelite, p. 1043).

ISOPYRE Haidinger, Ed. N. Phil. J., 3, 263, 1827.

In compact masses, with cleavage. Fracture flat conchoidal. Brittle. H.=6-6.5. = 2.912. Luster vitreous. Streak light greenish gray. Color grayish black or velvet-black. $G_{\cdot} = 2.912$. Luster vitreous. occasionally spotted red, like heliotrope. Opaque to subtranslucent. Analysis.—Turner, p. 265:

Al₂O₈ 13.91 Fe₂O₃ 20.07 CaO 15.43 CuO 1.94 = 98.44SiO, 47.09

B.B. fuses easily to a magnetic bead, and colors the flame green. A silica skeleton with salt of

phosphorus. With the acids decomposed with difficulty and imperfectly.

From St. Just, near Penzance, Cornwall, in a quartzose granite with tourmaline and tin ore, in pieces two inches in diameter. Also in breccia on the Calton Hill, Edinburgh, with limonite. Named from $i\sigma o s$, like, and $\pi \hat{v} \rho$, fire, because the fused bead resembles closely the original mineral.

The above supposed mineral species has been examined by N. Story Maskelyne and W. Flight and proved to be simply impure opal. J. Ch. Soc., 25, 1049, 1872. The same conclusion

has been reached by Fischer.

IVAARITE Iiwaarite, p. 448. Occurs in an Elæolite rock ("Ijolith") at Iiwaara, Finland. The analyses by Thoreld (p. 448) are questioned by Ramsay and Berghell on the ground that the material was probably not homogeneous; they obtained 25 42, 24 93 p. c. TiO₂. G. För. Förh., 13, 305, 1891.

JORDANITE, p. 141. Crystals from the Binnenthal are shown by Baumhauer to conform in angle to the monoclinic system. The axial ratio, calculated by him from the angles: $100 \land 001 = 89^{\circ}26\frac{1}{2}'$, $001 \land 101 = 28^{\circ}6\frac{1}{2}'$, $010 \land 250 = 38^{\circ}58\frac{1}{2}'$, is:

$$\hat{a}:\hat{b}:\hat{c}=0.49450:1:0.26552$$
 $\beta=89^{\circ}\ 26\frac{1}{2}$

The planes, which on p. 141 are taken as macropinacoid (a), brachypinacoid (b), and base (c), become, respectively, base (c), orthopinacoid (a), and clinopinacoid (b); further, κ (112) = 121, 121, m (110) = 101, $\bar{1}$ 01, y (101) = 011, p (011) = 110, etc. A number of new forms are added. Ber. Ak. Berlin, 697, 915, 1891.

Kallilite. H. Laspeyres, Zs. Kr., 19, 12, 1891. Wismuthnickelglanz.
Massive. Luster metallic. Color light bluish gray.
Comp.—NiBiS or NiS₂.NiBi₂ = Sulphur 10.7, bismuth 69.7, nickel 19.6 = 100. It thus belongs near ullmannite, etc., p. 91. Analysis:

	S	/ Sb	Bi	As	Ni	Fe	Co
3	14.39	44.94	11.76	2.02	26.94	0.28	0.89 = 101.22

Occurs at the Friedrich mine near Schönstein, a. d. Sieg. The name refers to the locality.

Kaolinite, p. 685. Crosby describes a bed of white kaolin of considerable extent in Blandford, Hampden Co., Mass. It has been produced by the decomposition of the feldspar of large veins of pegmatyte and is regarded as representing part of the pre-glacial soil. Tech. Q., 3, 228, 1890.

KARAMSINIT A. E. Nordenskiöld, Rg., Min. Ch., 683, 1875. A mineral supposed to be from Finland, containing, according to Thoreld: SiO2 51.53, Al2O3 3.20, Fe2O3 5.98, MnO 4.62, CaO 13.05, MgO 6.86, K2O 10.8, CuO 2.32, H2O 1.59.

Kentrolite, p. 544. Found at Långban, Sweden, intimately associated with braunite, also richterite, barite. Crystals prismatic with a (100), m (110), o (111), s (221) (cf. fig.). Axial ratio $\ddot{a}: \ddot{b}: \dot{c}=0.63278:1:0.89879$ from $mm''=*64^{\circ}39$ and $110 \wedge 111=*30^{\circ}45'$. Formula deduced, R_2SiO_4 , R_2SiO_5 , with R = Pb: Mn: Ca = 33:5:2, and R = Mn: Fe = 3 · 1. Analysis:

Flink finds an error in the axial ratio calculated by vom Rath (0.633:1:0.784), which, however, has been corrected on p. 544. Ak. H. Stockh., Bihang, 16 (2), No. 4, 1891.

Koulibinite. See Koksharov, Min. Russl., 4, 281; Dx., Min., 1, 57, 1862. KULIBINITE. From Transbaikal. Probably simply a kind of pitchstone, Kk., and Dx., Min., 2, xix, 1874.

Krennerite, p. 105. Miers notes on crystals from Nagyág, the new forms: d (021, 2-1), $q(031, 3-\check{i}), s(041, 4-\check{i}), w(124, \frac{1}{2}-\check{2}), t(121, 2-\check{2}), v(362, 3-\check{2}).$ Min. Mag., 9, 184, 1890.

LANGBANITE, p. 543. Sjögren (G. För. Förh., 13, 256, 1891) distinguishes two types of långbanite from Långban: A, occurring in hexagonal tabular crystals 0 5 to 1 cm. in diameter and some millimeters in thickness, associated with fine granular schefferite. B, small crystals of prismatic habit often embedded in calcite. Analyses 1, 2 (by R. Mauzelius) are of type B;

anal. 3, of type A. The formula deduced is $m\mathrm{Sb}_2\mathrm{O}_3$, $n\mathrm{Fe}_2\mathrm{O}_3$, $p\mathrm{Mn}(\mathrm{Mn},\mathrm{Si})\mathrm{O}_3$. The coefficients m, n, p vary, but the relation of $\mathrm{MnO}:(\mathrm{Mn},\mathrm{Si})\mathrm{O}_2$ is about constant =1:1. Attention is also called to the fact that the axial ratio, $a:\frac{5}{6}b$ (Flink) =1:1:3694, corresponds closely to that characteristic of the Hematite Group, p. 210 et seq. (cf. also pyrophanite, p. 1045). Further, some crystals seem to be hemihedral, i.e. rhombohedral, in habit.

Analyses, 1-3, Mauzelius:

	G.	SiO ₂	Sb_2O_3	Fe_2O_3	MnO_2	MnO	CaO	MgO
1.	4.66	12.23	11.76	14.15	26.15	31.54	2.24	1.61 = 99.68 (O 3.50)
2.	4.73	11.32	11.61	14.31	27.12	35.30	2.04	$0.86 \text{ H}_2\text{O} \ 0.32 = 99.88 \ (O \ 3.70)$
8.		8.95	12.92	4.33	35.15	36.39	1.95	0.47 = 100.16 (0.5.93)

The same subject is discussed by Bäckström (ibid., p. 271), who gives two new analyses and recalculates that of Flink (p. 543). Although differing as regards the state of oxidation of the manganese, he arrives at essentially the same conclusion as that of Sjögren, that the mineral is to $\frac{mn}{n}$

be referred to the hematite-ilmenite group. He writes the formula $\ddot{R}\ddot{R}O_3$, where m+n=6. Analyses, 4-6, Bäckström:

	SiO ₂	Sb ₂ O ₃	Mn ₂ O ₃	Fe ₂ O ₃	MnO	CaO	MgO	
4.	9.58	12.58	63.67	3.44	8.21	1.73	0.53 =	99.74
5.	8.75	15.35	61.04	4.75	5.86	2.98	0.40 =	99.13
6.	10.88	13.89	59.43	11.46	12.87	_	- =	108.53

LANTHANITE, p. 302. On the crystalline form of the analogous didymium carbonate $Di_2(CO_3)_3 + 8H_2O$, which is orthorhombic with $mm''' = 87^{\circ} 26'$, see Morton, Öfv. Ak. Stockh., 42, No. 6, 192, 1885.

Lautarite A. Dietze, Zs. Kr., 19, 447, Oct. 23, 1891.

Monoclinic. In large prismatic crystals sometimes weighing 20 grams. Prismatic angle of 83° 30'; basal plane rare. Crystals often radiately arranged or in stellate aggregates. G = 4.59.

Colorless to yellowish.

Comp.—Calcium iodate, Ca(IO₃)₂ = Iodine pentoxide 85·6, lime 14·4 = 100. It thus belongs to a group not before represented among minerals. Analysis gave: I 64·70 and 64·62, CaO 14·95, determined on three portions. Slightly soluble in water, 0·22 gram in 100 grams of water at 20°, or 1·43 grams of iodine to the liter. Aqueous solution colorless. Soluble in hydrochloric acid with evolution of chlorine.

Obs.—Occurs in the caliche or sodium nitrate deposits (cf. p. 871) of Atacama, Chili, especially in the "Pampa del Pique III" belonging to the Oficina Lautaro and to neighboring Pampas, all of which belong to the so-called calcium chloride class. The crystals are often

embedded in bands of gypsum.

On the form of the hydrous calcium iodate Ca(IO₃)₂ + 6H₂O, see Rg., Kr. Ch., 332, 1881.

The same region furnishes crystals in the caliche, as described by Dietze (ibid.), which seem to be a double salt of iodate and chromate of calcium, corresponding to $7Ca(IO_3)_2.8CaCrO_4$; or perhaps more simply $Ca(IO_3)_2.CaCrO_4$, which requires: Iodine pentoxide 61·1, chromium trioxide 18·4, lime $20\cdot 5=100$. Analysis gave:

I_2O_5	CrO_3	CaO		I
58.12	19.00	22.01 =	99.13	44.20
58.10	19.90	21.50 =	99.50	44.17
58.89	20.28	21.10 =	100.37	44.79

The crystals dissolve slowly, more readily on application of heat. On cooling, crystals of the hydrous calcium iodate (cf. above) separate out, while the calcium chromate remains in the solution. On a supposed chromate from the nitrate deposits, see tarapacaite, p. 916. Dietze, however, regards the chromic acid as always present as a double salt united with iodate.

On artificial double salts of iodic and chromic acid, see Berg, C. R., 111, 42, 1890.

LEAD SILICATE. An artificial lead silicate from Bonneterre, St. François Co., Missouri, has been described by E. S. Dana and S. L. Penfield (Am. J. Sc., 30, 138, 1885), and later by H. A. Wheeler (ibid., 32, 272, 1886.) It occurs associated with octahedral crystals of magnetite and cleavable galena; form, a hexagonal prism (m) with pyramids (p, q), and basal plane (c), $cp = 50^{\circ}$ approx., $cq = 25^{\circ}$; also in thin tabular crystals with apparently rhombohedral planes. Analyses of crystals: 1, Penfield; 2, Wheeler.

G.	SiO ₂	PbO	FeO	CaO	MgO	Na ₂ O	
5.92	17.17		0.51			0.35 = 98.46	
	17.11	73.66		2·35 O. 0·80		2·22 NiO 3·06, Cl 0	.08 = 100.03

Other analyses are given by Penfield of the massive silicate, and by Wheeler of fine crystals.

LAVENITE, p. 375. Occurs in the phonolytes of the Haute Loire, Lacroix, Bull. Soc. Min., 14, 15, 1891.

LEOPARDITE. A quartzose rock spotted with stains of manganese occurring in North Carolina.

LECCITE, p. 342. The characters and distribution of the altered leucite (pseudoleucite) and leucitic rocks of Magnet Cove, Arkansas, briefly alluded to on pp. 343 and 426, are fully described by J. F. Williams in the Ann. Rep. Geol. Arkansas, 1890, vol. 2, p. 267 et seq. Lacroix has noted the presence of leucite in a basalt of Mont Dore, Puy-de-Dôme. C. R.,

113, 751; Nov. 23, 1891.

LITHIDIONITE. Litidionite E. Scacchi, Rend. Accad. Napoli, 19, 175, Dec. 1880.

Birthiolaria. Entidionte E. Scaccii, Rend. Read. Rapon, 15, 176, Dec. 1860.

Blue lapilli, found at Vesuvius in 1873, 7 to 25 mm. in diameter, were found to consist of a white earthy substance, with a glassy blue crust. Of the latter, H. = 5-6, G. = 2.535. The mean of two analyses gave, after being washed: SiO₂ 71.57, CuO 6.49, FeO 4.02, K₂O 10.92, Na₂O 6.78 = 99.78. Slightly attacked by HCl; fuses very easily (the white nucleus, consisting of augite, olivine, etc., is infusible). The author, on the ground of the fusibility, regards the substance as a mixture of quartz and the carbonates of potassium and sodium.

LUZONITE, p. 148. Klockmann has investigated the famatinite of the Sierra de Famatina, Argentine Repub., and also a mineral which he identifies as luzonite from the same locality. He regards both these minerals as isomorphous and unlike enargite in form, while hitherto famatinite and enargite have been considered isomorphous, as given in p. 149. The argument is not conclusive. Anal.—Bodländer, quoted by Klockmann.

> $G_{\cdot} = 4.390$ S 32.40 As 16.94 Sb 3.08 $Cu\ 47.36 = 99.78$

Magnetite, p. 224. Kemp has given the results of a more minute study of the striated magnetite crystals from Mineville, near Port Henry, Essex Co., N. Y. Zs. Kr., 19, 183, 1891. Scheibe mentions on crystals from Magnet Cove and Moriah, Essex Co., N. Y., tw. striations and parting $\| o (111)$; also tw. lamelle $\| m (311)$; further, Moriah, $\| e (210)$. Zs. G. Ges., 42, 370, 1890.

A magnetite from Büchig near Hirschberg a. Saale in Oberfranken contains tin according to

Sandberger, Jb. Min., 2, 269, 1890.

Formation in slags and recent eruptive rocks, see Vogt, Arch. Math. Nat., 14, 25, 1890.

MANCINITE Jacquot, Ann. Mines. 19, 703, 1841. Described as a zinc silicate from Mancino near Leghorn, but according to Uzielli (Trans. Accad. Linc., 1, 108, 1877) the mineral is not, as supposed, from the hill Mancino, near Leghorn, nor is it a zinc trisilicate.

Manganoferrite Vogt, Arch. Math. Nat., 14, 35, 1890. Blackish brown skeleton crystals formed in some Martin and Bessemer slags, having the composition (Fe,Mn)₂O₄ and resembling hausmannite and magnetite. To which system they belong, tetragonal or isometric, is not determined.

MARCASITE, p. 94. Trechmann describes marcasite twins (tw. pl. m) implanted in parallel position on the faces of pyrite cubes from Bredlar near Brilon, Westphalia. Min. Mag., 9, 209, 1891.

MARIPOSITE B. Silliman, Jr., Cal. Acad. Sc., 3, 380, 1868. A light apple-green micaceous mineral, occurring in scales associated with pyrite in a gangue of dolomite (ankerite) and quartz; with the ore of the Mariposa region, California.

Melanophlogite, p. 194. The nature of this problematical mineral has been further discussed by Streng, Ber. Oberhess. Ges., 27, 123, 1890, and Jb. Min., 2, 211, 1891; also Friedel, Bull. Soc. Min., 13, 356, 1890, and 14, 74, 1891. Streng argues that the mineral contains silicon disulphide (SiS₂), not sulphur trioxide as ordinarily stated, but Friedel pretty conclusively shows that the latter view is correct. He concludes

further that the ordinary mineral is pseudo-isometric and tetragonal, optically negative; further, that it does not gain its form by pseudomorphism. There also occur forms which are hexagonal in structure, optically positive, and correspond to tridymite.

METACINNABARITE, p. 62. The form of the crystals, from New Almaden, described by Melville and briefly alluded to on p. 63 is given in the accompanying figure. The crystals are minute but brilliantly polished and gave good measurements, but the symbols obtained by him, especially for the hemi-scalenohedrons, are highly complex. The forms observed at the analogous pole are: c (0001, 111), m (1010, 100), $\{0554, 33\bar{2}\}, (13\bar{2}2, 21\bar{1});$ at the antilogous pole: $(50.0.\bar{5}0.\bar{1}, 33.\bar{1}\bar{7}.\bar{1}\bar{7}), (48.\bar{4}\bar{6}.\bar{2}.\bar{1}, 31.\bar{1}\bar{7}.\bar{1}\bar{5}),$ $(41\cdot\bar{3}\bar{8}\cdot\bar{3}\cdot\bar{1},\ 26\cdot\bar{1}5\cdot\bar{1}\bar{2})$. The specific gravity obtained was only 7·118. The relation of these crystals to those described by Penfield is at present undetermined.

Occurs with cinnabar at Knoxville, Cal., and at the Cerro Gordo mine, 11 Liles west of Panoche, Fresno Co. Melville & Lindgren, U. S. G. Surv., Bull.

61, 22, 1890.

Schrauf mentions the occurrence of metacinnabarite at Idria in hemispherical forms with concentric fibrous structure. They are implanted on calcite which coats the calcareous sandstone, forming the gangue rock. $G_{\cdot}=7.66$. The amount of sulphur was found to be 14.09 p. c. Anz. Ak. Wien, 156, 1890.

MICROCLINE, p. 322. On the structure of the microcline in pegmatytes from the Argentine Republic, see Sabersky, Jb. Min., Beil., 7, 359, 1891.

MICROLITES. A name proposed by Vogelsang (Philosoph. Geol., p. 139, 1867) and since used by Zirkel (Mikr. Beschaff. d. Min., pp. 33, 88, 1873) for microscopic crystals, sometimes belonging to known species, sometimes of indeterminate nature, but often observed in igneous rocks. The method of aggregation of these microlites is sometimes very remarkable. Trichite and belonite are names given by Zirkel (l. c.) to analogous forms.

MOLYBDENITE, p. 41. Occurs in spherical forms with concentric structure at Plataro, in Colorado.

MORINITE A. Lacroix, Bull. Soc. Min., 14, 187, 1891. A new species, announced but not fully described, occurring with the amblygonite at Montibras. In monoclinic crystals with a (100, i-i), b (010, i-i), c (001, 0), m (110, I). Cleavage: a (100). G. = 2.94. Ax. pl. | b. Bx inclined 30° in the obtuse angle ac. 2E variable, up to 40°.

B.B. the mineral bubbles up and fuses. In the closed tube gives off about 13.5 p. c. of cid-actor (with fluories). City are of the specific social selection and sade.

acid water (with fluorine). Gives reactions for phosphoric acid, alumina, and soda.

Morinite is associated with an undetermined hydrated phosphate free from fluorine, crystallizing in tetragonal octahedrons, which are optically positive. Named after M. Morineau.

Mursinskite Koksharov, Min. Russl., 9, 341, 1886.

Tetragonal. Axis $\dot{c} = 0.56641$; $001 \land 101 = 29^{\circ} 31\frac{3}{2}$. Forms: $y (503, \frac{5}{3}i)$, x (201, 2-i); o (111, 1); z (10.5.2, 5-2), s (841, 8-2); also two undetermined

zirconoids w, v.

Angles: $cy = 43^{\circ} 21$, $cx = 48^{\circ} 34'$, $co = 38^{\circ} 42'$, $yy' = 58^{\circ} 5'$, $xx' = 64^{\circ} 1\frac{1}{2}'$, $oo' = 52^{\circ} 28'$, $zz' = 35^{\circ} 6'$, $zz^{\circ 1i} = 50^{\circ} 29'$. $ss' = 36^{\circ} 9'$, $ss^{\circ 1l} = 52^{\circ} 3$. H. = 5-6. G. 4·149 (on 0·04 gram). Color wine- or honey-yellow. Transparent to semi-

transparent.

Comp. - Unknown.

Obs.—Known only from two specimens discovered about 1854; it occurs as inclusions in topaz. From Alabashka, near Mursinka (Mursinsk) in the Ural.

NATROLITE, p. 600. Gonnard has analyzed several specimens from the Puy-de-Dôme, Bull. Soc. Min., 14, 165, 1891:

	SiO ₂	Al_2O_3	Na ₂ O	CaO	H_2O
Puy-de-Marman	48.03	26.68	15.61		9.62 = 99.94
Tour de Gevillet	47.88	26.12	15.63	0.45	9.80 - 99.88

NATRON, p. 301. Described by E. Scacchi as occurring in colorless crystalline grains and prismatic crystals within the lava at the Fosso Grande, Vesuvius. An analysis gave: CO₂ 15 91, Na₂O 22 15, K₂O 0 41, H₂O 61 68 = 100 15. Rend. Accad. Napoli, 2, 488, Dec. 1888, and Zs. Kr., 18, 100, 1890.

NEPHELITE, p. 423. Continued studies on the nephelite rocks of Brazil are given by Derby, Q. J. G. Soc., 47, 251, 1891.

Described from the rock called Iiolyte (Ijolith) occurring at Iiwaara, Finland, by Ramsav and Berghell (G. För. Förh., 13, 308, 1891). Refractive indices: $\omega_v = 1.54515$, $\epsilon_v = 1.54200$. Analysis:

> Al₂O₃ CaO Na₂O K₂O SiO2 43.98 34.93 0.36 16.76 3.88 = 99.86

On the elæolite rocks of Magnet Cove and other regions in Arkansas, and their minerals. see J. F. Williams, Ann. Rep. G. Ark., vol. 2, 1891.

NESQUEHONITE, p. 300. Occurs forming white fibrous masses in the galleries of the anthracite mine of la Mure, Isère, France. An analysis by C. Friedel gave:

> \$ CO₂ 31.88 MgO 28.98 3 $H_2O 39.13 = 99.99$

This conforms to $MgCO_3 + 3H_2O$. Bull. Soc. Min., 14, 60, 1891.

Newboldire Piddington, J. Asiatic Soc. Bengal, 26, 1129, 1847. A mineral found by Capt. Newbold in some old lead mines "near Gazoopilly, Kurnool." Probably a ferruginous sphalerite. Cf. Mallet, Min. India, 18, 1887.

NICCOCHROMITE C. U. Shepard, Min. Contr., 1877. A canary-yellow substance, occurring as a coating on zaratite, rarely on chromite, at Texas, Pa. On the ground of a partial blowpipe examination, it is concluded to be a "dichromate of nickel."

NICKEL, cf. p. 29. The auriferous sands of the stream Elvo near Biella in Piedmont are shown by A. Sella to contain grains of an iron-nickel alloy corresponding nearly to Ni₃Fe. They resemble native platinum in appearance, are malleable and strongly magnetic, and have G. = 7.8. An analysis gave:

Ni (with some Co) 75.2

 $Fe\ 26.6 = 101.8$

Soluble in nitric and dilute hydrochloric acid. C. R., 112, 171, 1891. See Iron, p. 1037. Noselite, p. 432. A "hydronoseane" has been obtained by Charles & Georges Friedel by heating mica with soda and sodium sulphate. It is in hexagonal crystals (m, 1010) with a pyramid p, with $pp'=24^{\circ}$ 22.7. Here p corresponds to p (1011) of microsommite and q (1012) of nephelite. Analyses gave:

	SiO ₂	SO,	Al ₂ O ₃	Na ₂ O	K ₂ O	H_2O
1.	35.62	7.20	29.65	23.82		3.94 = 100.23
2.	34.81	7.25	29.91	23.34		3.95 = 99.26
3.	34.66	7.34	31.47	18.74	5.39	2.30 = 99.90
4.	34.20	7.98	30 78	21.53	3.08	2.34 = 99.91

Bull. Soc. Min., 13, 238, 1890, 14, 69, 1891.

OCTAHEDRITE, p. 239. Occurs in acute pyramidal crystals, resembling those from Tavetsch, with quartz and pyrite on joint-planes at the Arvon slate quarries, Buckingham Co., Va. Cf. G. H. Williams, Am. J. Sc., 42, 431, 1891. Occurs at Pranal, near Pontgibaud, Puy-de-Dôme, Lacroix, Bull. Soc. Min., 14, 191, 1891.

Offretite F. Gonnard, C. R., 111, 1002, 1890; Bull. Soc. Min., 14, 60, 1891. Hexagonal or rhombohedral. In very minute hexagonal prisms, often rounded and with vertical faces striated; also in hemispherical forms with radiate structure. Cleavage: normal to the base. Fracture uneven. Brittle. G. = 2·13. Luster vitreous. Colorless to white. Double refraction weak. Sections ± & show sectors analogous to herschelite.

Calculated formula, (K₂Ca)₂Al₃Si₁₄O₃₉.17H₂O. Anal.—Gonnard, l. c.

Al2O3 19:06 CaO 2.43 K2O 7.72 $H_2O 18.90 = 100.58$ SiO, 52.47

B.B. turns white and fuses quietly to a white enamel. Decomposed by acids with difficulty.

Occurs in the basalts of Mont Simiouse near Montbrison, France. Named after Professor Offret, of Lyons.

OLDHAMITE, p. 65. Vogt notes a similar compound (also MnS, FeS, etc.) in certain furnace slags. Arch. Math. Nat., 14, 72, 1890.

Orpiment, p. 35. Deposited with realgar by the hot springs of the Norris Geyser basin in the Yellowstone Park, cf. Weed & Pirsson, Am. J. Sc., 42, 403, 1891.

OTTRELITE, p. 642. Phyllytes with ottrelite (chloritoid) are described by E. Hussak as occurring with magnetite in São Paulo, Brazil. Bol. Comm. G., S. Paulo, No. 7, 1890.

Palagonit Sartorius v. Waltershausen, Subm. Vulk. Ausbr. Val di Noto, etc., Gött., 1846; Vulk. Gest., 1853. Bunsen, Lieb. Ann., 61, 265, 1847, Pogg., 83, 219, 1851. Melanhydrit A. Krantz, Vh. Ver. Rheinl., 6, 154, 1859.

A basaltic tufa consisting chiefly of glass lapilli and the products of their alteration. It formerly passed as a mineral species, but properly belongs to petrography. Cf. Rosenbusch,

Mass. Gest., 747, 1887.

PARAMELACONITE G. A. Koenig, Proc Acad. Philad., 284, 1891. Tetragonal. In pyramidal crystals p (111, 1), terminated by c (001, 0); the pyramidal faces, e (101, 1-i), strongly striated horizontally. Measured angle, $ce = 58^{\circ}$ 50', hence the axis

Cleavage not observed. H. = 5. G. = 5.833. Luster brilliant. Color on the faces purplish black, on the fracture pitch-black.

Composition, probably essentially CuO. but requiring further examination. The analysis is interpreted as CuO 87.66, Cu₂O 11.70, Fe₂O₃ 0.64 = 100. Analysis:

CuO 100.58 Fe₂O₃ 0.64 = 101.32

B.B. fuses on edges; in the reducing flame is reduced and yields metallic copper. Soluble in acids.

From the Copper Queen mine, Bisbee, Arizona, with footeite, etc.

PARATHORITE. Thorite Shep., Proc. Am. Assoc., 2, 321, 1850. Parathorite Shep., Min.,

287, 1857; Dana, Brush, Am. J. Sc., 24, 124, 1857.

Orthorhombic. In minute rectangular and rhombic prisms, with the planes a (100, i-i), b (010, i-i), m (110, I). Angles: $mm^{m} = 52^{\circ}$, $bm = 64^{\circ}$. H. = 5-5·5. Luster subresinous. Color garnet-red to pitch-black; thin edges of black crystals with a ruby translucence, a little like rutile. Translucent to opaque.

In the matrass decrepitates slightly, but does not appear to contain water. B.B. in the platinum forceps glows, fuses with difficulty on the edges, and becomes paler. In borax dissolves to a bead, which is yellow, from iron, while hot, and becomes colorless on cooling. With salt of phosphorus gives in the outer flame a bead, yellow while hot and colorless on cooling. In the inner flame the bead assumes a delicate violet color (due to titanic acid?), Brush.

Occurs embedded in danburite and orthoclase, and only in very minute crystals, at

Danbury, Ct.

Shepard made the crystallization erroneously tetragonal. There are also other discrepancies in his description, which may lead to the supposition that the mineral here described is a different mineral from Shepard's; but the evidence to the contrary is complete.

Paroligoclase. Paroligoklas E. E. Schmid, Jb. Min., 1, 78 ref., 1881.

A problematical substance occurring in indistinct prisms, with calcite grains, embedded in the ground-mass of a rock found between Ilmsenberg, Quäriberg, and Silberberg, in the Thüringerwald. It may be an impure scapolite. Cf. App. 111, p. 88; also Rosenbusch, Jb. Min., 1, 78, 1881.

Pelagosite K. Moser, Tschermak, Min. Mitth., 1, 174, 1878.

A substance occurring as a thin, dark-colored incrustation on limestone and dolomite, on the shores of the Mediterranean, as at the Island of Pelagosa (Moser). In some cases looking like varnish, and again resembling lichens. It consists of thin translucent layers, exerting on polarized light the effect of aggregate polarization. An analysis by J. Cloëz on similar material from Cape Ferrat afforded: $CaCO_3$ 91·80, $MgCO_3$ 0·90, Fe_2O_3 0·25, SiO_2 1·22, NaCl 0·49, H_2O_3 0·56, organic matter 0·71 = 99·93. It is regarded as produced by the action of sea-water on the dolomite.

Des Cloizeaux and Vélain have observed similar coatings on the feldspathic rocks of Corsica, on the coast of Oran, and on basaltic lava on the coast of Reunion Island, Bull. Soc. Geol., 6,

86, 1878.

PLATINUM, p. 25. Joly has described a method of obtaining crystals, by passing an electrical current through a ribbon of the pure metal upon which some topaz dust has been scattered. After maintaining a current sufficient to heat the strip to redness for half an hour, microscopic crystals are found clinging to the partially decomposed topaz, and after two hours some of these attain a size of 0.1 mm. The prevailing form is the octahedron. Nature, 43, 541, 1891. On artificial crystals, see also Törnebohm, G. För. Förh., 13, 81, 1891.

Present in the ores of Boitza, Transylvania, with gold and tellurium; a ton contains 33.6 gr.

gold and 2 gr. platinum, Vh. G. Reichs., 96, 1891.

POLLUCITE, p. 343. Described and analyzed from Hebron, Me., by H. L. Wells, Am. J. Sc., 42, 213, 1891. It was found by Loren B. Merrill chiefly in a single cavity, some 3×6 feet and 18 inches deep; it was in fragments in a loose heap mixed with clay, associated with quartz and a cæsium beryl (anal. 10, p. 407). About half a kilogram was found in all. In appearance it is similar to the Elba mineral. G. = 2.986, 2.977. Refractive indices, Penfield:

$$n_{\rm r} = 1.5215 \, {\rm Li}$$
 $n_{\rm y} = 1.5247 \, {\rm Na}$ $n_{\rm gr} = 1.5273 \, {\rm Tl}$

Analyses, Wells, l. c.

SiO ₂	Al ₂ O ₃	CaO	Cs ₂ O	K ₂ O	Na ₂ O	Li2O	H_2O		
43.48	16.41	0.21	36.77	0.47	1.72	0.03	1.53	=	100.62
43.59	16.39	0.22	35.36	0.51	2.03	0.04	-[1.53]	=	99 67
43.51	16.30	-0.22	36.10	0.48	1.68	0.05	1.50	=	99.84

The above analyses yield the formula $H_2Cs_4Al_4(SiO_3)_9$ or $H_2O.2Cs_2O.2Al_2O_3.9SiO_2 = Silica 40.7$, alumina 15.4, cæsium oxide 42.5, water 1.4 = 100.

Wells shows by a discussion of the earlier analyses (p. 344, also Plattner) that this composition probably also belongs to the Elba mineral. The unusually large amount of exist mobilined

from this source has enabled Wells and Penfield to make some important researches upon the cæsium trihalides.

POLYBASITE, p. 146. An analysis of polybasite from the Santa Lucia mine, Guanajuato, Mexico, gave Prior:

G. = 6.33S 15.43 Sb 10.64 As 0.50 Ag 68.39 $Cu\ 5.13 = 100.09$

The ratio calculated for $S: Sb: Ag(Cu) = 5:1:7\frac{1}{2}$. Min. Mag., 9, 13, 1890.

Occurs (Endlich) at the Yankee Boy mine, Ouray Co., Colorado, with pyrargyrite in a quartzose gangue. The crystals are hexagonal in outline and have $mm'' = 60^{\circ}$ approx. Pfd. Âm. J. Sc., 40, 424, 1890. See also p. 1049.

Polylite Thomson, Min., 1, 495, 1836, Perhaps a variety of pyroxene (augite). It is described as cleavable massive; G. = 3·231; H. = 6-6·5; color black; opaque. Stated to come from a bed of magnetic iron ore at Hoboken, N. J., where no such bed of ore exists.

Pyrite, p. 84. / Crystals from the Roetzgraben near Trofaiach show the new pyritohedron (10·1·0, i-10). Höfer, Mitth. Ver. Steiermark, 25, 230, 1889.

A manganiferous variety, containing 10·9 p. c. Mn, also a little Ag, is reported by Lang

(priv. contr.) as occurring at Mineral, Idaho.

Pyrolusite, p. 243. Manganese nodules from the deep-sea dredgings in the Pacific, also from Loch Fyne; cf. Murray, Proc. R. Soc. Edinb., Jan. 5, 1891. Buchanan shows that the deep ocean nodules approximate in composition to MnO2; those from Loch Fyne are nearly Mn₂O₃.

Pyrophanite *Hamberg*, G. För. Förh., **12**, 598, 1890. Rhombohedral; tetartohedral. Axis $\dot{c} = 1.3692$, $0001 \land 10\bar{1}1 = 57^{\circ} 41_{\bar{6}}^{1}'$, $10\bar{1}1 \land \bar{1}101 = 94^{\circ} 5_{\bar{6}}^{1}'$ Hamberg.

Forms: c(0001, 0), $a(11\overline{2}0, i\cdot 2)$, $g(10\overline{1}2, \frac{1}{2})$ cleavage, $d(02\overline{2}1, -2)$. Also undetermined vicinal + rhombohedrons, at a maximum, $2\frac{1}{2}^{\circ}$ from c.

Angles: $cg = 38^{\circ} 19\frac{1}{2}'$, $cd = *72^{\circ} 27'$, $gg' = 64^{\circ} 58'$, $dd' = 111^{\circ} 19'$, $ad = 34^{\circ} 20'$.

In very thin tabular crystals or scales; basal plane brilliant but with triangular striations

parallel to the zone of + rhombohedrons.

Cleavage: $d(02\overline{2}1)$ perfect; g less so. Etching-figures are asymmetric. H. = 5. G. = 4.537. Luster brilliant, vitreous to submetallic. Color deep blood-red; yellowish red in very thin plates. Streak ocher-yellow with a greenish tinge. Not pleochroic. Transparent in thin plates. Indices :

> $\omega_{\rm r} = 2.4408, 2.4419 \, {\rm Li}$ $\omega_{\rm v} = 2.4804, 2.4816 \, {\rm Na}$ $\epsilon_{\rm v}=2.21$

Comp.—MuTiO₃ = Manganese protoxide 46.9, titanium dioxide 53.1 = 100. A little silicon replaces part of the titanium.

Anal.—Hamberg, l. c.

SiO₂ 1.58 MnO 46.92 FeO₃ 1.16 $Sb_2O_3 \ 0.48 = 100.63$ TiO2 50.49

Obs.—Occurs at the Harstig mine, Pajsberg, Wermland, Sweden; found sparingly, associated with ganophyllite, also garnet and manganophyllite, in cavities later filled with calcite. from $\pi \hat{v} \rho$, fire, and $\phi \alpha v \dot{o} s$, shining, in allusion to its red color and brilliant luster.

Hamberg shows that pyrophanite is to be regarded as isomorphous with ilmenite. he suggests the following grouping to show the relation to other allied compounds:

Hematite Group. Rh	ombohedral	Ilmenite Group.	Rhomb., teta	rtohedral
Chromium sesquioxide	Cr ₂ O ₃ 1·368	Ilmenite	FeTiO ₃	<i>è</i> 1:385
Corundum	Al ₂ O ₃ 1.363	Pyrophanite Also Catapleiite		1.369
Hematite Titanium sesquioxide	Fe ₂ O ₃ 1·366 Ti ₂ O ₃ 1·316	Also Catapleiite	e ${ m SiO_3.Zr(OH)_2Si}$	1.3605

To the second group he would also add the hexagonal calcium metasilicate, CaSiO₃, further the artificial compound KBrO₃.

Pyroxene, p. 352. Wülfing (Habilitationsschrift, Heidelberg, 1891) has made a careful optical examination of a series of pyroxenes ranging from diopside to hedenbergite, and connected the results with the variation in chemical composition as given by the analyses of Doelter, Flink, and others. The optical constants deduced for a pure diopside CaMgSi₂O₆ are as follows:

	α	β	y	2V	ċ¢ .	
For Li	1.6649	1.6719	1.6941	58° 53′	37° 55′	
Na	1.6685	1.6755	1.6980	58° 40′	37° 50′	
TI	1.6722	1.6791	1.7015	58° 26′	37° 45′	1

For the ægirite from the Langesund-fiord a re-examination of the optical constants was made, with the following results:

	α	β	y	2V	c∧c
Eosin	1.7590	1.7929	1.8054	117° 25′	93° 30′
Na	1.7630	1.7990	1.8126	117° 47′	94° 0′
Tl	1.7714	1.8096	1.8238	118° 16′	94° 58′

The angles given in the last column correspond to $Bx_r \wedge \dot{c} = +3^{\circ} 30'$; $Bx_y \wedge \dot{c} = +4^{\circ} 0'$, $Bx_{gr} \wedge \dot{c} = +4^{\circ} 58'$.

On the alteration of pyroxene, or a mineral of the pyroxene group, into amphibole in gabbros

and related rocks, see Chester, U. S. Surv., Bull. 59, 1890.

On the relation between the gliding-planes and solution-planes with augite, see Judd, Min. Mag., 9, 192, 1890.

A chrome diopside from the basalt of Stempel near Marburg, investigated by Bauer (Jb. Min., 2, 187, 1891), has been analyzed by Friedheim, as follows:

Cr2O3 SiO, Al2O3 FeO CaO MgO $G_{\cdot} = 3.289$ 52.95 2.43 2:31 19.11 18.01 = 100

QUARTZ, p. 183. Minute crystals (cf. figs. 1-3), characterized by the presence of the rhombohedron j (3032) and the trapezohedrons N (2132) and L, (3122), are described by Iddings and Penfield from the hollow spherulites of the rhyolyte of Glade Creek, Wyoming. Am. J. Sc., 42, 39, 1891.

Friedel has described artificial crystals which seem to be twins with (4489, § 2) as tw. plane, the axes crossing nearly at right angles. Bull. Soc. Min., 11 29, 1888 (and Zs. Kr., 18, 333. On crystals from Sarolay, see Cesaro, Mem. Soc. G. Belg., 17, 1890.

Cathrein has described crystals of amethyst from the Zillerthal, Tyrol, showing the new

forms. Zs. Kr., 17, 19, 1889.

 ρ (7075, 7), (11.1. $\bar{1}\bar{2}$.12, +1. $\frac{1}{7}$ r), (1.11. $\bar{1}\bar{2}$.12, -1. $\frac{1}{7}$ l), (8.1. $\bar{9}$.10, + $\frac{9}{7}$.2 r), (9 $\bar{2}$ 78, + $\frac{9}{8}$.2 l).

Lacroix notes the occurrence of cristobalite and tridymite associated with quartz in the basalt of Mayen in the Eifel. Bull. Soc. Min., 14, 185, 1891.

Beaulard discusses the effect of pressure upon sections of quartz crystals in producing biaxial phenomena, etc., C. R., 112, 1503, 1891.

Realgar, p. 33. On the realgar, orpiment, and associated minerals of Casa Testi, M. Amiata, Prov. of Grosseto, Tuscany, see Grattarola, Giorn. Min., 1, 232, 1890. The new but uncertain form α (313, 1-3) is noted.

Occurs with orpiment as a hot-spring deposit in the Norris Geyser Basin in the Yellowstone Park, Weed & Pirsson, Am. J. Sc., 42, 403, 1891.

RESANITE Cleve, Ak. H. Stockh., 9, No. 12 (Nov. 1870). Geol. West India Islands, p. 28. Massive, olive-green color, uncrystalline. Analysis.—Fiebelkorn:

 SiO_2 35·08, CuO 23·18, Fe_2O_3 9·91, H_2O 23·15 (at 100°), H_2O 8·53 (ignition) = 99·85.

It is easily decomposed by HCl. Found with malachite and chrysocolla, at Puerto Rico (Luquillo), West Indies, and named from Don Pedro Resano.

Rhodonite, p. 378. Crystals from Pajsberg, of very varied habit, have been described by Hamberg. They show the new forms κ (221, '2), ϑ (403, $\frac{4}{3}$ - $\tilde{\iota}_1$), δ (623, 2-3). Careful measurements are given and a new axial ratio calculated, corresponding to a new position proposed.

G. För. Förh., 13, 545, 1891. New analyses (ibid., p. 572): 1, Fräulein Naima Sahlbom; 2-4, Gunnar Paykull.

	SiO ₂	MnO	FeO	CaO	MgO
1.	46.49	43.60	0.84	7.18	$0.90 \text{Al}_2\text{O}_3 \ 0.41 = 99.42$
2.	46.35	45.25	0.53	6.96	0.84 = 99.93
3.	46.53	43.20	3.03	6.20	0.72 Al ₂ O ₃ $0.15 = 100.13$
4.	45.86	45.92	0.36	6.40	1.65 = 100.19

RIEBECKITE, p. 400. A secondary amphibole, resembling that described by Cross (p. 402), has been noted by Lane in the rocks of the Lake Superior region. Am. J. Sc., 42, 508, 1891. On the occurrence in Great Britain, see Teall, Min. Mag., 9, 219, 1891; and Cole, ibid., p. 222.

ROWLANDITE W. E. Hidden, Am. J. Sc., 42, 430, 1891.

An yttrium silicate occurring in massive form with the gadolinite of Llano Co., Texas (pp. 511, 512). G. =4.515. Color pale drab-green when pure, transparent in thin splinters. Alters to a waxy brick-red mineral. A partial analysis gave:

SiO₂ 25·98 Y₂O₃ 61·91* FeO 4·69 UO₃ 0·40 CaO 0·19 ign., etc., 2·01 *At. wght. 118.

Oxygen ratio of bases to silica = 83.47:86.60 or nearly 1:1, hence the formula $2Y_2O_3.3SiO_2$. Easily soluble in acids, leaving gelatinous silica.

Named after Prof. Henry A. Rowland of Baltimore.

RUTILE, p. 237. The peculiar crystals of black rutile from the Black Hills, mentioned on p. 238, have been more fully studied by Headden and Pirsson; the form is shown in the accompanying figure. Am. J. Sc., 41, 249, 1891. Analyses by Headden: gave:

TiO ₂	SnO ₂	FeO	MnO
90.78	1.32	8.10	tr. = 100.20
90.80	1.38	7.92	tr. = 100.10

The paramorphs of rutile after brookite from Magnet Cove, Arkansas (pp. 239, 243), have been minutely described by Bauer (Jb. Min., 1, 217, 1891). Also the pseudomorphs of rutile after octahedrite ("captivos" Damour) from the gold-washings of Brazil, ibid., p. 232.

Sanguinite H. A. Miers, Min. Mag., 9, 182, 1890. Occurs in fine glittering scales usually curved or crumpled; crystallization hexagonal or rhombohedral. Fracture conchoidal. Color black by reflected light, but by transmitted light red like prousite only slightly darker; in very thin scales yellowish red. Streak dark purplish brown. Optically uniaxial. Determined by qualitative trials to be a sulpharsenite of silver, hence near proustite in composition, with which it occurs on argentite from Chañarcillo.

SARAWAKITE Frenzel, Min. Mitth., 300, 1877. Occurs in minute crystals, with many planes and rounded angles, "probably tetragonal." Soft. Luster adamantine. Colorless or wine-yellow to greenish yellow. Transparent. Contains antimony, is anhydrous, and, it is suggested, may be an antimony chloride. Found in cavities in the native antimony of Borneo.

Schuchardtite Schrauf, Zs. Kr., 6, 386, 1882. A name given by Schrauf to the so-called Chrysopraserde (p. 677), from Gläserndorf, Silesia. Cf. Starkl, ib.; 8, 239, 1883.

SERPENTINE, p. 669. On the serpentine of the Lizard district, Cornwall, see Bonney and McMahon, Q. J. G. Soc., 47, 464, 1891.

SHALKITE. Same as piddingtonite, p. 385.

SIDERITE, p. 276. A crystal from Algeria has been described by Cesàro which showed the new form $(4159, \frac{1}{3})$. Ann. Soc. G. Belg., 18, 1891.

SNARUMITE Breith., B. H. Zig., 24, 364, 1865. A mica-like cleavage in one direction, and another transverse imperfect. Occurs massive and in tufts columnar in structure, with H = 4 -5.5, the least on cleavage-surface; G = 2.826; luster on cleavage-face pearly, elsewhere

Yellowstone.

vitreous; color mostly reddish white, colorless, grayish white. Comes from the shore of the Snarum-Elf, near Snarum, in Norway. Analysis by Lichtenberger (Jb. Min., 820, 1872) gave:

	Al_2O_3						
67.42	28.21	0.42	0.18	0.24	0.93	2.15	0.23 = 99.78

On another snarumite, see p. 384.

SORDAVALITE. Sordawalit N. Nordenskiöld, Finl. Min., 86, 1820. A grayish or bluish black glassy substance from Sordavala in Finland. Like tachylyte earlier regarded as a mineral, but shown to be only a local vitreous form of diabase; a dike of this rock cuts through the hornblende schists, and while crystalline in the mass, becomes more compact toward the margin, and finally at the contact there is a vitreous band one to two inches thick of the so-called sordavalite. Of. Löwinson-Lessing, Min. Mitth., 9, 61, 1887, who also gives the literature and history.

Sphalerite, p. 59. Cesàro has described crystals showing the hemi-hexoctahedron (861, 8-\frac{4}{8}). Mem. Soc. G. Belg., 17, 1890.

Spinel, p. 220. Formation of various kinds of spinel in slags and recent eruptive rocks, see Vogt, Arch. Math. Nat., 14, 11, 1890.

STELLARITE. A name given by How to the so-called "stellar coal" or "oil-coal" which occurs with bituminous coal at the Acadia mines, Picton Co., Nova Scotia. It is regarded by Dawson as essentially an earthy bitumen.

STEPHANITE, p. 143. Prior (Min. Mag., 9, 11, 1890) has given the following analyses:

	G.	S	Sb	Ag	
1. Copiapo	6.26	16.02	15.22	68.65 As	tr. Cu tr. = 99.89
2. Cornwall	6.24	15.95	15.86	68.21	Fe $tr. = 100.02$

STIBNITE, p. 36. On the reflection of light from the cleavage (b) surface of stibnite crystals, see Drude, Wied. Ann., 34, 489, 1888.

Analysis of specimens from Hungary, see J. Loczka, Ber. aus Ungarn, 8, 99, 1891.

STROMEYERITE, p. 56. Occurs at the Silver King mine, Calico distr., San Bernardino Co., California. Analysis, Melville and Lindgren, U. S. G. Surv., Bull. 61, 27, 1890.

G. =
$$6.28$$
 S 15.51 Ag 53.96 Cu 28.58 Fe 0.26 gangue $1.55 = 99.86$

STRONTIANITE, p. 285. Buchrucker (Zs. Kr., 19, 146, 1891) has described crystals from Leogang, Salzburg, and made the following optical determinations; indices of refraction:

	α	β	γ
For Li	1.514	1.515	1.659
" Na	1.515	1.516	1.667
" Tl	1.519	1.520	1.670
Also $2E_r = 10^\circ$	30' Li 2E,	= 10° 36′ Na	$2E_{gr}=10^{\circ} 54' Tl$
From 2E and β ,	$2V_{r} = 6^{\circ} 55\frac{1}{2}'$	$2V_y = 62^\circ 59'$	$2\mathrm{V_{gr}}=7^\circ~10^\prime$

SULPHUR, p. 8. Crystals from "Bassick in the United States" described by Busz showed the new forms: g (337, $\frac{3}{8}$), f (335, $\frac{3}{8}$); calculated angles for the axial ratio of p. 8: $cg = 52^{\circ}$ 17', $cf = 61^{\circ}$ 5'. Zs. Kr., 17, 549, 1890.

Crystals with the above noted form $f(335, \frac{2}{5})$ have also been described by G. H. Williams from the Mountain View mine, Carroll Co., Md. They occur distributed through the decomposed galena, with anglesite, cerussite. Johns Hopkins Univ. Circ., No. 87, April, 1891.

Weed and Pirsson have described the occurrence and form of crystals from the Yellowstone Park, Am. J. Sc., 42, 401, 1891. They show the forms (cf. fig.), c (001), m (110), h (130), e (101), n (011), t (115), s (113), g (112), p (111), x (133), q (131). Crystals occurring with stibnite from Allchar, near Rozsdau in Macedonia have been described by Foullon, Vh. G. Reichs., No 17, Dec. 1890.

On the thermic constants, see Schrauf, Zs. Kr., 12, 321, 1886. On the optical constants at different temperatures, Id., ibid., 18, 113, 1890.

A new *rhombohedral* variety is described by Friedel, obtained by Engel by agitating with chloroform a solution of sodium hyposulphite treated with concentrated hydrochloric acid. The crystals are prisms terminated by

rhombohedral faces, with $rr'=40^\circ$ 50', and optically uniaxial, negative. G. = 2·135. Transparent when first found, but change gradually, with decrease of density into insoluble sulphur. A relation to the rhombohedral form of tellurium is suggested. C. R., 112, 834, 866, 1891.

The "black sulphur" of Magnus (p. 10) is regarded by Knapp as not properly a modification of sulphur, but as consisting of such a modification adhering to or condensed with a carbonization-product of the oil itself, containing sulphur. J. pr. Ch., 43, 305, 1891. Also earlier, ibid., 38, 55, 1888.

Sychnodymite Laspeyres, Zs. Kr., 19, 17, 1891.

Isometric. Observed forms: a (100, ii), o (111, 1), d (110, i)?, m (311, 3-3), n (211, 2-2). In small octahedral crystals, in part with polysynthetic twinning, tw. pl. o, analogous to polydymite; also massive. G = 4.758. Luster metallic. Color steel-gray. Comp.—Essentially (Co,Cu)₄S₅, like the nickel sulphide, polydymite; a small part of the

cobalt is replaced by nickel.

Anal.-1, 2, Laspeyres, l. c.

	S	Cu	Co	Ni	Fe
1.	40.64	18.98	35.79	3.66	0.93 = 100
2.	40.33	17.23	35.64	5.74	0.82 = 99.76

Dissolves in nitric acid, giving a red solution.

Obs.—From the Kohlenbach mine, south-east of Eiserfeld in the Siegen district; associated with quartz, siderite, tetrahedrite, etc. It is near carrollite (p. 76), to which, however, the formula R₃S₄(CuS. Co₂S₃) has been assigned.

Named from $\sigma v \chi v \dot{v} \dot{i} = \pi o \lambda \dot{v} \dot{i}$, as a name corresponding to the related species, polydymite.

SYLVITE, p. 156. On etching-figures, see Linck, Min. Mitth., 12, 82, 1891. On indices of refraction, see Dufet, Bull. Soc. Min., 14, 143, 1891. On double refraction developed by pressure, Pockels, Wied. Ann., 39, 440, 1890.

Tachhydrite, p. 178. Artificial rhombohedral crystals have been obtained by A. de Schulten. They have $rr'=101^\circ$ 20', and G. = 1.666. Analysis gave: Cl 40.40, Ca 7.56, Mg 9.25, H₂O 42.44 = 99.65 (author gives Ca 9.56 and sum 99.65). C. R., 111, 930, 1890.

TACHYLYTE Breith., Kastn. Arch. Nat., 7, 112, 1826. A glassy substance, pitch-black or velvet-black in color, at one time regarded as a homogeneous mineral, but undoubtedly only a basaltic glass. The original was from Säsebühl, between Dransfeld and Göttingen, but it is not an uncommon occurrence. Named from ταχύς, quick, and λυτός, dissolved, in allusion to its fusibility.

Hyalomelan (Hausm., Handb., 545, 1847) is a similar substance rightly referred by Gmelin to tachylyte from Vogelsberg. Hausmann applied to it the name hyalomelan. Here belongs

also the schlackige Augit of Karsten from Guiliana, Sicily.

Tamm analyzed a dark steel-colored crystalline powder, locality unknown, very hard. G. = 12·5. He obtained W 88·05, Fe 5·60, Mn 0·15, undetermined 6·20 = 100. The loss he says is not due to oxygen. He calls his unknown substance ferro-tungstine, and proposes, in case the character of the mineral is sustained, to give it the name crookesite. Mr. Crookes justly says that the name tammite should be preferred. Chem. News, 26, 13, July, 1872. It may be only an artificial alloy.

Telaspyrine C. U. Shepard, Contrib. Min., 1877. Pyrite containing tellurium, from Sunshine Camp, Colorado.

Tellurite, p. 201. Vrba has described artificial crystals which are in tetragonal pyramids with the forms: a (100, ii), p (111, 1), r (221, 2); $pp' = 51^{\circ} 42'$, hence c = 0.5539. Zs. Kr., 19, 1, 1891.

Tellurium, p. 11. Analyses 1, 2, from Facebaya, Transylvania, by J. Loczka, Ber. aus Ungarn, 8, 104, 1891. The material of anal. 1 contained quartz and pyrite.

Te Se Au Fe S Quartz
1.
$$80.39$$
 0.33 0.33 8.55 9.26 $1.54 = 100.40$
2. G. = 6.083 97.92 tr . 0.15 0.53 — 1.56 Cu $0.06 = 100.22$

TENNANTITE, p. 137. Penfield (priv. contr.) has investigated the tennantite and polybasite from the Mollie Gibson mine near Aspen, Colorado. The former occurs massive, of steel-gray color and reddish streak. Analysis gave:

	S	As	Sb	Cu	Ag	Zn	Fe	Pb
$G_{\cdot} = 4.56$	25.04	17.18	0 13	13.72	13.65	6.90	0.42	0.86 = 99.90

The ratio of all the metals to As₂(Sb)₂ is 4.00:0.99, agreeing closely with the formula

4Cu₂S.As₂S₃. It is remarkable in the high percentage of silver.

The polybasite, or "brittle silver" of the local miners, occurs both indistinctly crystallized and massive; it is associated commonly with a pink barite, also siderite, etc. Analyses gave the following results, after the deduction of 28:18 p. c. impurities from 1, and 12:81 p. c. from 2:

	S	As		Ag	Cu	Zn
1. Massive 2. Crystallized	17.73	6 29 7:01	0.18	59.73	12.91	3.16 = 100 2.81 = 100
2. Crystallized	18.13	7.01	0.30	56.90	14.85	

Both analyses conform to 9Ag₂S.As₂S₃.

Tennantite and polybasite appear to be rather common minerals in Colorado. Much of the so-called tetrahedrite or "gray copper" is the related arsenical species; thus it is common in the mines near Central City, at the Freeland lode and Crocett mine near Idaho Springs, and at the National Bell mine near Red Mountain. Further, in addition to the localities for polybasite, noted on pp. 146 and 1044, it occurs well crystallized in the mines about Georgetown, in the Markhall Basin near Tellurida and probably at a number of mines in the Red Mountain districts. Marshall Basin near Telluride, and probably at a number of mines in the Red Mountain district.

TEQUEZQUITE. Corruption of Tequixquitl, a mineral substance formed of mixtures of different salts, especially sodium carbonate and sodium chloride; from Texcoco, Zumpango, in the Valle de Mexico, and elsewhere in Mexico, chiefly as a surface efflorescence. Naturaleza, 3, 239-246, 1875.

TETRADYMITE, p. 39. New analyses: 1, from Norongo, near Captain's Flat, New South Wales, J. C. H. Mingaye, Rec. G. Surv. N. S. W., 1, 25. 2, Zsupkó, Hungary, J. Loczka, Ber. aus Ungarn, 8, 102, 1891. 3, Rezbánya, Hungary, Id., ibid., p. 107.

	G.	Te	S	Bi
1. Norongo	7.381	33.16	4.54	$59.66 \text{ Fe } 0.42, \text{ SiO}_2 \ 0.40 = 98.18$
2. Zsupkó	7.580	34.75	4.18	59.77 Fe $tr.$, insol. $0.16 = 98.86$
3. Rezbánya	7.022	35.69	4.00	57.42 Fe 0.19, Cu 0.03, insol. 2.04 = 99.37

All these analyses correspond to Bi₂Te₂S or 2Bi₂Te₃. Bi₂S₃, supporting the view of the composition taken on p. 39.

THERMONATRITE, p. 300. Described by E. Scacchi as occurring as an opaque white cavernous incrustation at the Fosso Grande, Vesuvius. Rend. Accad. Napoli, 2, 488, Dec. 1888.

Thomsonite, p. 607. Hahn has described crystals from Mettweiler, near St. Wendel. They are prismatic in habit, with a, b prominent, and show also the brachydome x (0.1.48) and the new pyramid s (334). Measured angles: $as = 57^{\circ} 26'$, $bs = 58^{\circ} 37'$. Zs. Kr., 19, 171, 1891.

Thorite, p. 488. A kind from Landbö, Norway, has a resin-yellow color, G. = 4.322, and contains 9 p. c. UO₃ (11.97 p. c. H₂O). Hidden, Am. J. Sc., 41, 440, 1891.

THROMBOLITE. Thrombolith Breith., J. pr. Ch., 15, 321, 1838.

An amorphous emerald-green mineral, found with malachite in a fine-grained limestone at Rezbanya, Hungary. According to an imperfect analysis by Plattner it contained chiefly P_2O_5 , CuO, H_2O . Schrauf, however, obtained: CuO 39 44, F_2O_3 1 05, H_2O 16 56, Sb_2O_5 6 65, Sb_2O_3 32 52, loss 3 78 = 100. G. = 3 67. Zs. Kr., 4, 28, 1879. Very probably only a mixture.

TIEMANNITE, p. 63. Occurs with eucairite in the Sierra de Umango, Argentine Republic. Analysis by F. Klockmann, after deducting 11.3 p. c. residue, gave:

Se
$$29.0$$
 Hg 56.9 Ag 5.3 Cu $8.8 = 100$

The silver and copper belong to admixed eucairite. Zs. Kr., 19, 267, 1891.

Tourmaline, p. 551. Memoir (in Russian) on the crystallographic and optical properties by A. N. Karnozhitsky, Vh. Min. Ges., 17, 209, 1891. F. Noetling describes the tourmaline mines near Mainglôn, Rec. G. Surv. India, 24, 125, 1891.

TRICHITE, BELONITE. The name *trichite* (from $\theta \rho i \xi$, hair) is applied by Zirkel (Zs. G. Ges., 19, 744, 1867) to microscopic capillary forms, often curved, bent, or zigzag, sometimes stellately aggregated, opaque and black or reddish brown, of undetermined nature, which he detected in some kinds of glassy or semi-glassy volcanic rocks; and *Belonite* (ib., 738) to microscopic acicular crystals (whence the name, from $\beta \in \lambda o \nu \eta$, a needle), colorless and transparent. The trichite, he states, is not pyroxene or hornblende; the belonite may be a feldspar.

TROILITE, p. 72. Artificial crystals, like wurtzite in form and having the composition FeS, have been obtained by Lorenz, by passing dry hydrogen sulphide over a bundle of iron wires in a tube heated in a combustion-furnace. Wurtzite, in well formed hemimorphic crystals, was obtained in a similar manner, also millerite and further greenockite; the last in forms like the native mineral and also in monoclinic crystals. Ber. Ch. Ges., June, 1891.

TyreeITE Heddle, Min. Mag., 4, 189, 1881. One and a half hundred-weight of the carnelian marble of Tyree, Scotland, dissolved in sixteen gallons of dilute hydrochloric acid left as a residue, thirty pounds salite, a little scapolite and titanite, and some ounces of a red mud. By decantation, 1.91 grams of a powder of deep brick-red color was obtained. Of this mud, sulphuric acid dissolved 0.78 gram, leaving 1.13 insoluble. The last was analyzed and decided to be an impure talc. The soluble portion yielded: Fe₂O₃ 38.22, Al₂O₃ 8.23, FeO 3.16, MnO 0.39, MgO 29.94, CaO 2.21, H₂O 12.47, P₂O₅ 4.71, SiO₂ 1.02 = 100.35. To this last obviously heterogeneous substance the new name is provisionally given.

ULLMANNITE, p. 91. Miers describes crystals of ullmannite, from Sarrabus, Sardinia,

which, as shown by the striations upon the cubic faces (cf. fig. 1) are twins of tetartohedral and enantiomorphous individuals. The faces of a trigonal trisoctahedron approximating to (27.27.1, 27) occur on the cubic edges. Min. Mag., 9, 211, 1891.

Crystals from the Landeskrone mine, near Wilnsdorf in the Siegen region, have been described by Laspeyres, which show the forms: a (100, $i \cdot i$), d (110, i), o (111, 1); pyritohedrons, $q(750, i \cdot \frac{1}{6}), f_i(130, -i \cdot 3)$, e, (120, $-i \cdot 2$), k (322, $\frac{3}{2} \cdot \frac{3}{2}$); diploid,

 $\rho_{1}(261, -6-3).$

Fig. 1, Sardinia, Miers

2, Siegen, Laspeyres.

The crystals are pyritohedral in habit (cf. fig. 2) and do not show the tetartohedral character noted above, Zs. Kr., 19, 424, 1891.

Umangite F. Klockmann, Zs. Kr., 19, 269, 1891.

Massive; in fine granular to compact masses, no cleavage observed. Fracture uneven to small conchoidal. H. = 3. G. = 5.620. Luster metallic. Color dark cherry-red with a violet tinge on the fresh fracture, soon tarnishing, the color becoming violet-blue. Streak black. Opaque.

Comp.— Cu_3Se_2 or CuSe. Cu_2Se = Selenium 45.4, copper 54.6 = 100.

Anal. -1, 2, F. Klockmann, P. c.: 1, of a relatively pure fragment; 2, of the portion of another sample insoluble in acetic acid reduced to 100.

> Ag 0.49 Se 41.44 Cu 56.03 $CO_2, H_2O, O [2.04] = 100$ 45.10 54.35 0.55

Obs.—Occurs with eucairite and tiemannite at the Sierra de Umango, La Rioja, Argentine Republic.

VALAITE W. Helmhacker, Jb. G. Reichs, 17, 210, 1867. Crystallized. Partly in small hexagonal tables, but forms not distinct. Also massive. Fracture uneven. H. below 1.5. Luster shining. Color pitch-black. Streak black. Odor aromatic when rubbed between the fingers. Belongs among the resins, but composition undetermined. B.B. swells to more than 10 times its former bulk, and becomes a light, porous mass, which in a higher heat is reduced to a grayish ash. Occurs in thin crusts on dolomite and calcite, or in druses of small crystals, in the Rossitz-Oslawaner Coal formation, Moravia. It is associated with hatchettite (p. 997) and the same bed affords some mineral oil.

VESBINE. A name given by *Scacchi* to the material forming thin yellow crusts on the lava of 1631, Vesuvius, which is supposed to contain a new element called by him *vesbium*. Att. Accad. Napoli, Dec. 13, 1879.

Vestorien. Bleu Egyptien. Bleu de Pouzzoles. Egyptian Blue. An artificial enamel used for ornament by the Romans in the early centuries of the Christian era. It is essentially a silicate of copper and calcium, corresponding approximately, according to Fouqué (Bull. Soc. Min., 12, 36, 1889) to the formula CaO. CuO. 48iO₂. G. = 3.04. Analysis, Fouqué:

See further Pisani, Bull. Soc. Min., 3, 197, 1880, and Michault, ibid., 4, 31, 1881, who give other analyses, showing a considerable variation in composition, in one case 6.7 p. c. Na₂O and 28.3 p. c. PbO.

Wehrlite, p. 40. Mingaye has noted the occurrence of a telluride, which he refers to wehrlite, at the Mt. Shamrock gold mine, Queensland. Found in thin folia with brilliant luster and light steel-gray color. G. = 8.05. Proc. R. Soc. N. S. W., 23, 327, 1890.

Wehrlite von Kobell. A doubtful mineral substance from Szurraskö, Zemescher Comitat, Hungary, referred to lievrite by Zipser, Jb. Min., 627, 1834. Shown by Fischer to be a mixture.

WICHTISITE. Wichtyne Laurent, Ann. Ch. Phys., 59, 107, 1835. Wichtisit Hausmann. Wibtisit. From Wichtis in Finland, probably the same substance as sordavalite, p. 1048.

Wollastonite, p. 371. Grosser has given a series of measurements on crystals from Vesuvius. From the measured angles, $001 \land 110 = 86^\circ$ 16, $001 \land 011 = 43^\circ$ 51', $100 \land 110 = 46^\circ$ 20', he calculates, $\grave{a}: \grave{b}: \grave{c}=1.05235:1:0.96494; \; \beta=84^\circ$ 35' 20". Zs. Kr., 19, 604, Dec. 4, 1891.

Among the contact-minerals occurring in connection with the igneous rock of the Potash Sulphur Springs, near Magnet Cove, Arkansas, J. F. Williams has described (Ann. Rep. G. Ark., 2, 355 et seq., 1891) a calcium silicate near wollastonite, but containing some water, which, however, is in part hygroscopic and in part due to alteration. Analyses by R. N. Brackett (p. 356 et seq.) gave:

	SiO ₂	CaO	FeO	MnO	MgO	Na_2O	K_2O	igņ.
1. White	51.93	42.55	2.03	2.08	0.44	_	2000	1.23 = 100.26
2. Pink	50.96	36.72	1.69	1.40	0.57	4.41	0.90	2.74 = 99.39

Both minerals are regarded as altered wollastonite; that of anal. 2 is peculiar in containing sodium and is called *natroxonotlite* since it approximates to the imperfectly known hydrous calcium silicate, xonotlite (p. 569).

ZINCITE, p. 208. Artificial crystals of a pale yellow color, with G. = 5.605, from a furnace at Mostyn, N. Wales, have been described by A. Hutchinson. They are doubly terminated pyramids or quartzoids, showing one form (y) only; also a number of pyramids in the same zone, with the basal plane and a pyramid of the other series r (1011) Hutchinson, = d (1121) of p. 208. Referred to these two positions the forms noted are:

p. 208 Hutchinson	p. 208 Hute	chinson
c(0001) = c(0001)	$n(10\bar{1}2) = m(1$	$1\bar{2}3)$
$d(11\bar{2}1) = r(10\bar{1}1)$	$p(10\tilde{1}1) = x(2)$	$(2\bar{4}3)$
$f(10\bar{1}8) = f(1\cdot 1\cdot \bar{2}\cdot 12)$	$y (20\bar{2}1) \doteq y (4$	$(4\bar{8}3)$
$s (10\bar{1}3) = k (22\bar{4}9)$	$m(10\bar{1}0) = a(1)$	$1\bar{2}0)$

Of the above, f is new but uncertain; the author suggests the complex symbol, $4.4.\overline{8.51}$, with which the observed angle ($ef = 12^{\circ} 14'$) agrees more closely. Min. Mag., 9, 5, 1890.

ZINC, p. 14. Stated to occur in Transvaal, S. Africa, W. E. Dawson, Min. Mag., 6, xix, 1885. The reported occurrence in Shasta Co., California, referred to on p. 14 has not been positively substantiated (Durden).

ZIRCARBITE C. U. Shepard, Contrib. Min., 1877. A massive, compact, or cellular, yellowish brown, opaque mineral. H. = 2-2-5. B.B. infusible. Chemical nature unknown. With cyrtolite, at the granite quarries of Rockport, Mass.

ADELITE H. Sjögren, G. För. Förh., 13, 781, 1891. A basic arsenate of calcium and magnesium from Nordmark and Långban, Sweden. In masses of a gray color. H.=5. G.=3.76. Calculated formula: $H_2O.2CaO.2MgO.As_2O_5$. A relation to the olivenite or wagnerite group is suggested.

SVABITE H. Sjögren, G. För. Förh., 13, 789, 1891. In hexagonal prisms with the forms: c (0001, O), m (1010, I), x (1011, 1), v (1121, 2-2); measured angles $xx' = 36^{\circ}$ 10', $mx = *50^{\circ}$ 29', .: b = 0.7143. H. = 5. G. = 3.52. Luster vitreous to greasy. Colorless. Also in fibrous crystalline aggregates. Calculated formula: $H_2O.10CaO.3As_2O_5$; a relation to the apatite group is suggested. From the Harstig mine at Pajsberg, Sweden, associated with schefferite.

CATALOGUE OF AMERICAN LOCALI-TIES OF MINERALS.

THE following catalogue of American Localities of Minerals is supplementary to the Descriptions of Species. It is intended to give fuller information than was possible in the preceding pages of the occurrence of individual species and their association. It is essentially an historical list, and does not claim to state what minerals may be found at a given place at the present time. Many localities once prolific are now exhausted, and many others will yield specimens only after much time and money have been spent in opening them. Notwithstanding these limitations, however, the catalogue will prove of great aid to the mineralogical collector in selecting his routes and arranging the plan of his journeys.

Except in the case of very rare species, only important localities, which have afforded cabinet specimens, are in general included; and the names of those minerals obtained in good specimens are distinguished by italics. When the name is not italicized, the occurrence is not regarded as especially noteworthy. When the specimens procured have been remarkably good, an exclama-

tion-mark (!) is added.

Localities for coal and oil are not given, and, for the most part, only general statements are made in regard to the occurrence of the peculiarly economic minerals, such as ores of iron, marble, etc. For detailed information in regard to these points, the reader should turn to the series of volumes on the *Mineral Resources of the United States*, published since 1882, under the auspices of the U. S. Geological Survey. The volume for 1887 (pp. 688-812) gives a summary for each state and territory of the localities of useful minerals, both those which are now mined and those which are not. In regard to the occurrence of marble and building stones in general, reference may be made to a recent work by George P. Merrill, Stones for Building and Decoration, New York, 1891.

This Catalogue has been carefully revised since it last appeared in print, and in this revision the author has been ably assisted by many gentlemen, whose contributions have done much to give it greater accuracy and completeness. Those who have taken chief part in the revision are

as follows:

as follows:
For Arizona and the south-western territories, also notes on Colorado, Mr. George L. English of New York City; California, Mr. Henry S. Durden of San Francisco; Colorado, also northern New York, Prof. S. L. Penfield of New Haven; Idaho and Montana, Mr. W. H. Melville of Washington; Maine, Prof. F. C. Robinson of Bowdoin College; Delaware, Mr. Fred. J. Hilbiber of Wilmington; Maryland, Prof. G. H. Williams of Baltimore; Michigan, Prof. A. C. Lane of Houghton; Minnesota, Prof. C. W. Hall of Minneapolis; Missouri, Mr. Walter P. Jenney of the U. S. Geol. Survey, and Prof. H. A. Wheeler of St. Louis; North Carolina (also notes on Pennsylvania), Dr. F. A. Genth of Philadelphia; Pennsylvania, Dr. F. A. Genth, Dr. T. D. Rand, and Col. Joseph Willcox of Philadelphia; Texas, also S. Carolina, and notes on N. Carolina, Mr. W. E. Hidden of Newark; Virginia, Profs. W. G. Brown and H. D. Campbell of Lexington, also Profs. F. P. Dunnington and W. M. Fontaine of the University of Virginia; Wisconsin, Prof. Wm. H. Hobbs of Madison; Canada, Mr. G. Ch. Hoffmann of Ottawa. Ottawa.

Also general notes from several of the gentlemen above named, and from Prof. F W. Clarke of Washington, Mr. George F. Kunz of New York City, and minor notes from others.

INDEX OF STATES AND TERRITORIES.

Also Dominion of Canada.... p. 1098; Newfoundland.....p. 1104.

MAINE.

General Notes for the New England States.—The most interesting localities of Maine, as of the other New England States, are those of the veins of albitic granite, often worked economically for their feldspar, mica, quartz, and frequently affording fine specimens of many rare minerals, chiefly as accessory original constituents of the veins, in part also secondary. Among these species may be mentioned, the lithium minerals, lepidolite, red and green tourmaline, amblygonite, spodumene, petalite, triphylite (and lithiophilite); also beryllium minerals, beryl, chrysoberyl, and rarely herderite, phenacite, beryllonite; further, columbite, cassiterite, uraninite, and many others.

In Maine, localities of this class are chiefly in the western part of the state in Oxford Co.; they also occur in New Hampshire, as at Acworth; in Massachusetts, as conspicuously at Chesterfield and Goshen; in Connecticut, as at Haddam, Middletown, Portland, Glastonbury, also at Branchville and vicinity, and elsewhere. Further, similar occurrences are found in Pennsylvania, Virginia, and North and South Carolina. The crystalline schists of New England often afford garnet, tourmaline, and alusite, staurolite, sillimanite, cyanite; also occasionally monazite, corundum, iolite, etc. In Massachusetts and Connecticut there are some interesting localities of zeolites and associated species (datolite, prehnite, etc.) connected with the dikes of "trap" rock.

In New England, mining for gold, silver, also tin (Maine, New Hampshire), has been attempted at various points on a small scale, but with no success; copper, however, is obtained in economic quantities (e.g., Vermont), while the iron mines of western Massachusetts and Connecticut have been long productive. Other useful minerals sometimes obtained in paying quantities (besides the feldspar, etc., noted above) are steatite, graphite, marble, etc.

Albany.—Beryl! green and black tourmaline, garnet, feldspar, rose quartz, rutile. Andover.—See Rumford.

Auburn, w. part, near Minot line.—Lepidolite, amblygonite, cassiterite, colorless, green, blue, etc., tourmaline! apatite, herderite, triplite, cookeite, allanite, garnet, molybdenite, beryl, albite, orthoclase, quartz, biotite, damourite.

Bath.—Vesuvianite, garnet, magnetite, graphite.

Bethel.—Cinnamon garnet, calcite, titanite, beryl, pyroxene, amphibole, epidote, graphite, talc, pyrite, arsenopyrite, magnetite.

Bingham.—Massive pyrite, galena, sphalerite, andalusite.

Blue Hill Bay. - Arsenical iron, molybdenite! galena, apatite! fluorite! black tourmaline (Long Cove), black oxide of manganese (Osgood's farm), rhodonite, bog manganese, wolframite. At the Blue Hill copper mines, chalcocite, chalcopyrite, cuprite, bornite, tetrahedrite, arsenopyrite, pyrite.

Bowdoin. - Rose quartz.

Bowdoinham.—Beryl, molybdenite.

Brunswick.—Green mica, garnet! black tourmaline! molybdenite, epidote, calcite, muscovite, feldspar. beryl, titanite, columbite, pyrite, rutile.

Buckfield.—Garnet (estates of Waterman and Lowe), muscovite! tourmaline! magnetite.

Byard's Point.—Arsenopyrite.

Camdage Farm.—(Near the tide mills), molybdenite, wolframite.

Camden.—Chiastolite, galena, epidote, black tourmaline, pyrite, talc, magnetite.

Canton.—Chrysoberyl, feldspar, mica (mined).

Carmel (Penobscot Co.).—Stibnite, tetrahedrite, pyrite, chiastolite.

Corinna. - Pyrite, arsenopyrite.

Deer Isle.—Serpentine, verd-antique, asbestus, diallage, magnetite, talc (mined), barite.

Dexter.—Galena, pyrite, sphalerite, chalcopyrite, green talc.

Dixfield.—Native copperas, graphite. East Woodstock. - Muscovite, garnet.

Farmington.—(Norton's Ledge), pyrite, graphite, garnet, staurolite.

Franklin Plantation.—Beryl.

Freeport. -Rose quartz, garnet, feldspar, scapolite, graphite, muscovite, amphibole, green

Fryeburg.—Garnet, beryl.

West Gardiner, along the Litchfield border. See LITCHFIELD. Georgetown. —(Parker's Island), beryl! black tourmaline, graphite.

Gorham. - Andalusite.

Greenwood.—Graphite, black manganese, beryl! chrysoberyl, arsenopyrite, cassiterite, mica,

rose quartz, garnet, corundum, albite, zircon, molybdenite, magnetite, melanterite.

Hebron, 7 m. s. of Mt. Mica in Paris.—Lepidolite, amblygonite (hebronite), rubellite! indicolite, green tourmaline, damourite (as altered tourmaline), mica, beryl, apatite, albite, pollucite, childrenite. herderite, cookeite, cassiterite, arsenopyrite, vesuvianite.

Katahdin.—Mines of limonite, hematite.

Linnæus. - Hematite, limonite, pyrite, bog-iron.

Litchfield.—Sodalite, cancrinite, elwolite, zircon, hydronephelite, albite, spodumene, muscovite, pyrrhotite (from boulders), biotite.

Lovell.—Beryl.

Lubec Lead Mines.—Galena, chalcopyrite, sphalerite, bornite.

Machiasport.—Jasper, epidote, laumontite. Madawaska Settlements. - Vivianite.

Minot.—Beryl, smoky quartz, vesuvianite.

Monmouth. —Actinolite, apatite, elacolite, zircon, staurolite, plumose mica, beryl, rutile.

Mt. Abraham. - Andalusite, staurolite.

Norway. - Chrysoberyl! molybdenite, beryl, rose quartz, orthoclase, green tourmaline, albite, lepidolite, cinnamon garnet, triphylite (lithiophilite), cookeite, cassiterite, amblygonite.

Orr's Island .- Steatite, garnet, andalusite.

Oxford. - Garnet. beryl, apatite, wad, zircon, muscovite, orthoclase.

Paris, on Mt. Mica.—Green! red! black and blue tourmaline! mica! lepidolite! feldspar, albite, quartz crystals! rose quartz, cassiterite, amblygonite, apatite, columbite, zircon, brookite, beryl, smoky quartz, spodumene, cookeite, löllingite, triphylite. See HEBRON.

Parsonsfield. — Vesuvianite! yellow garnet, pargasite, adularia, labradorite (cryst.), scapolite,

galena, sphalerite, chalcopyrite.

Peru. - Crystallized pyrite, columbite, beryl, spodumene, triphylite (cryst.), chrysoberyl, petalite, amblygonite.

Phippsburg. — Yellow garnet! munganesian garnet, vesuvianite, pargasite, axinite, laumont-

its! chabazite, an ore of cerium?

Poland.—Vesuvianite, smoky quartz, cinnamon garnet.

Portland. - Prehnite, actinolite, garnet, epidote, amethyst, calcite.

Pownal.—Black tourmaline, feldspar, scapolite, pyrite, actinolite, apatite, rose quartz. Raymond.—Magnetite, scapolite, pyroxene, lepidolite, tremolite, amphibole, epidote, orthoclase, yellow garnet, pyrite, vesuvianite.

Rockland.—Hematite, tremolite, quartz, wad, talc, calcite.
Rumford.—On n. slope of Black Mtn., tourmaline (red), lepidolite, spodumene, cookeite, yellow garnet, resuvianite, pyroxene, apatite, scapolite, cassiterite, amblygonite, muscovite, albite, graphite.

Sanford (York Co.). - Vesuvianite! albite, calcite, molybdenite, epidote, black tourmaline,

labradorite.

Searsmont. - Andalusite, tourmaline.

South Berwick.—Chiastolite.

Standish. — Columbite! tourmaline, and alusite, pyrrhotite.

Stoneham.—Columbite, chrysoberyl, herderite, topaz, beryllonite, cassiterite, bertrandite, phenacite, hamlinite, mica (curved), triplite, beryl, fluorite.

Stowe.—Chrysoberyl, sillimanite.

Streaked Mountain.—Beryl! black tourmaline, mica, garnet.
Sullivan.—At the Sullivan mining district (also in Franklin and Hancock), galena, argentite, silver, cerargyrite, pyrargyrite, chalcopyrite, pyrite, stephanite, sphalerite, also gold, native bismuth.

Thomaston. - Calcite, tremolite, hornblende, titanite, arsenical iron (Owl's Head), black man-

ganese (Dodge's Mountain), thomsonite, talc, sphalerite, pyrite, galena.

Topsham.—Quartz, allanite, chrysoberyl, garnet, orthoclase, muscovite, albite, black tour-maline, amphibole, apatite, zircon, beryl, galena, sphalerite, pyrite, gahnite, magnetite, bismuthinite, chalcopyrite, arsenopyrite, tungstite? molybdenite, columbite.

Union. - Magnetite, bog-iron ore.

Wales.—Axinite in boulder, alum, copperas.

Warren.-Calcite, dolomite.

Waterville. - Crystallized pyrite.

West Gardiner.—Iolite, blue sodalite. Whiting.—Chalcopyrite, molybdenite.

Windham (near the bridge). - Staurolite, spodumene, garnet, beryl, amethyst, cyanite tourmaline.

Winslow.—Cassiterite in thin veins on slate, white beryl.

Winthrop.—Staurolite, pyrite, amphibole, garnet, beryl, copperas.

Woodstock.—Graphite, hematite, prehnite, epidote, calcite.

York.—Beryl, vivianite, oxide of manganese.

NEW HAMPSHIRE.

Acworth.—Beryl! mica! tourmaline, orthoclase, albite, rose quartz, columbite! cyanite, au zuite, biotite, garnet, cyanite.

Alexandria. - Muscovite.

Alstead. - Mica! albite, black tourmaline, molybdenite, and alusite, staurolite. Amherst. - Vesuvianite, yellow garnet, pargasite, amethyst, pyroxene, magnetite.

Antrim. - Graphite.

Bartlett.—Magnetite, hematite, quartz crystals, danalite, limonite, smoky quartz.

Bath. - Galena, chalcopyrite, alum.

Bedford.—Tremolite, epidote, graphite, mica, tourmaline, alum, quartz, graphite.

Bellows Falls.—Cyanite, staurolite, prehnite, calcite.

Benton.—Epidote, beryl, magnetite.

Berlin.—Chalcopyrite, pyrite, magnetite, amphibole. Bristol.—Graphite, galena. Campton.—Beryl!

Canaan.—Gold in quartz veins and alluvium, garnet. Charlestown.—Staurolite, andalusite, prehnite, cyanite.

Chatham.—Green fluorite. Concord.—Sillimanite.

Cornish.—Rutile in quartz! (rare), staurolite, stibnite.

Croydon.—Iolite! chalcopyrite, pyrite, pyrrhotite, sphalerite.

East Wakefield.—Beryl.

Enfield.—Gold, galena, staurolite, green quartz, ripidolite. Francestown.—Soapstone, arsenopyrite, quartz crystals.

Franconia.—Arsenopyrite, chalcopyrite.

Gardner Mtn.—Chalcopyrite, pyrite, galena, azurite, malachite.

Gilmanton.—Tremolite, epidote, muscovite, tourmaline, limonite, quartz crystals.

Goshen. - Graphite, black tourmaline.

Grafton.—Muscovite (quarried at Glass Hill, 2 m. S. of Orange Summit), albite! blue, green, and yellow beryls! (1 m. S. of O. Summit), tourmaline, garnet, triphylite, apatite, fluorite, columbite, molybdenite, rhodonite.

Grantham. - Gray staurolite!

Groton.—Arsenopyrite, beryl, muscovite crystals, orthoclase, columbite.

Hanover.—Garnet, black tourmaline, quartz, cyanite, epidote, anorthite, cyanite, zoisite. Haverhill.—Garnet! arsenopyrite, native arsenic, galena, sphalerite, pyrite, chalcopyrite, magnetite, marcasite, steatite.

Hebron.—Beryl, andalusite, graphite.

Hinsdale. - Rhodonite, molybdenite, indicolite, black tourmaline.

Jackson.—Drusy quartz, cassiterite, arsenopyrite, native arsenic, fluorite, apatite, magnetite, molybdenite, wolframite, chalcopyrite, bornite.

Jaffrey (Monadnock Mt.).—Cyanite, limonite.

Keene.—Graphite, soapstone, milky quartz, rose quartz.

Landaff.—Molybdenite, magnetite, pyrrhotite.

Lebanon.—Limonite, arsenopyrite, galena, magnetite, pyrite.

Lisbon.—Staurolite, garnet, magnetite, amphibole, epidote, zoisite, hematite, arsenopyrite, galena, gold, ankerite. Franconia iron-mine, amphibole, epidote, zoisite, hematite, magnetite, garnet, arsenopyrite (danaite), molybdenite, prehnite, cyanite.

Littleton.—Ankerite, gold, bornite, chalcopyrite, malachite, ilmenite, chlorite.

Lyman.—Gold, arsenopyrite, ankerite, dolomite, galena, pyrite, pyrrhotite. Lyme.—Cyanite (N. W. part), black tourmaline, rutile, pyrite, chalcopyrite (East part), stibnite, molybdenite, cassiterite, staurolite.

Madison.—Galena, sphalerite, chalcopyrite, limonite.
Marlow.—Tourmaline.

Merrimack.—Rutile! (in gneiss nodules in granite vein).

Middletown.—Rutile, arsenopyrite.

Milan - Chalcopyrite, galena, sphalerite.

Millsfield.—Beryl, garnet.

Monadnock Mountain. - Andalusite, amphibole, garnet, graphite, tourmaline, orthoclase, sillimanite.

Nashua. - Muscovite,

New London.—Beryl, molybdenite, muscovite.

Newport. - Molybdenite, staurolite.

North Chatham (Bald Face Mt.).—Phenacite, topaz.

Orange.—Blue beryl! Orange Summit, chrysoberyl, muscovite (W. side of mountain), albite,

tourmaline, apatite, galena, limonite.

Orford.—Brown tourmaline (obtained with difficulty), steatite, rutile, cyanite, ilmenite, garnet, graphite, molybdenite, pyrrhotite, melaconite, chalcopyrite, chalcocite, malachite, galena, ripidolite.

Piermont.—Micaceous hematite, barite, mica, apatite. Plymouth.—Columbite, beryl.

Richmond.—Iolite, rutile, steatite, pyrite, anthophyllite, talc. Rye.—Chiastolite (at Boar's Head, in boulders). Saddleback Mt.—Black tourmaline, garnet, spinel.

Shelburne. - Galena, black sphalerite, chalcopyrite, pyrite, pyrolusite.

Springfield. - Beryl (eight inches in diameter), manganesian garnet! black tourmaline! in mica schist, albite, mica, rose quartz.

Sullivan.—Tourmaline (black) in quartz, beryl. Surry.—Amethyst, galena, tourmaline, cyanite. Sutton.—Graphite, beryl.

Unity (estate of James Neal).—Chalcopyrite, pyrite, chlorophyllite, green mica, actinolite, garnet, magnetite, tourmaline.

Wakefield.—Orthoclase, mica, columbite; in East Wakefield, beryl.

Walpole.—Chiastolite, staurolite, mica, graphite.

Ware. - Graphite.

Warren.—Chalcopyrite, sphalerite, epidote, quartz, pyrite, tremolite, galena, rutile, talc, molybdenite, cinnamon-stone! pyroxene, amphibole, beryl, cyanite, tourmaline (massive).

Waterville.—Labradorite, chrysolite, amethyst.

Westmoreland (south part).—Molybdenite! apatite! blue feldspar, bog manganese (north village), quartz, amethyst, fluorite, chalcopyrite, molybdite.

White Mts. (Notch near the "Crawford House").—Green fluorite, quartz crystals, black

tourmaline, and alusite, amethyst, amazon-stone; also and alusite abundant in the gneiss of Mt. Washington.

Whitefield.—Molybdenite.

Winchester.—Pyrolusite, rhodonite, rhodochrosite, magnetite, pyrite, spodumene, tourmaline.

VERMONT.

Athens. - Steatite, ankerite, actinolite, garnet.

Baltimore. - Serpentine, pyrite!

Barnet.-Graphite.

Belvidere.—Steatite, chlorite.

Bennington.—Pyrolusite, limonite.

Berkshire.—Epidote, hematite, magnetite.
Bethel.—Actinolite! talc, chlorite, octahedral iron, rutile, ankerite in steatite.

Brandon.—Pyrolusite, psilomelane, limonite, lignite, kaolinite, statuary marble; graphite, chalcopyrite, galena.

Brattleborough.—Black tourmaline in quartz, mica, zoisite, rutile, actinolite, scapolite,

spodumene, roofing slate.

Bridgewater.—Talc, dolomite, magnetite, steatite, chlorite, gold, native copper, sphalerite, galena, blue spinel, chalcopyrite.

Bristol. - Rutile, limonite, manganese ores, magnetite.

Brookfield.—Arsenopyrite, pyrite.

Cabot.—Garnet, staurolite, amphibole, albite.

Cavendish.—Garnet, serpentine, talc, steatite, tourmaline, asbestus, tremolite.

Chester. - Asbestus, feldspar, chlorite, quartz.

Chittenden.—Psilomelane, pyrolusite, limonite, hematite and magnetite, galena, iolite. Colchester.—Limonite, iron-sand, jasper, alum.

Corinth.—Chalcopyrite (has been mined), pyrrhotite, pyrite, rutile.

Coventry.-Rhodonite.

Craftsbury.—Mica in concretions, calcite, rutile.

Cuttingsville. - Chalcopyrite, pyrite.

Derby.—Mica (adamsite).

Ely.—Chalcopyrite, pyrite (copper mines recently reopened).

Fair Haven.—Roofing slate, pyrite.

Farmington.—Andalusite.

F' etcher.—Pyrite, magnetite, acicular tourmal'

Grafton.—The Grafton steatite quarry is in Athens; quartz, actinolite.

Guilford.—Scapolite, rutile.

Hartford.—Calcite, pyrite! cyanite, quartz, tourmaline.

Irasburgh.—Rhodonite, psilomelane.

Jay.—Chromite, serpentine, amianthus, dolomite.

Lowell.—Amianthus, serpentine, cerolite, talc, chlorite.

Manchester.—Limonite.

Marlboro'. - Rhomb spar, steatite, garnet, magnetite, chlorite.

Middlesex. -Rutile! (exhausted).

Monktown.—Pyrolusite, limonite, feldspar.
Moretown.—Smoky quartz! steatite, talc, wad, rutile, serpentine.

Mount Holly. - Asbestus, chlorite.

New Fane. - Glassy and asbestiform actinolite, steatite, green quartz (called chrysoprase at the locality), chalcedony, drusy quartz, garnet, chromic and titanic iron, ankerite, serpentine, rutile.

Norwich.—Actinolite, feldspar, brown spar in talc, cyanite, zoisite, chalcopyrite, pyrite.

Pittsford.—Limonite, manganese ores, statuary marble!

Plymouth.—Siderite, magnetite, hematite, gold, galena, also limonite, kaolin. Putney.—Fluorite, limonite, rutile and zoisite in boulders, staurolite.

Reading. - Glassy actinolite in talc.

Readsboro'.—Glassy actinolite, steatite, hematite.

Rochester.—Rutile, hematite cryst., magnetite in chlorite slate.

Rockingham (Bellows Falls).—Cyanite, indicolite, feldspar, tourmaline, fluorite, calcite, prehnite, staurolite.

Roxbury.—Dolomite, tale, serpentine, asbestus, quartz. Rutland.—Magnesite, white marble, hematite, serpentine.

Sharon. - Quartz crystals, cyanite.

Shoreham.—Pyrite, black marble, calcite.

Strafford.—Magnetite and chalcopyrite (has been worked), native copper, amphibole

Thetford.—Sphalerite, galena, cyanite, chrysolite in basalt, pyrrhotite, feldspar, roofing slate, steatite, garnet.

Townshend. - Actinolite, black mica, talc, steatite, feldspar.

Troy. - Magnetite, talc, serpentine, amianthus, steatite, ilmenite, chlorite; one mile south-east of village of South Troy, on the farm of Mr. Pierce, east side of Missisco, chromite, zaratite.

Vershire. - Pyrite, chalcopyrite, native copper, malachite, tourmaline, arsenopyrite, quartz.

Wardsboro'.—Zoisite, tourmaline, tremolite, hematite.
Warren.—Actinolite, magnetite, wad, serpentine.
Waterbury.—Arsenopyrite, chalcopyrite, rutile, quartz, serpentine.
Waterville.—Steatite, actinolite, tale.

Weathersfield.—Steatite, hematite, pyrite, tremolite.

Westfield.—Steatite, chromite, serpentine.

Westminster.—Zoisite in boulders.

Windham. - Glassy actinolite, steatite, garnet, serpentine.

Woodstock.—Quartz crystals, garnet, zoisite.

MASSACHUSETTS.

Athol.—Allanite, epidote! babingtonite? mica.

Auburn. - Masonite (chloritoid).

Barre.—Rutile! mica, pyrite, beryl, feldspar, garnet. Great Barrington.—Tremolite.

Bedford. - Garnet.

Belcherton.—Allanite.

Bernardston, - Magnetite at loc. of crinoidal limestone.

Beverly.—Columbite, green feldspar, cassiterite.

Blandford - Serpentine, anthophyllite, actinolite! chromite, cyanite, rose quartz in boulders. Bolton. - Scapolite! petalite, titanite, pyroxene, nuttalite, diopside, boltonite, apatite, magnesite, ankerite, allanite, yttrocerite, spinel.

Boxborough.—Scapolite, spinel, garnet, augite, actinolite, apatite.

Brimfield (road leading to Warren).—Iolite, andalusite, adularia, molybdenite, mica, garnet. Brookfield.—Limonite, garnet.

Carlisle.—Tourmaline, garnet! scapolite, actinolite.

Chelmsford. — Scapolite (chelmsfordite), chondrodite, blue spinel, amianthus! rose quartz. Chester.—Amphibole, scapolite, zoisite, spodumene, indicolite, garnet, apatite, magnetite, chromite, stilbite, heulandite, analcite, and chabazite.

At the Emery Mine, Chester Factories.—Corundum, margarite, diaspore, epidote, corundo-

philite. chloritoid, tourmaline, ilmenite, rutile, biotite, cyanite, amesite.

Chesterfield.—Blue, green, and red tourmaline, cleavelandite (albite), lepidolite, smoky quartz, microlite, spodumene, cyanite, apatite, beryl, garnet, quartz crystals, staurolite, cassiterite, columbite, zoisite, autunite, brookite (eumanite), scheelite, anthophyllite, bornite. Conway.—Pyrolusite, fluorite, zoisite, rutile! native alum, galena.

Curimington. - Rhodonite! cummingtonite (amphibole), marcasite, garnet.

Deerfield.—Chabuzite, heulandite, stilbite, datolite, prehnite, natrolite, analcite, calcite, fluorite, diabantite, saponire, amethyst, carnelian, chalcedony, agate, pyrite, malachite.

Fitchburg (Pearl Hill).—Beryl, staurolite! garnets, molybdenite, tourmaline.

Foxborough.—Pyrite, anthracite.

Framingham. - Garnet. Franklin. - Amethyst. Gloucester. - Danalite.

Goshen.—Mica, albite, spodumene! blue and green tourmaline, beryl, zoisite, smoky quartz, columbite, tin ore, galena, beryl (goshenite), cymatolite (mixture of albite and muscovite).

Greenfield (in sandstone quarry, ½ m. E. of village).—Allophane.

Hatfield.—Barite, galena, sphalerite, chalcopyrite, quartz crystals. Hawley.-Micaceous hematite, massive pyrite, magnetite, zoisite.

Heath.—Pyrite, zoisite.

Hinsdale.—Limonite, apatite, zoisite. Hubbardston.—Massive pyrite.

Huntington (name changed from Norwich). — Apatite! black tourmaline, beryl, spodumene! triphylite (altered), sphalerite, quartz crystals, cassiterite.

Lancaster. - Cyanite, chiastolite! apatite, staurolite, pinite, andalusite. Lee.—Tremolite, titanite; chondrodite in cryst. limestone in East Lee.

Leverett.—Barite, galena, sphalerite, chalcopyrite.

Leyden. - Zoisite, rutile.

Malden.-Galena.

Marblehead.—In zircon-syenyte, sodalite, elæolite. Martha's Vineyard.—Limonite, amber, radiated pyrite.

Mendon. - Mica! chlorite.

Middlefield.—Glassy actinolite, ankerite, steatite, serpentine, feldspar, drusy quartz, apatite, zoisite, nacrite, chalcedony, talc! deweylite.

Milbury .- Vermiculite, graphite.

Mt. Washington.—Garnet, staurolite, albite, ottrelite, ottrelite and ilmenite growths.

New Braintree,—Black tourmaline.

New Marlboro'.—Apatite, tourmaline, garnet (with granophyre structure), muscovite crystals, bi-pyramidal quartz (in pegmatyte of Tobey Hill); chalcopyrite, pyrrhotite, hornblende, magnetite (at Cleaveland "Gold mine"); diopside, tremolite, quartz crystals (in limestone).

Newbury.—Serpentine, chrysotile, epidote, vesuvianite, siderite.

Newburyport.—Serpentine, nemalite, autunite.—Argentiferous galena, tetrahedrite, chalco-

pyrite, pyrargyrite, siderite, etc.

Northfield. - Columbite, fibrolite, cyanite.

Norwich, -See Huntington. Oxford.—Arsenopyrite, pyrite.

Palmer (Three Rivers). -Feldspar, prehnite, calcite.

Pelham.—Asbestus, serpentine, quartz crystals, beryl, molybdenite, green hornstone, epidote, amethyst, corundum, vermiculite.

Plainfield.—Cummingtonite, pyrolusite, rhodonite.
Richmond.—Limonite, gibbsite! allophane.
Rockport (near the extremity of C. Ann).—Danalite, cryophyllite, annite, cyrtolite (altered zircon), amazon-stone, fergusonite, green and white orthoclase.

Rowe. - Epidote, talc; at Davis mine, pyrite, chalcopyrite, gahnite, zoisite.

Russell. - Garnet! mica, serpentine, beryl, galena, chalcopyrite.

Salem.—Cancrinite, sodalite, elæolite, zircon.

Sheffield.—Asbestus, pyrite, native alum, pyrolusite; rutile in limestone, garnet, staurolite, albite in schist.

Shelburne. - Rutile.

Shutesbury (east of Locke's Pond). - Molybdenite.

Somerville. - Prehnite, laumontite, stilbite, chabazite, quartz crystals, melanolite, babingtonite, calcite, epidote.

South Royalston. — Beryl! (now obtained with great difficulty), mica! feldspar! allanite. Four miles beyond old loc., on farm of Solomon Heywood, mica! beryl! feldspar! ilmenite. Southampton. - Galena, cerussite, anglesite, wulfenite, fluorite, bornite, barite, pyrite,

chalcopyrite, sphalerite, phosgenite, pyromorphite, stolzite, chrysocolla.

Sterling. - Spodumene, chiastolite, siderite, arsenopyrite, sphalerite, galena, chalcopyrite, pyrite, sterlingite (damourite).

Stoneham. - Nephrite.

Sturbridge.—*Graphite*, garnet, apatite, bog-ore. Swampscot.—*Orthite*, feldspar.

Taunton (one mile south).—Paracolumbite (ilmenite).
Turner's Falls (Conn. River).—Chalcopyrite, prehnite, chlorite, siderite, malachite,

Tyringham and on borders of Otis. - Pyroxene, scapolite, chondrodite, titanite, amphibole, spherostilbite.

Warwick. - Massive garnet, radiated black tourmaline, magnetite, beryl, epidote.

Washington.—Graphite.

Westfield.—Schiller spar (diallage), serpentine, steatite, cyanite, scapolite, actinolite.

Westford.—Andalusite!

West Hampton.—Galena, argentine, pseudomorphous quartz. West Stockbridge.—Limonite, fibrous pyrolusite, siderite.

Williamsburg.—Zoisite, pseudomorphous quartz, apatite, rose and smoky quartz, galena, pyrolusite, chalcopyrite.

Windsor. - Zoisite, actinolite, rutile!

Worcester.—Arsenopyrite, vesuvianite, pyroxene, garnet, amianthus, smoky quartz, graphite, calcite, bucholzite, siderite, galena.

Worthington. - Cyanite. Zoar.—Bitter spar, talc.

RHODE ISLAND.

Bristol. — Amethyst.

Burrillville.—Amethyst.

Cranston.—Actinolite in tale, graphite, cyanite, mica, melanterite, hematite. Cumberland.—Manganese, epidote, actinolite, garnet, titaniferous iron, magnetite, hematite, chalcopyrite, bornite, malachite, azurite, calcite, apatite, feldspar, zoisite, mica, quartz crystals, ilvaite. Beacon Pole Hill, crocidolite.

At Sneech Pond, chalcopyrite, ilvaite, wad, molybdenite, magnetite, epidote, chlorite.

Diamond Hill.—Quartz crystals, hematite. Foster.—Cyanite, hematite.

Gloucester.—Magnetite in chlorite slate, feldspar.

Johnston.—Talc, ankerite, calcite, garnet, epidote, pyrite, hematite, magnetite, chalcopyrite, malachite, azurite.

Lincoln.—Galena. Natick.—See WARWICK.

Newport.—Serpentine, quartz crystals.

Portsmouth.—Anthracite, graphite, asbestus, pyrite, chalcopyrite.

Smithfield.—Dolomite, calcite, bitter spar, siderite, nacrite, serpentine (bowenite), tremolite, asbestus, quartz, magnetite in chlorite schist. talc! octahedrite, feldspar; beryl.

Valley Falls.—Graphite, pyrite, hematite.

Warwick (Natick village). - Masonite (chloritoid), garnet, graphite, bog-ore.

Westerly.-Ilmenite. Woonsocket.—Cyanite.

CONNECTICUT.

Berlin.—Barite, datolite, sphalerite, quartz crystals.

Bethel.—Tourmaline.
Bolton.—Staurolite, chalcopyrite.

Branchville.—In a vein of albitic granite, garnet, albite, microcline, amblygonite, spodumene! cymatolite, margarodite (curved), eosphorite, triploidite, triplite, reddingite, dickinsonite, lithiophilite, natrophilite, hureaulite, rhodochrosite, fairfieldite, apatite, microlite, columbite, pyrite, tourmaline, staurolite, uraninite, torbernite, autunite, vivianite, eucryptite, chabazite, stilbite, heulandite, native bismuth, muscovite, biotite, beryl, montmorillonite.

Branford (Stony Creek).—Biotite, apatite.

Bristol. - Chalcocite, chalcopyrite, barite, bornite, allophane, pyromorphite, calcite, malachite, galena, quartz.

Brookfield.—Galena, calamine, sphalerite, spodumene, pyrrhotite, chalcopyrite.

Canaan.—Calcite (Canaan Lime Company's quarry), phlogopite, green tremolite (Maltby's quarry); diopside, in part changed to tremolite, fibrolite, garnet, hornblende (Canaan Mt.).

Chatham. - Arsenopyrite, smaltite, cloanthite (chathamite), scorodite, niccolite, beryl,

erythrite. Cheshire.—Barite! chalcocite, bornite, malachite, kaolin, natrolite, prehnite, chabazite,

datolite, cuprite. Chester.—Sillimanite! zircon, epidote.

Cornwall.—Graphite, pyroxene, actinolite, titanite, scapolite.

Danbury.—Danburite with oligoclase (formerly), brown tournaline, orthoclase, pyroxene, parathorite.

Derby. - Arsenopyrite.

Farmington.—Prehnite, chabazite, agate, native copper. diabantite.

Glastonbury (at Hale's quarry). - Columbite, muscovite, orthoclase, albite, uraninite.

Granby (Simsbury mines).—Bornite, chalcocite, chalcopyrite, malachite.

Guilford.—In gneiss, iolite: N. Guilford, rutile (boulder).

Haddam.*—Chrysobery!! beryl, epidote, tourmaline, orthoclase, garnet, iolite! chlorophyllite!

^{*} The pegmatyte veins of Haddam have their continuation in similar veins in Middletown, Portland, and Glastonbury, to the north; in some cases doubt exists as to the exact locality.

oligoclase, automolite, magnetite, adularia, apatite, columbite! zircon (calyptolite), mica, pyrite, marcasite, molybdenite, allanite, bismuth ocher, bismutite, cassiterite.

Hadlyme.—Chabazite and stilbite in gneiss. Hartford.—Datolite (Rocky Hill quarry).

Kent.-Limonite.

Litchfield.—Cyanite with corundum, apatite, and andalusite, ilmenite (washingtonite), chalcopyrite, diaspore, niccoliferous pyrrhotite, margarodite, staurolite, apatite.

Lyme. - Garnet, sunstone, microcline. Meriden. — Datolite (greenish), diabantite.

Middlefield Falls.—Datolite, chlorite, etc., in amygdaloid.

Middletown.—At the feldspar quarries, mica, albite, feldspar, columbite! prehnite, garnet, samarskite, biotite, monazite, vesuvianite, beryl, topaz, uranite, apatite, uraninite, lepidolite with green and red tourmaline; at lead-mine formerly galena, chalcopyrite, sphalerite, quartz, calcite, fluorite, pyrite sometimes capillary.

Milford.—Salite, pyroxene, asbestus, verd-antique marble. Monroe.—See Trumbull

New Britain.—Prehnite calcite, datolite, diabantite, agate, barite; copper minerals in small quantities.

New Haven.—Serpentine, salite; also with the trap rocks, prehnite, laumontite, and the zeolites, stilbite, apophyllite, very sparingly; as a contact-mineral, garnet.

New Milford.—Beryl (golden yellow and green), tourmaline, mica, feldspar.

Newtown.—Cyanite, diaspore, rutile, damourite, tourmaline.

Norfolk.—Biotite crystals, pseudomorphs of a colorless mica, quartz and fibrolite after plagioclase (at Norfolk granite quarry, the latter in blocks).

Norwich.—In gueiss, sillimanite, monazite! iolite, corundum, feldspar.

Portland.—At feldspar quarries, orthoclase, albite, muscovite, biotite, beryl, tourmaline, bismuthinite, bismutosphærite, columbite, apatite; at Pelton's feldspar quarry, monazite.

Plymouth.—Galena, heulandite, fluorite, chlorophyllite! garnet, rutile.

Roaring Brook (Cheshire).—Datolite! calcite, prehnite, saponite.

Roxbury.—Siderite, sphalerite, pyrite! galena, quartz, chalcopyrite, arsenopyrite, limonite.

Salisbury.—Limonite, pyrolusite, manganite, triplite, turgite, scovillite, staurolite. Seymour.—Arsenopyrite, pyrite, native bismuth.

Simsbury.—Chalcocite, green malachite.

Southbury.—Rose quartz, laumontite, prehnite, calcite, barite, staurolite, garnet.

Southington. - Barite, datolite, asteriated quartz crystals, diabantite.

Stafford. - Massive pyrite, alum, copperas.

Tariffville. - Datolite!

Trumbull and Monroe.—Chlorophane, topaz, beryl, diaspore, pyrrhotite, pyrite, scheelite, wolframite (pseudomorph after scheelite), native bismuth, tungstite, siderite, arsenopyrite, argentiferous galena, sphalerite, scapolite, tourmaline, garnet, albite, augite, graphic tellurium (?), margarodite.

Washington.—Tripolite, ilmenite! (washingtonite), rhodochrosite, natrolite, andalusite

(New Preston), cyanite.

Watertown (near the Naugatuck).-White salite, monazite.

West Farms.—Asbestus.

Willimantic. —In gneiss, topaz, monazite, ripidolite, sillimanite, bismuthinite, bismutosphærite, beryl, orthoclase, uraninite.

Winchester. — Magnetite.

NEW YORK.

Of economic minerals, halite is obtained as rock salt, also from salt wells, extensively in the western counties from Cayuga Lake west to L. Erie (see p. 155); further gypsum in the same region. Hematite at Antwerp, Jefferson Co.; limonite in the south-eastern part of the state east of the Hudson river, chiefly in Dutchess and Columbia counties; also siderite in Columbia Magnetite is largely mined in Essex Co., and occurs widely in the adjacent counties of the Adirondack region; also mined in the Highlands, in Orange, Westchester, and Putnam counties. The magnetite mines sometimes furnish beautiful specimens of rare minerals, e.g., allanite at

Moriah, chondrodite, etc., at Brewster.

The most interesting localities for minerals are those of the Archæan in St. Lawrence Co., also Franklin, Jefferson, Lewis, etc., counties. Here are obtained, at many points, fine pyroxene, amphibole, albite and other feldspars, phlogopite, tourmaline, apatite, titanite, zircon, etc.; they most commonly occur in crystalline limestone where it joins the schists. Other important localities, also in the Archæan, are those of Orange Co. (Warwick, Monroe), in the south-eastern part of the state, where in the crystalline limestone, chondrodite, spinel, etc., occur abundantly.

The limestone of the western part of the state affords (e.g., Lockport) calcite, dolomite,

celestite, anhydrite, etc.

ALBANY CO.—Bethlehem.—Calcite, stalactite, calcareous sinter, snowy gypsum. Coeymans Landing.—Gypsum, epsomite, quartz crystals at Crystal Hill, 3 m. S. of Albany. Watervliet. — Quartz crystals, yellow drusy quartz.

CAYUGA Co.—Auburn.—Celestite, calcite, fluorite, epsomite. Springport.—At Thompson's plaster beds, sulphur! selenite. Union Springs.—Selenite, gypsum.

CLINTON CO.—Arnold Iron Mine.—Magnetite, epidote, molybdenite. Finch Ore Bed.—Calcite, green and purple fluorite. Plattsburg.-Nugget of platinum in drift.

COLUMBIA Co.—Ancram.—Lead-mine, galena, sphalerite, wulfenite, chalcopyrite.

Canaan.-Chalcocite, chalcopyrite.

Catskill Station.—Siderite in large beds.

Copake.—Limonite (large ore beds), graphite.

Hudson.—Selenite! epsomite, brown spar, wad, siderite.

Linlithgo.—Siderite beds.

New Lebanon.-Nitrogen springs.

DUTCHESS Co.—Amenia.—Dolomite, limonite, turgite, siderite.

Dover.—Dolomite, tremolite, garnet (Foss Ore Bed), limonite, staurolite.

Fishkill.—Dolomite; near Peckville, talc, asbestus, graphite, amphibole, augite, actinolite, limonite.

North East.—Chalcocite, chalcopyrite, galena, sphalerite.

Union Vale.—At the Clove mine, gibbsite, limonite.

ESSEX Co.—Alexandria.—Kirby's graphite mine, graphite, pyroxene, scapolite, titanite. Crown Point.—Apatite (eupyrchroite of Emmons), brown tourmaline! in the apatite, chlorite, quartz crystals, calcite, pyrite; S. of J. C. Hammond's house, garnet, scapolite, chalcopyrite, aventurine feldspar, zircon, magnetite (Peru), epidote, mica.

Keene.—Scapolite.

Lewis. - Wollastonite, colophonite, garnet, labradorite, amphibole, actinolite; 10 m. S. of Keeseville, arsenopyrite.

Long Pond.—Apatite, garnet, pyoxene, vesuvianite, coccolite! scapolite, magnetite, blue calcite.

McIntyre.—Labradorite, garnet, magnetite.
Moriah, at Sandford Ore Bed.—Magnetite, apatite, allanite! lanthanite, actinolite, and feldspar; at Fisher Ore Bed, magnetite, feldspar, quartz; at Hall Ore Bed, or "New Ore Bed," magnetite, zircon; on Mill brook, calcite, pyroxene, amphibole, albite; in the town of Moriah, magnetite, black mica; Barton Hill Ore Bed, albite.

Newcomb.—Labradorite, feldspar, magnetite, hypersthene, tourmaline.

Port Henry.—Brown tourmaline, black tourmaline enclosing orthoclase, mica, rose quartz, serpentine, green and black pyroxene, amphibole, cryst. pyrite. graphite, wollastonite, pyrrhotite, adularia, phlogopite!; at Mineville, magnetite in large quantities, also in fine crystals; in Champlain iron region, uranothorite.

Roger's Rock.—Graphite, wollastonite, garnet, feldspar, adularia, pyroxene, titanite,

coccolite.

Schroon.—Calcite, pyroxene, chondrodite.

Ticonderoga. - Graphite! pyroxene, salite, titanite, black tourmaline, cacoxenite? (Mt.

Westport.—Labradorite, prehnite, magnetite.

Willsboro'. - Wollastonite, colophonite, garnet, green coccolite, amphibole.

JEFFERSON Co.—Adams.—Fluorite, calc tufa, barite.

Alexandria.—On S. E. bank of Muscolonge Lake, fluorite (exhausted), phlogopite, chalcopyrite, apatite; on High Island, in the St. Lawrence River, feldspar, tourmaline, amphibole,

orthoclase, celestite.

Antwerp.—Sterling iron-mine hematite, chalcodite, siderite, calcite, ankerite, millerite! red hematite, crystallized quartz, yellow aragonite, niccoliferous pyrite, quartz crystals, pyrite; at Oxbow, calcite! porous coralloidal barite; near Vrooman's lake, calcite! vesuvianite, phlogopite! pyroxene, titanite, fluorite, pyrite, chalcopyrite; also feldspar, bog-iron ore, scapolite (farm of Eggleson), serpentine, tourmaline (yellow, rare).

Brownsville,—Celestite, calcite (4 m. from Watertown).

Natural Bridge.—Gieseckite! steatite pseudomorphous after pyroxene, apatite, phlogopite, orthoclase.

New Connecticut.—Titanite, brown phlogopite.

Omar.—Beryl, feldspar, hematite.
Philadelphia.—Garnets on Indian River, in the village; hematite.
Pillar Point.—Massive barite (exhausted).

Theresa. - Fluorite, calcite, hematite, amphibole, quartz crystals, serpentine (associated with hematite), celestite, strontianite.

Watertown.—Tremolite, agaric mineral, calc tufa, celestite.

Wilna.—One mile N. of Natural Bridge, calcite.

GREENE CO. - Diamond Hill. - Quartz crystals.

HERKIMER Co. - Fairfield. - Quartz crystals, fetid barite.

Little Falls. - Quartz crystals! barite, calcite, smoky quartz; 1 m. S. of Little Falls, calcite, brown spar, feldspar

Middleville. — Quartz crystals! calcite, dolomite.

Newport. - Quartz crystals.

Salisbury. — Quartz crystals! sphalerite, galena, pyrite, chalcopyrite.

Stark.-Fibrous celestite, gypsum.

LEWIS Co.-Bonaparte Lake.-Wollastonite.

Diana (localities mostly near junction of crystalline and sedimentary rocks, and 2 m. from Natural Bridge).—Scapolite! wollastonite, green coccolite, feldspar, tremolite, pyroxene! titanite, mica, quartz crystals, pyrite, pyrrhotite, blue calcite, serpentine, rensselaerite, zircon, graphite, chlorite, hematite, bog-ore, apatite.

Greig. - Magnetite, pyrite.

Lowville.—Calcile, fluorite, pyrite, galena, sphalerite, calc tufa. Martinsburgh.—Wad, galena, etc. (formerly), calcile.

MONROE Co.—Rochester.—Dolomite, calcite, snowy gypsum, fluorite, celestite, galena, sphalerite, barite, hornstone.

MONTGOMERY Co.—Palatine.—Quartz crystals, drusy quartz, anthracite, hornstone, agate, garnet.

Root.—Drusy quartz, sphalerite, barite, stalactite, galena, pyrite.

NEW YORK CO.—Kingsbridge.—Tremolite, pyroxene, mica, tourmaline, pyrite.

New York.—Serpentine, amianthus, actinolite, pyroxene, hydrous anthophyllite, garnet, staurolite, molybdenite, graphite, chlorite, beryl, jasper, necronite, feldspar, xenotime, wollastonite, dumortierite. In the excavations for the 4th Avenue tunnel, 1875, harmotome, stilbite, chabazite, heulandite, etc.

NIAGARA CO.—Lewiston.—Epsomite.

Lockport. — Celestite, calcite, selenite, anhydrite, fluorite, dolomite, sphalerite.

Niagara Falls.—Calcite, fluorite, sphalerite, dolomite.

ONEIDA Co.—Boonville.—Calcite, wollastonite, coccolite.

Clinton.—Sphalerite, lenticular hematite in the Clinton group, strontianite, celestite, the former covering the latter.

ONONDAGA Co.—Camillus.—Selenite and fibrous gypsum.

Syracuse.—Serpentine, celestite, selenite, barite.

ORANGE Co.—Cornwall.—Zircon, chondrodite, amphibole, spinel, feldspar, epidote, hudsonite, ilmenite, serpentine, coccolite.

Deer Park.—Cryst. pyrite. galena.

Monroe.—Mica! titanite! garnet, colophonite, epidote, chondrodite, allanite, bucholzite, brown spar, spinel, amphibole, talc, ilmenite, pyrrhotite, pyrite, chromite, graphite, rastolyte, moronolite; Wilks and O'Neill Mine, aragonite, magnetite, dimagnetite (pseud.?), jenkinsite. asbestus, serpentine, mica, hortonolite; Two Ponds, pyroxene! chondrodite, amphibole, scapolite! zircon, titanite, apatite; Greenwood Furnace, chondrodite, pyroxene! mica, amphibole, spinel, scapolite! jilmenite, apamite. scapolite, biotite! ilmenite, anomite.

Forest of Dean.—Pyroxene, spinel, zircon, scapolite, amphibole.

Town of Warwick, Warwick Village.—Spinel! zircon, serpentine! brown spar, pyroxene! amphibole, pseudomorphous steatite, feldspar! (Rock Hill), ilmenite, clintonite, tourmaline (R. H.), rutile, titanite, molybdenite, arsenopyrite, marcasite, pyrite, yellow iron sinter, quartz, jasper, mica, coccolite

Amity.—Spinel! garnet, scapolite, amphibole, resurianite, epidote! seybertite, leuchtenbergite, magnetite, tourmaline, warwickite, apatite, chondrodite, tale! pyroxene! phlogopite, rutile, ilmenite, zircon, corundum, feldspar, fluorite, titanite, calcite, serpentine, schiller spar (?), silvery mica, graphite.

Edenville. - Apatite, chondrodite! hair-brown amphibole! tremolite, spinel, tourmaline, warwickite, pyroxene, titanite, mica, feldspar, arsenopyrite, orpiment, rutile, ilmenite, scorodite,

chalcopyrite, leucopyrite (or löllingite), allanite.

West Point.—Feldspar, mica, scapolite, titanite, amphibole, allanite.

PUTNAM Co.—Brewster, Tilly Foster Iron Mine.—Chondrodite! magnetite, dolomite, serpentine pseudomorphs. brucite, enstatite. clinochlore, biotite, actinolite. pyrrhotite, fluorite, albite, epidote, titanite! garnet, apatite, datolite, stilbite, prehnite, apophyllite.

Anthony's Nose, at top.—Pyrite, pyrrhotite, pyroxene, amphibole, magnetite.

Carmel (Brown's quarry).—Anthophyllite, arsenopyrite, epidote.

Cold Spring.—Titanite, epidote.

Patterson. — White pyroxene! calcite, usbestus, tremolite, dolomite, massive pyrite.

Phillipstown. - Tremolite, amianthus, serpentine, titanite, diopside, green coccolite, amphibole, scapolite, stilbite, mica, laumontite, gurhofite, calcite, magnetite, chromite. Phillips Ore Bed.—Hyalite, actinolite, massive pyrite.

RICHMOND Co.—Rossville.—Lignite, cryst. pyrite.

Quarantine.—Asbestus, amianthus, aragonite, dolomite, gurhofite, brucite, serpentine, talc, magnesite.

ROCKLAND Co.—Caldwell.—Calcite.

Ladentown. - Zircon, malachite, cuprite.

Piermont.—Datolite, stilbite, apophyllite, pectolite, prehnite, thomsonite, calcite, chabazite.

St. Lawrence Co.—Canton.—Massive pyrite, calcite, brown tourmaline, titanite, serpentine,

talc, rensseluerite, pyroxene, hematite, chalcopyrite.

DeKalb.—On Sprague Downing's farm and Calvin Mitchel's adjoining, diopside! cryst. with hornblende; datolite rare. On Andrew Murty's farm, white or colorless tourmaline! with pure white phlogopite, tremolite, pyroxene, serpentine, apatite, and pyrite. Near Osborn's lake, at Abner Crosse's, calcite crystals, barite, fluorite, brown tourmaline, tremolite and phlogopite. On Francis McIntyre's farm, barite!

Edwards.—At Freemansburgh, extensive talc mines, fibrous, pseud. after enstatite (agalite) pink tremolite (hexagonite), enstatite. Transparent white phlogopite at the Anthony Mine. Brown and silvery mica! scapolite, apatite, quartz crystals, actinolite, tremolite! hematite,

serpentine, magnetite.

Fine.—On Lorenzo Guinup's farm, in a granite vein, large pyroxene cryst. (prisms over a foot in diameter, looking like basaltic columns), titanite cryst. as large as a dinner-plate, fluorite, fine sage-green zircons, calcite. On Fida Scott's farm, large oligoclase cryst., pyroxene,

fluorité, calcité, zircon, pyrite, apatite, titanite.

Fowler.—Quartz (dihexahedral) with hematite and barite, sphalerite, galena, tremolite; foliated white tale at Wm. Woodcock's mine, near the village of Little York. Also galena, tremolite, chalcedony, bog-ore, satin spar (assoc. with serpentine), pyrite, chalcopyrite, actinolite,

rensselaerite (near Somerville).

Gouverneur.—At Richville, on the Reese farm, fine brown tourmaline! with tremolite! pyroxene, apatite, pyrite, titanite and phlogopite. Near David Downing's farm, fluorite in twin cubes (etched). Also calcite! serpentine! amphibole, scapolite! orthoclase, tourmaline! vesuvianite (1 m. S. of G.), pyroxene, diopside, apatite, renselaerite, serpentine, titanite, fluorite, barite (farm of Judge Dodge), black mica, phlogopite, tremolite! asbestus, hematite, graphite, vesuvianite (near Somerville in serpentine), spinel, houghite, scapolite, phlogopite, dolomite; \(\frac{3}{4}\) m. W. of Somerville, chondrodite, spinel.

Hammond. - Apatite! zircon! (farm of Mr. Hardy), orthoclase (loxocase), pargasite, barite,

pyrite, purple fluorite, tremolite, phlogopite.

Hermon.—Quartz crystals, hematite, siderite, pargasite, pyroxene, serpentine, tourmaline,

bog-iron ore.

Macomb.—On John McNiel's and Perry Washburn's farms, brown and black tourmaline! pyrovene, amphibole, albite (peristerite), graphite, apatite, phlogopite, scapolite. On Milton Truax's farm, large amphibole (six-sided prisms) in calcite. Veins of galena on many farms formerly extensively worked. On Vilas Ingram's farm, brown tourmaline! graphite and feldspar. Also sphalerite, mica, titanite, fluorite!

Mineral Point, Morristown. -Fluorite, sphalerite, galena, phlogopite (Pope's Mills), barite.

Ogdensburgh.—Labradorite.

Pierrepont.—On Ryland Crary's farm, black tourmaline! black phlogopite, pyroxene (often changed to uralite), quartz in calcite. On Allen W. Wells' farm, large light green amphibole with pyroxene and oligoclase. On Reuben Vaughn's farm, dark green amphibole. T. Fitzgerald's farm, large scapolite crystals, albite (peristerite), pyroxene.

Pitcairn.—Feldspar, pyroxene, zircon! titanite, satin spar, associated with serpentine. Pope's Mills.—See Mineral Point.

Potsdam.—Amphibole; eight miles from Potsdam, on road to Pierrepont, feldspar, tour-

maline, black mica, amphibole.

Rossie. - On James Martin's farm, scapolite, pyroxene, titanite, tourmaline, black phlogopite. Near Grasse Lake, on Abner Anables farm, pyroxene! scapolite, graphite! in splendid crystals, with titunite, and feldspar; tremolite in short prismatic crystals.

Also (Iron Mines).—Barite, hematite, coralloidal aragonite (near Somerville), quartz, pyrite, dolomite; Rossie Lead Mine, calcite, gatena, pyrite, celestite. chalcopyrite, hematite, cerussite, anglesite, octahedral fluorite, black phlogopite; elsewhere in Rossie, calcite, barite, quartz crystals, chondrodite (near Yellow Lake), feldspar! pargasite! apatite, pyroxene, amphibole, titanite, zircon, mica, fluorite, serpentine, automolite, pearl spar, graphite.

Russell.—On Sam. Moore's farm, light green pyroxene! (uralite on the exterior), amphi-

bole! feldspar, scapolite, phlogopite. On Chas. Buskurk's farm, danburite! datolite (rare), scapolite, pyroxene, black tourmaline, albite, quartz, calcite, pyrite, black phlogopite, amphibole.

SARATOGA Co. - Greenfield. - Chrysoberyl! garnet! tourmaline! mica, feldspar, apatite, graphite, aragonite (in iron mines).

SCHOHARIE Co.—Ball's Cave, and others.—Calcite, stalactites. Carlisle.—Fibrous barite, cryst. and fibrous calcite. Schoharie. - Fibrous celestite, strontianite! cryst. pyrite!

SULLIVAN Co.—Wurtzboro'.—Galena, sphalerite, pyrite, chalcopyrite.

ULSTER Co. - Ellenville. - Galena, sphalerite, chalcopyrite! quartz! brookite, pyrite.

WARREN Co.—Caldwell.— Massive feldspar. Chester. - Pyrite, tourmaline, rutile, chalcopyrite. Diamond Isle (Lake George).—Calcite, quartz crystals. Johnsburgh. -Fluorite! zircon! graphite, serpentine, pyrite.

WASHINGTON CO.—Fort Ann.—Graphite, serpentine. Granville.—Lamellar pyroxene, massive feldspar, epidote.

WAYNE Co.-Wolcott.-Barite.

WESTCHESTER CO.—Anthony's Nose.—Apatite, pyrite, calcite! in large tabular crystals, grouped, and sometimes incrusted with drusy quartz.

Cruger's. - White pyroxene, amphibole, magnetite (with greenish spinel), staurolite,

sillimanite, corundum, hercynite.

Davenport's Neck.—Serpentine, garnet, titanite.

Eastchester.—Sphalerite, pyrite, chalcopyrite, dolomite. Hastings.—Tremolite, white pyroxene.

New Rochelle.—Serpentine, quartz, mica, tremolite, garnet, magnesite, chromite.

Peekskill.—Amphibole, staurolite, graphite.

Rye.—Serpentine, chlorite, black tourmaline, tremolite.

Sing Sing.—Pyroxene, tremolite, pyrite, beryl; azurite, green malachite, cerussite, pyromorphite, anglesite, vauquelinite. galena, native silver, chalcopyrite, wulfenite, vanadinite. At openings for the aqueduct, rutile, harmotome, heulandite, pectolite, stilbite, etc., in gneiss.

West Farms.—Apatite, tremolite, garnet, stilbite, heulandite, chabazite, epidote, titanite.

Yonkers.—Tremolite, apatite, calcite, analcite, pyrite, tourmaline.

Yorktown. - Fibrolite, monazite, magnetite.

WYOMING Co.—Wyoming.—Rock salt (and at many other localities, see above).

NEW JERSEY.*

The most important mineral locality of the State is that of the zinc mines of Franklin Furnace and two miles from there at Sterling Hill (near Ogdensburgh) in Sussex Co., where containing zinc and manganese, have been found. Magnetite is also mined in the northern counties (Sparta, Vernon), where the association is similar to that of the adjoining Orange Co. in New York. Green sand marls are mined along a belt 90 miles long from Sandy Hook to Delaware Bay. Zeolites and associated minerals of secondary origin have been obtained in fine specimens from the R. R. tunnels passing through the trap rock at Bergen, Weehawken.

Andover Iron Mine (Sussex Co.).—Willemite, brown garnet, limonite, malachite, azurite, sphalerite, calamine, chalcopyrite, pyrolusite, orthoclase, calcite, fluorite, phlogopite, talc, amphibole, flos ferri, blue asbestus.

Allentown (Monmouth Co.). - Vivianite, dufrenite.

Beemersville.—Elæolite. sodalite, titanite, ægirite, fluorite, pyrite, in elæolite-syenite.

Bellville.—Copper mines.

Bergen.—Calcite! datolite! pectolite! analcite, apophyllite! gmelinite, prehnite! titanite, stilbite, natrolite, heulandite, laumontite, chabazite, thomsonite, mesolite, pyrite, pseudomorphous steatite after apophyllite, diabantite, amphibole, sphalerite, chalcedony, copper, dolomite, epistilbite, fire-opal, hydrophane, milky quartz.

^{*} See the Catalogue of Minerals found in New Jersey, by F. A. Canfield, published in vol. 2, Part 1, of the final Report of the State Geologist, 1889.

Brunswick.—Native copper, malachite, mountain leather.

Bryam.—Chondrodite, spinel, at Roseville, epidote, zircon. Bush Mine and Cannon Mine (Passaic Co.).—Epidote.

Cantwell's Bridge (Newcastle Co.).—Vivianite.

Chester. - Melanterite.

Danville (Jemmy Jump Ridge).—Graphite, chondrodite, augite.

Flemington.—Copper mines. Frankfort.—Serpentine.

E. Belleville (Hudson Co.).—Azurite, chalcopyrite, chrysocolla, native copper, malachite.

Franklin Furnace and Sterling Hill near Ogdensburgh (Sussex Co.).—Spinel! garnet! rhodonite (fowlerite)! franklinite! zincite! galnite! amphibole, tremolite, chondrodite, white scapolite, black tourmaline, epidote, mica, actinolite, augite, salite, coccolite, asbestus, jeffersonite (augite), polyadelphite, calamine, graphite, fluorite, beryl, galena, serpentine, honey-colored titanite, axinite, barite, quartz, chalcedony, amethyst, zircon, molybdenite, vivianite, tephroite, rhodochrosite, aragonite, sussexite, chalcophanite, repperite, vanuxemite, heterolite, pyrochroite, rammelsbergite, bementite, chloanthite, niccolite, apatite, smaltite, allanite, desaulesite. Also algerite in gran. limestone; green tourmaline! phlogopite.

Franklin and Warwick Mt.-Pyrite.

Gove Mine (Morris Co.) - Vivianite. clear crystals on magnetite.

Griggstown and Greenbrook.—Copper mines.

Hamburg (Sussex Co.)—One mile north, spinel! tourmaline, phlogopite, amphibole, limonite, hematite.

Harrisonville (Gloucester Co.).—Amber.

Hibernia (Morris Co.).-Enstatite, fluorite, molybdenite, pyrite, quartz (cap crystals),

Hoboken.—Serpentine (marmolite), brucite, nemalite (fibrous brucite), aragonite, dolomite, agate, cerolite, chromite, hydromagnesite, jasper, selenite.

Howell's Mill (Sussex Co.).—Vesuvianite, titanite, tourmaline, rutile.

Hurdstown.—Apatite, pyrrhotite, magnetite, pyrite.

Imlaystown.—Vivianite.

Lockwood.—Graphite, chondrodite, talc, augite, quartz, green spinel, phlogopite.

Montville (Morris Co.).—Serpentine, chrysotile, gurhofite (dolomite), marmolite, pyroxene. Mullica Hill (Gloucester Co.). - Vivianite lining belemnites and other fossils, beraunite.

Newton.—Spinel, blue, pink, and white, corundum, mica. vesuvianite, amphibole, tournaline, scapolite, rutile, pyrite, tale, calcite, phlogopite, wernerite, galena, barite, pseudomorphous steatite.

N. Brunswick.—Azurite, barite, bornite, chalcopyrite, native copper.

Paterson.—At Hoxie's quarry, prehnite, datolite, apophyllite, laumontite, stilbite, chabazite, heulandite, natrolite, analcite, pectolite, quartz, calcite, malachite, etc., also quartz pseud. after pectolite, stilbite, datolite and apophyllite.

Phillipsburg.—Anthophyllite, apatite, augite, beryl, pyroxene, serpentine, tremolite.

Pluckamin Copper Mines (Somerset Co.).—Prehnite! zoisite, epidote.

Red Bank.-Vivianite.

Roseville (Sussex Co.).—Epidote, amphibole.

Sparta. - Augite, chondrodite, corundum, franklinite, phlogopite, rutile, spinel of varied colors, talc.

Stanhope.—At the Hude mine, molybdenite, molybdite, magnetite, selenite, copper.

Sterling Hill.—See Franklin Furnace.

Vernon.—Serpentine, spinel, hydrotaleite, dipyre, chondrodite, corundum, salite.

Weehawken.—At the R. R. tunnel, natrolite, apophyllite, stilbite, heulandite, pectolite, laumontite, allophane, anthraconite, hyalite, aragonite, pyrite, wad.

PENNSYLVANIA.*

Besides the great production of coal and oil, Pennsylvania affords magnetite in considerable quantity, as in the South Mountain belt, at Durham, Northampton Co.; Jones's mine near Morgantown, Berks Co.; Cornwall iron mountain, Lebanon Co.; near Knauertown and the Warwick mines, Chester Co. Hematite, limonite, and siderite are also mined at many points; further, galena in Chester, Montgomery, Bucks, and Blair counties; copper ores (chalcopyrite, etc.), at Jones's mine, near Morgantown, Berks Co.; Cornwall, Lebanon Co.; Fritz Island near Reading; near Knauertown, Chester Co. Further, nickel ores are mined (millerite, niccoliferous pyrrhotite) at the Gap nickel mine, Lancaster Co.; also chromite at the Wood's mine and Texas mine, Lancaster Co., and elsewhere.

ADAMS Co.—Near Gettysburg.—Epidote, fibrous and massive, cuprite, native copper.

^{*} See also the Preliminary Reports on the Mineralogy of Pennsylvania by Dr. F. A. Genth, 1875, 1876; also the Mineralogy of Pennsylvania by John Eyerman, 48 pp., 1889.

BEDFORD Co.-Bridgeport.-Barite.

BERKS Co.—At Jones's mine, 1 m. E. of Morgantown, malachite, native copper, chrysosolla, magnetite, allophane, pyrite, chalcopyrite, aurichalcite, cuprite, melaconite, byssolite, aragonite, apatite, talc. 2 m. N. E. from Jones's mine, graphite, titanite. At Steele's mine, magnetite, micaceous iron, coccolite, brown garnet.

Reading.—Smoky quartz crystals, zircon, stilbite, iron-ore. Near Pricetown, zircon, allanite,

Zion's Church, molybdenite. Near Kutztown, in the Crystal Cave, stalactites of aragonite,

quartz.

Fritz's Island, apophyllite, thomsonite, chabazite, gismondite?, datolite, brucite, grossularite, marcasite, xanthite, calcite, azurite, malachite, magnetite, chalcopyrite, stibnite, prochlorite, precious serpentine.

Buckingham Township.—Crystallized quartz. Near New Hope, vesuvianite, epidote,

Southampton.—Near Feasterville, in G. Vanarsdale's quarry, graphite, pyroxene, salite, coccolite, titanite, green mica, calcite, wollastonite, glassy feldspar sometimes opalescent (microcline?), phlogopite, blue quartz, garnet, zircon, pyrite, pyrrhotite, moroxite, scapolite.

New Britain.—Dolomite, galena, sphalerite, malachite.

BLAIR Co.—Bell's Mills near Frankstown.—Celestite (fibrous), quartz crystals.

CARBON CO.—Summit Hill.—In coal mines, kaolinite.

CHESTER Co.—Avondale.—Asbestus, tremolite, garnet! opal, beryl (yellow), tourmaline, mountain leather.

Birmingham Township.—Amethyst, serpentine.

East Bradford.—Near Buffington's bridge, on the Brandywine, green, blue, and gray cyanite, gray crystals loose in the soil. Farms of Dr. Elwyn, Mrs. Foulke, Wm. Gibbons, and

Saml. Entrikin, amethyst. At Strode's mill, oligoclase, drusy quartz, collyrite?

Osborne's Hill, wad, manganesian garnet (massive), titanite. Caleb Cope's lime quarry, fetid dolomite, necronite, blue cyanite, talc. Near the Black Horse Inn, indurated talc, rutile. Amos Davis's farm, allanite! Near the paper mill on the Brandywine, zircon, ilmenite, blue

West Bradford.—Near village of Marshalton, green cyanite.

At Chester County Poorhouse limestone quarry, chesterlite! on dolomite, rutile! in acicular crystals, damourite! radiated on dolomite, quartz crystals.

Charlestown.—Pyromorphite, cerussite, galena, quartz, amethyst.

North Coventry.—Allanite, near Pughtown, black garnets.

French Creek Mines (St. Peters).—See WARWICK. East Goshen.—Serpentine, asbestus, magnetite.

Elk.—Ilmenite with muscovite, chromite.

West Goshen.—On the Barrens. 1 m. N. of West Chester, serpentine, indurated talc, deweylite, aragonite, staurolite, asbestus, zoisite on hornblende at West Chester water-works (not accessible at present).

New Garden.—At Nivin's limestone quarry, brown and yellow tourmaline, necronite,

aragonite, sillimanite, kaolinite, tremolite.

Kennett.—Actinolite, tremolite. On Wm. Cloud's farm, sunstone! At Pearce's old mill, sunstone.

East Marlborough.—On farm of Bailey & Brother, 1 m. S. of Unionville, yellow and white tourmaline, chesterlite, white pyroxene. Near Marlborough meeting-house, serpentine, zircon loose in the soil at Pusey's sawmill.

West Marlborough.—Near Logan's quarry, asbestiform tremolite, black tourmaline,

West Marlborough.—Near Logan's quarry, asbestiform tremolile, black fourmaline, cyanite, yellow tourmaline, rutile. Near Doe Run village, tremolite. In R. Baily's limestone quarry, 2½ m. S. W. of Unionville, fibrous tremolite, cyanite.

Newlin.—1½ m. N. E. of Unionville, corundum! often in loose crystals with a coating of a soda-margarite (Genth), diaspore! spinel (black), picrolite, black tourmaline with flat pyramidal terminations in albite, unionite (zoisite), euphyllite, feldspar, beryl! in one crystal weighing 51 lbs., pyrite, chloritoid, diallage, oligoclase; ilmenite, clinochlore, albite, orthoclase, halloysite, margarite, garnet, beryl. On J. Lesley's farm, corundum, a single mass weighing over 100 tons, diaspore! "lesleyite." In Edwards's limestone quarry, rutile. C. Passmore's farm, methyst amethyst.

East Nottingham.—Asbestus, chromite in crystals, hallite.

West Nottingham.—At Scott's chrome-mine, chromite, foliated tale, marmolite, serpentine, rhodochrome. Near Moro Phillips's chrome-mine, asbestus. At the magnesia quarry, deweylite, marmolite, magnesite, albite, serpentine, chromite, meerschaum. Near Fremont P. O., corundum.

West Pikeland.—In iron-mines near Chester Springs, turgite, limonite (stalactitic and in

geodes), göthite.

Pennsbury.—On John Craig's farm, brown garnets, mica. On J. Dilworth's, near Fair-ville, muscovite! in Fairville, sunstone. Near Brinton's Ford, chondrodite, titanite, augite. At Swain's quarry, orthoclase, muscovite containing magnetite.

Pocopson. - Farms of J. Entrikin and J. B. Darlington, amethyst.

Sadsbury.—Rutile! crystals loose for 7 m. along the valley, near the village of Parkesburg.

Near Sadsbury village, amethyst.

Schuylkill.—In railroad tunnel at Phœnixville, dolomite! quartz crystals, calcite. WHEATLEY, BROOKDALE, and CHESTER COUNTY LEAD MINES (now abandoned, and good specimens not obtainable), 11 m. S. of Phænixville, pyromorphite! cerussite! galena, anglesite! quartz crystals, chalcopyrite, barite, fluorite (white), wulfenite! calamine, sphalerite! mimetite! descloizite, göthite, chrysocolla, native copper, malachite, azurite, limonite, calcite, ankerite, sulphur, pyrite, melaconite, pseudomalachite, gersdorffite, chalcocite?, covellite.

Willistown.—Magnetite, chromite.

West Town.—Brinton's serpentine quarry, 3 m. S. of West Chester, clinochlore, jefferisite, amethyst, tourmaline, beryl.

West Whiteland.—At Gen. Trimble's iron-mine (southeast), stalactitic hematite! wavellite!

in radiated stalactites, cœruleolactite.

Warwick.—French Creek mines (Elizabeth mine and Keim's mine, 1 m. N. of Knauertown), garnet! micaceous hematite, pyrite (octahedral)! chalcopyrite massive and in crystals! in thuringite, magnetite, brown garnel, calcite, pyroxene, in part alt. to amphibole, scapolite, siderite, rhodochrosite, stilbite, apophyllite, erythrite, byssolite! serpentine. Near village of St. Mary's, magnetite (dodecahedral), melanite, garnet, actinolite. At Hopewell iron mine, 1 m. N. W. of St. Mary's, magnetite in octahedral crystals.

Yellow Springs.—Allanite.

DAUPHIN Co.—Near Hummelstown.—Green garnets, cryst. smoky quartz, feldspar.

DELAWARE Co.—Aston Township.—Amethyst, corundum (Village Green), sillimanite, black tourmaline, margarite, sunstone, asbestus, antholite, steatite, quartz in modified cryst., also with implanted rutile cryst. Bridgewater Station (the locality in Chester township), titanite! in twins 2 inches long and translucent. At Peter's mill-dam in the creek, garnet.

Bethel.-Garnet.

Birmingham. - Sillimanite, kaolin (abundant), rutile, amethyst. At Bullock's old quarry,

Chester.—Amethyst, black tourmaline, beryl, crystals of orthoclase, garnet, molybdenite, molybdite, muscovite.

Chichester.—Lower Chichester.—Orthoclase, tourmaline, beryl, garnet, kaolin, cyanite. Upper Chichester.—Spessartite, titanite, amethyst, orthoclase, green garnet, gahnite.

Concord.—Mica, feldspar, kaolin, drusy quartz, garnet, sillimanite, amethyst, manganesian garnet, meerschaum. In Green's creek, garnet.

Darby.—Blue and gray cyanite, beryl, garnet, smoky quartz, titaniferous garnet, zoisite, Babel quartz.

Edgemont.—Amethyst. One m. E. of Edgemont Hall, rutile in quartz, limonite.

Leiperville.—Garnet, zoisite (thulite), heulandite, leidyite, beryl (Deshong's quarry), black tourmaline.

Marple.—Tourmaline, andalusite, andalusite-pseud. (damourite), amethyst, bronzite, talc, radiated actinolite in talc, chromite, beryl, ilmenite in quartz, amethyst.

Middletown.—Amethyst, beryl, black mica, mica with dendritic magnetite, manganesian gurnets! some 3 inches in diameter, indurated talc, rutile, mica, green quartz! anthophyllite,

radiated tourmaline, staurolite, ilmenite, sillimanite, serpentine.

At Lenni, lennilite, chlorite, green and bronze vermiculite! green feldspar. At Mineral Hill, crystals of corundum, some of 6 inches, actinolite, bronzite, green feldspar (Lea's lennilite, etc.), moonstone, sunstone, magnesitc, chromite (octahedrons), columbite, beryl, asbestus, microcline, talc, muscovite, deweylite, stilbite, enstatite, rutile, melanosiderite, hallite. At Painter's Farm, zircon with oligoclase, painterite, tremolite, tourmaline. At Hibbard's Farm and at Fairlamb's Hill, chromite in brilliant octahedrons. John Smith farm, meerschaum,

Also orthoclase, muscovite, rose quartz, gahnite, zircon, amethyst, vermiculite, ferruginous

quartz, prase.

Newtown.—Serpentine, hematite, enstatite, stalactitic quartz.

Upper Providence.—Antholite, radiated asbestus, andalusite, radiated actinolite, tourmaline, beryl, green feldspar, amethyst (one of 7 lbs. from Morgan Hunter's farm), andalusite! At Blue Hill, green quartz in chlorite, chrysotile in serpentine, cassinite, enstatite, clinochlore, bronzite, diaclasite, apatite.

Lower Providence.—Amethyst, garnet, feldspar! (large crystals).

Radnor.—Enstatite, serpentine, pseudomorph after asbestus, quartz after serpentine, genthite, picrolite hornstone, chrysotile, chromite, garnet, staurolite, labradorite, blue quartz. Springfield.—Andalusite, tourmaline, beryl, ilmenite, garnet. On Fell's Laurel Hill, beryl,

garnet. Near Lewis's paper-mill, allophane, mica, albite. Waterville.—Near Chester and Upland, chabazite.

FRANKLIN Co.-Lancaster Station.—Barite, fluorite.

LANCASTER CO.—Drumore Township.—Quartz crystals.

Fulton.—At Wood's chrome mine, near Texas, brucite!! zaratite (emerald nickel), pennite, clinochlore! kammererite! bronzite, baltimorite, chromite, williamsite, chrysolite! marmolite, picrolite, hydromagnesite, dolomite, magnesite, aragonite, calcite, serpentine, hematite, ilmenite, genthite, chrome-garnet, millerite. At Low's mine, hydromagnesite, brucite, picrolite, magnesite, williamsite, chromite, talc, zaratite, baltimorite, serpentine, hematite. Ou M. Boice's farm, 1 m. N. W. of village, pyrite, enstatite. Near Rock Springs, chalcedony, carnelian, moss agate, green tourmaline in talc, titanic iron, chromite, octahedral magnetite in chlorite. At Reynolds's old mine, calcite, talc, picrolite, chromite. At Carter's chrome mine, brookite (one crystal found).

Gap Mines.—Chalcopyrite, pyrrhotite (niccoliferous), millerite (botryoidal radiations), vivi-

anite! actinolite, siderite, hisingerite, pyrite. Noblis mine, cacoxenite! on limonite.

Pequea Valley.—8 m. S. of Lancaster, argentiferous galena, vauquelinite, rutile, at Pequea mine. 4 m. N. W. of Lancaster, calamine, galena (with octahedral cleavage), sphalerite; pyrite in cubes near Lancaster. At the Lancaster zinc mines, calamine, sphalerite, tennantite? smithsonite (pseud. of dolomite), aurichalcite.

LEBANON Co.—Cornwall.—Magnetite, pyrite (cobaltiferous), chalcopyrite, native copper, azurite, malachite, chrysocolla, cuprite (hydrocuprite), allophane, brochantite, serpentine, quartz pseudomorphs; fluorite, covellite, hematite (micaceous), opal, asbestus, sphalerite, prehnite.

LEHIGH CO .-- Friedensville. -- At zinc mines, calamine, smithsonite, hydrozincite, massive sphalerite, greenockite, quartz, allophane, mountain leather, aragonite, lanthanite, sauconite. Near Allentown, magnetite, pipe-iron ore. Near Bethlehem. on S. Mountain, allanite, with zircon, magnetité, martite, black spinel, tourmaline, chalcocite, chloropal. Ironton.—Psilomelane in stalactitic, botryoidal, and reniform masses.

Macungie. — Wavellite!

Shimerville.—Corundum! in fine crystals, black spinel.

LUZERNE CO.—Scranton.—Under peat, phytocollite. Drifton.—Pyrophyllite.

MIFFLIN Co.—Opposite Mount Union.—Strontianite, aragonite.

MONROE Co.—In Cherry Valley, calcite, chalcedony, quartz. In Poconac Valley, near Judge Mervine's, cryst. quartz.

MONTGOMERY Co.—Conshohocken.—Fibrous tourmaline, ilmenite, aventurine quartz, phyllite, limonite, cacoxenite, pyrite. In the quarry of Geo. Bullock, calcite in hexagonal

Lafayette, at the Soapstone quarries.—Talc, jefferisite, garnet, albite, serpentine, zoisite, staurolite, chalcopyrite. At Rose's Serpentine quarry, opposite Lafayette, enstatite, serpentine, millerite! genthite, chalcanthite, bornite, epsomite, aragonite, chlorite, tremolite, steatite, dolo-

mite, serpentine pseudomorph after staurolite.

Lower Providence.—Perkiomen lead and copper mines, near village of Shannonville, azurite, sphalerite, galena, pyromorphite, cerussite, wulfenite, anglesite, barite, calamine, chalcopyrite, malachite, chrysocolla, ankerite, cuprite, covellite (rare), melaconite, pseudomalachite.

White Marsh.—D. O. Hitner's iron mine, limonite in geodes and stalactites. göthite, pyrolusite, wad, lepidocrocite. At Edge Hill Station (P. R. R.), ilmenite, braunite, pyrolusite, limonite, turgite, braunite, velvet manganese, titaniferous hematite, rutile, wad.

Near Marble Hall, at Hitner's marble quarry, white marble, granular barite, resembling marble. At Spring Mills, limonite, pyrolusite, göthite. At Flat Rock Tunnel, opposite Manayunk, stilbite, heulandite, chabasite, ilvaite, beryl, feldspar, mica.

NORTHAMPTON Co.—Bethlehem.—Axinite, zircon (3 m. N.). Bushkill T.—Crystal Spring on Blue Mountain, quartz crystals.

Nazareth -Quartz crystals.

Near Easton.—Zircon! (exhausted), coccolite, tremolite, pyroxene, salite, limonite, mag-

uetite, purple calcite, bowenite.

Williams Township.—Pyrolusite in geodes in limonite beds, göthite (lepidocrocite) at Glendon.

NORTHUMBERLAND CO.—Opposite Selin's Grove.—Calamine.

PHILADELPHIA CO.—Frankford.—At quarries on Frankford Creek, stilbite! molybdenite! in fine crystals, hornblende, titanite, apophyllite, tourmaline, fluorite, calcite, bornite, chalco-pyrite, malachite, chrysocolla, hyalite colored by uranium, apatite, lepidomelane, titanite, randite, Iceland spar, orthoclase, oligoclase. On the Connecting Railroad, wad, earthy cobalt, basanite in the drift.

Fairmount Water-works. - Autunite! torbernite, orthoclase, beryl, tourmaline, albite, wad,

intercrystallized black and white mica.

Near Girard Avenue and the Schuylkill, ilmenite. Thirty-sixth Street and Penn. R. R., garnet, wad. Fifty-ninth Street and Penn. R. R., halotrichite, glockerite. Darby Tunnel, B. & O. R. R., anhydrite.

Wissahickon Čreek.—McKinney's quarry on Rittenhouse Lane, orthoclase, apatite, stilbite, heulandite, epidote, bornite, malachite, chalcopyrite, chrysocolla, laumontite. Near Gorgas's and Crease's Lanes, tourmaline, cyanite, staurolite. Near Heft's Mill, alunogen, tourmaline, cyanite.

Cresheim Creek.—Antholite in radiated masses. One half mile above, staurolite, ilmen-

ite, hyalite, apatite, green mica, iron garnets in abundance.

Thorp's Lane.—Talc, magnetite.

Falls of Schuylkill.—Chabazite, titanite, fluorite, apatite, muscovite, tourmaline, prochlorite, quartz crystals, crocidolite laumontite, analcite.

SCHUYLKILL CO.—Tamaqua (near Pottsville), in coal mines.—Kaolinite. Lansford, near Tamaqua, in an anthracite mine, lansfordite, nesquehonite.

Near Mahanoy City.—Pyrophyllite, alunogen, copiapite, in coal-mines.

YORK Co.—Bornite, rutile in slender prisms in granular quartz.

DELAWARE.

KENT Co.—Near Middletown, Polk's marl-pits (not open).—Vivianite! East Dover.—Limonite.

NEWCASTLE CO.—Brandywine Springs.—Fibrolite, salite, pyroxene. Brandywine

Hundred, muscovite inclosing reticulated magnetite, garnet.

Dixon's Feldspar Quarries, 6 m. N. W. of Wilmington (not open).—Beryl, apatite, cinnamon-stone! magnesite, serpentine, asbestus, black tourmaline! cyanite.

Eastburn's Limestone Quarries, near the Pennsylvania line (not always worked).—Tremolite, bronzite.

Hockessin, on the Del. West. R. R.-Kaolin (large deposit), feldspar.

Kennett Turnpike, near Centreville.—Cyanite and garnet.

Near Newark, on the railroad. - Sphærosiderite on drusy quartz, jasper (ferruginous opal), cryst. siderite in cavities of cellular quartz, quartz crystals loose in soil; limonite mined at Chestnut Hill pits.

Quarryville.—Garnet, fibrolite.

On Talley's Farm near Shellpot Creek.—Feldspar, muscovite inclosing reticulated magnetite and layers of quartz, kaolin, hypersthene.

Way's Quarry, 2 m. S. of Centreville (not open).—Feldspar in cleavage masses, apatite,

mica, deweylite, granular quartz.

Near Wilmington.—Hornblende, bog-iron ore, hypersthene.

Wilmington Granite Co. Quarries on the Brandywine.—Metalloidal diallage, black hornblende, tourmaline, chalcopyrite, stilbite! (rare).

Wooddale Quarries.—Garnet, biotite, feldspar.

SUSSEX Co.—Near Cape Henlopen.—Vivianite. At various localities, limonite.

MARYLAND.

BALTIMORE CO.—Baltimore City, Jones Falls gneiss quarries.—Microcline, lepidomelane, epidote, titanite, siderite (sphærosiderite), barite, calcite, apatite, pyrite, chabazite (haydenite), heulandite (beaumontite), stilbite, laumontite, harmotome (rare). In pegmatyte veins, muscovite, tourmaline apatite, molybdenite, samarskite (?).

Bare Aills.—At the copper mines in hornblende gneiss, octahedral magnetite! amphiboleanthornyllite! bornite, chalcopyrite. At Blue Mount on Northern Central R. R., dodecahedral

garnet, sillimanite, and octahedral magnetite in chlorite schist.

Bare Hills and Soldier's Delight .- In serpentine, chromite, kämmererite, talc, steatite, chrysotile (baltimorite), magnesite (crystalline and earthy).

Texas.—In white marble, phlogopite, tremolite, pyrite, pink scapolite, brown and black tourmaline, rutile, green muscovite.

Owing's Mills, Western Run, and Warren Mills.-In muscovite-gneiss, staurolite, cyanite, garnet.

Green Spring Valley, Shoemaker's quarry.—In quartz schist, stretched black tourmaline!

muscovite.

CARROLL CO.—Marriottsville.—In marble, white augite, changed to tremolite! phlogopite. Near Union Bridge (Mountain View lead mine). - In white limestone, galena, anglesite, cerussite, sulphur.

Finksburg. —At copper mines in hornblende gneiss, chalcopyrite, bornite, siegenite, carrollite,

remingtonite, malachite, magnetite.

Mineral Hill.—Chalcopyrite, bornite, magnetite, gold.

Sykesville (Florence and Springfield mines, exhausted).—Gold on magnetite, chalcopyrite, bornite, pyrite, carrollite.

Piney Run.—In pyroxenyte, bronzite altering to talc, steatite.

CECIL Co.—Near the Pennsylvania line.—Chromite in serpentine.

CHARLES Co.—In Cretaceous clay, radiating groups of large gypsum crystals.

FREDERICK Co. - Dolyhyde copper mine (abandoned). - Formerly hornite, chalcopyrite, malachite, ottrelite.

Liberty copper mine.—Black, gray, and purple copper ore, chalcocite, malachite, hematite

in dolomite.

Catoctin Furnace.—Limonite, ocher, hematite, and franklinite in vein quartz.

1 mile south of Mechanicstown. - Manganese. Middletewn Valley.—Smoky quartz! stibnite.

HARFORD CO.—Cooptown and Tarrettsville.—In serpentine, chromite, kämmererite, green talc, chrysotile, tourmaline.

Near Deer Creek.—In chlorite schist, octahedral magnetite.

On Broad Creek.—Mottled and veined serpentine (quarried). In metamorphic sandstone at "The Rocks" of Deer Creek, blue cyanite! magnetite, chlorite.

At Pylesville.—Graphite.

HOWARD Co.—Ellicott City.—Envelope titanite, allanite-epidote, parallel growths (p. 525),

at the quarries on left bank of Patapsco River.

Ilchester.—In pegmatyte, microcline, garnets, black and white micas. In peridotyte, near station, peccilitic hornblende, and tale after hornblende. In pyroxenyte, near Gray's Bridge, smaragdite after pyroxene. In porphyritic noryte, hypersthene. In gabbro-dioryte, "titanomorphite," titanite around rutile and ilmenite.

MONTGOMERY CO.—Etchison P. O.—In serpentine, chromite, chrome-tourmaline! fuchsite. Great Falls and Sandy Spring, gold in vein quartz, manganese formerly mined, beryl, orthoclase, mica.

ST. MARY'S Co.-In Miocene clay, groups of large gypsum crystals.

WASHINGTON CO.—Maryland Heights, opposite Harper's Ferry.—Thuringite (owenite).

DISTRICT OF COLUMBIA.

Near Washington.—Prochlorite, yellow titanite, rutile, ilmenite, calcite, gold.

VIRGINIA.

Virginia affords some gold, both in gold gravel and in gold quartz; limonite abundantly, also hematite and magnetite; manganese (pyrolusite) in large quantities in Augusta Co., also Rockbridge and Smythe Cos., etc.; lead and zinc ores (galena, calamine, smithsonite, sphalerite) in Wythe and Pulaski Cos.; copper ores (chalcopyrite, etc.) in Floyd Co., Carroll Co., etc. Rock salt is obtained in Saltville, Smythe Co.; also salt from brines in Washington and Lee Cos.

ALBEMARLE Co. - Faber's. - Galena, sphalerite, fluorite, gold, serpentine or potstone, graphite.

Ragged Mountains, 4 miles west of Univ. of Virginia. -Quartz crystals. 6 miles west, 1 mile south of Univ. of Virginia, pseudomorphs of limonite after pyrite.

ALLEGHANY CO.—Limonite, hematite. The deposits also extend into Bath, Bland, Craig, Giles, and Highland Cos.

AMELIA Co.—Near Court House, mica! orthoclase, albite, microlite! columbite, allanite, helvite, spessartite! topazolite, amethyst, fluorite, apatite, white beryl, monazite, phenacite, fergusonite:

AMHERST Co.—Along the west base of Buffalo Ridge, copper ores. On N. W. slope of Friar Mtn.—Allanite, magnetite, zircon, sipylite, ilmenite.

AUGUSTA CO.—Crimora.—Pyrolusite (cryst.) and psilomelane, abundant $(\frac{1}{20})$ of product of

U. S., 1890). W. foot of Blue Ridge, hematite, limonite, graphite.

1 mile E. of Staunton.—Pseudomorphs of limonite after pyrite. At Weyer's (or Weir's) cave, calcite, stalactites.

BEDFORD CO.—Near Montvale.—Bronzite, pyrite. Near the Peaks of Otter, allanite. Tscheffkinite (exact local, not given).

BOTETOURT CO.—Limonite, hematite, psilomelane, pyrolusite.

BUCKINGHAM CO.—Gold at Garnett and Moseley mines, also pyrite, pyrrhotite, calcite, garnet. At Eldridge mine (now Loudon and Virginia mines) and the Buckingham mines near Maysville, gold, auriferous pyrite, chalcopyrite, tennantite, barite, cyanite, tourmaline, actinolite.

Arvon slate quarries. - Octahedrite. Willis Mt., cyanite, tourmaline.

CAMPBELL Co. - Near Lynchburg. - Rutile.

CARROLL and GRAYSON COS. - Chalcopyrite, pyrite, melaconite, galena, sphalerite, pyrrhotite, magnetite, limonite.

CULPEPPER Co., on Rapidan River.—Gold, pyrite.

FAUQUIER Co., Barnett's mills.—Asbestus, gold mines, barite, calcite.

FLOYD Co.—Pyrrhotite! magnetite, hematite, gold.

FLUVANNA CO.—Gold at Stockton's mine. Also tetradymite, at "Tellurium mine." Phenix Copper Mine, chalcopyrite, etc.

FRANKLIN Co.—Grayish serpentine, "potstone." [This substance is not steatite (as Rogers calls it), having much iron (27 p. c. FeO) and little or no alumina; the same is true of all in this belt, Albemarle, etc.—F. P. D.] Also bornite, chlorite, muscovite, pyrrhotite, magnetite.

GOOCHLAND CO. - Gold mines (Moss and Busby's).

GREENE CO. - Malachite, pyrolusite (also in Madison Co.), native copper in felsyte, hematite.

HALIFAX Co.—Chalcopyrite, graphite.

HENRICO CO. (also Hanover, Chesterfield, Caroline, Prince William, Spottsylvania, and Stafford Cos.).—Glauconite (greensand marl).

JEFFERSON Co.—Shepherdstown.—Fluorite.

LOUDON CO.—Tabular quartz, prase, pyrite, talc, chlorite, soapstone, asbestus, chromite, actinolite, quartz crystals, micaceous hematite, bornite, malachite, epidote, near Leesburg (Potomac mine).

LOUISA Co.—Walton gold mine, gold, pyrite, chalcopyrite, argentiferous galena, siderite, sphalerite, anglesite. Boulangerite, sphalerite (at Tinder's mine). Corundum (40 m. N. of Richmond). Pyrite in large quantities, pyromorphite, cerargyrite.

Tolersville.—Pyrite.

MONTGOMERY Co. - Chalcopyrite, pyrite, pyrrhotite, magnetite.

NELSON Co.-Near Fawbers.-Fluorite.

Near Lowesville.—Allanite. 6 miles east of Lowesville, massive rutile.

Near Arrington.—Crystallized rutile.—Also galena, chalcopyrite, malachite, allanite. Isolated mass of tscheffkinite at Hat Creek.

ORANGE CO.—Western part, Blue Ridge, hematite. Gold at the Orange G Vaucluse gold mines, worked by the "Freehold" and "Liberty" Mining Companies. Gold at the Orange Grove and PAGE CO.-Luray Cave.-Stalactites. On Stony Man Mtn., malachite, limonite.

PATRICK Co.—Magnetite, staurolite, chloritoid, cyanite, corundum.

PITTSYLVANIA Co.—Barite, hematite.

PULASKI CO.—Hematite, limonite,

ROANOKE Co.—At Bonsacks.—Smithsonite, sphalerite.

ROCKBRIDGE CO.—On Irish Creek.—Cassiterite, wolframite, arsenopyrite (auriferous), epidote, fluorite, pyrite.

Near Lexington.—Pyrite, limonite pseud. after pyrite. Three m. S. W. of Lexington,

barite, dufrenite, in bed 10 in, thick, with strengite. In Petetes Gap, zircon.

Near Buena Vista.—Wad, göthite. Mouth of Irish Creek, pyrolusite. In James River Gap, epidote (crystals). West of Lexington, galena, quartz crystals (in crystalline limestone) In James River calcite. In the Blue Ridge, magnetite.

SHENANDOAH CO .- Near Woodstock .- Fluorite.

SMYTH Co.—Near Marion.—Barite.

SPOTTSYLVANIA Co., 2 m. N. E. of Chancellorsville.—Cyanite; gold mines at the junction of the Rappahannock and Rapidan; on the Rappahannock (Marshall mine); Whitehall mine, affording also tetradymite.

STAFFORD Co.-8 or 10 m. from Falmouth.-Micaceous iron, gold, tetradymite, silver, galena, vivianite.

WASHINGTON Co.—18 m. from Abingdon.—Halite, gypsum.

WYTHE CO.—Austin's Mines.—Cerussite, minium, plumbic ocher, sphalerite, calamine, galena, graphite, aragonite.

Bertha Mines.—Calamine!! sphalerite, hematite, limonite.

WEST VIRGINIA.

MASON Co.—Glenwood and Mason.—Cassiterite.

MINERAL Co.—Brady's, 5 m. S. of Cumberland, Md.—In Helderberg, limestone, blue celestite!

There are also hematite, limonite, siderite mines; also salt wells, as in Mason Co.

NORTH CAROLINA.*

The following is a general statement in regard to the most important economic minerals of the state: Gold is found in quartz veins in gneissic, granitic, and dioritic rock, also in talcose, chloritic, argillaceous, and arenaceous slates or in beds in the slates; in veins generally associated with pyrite, chalcopyrite, more rarely with galena and sphalerite, and the products of their oxidation; or in auriferous gravels. The principal counties in which it has been found in quantity are: Franklin, Nash, Granville, Alamance, Chatham, Moore, Guilford, Davidson, Randolph, Montgomery, Stanly, Union, Cabarrus, Rowan, Mecklenburgh, Lincoln, Gaston, Catawba. Caldwell, Burke, McDowell, Rutherford, Polk, Cleveland, Cherokee, Jackson, Transylvania, and Watauga.

Iron Ores.—Valuable deposits of hematite and limonite are found in the counties of Chatham, Orange, Gaston, Lincoln, Catawba, Caldwell, Madison, and Watauga. Magnetite of superior quality occurs in belts, stretching through many counties for a distance of over 20 miles in the direction

^{*} See the Minerals of North Carolina by F. A. Genth, Bulletin 74 of the U. S. Geol. Survey, 1891. The list here given has been condensed for this place by Dr. Genth.

of the inclosing strata from N. E. to S. W.; titaniferous ores often in parallel bands between pure magnetite. The principal counties in which they occur are: Chatham, Davidson, Guil ford, Forsyth, Rockingham and Stokes, Yadkin, Davie, Lincoln and Gaston, Catawba, Swain, Madison, Mitchell, Ashe, and several others. West of the Blue Ridge many *mica* mines are worked, especially in Macon, Jackson, Haywood, Buncombe, Ashe, McDowell, Mitchell, Yancey, Alexander, Cleveland, and other counties; these mines have furnished many highly interesting minerals. Corundum is also found in the same region in connection with chrysolite rocks—which latter have furnished by their decomposition many interesting magnesian minerals. The state has also yielded large quantities of zircon, monazite, etc.

ALEXANDER Co.—White Plains.—Scorodite, columbite, tourmaline, beryl, rose quartz, smoky quartz, rutile in geniculated and acicular crystals in limonite and in quartz, spodumene, in emerald and yellowish green crystals (hiddenite).

Price and Keever Place.—Beryl, tourmaline, columbite, autunite, muscovite.

Lead Mine.—Amethyst.

Hiddenite P. O.—Beryl! and emerald! monazite! spodumene (hiddenite), green and yellowish crystals! apatite, calcite, dolomite! siderite, rutile! muscovite! hisingerite, tourmaline. Taylorsville, three miles distant, smoky quartz, rock crystal, tourmaline, beryl.

Marshall's Farm.—Garnets.

Elsewhere.—Green, brown, and black tourmaline, graphite, magnetite, tantalite, beryl (yellow, blue, green) quartz crystals! (highly modified), monazite, asbestus, pyrite, magnetite, chalcopyrite, pyrolusite, limonite pseudomorph after siderite, siderite, kaolinite, orthoclase, large crystals (one of 40 pounds), biotite, muscovite, rutile! very fine at Milholland's mill, tourmaline!

ALLEGHANY Co.—Peach Bottom Mine.—Pyrite, chalcopyrite, malachite, galena, cuprite, sphalerite, molybdenite.

ASHE Co.—Ore Knob Mine.—Pyrite, calcite, chalcocite, arsenopyrite, malachite, metallic copper.

New River (South Fork, near mouth).—Chrysolite, chalcopyrite, magnetite.

Gap Creek (Copper Knob mine).—Gold, silver, hematite, epidote, bornite, chalcocite, chalcopyrite, chrysocolla, malachite. On Gap Creek, cyanite, hornblende.

Elk Knob.—Chalcopyrite, epidote. Phoenix Mountain.—Rock crystal!

BUNCOMBE CO.—Asheville.—Garnet, magnetite, serpentine, barite (granular). On Fox Branch, chrysolite. 19 to 20 miles north, pyrrhotite, magnetite, hematite, corundum with horn-blende and culsageeite, serpentine, prochlorite, asbestus, actinolite, kaolin, jefferisite.

Black Mountain.—Almandite garnet, cyanite at Bowlen's Pyramid.

Balsam Gap mine.—Allanite! beryl, muscovite, biotite, albite, black garnet, columbite,

Ivy River.—Chrysolite, chromite, hornstone, genthite, talc, asbestus, tremolite.

Brushy Mountain Mine.—Muscovite, kaolinite, orthoclase, albite. Ream's Creek.—Garnet, large crystals.

Burnet Mine.—Muscovite, orthoclase crystals, large (100 to 1,000 pounds).

Swannanoa Gap.—Corundum in cyanite! muscovite.

Elsewhere. - Muscovite in many mica mines with beryl, talc, columbite, garnet, ilmenite.

BURKE Co.—Brindletcwn.—At Mills's and other placer gold mines, crystallized gold, tetradymite, montanite, brookite, octahedrite, rutile, zircon and malacon, cyrtolite, monazite, xenotime, sometimes in crystals an inch across, and rarely of a sage- to grass-green color, samarskite, columbite, fergusonite, hydrofergusonite, ilmenite, hematite, magnetite, chromite, limonite, pyrite, titanite, cyanite, fibrolite, corundum, muscovite, vermiculite, enstatite, hornblende (green and black) steatite, tourmaline (green and black) orthoclase, albite, zoisite (?), garnet, actinolite, beryl, talc, asbestus, quartz (clear, smoky, and amethystine) psilomelane, arsenopyrite (?), allanite, thorite, diamond.

Bear's Knob.—Corundum with muscovite, 4 miles southeast.

Linnville Mountain.—Ilmenite, hematite, itacolumyte! radiated pyrophyllite, limonite, graphite.

Shoup's Ford.—Beryl, garnet, corundum, in part altered to fibrolite gold, magnetite,

ilmenite, cyanite, tourmaline.

South Mountains. - Quartz crystals! inclosing liquid, garnet! beryl! yellowish green and deep green (aquamarine), tourmaline! serpentine, talc, chlorite, actinolite, hematite, magnetite, asbestus, magnesite. breunnerite, chrysolite, garnet, tremolite, corundum, arsenopyrite.

Sugar Mountains.—Quartz crystals, asbestus, gold, rutile, magnetite, beryl.

CABARRUS Co.—Gold in many veins and placers, sulphur, chalcopyrite, magnetite, limonite.

Daniel Barnhardt's Farm. - Barnhardtite.

Barringer's Mine.—Gold, arsenopyrite in calcite. Boger's Mine. - Tetradymite, chalcopyrite, azurite.

Cosby's Mine.—Wolframite, scheelite, cuproscheelite, siderite, barite.
Cullen's Mine.—Tetradymite, cuprite (cubes), pseudomalachite, scheelite, malachite, in part pseudomorphous after cuprite, azurite. Flowe's Mine.—Wolframite! scheelite, barite.

George Ludwick's Mine. - Gold, arsenopyrite, tetrahedrite, scorodite, pyrite, chalcopyrite. McMakin's Mine.—Silver, argentite, galena, sphalerite, proustite (?), tetrahedrite, var. freibergite! pyrolusite, pyromorphite, barite, goslarite, rhodochrosite, magnesite, calcite, wad, barite, talc.

Phœnix Mine.—Gold, tetradymite. In Orchard vein, barite, pyrite, chalcopyrite. Numerous

mines of gold and copper ores.

CALDWELI Co. Baker's Mine. Galena, serpentine, picrolite, chrysotile, chrysolite, pyromorphite, anglesite, cerussite, asbestus, marmolite, psilomelane, chromite. Elsewhere.—Gold, in placers and veins, chalcopyrite, mouth of Rocky River, amethyst,

kaolin, halloysite.

CATAWBA Co.—Many valuable magnetite deposits.

Hickory.—Graphite, crystallized, pyrite, alunogen, wad, amphibole, hematite, pyrolusite, limonite, quartz crystals, amethyst, garnet, muscovite, pyrrhotite, magnetite, chalcopyrite.

Elsewhere.—Gold, in placers and veins, graphite, rutile in acicular crystals in amethyst, rock crystal, quartz crystals inclosing liquid, beryl! garnet! cyanite, kaolinite, alunogen, wad, beryl.

CHATHAM Co.—Many deposits of magnetite, hematite and limonite, and black band and ball ore.

Buckhorn.—Rutile in quartz, manganese garnet.

Carbonton. - Pyrophyllite slate.

Clegg's Mine.—Galena, bornite, chalcopyrite, pyrite in cubo-octahedrons, cuprite, chrysocolla, pseudomalachite, cerussite, malachite, fibrous and earthy, azurite, anthracite, calcite, galena, prochlorite (?).

Deep River.—Pyrophyllite slate.

Egypt.—Siderite (black band and ball ore), dufrenite. Evans's Mine.—Hematite, chloritoid in pyrophyllite slate. Farmville and Gulf.—Siderite (black band and ball ore).

CHEROKEE Co.—Marble Creek.—Tremolite, talc, calcite (granular), white, pink, gray! Murphy.—Galena, pyrolusite, limonite, wad, tremolite, talc, cerussite, gold, galena (argentiferous).

Nantehaleh River.—Niter in slates, calcite, granular, white, and pink, talc, massive white.

Parker Mine.—Staurolite! gold, garnet.

Valley River.—Hematite, phlogopite, talc, calcite (granular), dolomite, gold in placers, staurolite, corundum in cyanite.

Valleytown,—Rutile.

Elsewhere.—Staurolite, pseudomorphs of muscovite after staurolite.

CLAY CO.—Cullakenee Mine, Buck Creek.—Corundum! white, gray, pink, and ruby, frequently altered into other minerals, spinel, chromite, drusy quartz, black hornblende or arfvedsonite, smaragdite, chrysolite, zoisite, andesine, labradorite, orthoclase, tourmaline, serpentine, massive and variety picrolite, willcoxite, margarite! talc, albite, cyanite, enstatite, augite (?)

Shooting Creek.—Corundum, pseudomorphous quartz after feldspar(?), actinolite, chrysolite, talc, prochlorite, willcoxite, margarite, rock crystal, magnetite, cyanite, muscovite, gold in placers, rutile in black crystals, garnet, pyrite, chalcopyrite, micaceous hematite, limonite,

prochlorite (?).

Tusquittah Creek.—Gold in placers and veins, staurolite, rutile.

Tipton's.—Corundum, cyanite (green), muscovite.

CLEVELAND Co.—Whiteside Mine.—Gold in placers.

Mountain Mine.—Rock crystal, tourmaline, garnets, gold in placers, graphite, arsenopyrite, galena, muscovite, melanterite, alunogen, pyrite, abundant in gneiss and mica schists, tourmaline. Shelby -Within a few miles, muscovite in large plates, magnetite, actinolite, tourmaline. Double Shoals.—Arsenopyrite.

DAVIDSON Co.—David Beck's Mine.—Tetradymite, montanite.

Conrad Hill.—Chalcopyrite, hematite, limonite, siderite, malachite, barite.

Allen Mine.—Gold, pyrite, chalcopyrite, arsenopyrite, tetradymite.

Silver Hill.—Silver! argentite, highly argentiferous galena, sphalerite, chalcocite, pyrite, chalcopyrite, cuprite, melaconite, zoisite (?), orthoclase, calamine, pyromorphite! (green, yellow, brown, black, and colorless) warellite, stolzite, anglesite, goslarite, chalcanthite, calcite, cerussite! in fine crystals, massive and in pseudomorphs after pyrite, malachite.

Silver Valley.—Galena, sphalerite, pyromorphite.

Uwharie River.—Sphalerite.

Russell Mine.—Gold, pyrite.
Ward's Mine.—Gold, electrum, pyrite, chalcopyrite.

FORSYTH Co.—Large beds of magnetite and titaniferous magnetite.

Near Salem.—Magnetite, manganese garnet, halloysite, hematite, micaceous hematite, graphite, emery variety of corundum, wad, halloysite.

Near Kernersville.—Bronzite, chrysolite, tourmaline, magnetite, hematite, chlorite, pyrite.

FRANKLIN Co.—Portis Mines.—Gold in placers, diamond.

GASTON CO.—Asbury's Mine.—Silver, tetradymite, galena, pyrrhotite, pyrite, leucopyrite, auriferous arsenopyrite, bismite, scorodite, montanite (?), cerussite, bismutite.

Cansler and Shuford Mine.—Gold ! galena.

Clubb's Mountain.—Corundum, red and blue! rutile! tourmaline, cyanite! pyrophyllite! muscovite! lazulite! talc, quartz crystals.

Clear Mountain.—Lazulite.

Crowder's Mountain.—Corundum, red and blue! rutile! gold, ilmenite, cyanite, pyrophyllite! muscovite, lazulite! barite, with galena (argentiferous), tourmaline, pyrite, chalcopyrite, manganese garnet, pyromorphite.

King's Mountain.—Gold, galena, altaite, chalcopyrite, sphalerite, tetrahedrite, nagyagite, magnetite, bismite, calcite, dolomite, pyrrhotite, chalcopyrite, limonite, barite, pyrite, graphite,

cassiterite.

Long Creek Mine.—Niccoliferous psilomelane, gold, pyrite, fluorite, sphalerite, arsenopyrite,

White's Mills.—Epidote, biotite, orthoclase! pycnite, titanite.

All-Healing Springs.—Barite.

GRANVILLE CO.—Bowling's Mountain.—Radiated pyrophyllite.

Sassafras Fork.—Gold, pyrite, (a few miles north) malachite, tourmaline, quartz crystals, agate.

Near Shiloh Church.—Epidote, labradorite, calcite.

Elsewhere.—Stibnite, in the northern part of the county, on land of N. A. Gregory.

GUILFORD CO.—Numerous gold veins with associated copper ores. Friendship. - Granular corundum (emery), titaniferous magnetite.

McCulloh Mine Copper, cuprite in acicular crystals, pyrite, chalcopyrite, siderite, malachite.

North Carolina (Fentress) Mine. — Cuprite in acicular crystals, pyrite, chalcopyrite, siderite, malachite.

Phœnix Mine.—Chalcopyrite, covellite.

HAYWOOD CO .- Presley Mine .- Corundum, blue and gray, altered into muscovite and albite; the muscovite in large crystals, also cryptocrystalline and compact.

HENDERSON CO.—Coleman's Station.—Zircon, phlogopite, jefferisite.

Green River. - On south side of Blue Ridge, at Freeman's, zircon, granular calcite. At Jones's mine, xanthitane, allanite, titaniferous garnet; also stilbite, orthoclase, epidote, titanite in granite, auerlite. On Price's farm, zircon, auerlite, staurolite. On the Davis land, polycrase, zircon, monazite, xenotime, cyrtolite, magnetite, apatite.

IREDELL Co.—Belt's Bridge.—Pyrite in soapstone, corundum in globular masses, partly altered into muscovite, etc. Corundum in hexagonal crystals! partly altered into soda-margarite at Hendrick's farm.

Dr. Halyburton's.—Leucopyrite, scorodite.

King's Mill.-Graphite, hematite in hexagonal plates in quartz, rutile! in quartz, rock crystal, chalcedony, tourmaline.

Mount Pisgah.—Rutilated quartz, chloritic mineral resembling thuringite.

Spring Mountain. - Graphite.

Statesville.—Near Statesville, titanite in gneiss, quartz crystals, allanite, corundum rarely altered into cyanite, orthoclase, cyanite, muscovite, göthite in thin scales, in light red feldspar (sunstone), titanite.

Bethany Church.—Allanite, with small crystals of zircon.

Hunting Creek.—Albite, blue corundum altered into rhätizite. Near Campbell's Mill, large boulders of cyanite inclosing crystals of blue corundum.

JACKSON Co.—Casher's Valley.—Bismutite, talc, muscovite, amethyst, rock crystal, gold, pyrite, chalcopyrite.

Cullowhee Mine.—Chalcocite, pyrite, melaconite, chalcopyrite! hornblende, malachite.

Hogback Mine.—Corundum, rutile in corundum, chromite, drusy quartz, chrysolite, andesine, tourmaline, muscovite, dudleyite, margarite.

Savannah Mine.—Chalcopyrite. hornblende, tourmaline, malachite.

Waryhut Mine.—Chalcocite, chalcopyrite, cuprite, malachite.

Webster.—Corundum, chromite, pyrolusite, wad, chalcedony, drusy quartz, enstatite, tremolite, actinolite, asbestus, chrysolite, talc, serpentine, marmolite, deweylite, genthite, penninite, magnesite! crystalline and earthy, magnetite, kaolin, kämmererite.

Wolf Creek Mine.—Chalcocite, native copper, chrysocolla, chalcopyrite, malachite.

Ainslie's.—Chrysolite, chromite, talc, chlorite, enstatite, smaragdite (?), asbestus, tremolite, garnet, actinolite, albite.

Scott's Creek.—Chrysolite, chromite, talc, penninite (var. kämmererite), enstatite, chlorite, corundum (blue and pink).

LINCOLN CO.—Cottage Home.—Diamond ! gold, chalcopyrite. Randleman's.—Quartz crystals, amethyst!

MACON CO.—Culsagee Mine or Corundum Hill.—Corundum! in beautiful varieties crystallized and massive, and frequently in part altered into other minerals; also chromite, spinel in crystals and granular, rutile rare, diaspore, one specimen only known, drusy quartz and quartz crystals, chalcedony, hyalite, enstatite, tremolite, chrysolite, oligoclase, tourmaline, talc, serpentine, deweylite, genthite, culsageeite, lucasite, kerrite, maconite, penninite, prochlorite, willcoxite, margarite, anthophyllite, actinolite, magnetite.

Highlands.—Bismutite, beryl, gold, rose quartz.

Jacob's Mine.—Corundum, asbestus, tremolite, chrysolite.

Nantehaleh River.—Asbestus, talc, compact limestone, niter. At mouth of river, orthoclase. Tennessee River, below Franklin.—Garnet, staurolite, cyanite, muscovite, columbite.

Tibbet's Mine.-Pleonaste, zircon.

West's Mine.-Ruby corundum with cyanite.

Ellijay Creek.—Near Higdon's, corundum, chlorite, asbestus, chromite, magnetite, hematite, garnet, chrysolite.

MADISON Co.—Mars Hill.—Monazite in large masses, zircon.

Carter's Mine.—Corundum! in peculiar white and pink varieties, spinel, chromite, tremolite, chrysolite, andesine, prochlorite, culsageeite, ilmenite, beryl!

French Broad River.—Orthoclase.

Near Marshall.—Rutile, limonite, magnetite, galena, bornite, chalcopyrite, epidote, talc, fluorite, hematite, corundum. 3 miles below Marshall, prochlorite, margarite, barite, smoky quartz, in doubly terminated crystals.

Haynie Mine.—Blue corundum, rutile, margarite, green crystals of hornblende, magnetite,

chlorite, ilmenite.

M'DOWELL Co.—Kirksey's Mine.—Tetradymite.

In the gold placers.—Gold, corundum, ilmenite, rutile, chromite, brookite, pyrope, zircon, epidote, sillimanite, xenotime, monazite, diamond, octahedrite.

MECKLENBURG Co.—Numerous gold veins, associated with copper ores, pyrite, etc.

Beattie's Ford .- Rutile! in acicular crystals.

Davidson College.—Radiated cyanite, pyrophyllite, gold. 7 miles south, fine crystals of rutile.

McGinn Mine.-Gold, pyrite, chalcopyrite, barnhardtite, cuprite in acicular crystals, melaconite, pseudomalachite.

Todd's Branch.—Gold, diamond, zircon, garnet, monazite.

Tuckasegee Ford.—Epidote, labradorite near Tuckasegee Ford.

MITCHELL Co.—Bakersville.—Muscovite, chalcopyrite, pyrite, pyrophyllite, chromite! quartz crystals, chalcedony, enstatite, tremolite, actinolite, chrysolite, talc, rutile penetrating corundum, serpentine, deweylite, penninite, magnesite, asbestus, At Hawk Mine, oligoclase I On Yellow Mountain, cyanite!

Buchanan Mine.—Gummite, yttrogummite (?), asbestus, beryl, allanite, muscovite, albite, phosphuranylite, cyanite, graphite, manganese garnet, black garnet, magnetite, limonite, apatite, orthoclase.

Cane Creek.—Ilmenite! actinolite, talc, asbestus, (near head) graphite, rutile, garnet, samarskite.

Cranberry. - Magnetite, pyroxene, epidote, picrolite, hematite, orthoclase.

Plum Tree Creek.—Corundum crystals, hyalite.

Near White Plains. - Gummite with uraninite in a mica mine.

Deake Mine.—Quartz, flattened out between muscovite, muscovite! columbite! gummite. albite, gahnite, monazite.

Flat Rock. - Ilmenite, uraninite, gummite, zircon, garnet, epidote, zoisite, var. thulite, muscovite, albite, orthoclase, uranotil, phosphuranylite, autunite!

Grassy Creek.—Samarskite, ilmenite, kaolinite, beryl, large muscovite, autunite, hyalite,

columbite, montmorillonite.

Green's Mine.—Fergusonite.

Point Pizzle.—Albite, apatite, pyrophyllite, actinolite, beryl, garnet, manganese garnet, muscovite.

Unaka Mountains. — Magnetite, zircon, epidote, hematite.
Wiseman Mine. — Muscovite! kaolinite, hatchettolite, columbite, samarskite! altered samarskite, rogersite, cyrtolite, epidote, garnet.

North Toe River.—Orthoclase, muscovite, chrysolite, talc, chrysotile, prochlorite, wad,

garnet, serpentine, kaolin, chalcedony.
Young's.—On South Toe River, serpentine, garnet, talc, chrysolite, prochlorite, tremolite, pyrite.

MONTGOMERY Co.—Cottonstone Mountain.—Pyrophyllite!

Crump Mine.—Gold in placers.

Steele Mine.—Gold! galena, sphalerite, chalcopyrite, albite, prochlorite, calcite.

Swift Island Mine.—Gold! in fine crystals.

MOORE Co.—Cheek Mine.—Chatcopyrite, malachite, azurite, galena, red jasper, epidote, talc, calcite, argentite, pyroxene, limonite.

Soapstone Quarry.—Slaty pyrophyllite! pseudomalachite.

ORANGE Co.—Hillsboro.—Pyrite in cubes, wad, limonite, hematite, pyrophyllite, chlorite in fine scales, epidote, barite. At Latta Mine, braunite (?).

PERSON CO.—Barnett Mountain. - White cyanite.

Dillahay's Mine. - Gold, radiated quartz.

Gillis Mine.—Chalcocite, pyrite, covellite, micaceous hematite, chrysocolla, cuprite, malachite, calcite, garnet, quartz, epidote.

Leasburg.—Tourmaline. albite (?).

POLK Co.—Numerous placer mines, with the usual associated minerals.

RANDOLPH Co.—Gold in beds and placers in numerous places. Near Ashboro.—Pyrophyllite.

Franklinsville.—Five to seven miles west-northwest, leucopyrite.

Pilot Klob.—Pyrophyllite, gold in placers, acicular rutile in quartz.

ROCKINGHAM CO.—Madison.—Chalcopyrite at W. Lindsay's, manganese garnet. Leaksville.—Semi-bituminous coal.

ROWAN Co.—Gold Hill.—Gold, bismuthinite, pyrite, chalcopyrite, arsenopyrite at Honeycutt's, magnetite.

Salisbury. - Orthoclase!

RUTHERFORD Co.—Brindletown Creek.—Diamond!

Rutherfordton.—Quartz, pseudomorphous after calcite!

Shemwell Mine. - Arborescent gold!

Twitty's Mine. - Diamond.

At the gold placers generally.—Gold, corundum in grains and crystals, ilmenite, rutile, chromite, brookite, garnet, zircon ! epidote, samarskite, xenotime! monazite, fergusonite octahedrite, fibrolite.

STOKES Co.—Bolejack's Quarry.—Calcite, phlogopite, actinolite.

Coffee Gap. - Lazulite with muscovite in quartz.

Danbury.—Magnetite, pyrolusite, cyanite, actinolite. At Roger's ore bank, titanite, sul-

Dan River.—Opalescent quartz, anthracite and bituminous coal, prochlorite, hematite, magnetite.

Germanton.—Fossil wood. 2 miles east, serpentine, calcite, garnet.

Peter's Creek. -Sulphur.

Sauratown Mountain. - Itacolumyte, asbestus.

Snow Creek.—Phlogopite, granular calcite, agate, amethyst, hyalite, jasper, hematite, albite, pyrolusite.

Stokesburg.-Rock crystal, anthracite and bituminous coal.

SURRY Co.—Magnetic iron-ore beds at numerous localities.

Dobson.—Pyrolusite, tale in green crystals, serpentine, steatite, actinolite, breunnerite, magnesite, magnetite, chlorite, wad. Near Dobson, magnetite in prochlorite.

Ararat River.—Pyrite! magnetite! garnet, white cyanite!

Chestnut Mountain.—Octahedral magnetite!

Pilot Mountain, -Tale !

SWAIN Co.—Bryson City.—Rutile, zoisite, limonite after pyrite. Oconaluftee River.—Gold, galena (argentiferous), pyrite, chalcopyrite. A Nichols's.—Pyrolusite, chalcocite, tourmaline.

Quallatown.—Gold in placers.

TRANSYLVANIA Co.—Boyston River.—Gold in placers, granular calcite, limonite.

Brevard.—Chlorite, graphite, limonite after pyrite, kaolin.

Elsewhere—Pyrite, chalcopyrite, rose quartz, pyrrhotite, tourmaline, graphite. mouth of Looking-glass Creek, kaolin. Near

UNION Co.—Gold in numerous veins and beds mostly associated with galena and sphalerite. Pewter Mine. - Electrum.

Stewart Mine.—Gold, electrum, galena, sphalerite, pyrite, arsenopyrite, pyromorphite. Walkup's Mine. - Barite !, granular.

WAKE Co.-Northwest corner of county-Serpentine, asbestus, actinolite, steatite, cyanite.

Raleigh.—Ilmenite, graphite, smoky quartz.

Graphite ! at Tucker's Mill.

WATAUGA Co.—Beech Mountain.—Fine-grained galena, pyrite, magnetite, hematite. At Pogie, galena.

Cooke's Gap.—Arsenopyrite, hematite, magnetite, itacolumyte, limonite, martite.

Rich Mountain.—Head of Cove Creek, chromite, quartz crystals, actinolite, chrysolite, epidote, penninite, tremolite.

Elk Knob.—Pyrite, chalcopyrite, pyrrhotite, epidote, limonite, garnet.

Flannery Mine. - Argentiferous galena. Boone Fork.—Quartz crystals (fine).

Elsewhere.—Gold in placers, galena, fluorite, epidote, limonite, magnetite, cyanite, talc, chromite, chlorite, ilmenite, asbestus.

WILKES CO -Brushy Mountains. - Asbestus.

Elk Creek. - Galena, cerussite.

Flint Knob.—Galena (argentiferous), pyrite.

Elkin Creek.—Barite, limonite, galena, cerussite. Honey Creek.—Rutile in acicular crystals in brownish amethyst.

Trap Hill Mine.—Galena, pyrrhotite, chalcopyrite (auriferous), pyrite, rutile, garnet, tour-

Elsewhere.—Graphite, corundum mostly altered into cyanite, pyrite, cyanite, mixture of muscovite, margarite, etc., resulting from the alteration of cyanite.

YADKIN Co.—Near Yadkinville.—Gold.

Hobson's Mine. - Magnetite, tremolite, magnetite. At East Bend and elsewhere. Jonesville.—Pyrite in cubes in slate, chalcopyrite.

YANCEY Co.—Grassy Knob (Black Mountains).—Cyanite, muscovite. Black Mountain.—Graphite.

Bald Mountain.—Grayish green actinolite, magnetite.

Hampton's, Mining Creek.—Chromite, chalcedony, enstatite, tremolite, actinolite, asbestus, chrysolite, orthoclase, tale, serpentine, deweylite, penninite, magnesite, epidote in fine green crystals, bronzite, hornblende, prochlorite (?).

Hurricane Mountain.—Cyanite, titanite, muscovite.

Ray's Mica Mine.—Fluorite, pseudomorphous after apatite, yttrocerite (?), beryl, garnet, zircon, rutile, muscovite, also a scaly pink variety, orthoclase, tourmaline, black and yellowish green; kaolinite, columbite, apatite, monazite, autunite, amazon stone, cyanite, albite, smoky quartz, quartz crystals, actinolite, talc, glassy feldspar.

South Toe River.-Muscovite, garnet, hyalite, gummite, autunite, garnet.

Proffit's.—Corundum, muscovite, asbestus, garnet, penninite (?), talc, chrysotile, fibrous talc.

Young's Mine.—Chlorite, serpentine, chrysolite, chromite, talc, asbestus, tremolite, pyrite, manganese garnet and garnet crystals, bronzite, tourmaline, muscovite.

Presnell (Young's) Mine.—Muscovite, albite, apatite, autunite. Gibb's Mine.—Muscovite, albite, garnet, glassy feldspar.

Guggenheim's Mine.—Muscovite, albite, manganese garnet, apatite, hyalite, tourmaline, autunite.

SOUTH CAROLINA.

The chief economic minerals of South Carolina are gold and calcium phosphate. The gold belt extends from the N. Carolina border southwest across the counties York, Lancaster, Chesterfield (incl. the Brewer mine), Kershaw, Fairfield, Union, Spartanburgh, Greenville, Pickens, Abbeville; there are also auriferous gravels, chiefly in York, Union, and Spartanburgh Cos. (Min. Res. U. S.). The phosphatic deposits are in Charleston, Berkeley, Colleton, and Beaufort Cos., as noted on p. 769.

ABBEVILLE CO.—Oakland Grove.—Gold (Dorn mine), galena, pyromorphite, amethyst, garnet.

ANDERSON Co.—Near Storeville.—Zircon! red, brown, gray, and black, in the surface-soil. Most abundant at Thompson's and at Strickland's. Also columbite, fergusonite, magnetite, and ilmenite. Corundum in crystals and massive, in the soil and in place, at Thompson's and elsewhere in the vicinity. Muscovite. with some columbite, at Wharton's, near the Savannah River. Garnet (spessartite) at Island Ford, Rocky River. (Note.—Three hundred pounds of zircons-some of over 2 oz. were gathered by hand, in about two weeks, from the region about Storeville, in 1888.—Hidden.)

Pendleton.—Actinolite, galena, kaolin, tourmaline, zircon.

Cheowee Valley. - Galena, tourmaline, gold.

CHESTERFIELD CO.—Gold (Brewer's mine), talc, chlorite, pyrophyllite, pyrite, native bismuth, bismuth carbonate, red and yellow ocher, whetstone, enargite.

GREENVILLE Co.—Near Marietta, polycrase! (pure black and a yellow hydrated variety), uraninite (nivenite), allanite. On Gap Creek, on Baynes' land, pyromorphite and cerussite) (argentiferous); on Tankersly's land, titanite, zircon, and corundum. Near Tigersville, zircon (pyramidal) in surface-soil.

Also galena, kaolin, chalcedony in buhrstone, beryl, graphite, epidote, tourmaline.

KERSHAW Co.-Rutile.

LANCASTER Co.—Gold (Hale's mine), talc, chlorite, cyanite, itacolumyte, pyrite. Gold at Blackman's mine, Massey's mine, Ezell's mine.

LAURENS Co.—Corundum, damourite.

NEWBERRY Co.—Leadhillite.

PICKENS Co.—Gold, manganese ores, kaolin.

RICHLAND Co.—Chiastolite, novaculite.

SPARTANBURGH CO.—Magnetite, chalcedony, hematite. At the Cowpens, limonite, graphite, limestone. copperas. Morgan mine, leadhillite, pyromorphite, cerussite.

UNION Co.—Fairforest gold-mines, pyrite, chalcopyrite.

YORK Co.—Gold at Magnolia mine; whetstones, witherite, barite, tetradymite.

GEORGIA.

Gold is present over a considerable portion of the state, particularly the northern part; it is mined both in quartz veins and as placer deposits, thus in Barton, Lumpkin, Rabun Cos.; also in Lincoln, Wilkes Cos., etc. (cf. p. 18). Hematite is also mined, as in Dade, Cherokee, and other northern counties; also limonite in Polk, Floyd Cos., etc.; pyrolusite at Cartersville, Bartow Co. There are also phosphatic deposits. The corundum belt extends across N. and S. Carolina to the northern part of this state as noted on p. 213.

BARTOW CO.—Cartersville, Stegall, Allatoona, barite Cartersville graphite, pyrolusite (mined). Stegall Station, graphite.

BURKE and SCRIVEN Cos.-Hyalite.

CHEROKEE Co.—At Canton Mine, chalcopyrite, galena, clausthalite, plumbogummite, hitchcockite, arsenopyrite, lanthanite, harrisite, cantonite, pyromorphite, automolite, zinc, staurolite, cyanite. Ball-Ground, spodumene. Mines of hematite.

CLARK CO.—Clarksville.—Gold, xenotime, zircon, rutile, cyanite, hematite, garnet,

quartz.

FANNIN Co.—Staurolite! chalcopyrite.

HABERSHAM Co.—Gold, pyrite, chalcopyrite, galena, amphibole, garnet, quartz, kaolinite, soapstone, chlorite, rutile, iron ores, tourmaline, staurolite, zircon.

HALL Co.—Gold, quartz, kaolin, diamond. Gainesville, corundum, margarite, etc.

HEARD Co. - Molybdenite, quartz.

LEE Co.—At the Chewacla Lime Quarry, dolomite, barite, quartz crystals.

LINCOLN CO - Lazulite! rutile! hematite, cyanite, ilmenite, pyrophyllite, gold.

LUMPKIN Co.—At Field's gold-mine, near Dahlonega, gold, tetradymite, pyrrhotite, chlorite, ilmenite, allanite, apatite.

PAULDING Co.—Dallas, pyrite.

POLK CO.-Various limonite mines.

RABUN Co.—Gold, chalcopyrite, muscovite, beryl, corundum.

SPAULDING CO.—Tetradymite.

Towns Co.—Hiawassee.—Corundum, pink, millerite, genthite.

WASHINGTON CO.—Near Saundersville, wavellite, fire-opal.

WHITE CO.-Racoochee Valley, diamond.

FLORIDA.

The phosphatic deposits, which have come into prominence since 1886, are noted on p. 769; cf. also Wyatt's work mentioned on p. 1027.

Near Tampa Bay.—Limestone, sulphur springs, chalcedony, agate, silicified shells and corals.

ALABAMA.

Hematite is extensively mined in the northern half of the state; this industry is of recent development and has gained great importance; the center is at Birmingham, Jefferson Co. (cf. p. 216). There are, further, limonite deposits, as in Cherokee, Etowah Cos., etc. Gold also occurs in quartz veins and gravels as in the adjoining states, thus in Talladego, Clay Cos., etc.

BIBB Co.—Centreville.—Iron ores, marble, barite, coal, cobalt.

CHAMBERS Co.—Near La Fayette, steatite, garnets, actinolite, chlorite. East of Oak Bowery, steatite.

CHILTON CO.—Muscovite, graphite, limonite, rutile.

CLEBURNE Co.—At Arbacoochee Mine, gold, pyrite, and three miles distant, cyanite, garnets. At Wood's Mine, black copper, azurite, chalcopyrite, pyrite.

CLAY Co.—Steatite, magnetite. Near Delta and Ashland, muscovite; southeast of Ashland, cassiterite.

COOSA Co.—Tantalite, gold, muscovite, cassiterite, rutile, mica. Near Bradford, zircon, corundum, asbestus. Near Rockford, tantalite.

JEFFERSON CO.—Birmingham.—Hematite mines.

RANDOLPH Co.—Gold, pyrite, tourmaline, muscovite. At Louina, porcelain clay, garnet. TALLADEGA CO.—Limonite.

TALLAPOOSA Co.—Dudleyville.—Corundum, margarite, ripidolite, spinel, tourmaline. actinolite, steatite, asbestus, chrysolite, damourite, corundum altered to tourmaline (containing a nucleus of corundum), dudleyite.

TUSCALOOSA Co.—Galena, pyrite, vivianite, limonite, calcite, dolomite, cyanite, steatite, quartz crystals, manganese ores.

LOUISIANA.

Rock salt (halite) is mined at Petite Anse Is., Saint Mary's parish, 4 miles west of Vermillion Bay. The deposit, of Tertiary age, is of considerable extent and is still productive (cf. p. 155). Gypsum is mined in Calcasieu parish near Lake Charles; there is also here a bed of native sulphur.

TEXAS.

BURNET Co.—Calcite rhombohedrons in Bat Cave on D. G. Sherrard's land on Spring Creek; lithographic limestone in ledges on Wood's land and elsewhere in the neighborhood; vesuvianite, hessonite, near Clear Creek. "Balls" of iron-ore in road, on the route to Llano C. H. near Colorado River; epidote, at Dupre's. Crystals of quartz, orthoclase, pyrite, and epidote, occasionally, at "Capitol Rock."

Beaver Creek Distr., galena.

Also sparingly cassiterite.

CASS Co., also MARION Co., and elsewhere in eastern Texas.—Iron ores, chiefly limonite.

EDWARDS Co.-Native sulphur.

EL PASO Co., etc.—In the Trans Pecos region, gold, native silver, cerargyrite, and other silver ores, native copper, chalcopyrite, chalcocite, galena, zinc ores, wulfenite, etc.; also cuprodescloizite (Clarke).

GILLESPIE Co.—Magnetite, hematite; further, garnet, beryl.

LAMPASAS Co.—Lampasas.—Celestite crystals, sometimes of gigantic size.

LLANO Co.—Near Bluffton (5 m. south).—At Barringer's mine, gadolinite! yttrialite, rowlandite, fergusonite (several varieties), and allanite, all in large masses, rarely as crystals; also thorogummite, nivenite, gummite, molybdenite, molybdite, cyrtolite, fluorite, tengerite (?), orthoclase in large crystals, magnetite, martite, and rarely quartz crystals in open pockets. Hiram Castner's, 1 m. S., gadolinite, fergusonite, and cyrtolite, in a coarse granitic vein. Also huge orthoclase crystals.

Babyhead Distr.—At the Mexican Diggings, galena, chalcopyrite, tetrahedrite, Also azurite, malachite; further, gold, magnetite, hematite, limonite, cassiterite.

MASON Co.—Iron ores, manganese ores (Spiller mine, south of Fly Gap), galena, cassiterite.

MITCHELL CO.—Rock salt near Colorado City at a depth of 850 ft.

TOM GREEN Co.—Native sulphur.

TRAVIS Co.—Celestite at Mount Bonnel, near Austin.

ARKANSAS.*

HOT SPRING and GARLAND COS.—In the elæolite-syenite and related rocks of Magnet Cove, near Hot Springs, elwolite, biotite, orthoclase, garnet, schorlomite, pyroxene, agirite! eudialyte! (eucolite), titanite, astrophyllite, ilmenite, magnetite (incl. lodestone), microcline, apatite, ozarkite (thomsonite); cancrinite (secondary), fluorite, wollastonite, natrolite, apophyllite, manganopectolite, brucite. Also in leucitic dike rocks, pseudo-leucite (leucite altered to sanidine, etc. p. 426), elæolite, pyroxene, ægirite, melanite, titanite. Further as a result of contact meta-morphism, in sandstone and novaculyte, quartz crystals! in the Crystal Mts., also brookite! (arkansite, in part alt. to rutile), rutile!; in calcite, perovskite! (dysanalyte), hydrotitanite, monticellite! apatite, vesuvianite, phlogopite. Also wavellite, thuringite.

At the Potash Sulphur Springs region, elæolite and sodalite syenite, with characteristic

species, also as contact minerals, natroxonotlite (near wollastonite), apatite, quartz.

Also rectorite, in the Blue Mt. mining distr., Marble township, 24 miles north of Hot Springs; further manganese ores.

INDEPENDENCE and IZARD Cos.—Manganese ores, incl. psilomelane, braunite, pyro lusite, wad.

^{*} See Arkansas Geol. Surv. (J. C. Branner), Report for 1888, vol. 1, pp. 274-292, T. B. Comstock. Also on the manganese deposits of the state, Rep. for 1890, vol. 1, Penrose; these deposits include (1) the Batesville region, chiefly in Independence and Izard Cos., and (2) the region in the southwestern part of the state extending from Pulaski Co. to Polk Co. and Indian Territory. On the igneous rocks of Arkansas, chiefly of the elæolite-syenite type, also in part leucitic, and their associated minerals, e.g. Fourche Mt., Pulaski Co., of Saline Co., and of the Magnet Cove region, Garland Co., see Rep. for 1890, vol. 2, by J. Francis Williams. Considerable deposits of bauxite occur in Salina and Pulaski Cos. Antimony mines occur in Sevier Co. in the southwestern corner of the state.

LAWRENCE Co. - Smithsonite, dolomite, galena, niter. At Calamine, smithsonite.

MARION Co.—Wood's Mine.—Smithsonite, hydrozincite (marionite), galena. Poke bayou, braunite? Morning Star mine, yellow smithsonite (containing cadmium, "turkey-fat ore").

MONTGOMERY Co. - Variscite, wavellite and quartz; manganese ores; galena, tetrahedrite, bournonite, cerargyrite.

NEWTON Co. - Sneeds Creek. - Newtonite.

POLK Co.—Manganese ores, incl. bog manganese, etc.

PULASKI Co.-Kellogg Mine.-10 m. north of Little Rock, tetrahedrite, tennantite, nacrite, galena, sphalerite, quartz, bauxite.

SALINE Co.—Elæolite, astrophyllite, eudialyte. Rabbit Foot mine, millerite, bauxite.

SEVIER Co.—In the Antimony district (northern part of county) on the Cossatot river, at the Stewart Lode, etc., stibnite, stibiconite, bindheimite, jamesonite, zinkenite, dufrenite, eleonorite.

MISSOURI.

For the distribution of the lead-mines, which are of great importance, see page 50. Mine la Motte, and some old openings in Madison Co., afford cobalt and nickel ores, associated with the galena; the amount of these ores, however, does not exceed 1 to 3 p. c. of the lead ore. At Granby, Newton Co., and Aurora, Madison Co., calamine is abundant in the surface ores, but below a depth of about 100 feet gives place to sphalerite. In other sections of central and but below a depth of about 100 feet gives place to sphalerite. In other sections of central and southwestern Missouri, sphalerite is the prevailing ore. Smithsonite is very rare in the southwest region, so much so as to be a mineralogical curiosity. At Carthage in Jasper county, smithsonite occurs massive and crystalline, formed by a pseudomorphic replacement of irregular masses of limestone included in the ore body, at the Porter mines. Sphalerite is now the most abundant zinc ore, aggregating more than 90 p. c. of the total production. The ores of this region were originally deposited as galena and sphalerite, the other minerals being formed by their oxidation and decomposition (Jenney). Gold has been found in the drift sand of Northern Missouri (Broadhead).

ADAIR Co.—Göthite in calcite.

BURTON Co.—McCarrow's mine, pickeringite.

COLE Co.—Old Circle Diggings and elsewhere. Barite! galena, chalcopyrite, malachite, azurite, pyrite, calcite, calamine, sphalerite.

COOPER CO .- Collins Mine .- Malachite, azurite, chalcopyrite, smithsonite, galena, sphalerite, limonite.

CRAWFORD Co.-At Scotia iron bed, hematite, amethyst, göthite, dufrenite at the Cherry Valley mines, cacoxenite, malachite.

DADE Co.—Smithsonite.

FRANKLIN Co.—Cove Mines, Virginia Mines, and Mine à Burton.—Galena, minium, cerussite, anglesite, barite. At Stanton copper-mine, native copper, chalcotrichite, malachite, azurite, chalcopyrite. Also, Mexican onyx.

IRON Co.-At Pilot Knob and Shepherd Mountain, hematite, magnetite, limonite, manganese oxide, bog manganese, serpentine, talc.

JASPER Co.—Joplin Mines.—Crystallized gatena! often octahedral, sphalerite! pink and white crystallized dolomite, crystallized calcite! in scalenohedrons with curved faces, bitumen, marcasite! greenockite coating sphalerite, chalcopyrite in small sphenoidal crystals.

Webb City and Carterville. - Galena, crystallized sphalerite, ruby blende (small brilliant crystals of transparent ruby-red or garnet-colored sphalerite, adhering to massive sphalerite and dolomite), crystallized marcasite, occasionally in brilliant iridescent crystals, ferro-goslarite.

At the Cave Springs mines, near Kansas boundary, crystallized pyrite associated with

sphalerite.

At the Empire mines, 21 miles southwest of Joplin, galena, sphalerite, greenockite, marcasite, barite.

JEFFERSON Co.—Valle's.—Galena, cerussite, anglesite, calamine, smithsonite, sphalerite, hydrozincite, chalcopyrite, malachite, azurite, pyrite, barite, witherite, limonite.
Frumet Mines.—Galena, barite! smithsonite! pyrite, limonite.

LAWRENCE Co.—Aurora Mines.—Galena, sphalerite, crystallized calamine, cerussite, dolomite, zinciferous tallow clay, crystallized calcite.

MADISON Co.—Mine la Motte.—Galena! cerussite! siegenite (nickel-linnæite), smaltite, asbolite (earthy black cobalt ore). bog manganese, marcasite, chalcopyrite, malachite, caledonite, plumbogummite, wolframite, aragonite.

At Einstein Silver-mine, galena (argentiferous), sphalerite, wolframite, pyrite, quartz, muscovite, actinolite, fluorite, tungstite (common). Also arsenopyrite, almandite, lepidolite in granite.

MORGAN Co.—Cordray Diggings.—Galena, sphalerite, crystallized barite. At Florence, flat crystals of barite banded with light blue. In the eastern part of the county, crystallized sphalerite.

NEWTON Co. (adjoins S. E. Kansas).—Granby Mines.—Galena! mimetite on galena (rare), cerussite, calamine! sphalerite, smithsonite, hydrozincite, buratite, greenockite (on sphalerite), pyromorphite, dolomite, calcite! bitumen. The cerussite and calamine occur in stalactites in small caves in the upper parts of the ore bodies. Zinciferous tallow clay is also very abundant in the upper parts of the ore bodies.

PETTIS Co.—Near Smithton and Sedalia, barite in flat crystals banded with white.

ST. FRANCOIS Co.—Iron Mountain.—Specular-hematite, ilmenite, limonite, rhodochrosite in seams, mangano-calcite, calcite, hessonite, apatite, tungstite, wolframite.

ST. GENEVIEVE Co.—At the Cornwall Copper-mines, chalcopyrite, cuprite, malachite, azurite, covellite, chalcocite, bornite, melaconite, chalcanthite, chrysocolla.

ST. LOUIS CO.—Near St. Louis.—Millerite (in the Subcarboniferous St. Louis limestone, largely a magnesian limestone) with calcite! and cryst. dolomite, barite, fluorite, anhydrite, gypsum, strontianite.

Cheltenham. - Gypsum in clay. Quarantine, magnesite.

WASHINGTON Co.—At Potosi, galena, cerussite, anglesite, barite.

WAYNE Co.—Granite bend, copiapite (rare) on pyrite, hyalite.

TENNESSEE.

There are copper mines in Polk Co.; extensive hematite and limonite deposits; zinc mines in Union and Jefferson Cos., etc.

Brown's Creek.—Galena, sphalerite, barite, celestite.

CLAIBORNE CO.—Calamine, galena, smithsonite, chlorite, steatite, magnetite.

COOKE Co.—Near Bush Creek.—Cacoxenite? dufrenite, iron sinter, stilpnosiderite, brown hematite.

DAVIDSON Co.—Selenite, with granular and snowy gypsum, or alabaster, crystallized and compact anhydrite, fluorite in crystals, calcite in crystals.

Near Nashville.—Blue celestite (crystallized, fibrous, and radiated), with barite in limestone, anhydrite. Haysboro', galena, sphalerite, with barite as the gangue of the ore.

DICKSON Co.—Manganite.

GREENE Co.—12 miles from Greeneville, barite in veins in dolomite.

JEFFERSON CO.—Mossy Creek.—Calamine, smithsonite, sphalerite, galena, fetid barite.

KNOX Co.—Magnesian limestone, native iron, variegated marbles.

MAURY Co.—Wavellite in limestone.

MCMINN Co.—Whetwell, near Mouse Creek.—Barite.

MONROE CO.—Carter Mine.—Galena. At Buck Miller mine, argentiferous tetrahedrite.

POLK Co.-Ducktown Mines, S. E. corner of state.-Melaconite, chalcopyrite, pyrite, native copper, bornite, rutile, zoisite, galena, harrisite, alisonite, sphalerite, pyroxene, tremolite, sulphates of copper and iron in stalactites, allophane, rahtite, chalcocite (ducktownite), chalcotrichite, azurite, malachite, pyrrhotite, limonite, graphite.

ROANE Co.—E. declivity of Cumberland Mts., wavellite in limestone.

SEVIER Co.—Alum Cove.—Alum (in part apjohnite), epsomite, melanterite in shale.

In caverns, epsomite, soda alum, niter, nitrocalcite, breccia marble.

SMITH Co.—Barite, gangue of lead vein, fluorite.

Smoky Mt.—On declivity, amphibole, garnet, staurolite.

UNION Co. - Stiner's Zinc-mine, Powell's River. - Sphalerite, calamine, smithsonite. Caldswell mine, galena.

KENTUCKY.

BOURBON Co. - Paris - Barite.

BOYLE Co.-Witherite, also in Garrard and Lincoln Cos.

CLINTON Co.-Geodes of quartz.

CRITTENDEN Co.—Columbia Mines.—Galena, fluorite, calcite.

EDMONDSON CO.—At Mammoth Cave, gypsum rosettes! calcite stalactites, niter, epsomite.

FAYETTE Co.—6 m. N. E. of Lexington, galena, barite, witherite, sphalerite.

LIVINGSTON CO.—Near the line of Union Co., galena, chalcopyrite, large vein of fluorite.

LYON Co.-Eddyville.-Vivianite.

MERCER CO.—At McAfee, fluorite, pyrite, calcite, barite, celestite. .

MONROE Co.-Sulphur Lick.-Sphalerite, galena.

OWEN Co .- Galena, barite.

OHIO.

Bainbridge (Copperas Mt., a few miles east of B.).—Calcite, barite, pyrite, copperas, alum. Canfield and Ellsworth.—Gypsum!

Lake Erie.—Green or Strontian Island, celestite! Put-in-Bay Island, sulphur! calcite.

Sinking Springs.—Hematite.

White House.—Celestite, calcite.

Youngstown.—Rock salt in borings for gas.

INDIANA.

Limestone Caverns, Corydon Caves, etc. - Epsomite.

In most of the southwest counties, pyrite, iron sulphate, and feather alum. On Sugar Creek, pyrite and iron sulphate. In sandstone of Lloyd Co., near the Ohio, gypsum. At the top of the blue limestone formation, brown spar, calcite.

LAWRENCE CO.-Indianaite.

PUTNAM Co.-Eaglesfield.-Siderite.

ILLINOIS.

Lead ores, chiefly galena, are extensively mined in the northwestern part of the State (cf. p. 50), thus in Jo Daviess and Stephenson Cos.

Gallatin Co., on a branch of Grand Pierre Creek, 16 to 30 m. from Shawneetown, down the Ohio, and from a half to eight miles from this river.—Violet fluorite! in Carboniferous limestone, barite, galena, sphalerite, limonite.

HANCOCK Co.—At Warsaw, quartz geodes containing calcite! chalcedony, dolomite, sphalerite! brown spar, pyrite, aragonite, gypsum, bitumen.

HARDIN CO.—Near Rosiclare.—Calcite, galena, sphalerite, chalcopyrite, fluorite. 5 m. back from Elizabethtown, bog-iron. One mile north of the river, between Elizabethtown and Rosiclare, niter.

JO DAVIESS Co.—At Galena, galena, calcite, pyrite, sphalerite. At Marsden's diggings, galena! sphalerite, marcasite (all together in stalactites), pyrite, cerussite.

Quincy.—Calcite! pyrite. Scales Mound.—Barite, pyrite.

POPE Co.-Galena, fluorite.

MICHIGAN.

A. LOWER PENINSULA.

BRANCH Co.-Coldwater.-Kidney ore, siderite and limonite.

Iosco Co. (Saginaw Bay).—Alabaster! gypsum.

Aux Grees River (headwaters).-Gypsum.

JACKSON Co.—Jackson.—Pyrite, kidney ore.

KENT Co.—Grand Rapids.—Gypsum (selenite), calcite, dolomite, anhydrite. Grandville. - Gypsum, etc.

MONROE Co.—Brest.—Calcite, amethystine quartz, apatite, celestite.

Monroe.—Aragonite, apatite.

Point aux Peaux.—Amethystine quartz, apatite, celestite, calcite.

Stony Point.—Apatite, amethystine quartz, celestite, calcite.

TUSCOLA CO.—S. 16, T. 13, R. 11.—Sphalerite.

B. UPPER PENINSULA.—The principal regions are the Marquette, Menominee, and Gogebic iron ranges, and the Keweenaw copper range.

MARQUETTE Co.—Presque Isle.—Serpentine, galena, pyrite, chalcopyrite, dolomite, chalcedony, agate, chrysotile, enstatite, diallage, olivine, native copper, sphalerite, calcite, chromite.

Partridge Island.—Agate (in narrow veins in gabbro).

Picnic Islands.—Epidote, hornblende. Mount Mesnard.—Chalcocite, hematite. Chocolate River.—Galena, chalcocite.

Marquette. —[The above localities are not far from the city], manganite, galena.

Holyoke Mine District.—Galena, gold, sphalerite, chalcopyrite.

Negaunee.—Hematite! martite, limonite, göthite, pyrolusite, manganite, psilomelane, wad, barite! kaolinite, rhodochrosite, jasper, calcite, quartz, orthoclase, tourmaline. The Jackson mine is prominent for minerals.

Goose Lake.—Dolomite, in flesh-colored rhombs, on lighter ground in bluffs N. E. of lake. Palmer.—Hematite. At the Wheat mine, rhodochrosite, dolomite, orthoclase, calcite, pyrite, chalcopyrite, chloritoid! especially \(\frac{1}{2} \) m. S. of the town, also in other places near by and in a line from here to Champion.

Ishpeming.—Hematite! micaceous, botryoidal and in cubes after pyrite, limonite, göthite,

jasper, pyrite, quartz, feldspar.

Moss Mountain (near Ishpeming).—Talc.
Ishpeming Gold Range.—Ropes, Michigan Gold, and other mines, gold, pyrite, pyrrhotite, tourmaline, epidote, molybdenite, magnetite, pyroxene, dolomite, picrolite, precious serpentine! williamsite, chrysotile, talc!

Humboldt, - Chloritoid! tourmaline. magnetite, hematite (martite), grünerite, garnet.

Republic. - Magnetite, hematite, hornblende, garnet. N. W. of the town, between here and Michiganime, staurolite, etc.

Champion.—Near the old furnace, magnetite, hematite, grunerite, garnet. At the mine, chloritoid! garnet, tourmaline, apatite, muscovite, chlorite, magnetite (lodestone), hematite (martite), grünerite, pyrite, jasper.

Michigamme.—Garnet, changed to chlorite, magnetite, etc.

Lake Michigamme.—On the islands, e.g. Goat Island and Silver Island, staurolite in schist, garnet, margarite, and in quartz veins andalusite! green apatite! mica, chlorite.

Wetmore, Webster, and Beaufort Mines.—Limonite, botryoidal and mammillary.

BARAGO Co.—Graphite, wad, limonite, pyrite, especially near L'Anse. Huron Islands.—Native copper in granite.

ONTONAGON, HOUGHTON, and KEWEENAW Cos.—The productive copper-mines lie in these counties. At the north end of Keweenaw Point the copper is mainly in fissure-veins across the formation, and from them some of the best crystallized specimens have come, but most of the mines are not now worked. About Portage Lake in Keweenaw County the copper occurs mainly impregnating amygdaloids and conglomerates, while near Rockland, in Ontonagon Co., the copper is collected in fissures running with the formation. So many minerals occur throughout the district, and the exact mines which may be open or yield a particular mineral vary so from time to time that only one list of minerals is given, and, further, after particular minerals the mine is mentioned with which they are or have been most closely associated.

Native copper! (Phœnix mine), native silver! chalcopyrite, chalcocite, domeykite (Albion mine, Keweenaw Co., also Sheldon and Columbia mine, Houghton), whitneyite (Houghton), algodonite (Houghton), bornite (Mendota, Mt. Bohemia, Huron mine), horn-silver, melaconite algodonite (Houghton), bornite (Mendota, Mt. Bohemia, Huron mine), horn-silver, melaconite (Copper Harbor), cuprite, manganese ores, saponite, azurite, malachite, chrysocolla, prehntie (Tamarack and Quincy mines), laumontite (leonhardite, white), datolite (crystals from Copper Falls, the porcelain-like var. widespread, e.g. Isle Royale, Quincy, Minnesota mines), heulandite, orthoclase (Superior mine), analcite! (Houghton, Phænix, pink at Copper Falls), chabazite, mesotype and natrolite (Copper Falls mine), apophyllite (Cliff mine), wollastonite (ib.), calcite! (large water-clear crystals often inclosing copper at many places, e.g. Central, Phænix and Cliff, Quincy and Franklin and National mines), dolomite (Phænix and National mines), quartz crystals from Franklin and Minnesota mines amethystine out on Keweenaw Point), harite crystals from Franklin and Minnesota mines, amethystine out on Keweenaw Point), barite (Centennial mine), selenite (National mine).

Isle Royale.—Formation and minerals similar to those of Keweenaw Point; also chlorastrolite, barite.

IRON, DICKINSON, MENOMINEE, and DELTA COS .- In these counties is the Menominee iron range, with the usual iron minerals; the ores are mainly soft hematite and limonite, with calcite (of peculiar habit at the Bessie, Metropolitan, and Chapin mines), siderite, chalcopyrite Chapin Mine), orthoclase (Norway), dolomite. In this district occur large crystals of tremolite and diopside in altered dolomites, e.g. at Metropolitan and S. 35, T. 42, R. 29, also S. 35, T. 42, R. 30.

Emmet Mine.—Pyrite, calcite, hematite, martite, chalcopyrite, azurite, malachite.

GOGEBIO CO.—Like the Menominee Range, hematites, limonite, jasper.

Bessemer.-With the iron ores, calcite, feldspar, kaolinite! aragonite, pyrite, dolomite, marcasite.

Copp's Mine, 6 m. N. of Marenisco.—The usual iron ores, and near by galena, chalcopyrite, chert, sphalerite, pink dolomite, siderite.

ALGER, LUCE, SCHOOLCRAFT, CHIPPEWA, MACKINAC COS. - Formation sedimentary with dolomite. calcite, fluorite, celestite, and bog-iron ore at times.

St. Ignace, gypsum. Drummond Is., celestite.

WISCONSIN.

Galena is extensively mined in La Fayette, Grant, Iowa, and Green Cos.; also zinc ores, smithsonite ("dry-bone"), and in the same region sphalerite. Iron (hematite, also limonite) is mined in the Menominee range, Florence Co.; in the Penokee-Gogebic range (in part magnetite), Lincoln and Ashland Cos.; also in Dodge Co. the Clinton red hematite or "fossil ore."

Blue Mounds.—Cerussite.

Hazelgreen (Grant Co.). - Calcite, cerussite. Lac de Flambeau R.-Garnet, cyanite.

Douglas Co., Left-Hand R. (near small tributary).—Malachite, chalcocite, native copper, cuprite, malachite, niccolite, tetrahedrite, epidote, quartz crystals.

Madison (Dane Co.).—Quartz with secondary enlargements (Potsdam sandstone of C. & N. E. R. R. cut).

Marshfield (Wood Co.). - Graphite

Mineral Point and vicinity, in S. W. counties of Wisconsin.—Copper and lead ores, chrysocolla, azurite! chalcopyrite, malachite, galena, cerussite, anglesite (rare), leadhillite? sphalerite, pyrite, barite, calcite, marcasite, smithsonite! (including pseudomorphs after calcite and sphalerite, so-called "dry-bone"), calamine, bornite, hydrozincite, melanterite, sulphur. Shullsburg, galena! sphalerite, pyrite. At Emmet's digging, galena and pyrite.

Montreal River Portage.—Galena in gneissoid granite.

Penokee and Menominee Iron Ranges S. of L. Superior. Hematite, magnetite, siderite, actinolite, garnet.

Plum Creek (Pearce Co.).—Diamonds.

Sauk Co.-Hematite, malachite, chalcopyrite.

Scales Mound.—Barite crystals. Tomah (Monroe Co.). - Glauconite.

Wauwatosa (Milwaukee Co.).—Celestite.

Wisconsin River.—Kaolin (near Grand Rapids), serpentine (below mouth of Copper River).

MINNESOTA.

Hematite and magnetite are extensively mined as ores of iron in Itasca, St. Louis, Lake, and Cook counties; labradorite (anorthite, R. D. Irving, Mon. 5, U. S. G. Survey, p. 438 et seg.) occurs in huge blocks in diabase and even forms mountain masses around Little Saganaga lake; several species of zeolites are abundant at many points in the diabase rocks of the N. shore of Lake Superior, e.g. in Cook Co.

Brown and Nicollet Cos.—Geodes and lenticular masses of calcite.

Carlton Co. - Amphibole (actinolite).

Chisago Co.—Calcite, copper, dolomite, epidote, malachite.

Cook Co.—Agate, apophyllite, bornite, barite, chlorite, copper, gold, graphite, hematite, labradorite, laumontite, thomsonite, lintonite, magnetite, ilmenite, chrysolite, silver, sphalerite, stilbite.

Fillmore, Houston, and Winona Cos.—Calcite (travertine), limonite (pseudomorph after marcasite of the cockscomb form).

Goodhue Co.—Amethyst and chert in cavities in dolomite.

Hennepin and Ramsey Cos.—Calcite, pyrite, selenite.

Itasca Co.—Hematite, magnetite.

Kanabec Co. - Muscovite, amphibole (actinolite).

Lake Co.—Hematite, labradorite, magnetite, ilmenite, chrysolite.

Morrison Co.—Actinolite, garnet, hypersthene, chrysolite, quartz, staurolite. Olmsted Co.—Gold in small placer deposits.

Olmsted Co.—Gold in small placer deposits Pine Co.—Copper, epidote, thomsonite? Pipestone and Rock Cos.—Catlinite.

Redwood Co.—Amphibole, orthoclase, red ocher, lignite.

Renville Co.—Quartz in partially filled veins in gneiss.

St. Louis Co.—Hematite, calcite, copper, chlorite, diallage and labradorite in large cleaved fragments from the gabbro, epidote, fluorite, hematite, heulandite, titaniferous magnetite, quartz.

Todd Co.—Apatite and epidote.

Washington Co.—Sphalerite.

Yellow Medicine Co.-Orthoclase.

IOWA.

Galena is extensively mined in the north-eastern part of the state near the Mississippi river, thus in Clayton, Allamakee Co. (p. 50).

Dubuque **L**ead **M**ines, and elsewhere.—*Galena!* calcite, sphalerite, black oxide of manganese' barite, pyrite. At Ewing's and Sherard's diggings, smithsonite, calamine.

Des Moines.—Quartz crystals, selenite.

Makoqueta R.—Limonite. Near Durango, galena. 7 m. from Dubuque, aragonite.

Cedar River, a branch of the Des Moines,—Selenite in crystals, in the bituminous shale of the Coal measures; also elsewhere on the Des Moines, gypsum abundant, argillaceous iron ore, siderite.

Fort Dodge.—Celestite, gypsum, pyrite.

New Galena. - Octahedral galena, anglesite.

Bentonsport, and elsewhere in southern Iowa, in geodes.—Chalcedony, quartz, calcite, dolomite, pyrite, kaolinite.

SOUTH DAKOTA.

The Black Hills region, in Lawrence, Pennington, and Custer counties, affords gold both in quartz veins and placers, tin (cassiterite) in some quantity and in similar relations; further, mica, feldspar, also columbite, tantalite, beryl, spodumene, uraninite, hübnerite, triphyllite, etc.

CUSTER Co.—Arsenopyrite, cassiterite, mica. Buffalo Gap.—Calcite!

LAWRENCE Co.—Nigger Hill Distr.—Columbite, cassiterite. Also galena, cerussite, cerargyrite, chalcopyrite, sphalerite. Redwater Valley.—Gypsum. Bear Lodge range, gold.

PENNINGTON CO.—Etta Tin Mine.—Cassiterite, spodumene! mica, orthoclase, columbite! arsenopyrite, scorodite, olivenite, tourmaline, garnet, hübnerite.

The Ingersoll Claim, 10 m. E. of Harney Peak.—Cassiterite, columbite, tantalite beryl.

Bald Mtn.—Uraninite, torbernite or autunite.

Nickel Plate Tin Mine.—Triphylite, spodumene, beryl.

Silver City. - Galena, arsenopyrite, jamesonite.

Rockford. - Graphite.

Sunday Gulch.—Barite, corundum.

Queen Bee Mine. - Galena, arsenopyrite.

Near Hill City.-Ottrelite.

The Bad Lands of North Dakota are stated to afford corundum; also fine jet is said to occur near Fort Berthold, N. D. (J. S. Murphy).

KANSAS.

Zinc and lead are extensively mined in the south-eastern part of the state in the counties adjoining Missouri. Rock-salt is obtained by borings in Saline, Harper, Davis, Ellsworth, Rice, and other counties, in beds of considerable extent and great purity; also gypsum in Saline Co., and common elsewhere.

Brown Co. - Red celestite.

Cherokee Co.—Galena, cerussite, anglesite, sphalerite, calamine, amorphous white sphalerite (p. 62), chalcopyrite in tetrahedral crystals, greenockite coating sphalerite.
Linn Co.—Lead and zinc ores. On Short Creek, galena, cerussite, anglesite, sphalerite,

calamine.

Saline Co.—Salina.—Barite, halite, gypsum. Wallace Co., etc.—Gypsum in crystals.

COLORADO.

BOULDER Co.—The Central part, between Jamestown and Magnolia, is noted for rick tellurides with tellurium.

Central Distr. (Smuggler mine, etc., in mica schist or gneiss).—Tellurides, pyrite.

Gold Hill Distr. (Red Cloud, etc., mines).—Gold, tellurides of gold, silver, mercury and lead, tetradymite, pyrite, sphalerite, chalcopyrite.

Magnolia Distr. - Tellurides, etc., tellurium ores of the range including altaite, hessite, petzite, sylvanite, tellurite, native tellurium, calaverite, coloradoite, melonite, magnolite, and the associated ores, argentite, amalgam, native mercury, native bismuth, bismuthinite, bismutite, pyrargyrite, iodyrite, kobellite, schirmerite, hübnerite. Sunshine and Sugar Loaf districts afford tellurides. Ward Distr.—Aurif. pyrite and chalcopyrite, gold.

Grand Island Distr., Caribou mine.—Silver, argentif. galena, chalcopyrite, pyrite, gold, sphalerite. Sugar Loaf distr., chalcocite, pyrrhotite, manganesian garnet.

CHAFFEE CO.—Arrow Mine, jarosite with turgite. Gold gravels at Cash Creek, etc.

Calumet. - Calumet mine, epidote.

Cotopaxi Mine. - Gahnite, galena, sphalerite, chalcopyrite.

Monarch Distr.—Massive anglesite, cerussite, brochantite, etc.

Mt. Antero (about 10 miles N. W. of Salida).—Phenacite! bertrandite! aquamarine! topaz!

orthoclase, hematite in crystals, bismutite, fluorite, muscovite, smoky quartz.

Nathrop.—In cavities in rhyolite, topaz, garnet (spessartite).

Salida.—At Sedalia copper mine, garnet! chalcopyrite, malachite, azurite and chrysocolla; corundum in mica schist.

CLEAR CREEK CO—Georgetown.—Argentif. galena, native silver, pyrargyrite, argentite, tetrahedrite (tennantite), pyromorphite, sphalerite, azurite, polybasite (Amer. Sister's mine), aragonite. barite, fluorite, polybasite (Terrible Lode), mica. Trail Creek, garnet, epidote.

Freeland Lode.—Tennantite, chalcopyrite, anglesite, caledonite, cerussite, tenorite, siderite, azurite, minium. Champion Lode, tenorite, azurite, chrysocolla, malachite. Gold Belt Lode,

vivianite. Coyote Lode, malachite, cyanotrichite.

Virginia District. — Galena, chalcopyrite, pyrite, tetrahedrite.

Idaho Springs. - Pyrite, chalcopyrite, fine crystallized tennantite at Crocett Mine, opal.

CUSTER Co.—Near Rosita and Silver Cliff, 6 m. W. of R., argentif. galena, sphalerite, pyrite, chalcopyrite, annabergite, carrying silver and gold, ores at the latter place incrusting fragments or pebbles of country rock, calamine, smithsonite, jamesonite, tetrahedrite, tellurides. of silver and gold, niccolite. Rosita Hills, alunite, diaspore.

At the Racine Boy mine, cerussite, cerargyrite. At the Gem mine, 12 m. N. of Silver Cliff, niccolite, bornite, pyrite. East slope of Sangre de Cristo, Verde mine, chalcopyrite, tetrahedrite,

pyrite, annabergite.

EAGLE Co.—Red Cliff.—Black Iron mine, fibroferrite. Holy Cross Mt., turquois.

DOUGLAS CO.—Devil's Head.—Topaz! microcline. albite, phenacite, smoky quartz, gothite, fluorite, allanite, manganite, gadolinite, samarskite, cassiterite.

El Paso Co.—In the granite of the Pike's Peak region, microcline! albite, smoky quartz, topaz, etc. Thus near Florissant, 12 m. N. W. from the Peak, microcline! topaz! On Elk Creek, phenacite, microcline (amazon-stone), smoky quartz! amethyst! albite, fluorite, zircon! columbite! South of Manitou, in Crystal Park, topaz, phenacite, zircon. Topaz Butte, 16 m.

from Peak, phenacite.

W. of Cheyenne, N. E. base of St. Peter's Dome, in quartz vein, zircon, astrophyllite, arfvedsonite, cryolite, thomsenolite, gearksutite, prosopite, ralstonite, elpasolite, tysonite, bastnäsite, xenotime, rutile, danalite (rare), fayalite. In another vein, prosopite, zircon, fluorite,

kaolinite, yellowish mica, cryolite.

Between Colorado Springs and Cañon City, barite.

Garden of the Gods, celestite, rhodochrosite.

GILPIN Co.—Veins in gneiss or granite. Near Central City, orthoclase crystals in porphyry, tennantite. Gregory distr. (near Central City), about Black Hawk (Bobtail mine, etc.), chalcopyrite, pyrite, sphalerite, galena, enargite, massive uraninite, and fluorite. In Willis Gulch.

uraninite (Wood mine). Nevada district (next west of Gilpin), galena, chalcopyrite, pyrite, sphalerite, etc. Russell distr. (in Russell Gulch), galena, tetrahedrite, enargite, pyrite, fluorite, chalcopyrite, pyrite, epidote, tennantite.

GUNNISON CO. (W. of Sawatch Mts. and S. of Elk Mts.).—Ruby district, arsenopyrite, in quartz vein, prousite, tetrahedrite, pyrargyrite. On Brush Creek, W. base of Teocalli Mtn., niccoliferous lollingite, smaltite, marcasite, native silver, proustite, pyrargyrite, argentite, galena, chalcopyrite, in a gangue of siderite, barite, and calcite.

Augusta Mt. - Freieslebenite.

Domingo Mine.—Uraninite, warrenite. Redwell Basin.—Kaolinite.

HINSDALE Co.—Lake City, Hotchkiss Lode, petzite, calaverite. Lake district, argent, galena, freibergite, sphalerite, aurif. chalcopyrite, argentobismutite. Park district, stephanite, galena, chalcopyrite. Galena district, argent. galena, freibergite, sphalerite, chalcopyrite, rhodocrosite, stephanite, ruby silver, gold, silver.

HUERFANO Co.—Southern border, N. slope, W. Spanish Peaks, galena, pyrite, chalcopyrite, tetrahedrite.

JEFFERSON CO .- Near Golden, on Table Mtn., leucite, analcite, apophyllite, chabazite, levynite, laumontite, mesolite, natrolite, scolecite, ptilolite, stilbite, thomsonile, calcite, aragonite. Turkey Creek, columbite.

LARIMER CO. -Fort Collins. - Muscovite.

LAKE Co. (between Mosquito Mts. and Sawach Range, both Archæan at center), supplying three fourths of the silver and gold of Colorado, with Paleozoic rocks between, and great eruptive formations. About Leadville (or California mining district), on W. portion of Mosquito Range, and mostly confined to Lower Carbonif. limestone, and generally beneath eruptive rocks, silver, galena, cerussite, aragonite, anglesite, cerargyrite, bromyrite, iodyrite, embolite, aurif. chalcopyrite, native arsenic, descloizite and pyrite, sphalerite, pyromorphite, mimetite, calamine, minium, pyrolusite, rhodochrosite, sphalerite, bismuthinite, bismutite, gold.

Alicante (16 m. N. of Leadville).—Rhodochrosite! sphalerite, pyrite; minium (Stone mine).

Lillian Mines (on Printerboy Hill), kobellite, lillianite, cerussite, caledonite.

Ute and Ule mines, stephanite, galena, sphalerite, chalcocite.

mine, bismutite. Ute and Ule mines, stephanite, galena, sphalerite, char Homestake Peak, N. W. corner of county, argent. galena. Golden Queen mine, scheelite, gold.

LA PLATA CO. (S. of San Juan Co.).—S. side of La Plata Mts., 2½ m. N. of Parrott City, aurif. pyrite, galena, tetrahedrite, cosalite, sphalerite, tellurides, sylvanite, gold (Comstock mine).

LASSEN CO.—Susanville.—Muscovite.

OURAY CO. (W. of N. end of Hinsdale Co., with Uncompagngré Mts. between).—Near Ouray, argent. galena, some freibergite, chalcopyrite, pyrite, hübnerite, rhodochrosite, tetrahedrite.

At Silver Bell mine, kobellite, barite, chalcopyrite.

At Sneffels (near Mt. Sneffels).—Freibergite, pyrargyrite, stephanite, argent. galena, cerussite, etc. Upper San Miguel and Iron Springs districts, similar ores. Yankee Girl Mine. stromeyerite, proustite.

PARK Co.—Mines chiefly along its northwest side, on the E. slope of the Mosquito Range, in the Paleozoic region of its eastern side, near eruptive rocks. In N. part Hall's Valley, veins in gneiss, galena, cuprobismutite (Missouri mine), tetrahedrite, enargite, pyrite, sphalerite, fluorite, barite, ilesite.

Near Grant, Baltic Lode, beegerite. N. W. of Alma, on Mt. Bross and Mt. Lincoln, in Carbonif. limestone, argent. galena, cerussite, anglesite, cerargyrite, barite, manganese oxide. In

Buckskin Gulch (between these mts.), in Cambrian quartzyte, aurif. pyrites, gold, silver, galena.

Sweet Home and Tanner Boy Mines, S. W. side of Mt. Bross, in Archæan, rhodochrosite in the latter. In Mosquito Gulch, south of Alma, near Horseshoe, argent. galena, cerussite. Mines of Lincoln Mtn. at 13,000 to 14,000 ft. elevation.

PITKIN Co. (between Elk Mts. and Sawatch Range).—At Independence, on W. slope of Sawatch, on the Roaring Fork, in Archæan, and west of Aspen, on the N. E. slope of Elk Mts., Alpine Pass, Pitkin and Tin Cup mines, in limestone, cerussite, cerargyrite, cuprite.

Aspen. - Polybasite, tennantite, argentite, pyrite, silver, aragonite, chalcopyrite, bornite.

PUEBLO Co.-Turkey Creek, near Pueblo, muscovite.

RIO GRANDE CO.—At head of Rio Alamosa, near Summitville, E. part of San Juan Mts., gold, in quartz vein, enargite.

SAN JUAN Co. (S. and S. E. of E. end of San Miguel Co., crossed by the San Juan Mts.).-

Silverton.—North Star mine, Sultan Mountain, tetrahedrite, chalcopyrite, pyrite, hübnerite, rhodochrosite, all in good crystals. Bonita Mt., hübnerite. Zuni mine, zunyite embedded in guitermanite. Whale Mine, massive anglesite.

Red Mountain District.—Enargite, tetrahedrite (argent.), tennantite, chalcopyrite, bornite,

stromeyerite, polybasite, argentite, cerussite, azurite, kaolinite.

Poughkeepsie Gulch, Alaska mine, alaskaite, chalcopyrite, tetrahedrite, barite, tellurite. Yankee Girl mine, cosalite.

SAN MIGUEL Co. (S. of Ouray Co., eastern part including N. portion of San Juan Mts.).— At Telluride, galena, stephanite, chalcopyrite, gold, electrum.

SUMMIT Co.—In southeastern part, on W. slope of Archæan "Front Range," near Montezuma and Peru, argent. galena, etc. In southern part, near headwaters of Blue R., S. of Breckenridge, near Robinson, on Quandary Park, etc., in limestone, argent. galena, pyrite, native gold, sphalerite, cerargyrite.

Chalk Mtn., junction of Summit Park and Eagle Cos., in rhyolyte (nevadite), sanidine,

topaz in small crystals.

Snake River District, alabandite (Queen of the West mine), with rhodochrosite, galena, argentite, pyrite. Black Prince mine, stromeyerite.

French Creek, native bismuth in placers.

Kokomo, orthoclase! in crystals.

Breckenridge, crystallized gold!

Near Montezuma, Rust Tunnel, pyrite! Josephine mine, pyrite.

WELD Co.—Near Sterling, blue barite!

WYOMING.

Albany Co., 14 m. S. W. of Laramie City. - Mirabilits.

Laramie Co.-Near Hartville, chalcocite, chrysocolla, cuprite, malachite. 18 m. E. of Laramie City, graphite.

Sweetwater Co.-Near Atlantic City, S. Pass City, and Miner's Delight, gold in quartz veins. Near Independence Rock, sodium carbonates (trona, etc.).

In fossils in Bad Lands, barite crystals.

YELLOWSTONE PARK and Vicinity.—At the Geyser Basins, geyserite! native sulphur. Mammoth Hot Springs, calcareous sinter! At the Joseph Coats Springs, scorodite, realgar, orpiment, sulphur.

Obsidian Cliff.—Tridymite, anorthoclase, fayalite. Between Clark's Fork and East Fork

in the Hoodoo Mts., mordenite.

Specimen Mt.—Amethyst! quartz crystals! silicified wood, calcite, calcite rombohedrons coated by quartz crystals.

Absaroka Range.—Leucite.

Glade Creek.—Quartz crystals in rhyolyte, tridymite, fayalite.

MONTANA.

Beaver Head Co.—Placer gold, gold in quartz, wire gold in calcite, auriferous chalcopyrite, nagyagite, argentiferous galena, pyromorphite, vanadinite, descloizite, pyrite, chalcocite, azurite, malachite, jasper, magnetite, limonite. At Dillon, cassiterite.

Deer Lodge Co.—Gold, nagyagite, argentiferous galena, pyrargyrite, argentiferous spha-

lerite, pyrite, pyrolusite, tetrahedrite.

Jefferson Co.—Gold, argentiferous galena with sphalerite and pyrite, auriferous pyrite, black and white wood-opal (silicified wood).

Lewis and Clarke Co. -Gold, auriferous arsenopyrite, pyrite, argentiferous galena, argen-

tiferous sphalerite, bituminous and lignite coal. Ruby, El Dorado, and other bars in the Missouri River, about 16 miles from Helena, corundum! both sapphire and ruby, mined for gem purposes; also topaz, garnet, cyanite, cassiterite, chalcedony, etc.

Madison Co.—Placer gold, gold in veins, argentiferous galena, silver, cerargyrite, minium,

chalcopyrite, cuprite, azurite, malachite, calcite, garnet, compact serpentine.

Missoula Co.—Lead ores, cerussite, yellow pyromorphite in St. Regis district.

Park Co.-Gold, auriferous chalcopyrite, argentiferous galena, cerussite, sphalerite, tetrahedrite, coking coal.

In the Crazy Mts., sodalite, nephelite, häuynite.

Silver Bow Co.—Butte City and vicinity, gold, silver, argentite, cerargyrite, silver on chalcocite, argentiferous pyrolusite, bornite, chalcocite, malachite, copper and cuprite in granite, rhodonite, rhodochrosite, siderite, calcite, galena, sphalerite, tetrahedrite.

Wurtzite at the Original Butte mine; goslarite at the Gagnon mine.

IDAHO.

Every county in the state yields placer gold.

Alturas Co.—The mining region is known as the Wood River district which includes Ketchum, Hailey, Atlanta, and the Sawtooth Range of mountains. Placer gold, auriferous pyrite, arsenopyrite carrying gold and silver, silver, proustite, pyrargyrite, argentite, cerargyrite, argentiferous galena, auriferous and argentiferous sphalerite, anglesite, cerussite, cervantite, stibnite, tetrahedrite, azurite, malachite, magnetite, hematite, bog iron.
At the Jay Gould mine, native lead, minium.
Ada Co.—Lignite, placer gold, auriferous sphalerite.

Boisé Co. - Deposits of lignite, placer gold, gold finely crystallized, rubies in placers bordering on Ada Co., mica (Payette), pyrolusite, dufrenoysite, argentite, cerargyrite, and other silver

Bingham Co.—Copper ores, besides placer gold.

Custer Co. - Gold, argentite, stephanite, cerargyrite, argentiferous galena, cerussite, azurite and other copper ores, asbestus.

Idaho Co.—Mica, native copper and other copper minerals; placer gold, silver ores.

At Warren's Camp (veins in slate and limestone), gold, silver, cerargyrite, etc., scheelite with gold (Charity mine).

Kootenai Co.—Placer gold.

Latah Co. - Opals! at Moscow, mica.

Lemhi Co.—Gold, argentiferous galena, cerargyrite, argentite, copper ores, chalcocite, cerussite.

Nez Percés Co.—Placer gold.
Oneida Co.—Placer gold, silver ores, silver, cerargyrite.

Owyhee Co.-Gold, silver, argentite, cerargyrite in thin transparent plates, stephanite,

stibnite, lignite.

Shoshone Co.—Cœur d'Alene district includes the camps Mullan, Burke, Wallace, and Bunker Hill mines. Argentiferous galena, cerussite, anglesite, pyromorphite, plattnerite (As You Like mine), malachite and azurite carrying cerargyrite (and bromyrite?), bornite, chalcopyrite, argentiferous tetrahedrite, massive barite, placer gold.

Washington Co.—Mining districts are Helena (Seven Devils) and Mineral City. Placer gold, plates of gold in malachite, bornite carrying silver, chalcocite, chalcopyrite, chrysocolla, malachite, azurite, covellite (impure), limonite, micaceous magnetite, quartz, dark tourmaline,

brown garnet rock, cinnamon garnet, epidote, powellite, limestone, silver ores.

UTAH. .

The silver mines are mostly in limestone, with eruptive rocks in the vicinity, and argentif. galena, cerussite, anglesite, cerargyrite, etc., the common ores. The veins in slate or quartzyte in part carry copper ores. There are also sandstones in Southern Utah impregnated by ores (cerargyrite, etc.) over large regions.

BEAVER Co.—Bradshaw.—Cerussite, cuprite, malachite, aragonite.

Frisco.—Cerussite, anglesite, galena, dufrenoysite, proustite, pyrargyrite, cerargyrite, argentite, barite.

Star.—Cerussite, cerargyrite, malachite, aurichalcite (Cave mine), bismuthinite.

IRON Co.—Coyote District.—Orpiment, realgar, thin layer in strata under lava, stibnite.

JUAB Co.—Tintic District.—Galena, anglesite, cerussite, malachite, bornite, cuprite, bismuthite.

Copperopolis mine (formerly called the "American Eagle"), conichalcite! clinoclasite, erinite, scorodite, enargite. tyrolite, olivenite! chenevixite, melaconite, lettsomite, selenite! mixite, borickite (?).

Mammoth mine, tyrolite! chalcophyllite! clinoclasite! olivenite! pharmacosiderite, jarosite! conichalcite, erinite, enargite! azurite! malachite, mixite, brochantite! jarosite.

Carissa mine, mixite! bismutite.

Eureka Hill mine (at Eureka, 6 m. from Silver City), utahite, olivenite, enargite, cerussite.

MILLARD CO.—Cove Creek.—Sulphur.

Shoebridge and Dragon mines, 40 m. N. of Sevier Lake and 40 m. W. N. W. of Deseret, topaz in rhyolyte, with garnet and sanidine.

PIUTE Co.—Ohio.—Galena, cerussite, malachite, chalcopyrite, chalcocite, tetrahedrite. Mt. Baldy.—Galena, cerussite, anglesite, wulfenite, argentite (Pluto mine). Marysvale.—Onofrite, tiemannite.

SALT LAKE Co.—Big Cottonwood — Galena, cerussite, anglesite; aurichalcite (Keeler mine), chrysocolla (at Emma mine), malachite, with sometimes pyrolusite. Little Cottonwood, same, with sometimes argentite, dufrenoysite, wulfenite, linarite (?), chalcopyrite, enargite (at Oxford and Geneva mine). West Mountain, same ores, with argentite, pyrargyrite, rhodochrosite, barite at Queen mine; binnite, etc., at Tiewaukee mine; dufrenoysite, etc., at Winnamuck mine.

Butterfield Canon.-Orpiment, realgar, mallardite, luckite.

Wasatch Mts., head-waters of Spanish Fork, ozocerite in beds. Great Salt Lake, mirabilite.

SUMMIT CO.—Uinta.—Cerussite, anglesite, cerargyrite, tetrahedrite, argentite, malachite.

TOOELE CO.—Camp Floyd.—Stibnite, etc.

Ophir.—Galena, cerussite, malachite, chalcopyrite, cerargyrite. Rush Valley, same ores. American Fork and Silver Lake, same ores.

WASATCH Co.—Blue Ledge and Snake Creek, galena, cerussite, pyromorphite, sphalerite, etc.

WASHINGTON CO.—Harrisburg.—In sandstone and clay, native silver, cerargyrite, argentite: fossil plants sometimes replaced by silver and cerargyrite.

NEW MEXICO.

DOÑA ANA Co.-Victoria mine, 40 m. below Nutt, anglesite. In the Organ Mts., aragonite (flos ferri), wulfenite.

GRANT CO .- Burro Mts., S. W. of Silver City.- Turquois.

Santa Rita Mines. - Azurite, malachite, native copper.

Ballard's Peak.—Pyrargyrite.

Georgetown.—Mimbres mine, vanadinite!

In N. E. corner of county, S. part of Mimbres Mtn., E. of Silver City.—Ores in limestone or shale, argentif, galena, cerargyrite, argentite, native silver, barite, fluorite.

Pinos Altos Mtn., N. of Silver City—Argent, galena, cerargyrite, cerussite, argentite, silver, gold, chalcopyrite, barite. Burro Mts., S. W. of Silver City, similar ores. In S. W. part of Co., near Barney's Station, and Warren, Virginia distr., veins of quartz, with argent, galena, cerargyrite, native silver. Atlanta distr., near Silver City, Gold Hill, and Kingston, pyrargyrite, silver, argentite.

LINCOLN Co.—Bonita Mt., near White Oaks.—Hübnerite.

SANTA FÉ Co.—Los Cerillos Distr., 22 m. S. W. of Santa Fé, in Los Cerillos Mts.— Turquois in trachyte, argent. galena, cerussite, wulfenite, manganese ores. Silver Bute distr., in quartzyte, gold, pyrite, azurite, malachite, cuprite, chalcopyrite, bournonite, chrysocolla.

SIERRA CO.—At Lake Valley.—In the Sierra mines, in limestone, argent. galena, cerussite, cerargyrite, embolite, iodyrite, manganese ores, vanadinite, endlichite, descloizite, native silver, pyrolusite, manganite, fluorite, apatite. At Kingston, in Black Range, aragonite. Near Hillsboro', gold in veins and placers.

Grafton.—Gold, cerussite, chalcocite, bornite, malachite, chalcopyrite, cerargyrite, ame-

thyst. Headwaters of Gila River, alunogen, halotrichite.

SOCORRO Co.—3 m. from Socorro, in Socorro Mts., cerargyrite, vanadinite, vanadiferous mimetite, barite. In Magdalena Mts., 27 m. W. of Socorro, galena, cerussite, anglesite, calamine, sphalerite. Oscuro Mts. to E., chalcopyrite, azurite, malachite, associated with fossil wood and plants. Merritt mine, willemite.

ARIZONA.

APACHE CO.—Copper Mountain.—Chalcocite, azurite, melaconite, sphalerite, pyrite. And at Greenlee Gold Mountain, chalcocite, malachite, cuprite, auriferous gravel.

Near Holbrook, in Chalcedony Park.—Forest of petrified wood! ("Jasperized" wood),

amethyst.

Navajoe Reservation (also in part in N. Mexico).—Pyrope garnets! chrysolite (Job's tears)! chrome-diopside.

COCHISE Co.—Bisbee.—Copper Queen mine (and Holbrook mine), azurite! malachite! cuprite! chrysocolla, melaconite, paramelaconite, footeite, wad, calcite inclosing malachite, stalactites of either aragonite or calcite (or perhaps both) aurichalcite.

Tombstone.—Emmonsite. At West Side mine, hessite, yellow wulfenite. At Empire mine, yellow wulfenite. At Contention mine, yellow wulfenite and hyalite. Lucky Cuss

mine, descloizite, cuprodescloizite.

GILA Co.—Globe.—Old Globe mine, malachite! azurite, chrysocolla! quartz on chrysocolla, melaconite, calcite. Vermont mine (near Globe), chalcocite. Stonewall Jackson mine (near Globe), native red silver in crystals, argentite.

MARICOPA Co.—Vulture.—Vulture mine (60 m. N. W. of Phœnix), jarosite, crystallized gold, yellow wulfenite. Farley's Collateral mine (about 20 m. N. E. of Vulture P. O.), vanadinite, red and yellow; yellow vanadinite in clear calcite! red voilfenite, chrysocolla, (and according to Silliman) crocoite, vauquelinite, etc. Phænix mine (about 20 m. N. E. of Vulture), vanadinite, yellow and red, the former very like mimetite; descloizite.

Hassayampa Distr.—Montgomery mine, tetradymite.
Santa Catarina Mts. (also in Pinal and Pima Cos., exact locality not known).—Aurichalcite !

Turquois Mts.—Turquois.

GRAHAM Co.—Clifton.—At the Longfellow Mine (5 m. from Clifton), malachite! azurite! cuprite! native copper. Metcalf mine (6 m. from Clifton), brochantite. At the Bon Ton mines (exact locality doubtful), dioptase. Garfield mine (about 9 m. from Clifton, on Chase Creek),

argentiferous tetrahedrite, azurite.

Morenci.—Humming Bird mine (about 6 m. from Clifton), malchite and azurite in short stalactites with concentric structure, chrysocolla, wad. Yavapai mine (about 5½ m. from Clifton, via the Longfellow mine, and 1 m. from Morenci), chalcanthite fibrous, brochantite, drusy azurite. Copper Mt. mine, in Morenci, lettsomite! chalcotrichite! cuprite! arborescent and bright native copper, azurite.

Mineral Park.—Turquois.

PIMA CO. -Flux Mine. - Cerussite!

PINAL CO.—Oracle.—At the Mammoth Gold mine, descloizite! vanadinite! wulfenite. Near Riverside.—Brochantite! dioptase! in small but well-defined crystals.

Pinal.—Hollow quartz crystals, chalcedony. Silver King Mine (near Pinal).—Fine aurichalcite, crystallized silver! sphalerite, argentite, pyrite, chalcopyrite. At Silver Queen mine (near Pinal), red cerussite! Picket Post.—Red wulfenite. Black Prince mine, red vanadinite.

YAVAPAI Co.—Boggs Mine, in the Big Bug distr.—Bournonite.

Grove Mine, in the Humbug distr.—Embolite! Also in same distr., brown vanadinite, barrel-shaped crystals. 2 miles from Bradshaw, tetradymite crystals!

Jerome (30 m. N. E. of Prescott).—In the United Verde copper mines, gerhardtite, ataca-

mite, brochantite, azurite, chalcanthite.

Rio Verde, near Camp Verde.—Glauberite, thenardite, mirabilite, halite, etc.

YUMA Co.—Red Cloud Mine (about 30 m. N. of Yuma).—Red wulfenite! mimetite, cerussite, hyalite, calcite. Also fine vanadinite! at the following mines: Hamburg, Princess, Clara, Black Rock, Rover, Melissa, etc. All of these mines (as also the Red Cloud) are in the "Silver District," and are one to five miles distant from the Red Cloud.

Melissa and Rover Mines. - Wulfenite (red), occasionally in simple octahedral crystals of

Clip (about 5 m. N. of Red Cloud),—Dumortierite! cyanite.

Castle Dome District (about 30 m. N. E. of Yuma.).—Wulfenite in gray, waxy, almost cubical crystals, green and purple fluorite and crystallized anglesite! galena and cerussite, also anglesite of woody appearance!

NEVADA.

The chief mining regions of Nevada affording silver and partly gold are either veins connected obviously with igneous eruptions, as the Comstock Lode; veins in granitic or metamorphic rocks, and in the Austin mines; and deposits of supposed veins in limestone, either of the Cambrian or later age, as the Eureka and White Pine mines.

CHURCHILL CO.—Ragtown.—Gay-lussite, trona, halite. Cottonwood Cañon.—Niccolite, annabergite, smaltite.

ELKO CO.—Tuscarora, veins in igneous rocks, stephanite, cerargyrite, ruby-silver ores (proustite and pyrargyrite), argentite, stephanite, chalcopyrite, pyrite, sphalerite, chrysocolla.

ESMERALDA Co.—In metamorphic slates and schists, or in granite, which are intersected by igneous rocks, at Columbus. gold, cerargyrite, tetrahedrite, galena, pyrite, sphalerite, pyrolusite, turquois, sulphur, stetefeldtite. Also gold in Esmeralda and Wilson in quartz. Silver, galena, and chalcopyrite in Oneota, in mica schist. Alum, 12 m. N. of Silver Creek. At Aurora, fluorite.

Near Mono Lake, native copper and cuprite, obsidian.

Columbus district, at Teel's Salt Marsh, Rhodes Marsh, Fish Lake Valley, etc., ulexite, thenardite, borax, common salt, sulphur; elsewhere, annabergite, variscite. Walker Lake, gypsum, hematite.

EUREKA CO.-Eureka, Ruby Hill, etc.-In Lower Cambrian limestone, gold, silver, cerussite, galena, anglesite, mimetite, wulfenite, limonite, aragonite.

Cortez. - Cerargyrite, tetrahedrite, silver, etc.

HUMBOLDT Co.-Veins in mesozoic slates, at Paradise, silver, cerargyrite, tetrahedrite, pyrargyrite, proustite, stephanite, arsenopyrite, chalcopyrite, sphalerite, pyrite. Winnemucca, between slate and granite, sulphides and antimonial sulphides of lead, with silver, jamesonite, stibnite, bournonite.

Near Lovelock's Station.—Erythrite, millerite, asbolite. Humbolt House, sulphur. Rabbit Hole Springs, sulphur.

LANDER Co.—Austin, near Reese River, in the Toyabe Range, which has a granitic axis flanked by Paleozoic strata, and the veins in the granite of Lander Hill (yielding \$1,000,000 of silver annually), situated near the western edge of the Paleozoic area of the eastern half of the Great Basin. Tetrahedrite, pyrargyrite, proustite, cerargyrite, stephanite, polybasite, rhodochrosite, embolite, chalcopyrite, pyrite, galena, azurite, whitneyite.

Also mines at Lewis of ruby silver, etc., in quartzyte. And at Battle Mountain, of galena

in Paleozoic slate.

LINCOLN Co.—Bristol.—Galena, cerussite, etc. Eldorado, cerargyrite, stromeyerite. Jack-Rabbit, argentif. galena, cerussite, cuprite, malachite. Ely, gold, cerargyrite, galena, sphalerite, pyrite. Rio Virgin, lalite in large deposits.

NYE Co.—Belmont (vein in Silurian slate).—Argent. galena, stephanite, pyrite, chalcopyrite, anglesite, stetefeldtite.

Morey.—Ruby silver and other arsenical and antimonial ores, etc.

Tybo.—Galena, cerargyrite, etc.

Union.—Cerargyrite, galena, sphalerite, etc.

Downieville.—Anglesite, cerussite, wulfenite, sphalerite, pyrite.

STOREY and LYON COS.—Mines of the Comstock Lode, gold, native silver, argentite, stephanite, polybasite, ruby silver ores, tetrahedrite, cerussite, wulfenite, küstelite, etc.

UNION Co. - Echo Distr. - Boulangerite.

WASHOE Co.—Steamboat Springs.—Sulphur, metastibnite, orpiment cinnabar.

WHITE PINE Co.—White Pine.—In Devonian limestone, cerargyrite. At Ward, same limestone, sulphantimonides, probably stromeyerite, pyrite, etc. Cherry Creek.—Copper carbonate, sulphides, etc.

CALIFORNIA.

The principal gold regions are in Amador, Butte, Calaveras, El Dorado, Fresno, Inyo, Mariposa, Mono, Nevada, Placer, Plumas, San Bernardino, San Diego, Shasta, Siskiyou, Sierra, Trinity, and Tuolumne counties.

Silver is mined chiefly in Inyo, Mono, San Bernardino, and Shasta counties. Copper mines are principally in Calaveras, Del Norte, Inyo, Nevada, and Plumas counties.

The principal mercury mines are the Altoona, in Trinity Co., the New Almaden in Santa Clara Co., the New Idria, in San Benito Co., the Bradford, Great Western, and Sulphur Bank, in Lake Co., the Manhattan, and Napa Consolidated, in Napa Co., and the Great Eastern, in Sonoma Co. Of these the Napa and Lake Co. mines are now producing one half the total yield of the State.

ALAMEDA Co.—Hydromagnesite, chromite, and pyrolusite, all abundant, also halotrichite.

ALPINE Co.—Morning Star mine, enargite, stephanite, polybasite, barite, quartz, pyrite, tetrahedrite, pyrargyrite.

AMADOR Co.—Volcano.—Chalcedony, hyalite, common garnet, diamond. Ione Valley. chalcopyrite, ionite, lignite. Fiddletown.—Diamond. Gold at several mines with chalcopyrite, pyrite, galena.

BUTTE CO.—Cherokee Flat.—Diamond, platinum, iridosmine, chromite, zircon. Forbestown.-Prochlorite.

CALAVERAS CO.—Copperopolis and Campo Seco.—Chalcopyrite, malachite, azurite, serpentine, picrolite, native copper. Near Murphy's, jasper, albite, with gold and pyrite. Melones Mine.—Calaverite, petzite. Stanislaus Mine.—Calaverite, petzite, melonite, altaite; also opal, chalcopyrite, galena, gold, etc. Bald Point.—Epidote and almandite.

COLUSA Co.—Sulphur Creek.—Electrum, sulphur (cryst.), cinnabar, aragonite (all mined).

DEL NORTE CO.—Crescent City.—Agate, carnelian. Low Divide.—Chalcopyrite bornite, malachite; on the coast, in auriferous sand, iridosmine, platinum, gold, zircon, microscopic rubies, diamonds?

EL DORADO Co.—Pilot Hill.—Chalcopyrite. Near Georgetown.—Hessite, from placer diggings. Roger's Claim, Hope Valley.—Grossular garnet, in copper ore. Coloma.—Chromite. Placerville.—Gold, brookite, octahedrite implanted on quartz crystals. Granite Creek.—Roscoelite, gold. Forest Hill.—Diamonds. Cosumnes mine, molybdenite, pyrophyllite.

FRESNO Co.—Chowchillas, andalusite. King's Creek Distr.—Bornite, columbite. North Fork Distr.—Sphalerite, bismuthinite. Raymond.—Molybdenite. Also tourmaline and satin spar.

HUMBOLDT CO.—Gold Bluff.—Spinel ruby. Yager.—Vivianite. At Red Cap Mines.—
Chalcocite. Elk River.—Pyrrhotite.

INYO Co.—Inyo Distr.—Galena, cerussite, anglesite, barite, calcite, grossular garnet? vesuvianite, datolite. Panamint.—Tetrahedrite, stromeyerite. Kearsarge Mine.—Cerussite, tetrahedrite, cerargyrite, argentite. Cerro Gordo Mines.—Wulfenite, cerussite, anglesite, polybasite, linarite? caledonite, calamine, bindheimite, mimetite, smithsonite, willemite, etc. Deep Spring Valley.—Bismuthite. Saline Valley.—Tincal, ulexite, halite, tourmaline. Death Valley.—Colemanite! abundant, borax, ulexite, all mined.

KERN CO.—Hot Springs Distr.—Antimony (native), stibnite, jarosite, almandite, lepidolite, chrysoprase. Green Monster Mine.—Cuproscheelite.

LAKE Co.—Borax, cinnabar, sulphur cryst., all mined; also semi-opal, hyalite, mercury (native), chromite, copiapite, posepnyte (Gt. Western mine), wollastonite, glaucophane, zoisite, etc.

Borax Lake.—Borax! sassolite, glauberite. Pioneer mine, cinnabar, native mercury, sulphur, hyalite, cinnabar. Lower Lake, chromite.

LASSEN CO.—Selenite in large slabs, andradite, tourmaline, smaltite, bernardinite.

Los Angeles Co.—San Gabriel Canon.—Asphaltum nodules with vivianite. At the "O. K. mine," silver (native), with argentite, smaltite, erythrite. On Santa Catalina Island, sphalerite. Near Santa Ana River, anhydrite. Williams Pass, chalcedony. Soledad Mines.—Chalcopyrite, garnet, gypsum. Mountain Meadows.—Garnet, in copper ores. Compton.—Kelsey mine, erythrite. Mt. Hoffman, almandite, epidote.

MARIPOSA Co.—Chalcopyrite, itacolumyte. Centreville.—Cinnabar. Pine Tree mine, tetrahedrite. Burns Creek.—Limonite. Geyer Gulch.—Pyrophyllite. La Victoria Mine.—Azurite! Near Coulterville, cinnabar, gold.

Mono Co.—Blind Spring.—Partzite (stibiconite), chalcocite, chalcopyrite, tetrahedrite, Bodie.—Gold, silver. Oasis.—Bismuthinite, bismutite. Mono Lake, thinolite.

MONTEREY Co.—Alisal Mine.—Arsenic. Near Panche, chalcedony, chromite. Near Pacheco's Pass, stibnite.

NAPA Co.—Chromite. At Cat Hill, Redington mine, cinnabar, metacinnabarite, marcasite, chromite, knoxvillite, redingtonite, napalite, magnesite, epsomite. Botryoidal pyrite at Manhattan mine. Phænix mine, millerite.

NEVADA CO.—Grass Valley.—Gold! in quartz veins, with pyrite, chalcopyrite, sphalerite, arsenopyrite, galena, quartz, biotite. Near Truckee Pass, gypsum. Excelsior Mine.—Molybdenite, with gold. Sweet Land.—Pyrolusite.

ORANGE Co.—Arch Beach.—Fuchsite. San Joaquin Ranch.—A mercury mineral not yet positively determined. At same locality and Santa Ana, gypsum.

PLACER Co.—Near Dutch Flat in Green Valley, American River, chromite, uvarovite, kotschubeite, serpentine. Miner's ravine, epidote! with quartz, gold.

PLUMAS Co.—At Cherokee, chalcopyrite. Taylorville.—Chrysocolla and erubescite, at Engels' mine. Rich Bar.—Tremolite.

SAN BENITO Co.—New Idria.—Cinnabar (mined); at the Gypsy, Alta, and Ambrose mines, stibnite (mined), often in fine crystals.

SAN BERNARDINO CO.—Colorodo River.—Agate, trona. Clarke and Silver Mountain.—Stromeyerite, malachite. Russ District—Galena, cerussite. Francis mine, cerargyrite. San Bernardino Mts.—Graphite. At Calico, colemanite! with pandermite (or priceite), celestite,

bernardinite, laumontite, cummingtonite, calamine, halite, Iceland spar, loadstone (Lake and Owen's mine). Stromeyerite at the Silver King mine.

Colton.—Aragonite.

Borax Lake.—Borax, thenardite, halite, hanksize, sulphohalite, glauberite, trona. Oro Grande.—Cookeite, leipidolite. Also realgar, 40 miles from the Needles.

The Temescal tin mines are stuated in the northern end of the San Jacinto estate, see p. 1030.

SANTA CLARA CO.—New Almaden.—Cinnabar, mercury, calcite, aragonite, serpentine, chrysolite, quartz, apophyllite, gyrolite, metacinnabarite, aragotite. North Almaden.—Chromite. Mt. Diabolo Range.—Magnesite. Near Gilroy, stibnite.

SAN DIEGO CO.—Lepidolite, rubellite, graphite, chalcocite, pyrophyllite.

SAN LUIS OBISPO CO.—Asphaltum, cinnabar, native mercury, chromite, pyrophyllite onyx marble!

SAN MATEO CO.—Pescadero — Carnelian, agate.

SANTA BARBARA CO.—On the islands of this county, sphærostilbite and gypsum crystals, pectolite; orthite. San Amedio Cañon.—Stibnite. asphaltum, bitumen, maltha, petroleum, cinnabar. Santa Clara River.—Sulphur. Santa Barbara.—Allanite. Point Sal, gypsum. Redwood City.—Sphalerite.

SHASTA CO.—Cow Creek.—Sphalerite. Tom Neal Mtn.—Molybdenite, green foliated tale. Shotgun Creek.—Uvarovite. Copper City.—Chalcanthite, native zinc (?).

SIERRA CO.—Goodyear's Bar.—Asbestus. Brandy City.—Emery. Forest City.—Gold, arsenopyrite, tellurides.

SISKIYOU Co.—Ottrelite, barite, aragonite.

SOLANO Co. - Aragonite! (fine).

SONOMA CO. - Guerneville. - Actinolite, garnets, chromite, serpentine, cinnabar, bitumen, silicified wood.

TEHAMA Co.—Pectolite, chromite, wollastonite.

TRINITY Co.—Altoona Mine.—Cinnabar; platinum in nuggets found in hydraulic mines on the old channel of the Trinity River.—Cinnabar,—Cinnabar, serpentine, realgar.

TULARE Co.-Minium, chrysoprase, sphalerite, graphite, epidote, almandite, grossularite, molybdenite, tourmaline, malacolite, topazolite, andradite, etc.

TUOLUMNE Co.—Tourmaline, tremolite. Sonora.—Graphite, gold, chalcopyrite, pyrite. York Tent.—Chromite. Golden Rule Mine.—Petzite, calaverite, altaite, hessite, magnesite, tetrahedrite, gold. Whiskey Hill.—Gold!—Jamestown.—Mariposite.

OREGON.

Gold is obtained west of the Cascade Range, in the southernmost counties, Josephine, Jackson, and Curry, in Coos and Douglas, the next north, and east of the range, in southeastern Oregon, in Grant and Baker counties, and to the north sparingly in Wasco, Umatilla, and Union counties. The most productive mines are in Baker Co.

Baker Co.—In northern part, about Baker City, Rye Valley, Bridgeport on Burnt River, Willow Creek, Silver Creek, gold; Rye Valley and Silver Creek, affording also stromeyerite, arsenopyrite, pyrite, malachite, azurite.

Curry Co.—Near Port Orford and Cape Blanco, and on the Rogue River, gold, platinum, iridosmine, laurite. On the seashore, 5 m. N. of Chetko, priceite, in veins and in masses from 20 lbs. weight to the size of peas and smaller, with bluish steatite.

Douglas Co.—New Idrian.—Cinnabar, limonite. Riddle.—Hydrous nickel silicate, near

genthite (garnierite), p. 677.

Grant Co.—Granite, in north part of county, tetrahedrite, polybasite, chalcopyrite, pyrite, sphalerite. At Elk Creek, auriferous gravel. Near Canyon City (on John Day's R.), cinnabar.

Jackson Co.—At Applegate and elsewhere, auriferous gravel.

Josephine Co.—At Yank, galena, chalcopyrite. Also in Jackson and Josephine counties,

native nickel-iron, in placers.

WASHINGTON.

King Co.—Seattle.—Scheelite, realgar, tourmaline. Magnetite at Iron Mt., 3 m. N. W. of Jaqualmie Pass, and also copper ores at the Denny Co. mine. Pierce Co.—Mt. Ranier, tridymite.

Spokane Co., Rockford, muscovite.

Stevens Co.—Colville district, mines of lead and silver reported.

Whatcom Co.—Fidalgo.—Tourmaline. Whitman Co., near Whelan, 20 miles S. W. of Colfax, fire-opal.

Yakima Co.—Auriferous gravel and quartz veins.

ALASKA.

Douglas Island.—Auriferous pyrite.

Fort Wrangell.—At the mouth of the Stickeen River, garnet! in mica schist. Glacier Bay.—Native silver, argentite, berthierite (?), tetrahedrite, graphite. Golovin Bay.—Argentiferous galena, pyrite, graphite.

Juneau.—Sphalerite.

Yukon R.—Gold placers; nephrite at the Jade Mts.

Gold quartz at various points.

DOMINION OF CANADA.

PROVINCE OF QUEBEC.

ARGENTEUIL Co.—Argenteuil.—Pyroxene, titanite, tourmaline. Chatham.—Fetid calcite,

Grenville. - Wollastonite, titanite, muscovite, vesuvianite, calcite, pyroxene, serpentine, steatite (rennselaerite), chondrodite, garnet (ciunamon-stone), zircon (hyacinih), graphite, scapolite, fetid calcite, tourmaline, graphite, orthoclase, phlogopite. Leeds.—Chalcocite.

ATHABASKA Co.—St. Norbert.—Amethyst in greenstone. Tingwich.—Chalcocite.

BAGOT Co.—Acton.—Bornite, chalcocite, kaolin. Upton.—Chalcopyrite, malachite, calcite.

BEAUCE Co.—Aubert.—Gold, iridosmine, platinum.

Broughton.—Serpentine, chrysotile, steatite, chlorite. Marlow (also Risborough).—Scheelite! cryst., tungstite, galena, sphalerite, pyrite, chalco-

Rivière du Loup.—Platinum, iridosmine, gold, rutile. St. Francis.—Gold, platinum, iridosmine, ilmenite, pyrite, magnetite, serpentine, chromite, soapstone, barite, actinolite, arsenopyrite, agalmatolite, garnet, pyrrhotite.

Lake St. Francis.—Andalusite (chiastolite) in mica schist.

St. Joseph.—Epidote in crystals in a concretionary epidotic rock. Ste. Marie.—Wad. Tring.—Aragonite, wad.

BERTHIER Co.—Maisonneuve Township.—Samarskite, beryl, muscovite,

BROME Co.—Bolton.—Chromite, magnesite, serpentine, picrolite, steatite, bitter spar, wad, rutile, actinolite, chalcopyrite, chlorite, chrysotile, kämmererite, pyrrhotite.

Brome. - Magnetite, chalcopyrite, titanite, ilmenite, chalcocite, galena, chloritoid, rutile. In elæolite-syenite, sodalite, cancrinite, orthoclase.

Sutton. - Magnetite, in fine crystals, hematite, rutile, dolomite, magnesite, chromiferous tale,

bitter spar, steatite, bornite, pyrrhotite, chalcocite, chalcopyrite, chloritoid.

CHAMBLEY CO.—Boucherville.—Augite in trap. Chambly.—Analcite, chabazite, and calc'te in trachyte, ilmenite. Montarville. - Augite, chrysolite.

CHAMPLAIN Co.—Cap de la Madeleine.—Limonite (iron ocher) in large beds.

CHARLEVOIX Co.—Bay St. Paul.—Ilmenite, apatite, allanite, rutile.

CHICOUTIMI Co. Jonquiére Township.—Beryl.

GASPÉ CO.-Mt. Albert.-Shickshock Mts., chrysolite, chromite, amphibole, garnet, serpentine. Mt. Serpentine.—Gaspé Bay, serpentine.

HOCHELAGA CO.—Montreal.—Calcite, augite, titanite in trap, chrysolite, natrolite, analcite, dawsonite (near McGill College), sodalite, elæolite, acmite, cancrinite. At St. Helen's Is., strontianite.

IBERVILLE Co.—Mt. Johnson.—In dioryte, amphibole, titanite, oligoclase.

JOLIETTE Co.—Daillebout.—Blue spinel with seybertite.

KAMOURASKA Co. - Riv. Ouelle. - Chalcedony, jasper.

L'ASSOMPTION Co.—St. Roch.—On Achigan R., transp. apatite, augite.

LEVIS CO.—Chaudière Falls, kaolin. Point Lévis, glauconite. St. Nicholas, agalmatolite.

MASKINONGE Co.—Hunterstown.—Scapolite, titanite, vesuvianite, garnet, brown tourmaline!

MEGANTIC CO.—Black Lake.—Scolecite, thomsonite. Coleraine.—Serpentine, chrysotile (asbestus) mined. Halifax.—Bornite, chalcocite, chalcopyrite. Inverness.—Bornite, chalcocite, pyrite, orthoclase.

Leeds - Dolomite, chalcopyrite, gold, chloritoid, chalcocite, bornite, pyrite, steatite,

chromite, magnetite, molybdenite, orthoclase.

Thetford.—Serpentine, chrysotile! (asbestus) extensively mined.

MISSISQUOI Co.—St. Armand.—Micaceous iron ore with quartz, epidote.

· MONTCALM Co.—Rawdon.—Garnet, ilmenite, labradorite.

MONTMORENCY Co.—Château Richer.—Labradorite, hypersthene, andesine, ilmenite.

OTTAWA Co. - Buckingham .- Apatite, phlogopite, titanite, asbestus, coccolite, graphite, crocidolite.

Clyde. - Albite, garnet.

Hull.—Apatite, amphibole, garnet, titanite, tourmaline, barite, fluorite, jasper (Chelsea), graphite, magnetite, oligoclase. wilsonite, pyroxene.

Lochaber.—Graphite.
Portland.—Apatite, wilsonite, pyroxene, coccolite, scapolite, mizzonite, cinnamon garnet.

Templeton.—Apatite! rutile, titanite, scapolite, tourmaline (blk.), hematite (Haycock mine), wollastonite, pyroxene, zircon, vesuvianite! phlogopite! garnet, chrysotile, amphibole, prehuite, wilsonite, chabazite, stilbite, uralite, fibrous calcite, crocidolite. Barite (michel-lévyte) at Perkin's Mill.

Villeneuve.—Albite, muscovite, microcline, tourmaline, garnet, monazite, uraninite,

spessartite.

Wakefield. - Apatite! titanite, pyroxene, garnet, zircon, vesuvianite, scapolite, phlogopite, calcite. garnet! spinel (blue), tourmaline (blk.), chrome garnet.

PONTIAC Co.—Aldfield.—Molybdenite! chondrodite, titanite, tremolite, resurianite.

ALLEYN Co. - Molybdenite, molybdite. Clarendon. - Tourmaline, pyrallolite.

Grand Calumet Island.—Apatite, phlogopite! pyroxene! sphalerite, titanite, vesuvianite! serpentine, tremolite, scapolite, brown and black tourmaline! pyrite, loganite. Calumet, sphalerite, retinalite, galena, pyrite.

Lichfield.—Calumet Falls, blue apatite, blue calcite, scapolite, loganite, serpentine,

phlogopite, pyroxene, tourmaline!

RICHMOND Co.—Brompton.—Chalcocite. Cleveland.—Chalcocite, chlorite, bornite. Melbourne.—Chalcocite, chlorite, chrysotile, pyrite, massive epidote, bornite, kämmererite.

ROUVILLE CO.—Belœil.—In elæolite-syenite, acmite (ægirite), cancrinite. Rougemont.— Augite in trap, chrysolite.

ST. MAURICE Co.—Point du Lac.—Limonite.

SHEFFORD CO.—Shefford.—Chalcocite, chlorite, titanite. Stukeley.—Serpentine, verdantique! schiller spar, chalcocite, chalcopyrite.

SHERBROOKE Co.—Ascot.—Chalcopyrite, chlorite. Capelton.-Chalcopyrite, pyrite, tennantite. Lenox.—Arsenopyrite.

Orford.-White garnet, chrome garnet, millerite, serpentine, pyroxene, diallage, magnetite, calcite.

Sherbrooke.—At Suffield mine, albite! native silver, argentite, chalcopyrite, sphalerite, jasper!

STANSTEAD CO.—Barford.—Pyrrhotite.

TERREBONNE Co.—Abercrombie.—Labradorite. Mille Isles. - Labradorite! ilmenite, hypersthene, andesine, zircon. Morin.—Titanite, apatite, labradorite, wollastonite North River. - Zircon.

St. Jérôme.—Titanite, apatite, chondrodite, phlogopite, tourmaline, zircon, garnet, molyb-

denite, pyrrhotite, wollastonite, labradorite,

VAUDREUIL Co.—Vaudreuil.—Limonite, vivianite.

WOLFE CO.—Ham (or Southam).—Chromite in serpentine, diallage, antimony! senarmontite! kermesite! valentinite, stibnite, chalcopyrite, chrysotile. Wolfstown.—Chromite.

YAMASKA Co.—Yamaska Mt.—Amphibole, titanite in trap.

PROVINCE OF ONTARIO.

ADDINGTON Co.—Clarendon.—Vesuvianite, tourmaline. Sheffield.—Stibnite in crystallized dolomite.

BROCKVILLE CO. -Brockville. - Pyrite.

FRONTENAC Co.—Marble Lake, Barrie Township.—Meneghinite, galena.

Bedford and Loughborough.—Graphite.

Kingston. - Celestite in Trenton limestone. Palmeston.—Hematite.

GREY Co.—Sydenham.—Celestite, limonite.

HASTINGS Co.—Elzevir.—Pyrite. Madoc.—Magnetite, hematite, pyrite, rutile, uraconite. Marmora.—Arsenopyrite! (argentiferous at Deloro), magnetite, serpentine, garnet, epsomite, atite, lepidomelane, steatite. Tudor.—Arsenopyrite, native bismuth, bismuthinite, pyrite. hematite, lepidomelane, steatite.

HURON Co.-Clinton.-Nat. sulphur.

LAMBTON CO.—Enniskillen.—Petroleum, bitumen.

LANARK Co.—Bathurst.—Barite. black tourmaline, perthite (orthoclase), peristerite (albite), bytownite, pyroxene, wilsonite, scapolite, apatite, titanite, amphibole.

Dalhousie.—Dolomite, amphibole, tremolite.

Lanark.—Raphilite (amphibole), serpentine, asbestus, perthite (aventurine feldspar), peristerite.

Elmsley.—Pyroxene, titanite, feldspar, tourmaline, apatite, biotite, zircon, red spinel,

chondrodite, orthoclase, garnet.

North and South Burgess. - Pyroxene, albite, mica, corundum, titavite, chalcopyrite, apatite, black spinel! spodumene (in a boulder), serpentine, biotite, barite, graphite, orthoclase, wilsonite, wollastonite, phlogopite, samarskite, zircon, tourmaline.

Perth. - Apatite in large beds, phlogopite.

LEEDS CO.—Bastard.—Wollastonite. Charleston Lake.—Tourmaline.

Elizabethtown.—Pyrrhotite, pyrite, calcite, magnetite, talc, phlogopite, siderite, apatite, cacoxenite. Leeds.-Hematite.

Lansdowne. - Celestite, vein 27 in. wide, and fine crystals, rensselaerite, sphalerite, wilson-

ite, labradorite.

North and South Crosby.—Chondrodite, graphite. Newborough.—Chondrodite, graphite.

NORFOLK Co.-Charlottesville.-Nat. sulphur. Walsingham.-Limonite.

PEEL Co.—Caledon (forks of the Credit River).—Red celestite, dolemite.

PETERBOROUGH Co.—Balsam Lake.—Pyrite, pyrrhotite. Burleigh. - Albite (peristerite). Dummer. - Barite, tourmaline.

Galway. - Barite, calcite! scapolite. Snowdon. - Uraconite, magnetite.

PRESCOTT Co.—Little Rideau.—Celestite (fibrous).

RENFREW Co.—Algona.—Scapolite, tremolite! Arnprior.—Calcite. Blythfield.—Pyroxene, tourmaline, pargasite, tremolite. Erudensville.—Zircon! Calabogie Lake.—Tremolite.

Eganville.—Titanite! apatite, zircon, etc., amphibole.

High Falls of the Madawaska.—Pyroxene! amphibole. McNab.—Hematite, barite. Ross Township.—Apatite, titanite, amphibole, pyroxene, orthoclase, scapolite, chrysotile, molybdenite, molybdite, spinel, tourmaline!

Sebastopol Township.—Apatite! titanite! zircon! hornblende, orthoclase, microcline,

scapolite, pyroxene, calcite (salmon-red).

SIMSCOE CO.—Nattawasga.—Limonite.

VICTORIA Co.—Balsam Lake.—Molybdenite, scapolite, quartz, pyroxene, pyrite.

DISTRICT OF ALGOMA.—Bruce Mines on Lake Huron.—Calcite, dolomite, quartz, chalcopyrite, chalcocite.

Jackfish Lake, Huronian Mine.—Sylvanite.

Sudbury.—Niccoliferous pyrrhotite and chalcopyrite, polydymite, sperrylite, cassiterite.

DISTRICT OF NIPISSING.—Iron Islands (Nipissing Lake).—Red barite, fluorite. McKim and adjoining towns. - Chalcopyrite, pyrrhotite, smaltite.

LAKE HURON, Owen Sound, on the Grand Manitoulin Islands, etc. — Celestite.

LAKE SUPERIOR, North Shore (east of Thunder Bay distr.).—Battle Island, native copper Jarvis Island.—Silver, argentite, barite, celestite, calcite. McKellar's Island.—Silver, sphalerite, galena, pyrite, argentite, barite, calcite.

Michipicoten Island.—Domeykite, niccolite, genthite, chalcopyrite, native copper, native silver, chalcocite, galena, amethyst, calcite, stilbite, analcite. At Maimanse Bay, coracite,

chalcocite, chalcocyvite, native copper, agate, argentite, chalcite, genthite.

Neepigon Bay.—Fluor Island, fluorite. St. Ignace Island, calcite, native copper, prehnite.

Pie Island.—Elæolite, zircon. On mainland opposite Pie Island, fluorite, barite.

Point-aux-Mines.—Native copper, coracite, mesolite, epidote, galena. Prince's Mine.— Erythrite, fluorite, calcite, galena.

Silver Islet.—Argentite, native silver, galena, niccolite, chalcocite, malachite, silver arsenide, pyrite, calçite. Edwards Is.—Native arsenic.

Spar Island — Apophyllite, argentite, silver, chalcocite, sphalerite, calcite. Terrace Cove. -Molybdenite.

THUNDER BAY DISTRICT AND WESTWARD.—Amethyst Harbour.—Amethyst! Dog Lake.—Native lead. Duncan Mine.—Dog-tooth spar, argentite. McIntyre.—Siderite. McKellar's Point.—Pectolite. Mouth of McKenzie River.—Amethyst, fluorite. Neebing.— Chalcopyrite, galena, marcasite. Neebing Lake, barite. O'Connor.—Beaver mine, asbestus. Thunder Cape.—Galena.

RABBIT MTS.—Twin Cities mine, witherite. 22 m. S. W. Port Arthur, harmotome.

PROVINCE OF NOVA SCOTIA.

Annapolis Co.—Chute's Cove.—Apophyllite, natrolite, heliotrope. Gate's Mountain.—Analcite, magnetite, mesolite! natrolite, stilbite.

Granville.—Carnelian.

Margaretville.—Apophyllite, gyrolite, stilbite, epistilbite, laumontite.

Martial's Cove.—Analcite! chabazite, heulandite. Moose River.—Beds of magnetite. Nictau River.—At the Falls, bed of hematite. Paradise River, black tourmaline, smoky

Peter's Point, west side of Stonock's Brook.—Apophyllite! calcite, heulandite, laumontite!

(abundant), native copper, stilbite.

Port George. Faröelite, laumontite, mesolite, stilbite. East of Port George, on coast, apophyllite containing gyrolite.

St. Croix's Cove.—Chabazite, heulandite.

ANTAGONISH Co.—College Lake.—Chalcopyrite. On St. George's Bay, and elsewhere, gypsum, in thick strata. Frenchman's Barn, gieseckite. South Lake, chrysolite. Arisaig Pier, gieseckite.

CAPE BRETON CO.—At Gabarus, molybdenite, bismuthinite. At Loch Lomond, Salmon River, manganese ore.

Plaister Cove. Mabou, Port Hood, etc.—Gypsum. Near Sidney, copper ores.

Little Glace Bay.—Cannel coal, melanterite.

New Annan. - Covellite.

COLCHESTER CO.—Five Islands, East River.—Barite, calcite, dolomite (ankerite), gmelinite, hematite, chalcopyrite.

Indian Point.—Malachite, magnetite, red copper, tetrahedrite.

Pinnacle Islands.—Analcite, calcite, chabazite! natrolite, siliceous sinter.

Londonderry, on branch of Great Village River.—Barite! ankerite, hematite, limonite, magnetite, aragonite, sideroplesite, wad.

Cook's Brook.—Ankerite, hematite. Martin's Brook.—Hematite, limonite. Folly River.—Below Falls, ankerite, pyrite. On high land, east of river, ankerite, hematite, limonite.

Archibald's Land.—Ankerite, barite, hematite.

Salmon River, south branch of.—Chalcopyrite, hematite.

Shubenacadie River.—Anhydrite, calcite, barite, hematite, oxide of manganese. At the Canal, pyrite.

Stewiacke River.—Barite (in limestone; 300 tons mined in 1885). Near Clifton, göthite. pyrolusite, calcite, barite.

Onslow. - Manganese ore.

CUMBERLAND Co.—Cape Chiegnecto, barite.

Cape d'Or. - Analcite, apophyllite! chabazite, faröeite, laumontite, mesolite, malachite, natrolite, native copper, obsidian, red copper (rare), vivianite (rare).

Horseshoe Cove, east side of Cape d'Or.—Analcite, calcite, stilbite.

Isle Haute, south side.—Analcite, apophyllite! calcite, heulandite! natrolite, mesolite, stilbite!

Joggins.—Coal, hematite, limonite, Malachite and tetrahedrite at Seaman's Brook.

Partridge Island.—Analcite, apophyllite! (rare), amethyst! agate, apatite (rare), calcite! chabazite (acadialite), chalcedony, cat's-eye (rare), gypsum, hematite, heulandite! magnetite, stilbite!

Swan's Creek.—West side, near the Point, calcite, gypsum, heulandite, pyrite. East side, at Wasson's Bluff and vicinity, analcite! apophyllite! (rare), calcite, chabazite! (acadialite), gypsum, heulandite! natrolite! siliceous sinter.

Two Islands.—Gmelinite, heliotrope, moss agate, analcite, calcite, chabazite, heulandite.

McKay's Head.—Analcite, calcite, heulandite, siliceous sinter!

Amherst. - Manganese ore.

Spring Hill coal field, Scotia mines. Alunogen.

DIGBY Co.—Briar Island.—Native copper, in trap, jasper.

Digby Neck, Sandy Cove, and vicinity.—Agate, amethyst, calcite, chabazite, hematite! laumontite (abundant), magnetite, martite, stilbite, quartz crystals.

Gulliver's Hole. - Magnetite, stilbite!

Mink Cove.—Amethyst, chabazite! quartz crystals.

Nichols Mountain, south side.—Amethyst, magnetite!
Williams Brook, near source.—Chabazite (green), heulandite, stilbite, quartz crystal.

Trout Cove.—Carnelian, chaicedony.

GUYSBORO Co.—Cape Canseau, andalusite. Sherbrooke.—Octahedrite.

HALIFAX Co. -Gay's River, galena in limestone. Southwest of Halifax, garnet, staurolite, tourmaline.

Tangier.—Gold! in quartz veins in clay state, associated with auriferous pyrite, galena, hematite, arsenopyrite, and magnetite. Gold at Country Harbour, Fort Clarence, Isaac's Harbour, Indian Harbour, Laidlow's Farm, Lawrencetown, Sherbrooke, Salmon River, Wine Cove, and other places. At Hammond's Plains and Musquodoboit, molybdenite, pyrolusite.

HANTS Co.—Cheverie.—Oxide of manganese (in limestone), gypsum. Petite River, gypsum, oxide of manganese.

Walton.—Pyrolusite, manganite.

Teny Cape. - Manganese ores, dog-tooth spar.

Windsor. - Calcite, gypsum (great bed), with cryptomorphite (baronatrocalcite), howlite, mirabilite, selenite, aragonite, epsomite, ulexite. At Rawdon, manganite, stibnite, of which 758 tons were exported in 1885, turgite, hematite.

Brookville.—Howlite, ulexite, cacholong! carnelian. Newport Station.—Howlite, ulexite. Noel, howlite. Douglas.—Psilomelane, pyrolusite. Seven Mile Plain, pyrite.

KINGS Co.—Black Rock.—Centrallassite, cerinite, dog-tooth spar, cyanolite. A few miles

east of Black Rock, prehnite? stilbite!

Cape Blomidon.—On the coast between the cape and Cape Split, the following minerals occur in many places (some of the best localities are nearly opposite Cape Sharp): analoite! agate! amethyst! apophyllite! calcite, chalcedony (blue), steeleite, chabazite, gmelinite (lederite), hematite, heulandite! laumontite, magnetite, malachite, mesolite, native copper (rare), natrolite! psilomelane, stilbite! thomsonite, faröelite, quartz.

North Mountains.—Amethyst, bloodstone (rare), ferruginous quartz, mesolite (in soil),

Long Point, five miles west of Black Rock.—Heulandite, laumontite, stilbite!

Morden.—Stilbite, apophyllite, mordenite.

Scott's Bay.—Agate, amethyst, chalcedony, rutile, mesolite, natrolite.

Woodworth's Cove, a few miles west of Scott's Bay.—Agate! chalcedony! jasper, rutile. Kentville, pyrolusite. Hall's Harbour, stilbite, sphærostilbite.

LUNENBERG CO.—Chester.—Gold River, gold in quartz, pyrite, arsenopyrite.

Cape la Have.—Pyrite. The "Ovens," gold, pyrite, arsenopyrite. Petite River, gold in slate.

PICTOU CO.—Pictou.—Jet, oxide of manganese, limonite. At Roder's Hill, six miles west of Pictou, barite. On Caribou River, gray copper and malachite in lignite.

Albion Mines.—Coal, limonite. East River, limonite, hematite, magnetite, siderite, ankerite. On Sutherland's R., siderite.

Smithfield.—Argentiferous galena.

QUEEN'S Co.—Westfield.—Gold in quartz, pyrite, arsenopyrite. Five Rivers.—Near Big Fall, gold in quartz, pyrite, arsenopyrite, limonite.

RICHMOND CO.—West of Plaister Cove, barite and calcite in sandstone. Nearer the Cove, calcite, fluorite (blue), siderite, gypsum in beds of great thickness (giving the name to Plaister Cove).

SHELBURNE Co.—Shelburne.—Near mouth of harbor, garnets (in gneiss). Near the town, rose quartz.

Jordan and Sable River.—Staurolite (abundant), schiller spar.

SYDNEY Co.—Hills east of Lochaber Lake.—Pyrite, chalcopyrite, siderite, hematite. Morristown.—Epidote in trap, gypsum (making a cliff of 200 feet, near Ogden's Lake).

YARMOUTH CO.—Cream Pot, above Cranberry Hill.—Gold in quartz, pyrite. Cat Rock, Fouchu Point, asbestus, calcite.

PROVINCE OF NEW BRUNSWICK.

Albert Co.—Hopewell on Shepody Bay.—Gypsum, manganese ores.

Albert Mines.—Near Hillsboro', albertite (largely exported).

Shepody Mountain.—Alunite in clay, calcite, pyrite, manganite, psilomelane, pyrolusite, gypsum (quarried), anhydrite (with the gypsum).

CARLETON CO. - Woodstock. - Chalcopyrite, hematite, limonite, wad.

CHARLOTTE Co.—Campobello, at Welchpool.—Sphalerite, chalcopyrite, bornite, galena, pyrite

At head of Harbour de Lute.-Galena.

Deer Island, on west side.—Calcite, magnetite, quartz crystals.

Digdighash River.—On west side of entrance, calcite! (in conglomerate), chalcedony. At Rolling Dam, graphite.

Grand Manan.—Between Northern Head and Dark Harbour, agate, amethyst, apophyllite, calcite, hematite, heulandite, jasper, magnetite, natrolite, stilbite.

Moore's Mills. - Andalusite (chiastolite), staurolite.

Whale Cove. — Calcite! heulandite, laumontite, stilbite, semi-opal!

Wagaguadavic River, at entrance.—Azurite, chalcopyrite, in veins, malachite.

GLOUCESTER CO.—Tête-à-Gouche River, eight miles from Bathurst.—Chalcopyrite (mined), oxide of manganese! formerly mined.

KINGS CO.—Sussex.—Near Cloat's mills, on road to Belle Isle, argentiferous galena. One mile north of Baxter's Inn, specular iron in crystals, limonite. On Capt. McCready's farm,

Upham. - Manganese ores, gypsum.

RESTIGOUCHE CO.—Belledune Point.—Calcite! serpentine, verd-antique. Dalhousie, agate, carnelian.

ST. JOHN Co.—Black River.—On coast, calcite, chlorite, chalcopyrite, hematite! Brandy Brook.—Epidote, hornblende, quartz crystals.

Carleton.-Near Falls, calcite.

Chance Harbour.—Calcite in quartz veins, chlorite in argillaceous and talcose slate. Little Dipper Harbour.—On west side, in greenstone, amethyst, barite, quartz crystals.

Moosepath.—Feldspar, amphibole, muscovite, black tourmaline.

Musquash.—On east side harbor, copperas, graphite, pyrite.
Shannon's.—Chrysolite, serpentine. East side of Musquash, quartz crystals!

Portland.—At the Falls, graphite.

Fort Howe Hill.—Calcite, graphite.

Crow's Nest.—Asbestus, chrysolite, magnetite, serpentine, steatite.

Lily Lake.—White augite? chrysolite, graphite, serpentine, steatite talc.

How's Road.—Two miles out, epidote (in syenite), steatite in limestone, tremolite.

Drury's Cove.—Graphite, pyrite, pyrallolite? indurated talc.

Quaco, at Lighthouse Point.—Large bed of oxide of manganese. Sheldon's Point, actinolite, asbestus, calcite, epidote, malachite, hematite.

Cape Spenser.—Asbestus, calcite, chlorite, hematite (in crystals).

Westbeach.—At east end on Evans's farm, chlorite, talc, quartz crystals. Half a mile west, chlorite, chalcopyrite, magnesite (vein), magnetite.

Point Wolf and Salmon River.—Asbestus, chlorite, chrysocolla, chalcopyrite, bornite, pyrite.

VICTORIA Co.—Tabique River.—Agate, carnelian, jasper. At mouth, south side, galena.

At mouth of Wapskanegan.—Gypsum, salt spring.

Petticodiac.—Selenite, gypsum. Three miles above, stalactites (abundant).

Quisabis River.—Blue phosphate of iron, in clay.

WESTMORELAND Co.—Bellevue.—Pyrite. Dorchester, on Taylor's Farm, cannel coal. clay ironstone. On Ayer's Farm, asphaltum, petroleum spring.

Grandlance.—Apatite, selenite (in large crystals). Memramcook, coal (albertite).

YORK Co.—Near Fredericton, Prince William parish, Brunswick mine, stibnite (mined), native antimony, jamesonite, berthierite, kermesite, valentinite. Pokiock River.—Stibnite, tin pyrites? in granite (rare).

PROVINCE OF BRITISH COLUMBIA.

Barclay Sound, Vancouver Is.-Ilvaite.

Cariboo District.—Native gold, galena. Cherry Creek, 33 m. E. of Head of Okanagon Lake.—Argentif. tetrahedrite, galena,

sphalerite.

Frazer River.—Near Lytton, boulders of nephrite. Foster Bar, 22 m. above Lytton, stibnite, massive garnet, tetrahedrite, ankerite. Seven m. up Wilson Creek, native arsenic. 10 m. below Lillicoot, platinum.

Ominica District.—Vital and Silver Creeks, native gold, argentiferous galena, native silver,

arquerite.

Howe's Sound.—Bornite, molybdenite, mica.

Texada Id.—Magnetite. Malaspina copper mine, andradite, chalcopyrite, tremolite, dolomite

Shuswap Lake.—Bismuthinite.

Hi-hum Lake, south of Loon L.—Hyalite.

Kootanie Lake. — At the International Claim and Hendrix Camp, galena (argent.), tetrahedrite. Jarvis Inlet, Salmon Arm.—Bornite.

Ice R. (branch of the Beaver Foot, Rocky Mts.).—Sodalite.

Hector (or Kicking Horse) Pass, Rocky Mts.—At the Ebenezer mine, cinnabar. Illecillewaet R., Selkirk Range.—Tetrahedrite (argentif.), galena, pyrite, chalcopyrite, sphalerite.

Kamloops Lake, Tranquille R.—Gold, platinum, in gravel.

Nicholas Valley.—At the Stump mines, tetrahedrite. North Thomson R.—Cyanite, tetrahedrite. Otter Tail Creek .- Cookeite (?) with galena.

Peace R.—At Fort St. John, on cliffs of shale, mirabilite, epsomite.

Similkameen R.—In gravel, gold, platinum. Skeena R.—Garnet! in mica schist.

Tulameen R., Granite Creek.—In gravel, gold, platinum.

NORTH-WEST TERRITORY.

Keewatin.—Mouth of Churchill river, lazulite. **Smoky R.**—Native sulphur, sal-ammoniac.

N. Saskatchewan.—Chemawinite on the shores of Cedar Lake.

Yukon R.—Gold in placers, nephrite.

NEWFOUNDLAND.

Antony's Island. - Pyrite.

Catalina Harbour. - On the shore, pyrite!

Chalky Hill.—Feldspar.

Copper Island, one of the Wadham group. - Chalcopyrite.

Conception Bay.—On the shore south of Brigus, bornite and tetrahedrite.

Bay of Islands. - Southern shore, pyrite in slate.

Lawn.—Galena, cerargyrite, proustite, argentite.

Placentia Bay.—At La Manche, two miles eastward of Little Southern Harbour, galena!

On the opposite side of the isthmus from Placentia Bay, barite in a large vein, occasionally accompanied by chalcopyrite.

Shoal Bay. - South of St. John's, chalcopyrite.

Tilt Cove. - Niccolite.

Trinity Bay. - Western extremity, barite.

Harbour Great St. Lawrence. - West side, galena.

INDEX TO SPECIES.

Note.—Names of numbered species and of a few important synonyms are printed in heavy-faced type.

Aftonite, v. Aphtonite, 137

ROBERT DRUMMOND AND COMPANY
BROOKLYN, N. Y.

PREFATORY NOTE.

This First Appendix to the Sixth Edition of the System of Mineralogy issued in 1892 is designed to make the work complete up to and including the early part of 1899.

This Appendix contains, first of all, full descriptions of the species announced as new since the publication of the System. There are no fewer than one hundred and sixty names here included, and their place in the general scheme of classification adopted in the System is shown in the classified list given in the Introduction. Unfortunately many of the new names, introduced into the science, during this period, have little claim to recognition, either because of the incompleteness of the original examination or the unsatisfactory nature of the material investigated. On the other hand a considerable part of the descriptions leave nothing to be desired both as regards fullness and accuracy. The relative importance of the new names is approximately indicated by the type used in the classified list.

In addition to the description of new minerals, this Appendix is intended to contain also references to all important papers on mineral species published during the period named; with each reference is given a concise statement of its character, and so far as possible a summary of its contents. Since, however, the additions to mineralogical literature have been very numerous, it has been necessary in order to keep this work within reasonable compass to adhere rigidly to a system of extreme brevity of expression and conciseness of arrangement. All minerals named are, for convenience, placed in alphabetical order.

For an explanation of the Abbreviations made use of in the case of periodicals, also of the crystallographical, optical and chemical symbols employed, reference is made to the Introduction to the System (1892), pp. xlv-li, and pp. xiii-xl. General abbreviations are explained on pp. lxi-lxiii.

The Bibliography includes the full titles of prominent volumes published since 1891. In addition attention is called to the large number of important memoirs on physical subjects, recently issued, particularly those on the molecular structure of crystals as related to the symmetry of form by Fedorow, Schönflies, Goldschmidt, Barlow, Viola, and others. These and other related papers will be found either in full or as abstracts in Groth's invaluable Zeitschrift für Krystallographie und Mineralogie, vols. 20-30 inclusive.

The thanks of the author are due to his colleagues, Prof. S. L. Penfield and L. V. Pirsson. The former has had the kindness to furnish brief accounts of some new species now for the first time publicly described.

NEW HAVEN, June 1, 1899.

WÜLFING, E. A. Tabellarische Uebersicht der einfachen Formen der 32 krystallographischen Symmetriegruppen. 1895.

- Die Meteoriten in Sammlungen und ihre Literatur. Tübingen, 1897.

ZEPHAROVICH, V. von. Mineralogisches Lexikon für das Kaiserthum Österreich. Vol. 3 (by F. BECKE). Vienna, 1893.

CLASSIFIED LIST OF NEW NAMES.

I. NATIVE ELEMENTS, Min. pp. 2-32.

JOSEPHINITE (p. 38), Fe₂Ni₅. Near Awaruite, Min. p. 29. Graphitite (p. 31). Var. Graphite, Min. p. 7.

II. SULPHIDES, TELLURIDES, ARSENIDES, ETC., Min. pp. 33-108.

Grünlingite (p. 31), Bi₄TeS₃. Near Tetradymite, Min. p. 39.

Quirogite (p. 58). An impure Galena, Min. p. 48?

Heazlewoodite (p. 33), Folgerite (p. 52). Essentially Pentlandite, Min. p. 65.

Gunnarite (p. 31), Fe, Ni, S.? Near Pentlandite.

Hauchecornite (p. 33), (Ni,Co)₇(S,Bi,Sb)₈. Near Polydymite, Min. p. 75.

BARRACANITE, Cupropyrite (p. 21). Near Cubanite, Min. p. 79.

Blueite (p. 56), Whartonite (p. 56). Same as Pyrite, Min. p. 84.

Willyamite (p. 73), CoSbS. NiSbS. Near Ullmannite, Min. p. 91.

BISMUTOSMALTITE, NICKEL-SKUTTERUDITE (p. 63). Varieties of Skutterudite, Min. p. 98.

Goldschmidtite (p. 30), Au₂AgTe₆. Near Sylvanite, Min. p. 103.

KALGOORLITE (p. 38), HgAu2Ag6Te6.

III. SULPHO-SALTS, Min. pp. 109-151.

1. SULPHARSENITES, SULPHANTIMONITES, ETC.

Andorite, Webnerite, Sundtite (p. 4), 2PbS.Ag₂S.3Sb₂S₃. Related to Zinkenite Group. Min. p. 111.

Lorandite (p. 43), Tl₂S.As₂S₃. Near Miargyrite, Min. p. 116.

Pearceite (p. 50), 9Ag₂S.As₂S₃. Near Polybasite, Min. p. 146.

Rathite (p. 58), contains S, As(Sb), Pb. Related to Dufrenoysite, Min. p. 120, and Jameson-ite, p. 122.

2. SULPHOSTANNATES.

Canfieldite (p. 13), 4Ag₂S.(Sn,Ge)S₂. Near Argyrodite, 4Ag₂S.GeS₂, p. 6, and Min. p. 150. Cylindrite, Kylindrit (p. 21), 6PbS.Sb₂S₃.6SnS₂. Franckeite (p. 26), 5PbS.Sb₂S₂.2SnS₂.

IV. CHLORIDES, BROMIDES, IODIDES, Min. pp. 152-182.

1. ANHYDROUS CHLORIDES, ETC.

Marshite (p. 45), Cu₂I₂. In Group with Nantokite, p. 154. Miersite (p. 47), Ag₂I₂. """""""Cupro-iodargyrite (p. 21), CuI.AgI or Cu₂I₂. Ag₂I₃.

2. OXYCHLORIDES.

Paralaurionite (p. 50), PbCl₂.Pb(OH₂)₂. Near Laurionite, p. 271. Penfieldite (p. 51), PbO.2PbCl₂.

CUMENGITE, PSEUDOBOLÉITE (p. 52). Near Percylite and Boléite, Min. pp. 172 and 1028. METANOCERINE (p. 46). Near Nocerite, Min. p. 174?

V. OXIDES, Min. pp. 183-260.

QUARTZINE, LUTÉCINE, LUTÉCITE (p. 58). Near Quartz, Min. p. 183. Cubaite, Guanabaquite, Guanabacoite (p. 58). Same as Quartz.

MITCHELLITE (p. 17). Var. Chromite (Magnochromite), Min. p. 228. Baddelevite, Brazilite (p. 8), ZrO2. Dicksbergite (p. 23). Same as Rutile, Min. p. 237. Mesabite (p. 30). Var. Göthite, Min. p. 247. Schulzenite (p. 61). Near Asbolite, Min. p. 258.

Geikielite (p. 28), MgO.TiO₂. Bixbyite (p. 10), FeO.MnO₂. Senaite (p. 61), (Fe,Pb)O.2(Ti,Mn)O₂. Zirkelite (p. 75), (Ca, Fe)O.2(Zr, Ti, Th)O₂. The above may properly be placed with the Titanates (Manganates, Zirconates).

VI. I. CARBONATES, Min. pp. 261-309.

Northupite (p. 49), MgCO₃. Na₂CO₃. NaCl. Pirssonite (p. 53), CaCO₃. Na₂CO₃. 2H₂O. KTYPEITE (p. 39), CaCO₃. Hydrocalcite (p. 36). Taraspite (p. 67). Var. Dolomite, Min. p. 271. Calcistrontite (p. 13). A mixture of Calcite and Strontianite.

VI. 2. SILICATES.

A. ANHYDROUS SILICATES, Min. pp. 310-562.

Epididymite (p. 24), HNaBeSi₂O₈. Near Eudidymite, Min. p. 313. Celsian (p. 15), BaAl₂Si₂O₈. Barium Feldspar, near Anorthite, Min. p. 337.

Urbanite, Lindesite (p. 70), (Ca, Mg)SiO₃ + 2NaFe(SiO₃)₂. Pyroxene Group, Min. p. 314. FEDOROVITE (p. 57). Bet. Ægirite-augite and Ægirite, Pyroxene Group, Min. p. 344. Hainite (p. 31), contains Ti, Zr, Na, Ca. Related to Låvenite, p. 375, Wöhlerite, Min. p. 376, etc. HASTINGSITE (p. 3), PHILIPSTADITE (p. 3), Xiphonite (p. 3). Referred to Amphibole, Min. p. 385.

RHODUSITE (p. 29). Near Glaucophane, Min. p. 399.

CATAPHORITE (p. 14). Bet. Arfvedsonite and Barkevikite, Min. pp. 401, 403.

CROSSITE 'p. 20). Bet. Glaucophane and Riebeckite, Min. pp. 399, 400.

VALLÉITE (p. 71). Near Anthophyllite, Min. p. 384.

Elpidite (p. 24), H₆Na₂ZrSi₆O₁₈. Related to Catapleiite, Min. p. 412.

Hardystonite (p. 32), Ca₂ZnSi₂O₇. Near Ganomalite, Min. p. 422?

Nasonite (p. 48), (Ca, Pb)10 Cl2Si6O21.

RHODOLITE (p. 28), LAGORIOLITE (p. 28). Varieties of Garnet, Min. p. 437.

Ransätite (p. 28). Same as Garnet (spessartite), Min. p. 442.

Glaucochroite (p. 29), CaMnSiO₄. Chrysolite Group, Min. p. 449.

Iddingsite (p. 36). Probably an altered Chrysolite, p. 451.

Fuggerite (p. 27). Near Gehlenite, Min. p. 476.

MANGANANDALUSITE (p. 4), MALTESITE (p. 4). Varieties of Andalusite, Min. p. 496. Thalenite (p. 68), H₂Y₄Si₄O₁₅. Near Yttrialite, Min. p. 512.

CLINOZOISITE, Klinozoisit (p. 17). Calcium-epidote (monoclinic), Min. p. 516.

Eanoockite (p. 32), contains Si, Pb, Ca, Sr, Al, Fe. Epidote Group? Prolectito (p. 55), probably Mg[Mg(F,OH)]SiO₄. Humite Group, Min. p. 535. Clinohedrite (p. 17), H₂ZnCaSiO₄. Near Calamine, Min. p. 546. Lawsonite (p. 41), H₄CaAl₂Si₂O₁₀. Near Carpholite, Min. p. 549. Roeblingite (p. 60), 5H₂CaSiO₄.2CaPbSO₄. Cosmochlore, Kosmochlor, Kosmochromit (p. 20). A chromium silicate.

B. OTHER SILICATES, CHIEFLY HYDROUS SPECIES, Min. pp. 562-711.

Wellsite (p. 72), RAl₂Si₅O₁₀.3H₂O. Phillipsite Group, Min. p. 579. Erionite (p. 25), H₂CaK₂Na₂Al₂Si₆O₁₇ + 5H₂O.

Gonnardite (p. 30), (Ca, Na₂)₂Al₂Si₆O₁₅ + 5½H₂O.

METADESMINE (p. 65). Near Stilbite, Min. p. 583.

METASCOLEZITE (p. 61). Near Scolezite, Min. p. 604.

LEMBERGITE (p. 42), 5Na₂Al₂Si₂O₈ + 4H₂O.

BADDECKITE (p. 7). Near Muscovite, Min. p. 614.

Caswellite (p. 14). Altered mica.

BEACONITE (p. 66). Var. Talc, Min. p. 678.

PSEUDOPYROPHYLLITE (p. 56). Near Pyrophyllite, Min. p. 691.

HOEFERITE (p. 35), 2Fe₂O₃.4SiO₂.7H₂O. Near Chloropal, Min. p. 701.

ALEXANDROLITE (p. 7), contains H₂O,Al₂O₃,Cr₂O₃,SiO₂.

BATAVITE (p. 9), contains H₂O,MgO,Al₂O₃,SiO₂.

Taylorite (p. 67). A clay.

Weldite (p. 72), contains SiO₂, Al₂O₃, Na₂O.

TITANO-SILICATES, TITANATES, Min. pp. 711-724.

LAMPROPHYLLITE (p. 40). Near Astrophyllite, Min. p. 719?

Neptunite (p. 49). Near Titanite, p. 712.

Knopite (p. 39). Near Perovskite and Dysanalyte, Min. pp. 722, 724.

Other Titanates are mentioned on the preceding page.

VI. 3. NIOBATES, TANTALATES, Min. pp. 725-746.

Mossite (p. 48), Fe(Nb, Ta)₂O₆. Near Tapiolite, p. 738. STIBIOTANTALITE, Sb₂O₃. (Ta, Nb)₂O₅?

VI. 4. PHOSPHATES, ARSENATES, ETC., Min. pp. 747-861.

Adelite (p. 1, also Min. p. 1052), (MgOH)CaAsO₄. Wagnerite Group, Min. p. 775.

Tilasite (p. 68), Fluor-adelite, (MgF)CaAsO₄. " " " "

MANGANBERZELIITE (p. 10). Near Berzeliite (Pyrrharsenite), Min. 753.

Rhodophosphite (p. 59). Same as Apatite, Min. p. 762?

Retzian (p. 59). Basic arsenate of manganese, etc.

Gersbyite (p. 28). Near Lazulite, Min. p. 798.

HAUTEFEUILLITE (p. 33), (Mg,Ca)₂P₂O₅ + 8H₂O. Near Bobierrite, Min. p. 817.

Wardite (p. 71), 2Al₂O₃. P₂O₅. 4H₂O.

MINERVITE (p. 47), Al₂O₃. P₂O₅. 7H₂O.

Utahlite (p. 71). Same as Variscite, Min. p. 824.

KEHOEITE (p. 38), ZnO 4Al₂O₃. 5P₂O₅. 9H₂O.

Carnotite (p. 13), K₂O.2U₂O₃. V₂O₆. 3H₂O.

The following are imperfectly described arsenates, or antimonates, of manganese or iron, or both:

Basiliite (p. 9), Chloroarsenian (p. 16), Chondrostibian (p. 17), Elfstorpite (p. 24), Lamprostibian (p. 40), Magnetostibian (p. 44), Melanostibian (p. 44), Rhodoarsenian (p. 59), Sjögrufvite (p. 62).

ANTIMONATES, Min. pp. 861-866.

Tripuhvite (p. 70), 2FeO.Sb₂O₅. Derbylite (p. 22), 6FeO.5TiO₂.Sb₂O₅. Lewisite (p. 42), 5CaO.2TiO₂.3Sb₂O₆.

Mauzeliite (p. 45), 4(Ca, Pb)O.TiO₂.2Sb₂O₅.

PHOSPHATES (ARSENATES) WITH SULPHATES, Min. pp. 866-869.

VI. 5. BORATES, Min. pp. 874-889.

Ascharite (p. 6), 3Mg₂B₂O₅.2H₂O. Sulphoborite (p. 65), 4MgHBO₅.2MgSO₄.7H₂O.

URANATES, Min. pp. 889-893.

Mackintoshite (p. 44), UO2.3ThO2.3SiO2.3H2O. Near Thorogummite, Min. p. 893.

VI. 6. SULPHATES, CHROMATES, Min. pp. 894-981.

Langbeinite (p. 40), K₂SO₄.2MgSO₄. Dietzeite (p. 23), 7Ca(1O₃)₂.8CaCrO₄.

BERESOVITE (p. 9), 6PbO.3CrO₃.CO₂.

SALVADORITE (p. 60), (Cu, Fe)SO₄ + 7H₂O. Near Pisanite, Min. p. 943.

SIDEROTIL (p. 62), $FeSO_4 + 5H_2O$.

Leonite, Kaliblödite, Kaliastrakanite (p. 42), K_2SO_4 . $MgSO_4 + 4H_2O$. Near Blödite, Min. p. 946.

Seelandite (p. 61). Near Pickeringite, Min. p. 953.

Masrite (p. 45). An alum near Halotrichite, Min. p. 954.

KAMAREZITE (p. 38), (CuOH)₂SO₄. Cu(OH)₂.6H₂O. Near Langite, Min. p. 961.

PLANOFERRITE (p. 54), Fe₂O₃.SO₃.15H₂O.

IDRIZITE (p. 36). Near Botryogen, Min. p. 972.

CUBEITE, Kubeit (p. 21), contains SO₃, Fe₂O₃, MgO, H₂O.

Kauaiite (p. 38), contains SO₃, Al₂O₃, K₂O, Na₂O, H₂O.

Bouglisite (p. 4). A mixture of anglesite and gypsum,

VI. 7. TUNGSTATES, MOLYBDATES, Min. pp. 982-995.

Raspite (p. 58), PbWO₄. Wolframite Group, Min. p. 982?

VIII. HYDROCARBON COMPOUNDS, Min. pp. 996-1024.

Alexjejevite (p. 2), Allingite (p. 2), Burmite (p. 12), Cedarite (p. 14). All near Succinite and Amber, Min. p. 1002.

Courtzilite (p. 20). Same as Uintahite, Min. p. 1020.

Pelionite (p. 51), Var. Cannel Coal.

Libollite (p. 43). Near Albertite, Min. p. 1020.

Tiffanyite (p. 68). Undetermined hydrocarbon.

APPENDIX I.

ACANTHITE, p. 58.—Crystals of silver sulphide, prismatic and apparently orthorhombic, occur at the Enterprise mine, Rico, Colorado. Chester, School Mines Q., 15, 303, 1894.

Wire-like forms from Guanajuato, Mexico, referred to acanthite, have been analyzed by Genth, Am. J. Sc., 44, 383, 1892.

ADELITE, p. 1052.—The following is a full description, Hj. Sjögren, G. För. Förh., 13, 781, 1891; Bull. G. Inst. Upsala, 1, 56, 1892:

Monoclinic. Crystals rare, tabular | c or prismatic (m). (Figs. 1, 2.) Observed forms: a (100), c (001), m (110), f (011), d ($\bar{2}21$). Measured angles: $ac = 73^{\circ}$ 15'. mm''' (110 \wedge 110) = 87° 5'*?, m d ($\bar{1}10 \wedge \bar{2}21$) = 24° 45'; a relation to wagnerite is suggested (see foot-note). Usually massive, in embedded grains.

Fracture conchoidal to un-Cleavage none. G = 3.71-3.76. Luster res-H. = 5.even. inous to greasy. Color gray, yellowish gray, Translucent. Optically +. $Bx_a \wedge b = +38^{\circ} 45'$. Axial angle large, $2E = 106^{\circ} 40'$, also $2K_{ay} =$ 58° 47′ (n = 1.6703); $\rho > v$.

Composition, HCaMgAsO₅ or (MgOH)CaAsO₄, analogous to the wagnerite group (p. 775). Analyses, R. Mauzelius, quoted by Sjögren:

- As₂O₅ CaO MgO BaO PbO CuO FeO MnO H₂O Cl G. 0.39
- 1. Nordmark 3.71 50.04 25.43 17.05 tr. 1.64 4.25 0.24
- [Fe₂O₃, Al₂O₃ 0·30 Cu 0·26 = 99·60 0·08 0·48 3 90 tr. = 100·0217.90 2.79 3.76 50.28 24.04 0.23 0.32 2. Långban 0.09 1.27 3. Jakobsberg 3.72 48.52 23.13 19.25 2.41 3.99 SiO₂ 1.88=100.54

Fuses easily B. B. to a gray enamel. With soda on charcoal yields arsenical fumes. Soluble in dilute acids. The water goes off completely only at a high temperature,

Occurs with grains of magnetite and scales of native copper at the Kittel mine, Nordmark, Sweden; also at the Jakobsberg mine with hausmannite, etc., in limestone; with other arsenates and manganese minerals at Långban. Named from άδηλος, indistinct.

A related mineral from the Moss mine gave Lundström (quoted by Sjögren, G. För. Förh., 7, 412, 1884, Upsala, p. 60): As₂O₅ 49·73, CaO 25·52, MgO 18·98, BaO 0·81, MnO 1·69, ZnO? 0·08, Al₂O₃, Fe₂O₃ 0·83, loss (H₂O) 2 36 = 100. Its character is somewhat uncertain.

See also Tilasite, which is a fluor-adelite, (MgF)CaPO4.

ÆGIRITE, pp. 364, 1046.—Reported as occurring in the nephelite-syenite of Paisano Pass, Davis Mts., Texas, A. Osann, 4 Ann. Rep. Geol. Surv. Texas, 128, 1892. Noted also in rocks at various points, as Salem, Mass.; Cripple Creek, Colo.; Black Hills; Bearpaw Mts., Judith Mts. and Crazy Mts., Montana.

^{*} The author's angles and axes are hopelessly at variance. He calculates $\hat{a}:\hat{b}:\hat{b}=$ The author's angles and acceptance in policies of a constance. The calculates u.v.v.=1 10989:1:1:5642, $\beta=73^\circ$ 15'. This ratio for $d:\delta$ requires, however, mm''' (110 \wedge 110) = 92° 55', not 87° 5' as stated; also the value 92° 55' gives the author's angle $cm=78^\circ$ 33'. Furthermore he gives $110 \wedge 221=24^\circ$ 45' and $001 \wedge 221=75^\circ$ 27' (76° 26' meas.), but $001 \wedge 110=101^\circ$ 27', hence $001 \wedge 221$ should be 76° 42'. The value of c deduced from the author's fundamental angles (using $110 \land 1\overline{10} = 92^{\circ}$ 55) is 0.8799, not 1.5642; but the measured angles, $ca = 73^{\circ}$ 15' and $cf = 56^{\circ}$ 27', give c = 1.5748.

ENIGMATITE, p. 403.—An amphibole occurring in the "heumite" of Heum, Norway, may belong here, cf. Brögger, Eruptivgesteine d. Krist., 3, 93, 1898. Reported as occurring in Texas.

Investigation of etching-figures, R. A. Daly, Proc. Am. Acad. Sc., 34, 425, 1899.

AGRICOLITE, p. 448.—From near Schwarzenberg, Saxony, Frenzel, Min. petr. Mitth., 16, 528, 1896.

AGUILARITE, p. 1025.—Several analyses have been made by Genth on material from the original locality; the purest yielded: Se 13'96, S 5'93, Ag 79'41, Cu 0'50 = 99'80 Dodecahedral crystals gave the composition of argentite, with Se = 3'75 (S:Se = 7:1). Other crystals were partially altered to uephanite, etc. Am. J. Sc., 44, 381, 1892.

ALABANDITE, p. 64.—Occurs at Tombstone, Arizona, in large but rough twinned cubic crystals with tetrahedral faces; G. = 4.031, 4.040; analysis gave (Volckening): S 36.91, Mn 63.03 = 99.94. Moses and Luquer, Sch. Mines Q., 13, 236, 1892; Moses, Zs. Kr., 22, 18, 1893.

Albite, pp. 327, 1025.—On crystals from Revin, Belgium, see Franck, Bull. Acad. Belg., 21, 603, 1891.

Crystallographic and optical investigation of a variety free from calcium from Lakous, Crete, Viola, Min. petr. Mitth., 15, 135, 1895, Zs. Kr., 30, 423, 436, 1898. Same of varieties from Russian localities, Glinka, Zs. Kr., 22, 63, 1893; 26, 509, 1886; Vh. Min. Ges., 31, 1, 1894. Cleavage and parting investigated, Penfield, Am. J. Sc., 48, 115, 1894.

Etching-figures, T. L. Walker, Am. J. Sc., 5, 182, 1898.

See also Feldspar.

Alexandrolite. S. M. Losanitsch, Ber. Chem. Ges., 28, 2631, 1895, and Chem. News, 69, 243, 1894.—See Avalite.

Alexjejevite. A resin from the Kaluga Govrn., Russia. Composition: C 75.5, H 12.5, O 12.0. Investigated by Alexjejev (Vh. Min. Ges. St. Pet., 29, 201, 1892) and named by Karnojitsky, Zs. Kr., 24, 504, 1895.

ALLANITE, p. 522.—Crystals described from Franklin Furnace, N. J., Eakle, Am. J. Sc., 47, 436, 1892; also from the Harz (orthite), Luedecke, Min. d. Harzes, 444, 1896; from Mineville, Essex Co., N. Y., H. Ries, Trans. N. Y. Acad. Sc., 16, 327, 1897.

Forms about 56 p. c. of a granite on the east shore of Lac à Baude, Champlain Co., Quebec. Hoffmann, Rep. G. Canada, 7, 12 R, 1894.

Allingite E. Aveng [Arch. Pharm., 232, 1894]. Jb. Min., 2, 254 ref., 1896. A fossil resinfrom Switzerland, related to succinite.

Allophane, p. 693.—Analyses of Italian varieties, G. D'Achiardi, Att. Soc. Tosc., Proc. Verb., March 13, 1898.

ALSTONITE. - See Bromlite.

ALTAITE, p. 51.—Occurs near Liddle Creek, West Kootanie, Br. Columbia, Hoffmann, Rep. G. Canada, 6, 29R, 1893; also on Long lake, Yale district, B. C. (anal. by Johnston), ibid., 8, 11 R, 1895; at Choukpazat, Upper Burma, Louis, Min. Mag., 11, 215, 1897.

Alunite, p. 974.—Occurs at Tres Cerritos, Mariposa Co., California, in an alunite-quartzite, Turner, Am. J. Sc., 5, 424, 1898. At Red Mountain, Ouray Co., Colorado, in aggregations of minute crystals with enargite, etc. Analysis; SO₃ 38-93, Al₂O₃ 39-03, K₂O 4-26, Na₂O 4-41, H₂O 13-35, insol. 0·50 = 100·48. E. B. Hurlburt, Am. J. Sc., 48, 130, 1894. From Knickerbocker Hill, Custer Co., Colo., anal., Eakins, Bull. U. S. G. Surv., 90, 62, 1892.

ALURGITE, p. 635.—The deep-red manganese mica from St. Marcel, Piedmont, has been analyzed by Penfield, as follows .

SiO2 Al₂O₃ Fe₂O₃ Mn₂O₃ MnO MgO K2O Na₂O H,O 53.22 21.19 1.22 0.87 5.75 = 99.990.18 6.02 11.20 0.34

For this the formula preferred is $HR_2(AlOH)Al(SiO_3)_4$ with R = MgOH, K chiefly; it is thusdistinct from other species of the mica group. It is monoclinic; cleavage basal; laminæ flexible. H. = 3. G. = 2.835-2.849. Not highly pleochroic. $2E_y = 56^{\circ} 5'-57^{\circ}$. Am. J. Sc., 46, 288, 1893.

AMBER. - See Succinite; also the new names, Allingite, Burmite, Cedarite, etc.

AMPHIBOLE, pp. 385, 1026.—K. von Kraatz divides the varieties here included into three groups according to prismatic cleavage angle: Tremolite scries, cleavage angle 55° 10′ to 55° 25′; common green hornblende, 55° 25′ to 55° 35′; brown basaltic hornblende, 55° 40′ to 55° 50′. Zs. Kr., 30, 664, 1899.

A discussion of the variation of extinction-angle in the prismatic zone is given by R. A. Daly. Proc. Am. Acad. Sc., 34, 311, 1899. See also by the same author an exhaustive investigation of

etching-figures of different members of the amphibole group, *ibid.*, p. 374 (see *philipstadite* below). On the composition of certain rock-making amphiboles, from the Sierra Nevada, California, see Turner, Am. J. Sc., 7, 297, 1899. Analysis (2.72 H₂O) of amphibole from the Durbach micasyenite, Sauer, Beitr. G. Heidelberg, Mitth. Bad. G. Landesanst., 2, 252. Analyses are given also in many petrographical memoirs, Jahrb. Min., et al.

Synthetic experiments leading to the formation of this and other species, Doelter, Jb. Min.,

1, 1, 1897.

Au unusual variety (monoclinic-hemihedral or triclinic?) occurs in the trachyte of Montesanto, Italy, Franco, Zs. Kr., 25, 328, 1895; Rend. Accad. Napoli, May-June, 1895.

An amphibole having the composition of an orthosilicate analogous to garnet, (R2,R)3R2Si3O12 (cf. syntagmatite, Min., p. 388), has been called hastingsite by Adams and Harrington (Am. J. Sc., 1, 210, 1896). Occurs in grains in the nephelite-syenite of Dungannon, Hastings Co., Ontario. Optically —. Birefringence low. \mathfrak{c} nearly coincident with $\dot{\mathfrak{c}}$. Ax. pl. $\parallel b$ (010). Ax. angle small, 30° to 45°. Dispersion $\rho > v$. Absorption $\mathfrak{c} = \mathfrak{b} > \mathfrak{a}$. Pleochroism, \mathfrak{a} yw.-green; \mathfrak{b} and \mathfrak{c} deep bluich green. deep bluish green. Analysis, Harrington:

SiO2 TiO2 Al2O3 Fe2O3 FeO MnO CaO MgO K2O Na2O H2O $G_{\cdot} = 3.433$ 34.18 1.53 11.52 12.62 21.98 0.63 2.28 9.87 1.35 $3.29 \quad 0.35 = 99.60$

Another aluminous amphibole, from the gabbro of Pavone, near Ivrea, Piedmont, Italy, investigated by Van Horn is also nearly an orthosilicate. Cleavage-angle 55° 42′. G. = 3.217-3.222. Extinction-angle 14° 30′ to 15° 30′ on b (010). Pleochroism strong: a light yellow; b brown, tinge of red; c brown, tinge of yellow. Analysis by Dittrich:

SiO2 TiO, Al203 Fe,O, FeO MnO CaO K,O ·Na2O MgO H20 39.58 14.91 4.01 10.67 11.76 13.06 0.62 2.87 2.79 = 100.27tr.

This corresponds nearly to $R_{\bullet}R_{\bullet}R_{\bullet}Si_{\bullet}O_{16}$ or $R_{\bullet}R_{\bullet}Si_{\bullet}O_{12}$ (syntagmatite) + $R_{\bullet}SiO_{4}$. Amer. Geol., 21, 370, 1898.

An amphibole from Philipstad, Sweden, has been called philipstadite by R. A. Daly (Proc. Am. Acad. Sc., 34, 433, 1899). It shows anomalous etching-figures on m (110) and b (010) (ibid., p. 399); pronounced zonal structure; small optic axial angle (about 50°); also unusual pleochroism and absorption: viz., a light brownish green, t dark yellow-green, t dark blue-green; t > t > a. It is optically –, with an extinction-angle on b(010) with $b = +15^{\circ}9'$ (Na). An analysis by Pisani

Na₂O SiO2 TiO2 Al2O3 Fe2O3 FeO MnO CaO MgO K2O ign. 45.20 0.84 7.34 7.55 15.80 1.52 12:30 8.40 0.80 0.37 0.70 = 100.82

Xiphonite is a name given by G. Platania (Accad. Sc. Acircale, 5, 1893) to a variety occurring in minute crystals with hematite in cavities of a slag-like rock at Acicatena (Etna), Sicily. Form, angles and cleavage like amphibole, but characterized by light honey-yellow color and by feeble pleochroism. Composition undetermined. Named from Xiphonia, an old town near the locality.

See Richterite (astochite); also other species of the group; new names are Cataphorite (Kataforite), Crossite, Rhodusite.

Analcite, p. 595.—Crystals described from the Harz, Luedecke, Min. d. Harzes, 576, 1896. Also from Boylestone Quarry, near Barrhead, Renfrewshire, Scotland; doubtful forms

2 (543), t (421), also (332). Heddle, Trans. Edinb. G. Soc., 7, 241, 1897.

Optical structure investigated, Monte Somma, P. Franco, Giorn. Min., 3, 232, 1892. Same, from Monte Catini, G. D'Achiardi, Att. Soc. Tosc., Pisa, 1897. Discussion of optical structure, with relation to a new artificial silicate, G. Friedel, Bull Soc. Min., 19, 14, 5, 1896; also with reference to effect produced by loss of water, *ibid.*, pp. 94, 363. Further discussion of optical structure, especially in relation to leucite, Klein, Ber. Ak. Berlin, 290, 1897, and Jb. Min., Beil.-Bd., 11, 474, 189.

Analysis, from Friedersdorf on the Lahn, Brauns, Jb. Min., 2, 4, 1892. From the Planenschen

Grund, Dresden, Zschau, Abh. Ges. Isis, p. 94, 1893.
Occurs in a dike-rock at Hamburg, N. J., derived from leucite, Kemp, Am. J. Sc., 45, 298, 1893. Also in analcite-diabase of San Luis, California, Fairbanks, Bull. Dept. Geol. Univ. California, 1, 273, 1895.

Present as a primary constituent in certain igneous rocks (monchiquite), Pirsson, J. Geol., 4, 679, 1896; also in an analcite-basalt near Cripple Creek, Colorado, Cross, J. Geol., 5, 684, 1897.

ANATASE. - See Octahedrite.

Andalusite, p. 496.—Crystals from the Pitzthal, Tyrol, show the new forms, i (320), t (013), v (054), u (032), x (112). Haefele, Zs. Kr., 23, 551, 1894.

A variety of chiastolite from the crystalline schists of the region north of Ladoga Lake in eastern Finland is called mattesite by J. J. Sederholm. The large nodules show a Maltese cross of wedge-shaped parts of pure material, separated by areas of impure material. G. För. Förh., 18, 390, 1896.

A variety containing 6.91 p. c. Mn₂0₃ is called *Manganandalusite* by H. Bäckström. Occurs in muscovite-quartzite of Vestanå, Sweden, differs from ordinary and alusite in its grass-green color and strong pleochroism: c (a) and b (b) blue-green, a (c) pure yellow and most absorbed. Investigation of a mineral related to and alusite and dumortierite, from the granite of the

Argentine Republic. It is marked by deep-red pleochroism. Romberg, Jb. Min., Beil-Bd., &

340, 1893.

See also Westanite.

Andesine. p. 333.—Stenzelberg, Siebengebirge, crystals described (new form, 120), Busz, Jb. Min., 1, 36, 1898. See also Feldspar.

Andorite. J. A. Krenner [Math. term. Értesitö, 11, 119, 1892], Zr. Kr., 23, 497, 1894; G. T. Prior and L. J. Spencer, Min. Mag., 11, 286, 1897; and Zs. Kr., 29, 346. Sundtite, W. C. Brogger, Zs. Kr., 21, 193, 1893; Pöhlmann, ibid., 24, 124, 1894. Webnerite, Stelzner, ibid., 24, 125, 1894.

Orthorhombic. Axes $\check{a}: \check{b}: \dot{c} = 0.6772: 1: 0.4458.$ 100. $110 = 34^{\circ}$ 6 $_{1}^{\circ}$, 001 \wedge 101 = 33° 21 $_{2}^{\circ}$, 001 \wedge 011 = 24° 1 $_{3}^{\circ}$. Forms: a (100), b (010), c (001); ϕ (610), ψ (510), n (210), o (320), m (110), l (230), k (120); k (102), θ (305), σ (203), κ (405), f (101), e (302), λ (301), μ (902); x (011), v (043), π (032), γ (021), y (031); v (112), χ (223), p (111), z (332), q (221), ρ (331); s (211), δ (364), r (121), e (362); ω (132); β (131); α (162); ζ (2:21°7). Angles: $mm''' = 68^{\circ}$ 12', $ff' = 66^{\circ}$ 43', $xx' = 48^{\circ}$ 3', $yy' = 106^{\circ}$ 26', $vv' = *35^{\circ}$ 37' $_{1}^{\circ}$ ', $vv'' = *23^{\circ}$ 54 $_{1}^{\circ}$ '.

In aggregates of highly modified prismatic crystals, tabular | a (100); faces in prismatic zone

vertically striated. Also massive.

Cleavage none. Fracture conchoidal. Brittle. H. = 3-3.5. G. =5.50. Luster metallic, bril-

liant. Color steel-gray. Streak black.

Composition, PbAgSb₃S₆ or 2PbS.Ag₂S.3Sb₂S₃. Analyses.—1, Loczka; quoted by Krenner. 2, 3, G. T. Prior. 4, P. J. Mann, quoted by Stelzner (also other anals. on less pure material).

	G.	S	Sb	Pb	Ag	Cu	Fe
1. Felsöbanya	5.341	23.32	41.91	22 07	11.31	0.69	0.70 insol. 0.04 = 100.04
2. "	5.33	22.19	41.76	21.81	11.73	0.73	1.45 = 99.67
3. Oruro	5.377	22.06	41.31	24.10	10.94	0.68	0.30 = 99.39
.4. "		23.10	40.86	24.30	10.25	0.65	0.53 = 99.69

First described by Krenner from Felsőbanya, Hungary, where it occurs with stibnite, quartz, and sphalerite, also barite and manganosiderite. Also found at the silver-tin mines of Oruro, Depart. of Oruro, Bolivia, especially the Itos mine (webnerite) with stibnite, pyrite, etc. The name Andorite is given for Andor von Semsey; Sundtite, for the mining director L. Sundt; Webnerite, for the mining engineer, A. Webner.

The identity of andorite, sundtite and webnerite was established by Prior and Spencer. The observed list of forms is that given by them; the position and fundamental angles are those of Brögger (sundtite). It is to be noted that the analysis of "sundtite" by Thesen, quoted by Brögger and which shows only a trace of lead (G = 5.50), it is now stated was not made upon

measured crystals, hence it appears to represent another species.

Anglesite, p. 907.—Crystals described from the Altai, new form (016), Jeremejev, Vh. Min. Ges., 29, 174, 1892. Crystals from unknown source show the new form Γ (255), L. J. Spencer, Min. Mag., 11, 197, 1899.

Occurs at the Wellington mine, Bear Lake, West Kootanie, Br. Columbia, Hoffmann, Ref. G.

Canada, 6, 27 R, 1892-93.

A mineral having the form of anglesite, associated with the boléite of Boléo, Lower California, is shown by Genth to have the composition 2PbSO₄.CaSO₄.CaSO₄.Pd₂O, and to be a mechanical mixture of anglesite and gypsum. An origin from a possible mineral 2PbSO₄.CaSO₄ is suggested. Am. J. Sc., 45, 32, 1893. See also Mallard, Bull. Soc. Min., 16, 195, 1893. This substance has been called *bouglisite* by Cumenge, after M. de La Bouglise (cf. Lacroix, Bull. Mus. d'Hist. Nat., 42, 1892).

ANHYDRITE, p. 910.—Molecular properties investigated, also of other species, Mügge, Jb. Min., 1, 71, 1898.

Refractive indices, Zimanyi, Zs. Kr. 22, 341, 1893.

Deposits of anhydrite and gypsum of Oulx described by Colomba, Att. Accad. Torino, 33, 779, 1897-98.

Formation discussed, R. Brauns, Jb. Min. 2, 257, 1894. Occurs in bluish tabular masses in cavities in trap rock at Larrabee's quarry, Northampton, Mass. Emerson, Bull. U. S. G. Surv., 126, 26, 1895.

Anorthite, p. 337.—Occurs at Buck Creek, Clay Co., N. C., analysis by C. H. Baskerville, quoted by Pratt, Am. J. Sc., 5, 128, 1898. Occurs with epidote at Phippsburg, Me., Clarke, Am. J. Sc., 48, 429, 1894. From Raymond, Me., anal., Melville, Bull. U. S. G. Surv., 113, 110, 1893. See also Feldspar.

Anorthoclase, p. 324.—Analysis from acmite-trachyte of the Crazy Mts., Montana, Hillebrand, quoted by Wolff and Tarr, Bull. Mus. Comp. Zool. 16, 227, 1893.

Brögger proposes the name soda-microcline (Natronmikroklin) and discusses relation to other allied feldpars, Eruptivgest. d. Kristianiagebietes, 3, 11, 1898.

ANTHOPHYLLITE, p. 384.—Occurs at Bakersville, N. C., in dunite; crystals analyzed by Baskerville yielded results identical with those of Penfield (anal. 1, p. 385); it is concluded that the latter's specimens came from this locality, Pratt, Am. J. Sc., 5, 429, 1898.

Gedrite (14 p. c. Al₂O₃) occurs as a coarse, granular rock near Harris's Soapstone quarry, Warwick, Mass. Emerson, Bull. U. S. G. Surv., 126, 86, 1895 (anal., Schneider, Eakins). On gedrite-schist from Vester Silfberg, Sweden, see Weibull, G. För. Förh., 18, 377, 1896.

Investigation of etching-figures, R. A. Daly, Proc. Am. Acad. Sc., 34, 424, 1899.

See also Asbestus and Valleite.

APATITE, pp. 762, 1027.—Cryst.—From the granite of Alzo, Lake Orta, Italy, G. Strüver, Riv. Min. Ital., 12, 52, 1893. From Zöptau, Graber, Min. petr. Mitth., 14, 269, 1894. From the emerald mines in the Ural, with (8087) Jeremejev, Vh. Min. Ges., Prot., 33, 65, 1895. Elba, Artini, Riv. Min. Ital., 16, 15, 1896, and Rend. Accad. Linc., 4 (2), 259, 1895. Crystals of manganapatite (5.95 p. c. MnO) from the Vestanå mines, Sweden, gave Weibull cx (0001 A 1011) = 40° 17′ 20″. G. För. Forh., 20, 63, 1898.

Twin crystals with tw. pl. s (1121), inclusions in the andesite of Mt. Stavro, Algeria, are noted by Washington, J. Geol., 3, 25, 1895.

Discussion of vicinal faces, Karnojitsky, Vh. Min. Ges., 33, 65, 1895.

Comp.—Composition discussed, Rammelsberg, Jb. Min. 2, 38, 1897. Analyses of many specimens and discussion of variation in composition, Carnot, Bull. Soc. Min., 19, 135, 1896; Ann. Mines, 10, 137, 1896, (also other phosphates, ib., 8, 321, 1895,) and C. R., 122, 1375, 1896. Montebras, analysis of blue variety, Carnot, Bull. Soc. Min., 19, 214, 1896. Ceylon, occurring with graphite, Jannasch and Locke, Zs. anorg. Ch., 7, 154, 1894.

APHTHITALITE, p. 897.—Vesuvius, natural crystals seem to be in part rhombohedral, in part orthorhombic and biaxial, P. Franco, Giorn. Min., 4, 151, 1893.

APOPHYLLITE, p. 566.—Cryst.—Harz Mts., Luedecke, Min. d. Harzes, 572, 1896. Kimberley, S. Africa, new forms, \(\xi\) (119), \(\chi\) (223), \(k\) (332), Currie, Trans. Edinb. G. Soc.. 7, 252, 1897.

Collo, Constantine, Algeria, crystals described and analysis, Gentil, Bull. Soc. Min., 17, 11, 1894. No fluorine was found; Friedel also remarks on its absence while he obtains an ammonia-cal reaction, *ibid.*, p. 142. A. E. Nordenskiöld found fluorine in the Collo mineral examined by him; he also shows that the presence of ammonia was early established (1805, Rose), G. För. Förh., 16, 579, 1894.

Discussion of optical properties as influenced by heat and pressure, Klein, Jb. Min., 2, 165,

1892 (also less complete in Ber. Ak. Berlin, 1892, p. 217).

Anal.—Grängesberg, Hallberg, G. För. Förh., 15, 327, 1893. From the "blue ground" of Koppiesfontein, near Jagersfontein, So. Africa, J. A. Leo Henderson, Min. Mag., 11, 318, 1897. From the Grand Marais, Minn., Berkey, 23 Ann. Rep. G. Surv. Minnesota, 1894, p. 195. See also above.

Aragonite, pp. 281, 1027.—Cryst.—Neussargues (Cantal), Gonnard, Bull. Soc. Min., 14, 183, 1891; 16, 10, 1893. Framont, new forms (572), (231), (341), (8·11·3), and others doubtful, Stöber [Mitth. G. Landes. Els.-Lothr., 4, 113, 1894], Zs. Kr, 27, 531. Monte Ramazzo. Liguria, Italy, new forms (430), (570), (073), (052), (331), (512), (9·2·16), (413), (3·2·12). (431), (24·25·1), (342), (7·10·3), (352), (133), (271), Negri, Riv. Min. Ital., 15, 65, 1896. Harz Mts., (0·1·12), Luedecke, Min. d. Harzes, 338, 1896. Chaudfontaine, Belgium; G. Cesaro, Mem. Acad. Belg., 53, 1897. From the amianthus deposits of Val Lanterna, Italy, with doubtful new forms (17·16·0), (11·13·0), (16·23·1), Brugnatelli, Riv. Min. Ital., 18, 51, 1898, and Rend. Ist. Lombardo, 30, 1116, 1897 (also Zs. Kr., 21, 56, 1890)

Crystals from Sicily are referred to the monoclinic system by Viola, Zs. Kr., 28, 225, 1897. Determination of the heat of formation, Le Chatelier, C. R., 11, 390, 1893,

Tarnowitzite in crystals from Tarnowitz described with 2.2 to 4.8 p. c. PbO, Traube, Zs. G-Ges., 46, 64, 1894.

ARFVEDSONITE, p. 401.—Investigation of etching-figures, also of other members of the amphibole group, R. A. Daly, Proc. Am. Acad. Sc., 34, 404, 1899.

See also Cataphorite.

ARGYRODITE, p. 150.—Shown by Peufield to be isometric and tetrahedral, not monoclinic in crystallization. The faces m and o (fig. 1, p. 150) belong to the dodecahedron, d (110); f and k to the tetrahedron o (111), and v to (311). Am. J. Sc., 46, 107, 1893, and 47, 451, 1894. Cf. Weisbach, Jb. Min., 1, 98, 1894. The mineral described by Penfield was from Bolivia, and was first named canfieldite, on the supposition that it was a new species, like argyrodite in composition, but isometric; later this name (see this Appendix, p. 13) was transferred to another sulphostannate of analogous composition also from Bolivia. Penfield shows that the formula of argyrodite is $Ag_{\theta}GeS_{\theta}$ or $4Ag_{\theta}S.GeS_{\theta} = Sulphur 17·1, germanium 6·4, silver <math>76·5 = 100$. Analyses:

	S	Ge	Ag	Fe, Zn	Insol.
 Bolivia G. = 6.26 Freiberg G. = 6.16 	$(\frac{2}{2}) 17.04$ 16.97	$\binom{3}{3}$ 6.55 $\binom{2}{2}$ 6.64	76.05 (2) 75.55	(3) 0·13 0·24	0.29 = 100.06 Hg $0.34 = 99.74$

A stanniferous argyrodite from Aullagas, Bolivia, described by Prior and Spencer (Min. Mag., 12, 6, 1898) occurs in regular octahedrons, in part spinel-twins; also in twinned dodecahedrons. G. = 6·19. Composition as given above, but Ge: Sn = 5:2. Analysis, Prior: S 16·45, Ge 4·99, Sn 3·36, Ag 74·20, Fe 0·68, Sb $tr. = 99\cdot68$.

Arsenic, p. 11.—Occurs at Akadanimura, Ohnogori, Japan, in rhombohedral crystals, Frenzel, Min. petr. Mitth., 16, 529, 1896.

ARSENOPYRITE, p. 97.—Weibull, after an investigation of the mineral from various Swedish localities (also Freiberg), concludes that the composition and form vary somewhat for different occurrences, but the species (when pure) has the formula Fe(As,S); well-formed crystals often enclose impurities. Zs. Kr., 20, 1, 1891. Scherer has made a still more extended investigation of the form and composition of the mineral from many localities; he finds crystals often impure, having a zonal structure, but aside from this he concludes that the composition is expressed by $mFeS_2 + nFeAs_2$ with m: n = 1:1 nearly. No simple relation between axial ratio and composition was found. The list of forms (p. 383) contains the following not given in Min., p. 98: δ (310), ζ (0·17·2), ε (054). Zs. Kr., 21, 354, 1893. See also idem. ib., 22, 61, 1893, analysis of crystals from Weiler in Elsass.

The composition of this and related species has been also discussed by Rammelsberg, Jb.

Min., 2, 45, 1897; by Starke, Shock and Smith, J. Am. Ch. Soc., 19, 948, 1897.

Danaite occurs in Graham township, Algoma, Ontario (analysis by Johnston with 4 p. c. Co, 0.9 Ni), Hoffmann, Rep. G. Canada, 5, 19 R., 1889–90. Also occurs at the Evening Star mine, Trail creek, West Kootenay, Br. Columbia, ib., 8, 13 R, 1895.

ASBESTUS, p. 386.—Investigation of various asbestiform minerals, many of which are shown to belong to fibrous anthophyllite, Merrill, Proc. U. S. Nat. Mus., 18, 281, 1895.

Ascharite. W. Feit [Ch. Ztg., 15, 327, 1891], Zs. Kr., 24, 625, 1894. Found in white lumps with boracite, in kainite and halite at Schmidtmannshall near Aschersleben. The lumps are made up of microscopic grains showing no crystallization. $G_1 = 1.85-1.95$. Nearly insoluble in water and more difficultly soluble than stassfurtite in acids. Composition of material freed from other salts by water $3Mg_2B_2O_6.2H_2O$. Analysis: $\frac{3}{8}B_2O_3.49.2$, MgO.42.8, $H_2O.8.0 = 100$.

ASTOCHITE, p. 1027.—The brown variety of this supposed new kind of amphibole is identical with Breithaupt's richterite (p. 391), cf. Hamberg, G. För. Förh., 13, 801, 1891; Sjögren, ib., 14, 253, 1892. The latter author, however, suggests the name natronrichterite for the blue variety, which contains more soda and less potash than the brown. See Richterite.

ASTRAKANITE, see Blödite. KALIUM-ASTRAKANITE, see Leonite.

Atacamite, p. 172.—Crystals from Sierra Gorda, Chili, examined by G. F. Herbert Smith, are prismatic in habit with the pyramids r (111) and n (121) prominent; ε (011) small; a new pyramid h striated $\|$ edge h/ε in part corresponds to (132). The axial ratio calculated from excellent measurements is $\check{a}:\check{b}:\dot{c}=0.66130:1:0.75293$. Other more complex crystals, also from Atacama, show ϕ (131), ρ (443), σ (332) and forms with doubtful indices. Min. Mag., 12, 15, 1898.

AUGELITE, p. 847.—Crystallized specimens of this hitherto doubtful species examined by Prior and Spencer establish its character, Min. Mag., 11, 16, 1895.

Monoclinic with the forms a(100), b(010), c(001), m(110), $x(\bar{1}01)$, r(011), n(112), $o(\bar{1}12)$, and others doubtful. Axial ratio: $a:\bar{b}:\bar{b}=1$ 6419:1:12708, $\beta=67^{\circ}$ 33½. Habit tabular $\|e\|$;

also triangular and tabular $\|m\|$ or prismatic with c and x equally developed. Cleavage: m perfect; x (101) less perfect. Fracture uneven. Brittle. H. = $4\cdot5-5$. G. = $2\cdot696$. Luster vitreous. Colorless to white. Optically +. Ax. pl. $\|b\|$ Bx_a $\wedge b = -34^\circ$. $2E_{a\cdot y} = 84^\circ$ 42'. Indices: $\alpha = 1\cdot5736$, $\beta = 1\cdot5759$, $\gamma = 1\cdot5877$. Composition: AlPO₄.Al(OH)₅ or $2Al_2O_3.P_2O_5.3H_2O$. Analyses, Prior:

	P2O5	Al ₂ O ₃	CaO	H_2O
1.	34.60	51.40	0.11*	13.77 = 99.88
2.	35.33	50.28	0.90*	13.93 = 100.44

* Probably foreign to the mineral.

The specimens examined were from Machacamarca, near Potosi, Bolivia, where it occurs with bournonite, octahedral pyrite, zinkenite, etc. The original mineral, described by Blomstrand, was from Westanå, Sweden; his results are here confirmed. Augelite also occurs in Bolivia at the silver mines of Tatasi and Portugalete, province of Sudchichas, dept. of Potosi (Spencer, Min-Mag., 12, 1, 1898).

AURICHALCITE, p. 298.—Analysis, Torreon, Chihuahua, Mexico, Collins, Min. Mag., 10, 15, 1892. Campiglia Maritima, also optical examination, G. D'Achiardi, Att. Soc. Tosc., Mem., 16, 3, 1898.

Avalite. p. 617.—An analysis gave Losanitsch (Ber. Ch. Ges., 28, 2631, 1895, and Ch. News, 69, 243, 1894) the results below (1). According to the author the so-called milosin of Breithaupt (1838) is derived from the alteration of avalite and is a mixture of two minerals, to one of which (2) he limits this name, the other he calls Alexandrolite, anal. (3).

	SiO ₂	Al ₂ O ₃	Cr ₂ O ₃	Fe ₂ O ₃	MgO	K ₂ O	H ₂ O
1. Avalite	54.66	20.46	10.88	1.18	2.06	4.61	5.66 = 99.51
2. Milosin	46.37	30.18	9.75	0.91	tr.	tr.	13.76 = 100.97
3. Alexandrolite	52.07	20.76	13.74	2.22	tr.	tr.	10.88 = 99.67

Milosin is described as having a bluish-gray color; under the microscope, transparent, crystal-line. Insoluble in acids. Analysis (2) made of material dried at 130°. Alexandrolite has a green color, opaque, amorphous. Soluble in hydrochloric acid. Also dried at 130°.

AXINITE, p. 527.—Cryst.—Nordmark, Sweden, new forms Ξ (130), γ (1 $\overline{2}$ 0), U (061), R (081), Z ($\overline{4}$ 41), Q (327). λ ($\overline{2}$ 85), Hj. Sjögren, Bull. G. Inst. Upsala, 1, 1, 1893 and G. För. Förh., 14, 249, 1892. Bourg d'Oisans, Dauphiné, Gonnard and Offret, Bull. Soc. Min., 16, 75, 1893. Quenast, Belgium, Franck, Bull. Acad. Belg., 25, 17, 1893. Harz Mts., Luedecke, Min. d. Harzes, 464, 1896.

Etching-figures investigated, T. L. Walker, Am. J. Sc., 5, 180, 1898.
Composition discussed, Rheineck, Zs. Kr., 22, 275, 1893. Analyses by Mauzelius of varieties from Nordmark and Dannemora and discussion of composition, Hj. Sjögren, G. För. Förh., 17, 279, 1895. Bourg d'Oisans, analysis, Jannasch and Locke, Zs. anorg. Ch., 6, 57, 1894.
Occurrence in the Pyrenees described, Lacroix, C. R., 115, 739, 1892.

AZURITE, p. 295.—Cryst.—From Laurion, new forms $I(\bar{2}05)$, $T(\bar{4}05)$, $W(\bar{6}05)$, Zimányi, Zs. Kr., 21, 86, 1892. Willow's mine, Pretoria, Transvaal, new forms A(0.1.10), $\Gamma(263)$, $W(\bar{1}.3.15)$. Molengraaf, Zs. Kr., 22, 156, 1893. Mineral Point, Wis., new forms c (307), b (203), b (9·12·8), Hobbs, Bull. Univ. Wisconsin, 1, 145, 1895, and Zs. Kr., 25, 270, 1895.

Babingtonite, pp. 381, 1027.—Occurs in minute crystals on gneiss at Buckland, Mass., Emerson, Bull. U. S. G. Surv., 126, 32, 1895 (anal. by Schneider).

A pyroxenic mineral from the "mijakite" (augite-andesite) of the island of Mijakeshima is

interpreted by Petersen as being a manganiferous babingtonite, Jb. Hamb. Wiss., 8, 49, 53, 1890.

Baddeckite. G. Chr. Hoffmann, Rep. G. Canada, 9, 11 R, 1896; Am. J. Sc., 6, 274, 1898. Occurs in small isolated scales embedded in a plastic clay near Baddeck, Victoria Co., Nova Scotia. G. = 3.252. Luster pearly. Color copper-red. Streak tile-red. Analysis, R. A. A. Johnston:

SiO ₂	Al2O3	Fe ₂ O ₃	CaO	MgO	K20	Na ₂ O	H ₂ O
48.96	13.85	25.82	1.17	2.65	3.47	0.22	3.78 = 99.92

Ratio for RO: R_2O_3 : SiO₂: $H_2O = 1:3:8:2$, or formula $H_4R(R_2)_3Si_8O_{24}$, the quantivalent ratio for which (3:4) approximates to some muscovites, to which it is referred as a ferruginous variety. B. B. fuses at 4.5 to a shiny black slag, becoming magnetic. Decomposed by strong hydrochloric acid with separation of slimy silica.

Baddeleyite. L. Fletcher, Nature, 46, 620, 1892; Min. Mag., 10, 148, 1893. E. Hussak, Jb. Min., 2, 141, 1892; 1, 89, 1893; Min. petr. Mitth., 14, 395, 1895.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c} = 0.9871:1:0.5114$; $\beta = *81^{\circ} 14\frac{1}{2}' = 0.01 \land 100$ Hussak. $100 \land 110$ = *44° 17½°, $001 \land \bar{1}01 = *29^{\circ} 4\frac{1}{2}'$, $001 \land 011 = 26^{\circ} 48\frac{1}{8}'$. Observed forms: a (100), b (010), c (001); m (110), b (230), b (120), s (203), b (1201), a (201) as tw. pl., a (101), a (201); a (221); a (211). Angles: a (101), a (201),
Crystats assumpt twins: (1) a (100) most common, also as physymmetric twining lamener; (2) m (110) both contact- and penetration-twins, also as thin lamellæ; (3) a (201) rather rare. Habit tabular ||a|. Cleavage: c rather perfect; b much less so; also parting ||m|. H. = 6.5. G. = 5.5 Hussak; 6.025 Fletcher. Luster greasy to vitreous, on opaque crystal nearly submetallic resembling columbite. Color variable, from colorless to yellow, brown and finally black and opaque. Streak white to browish white. Pleochroic. Optically —. Ax. pl. ||b|. Bx_a inclined to c about + 13° Fletcher. Dispersion inclined. Ax. angle large, $2E = 70^{\circ}$ -75°.

Composition, zircon dioxide, ZrO₂. Analysis, C. W. Blomstrand, quoted by Hussak, Jb. Min.,

1, 89, 1893:

ZrO2 SiO, Al₂O₃ Fe₂O₃ CaO MgO Alk. ign. 96.52 0.70 0.43 0.41 0.55 0.10 0.42 0.39 = 99.52

Of the accessory constituents above given, only the iron belongs to the mineral itself; the varia-

tion in color is probably due to variation in amount of iron.

B. B. nearly infusible, glows brightly; reacts faintly for iron with borax. When cooled suddenly and pressed flat in the borax bead microlites and microscopic crystals are formed. Insoluble in acids; only slightly attacked by concentrated sulphuric acid if in fine powder. Decomposed

by fusion with acid potassium sulphate.

First identified by Fletcher, and described both as regards form and composition, on a single fragment of a crystal (3 grams) from the gem sands of Rakwana. Ceylon; geikielite was obtained from the same source. About the same time discovered by Hussak from Brazil and named brazilite, but the composition was only later correctly determined by the analysis of Blomstrand. The Brazilian mineral occurs as an accessory constituent of a decomposed magnetite-pyroxenite (jacupirangite of Derby) of the magnetite deposits of Jacupiranga, on the branch of the same name of the Rio Ribeira. State of São Paulo. It is associated with magnetite, apatite, perovskite, ilmenite, titanite, microlite, zircon, etc. Also identified as an accessory constituent of a rock resembling jacupirangite from the nephelite-syenite region of Alnö, Sweden, cf. Hussak, Jb. Min., 2, 238, 1898.

Named after Mr. Joseph Baddeley, who brought the specimen from Rakwana.

BAGOTITE. — Green pebbles, identified as lintonite from Bagot, Ontario. See Egleston, Cat. Min., 192, 1889 (1887); Chester, Dict. Names Min., 25, 1896; Spencer, Min. Mag., 11, 323, 1897.

BARITE, pp. 899, 1027.—Cryst.—Lunkány, Hungary, Zimanyi, Földt. Közl., 22, 267, 1892. Montevecchio, Sardinia, new forms (1·0·25), (403)?, (123), (157), (2·5·11), (163)?. Negri, Riv. Min. Ital., 12, 3, 1893. Bergheim, Ober-Elsass, Feurer, Mitth. G. Land. Els.-Loth., 4, 89, 1893; Zs. Kr., 25, 623. Caucasus, new form *I* (355), Zimanyi, Földt. Közl., 24, 404, 1894. From Harz Mts., Luedecke, Min. d. Harzes, 357, 1896. Dobsina, new form p (772), Melczer, Földt. Közlöny, 26, 357, 1896, Zs. Kr., 30, 183. Vassera, Lombardy, Italy, Artini, Riv. Min. Ital., 16, 1896. Odanwald occurrence described also complete crystals, new form p (196). Krastz 10. 1896. Odenwald, occurrence described, also complex crystals, new form f (196), Kraatz-Koschlau, Abh. Hess. G. Land., 3, No. 2, 55, 1897. From various localities in Belgium, Cesaro, Mem. Acad. Belg., 53, 1897. Körösmezö, Hungary, G. Moesz, Földt. Közl., 27, 495, 1897. Apparent hemimorphism discussed, Beckenkamp, Zs. Kr., 27, 583, 1896. See also idem, ibid., 20, 25, 1896.

30, 55, 1898.

As cementing material in sandstone, F. Clowes, Proc. Roy. Soc., 64, 374, 1899 (Min., p. 903).

BARIUM ANORTHITE.—See Celsian.

BARIUM HEULANDITE. - See Heulandite.

Barkevikite, p. 405.—Daly's investigation of etching-figures shows it to be more closely related to common hornblende than to arrived sonite. Proc. Amer. Acad. Sc., 34, 374, 1899. A related amphibole occurs in the sodalite-syenite of Montana ($\mathfrak{c} \wedge \mathfrak{b} = 13^{\circ}$), Lindgren and

Melville, Am. J. Sc., 45, 292, 1893.

See also Cataphorite.

Barracanite. R. Schneider, J. pr. Ch., 52, 555, 1895.—See Cubanite.

BARYTOCALCITE, p. 289.—In parallel cryst. growth with barite, Mügge, Jb. Min., 1, 252, 1895. Optical examination ($\beta = 1.684$) and relation to bromlite, also to calcite, aragonite and witherite, Mallard, Bull. Soc. Min., 18, 10, 1895.

BARYTOCELESTITE. - See Celestite.

Basilite. Igelström, G. För. Förh., 14, 307, 1892; Zs. Kr., 22, 470, 1893. In foliated forms. Luster metallic or submetallic. Color steel-blue, but in very thin splinters blood-red. Not magnetic. Several partial analyses yielded:

> Fe₂O₃ 1.91 Sb2Os 13.09 Mn2O3 70.01 H₂O 15.00

Calculated formula, $11(Mn_2O_3,Fe_2O_3).Sb_2O_5.21H_2.O$. Dissolves readily in warm hydrochloric acid with evolution of chlorine. Yields water in the closed tube and turns black and finally red-brown. Occurs with hausmannite and calcite at the Sjö mine, Örebro, Sweden. Named after the alchemist, Basilius Valentinus.

Bastnäsite, p. 291.—Colorado, analysis, Hillebrand, Am. J. Sc., 7, 51, 1899.

Batavite. E. Weinschenk, Zs. Kr., 28, 160, 1897. A decomposition-product from the graphite district of Passau, Bavaria. Occurs in aggregates of pearly micaceous scales, hexagonal in outline. G. = 2.183. Approximate composition, 4H2O.4MgO. Al2O2. 4SiO2. Analysis:

2 SiO, 42.33 Al2O2 16:35 MgO 28.17 $H_2O 13.19 = 100.04$

Named from Castra Batava, Roman name for Passau.

BAUXITE, p. 251.—Description of deposits in Arkansas, Branner, Amer. Geol., 7, 181, 1891, J. Geol., 5, 263, 1897; in Georgia, Alabama, etc., C. Willard Hayes, 16 Ann. Rept., U. S. G. Surv., Pt. III, pp. 547-597, 1896; also McCalley, Proc. Ala. Ind. Sc. Soc., 2, 21, 1892; Laur, Trans. Am. Inst. Mng. Eng., 24, 234, 1894. Analyses, from Calhoun Co., Alabama, Hillebrand, Bull. U. S. G. Surv., 113, 109, 1893.

A general investigation (with analyses) of material from the Vogelsberg has led Liebrich to the conclusion that heavite is an alteration product of a hasaltic rock. It is in part amore

the conclusion that bauxite is an alteration-product of a basaltic rock. It is in part amorphous, in part crystalline and having the composition of the aluminium hydrate gibbsite, crystals of which occur in cavities in the mass Ber. Oberhess. Ges., 28, 57, 1892 (abstr. in Zs. Kr., 23, 296, 1894); also Zs. prakt. Geol., 5, 212, 1897. On the relation of bauxite to laterite, see Bauer, Jb. Min., 2, 208, 1898.

Contains a supposed new element, R. S. Bayer, Ch. News, 71, 128, 1895.

Beaconite.—See Talc.

Bentonite.—Eng. Mng. J., Oct. 22 and Nov. 26, 1898. A Wyoming clay used in making candy, in adulterating candy, etc.

Beresowite. Beresovit. Berezovite. J. Samoilow, Bull. Soc. Moscou, 290, 1897.

A chromate and carbonate of lead from Berezov in the Ural, associated with galena and cerussite; occurs also altered to crocoite. Crystalline in small lameliæ with one perfect cleavage, G = 6.69. Color deep red. Birefringent. Composition 6PbO.3CrO₃.CO₂. Analysis: CrO₃.217.93, PbO \$ 79.30, CO2 2.46.

BERTHIERITE, p. 114.—This or a related mineral occurs on Mt. Gibbs, Tuolumne Co., California, Turner, Am. J. Sc., 5, 428, 1898.

From Přibram, anal., Hofmann, Ber. Ak. Böhm., Oct. 15, 1897.

BERTRANDITE, pp. 545, 1028.—Occurs with hamlinite in Oxford Co., Me., in twin crystals, prismatic \parallel \ddot{a} (Fig. 1, $k=0.12\cdot1$); G. = 2.571. Penfield, Am. J. Sc., 4, 316, 1897. Crystals, in part twins, are described from Pisek and 1. other localities, by Vrba. Zs. Kr., 24, 112, 1894.

Beryl, pp. 405, 1028.—Cryst.—Mursinka, crystals of rhombohedral habit as regards the s-faces (1121); etching-prominences show the forms (4274), (5495) (6.5 $\bar{1}\bar{1}$.5), (5494), (4873), Arzruni, VII. Min. Ges., 31, 155, 1894. Mursinka, with $(13^{\circ}1^{\circ}1^{\circ}4^{\circ}0)$ and $(19^{\circ}1^{\circ}2^{\circ}1^{\circ}1)$, Jeremejev, *ibid.*, 29, 230, 1892; also Ilmen Mts. (1126), Mursinka (2243), Nerchinsk (4045), *idem.*, *ibid.*, Prot., 33, 26, 1895. Pisek, with λ $(15^{\circ}1^{\circ}1^{\circ}6^{\circ}1^{\circ}1^{\circ})$, also supposed twins, with $(5^{\circ}5^{\circ}1^{\circ}1^{\circ}8)$ as twinning plane; further, corrosion also supposed twins, with $(3 \cdot 3 \cdot 10 \cdot 8)$ as twinning plane; in ther, corresponding the forms e (6065), r (3052), u (2021), ξ (1124), o (1122) and others, Vrba, Zs. Kr., 24, 104, 1894. On a crystal from New York Island. Ries, Trans. N. Y. Acad. Sc., 16, 329, 1897. Etching-figures investigated, Traube, Jb. Min., Beil.-Bd., 10, 464, 1896.

On optical characters as influenced by heat and pressure, Pockels, Jb. Min., Beil.-Bd., 8, 217, 1900.

1893.

A variety from German So. West Africa showed distinct asterism, also cat's-eye effect, Stapff, Zs. prakt. G., 1, 244, 1893.

Analysis of emerald from Chanteloube, Haute-Vienne, Lebeau, C. R., 121, 601, 1895. Occurrence of emerald on Big Crab-Tree Mt., near Bakersville, Mitchell Co., N. C., Kunz, Am. J. Sc., 48, 429, 1894. On synthesis, Traube, Jb. Min., 1, 275, 1894.

Berzelite, p 753.—A soda-berzeliite from Långban, Sweden, has been described by Hj. Sjögren (Bull. G. Inst. Upsala, 2, 92, 1895). Usually massive, also in isometric crystals (110, 211). No cleavage. H. = 4 - 4:5. G. = 4:21. Luster greasy. Color fire-red or orange-yellew. Isotropic. Composition near caryinite (wh. see), but contains soda and differs in crystallization. Analysis, R. Mauzelius:

$$As_2O_6$$
 $Sb_2^*O_6$ V_2O_6 MnO CaO FeO MgO Na_2O K_2O H_2O 52.90 $tr.$ 0.24 21.41 18.34 0.38 0.72 5.05 0.09 $0.40 = 99.53$

Sjögren notes the similarity of the above berzeliite to pyrrharsenite (Min., p. 753), and Igelström, giving another analysis of the latter, calls it mangan-berzeliite, Zs. Kr., 23, 592, 1894.

An incomplete analysis of berzeliite is given by Church, Min. Mag., 11, 10, 1895.

BEYRICHITE, p. 76.—Crystals from Altenkirchen have been investigated by Laspeyres, who finds it in form and composition ((Ni,Co,Fe)S) like millerite, but the sp. gravity = 4.699 (G. = 5.3 -5.9 for millerite); he regards all millerite as formed by paramorphism from beyrichite. Crystals, in part twins, are described with the forms: m (10 $\overline{1}0$), a (11 $\overline{2}0$), i (41 $\overline{5}0$), r (10 $\overline{1}1$), e (10 $\overline{1}2$). Axis \dot{e} = 0.3277. Zs. Kr., 20, 535, 1892; also Vh. Ver. Bonn, 50, 157, 1893.

BINNITE. p. 118.—Tetrahedral crystals are described by Baumhauer, Zs. Kr., 21, 202, 1892. Same conclusion reached by Trechmann, who adds many new forms, in part doubtful, Min. Mag.,

10, 220, 1893. Later Baumhauer adds further new forms, Zs. Kr., 28, 545, 1897.

Announced by Prior and Spencer to be identical with tennantite, Min. Soc. Gt. Britain, Jan. 31, in Nature, 54, 454, 1899.

BIOTITE, p. 627.—Twin crystals (Servian twins) from Dschepa, Servia, formed of two interpenetrating crystals which have the base parallel while one is turned 30° with reference to the

other, Uroschewitsch, Zs. Kr., 29, 278, 1897. Composition (anal.) of some rock-forming varieties from California, Turner, Am. J. Sc., 7.

294, 1899.

Discussion of conditions of alteration in a magma (also of amphibole), Washington, J. Geol.,

4, 257, 1896.

On the alteration-products of magnesia mica and the relation between composition and optic axial angle, Z. Schimmer, Inaug. Diss., Jena, 1898, pp. 1-70, and Jenaisch. Zeitschr., 32, 351, 1898. See also Mica.

Birmite.—See Burmite.

n

a

 α

BISMUTHINITE, pp. 38, 1028.—Occurs in Jonquière township, Chicoutimi Co., Quebec (analysis by Johnston), Hoffmann, Rep. G. Canada, 6, 19 R, 1892-93. Also Lyndoch, Renfrew Co., Ontario, ib., 8, 14 R, 1895. From Sinaloa, Mexico, analysis, Melville, Bull. U. S. G. Surv., 90, 40, 1892.

BISMUTITE, p. 307.—From Mt. Antero, Chaffee Co., Colorado, analysis of an impure variety, Genth, Am. J. Sc., 43, 188, 1892.

Bismutosmaltite. A. Frenzel, Min. petr. Mitth., 16, 524, 1896.—See Skutterudite.

Bixbyite. S. L. Penfield and H. W. Foote, Am. J. Sc., 4, 105, 1897. Isometric; in cubes with n (211). Cleavage: octahedral in traces. Brittle. H. = 6-6.5. G. = 4.945. Luster metallic, brilliant. Color and streak black. Opaque. Composition, essentially FeO.MnO2, or analogous to perovskite. The analysis may also be interpreted as R_2O_2 , where R = Fe and Mn in

nearly the ratio of 1:1. The SiO2 and Al2O3 of the analysis are due Analysis: to impurities.

TiO₂ Fe₃O₃ MnO MgO O SiO₂ Al₂O₃

$$\frac{1.70}{3}$$
 1.70 47.98 42.05 0.10 4.38 1.21 2.53 = 99.95

Fuses B.B. at 4 and becomes magnetic. In very fine powder is dissolved with some difficulty in hydrochloric acid, evolving chlorine.

Occurs with topaz and decomposed garnet in rhyolite on the edge of the desert, thirty-five miles southwest of Simpson, Utah. Named after Mr. Maynard Bixby of Salt Lake City.

BLIABERGSITE.—L. J. Igelström, G. För. Förh., 18, 41, 1896; Zs. Kr., 27, 603. M. Weibull, ibid., 18, 515, 1896.—See Ottrelite.

BLÖDITE, p. 946.—Crystals with \(\tau \) (450) described and measured, from the salt seas of the Astrakan Govt., Jeremejev, Zs. Kr., 23, 268, 1894, and Vh. Min. Ges., 28, 430, 1891. Salt Range, crystals described with analysis, F. R. Mallet, Min. Mag., 11, 311, 1897.

A related potash compound $(K_2Mg(SO_4)_2 + 4H_2O)$, called Kaliastrakanite or Kalium-astra-

chanite, has been named Leonite (wh. see).

Blueite. S. H. Emmens, J. Am. Chem. Soc., 14, No. 7, 1892.—See Pyrite.

Boléite, p. 1028.—The complex relations of percylite, boléite, pseudoboléite, cumengéite are discussed under Percylite.

Boracite, p. 879.—Etching-figures described, Baumhauer, Die Resultate d. Aetzmethode, . etc., 1894.

Specific heat as influenced by the temperature, Kroeker, Jb. Min., 2, 125, 1892.

Occurrence at Westeregeln, Bücking, Ber. Ak. Berlin, 539, 1895.

Formation of isomorphous chloroborates, Rousseau and Allaire, C. R., 116, 1195, 1893.

Bornite, p. 77.—Crystals from Virgen, near Prägratten, Tyrol, described with (533) and (322)?, Heimerl, Bull. Soc. Min., 17, 289, 1897. See also Klein, Ber. Ak. Berlin, 385, 1898, who describes a crystal from the Frossnitz glacier, Tyrol, with (322) and (211), symmetry tetrahedral. Occurs as a copper ore in western Idaho, Packard, Am. J. Sc., 50, 298, 1895.

Bouglisite. E. Cumenge (Lacroix, Bull. Mus. d'Hist. Nat. Paris, 42, 1895).—See Anglesite.

Boulangerite, p. 129.—Described by Hj. Sjögren (G. För. Förh., 19, 153, 1897), from the mines of Sala, Sweden. In orthorhombic crystals, prismatic or tabular | a (100). Axes $\check{a}:\check{b}:\check{c}=0.5527:1:0.7478$. Forms: a (100), b (010); r (210), q (320), m (110), n (120), μ (140), l (160), k (180). i (1·10·0), h (1·14·0); u (012). Angles: $mm'''=57^{\circ}$ 52', $b\mu=*24^{\circ}$ 20', $bu=*69^{\circ}$ 30'. The form approximates to that of diaphorite. Composition: Pb_{\$}Sb_{\$4}S₁₁ or 5PbS.2Sb_{\$2}S₃. Analysis, R. Mauzelius:

S Sb Pb Zn Ag
$$G. = 6.185$$
 18.91 25.54 55.22 0.06 tr . insol. 0.23 = 99.96

The author concludes that boulangerite has the composition 5PbS.2Sb2S3 like diaphorite, to which it also approximates in form. Further he shows that the earlier analyses do not correspond to 3PbS,Sb2S3, the formula usually accepted. The minerals plumbostib and embrithrite (10PbS.3Sb₂S₃ Frenzel) do not belong to boulangerite, but he regards them as independent species.

BOURNONITE, p. 126.—Cryst.—Nagybánya, complex crystals described with the new forms, C (503), \(\frac{2}{3}\)(021), Schmidt, Zs. Kr., 20, 151, 1892. Harz Mts., Luedecke, Min. d. Harzes, 150, 1896. Peychagnard, Isère, France, new forms (950), (780)? (380), (034), (032), (11.3.4), (568), Termier, Bull. Soc. Min., 20, 101, 1897. Pontgibaud, Puy-de Dôme, supposed new forms (18.5.0), (5.7.12), (50 66.59), (918). Gonnard, Bull. Soc. Min., 20, 312, 1897.

Measurements of crystals from different localities show irregularities in angle, but fail to

establish monoclinic symmetry, F. B. Peck, Zs. Kr., 27, 299, 1896. Measurements of heat con-

ductivity, idem. ibid., p. 319.

Occurs massive in Bagot township, Renfrew Co., Ontario, Hoffmann, Rep. G. Canada, 7, 13 R. 1894. Also at the mine Pulacayo, Huanchaca, Bolivia, Penfield and Frenzel, Zs. Kr., 28, 608, 1897.

Braunite, pp. 232, 1029.—Saint Marcel, analyses, Gorgeu, Bull. Soc. Chim., 9, 656, 1893.

Brazilite. E. Hussak, Jb. Min., 2, 141, 1892; 1, 89, 1893.—See Baddeleyite.

Breislakite, p. 391.—Referred by Wichmann to fayalite, Zs. Kr., 28, 529, 1897.

Breithauptite, pp. 72, 1029.—Crystals from Andreasberg show the forms c, m, w (3051) and (7071); axis $\dot{c}=0.8627$. Busz, Jb. Min., 1, 119, 1895; also idem, quoted by Laspeyres, Zs. Kr., 24, 496, 1895.

Linc., 3 (1), 86, 1894: As 29.82, Sb 26.57, Bi 0.99, Ni 36.81, Co 3.91, Fe 0.98, S 0.85, Zn undet. = 99.93. Analyses are also given of an impure breitherntite. of a mineral state of a mineral state of a mineral state of a mineral state. Analysis (by Fasolo) of arite from Nieddoris, Sardinia, quoted by Brugnatelli, Rend. Accad. = 99 93. Analyses are also given of an impure breithauptite; of a mineral near gersdorffite (Sb 3 11 p. c.) corresponding to (Ni,Fe,Co)₂(S,As,Sb)₃; also of smaltite.

Brewsterite, p. 576.—Occurs in the Harz, Luedecke, Min. d. Harzes, 587, 1896.

BRÖGGERITE, p. 889.—See Uraninite.

Bromlite, p. 283.—Optical examination and relation to barytocalcite, etc., Mallard, Bull. Soc. Min., 18, 7, 1895.

Brongniardite, p. 123.—The supposed isometric crystals are shown to belong to the species argyrodite or canfieldite, Prior and Spencer, Min. Mag., 12, 11, 1898. It is further suggested by Spencer that brongniardite and diaphorite may be identical, Am. J. Sc., 6, 316, 1898.

Brookite, pp. 243, 1029.—Crystals from Brazil show the new forms g (305), ν (124), ξ (146), Hussak, Min. petr. Mitth., 12, 460, 1892. On secondary twin formation, Hussak, Jb. Min., 2,

Occurs with octahedrite on quartz at Placerville, Eldorado Co., California, Kunz, Am. J. Sc., 43, 329, 1892.

BRUCITE, p. 252.—Analysis of nemalite from Afghánistán, Mallet, Min. Mag., 11, 211, 1897,

Rec. G. Surv. India, 30, 233, 1898.

Nemalite absorbs electric waves vibrating in a certain plane and transmits those vibrating normal to it; so also tourmaline (with planes reversed), but not to so great a degree. J. C. Bose, Nature, 57, 353, 1898.

BRUSHITE, p. 828.—A calcium phosphate found in human skeletons (1630) unearthed at Paris in 1896 (Lacroix, Bull. Soc. Min., 20, 112, 1897), has the optical characters of pharmacolite, viz.: optically —; ax. plane and $Bx_0 \perp b$; Bx_a inclined 25° forward to trace of c; $2V_a = 81^\circ$. It might hence be inferred to belong to brushite; however, $G_a = 2.31$ and the amount of water was too small (loss on ignition = 25.5 p. c.; this is probably too high). For metabrushite from Sombréro, G. = 2.30 was obtained, from the Île des Oiseaux 2.33.

Burmite. Birmite. Otto Helm, Rec. G. Surv. India, 25, 180, 1892; 26, 61, 1893. Schrift. Ges. Danzig, 8, Nos. 3-4, p. 63, 1893. Fritz Noetling, Rec. G. Surv. India, 26, 31, 1893. A fossil resin, resembling amber, but harder and tougher. Occurs abundantly in Upper Burma. An analysis gave Itelm: C 80.05, H 11.50, O 8.43, S 0.02 = 100.

CACOXENITE, p. 848.—Partial optical examination, Luquer, Am. J. Sc., 44, 154, 1893. Analysis by Church from Hrbek, near St. Benigna, Bohemia (Min. Mag., 11, 8, 1895), gave: P_2O_5 19.76, Fe_2O_3 48.57. H_2O (ign.) 13.11 (F tr.), H_2O (vacuo) 18.69 = 100.13. This corresponds to the complex relation $9Fe_2O_3$. $4P_2O_4$. $51H_2O$.

CALAMINE, p. 546.—Cryst.—Radzionkau, Silesia, Traube, also anal. (Breitfeld) showing presence of 2:17 p. c. PbO, Zs. G. Ges., 46, 65, 1894. Sterling Hill, N. J., and Clear Creek Co., Colorado (Figs. 1, 2), Pratt, Am. J. Sc., 48, 213, 1894. Gorno, Val Seriana, Italy, new form (503), Artini, Riv. Min. Ital., 16, 19, 1896. Moresnet, new form (311), Buttgenbach, Ann. Soc. G. Belg., 24, xl, 1897. Nebida, Sardinia, C. Riva, Rend. Accad. Linc., 6 (1), 421, 1897.

Analysis of pure variety from Wythe Co., Va., Jones, Am. Ch. J., 14, 621, 1892.

Occurs in West Kootanie district, Br. Columbia, Hoffmann, Rep. G. Canada, 6, 28 R, 1893.

Also finely crystallized at the Elkhorn mines, Jefferson Co., Montana.

CALAVERITE, p. 105.—Hillebrand refers here gold tellurides from Cripple Creek, Colorado (Am. J. Sc., 50, 128, 426, 1895). A crystallized specimen from the Prince Albert mine, which (according to Penfield) seemed to be triclinic, but approximating toward sylvanite in angle, though without its cleavage, gave the results of anal. 1a (1b deducting impurities). Color pale bronze-yellow. H = 3. G. (corrected) = 9.00. Two other less pure samples from different mines gave anals, 2, 3 deducting impurities; all correspond to AuTe₂. Krennerite also occurs at Cripple Creek, and according to Pearce sylvanite. See Geol. Cripple Creek Dist., Colorado, by Whitman Cross and R. A. F. Penrose, Jr., 16 Ann. Rept. U. S. G. Surv., Part II.

	Te	Au	Ag
1a.	57.27	38.95	3.21 insol, 0.33 , Fe_2O_3 $0.12 = 99.88$
1b.	57.60	39.17	3.23 = 100
2.	57.40	40.83	1.77 = 100
3.	57.30	41.80	0.90 = 100

See also Goldschmidtite, Kalgoorlite and Krennerite.

Calcistrontite. Von der Marck, Vh. Ver. Rheinl. Corrbl., 39, 84, 1882. A mineral substance from near Hamm, Westphalia, supposed to have the composition 3CaCO₂. SrCO₂. It is shown by Laspeyres and Kaiser to be a mechanical mixture of calcite and strontianite, Zs. Kr., 27, 41,

CALCITE, pp. 262, 1026.—Cryst.—Landelies, Belgium, Renault, Ann. Soc. G. Belg., 20, 75, 1892. Nieder-Rabenstein, crystals perhaps to be referred to the dolomite (phenacite) type, Beckenkamp, Zs. Kr., 20, 163, 1892; cf. also Gaubert, Bul. Mus. d'Hist. Nat., p. 39, 1897. Feldkirch, Gissinger, Zs. Kr., 22, 359, 1893. Visby, Gotland, crystals of pyramidal habit, Hamberg, G. För. Förh., 15, 709, 1894. Freiberg, Sansoni, Giorn. Min., 5, 72, 1894, and Zs. Kr., 23, 451, 1894. Crystals from the Galena limestone, Wisconsin, Hobbs, Bull. Univ. Wisconsin, 1, 115, 1895, and Zs. Kr., 25, 257, 1895. Lake Superior, Palache, Zs. Kr., 24, 588, 1895. Framont et al. in Elsass-Lothringeu, Stöber, Zs. Kr., 24, 629, 1895. Körösmezö, G. Moesz, Földt. Közl., 27, 495, 1898. Couzon, Rhône, Gonnard, C. R., 122, 348, 1896, and Bull. Soc. Min., 20, 18, 330, 1897. Nordmark, Sweden, K. Winge, G. För. Förh., 18, 527, 1896. Harz Mts., Luedecke, Min. d. Harzes, 285, 1896. Kr., 30, 660. Auerbach, Hesse, A. Leuze (1896), ref. in Zs. Kr., 30, 662. Montecatini, G. D'Achiardi, Att. Soc. Tosc., Proc. Verb., May 9, 1897. Jarow near Wran, Bohemia, Polak, Lotos, 17, 169, 1897. Selective absorption investigated, Nichols and Snow, Phil. Mag., 33, 379, 1892. Refractive indices of Iceland Spar, Dufet, Bull. Soc. Min., 17, 149, 1894. 1892. Nieder-Rabenstein, crystals perhaps to be referred to the dolomite (phenacite) type, Beck-

Refractive indices of Iceland Spar, Dufet, Bull. Soc. Min., 17, 149, 1894. Dichroism for infra-red waves, E. Merritt, Wied. Ann., 55, 49, 1895.

Investigation on the influence of substances in solution upon the crystallization, etc., Vater, Zs. Kr., 21, 433; 22, 209, 1893; 24, 366, 378, 1895; 27, 477, 1896; 30, 295, 373, 485, 1898. Formation of stalactites in caves, G. P. Merrill, Proc. U. S. Nat. Mus., 17, 77, 1894. Discussion of origin, composition and uses of onyx marble from many localities; with one exception these belong to calcite, idem, Rep. U. S. Nat. Mus., 16, 539, 1893. Investigation of hislopite (Min., p. 266) showing great variation in the amount of glauconite, while other inclusions also occur, Holland, Rec. G. Surv. India, 26, 166, 1893.

Caledonite, p. 924.—Crystals described with τ (113), κ (023) as new forms, Busz, Jb. Min., 1, 111, 1895.

CALOMEL, p. 153.—Optical characters determined, confirming results of Senarmont (Min., p. 154), who showed its very high birefringence; Dufet obtained (Bull. Soc. Min., 21, 90, 1898):

	ω	. €	€ − ω
Li	1.95560	2.6006	0.6450
Na	1.97325	2.6559	0.6827
ויוי	1.99085	2.7129	0.7220

Canfieldite. S. L. Penfield, Am. J. Sc., 47, 451, 1894 (not canfieldite, same author, ib., 46, 107, 1893, = argyrodite).

Isometric, perhaps tetrahedral. In octahedrons o (111) with d (110). Fracture uneven to small conchoidal. Brittle. H. = 2.5-3. G. = 6.276. Luster metallic, brilliant. Color black with bluish tint.

Composition, Ag. (Sn. Ge)So; essentially Ag. SnSo or 4Ag. S. SnSo, but with the tin in part replaced by germanium, ratio Sn, Ge = 12:5. Analysis:

S	Su	Ge	Ag	Fe,Zn
16.22	6.94	1.82	74.10	0.21 = 99.29

As noted on p. 6, Penfield has shown that argyrodite has the corresponding composition

Ag₈GeS₅. Franckeite (wh. see) is another new sulpho-stannate.

B. B. fuses at 2 on charcoal, yielding a coating of the mixed oxides of tin and germanium, white or grayish near the assay, tinged with yellow on the edges. By long blowing a globule of silver covered by tin oxide is obtained. In the closed tube sulphur is given off, and at a high temperature a slight deposit of germanium sulphide.

Occurs intimately associated with native silver at La Paz, Bolivia. Named after F. A. Can-

field, of Dover, N. J.

CARNALLITE, p. 177.—Discussion of conditions of formation and of alteration, Van't Hoff and Meyerhoffer, Ber. Ak. Berlin, 488, 1897; also later papers by Van't Hoff and others, 1897 and 1898.

Carnotite. C. Friedel and E. Cumenge, C. R., 128, 532, 1899, and Bull. Soc. Min., 22, 26,

Occurs as a yellow crystalline powder, or in loosely cohering masses, easily separated by the fingers; intimately mixed with a quartzose sand.

Composition, perhaps K₂O.2U₂O₂.V₂O₃.3H₂O. Analyses, after the separation of silica, of airdried material:

V ₂ O ₅	U_2O_3	K ₂ O	H_2O
20.12	63.54	10.37	5.95 = 99.98
20.31	64.70	10.97	$5.19 \text{ Fe}_{2}O_{3} 0.96 = 102.13$
19.95	62.46	11.15	— Fe ₂ O ₃ 06·5

The radiant power has been investigated by M. and Mde. P. Curie.

Occurs in Montrose Co., Colorado, in cavities or associated with malachite and azurite. Some samples show 60 p. c. of SiO₂, the purest 2.6 to 7.2 p. c. Separation is accomplished by nitric acid. Named after M. Adolphe Carnot.

CARYINITE, p. 754 — Further described by Hj. Sjögren. Occurs at Långban, massive, filling fissures in a coarse mixture of schefferite, rhodonite and hedyphane. Anisotropic, without pleochroism. Two cleavages noted parallel to m (110) and b (010), $bm = 49^{\circ}$ 15'. Extinction-observations on plates || and | to b make the system orthorhombic. Optically +. $\mathbf{B}\mathbf{x_a} \perp b$. Ax pl. | a (100). An analysis by R. Mauzelius gave:

As2O6 P2O6 V2O6 PbO MnO FeO CaO MgO BaO Na2O K2O H2O Cl $G_{1} = 4.29 \cdot 49.78 \quad 0.19 \quad tr. \quad 9.21 \quad 18.66 \quad 0.54 \quad 12.12 \quad 3.09 \quad 1.03 \quad 5.16 \quad 0.37 \quad 0.53 \quad tr. = 100.68$

This leads to the formula $10\mathrm{RO.3A_2O_6}$ or, if the presence of the radical (OH) is assumed to $\mathrm{R_sAs_2O_6}$. Nearly the same composition is obtained for the soda-berzeliite (see p. 10). The origin of berzeliite by the alteration of caryinite is confirmed. Bull. G. Inst. Upsala, 2, 87, 1895.

Cassiterite, pp. 234, 1030, 1037.—Crystals described with new forms λ (10.9.0), f (835), Kohlmann, Zs. Kr., 24, 350, 1895. On artificial crystals, A. Arzuni, Zs. Kr., 25, 467, 1895. Description of occurrence of tin ores in Bolivia, A. W. Stelzner, Zs. G. Ges., 49, 51, 1897. On the tin deposits of Temescal, So. California, Fairbanks, Åm. J. Sc., 4, 39, 1897.

Caswellite. A. H. Chester, G. Rep. N. J., 1895. Trans. N. Y. Acad. Sci., 13, 181, 1894. An altered mica of a light copper-red color and bronze-like luster resembling clintonite. Structure micaceous. Inelastic. H. = 2.5-3. G. = 3.54. Double refraction feeble. Not pleochroic. Analysis:

> Al₂O₃ Fe₂O₃ SiO2 Mn2O3 CaO MgO Ign. 6.85 £ 38·74 6.58 15.95 22:30 5.52 4.64 = 100.58

Occurs with rhodonite, polyadelphite and a dark-colored biotite, from which it is believed to have been derived at the Trotter mine, Franklin Furnace, N. J. Named after Mr. John H. Caswell.

Cataphorite. Kataforit, W. C. Brögger, Die Eruptivgest. d. Kristianiagebietes, 1, 37, 73, 1894:

3, 169, 1898, et al.

An alkali-iron amphibole, intermediate between barkevikite and arfvedsonite, but not yet analyzed. Occurs in the groundite-tinguaite series of rocks of southern Norway. Cleavage-angle about 56°. Extinction-angle on b (010), $\mathfrak{c} \wedge b = 30^{\circ}$ to 60°. Predominating absorption-colors reddish; b > c > a. Lacroix gives for a similar amphibole (but nearer barkevikite) from the Haute-Loire. $2E = 60^\circ$; a yellowish brown; b violet; t yellow, slightly greenish. Min. France, 1, 689, 1893. Brögger suggests that the amphibole of pulaskite (J. Fr. Williams, Ign. Rocks Arkansas, p. 64) may also belong between barkevikite and cataphorite. See also Barkevikite.

CATAPLEHTE, p. 412.—Occurs at Kangerdluarsuk, Greenland, with neptunite, epididymite, ægirite, etc., in crystals with (1013); G. = 2.743; analysis by Flink: SiO₂ 44.08, ZrO₂ 31.83, CaO 0.17, Na₂O 14.80, H₂O 9.12 = 100. This corresponds to a pure natron-catapletite, G. För. Förh., 15, 206, 1893.

Cedarite, R. Klebs [Jb. preuss. geol. Landesanst. 1896], Jb. Min., 2, 212 ref., 1898. A fossil resin resembling amber somewhat widely distributed in the alluvium of the Saskatchewan river in Canada. Cold clear yellow, or clouded. Composition: C 78.15, H 9.89, O 11.20, S 0.31, ash 0.45 = 100. Partially soluble in the usual solvents.

Celestite, p. 905.—Cryst.—List of cryst. forms with references, also optical characters, etc. Grunenberg [Inaug. Diss., Breslau, 1892]. Zs. Kr., 24, 199, 1894. Brousseval, Ville-sur-Saulx, France, new form (1·10·10), Stöber, Zs. Kr., 21, 339, 1893. From the Romagna with new forms (450), (230), (105), (087)?, (326), (562), Artini, Rend. Ist. Lomb. Sc., 26, 323, 1893. Westeregln, Bücking, Ber. Ak. Berlin, 536, 1895. Giershagen Stadtberge, new forms N (705), Q (332), R (1·19·19), also discussion of variation in axial ratio, physical characters, etc., Arzuni and Thaddeeff, Zs. Kr., 25, 38, 1895. Bessarabia, Prendel, Vh. Min. Ges., 34, 185, 1896. Occurs in Lansdowne township, Leeds Co., Ontario (anal. by Johnston, BaO tr.), Hoffmann,

Rep. G. Canada, 7, 9 R, 1894; cf. also ib., 5, 25 R, 1889-90.

A fibrous radiated variety from the Silurian crystallized limestone of Eastern Ontario gave C. W. Volney: SrSO₄ 70 01, BaSO₄ 30 S5, Al₂O₃, Fe₂O₃ 0 005 = 100 865. G. = 4 123. J. Am. Ch. Soc., 21, 386, 1899. Another specimen from Lansdowne, Ontario, gave, SrSO₄ 58 20, BaSO₄ 39.85 = 98.05. G. = 4.188. Still another celestite showed over 3 p. c. BaSO₄; G. = 4.41. *Ibid.*, 13, 290, 1891. Cf. Hoffmann, above.

Celsian. Hj. Sjögren, G. För. Förh., 17, 578, 1895. Triclinic. Massive. Cleavage: c (001) perfect; b (010) distinct; m (110) and M (1 $\bar{1}$ 0) less distinct. Angles: $bc = 89^{\circ}$ 34'-89° 37', $cm = 68^{\circ}$ 30'-68° 45', $bm = 59^{\circ}$ 18'. H. = 6 to 6.5. G. = 3.37. Luster vitreous. Colorless. Extinction on c inclined 3° 10', and on b, 26° 45' to edge b/c. Optic axis seen obliquely in sections | c.

Composition analogous to that of anorthite, BaAl₂Si₂O₈ or BaO, Al₂O₃. 2SiO₂. Analysis R.

Mauzelius:

SiO2 Al₂O₃ Fe₂O₃ BaO CaO MgO K₂O Na₂O H₂O 26.55 32.43 0.12 39.72 0.23 0.11 0.22 0.16 0.64 0.64 = 100.82

B. B. scarcely fusible even on thin splinters.

From the manganese mines of Jakobsberg, Sweden, with schefferite and manganophyllite. Named after Anders Celsius, the Swedish naturalist.

CELYPHITE.—Same as Kelyphite, p. 447.

Cenosite, p. 698.—Described by Hj. Sjögren, from the Ko mines, Nordmark, Sweden; occurs with diopside, clinochlore, magnetite and apatite. Crystallization orthorhombic. Axes a:b:c=0.9517:1:0.8832, or near those of cerite. Forms: b(010), c(001); m(110), h(230); g(201); f(023), d(011), e(021). Habit short prismatic. Angles: $mm'''=87^\circ$ 10', $mm'=*92^\circ$ 50', $bd=*48^\circ$ 33' (see below). Cleavage not observed. G. = 3.38. Luster greasy. Color yellow-brown to dark chestnut-brown. Analysis (on 0.067 gr.), R. Mauzelius:

SiO₂
$$Y_2O_3$$
, etc. Fe₂O₃ CaO MgO Alk. H₂O CO₂ 31·7 35·9 2·9 16·5 1·4 3·6 2·9 [5·1] = 100

The author gives $bd = 41^{\circ}$ 33', which is obviously an error; 48° 33' agrees with his axial ratio. G. För. För., 19, 54, 1897.

Cerussite, pp. 286, 1030.—Cryst.—Pacaudière, Loire, and Roure, (Pontgibaud), France, Gonnard, Bull. Soc. Min., 15, 35, 41, 1892. Norberg, twins, Johansson, G. För. Förh., 14, 49, 1892. Black Hawk, Montana, Pratt, Am. J. Sc., 48, 212, 1894. Cabo de Gata, Osann, Zs. Kr., 23, 264, 1894. Tarnowitz, Silesia, new forms a (441), f (170), ε (025), g (171); also on iglesiasite, from Radzionkau (3.4 ZnO), i (210), Traube, Zs. G. Ges., 46, 60, 1894. From the Galena. limestone, Wisconsin, with the new form λ (0.25.4), Hobbs, Zs. Kr., 25, 265, 1895, and Bull. Univ. Wisconsin, 1, 128, 1895; also from Missoula, with b (380), id., Am. J. Sc., 50, 121, 1895. Gorno, Val Seriana. Italy. crystals described, with new form (0.13.1), Artini, Riv. Min. Ital., 16, 21, 1896, and Rend. Ist. Lombardo, 30, 1529, 1897. Nebida, Sardinia, Riva, Riv. Min. Ital., 18, 54, 1898, and Rend. Accad. Linc., 6 (1), 421, 1897.

Chabazite, p. 589.—Tulferthal, Tyrol, crystals described (twins), Habert, Zs. Kr., 28, 243, 1897. Investigation of the absorption of gases after having been partially deprived of water, G. Friedel (also other zeolites), Bull. Soc. Min., 19, 102, 1896; 22, 5, 1899. Also Rinne, Jb. Min., 2, 28, 1897.

CHALCANTHITE, p. 944.—Etching-figures investigated, T. L. Walker, Am. J. Sc., 5, 176. 1898. Occurs at the Avoca claim, Bonaparte river, Lillooet district, Br. Columbia, Hoffmann, Rep. G. Canada, 9, 12 R, 1896.

Chalcocite, p. 55.—Crystals from Bristol, Conn., with (130) as tw.-plane, Kaiser, Zs. Kr., 24, 498, 1895. From Montecatini, with new form (052), Boeris, Zs. Kr., 23, 235, 1894, and Riv. Min. Ital., 14, 26, 1895.

Chalcophanite, p. 256.—Hydrofranklinite of Roepper (Min., p. 259) is shown by Penfield and Kreider (Am. J. Sc., 48, 141, 1894) to be identical with chalcophanite. The form is not octahedal, but rhombohedral, a combination of c and r. Analysis: FeO 10.00, MnO 48.27, ZnO 18.25, O 11 21, H₂O 11.85, insol. 0.25 = 99.83; G. = 4.012.

Chalcopyrite, pp. 80, 1030.—Cryst.—Westphalia, new form, s (555), Cesàro, Bull. Ac. Belg., 28, 182, 1894. Victoria mine, near Burgholdingshausen, Siegen, new forms (312), (534),

Sonheur, Zs. Kr., 23, 545, 1894. Kis-Almás, Hungary, new forms τ (605), ζ (907), χ (704), Zimanyi, Zs. Kr., 27, 95, 1896. Harz Mts., Luedecke, Min. d. Harzes, 123, 1896.

Occurs at Müsen, in capillary forms, Laspeyres, Zs. Kr., 20, 529, 1892.

Chalcostibite, pp. 113, 1030.—Penfield and Frenzel have shown (Am. J. Sc., 4, 27, 1897, and Zs. Kr., 28, 598) that the guejarite of Cumenge (Min., pp. 110, 1030) is identical with chalcostibite (wolfsbergite*). Referred to the axial ratio $\hat{a}:\hat{b}:\hat{c}=0.5283:1:0.6364$, which is that of Laspeyres (p. 1030, Wolfsberg cryst.) modified to correspond with the symbol 6:12:7 of p

Guéjar.

(not 7·14·8 Lasp.), the forms are: b (010), c (001), h (203), d (101), i (302), g (201), t (021), u (061).

Analyses (Frenzel) 1, 2, below. G. = 4.959 Pfd.

Crystals of chalcostibite from the Pulacayo mine, Huanchaca, Bolivia, showed (l. c.) the new forms ℓ (130), Δ (209), Δ_1 (207), Δ_3 (205), s (065), μ (136), ν (133), π (265), ρ (263), σ (4·12·5), τ (261). The axial ratio deduced is $\check{a}: \check{b}: \dot{c}=0.5312:1:0.63955$. Other crystals from the same locality examined by L. J. Spencer (quoted above) showed the additional forms: α (233), β (354), γ (474). δ (475), ϵ (476). The crystals are prismatic ||b| and striated in this direction. Cleavage: basal, perfect; a and b also observed.

Analyses, Frenzel: 1 of chalcostibite from Guéjar, G. = 4.96; 2 of the original guejarite; 3 of

chalcostibite from Bolivia:

	S	Sb	Cu	Pb	Fe
1. Guéjar	26.28	48.86	24.44	0.58	0.42 = 100.58
2. "	26.12	48.44	25.23	0.32	0.49 Zn 0.18 = 100.78
3. Huanchaca	26.50	48.45	24.72	-	- = 99.37

CHLORASTROLITE, p. 610 .- Examined by N. H. Wirchell, who concludes that, while the chlorastrolly, p. 610.—Examined by N. H. Whenen, who concludes that, while the material may be somewhat impure (delessite, etc.), it has constant and distinguishing optical characters. Occurs in small round pebbles with fine fibrous, stellate structure. H. = 5.5. G. = 3.155. Color light and dark green. Fibers elongated | t. Extinction oblique, to 20°. Refractive index higher than for thomsonite. Pleochroism: distinct, colorless and light green. From Isle Royale, Lake Superior. Remarks are also made on the possible relation of "zono-chlorite" to chlorastrolite and mesolite. Amer. Geol., 23, 116, 1899.

Chlorites, pp. 643-664.—Discussion of composition and analyses, F. W. Clarke and Schneider, Am. J. Sc., 43, 378, 1892. Also Bull. U. S. G. Surv., 113, 11, 27, 1893. See also Clinochlore, Penninite, etc.

CHLORITOID, pp. 640, 1031.—Occurs in blocks on the south shore of Michigamme lake, Mich., W. H. Hobbs (anal. Kahlenberg), Am. J. Sc., 50, 121, 1895; 2, 87, 1896; cf. Lane and Kellar, Min., p. 1031, also Rominger, Geol. Surv. Michigan, vol. 5, p. 31.

From Lainicium, Carpathian Mts., anal., Duparc and Mrazek, C. R., 116, 601, 1893. Also in Kincardineshire described (anal.) by G. Barrow, Q. J. G. Soc., 54, 149, 1898.

See also Ottrelite.

Chloroarsenian. L. J. Igelström, G. För. Förh., 15, 471, 1893; Zs. Kr., 22, 468. An imperfectly described mineral occurring with basilite (p. 9) at the Sjö mine, Örebro. Sweden. In crystals, showing one cleavage and having a vitreous luster and yellowish green color. Contains MnO and As₂O₆ (or As₂O₃), but no Sb₂O₆ nor H₂O. It is to be regretted in the case of this and other supposed new minerals from the same locality that the name was not withheld until they could be adequately described according to scientific methods.

CHONDRODITE, p. 535.—See Humite.

^{*} The probable identity of chalcostibite and guejarite was urged by L. J. Spencer in 1896. See Min. Mag., 11, pp. x and 188, 1897.

Chondrostibian. L. J. Igelström, G. För. Förh., 15, 343, 1893; Zs. Kr., 22, 48, 1893 grains and perhaps also in octahedral crystals (?) embedded in barite at the Sjō mine, Orebro, Sweden. Color dark brownish red to yellowish red in small grains. Feebly magnetic. An analysis on very impure material gave after the deduction of 51 p. c. of foreign substances (calcite, tephroite, barite, etc.): Sb₂O₅ 30·66, As₂O₅ 2·10, Mn₂O₅ 33·13, Fe₂O₅ 15·10, H₂O 19·01 = 100. The result thus obtained has obviously little claim to accuracy.

CHROMITE, pp. 228, 1031.—Crystals from the Bendegó meteoric iron show the forms (111), (110), (311), (221); (001) rare; also faces of (510), (310), (210, (211), (553), (774)?, (552)?, (331), (441). Hussak, quoted by Derby, Arch. Mus. Nacional de Rio de Janeiro, p. 165, 1896.

A variety (magnochromite) from Tampadel, Zobtengebirge, Lower Silesia, gave Laszczyński (quoted by Traube, Zs. G. Ges., 46, 52, 1894): Cr₂O₃ 41·23, Al₂O₃ 24·58, FeO 19·04, MnO 0·58,

MgO 14.77 = 100.20; the iron may be partly Fe₂O₂. G. = 4.21.

J. H. Pratt, discussing the occurrence and origin of chromite (Am. J. Sc., 7, 281, 1899), has proposed the name *mitchellite*, after Prof. Elisha Mitchell of North Carolina (1793-1857), for a magnesian variety represented by the mineral from Webster, N. C. An analysis by H. W. Foote gave:

Cr2O, Al203 FeO MgO 13.90 39.95 29.28 17.31 = 100.44

The calculated formula is 2MgAl₂O₄.MgCr₂O₄.FeCr₂O₄. This corresponds closely to the magnochromite of Bock (Min., p. 228) and to the similar mineral from Tampadel, Silesia, noted above.

CHRYSOLITE, pp. 441. 1031.—Crystals from Monte delle Croce, near Montefiascone, described and measured. Fantappié, Riv. Min. Ital., 17, 3, 1897.

A minute discussion of the form, composition, etc., of minerals of the Chrysolite Group is given

by Thaddéeff. Zs. Kr., 26, 28, 1896.

Crystals altered to serpentine from Middlefield, Mass., Emerson, Bull. Amer. G. Soc., 6, 473; Bull. U. S. G. Surv., 126, 152, 1895.

An alteration-product from the north shore of L. Superior is referred to bowlingite (Min.,

p. 682) by Winchell, Amer. Geol., 23, 43, 1899. See also Iddingsite.

A lead-zink chrysolite (Bleizinkchrysolith) from a slag is noted by Heberdey, Zs. Kr., 21, 61,

CINNABAR, pp. 66, 1031.—Occurs in fine crystals at Ouen-Shan-Tchiang, central China, Ter-

mier, Bull. Soc. Min., 20, 204, 1897.

On occurrences in Canada, see Hoffmann, Rep. G. Canada, 5, 66 R, 1889-90; 6, 31 R, 1892-93. The occurrence in Southern Texas near the Rio Grande (Long. 27° W., Lat. 29° 30′ N.) is described by W. P. Blake (Trans. Am. Inst. Mng. Eng., March, 1895); in grains and small rhombohedral crystals.

On synthesis, Ippen, Min. petr. Mitth., 14, 114, 1894.

CLEVEITE, p. 889.—See Uraninite.

CLINOCHLORE, p. 644.—Crystals from the Ural described, Jeremejev, Vh. Min. Ges., 31, 417, 1894.

A discussion of optical characters specially with reference to the relations of clinochlore and penninite is given by Klein, Jb. Min., 2, 119-132, 1895. Clinochlore is found to be always optically positive, even when it becomes uniaxial on heating; penninite, however, is negative.

Analyses, of specimens from Zlatoust (also leuchtenbergite), Clarke and Schneider, Am. J.

Sc., 43, 378, 1892.

From Buckingham, Ottawa Co., Quebec, and Bagot township, Renfrew Co., Ontario (analyses by Johnston), Hoffmann, Rep. G. Canada, 6, 17 R, 1892-93.

CLINOCLASITE, p. 795.—Analysis by Church, Min. Mag., 11, 4, 1895.

Clinohedrite, S. L. Penfield and H. W. Foote, Am. J. Sc., 5, 289, 1898.

Monoclinic-clinohedral. Axes $\hat{a}: \hat{b}: \hat{b} = 0.68245: 1: 0.3226; \beta = 76^{\circ} 2\frac{1}{2}' = 100 \land 001$. Angles Habit of crystals varied as shown in figures, but conforming to the group under the monoclinic

system (clinohedral or domatic group) which has a plane of symmetry, but no axis of symmetry. Cleavage: b (010) perfect. Brittle. H. = 5.5. G. = 3.33. Luster vitreous. Colorless to white and amethystine. Transparent. Optically -. Birefringence not high. Ax. pl. and Bx_o $\pm b$.

 $b \wedge b = -28^{\circ}$. Strongly pyroelectric. Composition analogous to calamine, H₂ZnCaSiO₄ or (ZnOH)(CaOH)SiO₅; this requires: Silica 27-92, zinc protoxide 37-67, lime 26-04, water 8-37 = 100. Analysis (Foote):

	SiO,	ZnO	MnO	CaO	MgO	H,0	(Fe, Al)2O2	
2 2	27.22	37.44	0.50	26.25	0.07	8.56	0.28 = 10032	

B.B. exfoliates and then fuses at 4 to a yellowish enamel; the water is expelled at a faint red heat. Yields a coating of zinc oxide on charcoal. Dissolves readily when powdered in hydrochloric acid, yielding gelatinous silica on evaporation.

From the Trotter mine, Franklin Furnace, N. J., associated with willemite, brown garnet, axinite, datolite, phlogopite. This name had previously been used for a variety of tetrahedrite supposed (Breithaupt) to differ from others in form.

Clinozoisite. Klinozoisit. E. Weinschenk, Zs. Kr., 26, 161, 433, 1896. A name proposed for those members of the zoisite-epidote group, which are near zoisite in composition but monoclinic in crystallization; they are further optically + and of feebler refringence and birefringence than typical epidote; zoisite is regarded as dimorphous with epidote. To clinozoisite belong crystals, like epidote in habit, from rolled pebbles at the foot of the Goslerwand, Prägratten, Tyrol. Color pale rose-red, transparent. Optically +. Bx_a \wedge $\dot{c}=2^{\circ}$. $\beta=1.7195$. $\gamma-\alpha=0.0056$. $2V_y=81^{\circ}$ 40°. Analysis gave:

$$SiO_2$$
 Al_2O_3 Fe_2O_3 FeO MnO CaO H_2O $G. = 3.372$ 39.06 32.57 1.68 0.29 tr . 24.53 $0.01 = 100.14$

An epidote from the Rothenkopf, Zillerthal, with only 3.52 Fe₂O₃, was optically negative, with $\gamma - \alpha = 0.0105$. See also Fouquéite (Min., p. 1035) and Zoisite.

Cobaltite, p. 89.—From Siegen, twins with o (111) as tw.-plane, Laspeyres, Zs. Kr., 20, 550, 1892.

Cohenite, pp. 31, 1038.—Noted in the Bendegó, Brazil, meteoric iron, in dendritic aggregates, also in isolated isometric crystals with the forms a (100), o (111), d (110), p (221), β (322), (944)? Hussak, quoted by Derby, Arch. Mus. Rio de Janeiro, p. 160, 1896. Also described from other meteoric irons (Cohen) and in the terrestrial iron of Niakornak, Greenland. Analyses by Cohen, Medd. om Grönland, 15, 293, 1897.

COLEMANITE, p. 882.—Anomalous etching-figures examined, Baumhauer, Zs. Kr., 30, 97, 1898.

COLUMBITE, p. 731.—Crystals of a mangano-columbite from Rumford, Me., are described by H. W. Foote (Figs. 1, 2). G. = 6.44, color dark reddish brown, Am. J. Sc., 1, 460, 1896.

Analysis from North Carolina, Khrushchov, Vh. Min. Ges., 31, 412, 1894.
Occurs (G. = 5.36) in the township of Sebastopol, Renfrew Co., Ontario, W. G. Miller, Rep't Bureau of Mines, 7, Part III, p. 234, Toronto, 1898.
See also *Tantalite* and *Tapiolite*.

COOKEITE, p. 625.—From Hebron, Me., analyzed by Penfield, Am. J. Sc., 45, 393, 1893, and shown to have the formula Li[Al(OH)]3[SiO3]2. Crystallization monoclinic, the crystals

often formed of wedge-shaped cleavage-plates grouped as in figures 1-3; the center a of 3 uniaxial. Analysis:

A mineral referred here by Hoffmann occurs in the sericite-schist of Wait-a-bit creek, Columbia river, British Columbia (analysis by Johnston), Rep. G. Canada, 6, 22 R, 1892-93.

COPPER, p. 20. — Crystals in aventurine glass described, Washington, Am. J. Sc., 48, 411, 1894. Crystals from Burra-Burra, S. Australia, are covered with an incrustation of minute crystals of cuprite in parallel position with it, Mügge, Jb. Min., 2, 151, 1898.

Occurs at Franklin Furnace, N. J., J. E. Wolff, Proc. Am. Acad., 33, 429, 1898.

CORDIERITE. - See Iolite.

CORUNDUM, pp. 210, 1031.—Description of twin crystal (showing the new form (5.5.10.4)) with r (1011) as tw.-plane; also a similar contact-trilling, etc., H. Barvíř, Ann. Mus. Wien, 2, 135, 1892.

Discussion of planes of parting, viz., parallel to c (0001), a (1120), both normal "solution-planes"; also r (1011), a gliding plane and sometimes a secondary solution-plane, Judd, Min. Mag., 11, 49, 1895.

Fratt has described crystals of sapphire (Figs. 1-3) from Yogo Gulch, Montana, with x (3052); also showing natural etching-figures, Am. J. Sc., 4, 424, 1897. See also below. Bauer notes the new form r (0112) on Burma rubies, Jb. Min., 2, 197, 1896.

Investigations of hardness of minerals in the scale of Mohs compared with corundum, Rosiwal, Vh. G. Reichs., 475, 1896. See also Auerbach, Wied. Ann., 58, 357, 1896; Jaggar (microsclerometer), Am. J. Sc., 4, 399, 1897.

In regard to the occurrence of corundum, recent investigations show that it is often associated with igneous rocks and is itself of igneous origin, though also of secondary origin in crystalline limestone and, further, the result of contact-metamorphism. These subjects have been discussed by the following authors:

Ou the occurrence and origin of the rubies of Burma (and associated minerals), C. Barrington Brown and J. W. Judd, Phil. Trans., 187 (A), 151-228, 1896. See also Bauer, l. c.; on the rubies of Siam, Louis, Min. Mag., 10, 267, 1894.

On the corundum of India, T. H. Holland, Geol. India, 2d Ed., Part I, pp. 1-79, Calcutta,

1898. See also Judd, Min. Mag., 11, 56, 1895.

Corundum deposits of Georgia, F. P. King, Geol. Surv. Georgia, Bull. 2, 1894. Associated with peridotite of N. Carolina, igneous origin discussed, Pratt. Am. J. Sc., 6, 49, 1898.

Sapphire of Yogo Gulch, Fergus Co., and elsewhere, Montana, Kunz, Am. J. Sc., 4, 417, 1897;

Pirsson, ibid., p. 421. Corundum of Eastern Ontario, W. G. Miller, Rep. Bureau of Mines, Vol. 7, Pt. III, Toronto, 1898.

Produced by contact-metamorphism on the border of the Dartmoor granite, Devonshire, Busz, Geol. Mag., 3, 492, 1896.

Experimental investigation of conditions of formation in a magma, Morozewicz, Min. petr. Mitth., 18, 22, 202, 1898; see also Zs. Kr., 24, 281, 1894.

Description of emery from Naxos, Tschermak, Min. petr. Mitth., 14, 311, 1894.

Cosmochlore. Kosmochlor, Laspeyres, Zs. Kr., 27, 592, 1896. Kosmochromit, Groth, Tab. Ueb., 132, 1898.

Monoclinic, probably. In embedded splinters, showing, in thin sections, cleavages parallel to a (100), b (010), also less distinct prismatic (30° and 150°). H. = 5-6. Color emerald-green, strongly pleochroic. Extinction oblique. $a \wedge b = 12^{\circ}$. Birefringence high. Ax. pl. ||b| (010). In composition a chromium silicate. An approximate analysis (on 0.003 gr.) gave:

> Cr2O3 Al₂O₃ Fe₂O₃ SiO2 CaO MgO 9.09 31.82 39.39 9.09 6.06 4.55 = 100.

Identified in minute amount in the stony portion of the Toluca meteoric iron. found also orthoclase, plagioclase, pyroxene, quartz, zircon, chromite, and others not fully determined, perhaps new.

COTUNNITE, p. 165.—Study of artificial crystals, Stöber, Bull. Ac. Belg., 30, 345, 1895.

Courtzilite. 17th Ann. Rep. U. S.G. Surv., Part III., p. 752, 1895-96. A form of asphaltum allied to uintahite (gilsonite), etc.

COVELLITE, p. 68. Occurs in fine indigo-blue masses at the East Gray Rock mine, Butte, Montana; analysis by Hillebrand, Am. J. Sc., 7, 56, 1899. Also massive from La Sal mine, La Sal distr., Utah; in plates from Rio Grande Co., Colo. (Pfd.).

CROCOITE, p. 913.—Crystals from Penchalonga, Mashonaland, described (new form 403), Red-

lich. Zs. Kr., 27, 607, 1896. See also Alford, Q. J. G. Soc., 50, 8, 1894.

Occurs finely crystallized at the Adelaide mine, Mt. Dundas, Tasmania, new forms S (10·3·0), T (530), Palache, Am. J. Sc., 1, 389, 1896. On the occurrence in Tasmania, see also Petterd, Min. Tasmania, p. 24, 1893, p. 30, 1896; further, Liversidge (anal.), Proc. R. Soc. N. S. W., 29, 318,

Obtained in minute crystals by exposing for several months to the air a solution of lead chro-

mate in caustic potash, Ludeking, Am. J. Sc., 44, 57, 1892.

Crossite. Charles Palache, Bull. G. Univ. California, 1, 181, 1894.

A mineral of the amphibole group, characterized by its blue color, occurring somewhat widely distributed in the crystalline schists of the Coast Ranges of California. The following descrip-

tion belongs to specimens from near Berkeley:

Occurs in lath-shaped crystals; also in irregular prisms and rounded grains. Form and cleavage like ordinary amphibole. G. = 3.16. Color fine blue, yellowish blue. Pleochroism strong: c brown to greenish yellow; to reddish or bluish violet; a deep blue. Absorption $a \ge b > c$. Ax. pl. ||b|(010). $a \wedge c = 13^{\circ}$ (assumed as $+13^{\circ}$).

In composition between glaucophane and riebeckite, being optically more nearly related to the er. Analysis, W. S. T. Smith:

latter.

CaO Na₂O K₂O SiO Al2O3 Fe₂O₃ FeO MgO MnO tr., H_2O undet. = 99.76 55 02 4.75 9.30 2.38 7.62 0.2710.91 9.46

Named after Mr. Whitman Cross of the U. S. Geol. Survey.

A blue amphibole of like optical characters occurs as a secondary growth on brown hornblende and on pyroxene in Custer Co., Colorado, (cf. Min., p. 402, where it is provisionally placed under arfvedsonite).

CRYOLITE, pp. 166, 1032.—Description of twin crystals, Baumhauer, Zs. Kr., 24, 87, 1894.

CRYSTALLITES. - Discussion of various forms with introduction of new names: clavalite. spiculite, bacillite, scopulite, arculite, rotulite, furculite, crenulite, Rutley, Min. Mag., 9, 261, 1891.

Cubaite.—See Quartz.

CUBANITE, p. 79.—Analyses of a mineral having the external characters of Breithaupt's species gave Schneider:

1. S 34.37 Cu 24.32 Fe 41.15 = 98.842. 34.01 23.00 Fe 42.51 = 99.52

This leads to the formula CuFe₂S₃, agreeing with the analysis of Scheidauer (anal. 4, Min., p. 79). For the mineral analyzed by Eastwick and others (anals. 1-3, *ibid.*) which corresponds to CuFe₂S₄, the author proposes the name *barracanite* or *cupropyrite*. J. pr. Ch., 52, 555, 1895.

Cubeïte. Kubeit, L. Darapsky, Jb. Min., 1, 163, 1898. This name was earlier suggested for an imperfectly known iron sulphate from the neighborhood of the Loa river, desert of Atacama. Now obtained in druses of elongated rhombic or monclinic double pyramids. Brittle, of vitreous luster. Analysis gave: SO₃ 36·4, Fe₂O₃ 19·3, MgO 7·8, H₂O 33·7, CaO [0·1], insol. 2·7′ = 100.

Cumengéite. E. Mallard, Bull. Soc. Min., 16, 184, 1893. Cumengite. - See Percylite.

CUPRITE, p. 206.—Etching-figures do not show the trapezohedral symmetry sometimes exhibited in the distribution of the faces. Traube, Jb. Min., Beil.-Bd., 10. 455, 1896. Fig. shows a crystal from Cornwall, drawn by J. H. Pratt (priv. contr.), in which the trapezohedral symmetry is marked.

See also Copper.

Cuprocassiterite. Titus Ulke, Trans. Am. Inst. Mng. Eng., 21, 240, Feb. 1892.—See Stannite.

Cuproiodargyrite. H. Schulze [Ch. Ztg., 16, 1952, 1892], Zs. Kr., 24, 626, 1895.

Occurs as an incrustation or filling crevices in limestone. Somewhat harder and less sectile than iodyrite. Color sulphur-yellow. Translucent. Composition CuI.AgI. Analysis: I 57.75, Ag 25.58, Cu 15.91 = 99.24. Occurs at the mine San Agustin, Huantajaya, near Iquique, Chili, as a decomposition-product of stromeyerite.

Z Z Z

Cuprite.

CUPROPLUMBITE, p. 51.—From Butte City, Montana, analysis by J. T. De Bell: S 17-77, Cu 61-32, Pb 18-97, quartz 1-58 = 90-64. This gives 5Cu₂S.PbS. The corrected specific gravity (5-39) is shown to correspond with that called for (5-45) on the supposition that it is to be classed with isometric galena. Am. Ch. J., 14, 620, 1892.

From Semipalatinsk, anal. by Antipov, Vh. Min. Ges., 28, 527, 1891, and Zs. Kr., 23, 275, 1894.

CYANITE, p. 500.—Etching-figures investigated, Traube, Jb. Min., Beil.-Bd., 10, 459, 1896; same by T. L. Walker, Am. J. Sc., 5, 181, 1898.

Occurs in rich grass-green crystals with t (520), often perfectly transparent, on North Toe river, Yancey Co., N. C.; also pale green cyanite elsewhere in the state, Pratt, Am. J. Sc., 5, 126, 1898.

Cylindrite. Kylindrit, A. Frenzel, Jb. Min., 2, 125, 1893.

Massive; in cylindrical forms separating under pressure into distinct shells or folia, difficult to pulverize, like graphite. Soft; H.=2.5-3. G.=5.42. Luster metallic. Color blackish lead-gray. Streak black.

Composition, Pb₆Sb₂Sn₆S₂₁ or 3PbS.Sb₂S₂ + 3(PbS.2SnS₂). Analysis:

S Sn Sb Pb Ag Fe 24.50 26.37 8.73 35.41 0.62 3.00 = 98.63

Obtained from the Mine Santa Cruz, at Poopó, Bolivia. The same country has also afforded the allied minerals plumbostannite, Min., p. 108; franckeite, this App., p. 26; also canfieldite, ib., p. 13.

CYRTOLITE, p. 487.—See Zircon.

Dahllite, p. 866.—Shown by Hamberg to be an alteration-product of apatite somewhat analogous to staffelite (Min., p. 764). G. För. Förh., 13, 802, 1891.

Danalite, pp. 435, 1032.—Occurs at Redruth, Cornwall, in large rough tetrahedral crystals, of a columbine-red; H. = 5.5; G. = 3.350. Analysis: SiO, 29.48, FeO 37.53, MnO 11.53, ZnO 4.87, BeO 14·17, CaO tr., S 5·04 = 102·62. Calculated ratio, SiO₂:RO:RS = 3:7:1 nearly. Miers and Prior, Min. Mag., 10, 10, 1892.

DANBURITE, p. 490 —Occurs in crystals in the Cimina region, Rome, Italy; in erratic blocks with dayne, tour maline, etc., Fantappié, Riv. Min. Ital., 16, 82, 1896; 18, 7, 1898; also Rend. Accad. Linc., 5 (2), 108, 1896.

DARAPSKITE. p. 873. — Shown by Osann to be monoclinic. Axial ratio $\hat{a}:\hat{b}:\hat{b}=1.5258:1:0.7514.$ $\beta=77^{\circ}$ 5′ = 001 \wedge 100. 100 \wedge 110 = 56° 5′. 001 \wedge 101 = 23° 23′, 001 \wedge 011 = 36° 13′. Observed forms: a (100), b (010), c (001); m (110); r (101), e (302); n (101), d (201); q (011); o (111), s (111), v (121). Angles: $ac=*77^{\circ}$ 5′, $am=*56^{\circ}$ 5′, $ar=*53^{\circ}$ 42′, $cr=23^{\circ}$ 23′. Crystals tabular $\parallel a$; often twins, tw. pl. a. Cleavage: a perfect. Ax. pl. 1 b, b=a. Axial angle large. H. = 2–3. G. = 2·203. Zs. Kr., 23, 584, 1894.

Artificial formation, A. de Schulten, Bull. Soc. Min., 19, 161, 1626.

 \underline{a}

m

a

Derbylite.

1896.

Etching figures investigated and figured, Baumhauer, Die Resultate d. Aetzmethode, 1894.

Analysis, Grand Marais, Minn., Berkey, 23 Ann. Rept. Minn.

G. Surv., p. 197.

DAVYNE, p. 428.—Occurrence in the Cimina region near Rome, see Danburite.

Derbylite. E. Hussak and G. T. Prior, Min. Mag., 11, 85, 176, 1897.

Orthorhombic. Axes $\check{a} : \bar{b} : \dot{c} = 0.9661 : 1 : 0.5502$. Forms: a (100), c (001), m (110); also (011) as tw. pl. Angles: $am = *44^{\circ} 0_{4}^{2}'$, $c \wedge 011 = 28^{\circ} 49_{4}^{1}'$, $mm = 39^{\circ} 8_{1}^{2}'$ Hussak. In slender prismatic crystals, 2 to 3 mm. long; often in cruciform twins crossing at an angle of 57° 39'; rarely in trillings.

Fracture conchoidal. Very brittle. H. = 5. G. = 4.512-4.530. Luster resinous. Color pitch-black, dark brown and translucent

in thin splinters.

Composition perhaps FeO.Sb₂O₅ + 5FeO.TiO₂. Analysis on material not entirely pure (hence SiO2, etc.), Prior:

B.B. in salt of phosphorus gives a bead (R.F.) yellow when hot, violet when cold. Insoluble

in acid, but decomposed by acid potassium sulphate.

Occurs in the cinnabar-bearing gravel of Tres Cruzes, Tripuhy near Ouro Preto, Mina Geraes, Brazi; lewisite, xenotime, monazite, zircon, rutile, etc., are associated. Named after Dr. O. A. Derby, Director of the Geological Survey of Brazil.

Descloizite, p. 787.—Analyses, from Obir, Carinthia, Brunlechner, Zs. Kr., 24, 626, 1895.

DIAMOND, pp. 3, 1033.—Crystals from the Ural described with (971), (432), Jeremejev, Vh. Min. Ges., 34, 59, 1896.

Artificial corrosion-figures, Luzi, Ber. Ch. Ges., 25, 2470, 1892.
Refractive indices measured, Wülfing, Min. petr. Mitth., 15, 61, 1895. Investigation of variation of refractive indices with the temperature, A. Sella, Riv. Min. Ital., 10, 65, 1892. Thermal

expansion, J. Joly, Nature, 49, 480, 1894.

Shown to be transparent to X-rays (while paste is opaque), also investigation of behavior of many species toward X-rays, Doelter, Jb. Min., 2, 87, 1896; 1, 256, 1897. (See further on the

general subject, Zs. Kr., 30, 610, 1899.)

Found in the glacial drift of Wisconsin, at Plum Creek, Pierce Co.; Oregon, Dane Co.; Kohlsville, Washington Co. (214 carats); Eagle, Waukesha Co. (16 carats), cf. Kunz, Bull. G. Soc. Am., 2, 638, 1891, and Min. Res. U. S.; Hobbs, Amer. Geol., 14, 31, 1894; Bull. Univ. Wisconsin, 1, 152, 1895.

Occurrence and origin in California, Turner, Amer. Geol., 23, 182, 1899. Also in South Africa,

a

Stone, Bonney and Raisiu, Geol. Mag., 2, 492, 1895; Moissan, C. R., 116, 292, 458, 460; 117, 423, 1893. Description of the Kimberley mines, Stelzner, Isis, p. 71, 1893. Discussion of origin as illustrated in Brazil, Derby, J. Geol., 6, 121, 1898.

See also the works of L de Launay and H. Carvill Lewis noted in the bibliography.

In the meteoric iron of Canon Diablo, Arizona, A. E. Foote, Am. J. Sc., 42, 413, 1891; Kunz and Huntington, Am. J. Sc., 46, 470, 1893. Also C. Friedel, Bull. Soc. Min., 15, 258, 1892 (C. R., 115, 1037, 1892); 116, 290, 1893. Also Moissan, C. R., 116, 288, 1893 (Bull. Soc. Chim., 9, 967, 1893). Occurrence in meteorites in general, Huntington, Proc. Amer. Acad., 29, 204, 1894.

Formed artificially, Moissan, C. R., 116, 218, 1893; Friedel, *ibid*, p. 224; Rousseau, *ib.*, 117, 164; further, Moissan, *ib.*, 118, 320, 1894; 123, 206, 210, 1896. Also J. Friedländer, Berlin, 1898, Jb. Min., 1, 202, 1899. Reproduction, Q. Majorana, Riv. Min. Ital., 19, 22, 1898.

DIAPHORITE, p. 124.—Identified by L. J. Spencer (Am. J. Sc., 6, 316, 1898) with pyrargyrite, galena, dolomite on a specimen of stephanite from the Lake Chelan distr., Okanogan Co., Washington; also with miargyrite, etc., from Santa Maria de Catorze, San Luis Potosi, Mexico.

Dicksbergite. L. J. Igelström, G. För. Förh., 18, 231, 1896. A supposed new species occurring with cyanite at Dicksberg, Ransät parish, Wermland, Sweden. Shown by Weibull and Upmark (ibid., p. 523) to be rutile.

Dietzeite. A. Osann, Zs. Kr., 23, 588, 1894.

Monoclinic. Axes $\hat{a}: \hat{b}: \hat{c}=1.3826:1:0.9515$; $\beta=*73^{\circ}28'=001 \land 100$. $100 \land 110=*52^{\circ}$ 58', $001 \land 101 = 39^{\circ}$ 22', $001 \land 011 = 42^{\circ}$ 224'. Observed forms: a (100), b (010), c (001); l (210), m (110); r (101), s (223), o (221). Angles: $mm''' = 105^{\circ}$ 56', $a'r = *67^{\circ}$ 10', $cm = 80^{\circ}$ 8'. Crystals prismatic, tabular | a and

elongated & Commonly fibrous to columnar.

Cleavage: a imperfect. Fracture conchoidal. H. = 3-4. G. = 3.698. Luster vitreous. Color dark gold-yellow. Optically +. Ax. pl. \pm b. Bx. \pm a in obtuse angle \dot{b} \dot{a} ; extinction on b (010) 5° to 7° with \dot{b} . $2G_{a\cdot y} =$

87° to 88°. Dispersion horizontal and $v > \rho$, both strongly marked. Composition, $7\text{Ca}(\text{IO}_3)_2$. 8CaCrO₁. Soluble in hot water; from the solution the colorless calcium iodate (Ca(IO₃)₂ + 6H₃O) separates on cooling, leaving

the calcium chromate in solution. Obtained from the same region which furnished the calcium iodate

lautarite (Min., p. 1040). The occurrence of this salt was earlier described by Dietze (after whom it is named), see Min., l. c.

DIOPSIDE.—See Pyroxene.

DIOPTASE, pp. 463, 1033.—Occurs in crystals in the neighborhood of Mindouli, east of Comba, on the road to Brazzaville, French Congo; also at other points in the Congo region. Lacroix, C. R., 114, 1384, 1892. See also A. Le Chatelier, C. R., 116, 894, 1893. Etching-figures investigated, Traube, Jb. Min., Beil.-Bd., 10, 462, 1896.

DIPYRE. - See Wernerite.

DOLOMITE, pp. 271, 1033.—From Raibl, containing traces of thallium and lithium, Heberdev. Zs. Kr., 21, 71, 1892.

Origin discussed, Klement, Min. petr. Mitth., 14, 526, 1895; Pfaff, Jb. Min., Beil.-Bd., 9, 485,

The black crystals from Teruel, Spain, occurring embedded in gypsum have been long called teruelite.

DUFRENOYSITE, p. 120.—Description by Baumhauer of crystals (anal., König) with the new forms (223), (441), (207), (103), (205), (407), (027), (013), (025), (049), (047), Zs. Kr., 24, 85, 1894; 28, 551, 1897.

Dundasite. W. F. Petterd, Catalogue of Minerals of Tasmania, p. 26, 1893. Inferred from qualitative tests to be a hydrated carbono-phosphate of lead and aluminium. Occurs as an incrustation on a ferro manganese gossan with crocoite; consists of small spherical aggregates with radiated structure; color within white and silky, externally yellow-brown. H. = 2. From the Adelaide Proprietory mine, Dundas, Tasmania.

DURDENITE, p. 980.—F. C. Knight has noted an oxidation-product of the tellurides of Cripple Creek, Colo. The soluble (HCl) portion of the mixture analyzed was perhaps 2Fe₃O₃.2TeO₂.H₂O₃, the insoluble calaverite. Proc. Colo. Soc., Oct. 1, 1894.

Dyscrasite, p. 42.—Crystals from the Harz described, Luedecke, Min. d. Harzes, 48, 1896.

EDINGTONITE, p. 599.—Occurs in large crystals (to 3 cm. in length) at the mines of Bôhl, Sweden. Habit prismatic, tabular | one pair of m-faces; twins, pseudo-tetragonal. referred to the orthorhombic system (hemihedral) with the forms: c (001), m (110), p (111), p, (111), r, (121), r, (121). Axes $\check{a}:\check{b}:\check{b}=0.9873:1:0$ 6733. Angles: $mm'''=89^\circ$ 16', $cp=43^\circ$ 47'. G. = 2.776. 2Ey = 87° 17'. O. Nordenskiöld. Bull. Soc. Min., 18, 396, 1895, and G. För. Förh., 17, 597, 1895. An analysis is given by G. Lindström, Öfv. Ak. Stockh., 53, 469, 1896.

Elfstorpite. L. J. Igelström, G. För. Förh., 15, 472, 1893; Zs. Kr., 22, 468. An imperfectly described mineral from the Sjö mine, Orebro, Sweden. Occurs in crystals and crystalline particles with one cleavage. H. = 4. Brittle. Color and streak whitish gray. Inferred, on the basis of a partial qualitative analysis, to be a hydrated arsenate of manganese (MnO).

Elpidite. G. Lindström, G. För. Förh., 16, 330, 1894. G. Nordenskiöld, ibid., p. 343.

Orthorhombic. Axes: $\check{a}: \check{b}: \dot{c}=0.5117:1:0.9781.$ 100 \wedge 110 = 27° 6′, 001 \wedge 101 = 62° 23′, 001 \wedge 011 = 44° 22′. Forms a (100), b (010), c (001), m (110), n (120), e (013), d (011); also doubtful u (540), t (580), s (5·12·0). Angles: $mm''' = *54^\circ$ 12′, $cd = *44^\circ$ 22′. Crystals prismatic, rarely distinct (described by G. Nordenskiöld). Usually massive, fine fibrous or columnar; also as a felt-like mass.

Cleavage: m (110). H. nearly 7. G. = 2.524 white, 2.594 red. Luster silky. Color white to

brick-red. Extinction parallel to prismatic direction, which corresponds to a.

Composition, essentially, H₆Na₂ZrSi₆O₁₈ or Na₂O.ZrO₂.6SiO₂.3H₂O. Analysis, Lindström:

SiO. ZrO2 FeO CaO Na₂O K₂O H₂O (ign.) H₂O (100°) Cl 0.17 10.41 0.13 $0.15 \text{ TiO}_2, \text{CuO } tr. = 100.53.$ 59.44 20.48 0.14 5.72 3.89 *Another determination gave: Na₂O 10·29, K₂O 0 21.

From the locality in southern Greenland (probably Nagssarsuk near Igaliko) which has afforded neptunite (see this App., p 49) and epididymite, p. 25. Named from $\epsilon \lambda \pi \iota s$, hope.

ENARGITE, pp. 147, 1033.—Occurs at the Ida mire, also at Red Mountain, Summit distr., Colorado; crystals from the latter locality show the new forms v (210), e (012), z (134); habit prismatic or tabular (figs. 1-5, Red Mountain). Pirsson, Am. J. Sc., 47, 212, 1894.

Monograph on the crystallization, L. J. Spencer; new forms noted are: y (610), f (520), i (540), N (230), t (108), A (207), w (709), u (301). The author concludes that clarite (Min., p. 148) is identical with enargite. Min. Mag., 11, 69, 1895. Crystals from Peru show the new forms π (031), ϕ (132), ϕ_1 (394), ϕ_2 (131), ϕ_3 (392), idem, Min. Mag., 11, 196, 1897. Occurs in large crystals at the Bell Stow mine, Missoula Co., Montana, Moses, School Mines

Q., 16, 230, 1895. Analysis, from Butte, Montana, Hillebrand, Am. J. Sc., 7, 56, 1899.

Enstatite, p. 346.—From Corundum Hill, N. C., also Webster, Jackson Co., N. C., analyses

quoted by Pratt, Am. J. Sc., 5, 430, 431, 1898. Investigation of alteration-products, Johansson, Ak. H. Stockh., Bihang, 17 (2), No. 4, 1891. (Ref. in Zs. Kr., 23, 152.)

Epididymite. G. Flink, G. För. Förh., 15, 201, 1893; Zs. Kr., 23, 353, 1894. G. Nordenskiöld, G. För. Förh., 16, 345, 1894.

Orthorhombic. Axes $\check{a}:\check{b}:\dot{c}=0.5758:1:0.5340$ or 1:1.7367:0.9274. $100 \land 110=29^{\circ}$ 56', $001 \land 101=42^{\circ}$ 50 $\overset{1}{b}'$, $001 \land 011=28^{\circ}$ 6\; Observed forms: a (100), b (010), c (001); m (110), b (120), n (130); i (023), b (034), g (011), e (043), d (021), f (041), λ (061), χ (081); p (221). Angles: $mm''=59^{\circ}$ 52', $nn'=119^{\circ}$ 52', $bn=*30^{\circ}$ 4', $cd=*46^{\circ}$ 53'. Crystals usually tabular $\parallel c$ and elongated by extension of the faces in the brachydome zone; these

faces horizontally striated. In part in hexagonal tables, b and m being equally developed: these also twinned, having c in common but revolved 60° about the vertical axis, and as tw. lamellæ.

Cleavage: b and c perfect. H. = 5.5, G. = 3.548. Luster vitreous, on b and c pearly.

Optically -. Ax. pl | c. Bx_a \perp b. Indices For Na, $\alpha = 1.5645$, $\beta = 1.5685$ Colorless. y = 1.5688. $\therefore 2V_{a,y} = 31^{\circ} 4'$. Composition HNaBeSi₃O₈ like eudidymite (Min., p. 313).

Analysis, G. Flink

Na₂O BeO H₀O 10 14 10.56 12.88 3.73 = 100.92

B.B. fuses easily to a colorless glass, but yields water only at a high temperature. Not attacked by acids.

From Greenland, exact locality uncertain, probably Narsasik (or Nagssarsuk, Lindström) near

(galiko, cf. neptunite and elpidite.

EPIDOTE, p. 516.—Crystals from Quenast described, Stöber, Bull. Ac. Belg., 29, 403, 1895. Also from the Comba di Compare Robert, Avigliana, G. Boeris, Atti Accad. Sc. Torino, 32, Apri 25, 1897, and Riv. Min. Ital., 20, 65, 1898.

Optical examination of isomorphous layers of crystals, Ramsay, Jb. Min., 1, 111, 1893.

Occurrence as a primary constituent of igneous rocks, Keyes, Bull. G. Soc. Amer., 4, 305

The relation of epidote to zoisite is discussed by Weinschenk, Zs. Kr., 26, 166, 1896. See also Clinozoisite.

Epsomite, p. 938.—Description of natural crystals from Stassfurt (new form g (210)), also optical determination, Milch, Zs. Kr., 20, 221, 1892.

Erionite. A. S. Eakle, Am. J. Sc., 6, 66, 1898, and Zs. Kr., 30, 176, 1898.

Orthorhombic. In aggregates of very slender fibers, resembling woolly hairs. G. = 1.99% Luster pearly. Color white. Optically biaxial, positive. Extinction and Bx. (c) parallel to fibers Birefringence high.

Composition, $H_2CaK_2Na_2Al_2Si_0O_{17} + 5H_2O$ or $CaO.K_2O.Na_2O.Al_2O_3.6SiO_2.6H_2O$. Analy-

sis:

CaO K20 H₂O SiO, Ala Da MgO Na₂O 2.47 17.30 = 100.6857.16 16.08 3.50 3.51

Fuses B.B. easily and quietly to a clear, colorless glass. Easily soluble in hydrochloric acid. Occurs with milky opal in cavities in a rhyolite tuff at Durkee, Oregon. Named from epior wool.

ERYTHRITE, p. 817.—Occurs on the west shore of Rabbit Lake, Nipissing, Ontario, Ferrier. Ottawa Naturalist, 9, 193.

ETTRINGITE, p. 976. — From Tombstone, Arizona, analyzed by Moses (after deducting 1.91, SiO₂): SO₃ 18.54, Al₂O₃ 9.72, CaO 26.31, H₂O (red heat) 10.88, H₂O (115°) 34.53 = 99.98. Formula deduced 10CaO.2Al₂O₃.5SO₃.54H₂O; 14 parts of H₂O go off at a red heat, the formula then reduces to $2R_2O_3$.SO₃ + $8H_2O$. Occurs in bunches of white, silky fibers. H. = 2. G. = 1.55 Shows double refraction with parallel extinction. Am. J. Sc., 45, 489, 1893; Zs. Kr., 22, 16

Euchlorine. A Scacchi, 1869; E. Scacchi, Rend. Accad. Napoli, 23, 158, 1884. A this emerald-green incrustation on the lava at Vesuvius. The analysis by Pisani (quoted by Scacchi) made it a compound of copper sulphate and cuprous chloride. According to a later investigation, however (E. Scacchi), it is made up of an insoluble and a soluble portion. The proper euchlorine yielded: SO₃ 43·98, CuO 41·50, K₂O 8·04, Na₂O 6·48 = 100. The crystallization is orthorhombic. Observed forms: b (010), c (001), e (011), d (103), o (101); measured angles: $ce = 61^{\circ}$ 56'. $co = 67^{\circ}$ 54'. An analysis by Rammelsberg (Min. Ch., Erg.-Heft, 87, 1886) gave: SO₃ 42·96, CuO 37·87, Na₂O 5·48, K₂O 10·34, H₂O [3·35] = 100.

EUCHROITE, p. 838.—Libethen, crystals with the new forms, f (102), d (101), Gissinger, Zs. Kr., 22, 367, 1892. An analysis by A. H. Church shows 1.48 p. c. P₂O₅, Min. Mag., 11, 1, 1895

EUCLASE, p. 508.—Bahia, Brazil, crystals described, Hussak, Min. petr. Mitth., 12, 473, 1892

EUDIALITE, pp. 409, 1034.—Kola peninsula, optical investigation of crystals, confirming and extending earlier results (Min., p. 410), Ramsay, Jb. Min., Beil. Bd., 8, 722, 1893.

EVANSITE, p. 846.—Occurs at a mine in the Zeehan district, Tasmania. G. = 1.939. Analysis P_2O_3 18.11, Al_2O_3 40.19, $H_2O=41.27=99.57$. H. G. Smith, Proc. R. Soc. N. S. W., 27, 382 1893.

FAYALITE, pp. 456, 1034.—From Rockport, Mass., analysis (nearly pure Fe₂SiO₄, G. = 4·318) and optical properties with discussion of the relation of the latter to composition in the species of the Chrysolite Group; also analysis of hortonolite. Penfield and Forbes, Am. J. Sc., 1, 129, 1896. Analysis of crystals from slag, G. O. Smith, Johns Hopkins Univ. Circ., 112, May 1894. See also Neochrysolite and Breislakite.

Fedorovite. Fedorowit, C. Viola, Jb. Min., 1, 121, 1899.—See Pyroxene.

FELDSPARS, pp. 314, 1034.—Much work has been done recently upon the optical characters of the feldspars, and chiefly those of the plagioclase series; this has to a large extent had as its object the determination of the different species under the microscope, as, for example, in the form they

appear in thin-sections of rocks. Prominent contributions are the following:

Michel-Lévy, an important work entitled "Étude sur la détermination des feldspaths dans les plaques minees." Paris (two parts), 1894 and 1896 (see Bull. Soc. Min., 18, 79, 1895). A summary of this (and other papers) is given by N. H. Winchell in Amer. Geol., 21, 12, 1898; see also G. F. Becker, Am. J. Sc., 5, 349, 1898.

Fedorow, feldspar studies, Zs. Kr., 22, 248, 1893; 26, 225, 1896; 27, 337, 1896; 29, 604, 1898.

Viola, Zs. Kr., 30, 23, 232, 1898.

Fr. Becke, determination of refractive indices, Ber. Ak. Wien, 102 (1), 358, 1893; also determination by interference figures, etc., Min. petr. Mitth., 14, 415, 1895.

Bertrand, Bull. Soc. Min., 20, 219, 1897. Wallerant, rapid determination in rocks, ibid., 21,

268, 1898.

Many optical determinations with analyses are given by Fouqué, Bull. Soc. Min., 17, 283-611, 1894. See also Brögger. Eruptivgesteine d. Kristianiagebietes, 1894-98; also many memoirs on petrography (Jb. Min., Min. petr. Mitth., et al.).

Discussion of composition of plagioclase feldspars, Rammelsberg, Jb. Min., 2, 165, 1896.

See also the species Albite, Anorthite, Anorthoclase, Celsian, Microcline, Orthoclase.

FERGUSONITE, p. 729.—From Ceylon, analysis. Prior, Min. Mag., 10, 234, 1893. Examination of gases yielded (helium, etc.), Ramsay, Proc. Roy. Soc., 59, 325, 1896; Ramsay and Travers, ib., 60, 443, 1897. Investigation of endothermic properties, Ramsay, ib., 62, 325, 1898.

FIEDLERITE, p. 172.—Description of crystals from Laurion, Greece, Lacroix, C. R., 123, 955, 1896. Also G. F. Herbert Smith, Min. Mag., 12, 107, 1899.

FLUOCERITE, pp. 175, 1034.—Weibull has described a fragment of an hexagonal crystal from Österby (cf. anal., Min., p. 175) with m (1010) and p (1122); $mp=51^\circ$, whence $a:\dot{c}=1:1.06$. Optically uniaxial, positive; $\epsilon-\omega=0.002$ approx. G. För. Förh., 20, 54, 1898.

Fluor-adelite.—See Tilasite.

FLUORITE, pp. 161, 1034 — Sarnthal, Tyrol, crystals described with the form (27·12·5) developed by corrosion, Höfer, Min. petr. Mitth., 12, 500, 1892. On crystals from the Harz Mts., Luedecke, Min. d. Harzes, 252, 1896.

Tenacity investigated, Sella and Voigt, Wied. Ann., 48, 663, 1893. Anomalous optical characters, Wallerant, Bull. Soc. Min., 21, 44, 1898.

Phosphorescent under the action of X-rays, this is also true of calcite and other species, Bur-

bank, Am. J. Sc., 5, 53, 1898.

Refractive indices for long waves, Carvallo, C. R., 116, 1189, 1893; Rubens and Snow,

Wied. Ann., 46, 529, 1892.

Dispersion in the infra-red, Paschen, Wied. Ann., 53, 301, 1894.
Photoelectrical properties, Schmidt, Wied. Ann., 62, 407, 1897.
From Quincié, containing free fluorine (anal., G. = 3·117), to which the odor on fracture is due, Becquerel and Moissan, Bull. Soc. Chim., 5, 154, 1891.
On the fluorite deposits of southern Illinois, see S. F. Emmons, Trans. Am. Inst. Mng. Eng.

21, 31, 1892.

Occurs on a large scale at San Roque, Cordoba, Argentina, Valentin, Zs. prakt. Geol., 4, 104, 1896.

Folgerite. S. H. Emmens, J. Am. Chem. Soc., 14, No. 1, 1892.—See Pentlandite.

FOSTERITE, p. 450.—Colorless transparent crystals from Monte Somma have been measured by Jolles and analyzed by Thaddeeff, see Arzruni (Zs. Kr., 25, 471, 1895); the latter also gives the optic-axial angles and notes twins with (031) as tw. pl.

Analysis, from the crystalline limestone of the Passau graphite region, Weinschenk, Zs. Kr.,

28, 145, 1897.

A. W. Stelzner, Jb. Min., 2, 114, 1893.

Massive, with imperfect radiated and foliated structure; in part in spherules aggregated in

reniform shape. Cleavage perfect in one direction. Somewhat malleable, making a mark on paper. H = 2.75. G. = 5.55. Luster metallic Color blackish gray to black. Opaque. Composition, Pb₅Sn₂Sb₂S₁₂ or 2PbSn₃.Pb₅Sb₂S₆. Analysis by C. Winkler:

Gangue 1 22 50.57 0.71 = 98.8721.04 10.51 12.34 2.48

Germanium is present in small amount (0 1 p. c.); also about 1 p. c. silver.

B.B. on charcoal gives a yellow coating of lead oxide, and farther from the assay one of oxide of antimony. In the open tube yields sulphurous and antimonial fumes. In the closed tube, a slight coating of germanium sulphide if no air is present. Dissolved by nitric acid with the separation of a white powder (oxides of antimony, tin and germanium); also readily in aqua regia with separation of sulphur.

From the silver-mining region of Las Animas, southeast of Chocaya, Bolivia; it is locally known as llicteria; wurtzite is closely associated. Named after the mining engineers, Carl and

Ernst Francke.

FRIEDELITE, pp. 465, 1035.—From the Sjö mine, Wermland, Sweden, analysis, Igelström: SiO₂, 34·36, MnO 45·88, FeO 1·35, CaO 1·50, MgO 1·50, Mn 2·79, Cl 3·00, H₂O 9·00, P₂O₆ tr. = 99.38. G. För. Förh., 14, 505, 1892; Zs. Kr., 21, 92, 1892.

Fuggerite. E. Weinschenk, Zs. Kr., 27, 577, 1896.

In thick four-sided tabular crystals, probably tetragonal. G. = 3.18. Color light apple-green; also white and dull. Cleavage: basal, perfect. H = 6.5. Birefringence very low, for yellow (Na) sensibly isotropic; $\omega_{\rm na} = \epsilon_{\rm na} = 1.691$.

Corresponds in composition to a member of the gehlenite-akermanite series (3 Åk: 10 Gehl), but deviates in physical characters. Analysis, E. Mayr:

Fe₂O₃ SiO2 Al₂O₃ CaO MgO Na₂O MnO, K2O insol. 34 04 17.97 37.65 4.89 2.04 tr. 0.12 = 100.20

Occurs on the contact-zone adjoining the monzonite of the Monzonithal; in part as a microscopic constituent, in part in nests of crystals, also as a coarse-granular aggregate with calcite.

GADOLINITE, pp. 509, 1035.—Crystals from the Harz described by Luedecke, Min. d. Harzes, 438, 1896.

GAHNITE, pp. 223, 1035.—Occurs in Raglan township, Renfrew Co., Ontario, Hoffmann, Rep. G. Canada, 9, 15R, 1896.

GALENA, p. 48.—Cryst.—From Neudorf with the new form (551), Cesàro, Zs. Kr., 20, 468, 1893. From the Harz, Luedecke, Min. d. Harzes, 16, 1896. On the octahedral cleavage of a variety from Nil-St.-Vincent containing tellurium, Cesaro, Ann. Soc. G. Belg., 19, Bull, 76, 1892.

Freiberg, new form (447), Cesàro, Ann. Soc. G. Belg., 24, lxxix, 1898.

From Broken Hill, N. S. W., containing 15.5 p. c. Zn, Liversidge, Proc. Roy. Soc., N. S. W., 29, 320, 1895. Cubic crystals stated to be from Bingham, Utah, gave Hartley 4.97 p. c. Zn, Miers,

Min. Mag., 12, 112, 1899.

GARNET, pp. 437, 1035.—Pyrope of cubic form occurs in the diamond sands of Agua Suja, Minas Geraes, Brazil, Hussak, Ann. Mus. Wien, 6, 113 (not.), 1891.

Optical investigation of crystals from many localities with references to the recent literature (since 1882, cf. Min., p. 439), etc., Klein, Jb. Min., 2, 68, 1895, also Ber. Ak. Berlin, 723, 1895; 676, 1898. See also Brauns, Opt. Anom., 1891, p. 133; Karnojitsky, Vh. Min. Ges., 34, 1, 1896; Fedorow, Zs. Kr., 28, 276, 1897.

Optical character of pyrenéite corresponding to that of an orthorhombic crystal, Mallard, Bull. Soc. Min., 14, 293, 1891. Same of melanite from Algeria, Gentil, Bull. Soc. Min., 17, 269, 1894; of crystals from Affaccata, Elba, G. D'Achiardi, Annal. Univ. Tosc., 20, 1896.

Grossularite, analysis of an apple-green variety resembling jade, found as a water-worn pebble near Eltoro, California, F. W. Clarke, Am. J. Sc., 50, 76, 1895. Analyses, Rothenkopf, Zillerthal, Schnerr, Zs. Kr., 27, 431, 1896.

Almandite, analysis, Sydney, N. S. W., H. G. Smith, Proc. Roy. Soc., N. S. W., 28, 47, 1894. Andradite from nephelite-syenite of Dungannon, Hastings Co., Ont., with 1.08 p. c. TiO₂, Adams and Harrington, Am. J. Sc., 1, 217, 1896. Italian Peak, Gunnison Co., Colo., Eakins, Bull. U. S. G. Surv., 113, 112, 1893.

Topazolite, Melanite, analyses, Piners, Zs. Kr., 22, 479, 1894.

Pyrope, etc., chemical composition discussed with analysis, C. v. John, Jb. G. Reichs., 42, 53, 1892.

Spessartite, analyses from Llano Co. Texas, W. H. Melville, Bull. U. S. G. Surv., 90, 40, 1892. Silberberg near Bodenmais, analysis, Weinschenk, Zs. Kr., 25, 357, 1895. Aschaffenburg (analysis by Wehr and Schröder), Weinschenk, Zs. Kr., 28, 162, 1897. Caprera, Sardinia, Lovisato, Rend. Accad: Linc., 5 (1). 56, 1896.

Analyses by Wait of varieties from Canada, Hoffmann, Rep. G. Canada, 6, 16R, 1892-93, Discussion of composition with analyses, K. H. Schnerr, Inaug. Diss. Munich, 1894, abstract in Jb. Min., 1, 432 ref., 1897.

Occurrence in the dune sands of Holland (analysis), Retgers, Jb. Min., 1, 16, 1895.

Discussion of relation of subspecies, Weinschenk, Zs. Kr., 25, 365, 1895.

Hrubschitz, altered to diopside, hornblende, and plagioclase, Barviř, Ber. Böhm. Ges., May 19, 1893.

Artificial formation of melanite, Michel, C. R., 115, 830, 1892.

Rhodolite is a variety from Mason's Branch, Macon Co., N. C., described by Hidden and Pratt (Am. J. Sc., 5, 294, 1898). Characterized by its rose-like color and brilliant luster by reflected light. Occurs in rolled pieces and etched fragments G.=3.838. Composition corresponds to 2 molecules of pyrope, $Mg_3Al_2[SiO_4]_3$, and 1 of almandite, $Fe_3Al_2[SiO_4]_3$. Analysis, Pratt:

	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	FeO	MgO	CaO
(2)	41.59	23.13	1.90	15.55	17.23	0.92 = 100.32

Lagoriolite (Lagoriolith) is an artificial compound obtained by Morozewicz, corresponding in composition to a soda-variety of grossular garnet; formula $(\mathrm{Na}_2,\mathrm{Ca})_3\mathrm{Al}_2[\mathrm{SiO}_4]_3$, with $\mathrm{Na}_2:\mathrm{Ca}=3:2$. An analysis (deducting 14'8 p c insol.) gave: SiO_2 39·6, $\mathrm{Al}_2\mathrm{O}_3$ 21·4, CaO 14·2, $\mathrm{Na}_2\mathrm{O}$ 23·6, SO_3 1·2 = 100. The crystals obtained seemed to be isometric in form (100 and 110), but showed optical anomalies, twinning, etc., analogous to some garnet, also particularly to noselite and haüynite. Named after Professor A. Lagorio. Min. petr. Mitth., 18, 147, 1898.

Schneebergite of Brezina is shown by Eakle and Muthmann to be a garnet of the topazolite type in octahedral form. Am. J. Sc., 50, 244, 1895; Zs. Kr., 24, 583, 1895.

Ransātite is a supposed new mineral from the damourite of Bliaberg, Ransāt, Wermland, Sweden, described by Igelström (G. För. Förh., 18, 41, 1896). It is shown by Weibu'. (*ibid.*, 20, 53, 1898) to be an impure manganesian garnet.

GARNIERITE, p. 676.—N. Caledonia, analysis of a related silicate, Pisani, Bull. Soc. Min., 15, 48, 1892. Various nickel silicates have been examined by H. v. Foullon, Jb. G. Reichs., 42, 223 1892.

GAY-LUSSITE, p. 301.—Crystals described from Borax Lake, San Bernardino Co., Cal. (Figs 1-3). G. = 1.992. J. H. Pratt, Am. J. Sc., 2, 130, 1896.

Occurs in a confused crystalline mass at the borax locality in San Bernardino Co., Cal., Hr., ks, Am. J. Sc., 43, 540, 1892, Mng. Sc. Press, March 26, 1892.

On the artificial formation, A. de Schulten, C. R., 123, 1023, 1896.

GEHLENITE, p. 476.—Occurs in limestone of the Kaiserstuhl, Brauns, Jb. Min., 1, 81, 1899. See also Fuggerite.

Geikielite. L. Fletcher, Nature, 46, 620, Oct. 27, 1892. A. Dick, Min. Mag., 10, 145, 1893. Massive; in rolled pebbles. Cleavage: in one direction perfect; also imperfect in another, nearly normal to it. Brittle. H. = 6. G. = 3.98-4. Luster metallic-adamantine on the cleavage-face. Color bluish or brownish black; microscopic fragments transmit a purplish-red light. Optically uniaxial, negative. Birefringence high.

Composition, essentially magnesium titanite, MgTiO₃. Analysis, Dick:

TiO₂ 67.74 MgO 28.73 FeO 3.71 = 100.38

B.B. infusible; reacts for titanium with salt of phosphorus. Slowly decomposed by hot hydrochloric acid if in fine powder.

Obtained from the gem mines of Rakwana, Ceylon, a locality which has also furnished baddeleyite. Named after Sir Archibald Geikie, Director of the Geological Survey of Great Britain.

Gersbyite. L. J. Igelström, Zs. Kr., 28, 310, 1897. Occurs in pale-blue to deep-blue grains embedded in quartzose damourite-schist at Dicksberg, Wermland, Sweden. Closely resembles

lazulite and is near it in composition. One of several analyses gave: P2O2 32.26, Al2O3 46.68, CaO, FeO, MnO 6.66, MgO 5.33, H_2O 9.07 = 100.

Gersdorffite, p. 90.—Occurs in octahedral crystals in Denison township, Algoma district, Ontario (analysis by Johnston), Hoffmann, Rep. G. Canada, 5, 22R. Also on Kootenay Mountain, near Rossland, British Columbia. *ibid.*, 9, 15R, 1896. Analysis from Goslar in the Harz, Klockmann, Zs. prakt. Geol., 1, 387, 1893.

GIBESITE, p. 254 —Artificial formation of crystals, A. de Schulten, Bull. Soc. Min., 19, 157, 1896.

GILSONITE. - See Uintaite.

GISMONDITE, p. 586.—Occurrence in basalt, St.-Agrève, Ardèche, France, Gonnard, C. R., 117, 590, 1893.

GLAUBERITE, p. 893.—Description and measurements of crystals from Westeregeln, W. von Schulz, Vh. Min. Ges., 30, 75, 1893.

Glaucochroite. S. L. Penfield and C. H. Warren, priv. contr.

Orthorhombic. In embedded prismatic crystals without distinct terminations. Prismatic angle $m \wedge m$ 47° 30'. Twins with the brachydome (011) as tw. plane, the vertical axes crossing at an angle of 58°30′ (microscope). Axes $\check{a}:\check{b}:\dot{c}=0.44:1:0.56$. H. about 6. G. = 3.407. Color a delicate bluish-green like some beryl.

Composition, CaMnSiO4, analogous to the Chrysolite Group; corresponds to a manganese

monticellite. Analysis, Warren:

SiO2 MnO CaO PhO 31.48 38.00 28.95 1.74 = 100.17

B.B fuses quietly at 3.5. Easily soluble in hydrochloric acid and yields gelatinous silica upon evaporation. Reacts for manganese with borax.

Occurs at Franklin Furnace, N. J., with nasonite, brown garnet, axinite and a little franklinite. Named from ylavkos, blue-green, and xpoa, color, in allusion to its color.

GLAUCONITE, p. 683.—Extensive beds occur in Spottsylvania and Stafford Cos., Va., analysis, Corse and Baskerville, Am. Ch. J., 14, 627, 1892.

In Woodburn, Antrim, Ireland, analysis, Hoskins, Geol. Mag., 2, 317, 1895.
General discussion of composition, origin, etc., Gümbel, Ber. Ak. München, 26, 545, 1896; also Glinka, Zs. Kr., 30, 390, 1898.

GLAUCOPHANE, p. 399.—Investigation of etching-figures, R. A. Daly, Proc. Am. Acad. Sc., 34, 404, 1899.

Analysis, Beaume, Dora Riparia, Colomba, Att. Accad. Torino, 29, 404, 1893.

Rhodusite is a variety of glaucophane described by Foullon as occurring in the Eocene Flysch rocks of the island Rhodus. It is characterized by a fibrous asbestus-like structure. lavender-blue. Analysis of purified material gave:

SiO2 Al203 Fe₂O₃ FeO MgO CaO Na₂O K2O 55.03 0.49 15.47 7.39 11.48 0.98 6.38 0.80 1.98 = 100

This corresponds to a glaucophane, in which Fe₂O₃ has taken the place of Al₂O₃. Ber. Ak. Wien, 100 (1), 176, 1891

See also Crossite.

GLOCKERITE, p. 970.—An orange-yellow ocherous basic ferric sulphate from Parys Mount, Anglesea, analyzed by Church, corresponds nearly to 2Fe₂O₃.SO₃.8H₂O. Loss of H₂O at 100° 13.51 p. c., on moderate ignition 12.85. Glockerite is 2Fe₂O₃.SO₃.6H₂O. Min. Mag., 11, 13, 1895.

GMELINITE, p. 593.—Crystals from Montecchio Maggiore, described with new forms (2150), (2133), (1233), Artini, Giorn. Min., 2, 262, 1891.

Gold, p. 14.—Crystals from the Ural, described, new form (811), Jeremejev, Vh. Min. Ges., Prot., 33, 60, 1895.

Crystalline structure of nuggets investigated by Liversidge, Proc. R. Soc. N. S. W., 31, 70, 1897 (read Oct. 3, 1894). Discussion as to the origin of moss gold and of gold nuggets, Liver-Gold containing palladium occurs in the Caucasus, Th. Wilm, Zs. anorg. Chem., 4, 300, 1893.

Occurs in California with albite, barite, calcite, etc., Turner, Am. J. Sc., 47, 467, 1894.

On the gold fields of the Southern Appalachians, G. F. Becker, 16th Ann. Rept. U. S. G. Surv., Part II, 18:4. Of Transvaal, the same, 18th Ann. Rept. U. S. G. Surv., Part V, 1896. Of Alaska, the same, 18th Ann. Rept. U. S. G. Surv., Part III (also Map of Alaska, etc., S. F. Emmons, U. S. G. Surv., 1898). Of Georgia, Geol. Surv. Georgia, Bulletin 4A, Yeates, McCallie and King, 1896. On the mining region of Cripple Creek, Colorado, Cross and Penrose, 16th Ann. Rept. U. S. G. Surv., Part II.

The world's production of cold has in the colorado of the cold has in the colorado.

The world's production of gold has increased at a very remarkable rate during the past decade. In 1890 the value of the total amount produced (see Min., p. 19) was less than 120 million dollars; in 1896 it was about 200 millions, in 1897 237 millions, and the amount estimated for 1898 is upwards of 280 millions. Of this increase, South Africa has contributed relatively the largest amount. For the United States the amount for 1898 is nearly 66 millions, or double that of 1890; for Colorado the amount has increased from 4 millions in 1890 to more than 24 millions for 1898, chiefly through the productivity of the Cripple Creek mines. Canada's amount for 1898 is 141 millions, of which it is estimated that the Klondike region on the tributaries of the Yukon river has yielded 12 millions.

Goldschmidtite. W. H. Hobbs, Am. J. Sc., 7, 357, 1899.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=1.8561:1:1.2980; \beta=89^{\circ}11'=100 \land 001.$ Forms a (100), b (010),

c (001); g (310), f (210), m (110), t (370), l (130); y (508), k (032). Angles: $am = *61^{\circ}$ 41', $mm''' = 123^{\circ}$ 22', $as = 54^{\circ}$ 29', $a'S = *55^{\circ}$ 35', $an = 35^{\circ}$ 17', $a'N = 35^{\circ}$ 50', $ac = 89^{\circ}$ 11' (mean derived (following Hobbs) from the measured angles: $as = 54^{\circ}$ 57', $a'S = 55^{\circ}$ 35' and $an = 34^{\circ}$ 13', $a'N = 34^{\circ}$ 58). In form related to calaverite).

Crystals prismatic | c. Twins common, tw. plane

a (100) (Fig. 2).

Cleavage, b(010) perfect. Brittle. H. = 2. G. = 8.6 Luster metallic. Color silver - white. (estimated). Streak dull grayish black. Opaque.

Composition, Au₂AgTe₆. Analysis (on 0.1 gram):

Te [59.64] Au 31.41 Ag 8.95 = 100

B.B. fuses easily on charcoal, giving a bluish-green flame (Te) and yielding a white sublimate of tellurium oxide with a yellowish-white button of gold and silver.

Occurs sparingly at the Gold Dollar mine in Arequa Gulch, Cripple Creek district, Colorado. Named after Professor Victor Goldschmidt of Heidelberg.

See also Calaverite and Krennerite.

Gonnardite. A. Lacroix, Bull. Soc. Min., 19, 426, 1896. Min. France, 2, 279, 1896.

Orthorhombic? In spherules with fibrous structure. H. = 4.5-5. G. = 2.246-2.26; 2.357Gonnard. Color white. Luster silky. Translucent. Optically biaxial, positive. Bx and ax. pl. parallel to the fibers. Ax. angle very small. Composition, $(Ca, Na_2)_2Al_2Si_5O_{15} + 5\frac{1}{2}H_2O$ with $Ca: Na_2 = 5:3$. Analysis, Pisani, quoted by F. Gonnard, C. R., 73, 1448, 1871:

K₂O SiO2 Al203 CaO Na₂O H_2O 42.3 28.1 10.0 6.7 14.1 = 101.2

From cavities in the doloritic basalt of Gignat, Puy-de-Dôme and elsewhere in the same region; early analyzed by Pisani, l. c.; in Dana's Min. (p. 606) provisionally referred to mesolite. Named after M. Gonnard of Lyons, France.

Goslarite, p. 939.—Occurs in white silky fibrous masses at Altenberg (anal.). Graff, Jb. Min., 1, 76, 1899.

GÖTHITE, pp. 247, 1036.—Optical investigation of crystals from Ouro Preto, Brazil, giving results differing from those of Palla. Ax. pl. $\parallel \alpha$ (100) for red, \parallel (001) for green (and yellow); optically negative for both colors. $2E_r = 58^\circ$ 31', $2E_{gr} = 67^\circ$ 42'. $\beta = 2.5$. Pelikan, Min. petr. Mitth., 14, 1, 1894.

The otherous variety abundant at Mesabi, Minnesota, has been called mesabite by H. V.

Winchell, Trans. Am. Inst. Mng. Eng., 21, 661, 1893.

GRAHAMITE, p. 1020.—A related mineral substance occurs at various points in Texas, cf. Dumble, Trans. Amer. Inst. Mng. Eng., 21, 602, 1892.

Origin di-cussed (derived like albertite, uintabite, etc., from the oxidation of petroleum), I. C. White, Bull. G. Soc. Amer., 10, 277, 1897.

Graphite, pp. 7, 1036.—The relations of the different forms of carbon are discussed by Moissau, Ann. Ch. Phys., 8, 289, 306, 466, 1896, and C. R., 121, 538, 540, 1895. Also by Luzi, Ber. Ch. Ges., 24, 4085, 1891, 25, 214, 1378, 1892, 26, 890, 1893; Zs. Na¹. Halle, 64, 224; B. H. Zig., 52, 12, 1893 (cf. Jb. Min., 2, 241 ref., 1893). Finally by Weinschenk, Zs. Kr., 28, 291, Churchitic of Luci (cf. 20, 200), 1893; Churchitic of Luci (cf. 20, 2 1897. Graphitite of Luzi (l. c.), a supposed new form of amorphous carbon (cf. Zs. Kr., 24, 639), is shown by Weinschenk to have no real distinctive characters.

On the graphite and associated minerals of the Passau region in Bavaria, see Weinschenk,

Zs. Kr., 28, 135, 1897.

Graphitite.—See Graphite.

GREENOCKITE, pp. 69, 1036.—Occurs with wurtzite and smithsonite at the Lüderich mine, near Bensberg, Sonheur, Zs. Kr., 23, 549, 1894. Also at Laurion, Greece, (analysis,) as a yellow pulverulent incrustation on an amber-colored smithsonite (with 2.70 CdO), A. C. Christomanos, Min. petr. Mitth., 16, 360, 1896; C. R., 123, 62, 1896.

Grünlingite. W. Muthmann and E. Schröder, Zs. Kr., 29, 144, 1897.

Rhombohedral? Massive, with one distinct cleavage; resembling tetradymite. G. = 7.321.

Color gray, tarnishing black.

Composition, Bi₄TeS₃ or Bi₄Te,S) with Te:S = 1:3; this requires, tellurium 12:0, sulphur 9:1, bismuth 78:9 = 100. Analyses:

Te 12.82 S 9.31 Bi 79·31 = 101·44 12.66 9.40 78.82 = 100.88

From Cumberland, England; an approximate analysis was earlier made by Rammelsberg (Min. Ch., p. 5, 1875).

Guanabacoite, Guanabaquite. - See Quartz.

GUARINITE, p. 717.—The absence of titanium, early shown by Mauro, is confirmed by O. Rebuffat. Analysis gave:

SiO2 Y2O3(?) Fe₂O₃ Al2O3 Ce2O3 Na₂O K.O CaO 1.69 25.37 3.45 25.20 6.57 1.56 = 99.91

Calculated formula: 2(Na, K)₂O.8CaO.5(Al, Fe, Ce)₂O₃.10SiO₂. Lab. Chim. Napoli, 1894; abstract in Zs. Kr., 26, 219, 1896.

Gummite (Eliasite), p. 892.—Investigations of gases yielded, Lockyer, Proc. Roy. Soc., 59, 1, 1895.

Gunnarite. G. Landström, G. För. Förh., 9, 368, 1887. A briefly described nickel-iron sulphide containing S 45 p. c., Ni 22, Fe 33; formula suggested 3FeS₂.2NiS. Color tin-white with tinge of yellow, tarnishing yellowish brown. G. = 4.4. Not magnetic. Dissolves with difficulty in hydrochloric acid; more easily in aqua regia with separation of sulphur. Occurs embedded in pyrrhotite at Rud, parish of Skedevi, Östergötland.

Gypsum, p. 933.—Cryst.—Discussion of symbols of doubtful forms, Cesàro, Bull. Ac. Belg., 29, 385, 1895. Crystals from Girgenti with (350), Kraatz, Zs. Kr., 27, 604, 1896. Harz, forms (510), (350), etc., Luedecke, Min. d. Harzes, 377, 1896. From the environs of Paris, forms (503), (011), (031), (511), (549), (15·21·26), Lacroix, Bull. Soc. Min., 21, 39, 1898, and N. Arch. Mus. Paris, 9, 201.

On cleavage-planes, Cesàro, Ann. Soc. G. Belg., Mem., 22, 23, 1895.
On gliding-planes, Nics, Zs. Kr., 30, 662, 1899
On etching-figures, Viola, Zs. Kr., 28, 573, 1897; also K. von Kraatz, Zs. Kr., 30, 662, 1899.
Corrosion-figures due to loss of water, Sohncke, Zs. Kr., 30, 1, 1898.

Analysis of saline water contained in cavities in crystals from Sicily, Hj. Sjögren, Bull. G.

Inst. Upsala, 1, 277, 1893.

On the formation of incrustations in caves, G. P. Merrill, Proc. U. S. Nat. Mus., 17, 77, 1894. Gigantic crystals have been obtained from a cave at South Wash, Wayne Co., Utah. see Talmage, Science, 21, p. 85, Feb. 17, 1893. On the occurring forms including (450) or (340) and (013), see Moses, School Mines Q., 14, 325, 1893; also G. O. Smith, Johns Hopkins Univ., 112, May, 1894.

Crystals containing fine sand, about 50 p. c., occur at Carcote, Bolivia, Pohlmann, Vh. Ver. Santiago, 2, 238, 1892. Also others similar from the Astrakan steppes described by Doss, Zs. G.

Ges., 49, 143, 1897.

Hainite.

Jos. Blumrich, Min. petr. Mitth., 13, 472, 1893. In slender needles and plates. Twins tw. pl. a (100). Angles $ab = 78^{\circ}$ 14', $b ilde{\wedge}$ Triclinic. $hko_1 = 31\frac{1}{2}^{\circ}$. Cleavage: b (010) rather perfect; a (100) faintly indicated. Brittle, H. = 5. G.

= 3.184. Luster vitreous to adamantine. Color wine-yellow, honey-yellow, colorless. Optically +. Ax. pl. $\perp b$ and oblique to α . Ax. angle large. Dispersion strong; $\rho > v$. Birefringence low; $\gamma - \alpha = 0.012$. Pleochroism not marked; c > b > a.

Qualitative trials make it a silicate of sodium, calcium, titanium and zirconium; probably

allied to wöhlerite, mosandrite, låvenite, etc.

Occurs in crystals in cavitities, and in embedded needles or plates of the groundmass of the phonolite of the Hohe Hain, near Mildenau in northern Bohemia.

Halite, pp. 154, 1036.—Description of crystals (artif.) with h (410), n (211), p (221), r (332). Traube, Jb. Min., 2, 163, 1892. Starunia, crystals with the rare form (210), Pelikan, Min. petr. Mitth., 12, 483, 1892.

Capillary relations of crystal faces with reference to the mother liquor (also of sylvite),

Berent, Zs. Kr., 26, 529, 1896.

Investigation of tenacity, Sella and Voigt, Wied. Ann., 48, 636, 1893. Refractive indices for long waves, Rubens and Snow, Wied. Ann., 46, 529, 1892. Dispersion in the infra-red, Paschen, Wied. Ann., 53, 337, 1894. Dispersion and absorption, Rubens and Trowbridge, Wied. Ann., 60, 724, 1897; Am. J. Sc., 5, 33, 1898.

The skeleton crystals of calcite (resembling chiastolite) embedded in black slate at West Springfield, Mass. (and at other points), and variously interpreted (see Min., p. 222), are shown to be pseudomorphs after salt by Emerson, Bull. U. S. G. Surv., 126, 145, 1895.

have been deducted as impurities.

P2O5 Al2O3 SrO BaO H2O F

2. 30.20 32.67 $12.53 \quad 2.01 = 100.84 \text{ (less O } 0.84) = 100$ 19.25 4.18

Hancockite. S. L. Penfield and C. H. Warren, priv. contr.

Monoclinic. In very small, lath-shaped crystals and crystal aggregates. Habit like that of epidote. Forms a (100), c (001), e (101), r (101) and n (111). Approximate measurements of the angles gave values near those of epidote. Color of the mass brownish red; of an isolated crystal under the microscope, golden-brown for rays vibrating parallel to the axis of symmetry and somewhat variable for the direction at right angles to this. A crystal shows a delicate greenish-brown color near the termination and a pale rose at the attached end. Ax. pl. b (010). $2V = 50^{\circ}$ approximately. Cleavage basal. H. = 6-7. G = 4.03.

Analysis (Warren) as yet incomplete, but shown to be a silicate of aluminum, ferric iron, lead, calcium and strontium. Yields a small amount of water and may be expected to conform to the general formula of the epidote group. Fusible B.B. with intumescence at 3 to a black globule. Alone on charcoal becomes magnetic. With soda on charcoal gives a coating of lead oxide. Insoluble in hydrochloric acid, but after fusion dissolves and yields gelatinous silica

upon evaporation.

Prismatic cryst., Fig. 1 45.92

Occurs at Franklin, N. J., with clinohedrite, axinite, garnet, phlogopite, willemite, ræblingite, native lead and copper. Named after Mr. E. P. Hancock of Burlington, N. J.

Hanksite, p. 920.—Borax Lake, San Bernardino Co., Cal., analyses (deducting insol., 0.19 0.12l p. c.), J. H. Pratt:

CO2 SO. Na₂O CI K Tabular cryst. 46.11 5.66 43.53 2.215 2.485 = 1000

43.74

2.29

2.40 = 100

m

The chlorine is shown to be essential, and the following formula is obtained: $9Na_2SO_4.2Na_2CO_3.KCl$. Indices (Na): $\omega=1.4807$, $\epsilon=1.4614$. Am. J. Sc., 2, 133, 1896. On the formation of artificial crystals, A de Schulten, C. R., 123, 1325, 1896.

5.65

Hardystonite. J. E. Wolff, Proc. Amer. Acad. Sc., 34, 479, 1899.

Tetragonal. In granular masses showing good cleavages $\| c(001)\|$, also secondary Hanksite. cleavages $\| a(100)\|$ and m(110). H. = 3-4. G. = 3 396. Luster vitreous. Color white. Optitically uniaxial, negative. Birefringence high.

Composition essentially Ca₂ZnSi₂O₇ or 2CaO.ZnO.2SiO₂; perhaps related to ganomalite (Min., p. 422). Manganese replaces part of the zinc and magnesium of the calcium. Analysis (also others less complete):

SiO2 ZnO MnO CaO MgO Fe₂O₃ Ign. 24.30 38.10 1.50 33.85 1.62 0.57 0.52 = 100.46.

B B. fuses with difficulty to a cloudy glass, giving a red calcium flame; on charcoal glows and

yields a sublimate of zinc oxide. Gelatinizes easily with hydrochloric acid.

Obtained from the North Hill mine at Franklin Furnace, N. J. Occurs in a fine granular banded ore associated with willemite, rhodonite and franklinite. Named from the township in which the locality is situated.

HARMOTOME, p. 581.— Analysis from the Beaver mine, Thunder Bay district, Ontario, Hoffmann, Rep. G. Canada, 5, 16R, 1889-90.

Hastingsite. F. D. Adams and J. B. Harrington, Am. J. Sc., 1, 210, 1896.—See Amphibole.

Hauchecornite. Scheibe, Zs. G. Ges., 40, 611, 1888; Jb. preuss. G. Land., 1891, p. 91.

Tetragonal. Axis $\overset{1}{c}=1.05215$; 001 \wedge 101 (ce) = 46° 27‡. Forms: a (100), c (001), m (110), e (101), s (112), p (111). Augles: $cp=56^\circ$ 6', $me=*59^\circ$ 10'. In tabular crystals, pyramidal or short prismatic. H. = 5. G. = 6.4. Luster metallic. Color light bronze-yellow. Composition, (Ni,Co)₁(S,Sb,Bi)₈. Analyses, 1, R. Fischer; 2, 3, Hesse: 4, Fraatz:

S	Bi	Sb	As	Ni	Co	Fe	Zn	Pb
22.71	24.06	5.69	1.96	41.08	2.83	0.89	0.13	0.64 = 99.98

22.71	24.74	3.14	3.04	45.26	_	tr.	- C	$u \cdot 0.09 = 98.98$

Occurs with millerite, bismuthinite, etc., in cavities in siderite at the Friedrich mine, near Hamm a. d. Sieg, Prussia.

HAUSMANNITE, pp. 230, 1036.—Ilmenau, analyses, Gorgeu, Bull. Soc. Chim., 9, 653, 1893.

Hautefeuillite. Michel, Bull. Soc. Min., 16, 38, 1893, and C. R., 116, 600, 1893.

Monoclinic. In lamellar masses with radiated structure: these are made up of minute prismatic crystals with the forms a (100), b (010), m (110).

Cleavage: b perfect. H. = 2.5. G. = 2.435. Colorless. Transparent. Optically +. Ax. pl. || b. Bx_a inclined 45° to a. $2E_y = 88^\circ$. $n_y = 1.52$. Dispersion $\rho < v$; inclined strong. Composition, (Mg, Ca)₃P₂O₈ + 8H₂O. This is like bobierrite except in the calcium present. The two minerals also differ optically. Analysis:

> P2Os MgO CaO H₂O 34.27 = 99.6234.52 25.12 5.71

B.B. exfoliates and fuses to a greenish-white globule. Dissolves with difficulty in acids. Occurs with apatite, monazite and pyrite at the mines of Ödegaarden, Bamle, Norway. Named after M. Hautefeuille.

HAUTNITE, p. 431.—A variety from the Kaiserstuhl exhibits phosphorescence, Brauns, Jb. Min., 1, 84, 1899.

Heazlewoodite. W. F. Petterd, Catalogue of Minerals of Tasmania, p. 47, 1896. A sulphide of nickel and iron related to pentlandite, occurring in narrow bands in the serpentine of Heazlewood. Tasmania. Color light yellow-bronze; streak light bronze. Highly magnetic. H. = 5. G. = 4.61. Rich in nickel, up to 38 p. c., but not analyzed.

HEDENBERGITE.—See Pyroxene.

HEDYPHANE, p. 775.—Occurs in distinct crystals at the Harstig mine, Norway, with tephroite in calcite. Hexagonal; forms: $m, c, r, x, \alpha(3032), y, v, s;$ axis c = 0.7063, or near that of apatite. Cleavage x(1011). Hj. Sjögren, G. För. Förh., 14, 250, 1892; Bull. G. Inst. Upsala, 1, 11, 1893.

HEINTZITE, p. 885.—Crystals from Westeregeln examined by Bücking, Ber. Ak. Berlin, 58, 1895.

Lucdecke remarks on the identity of heintzite, hintzeite and kaliborite (Min., p. 885), Zs. Ges. Nat. Halle, 64, 423, 1892.

Helvite, p. 434.—Schwarzenberg, associated with fluorite, scheelite, etc. Analysis after deducting fluorite (corresponding to 3.16 p. c. CaO): SiO₂ 39.33, FeO 4.45, MuO 44.43, BeO 14.92, Al₂O₃ 0.77, S 5.03 = 102.93. G. = 3.202. Miers and Prior, Min. Mag., 10, 13, 1892. Discussion of composition with the conclusion that the ratio Be: Mn + Fe + Zn is constant,

= 1:1; hence the formula 3Be(Mn, Fe, Zn)SiO₄+(Mn, Fe, Zn)S, Retgers, Zs. phys. Ch., 20, 488, 1896

HEMATITE, pp. 213, 1037.—Cryst, study, Framont, Schweitzer [Inaug. Diss., Strassburg, 1892], Zs. Kr., 24, 627, 1895. Crystals from Puy de la Tache, Mont Dore, with new forms, F. Gonnard, C. R., 126, 1048, 1898. Artificial crystals with μ (0115), etc., Doss, Zs. Kr., 20, 567, 1892.

Refractive indices measured, mean value for A 2.834, for C 2.964, Wülfing, Min. petr. Mitth...

15, 68, 1895.

Occurrence of hematite and martite ores in Mexico, Hill, Am. J. Sc., 45, 111, 1893.

On the action of a powerful magnet upon minerals containing iron, as hematite, limonite, siderite, franklinite, etc., see Wilkens and Nitze, Trans. Am, Inst. Mng. Eng., 26, 351, Feb., 1896.

HERCYNITE, p. 223.—From the Veltlin forming a granular aggregate with corundum, sillimanite, etc., analysis by Linck, after deducting 2.8 p. c. pyrrhotite: Al₂O₃ 61.21, Fe₂O₃ 3.18, FeO 25.98, MgO 9.63 = 100. Ber. Ak. Berlin, 47, 1893.

Herderite, p. 760.—Shown by Penfield (Am. J. Sc., 47, 329, 1894) to be monoclinic in crystallization. Axes $\hat{a}:\hat{b}:\hat{b}=0.63075:1:0.42742$; $\beta=*89°54'$ for crystals from Paris, Me. Forms: a (100), b (010), c (001); m (110), b (120), μ (130); d (101), e (302), e (302), e (301); u (311); u (011), u (032), u (331), u (361); u (112), u (311), u (362), u (362), u (361); u (361). Also u (361). Angles u (362), u (362), u (362), u (363), u (

Crystals sometimes monoclinic in habit (Paris), but commonly penetration-twins with c (001) as tw. pl. and then pseudo orthorhombic, analogous to stilbite (Figs. 4, 5). Sections | b (010) show

for Na. Dispersion inclined, distinct, $\beta = 1.632$, $2H_a = 70^\circ$ 44' and $\therefore 2V_a = 71^\circ$ 59' for Na, Paris. Also $\beta = 1.612$, $2H_a = 66^\circ$ 0', $\therefore 2V_a = 68^\circ$ 7', again $2E_a = 128^\circ$ 25' for Na, Stopphen Sections of twins show more Stoneham. Sections of twins show monoclinic character (Figs. 10, 11 (cf. Fig. 5)).

The composition is shown to vary according to the relative amounts of fluorine and hydroxyl present, the general formula being Ca[Be(F,OH)]PO4. The pure fluor-herderite has not been noted as yet, but the Stoneham

Stoneham.

mineral is a hydro-fluor-herderite, while that from Paris (new local.) and Hebron is hydro-herderite as shown below. Greenwood is another new locality affording both kinds. Analyses, 1, 2, H. L. Wells, quoted by Penfield, also Am. J. Sc., 44, 114, 1892. Anal. 2 after deducting 5.27 insol.

G.	P2O5	BeO	CaO	H_2O	F	
						insol. $0.44 = 100.51$ = 100.18

HESSITE, pp. 47, 1037.—San Sebastian distr., Jalisco, Mexico, analysis by J. S. de Benneville, quoted by Genth and Penfield, Am. J. Sc., 43, 187, 1892.

Occurs in Yale district, Br. Columbia, Hoffmann, Rep. G. Canada, 8, 11R, 1895.

HETEROMORPHITE, p. 122,—See Plagionite.

HEULANDITE, p. 574. — Crystals described from Tulferthal, Tyrol, Habert, Zs. Kr., 28, 250, 1897:

Relation in physical characters and composition to brewsterite, stilbite, etc., discussed by

Rinne, Jb. Min., 1, 12, 1892.

Analysis from the granite on the Struth, Thuringia, Fomme, Ber. phys.-med. Soc. Erlangen, 25, 1893. Also from Anthracite Creek, Gunnison Co., Colo., Eakins, Bull. U. S. G. Surv., 90, 62, 1892. From Pula, Sardinia (anal., 2.55 p. c. BaO), Lovisato, Rend. Accad. Linc., 6 (1), 260, 1897; Riv. Min. Ital., 18, 33, 1898.

Results of treatment with sulphuric acid and hydrochloric acid, Rinne, Jb. Min., 1, 139, 1896.

HISLOPITE, p. 266.—See Calcite.

Hoeferite. Höferite, F. Katzer, Min. petr. Mitth., 14, 519, 1895.

Amorphous; earthy, granular or scaly. H. = 1-3. G. = 2.34 (air-dried). Luster glimmery to greasy. Color siskin-green, also apple- to grass-green. Streak slightly lighter. Adheres to the tongue.

Composition, 2Fe₂O₃.4SiO₂.7H₂O; or Fe₂O₃.SiO₂.H₂O if the water lost at 120° is neglected Silica 35.2, iron sesquioxide 46.5, water 18.3 = 100. Hence closely related to chloropal (non-

tronite). Analyses:

Fe₂O₃ª SiO2 Al2O3 Tgn. 36.14 1.11 18.15 = 100.6618.20 = 100.7235.88 *Includes a little FeO.

B.B. becomes reddish brown, then dark grayish black, and fuses with difficulty to a black magnetic slag. Insoluble in dilute acids, and only in part decomposed by hot sulphuric acid with

separation of pulverulent silica.

Occurs at Křitz, near Rakonitz, Bohemia, at the formerly worked antimony mines. Named after Professor H. Hoefer of Leoben.

HOPEITE, p. 808.—Crystals described from Moresnet, Belgium, G. Cesàro, Mem. Acad. Belg., 53. 1897.

HUMITE GROUP, p. 535.—Analyses on carefully selected material, identified by crystallographic study, have enabled Penfield and Howe (Am. J. Sc., 47, 188, 1894) to establish the following formulas for the three species of the group:

 $\begin{array}{ll} Chondrodite, & Mg_s[Mg(F,OH)]_2[SiO_4]_2\\ Humite, & Mg_s[Mg(F,OH)]_2[SiO_2]_3\\ Clinohumite, & Mg_7[Mg(F,OH)]_5[SiO_4]_4 \end{array}$

These formulas vary progressively by an increase of one molecule of (Mg2SiO4), and this variation is closely connected with the crystallization (see Min., p. 534). The vertical axes are in the ratio of 5:7:9, that is, of the total number of magnesium atoms present. The same result was reached at nearly the same time by Hj. Sjögren, Bull. G. Inst. Upsala, 2, 39-54, 1894.

Penfield and Howe also remarked that another member of the series, having the composition $Mg[Mg(F,OH)]SiO_4$, was to be expected, whose axial ratio should be about 1.086: 1:1 887, $\beta = 90^{\circ}$. This would then give for the vertical axes of the four compounds the ratio of 3:5:7:9 Λ member of the group having this form was later discovered by Hj. Sjögren and called *Prolectite*. Though not yet analyzed, its composition is probably expressed by the formula given above. See *Prolectite*. Cf. also Lewis, Min. Magg. 11, 137, 1896.

A full study of the form and optical characters of crystals of the three members of the group,

humite, chondrodite, clinohumite, has been also given by Sjögren, G. För. Förh., 14, 423, 1892;

Bull. G. Inst. Upsala, 1, 16-40, 1892.

A humite, occurring in serpentine in the Allalin region, Valais, Switzerland, contains no fluorine, having the composition Mg₆(MgOH)₂(SiO₄)₃, see analyses by Jannasch and Locke, Zs. anorg. Ch., 7, 92, 1894; occurrence described by Schäfer, Min. Mitth., 15, 126, 1895.

Huronite, p. 340.—Investigation, chemical and microscopic, showing it to be a basic plagioclase, more or less altered to saussurite. Barlow, Ottawa Naturalist, 9, 25; Jb. Min., 1, 430 ref., 1897.

Hydrocalcite. K. Kosmann, B.-H. Ztg., No. 38, 1892; Zs. G. Ges., 44, 155, 1892; Jb. Min., 1, 260 ref., 1894. A soft white pulpy substance occurring in a limestone cave at Wolmsdorf, Glatz, Silesia. Dried over sulphuric acid, it yields the composition CaCO(OH)₄ or CaCO₃.2H₂O. When free from water it forms a "Bergmilch," containing needle-like crystals with strong double refraction. The author would regard the "Bergmilch" as a third form of calcium carbonate.

HYDROFRANKLINITE, p. 259.—See Chalcophanite.

Hydrogiobertite, p. 305.—A mineral provisionally referred here, but perhaps new, has been noted by Brugnatelli at the amianthus deposits of Val Brutta. In loose aggregates of prismatic (orthorhombic) crystals, biaxial with parallel extinction. G. = 2.013. Analysis: CO₂ 21.85, MgO 43.32, H₂O 34.32 = 99.49. Rend. Ist. Lombardo, 30, 1109, 1897, and Riv. Min. Ital., 18, 44, 1898; also Zs. Kr., 31, 54, 1899.

HYDROHERDERITE.—See Herderite.

Hydrozincite, p. 299.—Analysis from Bleyberg, Belgium, G. Cesàro, Mem. Acad. Belg., 53, 1897.

Ice, p. 205.—Photographs of snow-crystals, G. Nordenskiöld, Bull. Soc. Min., 16, 59, 1893, and G För. Förh., 20, 163, 1898. Also by W. A. Bentley, noted by J. E. Wolff, Proc. Am. Acad., 33, 431, 1898 and Bentley and Perkins, Pop. Sci. Monthly, May, 1898.

Resemblance of spherical crystals to chondrules in meteorites, Rinne, Jb. Min., 1, 259, 1897.

Plasticity of crystals measured, Mügge, Jb. Min., 2, 211, 1895. Observed in hollow, hopper-like, hexagonal crystals, Grossmann, Proc. Roy. Soc., 54, 113, 1894.

Density determined, E. L. Nichols, Phys. Rev., 8, 21, 1899. The final results for 0° reached are: 0.9181 for natural ice, 0.9161 for artificial ice (obtained with CO2 and ether).

Iddingsite. A. C. Lawson, Bull. G. Univ. Cal., 1, 81, 1893. A mineral substance occurring in the carmeloite (augite-andesite) of Carmelo Bay, California, probably an alteration-product of chrysolite. Structure lamellar. Cleavage easy $\| a (100) \|$; also parallel to a brachydome of 80°. H. = 2·5. G. variable, 2·839 a maximum. Luster on a (cleavage) bronze-like. Color brown. Optically biaxial. Ax. plane $\| 010 \text{ and } \pm a \text{ (cleavage)}$. Pleochroism on a chestnut- and lemon-yellow. Absorption $\mathfrak{c} > \mathfrak{b} > \pi$. A silicate of iron, calcium and magnesium. B. B. infusible. Finally decomposed by hydrochloric acid. Named after Prof. J. P. Iddings of Chicago.

Idrizite. A. Schrauf, Jb. G. Reichs., 41, 379, 1892. A sulphate related to botryogen from the Idria mercury mines in Carniola. Compact to cystalline. Color yellow-gray. H=3. G. = 1829. Analysis gave: SO₃ 33.94, Al₂O₃ 8.59, Fe₂O₃ 8.70, Fe(Mn)O 3.10, MgO 4.51, H₂O 40.80 = 99.64. The formula (Mg,Fe)(Fe,Al)₂Si₃O₁₃ + 16H₂O is deduced. Insoluble in hot or cold water, but soluble in dilute hydrochloric acid.

ILMENITE, p. 217.—Discussion of composition leading to formula FeTiO₃, Th. Koenig and O. von der Pfordten, Ber. Chem. Ges., 22, 1488, 2070, 1889. This subject has been also treated

by Penfield and Foote. A new analysis (Foote) of the crystallized minera (G. = 4.345) from Layton's Farm, Warwick, N. Y., gave: ($\frac{2}{3}$) TiO₂ 57.29, SiO₂ 0.37, FeO 24.15, MgO 15.97, MnO 1.10, Fe₂O₃ 1.87 = 100.75. This (which confirms the analysis of Rammelsberg) yields the formula RO.TiO₂, where R = Mg and Fe. Hence it is inferred that the composition should be regarded as an isomorphous mixture of MgO.TiO₂ and FeO.TiO₂. Am. J. Sc., 4, 108, 1897.

Variety containing 11.9 (§) p. c. MgO, from the Magnolia district, Colorado, analyzed by Whitaker (G. = 4.44), Colorado Sc. Soc., Feb. 5, 1898.

Analysis from Bedford Co., Va., Peck. Am. Ch. J., 19, 232, 1897.

ILVAITE, pp. 541, 1037.—Occurs in crystals with rhodonite (bustamite) at Cap Bon-Garonne, Algeria, Gentil, Bull Soc. Min., 18, 410, 1895. Also occurs near the head of Barclay Sound, vancouver Is., Br. Columbia (analysis), Hoffmann, Rep. G. Canada, 5, 12R, 1889-90.

Inesite, p. 564.—Crystals from Jakobsberg, Nordmark, Sweden, described by Hamberg, show the forms: a (100), b (010), c (001), d (011), g (201), and f (301) new; analysis, G. Lundell: SiO₂ 42-92, MnO 36-31, PbO 0.73, CaO 8.68, MgO 0.37, H₂O 10.48 (0.62 over H₂SO₄) = 99.49, G. För, Förh., 16, 325, 1894.

IOLITE, p. 419.—Crystals from Selrain, Montavon and the Pitzthal in the Alps, described by *emböck (new forms 350, 120, 160, 501, 351, 261, 281), Zs. Kr., 29, 305, 1898.

Occurrence in an eruptive rock from S. Africa, Molengraaf, Jb. Min., 1, 79, 1894.

Experimental investigation of conditions of formation in a magma, Morozewicz, Min. petr. Mitth., 18, 22, 1898.

IRON, pp. 28, 1037.—Discussion of twinning structure, Linck, Zs. Kr. 20, 209, 1892; Ann. Mus. Wien, 8, 113, 1893. See also papers by Cohen on the investigation of meteoric iron, Ann. Mus. Wien, 7, 143, 1892; 9, 97, 1894; 12, 42, 119, 1897.

Many papers on meteoric from have been published (Am. J. Sc., Ann. Mus. Wien, Ber. Ak. Berlin, etc.) See also the classification of meteorites and catalogue of Vienna collection, Brezina, Ann. Mus. Wien, 10, 231, 1895.

Terrestrial native iron occurs in minute spherules in feldspar in Cameron township, Nipissing district, Ontario, Hoffmann, Rep. G. Canada, 6, 23R, 1895. Noted also in connection with the coal measures of Missouri, E. T. Allen, Am. J. Sc., 4, 99, 1897.

The Coahuila and Toluca irons yield minute quantities of platinum, also iridium, Davison,

Am. J. Sc., 7, 4, 1899.

JACKSONITE, p. 531.- Examined by N. H. Winchell, who concludes that it is optically disand thomsonite, but may perhaps be the same as lintonite (wh see). Amer. Geol., 23, 250, 1899.

Jadeite, p. 369.—Analyses of chloromelanite, Damour, Bull Soc Min., 16, 57, 1893. From Mogoung, Burma, analysis, Farrington, Proc. U. S. Nat. Mus., 17, 29, 1894.

Occurrence in Upper Burma described, Noetling, Jb. Min., 1, 1, 1896 (Rec. G. Surv. India,

26, 26, 1893); Bauer, ib., p. 18; from "Thibet," Bauer, ib., p. 85.

A soda pyroxene, allied to jadeite, occurring with allurgite, at St. Marcel, Piedmont, has been investigated by Penfield. Tough, forming an interwoven aggregate of coarse prismatic crystals. Color ash-gray. G. = 3 26-3 38. Analysis (\$): SiO₂ 54 59, Al₂O₃ 9 74, Fe₂O₃ 11 99, Mn₂O₃ 1 06, Mn₂O₃ 58, MgO 5 03, CaO 7 24, Na₂O 9 32, K₂O 0 24, H₂O 0 37 = 100 16. Am. J. Sc., 46, 291,

JAMESONITE, p. 122.—Occurs in East Kootanie, Br. Columbia, Hoffmann, Rep. G. Canada, 5. i5R. Also from Barrie township, Frontenac Co., Ontario, ib, 6, 30R, 1892-93.

On the historical relations of jamesonite and heteromorphite, see L. J. Spencer. Min. Mag, 12, 58, 1899. The crystallized jamesonite from Bolivia is stated not to conform to 2PbS.Sb₂S₃ (Rose's original formula was 3PbS Sb2S3).

JAROSITE, p. 974.—Occurs in auriferous quartzite at the Buxton mine, Lawrence Co., So. Dakota, W. P. Headden (analysis), Am. J. Sc., 46, 24, 1892. Also at the Jarilla Mts., Doña Ana Co., N. M., Hidden, Am. J. Sc., 44, 255, 1893. At Pisek, Bohemia, in crystals with c, r, s (0221), Krejči, Ber. Ak. Böhm., Feb. 21, 1896.

JARROWITE.—A local name for pseudomorphs of calcite, perhaps after celestite, from the Jarrow Docks, Durham, England (= pseudo-gaylussite, this Appendix, also Min., p. 907). See Miers, Min. Mag., 11, 264, 897.

JEFFERSONITE.—See Pyroxene.

Jordanite, pp. 141, 1039.—Further description of Binnenthal crystals, monoclinic in symmetry, with new forms, Baumhauer, Zs. Kr., 24, 78, 1894.

Josephinite. W. H. Melville, Am. J. Sc., 43, 509, 1892.

Massive, granular, forming the metallic portion of ellipsoidal pebbles whose sp. gravity is 6.204. Their complex composition is noted below; the metallic part has the following characters: Malleable and sectile. H. = 5. Luster metallic. Color gray. Opaque. Magnetic. Composition Fe₂Ni₅. Analysis gave (2): Fe 23·23, Ni 30·45. A little cobalt, copper and arsenic were also

present; phosphorus was absent.

The pebbles consist of 13:38 p. c. of silicates, of which 12:88 p. c., soluble in HCl. is serpentine; the remainder, insoluble, is perhaps bronzite. A very small amount of chromite, magnetite, pyrrhotite are also present, further a trace of chlorine (0.04 p. c.) of uncertain relations. Occur in the placer gravel of a stream in Josephine and Jackson counties, Oregon, which it is inferred probably came from an eruptive dike in the vicinity. Deposits of nickel silicate occur in Douglas Co. to the south of the locality here noted (see Min., p. 677; also awaruite, Min., p. 29).

Kainite, p. 918.—Analyses of kainite and other salts from Kalusz and Aussee, C. v. John, Jb. G. Reichs., 42, 341, 1892.

KAINOSITE -See Cenosite.

Kalgoorlite. E. F. Pittman, Rec. G. S. New South Wales, vol. 5 (separate). Massive. Fracture subconchoidal. Color iron-black. G. = 8.791. Composition, HgAu2Ag6Te6. Analysis by J. C. H. Mingaye:

Te S
$$\Lambda u$$
 Ag Hg Cu [37:26] 0.13 20.72 30.98 10.86 0.05 = 100

Occurs at the telluride deposits at Kalgoorlie, West Australia. A yellow gold telluride (G. = 9.377) referred to calaverite is associated; this gave Te 56.65, Au 41.76, Ag 0.80 = 99.21.

Kaliastrakanite. Kalium-astrakanite, J. K. van Heide, Ber. Ch. Ges., 26, 414, 1893; Naupert and Wense, ibid., p. 873 .- See Leonite.

Kaliblödite. C. A. Tenne, Zs. G. Ges., 48, 632, 1896.—See Leonite.

Kamarezite. . K. Busz, Ber. Ges. Bonn, 50, 83, 1893; Jb. Min., 1, 115, 1895.

Orthorhombic? In minute crystals, tabular ||b| and vertically striated; terminations formed by two domes (assumed as 101 and 201 (d)); crystals in cavities of a crystalline mass. Cleavage: perfect \(\psi \) b. H. = 3. G. = 3.98. Color grass-green. Ax. pl. \(\begin{aligned} \begin{

Composition, (CuOH)₂SO₄.Cu(OH)₂ + 6H₂O, thus related to langite and arnimite. Analysis

$$8O_3$$
 CuO

 17.52
 $(\frac{3}{8})$
 51.50
 0.69
 $[30.29] = 100$

B.B. in the closed glass tube decrepitates strongly and gives off first water and then sulphuric acid. Insoluble in water, but readily soluble in ammonia and acids.

From Laurion, Greece; named from Kamareza in Greece.

W. C. Brögger, Die Eruptivgesteine d. Kristianiagebietes, 1, 37, 73 (et al.), 1894; Katoforite. 3, 169, 1898 .- See Cataphorite.

Kauaiite. Goldsmith, Proc. Acad. Nat. Sc., Philad., 1894, 105. Occurs on the island Kauai, Hawaiian Is., as a soft, amorphous chalk-like mass. G. = 2.566. Analysis: Al₂(SO₄)₃ 7.18, Al_2O_3 33.40, K_2SO_4 17.00, Na_2SO_4 4.91, H_2O 31.57, X [5.94] = 100.

Kehoeite. W. P. Headden, Am. J. Sc., 46, 22, 1893.

Massive, amorphous, forming seams and bunches in the ore (argentiferous galena with sphalerite and pyrite) of the Merritt mine, Galena, So. Dakota. G. = 2.34. Insoluble in water, soluble in dilute acids; becomes insoluble after ignition. Infusible. Analysis gave, after deducting 1.76 insoluble:

P ₂ O ₅	Al ₂ O ₃	Fe ₂ O ₃	ZnO	CaO	MgO	H_2O	SO ₃
27.13	25.29	0.79	11.74	2.75	0.08	31.60	0.51 = 99.89

This corresponds to 4R₂O₃.RO.5P₂O₅.9H₂O. Of the water 14.2 per cent are lost between 105° and 110°, 3.34 between 115° and 120°; the remainder is expelled only at a red heat.

Kentrolite, pp. 544, 1039.—Described by Flink as occurring in crystals at Långban, Sweden,

with barite and calcite, as noted in Min., p. 1039.

Crystals from Jakobsberg have been examined by G. Nordenskiöld, G. För. Förh., 16, 153, 1894. Forms: e (102), v (115), u (114), o (111), s (221), z (3·15·10)? Habit usually pyramidal, o, n, with m and e small; rarely prismatic, m, o. Angles pp^{1v} (111 \wedge 11 $\bar{1}$) = 62° 31.7′, pp' (111 \wedge 111) = 92° 34′. Ax. pl. (on Långban sections) | b; also a = a, $b = \bar{b}$, c = b. Birefringence high. Occurs with inesite. - See also Melanotekite.

KERMESITE, p. 106.—Revision of crystallographic data with new forms, in part doubtful, Pjanitsky, Zs. Kr., 20, 417, 1892; cf. also Goldschmidt, Kryst. Winkeltabellen, 389, 1897. Discussion of composition, Baubigny, C. R, 119, 737, 1894.

KIESERITE, p. 932.—Occurs in crystals at Westeregeln with carnallite, etc.; new forms c (001), y (335), Bücking, Ber. Ak. Berlin, 533, 1895.

Klinozoisite. E. Weinschenk, Zs. Kr., 26, 161, 433, 1896.—See Clinozoisite.

Knebelite, p. 457.—A variety containing magnesia (4.7 p. c. MgO) has been called talk-knebelite by Igelström (Jb. Min., 1, 248, 1890). It occurs with eisenknebelite (Min., p. 457) at the Hillang mine, Dalecarlia, Sweden.

Knopite. P. J. Holmquist, G. För. Förh., 16, 73, 1894; also ibid., 15, 588, 1893.

A mineral closely related to perovskite (Min., p. 722), but containing cerium without niobium

tantalum and thus intermediate between it and dysanalyte (p. 724).

Type A is in cubo-octahedrons also with (911) and (920); color lead-gray; luster metallic; these show on a polished surface lamellæ, thus on a, parallel to the cubic edges, also diagonal. In thin sections optically biaxial with high birefringence and a lamellar structure. H. = 5-6. G. = 4.11.

Type B is in cubes, o very small or absent; penetration-twins with o as tw. pl.; without distinct

lamellæ and opaque except in fine powder. H. = 5-6. G. = 4.21-4.29. Composition corresponds to RO.TiO₂. Analyses:

1. Type A.							K ₂ O Na ₂ O 0·75 0 29	H ₂ O 1·00=99·41
2. " 3. Type B.	_ 54·12		5·1 6·81	2·63 4·19			1·99 0·38 0·79	0.51=99.83
4. "5, "	56·30 54·52	=	4·46 4·42	5·15 4·94	0·35 0·35	32·22 32 84	0·39 1·68	0 30=99·17 0·92=99·64

From Alnö, Sweden, and the neighboring mainland. Type A occurs in a limestone, crystalline, as a result of contact-metamorphism, with garnet, titanomagnetite, etc. Type B is from a brecciated limestone also in a syenitic rock. Named after Prof. A. Knop of Carlsruhe, who described dysanalyte.

Kosmochlor. Laspeyres, Zs. Kr., 27 592, 1896.—Kosmochromit, Groth, Tab. Ueb., 132, 1898. -See Cosmochlore.

Kosmochromite.—See Kosmochlor and Cosmochlore.

KRENNERITE, pp. 105, 1039.—Chester quotes the results of an examination by Penfield of crystals from Cripple Creek, Colorado, which have the habit of Fig. 1.

1. Myers obtained for them (deducting 1.21 insol.): Te 55.68, Au

43.86, Ag 0.46 = 100, or AuTe₂. The original Nagyág mineral contained silver. It is urged that calaverite is probably a sylvanite essentially free from silver. Am. J. Sc., 5, 375, 1898. See also Calaverite and Goldschmidtite.

Ktypeite. A. Lacroix, C. R., 126, 602, 1898. Calcium carbonate in the form of pisolites from Carlsbad, Bohemia, and Hammam-Meskoutine in Algeria; formerly referred to aragonite. The specific gravity varies from 2.58 to 2.70, or less than that of calcite. Birefringence = 0.020. In parallel polarized light a distorted black cross is noted, while portions give a positive black cross in converging light. Heated to low redness, the pisolites decrepitate and are finally transformed into calcite; the name given refers to this fact.

Krennerite.

Kylindrite. A. Frenzel, Jb. Min., 2, 125, 1893.—See Cylindrite.

Lagoriolite. Kalk-Natron-Granat, Lagoriolith, J. Morozewicz, Min. petr. Mitth., 18, 147, 1898.—See Garnet.

Lamprophyllite. W. Ramsay, V. Hackman, Fennia, 11, No. 2, p. 119, Helsingfors, 1894.

Also W. Ramsay, ibid., 3, No. 7, p. 45, 1890.

A mineral related to astrophyllite in form and cleavage, occurring in the nephelite-syenite of Lujavor-Urt, peninsula of Kola, Russian Lapland. Occurs macroscopically in minute flattened prisms with mica-like cleavage. Color yellow-brown and luster submetallic. Obtuse negative bisectrix with large axial angle symmetrically normal to cleavage. Pleochroism distinct, c brownyellow, b bright golden yellow. Absorption $\mathfrak{c} > \mathfrak{b}$ (for astrophyllite $\mathfrak{b} > \mathfrak{c}$). In thin sections, a form (110) was noted inclined 41° to 42° with the cleavage (100), also terminations. Twins common, parallel the direction of elongation; also polysynthetic twinning. Pleochroism distinct, a, b straw-yellow, c orange-yellow.

These observations agree with earlier ones by Ramsey (l. c.); he remarks on the resemblance to låvenite, noting also a form (210) inclined 27° to 100. G. = 3.45. Absorption $a \leq b < c$. Birefringence lower than with ægirite. Contains silica, titanium, iron, manganese, and sodium.

Lamprostibian. L. J. Igelström, G. För. Förh., 15, 471, 1893; Zs. Kr., 22, 467, 1893. A partially described mineral from the Sjö mine, Örebro, Sweden. Occurs in foliated or scaly forms, H. = 4. Brittle. Luster brilliant. Opaque and color lead-gray, except in very thin layers, then blood-red in color. Streak red. Not magnetic. Difficultly soluble in hot concentrated hydrochloric acid without evolution of chlorine. Inferred to be an anhydrous antimonate of iron and manganese (FeO, MnO).

LANARKITE, p. 923.—Artificial production of crystals, A. de Schulten, Bull. Soc. Min., 21, 142, 1898.

LANGBANITE, Longbanite, pp. 543, 1039.—Crystals from Långban examined by Hj. Sjögren (Bull. G. Iust. Upsala, 1, 41, 1892) are shown to be rhombohedral, not hexagonal. Crystals complex; habit varied, prismatic or tabular, sometimes with prominent rhombohedral development.

Also occurs with rhodonite, manganophyllite, braunite, calcite, at the Sjö mine, wid., 2, 96,

1894. Analyses by R. Mauzelius quoted by Sjögren:

H2O G. Sb₂O₃ Fe₂O₃ SiO₂ MnO₂ MnO CaO Mg = 99.68 (O 3.50) 4.65 11.76 14.15 12.23 26.15 31.54 2.24 1.61 1. Långban 4.73 11.61 14.31 11.32 27.13 32.30 2 04 0.86 0.32 = 99.89 (O 3.70)2. 36.39 1.95 0.47 = 100·16 (O 5·03) 4.83 4.33 8.95 35.15 12.9532.22 = 99.92 (O 3 09)4.60 12.51 13.98 12.82 24.36 2.40 1.11 0.52 4. Sjö mine

The formula calculated is mSb₂O₃.nFe₂O₃.pRRO₃; a relation to hematite is suggested.

Langbeinite. S. Zuckschwerdt, Zs. ang. Ch., 356, 1891. O. Luedecke, Zs. Kr., 29, 255, 1897. Isometric-tetartohedral. Observed forms: a (100), o (111), o (111), d (110), y (920), f (310), e (210), p (221), n (211). Crystals highly modified.

Fracture conchoidal. H. = 3-4. G. = 2.81-2.86. Luster greasy to vitreous. Colorless when fresh, but speedily taking up water when exposed to the air. Tasteless. Index $n_y = 1.5329$.

Shows no circular polarization.

Composition, K₂Mg₂(SO₄)₃ or K₂SO₄.2MgSO₄ = Potassium sulphate 42·1, magnesium sulphate 57 9 = 100. Analyses: 1, 2, Zuckschwerdt, Zs. ang. Ch., 356, 1891. 3, Edw. Wagner, quoted by Luedecke:

ALL STATE OF THE STATE OF	K2SO4	Mg2SO4	CaSO4	MgCl2	MgO	NaCl	H_2O
1. Colorless	41.30	58.20	_	0.22	0.08	White he	0.20 = 100
2. Grayish-white	38.99	58.55	0.57	0.55	0.13	0.43	0.78 = 100
3. Colorless. G. $= 2.81$	41.0	58.1	T		MICH SE		1.0

Occurs in beds of rock salt (taking the place of polyhalite) at Wilhelmshall near Anderbeck, and at Thiederhall; also at Westeregeln and Neu-Strassfurt as a secondary mineral; at Solvayhall near Bernburg with carnallite. Named after A. Langbein of Dessau.

LAUMONTITE, p. 587.—Anal., from the Plauenschen Grund, Dresden, Zschau, Abh. Ges. Isis, p. 90, 1893. Caucasus (also of stilbite). Zjemjatschensky, Zs. Kr., 25, 574. 1895. Grand Marais, Minn., Berkey, 23 Ann. Rept. Minn. G. Surv., p. 196.

m m

LAURIONITE, p. 171.—Twin crystals with rectangular axes from Laurion, noted by Lacroix, C. R., 123, 955, 1896. See also (new forms) G. F. Herbert Smith, Min. Mag., 12, 102, 1899. On the formation of artificial crystals, also of (PbBrOH), A. de Schulten, Bull. Soc. Min., 20,

186, 194, 1897.

See also Paralaurionite.

Lautarite, p. 1040.—Crystals examined by Osann showed the forms: b (010), c (001), m (110), l (120), r (101), n (101), q (011); habit prismatic. Angles: $mm'''=*62^\circ$ 33', $qq'=*63^\circ$ 36', $mr=*46^\circ$ 31', whence a:b:c=0.6331:1:0.6462, $\beta=73^\circ$ 38'. Zs. Kr., 23, 586, 1894. Crystals artificially produced, A. de Schulten, Bull. Soc. Min., 21, 144, 1898.

LAUTITE, p. 148.—Analysis of the pure mineral gave Frenzel: S 17.88, As 45.66, Cu 36.10 = 99.64. This leads to the formula CuAsS. Min. petr. Mitth., 14, 125, 1894.

LAVENITE, pp. 375, 1040.—Reported as occurring in nephelite-syenite of Paisano Pass, Davis Mts., Texas, Osann, 4th Ann. Rep. G. Surv. Texas, 128, 1892.

Lawsonite. F. Leslie Ransome, Bull. Univ. California, 1, 301, 1895. Ransome and Palache. Zs. Kr., 25, 531, 1895.

Orthorhombic. Axes $\check{a}:\check{b}:\dot{c}=0.66524:1:0.7385$. Forms: b (010), c (001), m (110), d (011), δ (041). Angles: $mm'''=*67^{\circ}36'$, $dd'=*72^{\circ}$

m

534'. Crystals rather large, prismatic or tabular | c, also distorted by extension of an m-face. Twins: tw. pl. m. Faces m, d

striated | intersections with c.

Cleavage: b very perfect; c perfect; m indistinct. Fracture uneven. Brittle. H. = 8.25. G. = 3.084, 3.091. Luster vitreous to Color pale blue to grayish blue. Absorption distinct; a > b > c. Pleochroism distinct in thick sections: a blue, b yellow-

Composition, H4CaAl2Si2O10 or Ca[Al(OH)2]2[SiO3]2 Groth. Hence, analogous to carpholite (Min., p. 549). Analyses, 1, Ransome; 2, Palache:

	SiO2	Al ₂ O ₃	Fe ₂ O ₃	CaO	MgO	Na ₂ O	H ₂ O
1.	38.10	28.88		18.26	0.23	0.65	11.42 = 98.39
9	37.32	35	14	17.83	and most in the	Salar Milat	11.21 - 101.50

B.B. becomes clouded and fuses easily to a colorless, blebby glass. Yields water in the closed tube. Resists acids, but easily decomposed with gelatinization after ignition. The specific grav-

ity of the ignited powder was 2.558.

Occurs in a crystalline schist (lawsonite-schist), which is associated with serpentine in the Tiburon peninsula, Marin Co., California. The schist also contains glaucophane abundantly, actinolite, margarite, epidote, garnet; also rutile, titanite. Further in glaucophane-schist at other points near Berkeley, and probably at Sulphur Creek, Sonoma Co., Cal. Also observed in the metamorphic rocks of the Piedmontese Alps near Elva, Val Maira and at other points (Franchi, Bull. Soc. Min., 20, 5, 1897, and Att. Accad. Torino, 32, 260, 1896). In the massive rocks (gabbro-diabase-peridotite types) of the Southern Apennines, on the boundary between the provinces of Basilicata and Calabria (Viola, Zs. Kr., 28, 553, 1897). In the glaucophane rocks of Corsica; also in New Caledonia (Lacroix, Bull. Soc. Min., 20, 309, 1897).

Named after Prof. A. C. Lawson of the University of California.

LAZULITE, p. 798.—Occurs with quartz near Lake Mistassini, Quebec, Hoffmann, Rep. G. Canada, 5, 66R, 1889-90.

Lead, p. 24.—Occurs with reblingite, native copper, etc., at Franklin Furnace, N. J., W. M. Foote, Am. J. Sc., 6, 187, 1898.

On artificial crystals with hexagonal pseudo-symmetry, Miers, Min. Mag., 12, 113, 1899; A.

Dick, ibid., p. 118,

LEADHILLITE, p. 921. Occurs at Granby, Mo., in well-formed prismatic crystals (Figs. 1, 2). Pirsson and Wells. Am. J. Sc., 48, 219, 1894. Wells obtained on pure material: SO₃ 7.33, CO₂ 8.14, PbO 82.44, H₂O 1.68 = 99.59, confirming the formula given by Groth (Dana Min., p. 921),

which is equivalent to PbSO_{4.2}PbCO_{3.}Pb(OH)₂. Pseudomorphs after calcite and galena alsi observed, W. M. Foote, i id., 50, 99, 1895.

Occurs in ancient lead slags from the Mendip Hills, L. J. Spencer, Rep. Brit. Assoc., 1898.

Lagorio [Trav. Soc. Nat. Varsovie, 6, xi, 7-9, 1895], Zs. Kr., 28, 526, 1897. This is the artificial mineral, $5Na_2Al_2Si_2O_8 + 4H_2O$, called by Lemberg nephelin-hydrat (see Zs. G. Ges., 39, 562, 1887).

Leonite. Kalium-Astrachauite, J. K. van der Heide, Ber. Ch. Ges., 26, 414, 1893; Naupert and Wense, wid., p. 873. Leonite, C. A. Tenne, Zs. G. Ges., 48, 632, 1896. Kaliastrakanite. Kaliblödite.

Axes $\hat{a}:\hat{b}:\hat{c}=1.03855:1:1.23365$, $\beta=*84°50'$. Forms: b (010), c (001), μ (120); d (102), δ (102); o (013), n (011); q (113), p (111), π (111). Angles: $\mu\mu' = 51^{\circ}$ 36', $nn' = 101^{\circ}$ 43', $cp = *57^{\circ}$ 1', $pp' = *74^{\circ}$ 21' Tenne.

In tabular crystals, also commonly massive. Cleavage not distinct. Fracture conchoidal. Luster vitreous. Colorless, white or yellowish. Ax. pl. $\pm b$. Bx₀ nearly $\pm c$ (001). Composition, probably K₂SO₄.MgSO₄ + 4H₂O, the potash salt corresponding to blödite (astrakanite), which is known as an artificial compound (van der Heide). Groth calls attention to the fact that the correspondence in form is apparently not what would be expected, Zs. Kr., 30, 655, 1899. Analysis, Tenne:

SO ₄	Mg	K	C1	H ₂ O	insol.
43.73	6.54	25.48	4.84	18.99	0.42 = 100

Occurs usually massive, also in crystals with kainite, in the salt deposits of Westeregeln, and Leopoldshall, Germany.

LEPIDOLITE, p. 624.—Tanagama Yamo, Japan, analysis of grayish-white or slightly pinkish plates, Genth, Am. J. Sc., 44, 387, 1892.

Composition of the lithia micas discussed by F. W. Clarke, J. Am. Chem. Soc., 15, No. 5, 1893; Bull. U. S. G. Surv., 113, 1893.

LEPIDOMELANE, p. 634.—Occurs with arsenopyrite at the Bob Neil mine, Marmora, Hastings Co., Ontario (analysis by Wait), Hoffmann, Rep. G. Canada, 6, 14R, 1892-93.

LEUCITE, pp. 341, 1041.—Discussion of optical characters, relation to analcite, etc., Klein, Jb. Min., Beil.-Bd., 11, 475, 1898 (Ber. Ak. Berlin, 290, 1897).

Occurs (chiefly altered to analcite) in a leucite-tephrite associated with elæolite-syenite at Hamburg, Sussex Co., N. J., Kemp, Am. J. Sc., 45, 298, 1893; 47, 339, 1894. In bowlders in the auriferous gravels of the Horsefly river, Cariboo district, Br. Columbia, Hoffmann, Rep. G. Canada, 7, 14R, 1894. In the Highwood and Bearpaw Mts., Montana, Weed and Pirsson, Am. J. Sc., 2, 143, 1896. In igneous rocks, Province of Rome, Viola, Jb. Min., 1, 121, 1899. In the lawar of the lower Celebes (Wichmann) lavas of the lower Celebes (Wichmann).

Lewisite. E. Hussak and G. T. Prior, Min. Mag., 11, 80, 1895.

Isometric. In minute octahedrons. Cleavage octahedral, nearly perfect. H. = 5.5. G. = 4.950. Luster vitreous to resinous. Color honey-yellow to colophony-brown. Streak light yellowish brown. Translucent.

Composition, 5CaO.2TiO2.3Sb2O5; closely related to mauzeliite. Analyses, Prior:

Sb ₂ O ₅	TiO2	CaO	FeO	MnO	Na ₂ O
67.52	11.35	15.93	4.55	0.38	0.99 = 100.72
65.52	11.70	15.47	6.79		1.06 = 100.54

Fuses rather readily on the edges in the Bunsen flame, coloring it greenish blue. In salt of phosphorus yields a bead, yellow when hot and violet when cold. Insoluble in acids.

From the cinnabar mine of Tripuhy, near Ouro Preto, Minas Geraes, Brazil; occurs in the gravel, consisting largely, after washing, of cinnabar and hematite; also xenotime, monazite, zircon, cyanite, rutile, etc. Named after Prof. W. J. Lewis of Cambridge, Eugland.

A new titano-antimonate of iron in slender six-sided (m, a) crystals of a resinous black color, G. = 4.529, was also noted, but owing to lack of material it has not yet been fully investigated.

Libollite. J. P. Gomes, Comm. Dir. Trabalhos Geol. Portugal, 3, 244, 290, 1896-98. A kind of asphaltum occurring near Libollo, in western Africa, has been called libollite by Gomes. It resembles albertite, having a pitch-black color, brilliant luster, and more or less conchoidal fracture. H. = 2.5; G. = 1.1. An analysis by A. Machado and A. Noronha gave: C 80.30, H 8.41, O 9.45, N 1.84 = 100. The ash (6.92 p. c.) has been deducted. Compare albertite and grahamite, Min., p. 1020.

LINARITE, p. 927.—From San Giovanni mine, Sardinia, crystals described by Brugnatelli (new form (718)), also optical characters. Optically – . Ax. pl. and Bx₀ \pm b. Bx_a \wedge $\dot{b}=-24^{\circ}$ (hence Bx_a nearly coincident with the normal to s (101)). $2H_a=106^{\circ}$ 21' red, = 106° 42' Na, = 110° 12' blue. $2V_a=79^{\circ}$ 59' Na. Indices $\alpha=1.8092$, $\beta=1.8380$, $\gamma=1.8593$. Riv. Min. Ital., 17, 56, 1897, and Zs. Kr., 28, 307, 1897. Occurs in New Caledonia, Lacroix, C. R., 118, 553, 1894.

Lindesite. L. J. Igelström, Zs. Kr., 23, 590, 1894.—See Urbanite.

LINTONITE, p. 607.—Shown by N. H. Winchell to differ in optical characters from thomsonite. with which it agrees chemically and to which it has been referred. Amer. Geol., 22, 348, 1898.

LIROCONITE, p. 853.—Cornwall, analysis by Church, Min. Mag., 11, 3, 1895.

Löllingite, p. 96.—Occurs at Drum's Farm, Alexander Co., N. C., massive, G. = 7.031, analysis, Genth: As 27.93, S 0.77, Fe 70.83, Cu tr. = 99.53. Am. J. Sc., 44, 384, 1892.

Also occurs in Galway township, Peterborough Co., Ontario, analysis (2.88 p. c. Co) by Johnston, Hoffmann, Rep. G. Canada, 6, 19R, 1892-93.

Longbanite.—See Långbanite.

Lorandite. J. A. Krenner [Mat. es Értesitö, 12, 473, 1894; 13, 258, 1895], Zs. Kr., 27, 98, 1897. Goldschmidt, Zs. Kr., 30, 272, 1898.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c}=1.3291:1:1.0780$. $\beta=52^{\circ}\ 27'$ Goldschmidt. Forms: a (100, t).

Monocinic. Axes $a: o: c = 1.5291; 1: 1.0100. \rho = 52.51 \text{ folias}$ $b (010). c (001. a); q (210). c (320). m (110. x), e (120). \mu (130). \mu (140)?; <math>b (205). d (101). \kappa (201. c); \alpha (034). h (045). w (021): v (112). s (112). z (111); g (425). f (212). v (748). j (536); i (324)?, l (122). \delta (1.13.8)?; y (312). n (525). p (212). r (211). <math>\zeta (324). k (322). \eta (2.5.10)?$ Angles $ac = 52^{\circ} 57'. mm''' = 93^{\circ} 0'. qq''' = 55^{\circ} 24'. c\kappa = 89^{\circ} 29'.$ Crystals highly modified, often tabular, or prismatic (m); faces in the state of the

in prismatic zone vertically striated, especially m (x). A similarity to miargyrite is noted (cf. Gdt.). Cleavage: a perfect; c and d (101) good. Flexible, separating easily into cleavage lamellæ. H. = 2-2·5. G. = 5.529 Loczka. Luster metallic-adamantine. Color cochinealto carmine-red, often dark lead-gray on the surface and frequently covered with an ocher-yellow powder. Streak dark cherry-red. Translucent to transparent. Refractive index high.

Lorandite, Gdt.

Composition, a sulpharsenide of thallium, TlAsS2 or Tl2S. As2S3 = Sulphur 18.7, arsenic 21.9. tnallium 59.4 = 100. Analysis by J. Loczka:

S 19.02 As [21.47] Tl 59.51 = 100.

B.B. on charcoal fuscs easily, colors the flame bright green, yields arsenical fumes and volatilizes completely. In the closed tube fuses and yields a black sublimate of thallium sulphide, also an orange one of arsenic sulphide, further some arsenic oxide. Soluble in nitric acid with separation of sulphur.

From Allchar in Macedonia, where it occurs in crystals implanted upon realgar.

The position of Goldschmidt is here provisionally accepted: 100, 001, 110, 201 of Gdt. correspond to 101, 100, 121, 001 of Krenner.

Lossenite. L Milch, Zs. Kr., 24, 100, 1894. Orthorhombic. Axes $\check{a}:\check{b}:\dot{b}=0.843:1:0.945$ approx. In acute pyramids, resembling scorodite in angle, with $pp'=79^\circ$ and $pp'''=64^\circ$. Color brownish red, often altered on the surface. Optically +. Ax. pl. $\parallel a$. Bx. $\perp c$. Composition probably 2PbSO_4 . $3(\text{FeOH})_3\text{As}_2\text{O}_8 + 12\text{H}_2\text{O}$. Analysis:

Fe₂O₃ SOs PbO H.O H.O As₂O₅ 33.44 3.74 10.63 34.53 3.74 11.81, SiO₂ 1.13, CaCO₃ 1.46 = 100.48 * Water of crystallization.

r'rom Laurion, Greece, where it was found in a drusy ferruginous quartzose rock.

LOVENITE. - See Lavenite.

Lutécine, Lutécite. Michel-Lévy and Munier-Chalmas, Bull. Soc. Min., 15, 159, 1892.—See Quartzine.

Mackintoshite. W. E. Hidden, Am. J. Sc., 46, 98, 1893.

Tetragonal, in square prisms with pyramid; commonly massive, nodular. Fracture small subconchoidal. H. = 5.5. G. = 5.438. Luster dull. Color black. Opaque. In composition allied to thorogummite (Min., p. 893); perhaps UO2.3ThO2.3SiO2.3H2O. Analyses, W. H. Hillebrand:

SiO₂ UO₂ ZrO₂? ThO₂, Ce₂O₃ La₂O₃, Y₂O₃ PbO FeO CaO Mg() K₂O (Na,Li)₂O P₂O₅ H₂O 13.90 22.40 0.88 45.30 1.86 3.74 1.15 0.59 0.10 0.42 4.81 = 96.50 13.92 21.86 3.92 0.13 undet. 0.44 0.70 0.350 0.46 * Above 100° 4.31, below 0.50. b Below 100°.

From the gadolinite locality of Llano Co., Texas. The alteration of mackintoshite seems to have yielded thorogummite. Named after James B. Mackintosh (died 1891), chemist of New York City.

MAGNESIOFERRITE, p. 226.—Roc de Cuzeau, Mont Dore, France, crystals (largely made up of plates of hematite) similar to those of Mte. Somma, Lacroix, Bull. Soc. Min., 15, 11, 1892.

Magnesite, p. 274.—Crystals from Val Lanterna, Brugnatelli, Zs. Kr., 31, 55, 1899.

Magnetite, pp. 224, 1041.—Occurs in cubic crystals, in part penetration-twins, at the Moss mine, Nordmark, Sweden. Hj. Sjögren, Bull. G. Inst. Upsala, 2, 63, 1894.

Crystals described from Acquacetosa, near Rome, new forms (520), (331), Zambonini, Riv. Min.

Ital., 21, 21, 1898.

Magnetic properties of crystals investigated, Weiss, Bull. Soc. Min., 20, 137, 1897.

Present in various minerals (hematite, etc.), and thus giving them magnetic properties, Liversidge, Trans. Austr. Assoc. Adv. Sci., 1892.

Occurs at the Kodúr mines, Vizagapatam, Madras, India, containing manganese (2.08 Mn₂O₄) and alumina (2.54 p. c. Al₂O₃), G. = 5.045. Holland, Rec. G. Surv. India, 26, 164, 1893.

Ch. Friedel shows that slow heating in the air at a rather high temperature changes crystals to hematite (i.e. martite). Bull. Soc. Min., 17, 150, 1894.

A titaniferous variety containing nickel occurs in Eastern Ontario, W. G. Miller, Rep't Bureau of Mines, Toronto, 7, Part III, p. 230, 1898.

Magnetostibian. L. J. Igelström, Zs. Kr., 23, 212, 1894. A partially investigated mineral from the Sjö mine, Örebro, Sweden. Occurs in grains and granular aggregates. Luster metallic. Color and streak black. Magnetic. An analysis (after deducting 68 6 p. c. impurities, CaCO₃, MgCO3 and tephroite) gave:

Sb2O5 9.83 As₂O₅ 1.54 Fe₂O₅ 12.36 FeO 17.16 MnO 59.11 = 100

MAGNOCHROMITE, p. 228.—See Chromite.

MAGNOFRANKLINITE.—A local name (credited to Koenig) for a highly magnetic franklinite containing little zinc. From Sterling Hill, N. J.; see Rep. G. Surv. N. J., 2, (1) 14, 1892; also Chester, Dict. Names Minerals, 164, 1896.

MALACHITE, p. 294.—Artificial formation by a new process, A. de Schulten, C. R., June 8, 1896.

Maltesite. J. J. Sederholm, G. För. Förh., 18, 390, 1896.—See Andalusite.

Manganandalusite H. Bäckström, G. För. Förh., 18, 386, 1806.—See Andalusite.

Manganberzeliite. L. J. Igelström, Zs. Kr., 23, 592, 1894.—See Berzeliite.

Manganite, p. 248.—Crystals from the Harz described, Luedecke, Min. d. Harzes, 237, 1896. Analyses, Ilfeld, Gorgeu, Bull. Soc. Chim., 9, 650, 1893.

MANGANOSITE, p. 207.—Discussion of origin at Långban and Nordmark, Hj. Söjgren, G. För., 20, 25, 1898.

Marcasite, pp. 94, 1041.—Crystals from Capo Schino, Sicily, described, G. La Valle, Riv. Min. Ital., 13, 3, 1893.

Occurs at Pontpéan, Ille et Vilaine, forming with galena pseudomorphs after pyrrhotite with regular orientation of its minute crystals, Lacroix, Bull. Soc. Min., 20, 223, 1897, and C. R., 125, 265, 1897.

Occurs in spear-head forms in the Raritan clay at Sayreville, near New Brunswick, N. J.,

Hamilton, Proc. Acad. Nat. Sc. Philad., 485, 1898.

See also Pyrite.

MARIPOSITE, p. 1041.—Analyses by Hillebrand of green and white varieties are quoted by Turner. The former (G. = 2.817) contains chromium, the latter has none (G. = 2.787); a similarity to pinite is noted Am. J. Sc., 49, 377, 1895,

Marshite. Liv Kr., 24, 207, 1894. Liversidge, C. W. Marsh, Proc. Roy. Soc. N. S. W., 26, 326, 1892. Miers, Zs.

Isometric-tetrahedral. Fracture subconchoidal. Brittle. Luster adamantine. Color oil-brown. Streak orange-yellow. Translucent. Consists essentially of cuprous iodide, Cu₂I₂. Occurs in cerussite or anglesite at the Broken Hill mines, New South Wales.

MARTITE, p 216.—See Magnetite.

Masrite. H. Droop Richmond and Hussein Off, J. Ch. Soc., 61, 491, 1892. A fibrous alum from Egypt, containing a small amount of cobalt and the supposed new element masrium (called after the Arab name of Egypt). Composition, RO.Al₂O₃.4SO₃.20H₂O. Analysis:

MnO CoO FeO H₂O Al2Os Fe₂O₃ MsO SOs 36.78 10.62 1.63 0.20 2.56 1.02 4.23 [40.35] insol. 2.61 = 100

Massicot, p. 209.—Occurs in the lead slags of Laurion, Greece.

Mauzeliite. Hj. Sjögren, G. För. Förh., 17, 313, 1895.

Isometric. In octahedrons, o(111), with a(100) and m(311). H. = 6-6.5. G. = 5.11. Color dark brown, lighter in fragments, and of the powder light yellow or yellowish white. Translucent.

In composition, a titano-antimonate of lead and calcium chiefly. Assuming that the water is present as (CaOH), the ratio calculated is RO:TiO₂:Sb₂O₅: F = 4:1:2:1. It is related to lewisite, p. 42 Analysis, R. Mauzelius:

Sb₂O₅ TiO₂ PbO FeO MnO CaO MgO K₂O Na₂O F H₂O \$ 59.25 7.93 6.79 0.79 1.27 17.97 0.11 0.22 2.70 [3.63] 0.87=101.53 less (O=F) 1.53=100

Occurs with svabite and calcite at Jakobsberg, Wermland, Sweden; these minerals form narrow veins in a mixture of hausmannite, limestone, a yellow garnet, schefferite and manganophyllite.

Melanophlogite, pp. 194, 1041.—Discussion of conditions of formation, G. Friedel, Bull. Soc. Min., 15, 49, 1892; Bombicci, *ibid.*, p. 144. Investigated by Bombicci, Accad. Sc. Ist. Bologna, March 22, 1891.—Giona, G. Spèzia, Riv. Min. Ital., 11, 37, 1892.

Melanostibian. L. J. Igelström, G För. Förh., 14, 583, 1892; Zs. Kr., 21, 246, 1893. sive, foliated; also in microscopic crystals H. = 4. Luster metallic. Color black. Streak cherry-red. Composition, perhaps 6(Mn, Fe)O. Sb₂O₂. Analysis (assuming the state of oxidation as given):

> Sb2O3 FeO MnO CaO MgO H_2O 27.30 29.62 1.97 37.50 1.03 1.06 = 98.48

From the Sjö mine, Örebro, Sweden, where it occurs in veins in dolomite.

MELANOTEKITE, p. 545.—Occurs in prismatic crystals with a (100), m (110), d (110), o (111),

Melanotekite, New Mexico.

16, 158, 1894; in habit and angles resembling kentrolite.

Also found at Hillsboro, New Mexico, associated with cerusite and a brown jasper-like material, C. H. Warren. Crystals (Figs. 1, 2) with forms a (100), b (010), m (110), n (130), k (150), o (111). Habit like kentrolite, angles $oo'' = *119^\circ$ 13', $oo''' = *55^\circ$ 0', $mm''' = 64^\circ$ 44' (calc.). Axes $\check{a}: \bar{b}: \dot{c} = 0.6338: 1: 0.9127$ (Nordenskiöld obtained 0.6216: 1: 0.9041). Analysis gave:

SiO2 PbO Fe2O3 H₂O 0.82 \$ 5·854 15.49 55.56 27.51 0.68 = 100.06

whence the formula Fe4Pb3 Si3O10 or (Fe4O3) Pb3 (SiO4)3. It is shown that the analogous formula $(Mu_4O_3)Pb_3(SiO_4)_3$ probably belongs to kentrolite (p. 39, Min. p. 544). Am. J. Sc., 6, 116, 1898.

MELANTERITE, p. 941.—Laurion, Greece, analysis of zinc-bearing variety, L. Michel: SO₃ 28·85, FeO 17·74, ZnO 8·93, H₂O 44·21 = 99·72. Bull. Soc. Min., 17, 204, 1894.

Discussion of the chemical constitution and genesis of various iron sulphates, Scharizer, Zs. Kr., 30, 209, 1898.

MELILITE, p. 474 —Crystals from Vesuvius described with new form (201), Kaiser, Zs. Kr.,

31, 24, 1899. Discussion of microscopic structure, Gentil, Bull. Soc. Min., 17, 108, 1894. Composition discussed, Bodländer, Jb. Min., 1, 15, 1393; cf. Vogt, ibid., 2, 73, 1892. Occurs at Ste. Anne de Belleville, near Montreal, Canada, in alnoite, F. D. Adams, Am. J. Sc., 43, 269, 1892; also (optically positive) in alnoite of Manheim, N. Y., C. H. Smith, ibid., 46, 104, 1893. Cf. Berwerth, Ann. Mus. Wien, 10, 75, 1895.

Formed by the burning of Portland cement, Bodländer, Jb. Min, 1, 53, 1892.

A soda-alumina silicate, tetragonal, and resembling melilite in habit, which occurs in the new rock-type farrisite, from Norway, has been called natronmelilith by Brögger (Die Eruptivgesteine d. Kristianiagebietes, 3, 69, 1898). It is largely altered to natrolite. A later examination (ibid., p. 366) has led to the conclusion that it should perhaps be referred to the Scapolite Group.

A new type of rock containing melilite, a chrysolite-melilite-leucite rock, occurs as a volcanic cone at San Venanzo, Umbria, Italy, and is called venanzite, by Sabatini Boll. Com. Geol., Sept., The same rock was later described by Rosenbusch and by him named euctolite (Ber. Ak. Berlin, 110, 1899).

Mesabite.—See Göthite.

METABRUSHITE, p. 828.—Brushite, or metabrushite, occurs with minervite (wh. see) in the lime-stone caves of the Nummulite limestone of Southern France; thus in the Grotto of Minerva on the Cesse, Valley of the Aude, Gautier, C. R., 116, 1171, 1893.—See also Brushite.

METACINNABARITE, pp. 62, 1041.—Idria, discussion of occurrence, paragenesis, etc.; crystals are dodecahedral in habit with also a (100) and o (111), Schrauf, Jahrb. G. Reichs., 41, 349, 1891.

Occurs at San Joaquin. Orange Co., California, in iron-black particles in barite; G. = 7.706; analysis: S 13.69, Hg 85.89. Cl 0.32 = 99.90, Genth, Am. J. Sc., 44, 383, 1892.

Also occurs amorphous filling cavities in quartz on the west side of Read Is., near Vancouver Is., Br. Columbia, Hoffmann, Rep. G. Canada, 5, 66R, 1889-90.

Metadesmine. F. Rinne, Jb. Min., 1, 57, 1897.—See Stilbite.

Metanocerine. Sandberger, Jb. Min., 1, 221, 1892. A partially investigated mineral occurring with the babingtonite of Arendal in white crystals resembling bromlite; H. = 4.5. From the qualitative analysis a possible relation to nocerite (Min., p. 174) is inferred, and the name provisionally given refers to this.

Metascolecite. F. Rinne, Jb. Min., 2, 51, 60, 1894.—See Scolecite.

MICA GROUP, p. 611.—Discussion of the crystalline form based upon the percussion-figure, the etching-figures, etc. It is concluded that probably phlogopite, biotite and perhaps the lithia micas should be regarded as triclinic; muscovite appears to be monoclinic. T. L. Walker, Am. J. Sc., 7, 199, 1899.—See also G. Friedel, Bull. Soc. Min., 19, 18, 1896.

General discussion of chemical composition, F. W. Clarke, Bull. U. S. G. Surv., 113 and 125, 1893; Clarke and Schneider, Am. J. Sc., 43, 378, 1892.
 Analyses are quoted by Stelzner, Zs. prakt. Geol., 4, 377, 1896.

MICROLINE, pp. 322, 1042.—From the Spessart, analysis, E. Philippi, Ber. Senck. Nat. Ges., 1896, p. 125. Analyses, Jones Falls, Maryland, Hillebrand, Bull. U. S. G. Surv., 113, 110, 1893.— See also Anorthoclase.

MICROLITE, pp. 728, 1042.—Igaliko, Greenland, approximate analysis of impure material, G. Nordenskiöld, G. För. Förh., 16, 336, 1894.

Occurs at Rumford, Me., in honey-yellow crystals, G. = 5.17 (Penfield), Foote, Am. J. Sc.,

1, 461, 1896.

Miersite. L. J. Spencer, Nature, 57, 574, 1898.

Isometric-tetrahedral. In small cubes, with o (111) and o_1 (111), the latter differing in size but not in luster. Twins; tw. pl. o. Cleavage; dodecahedral. Brittle. Luster adamantine. Color pale to bright yellow. Streak the same or deeper. Optically isotropic.

Composition essentially silver iodide, probably Ag₂I₂, analogous to marshite, Cu₂I₂ (this Ap-

pendix, p. 45), and nantokite, Cu₂Cl₂ (Min., p. 154).

From the Broken Hill mines, New South Wales, associated with chalcocite, garnet, quartz; also with malachite, anglesite. Named after Prof. H. A. Miers of Oxford, England.

MILARITE, p. 312.—Analysis, Treadwell, SiO₂ 72.79, Al₂O₃ 10.12, CaO 11.32; MgO tr., K₂O 4.32, Na₂O 0.21, H₂O 1.19 = 100. Jb. Min., 1, 167, 1892.

MILLERITE, p. 70.—Occurrence (also of other nickel minerals) in the Rhine region, Laspeyres, Vh. Nat. Ver. Bonn, pp. 143, 375, 1893.

MILOSIN. - See Avalite.

Minervite. A. Gautier, Ann. Mines, 5, 23, 1894; C. R., 116, 928, 1022, 1171, 1271, 1893. An aluminium phosphate, Al₂O₃. P₂O₅. 7H₂O, occurring with phosphate of lime as a white plastic mass mixed with clay, etc., in the "Grotte de Minerve" on the shores of the Cesse, Valley of the Aude, France. Analyses of impure material are given. The above formula applies to airdried material.

Mitchellite. J. H. Pratt, Am. J. Sc., 7, 286, 1899.—See Chron

MIZZONITE, p. 471.—Franco obtained $ar = 67^{\circ}$ 56' and 67° 58'; also $\omega_y = 1.563$, $\epsilon_y = 1.545$, Giorn. Min., 5, 193, 1894.—See also Wernerite.

MOLYBDENITE, pp. 41, 1042.—Crystals from Frankford, Penn., examined by A. P. Brown, are hexagonal in habit, prismatic or barrel-shaped, resembling some mica. Forms as interpreted: c (0001), m (1010) o (1011), p (2021), q (3051). Angles: $co = *65^{\circ}$ 35', $cp = 77^{\circ}$ 13', $cq = 81^{\circ}$ 24'; axis c = 1.9077. Proc. Acad. Nat. Sc. Philad., 210, 1896

Occurs in large crystals (3.5 × 5.5 in. and 2 or 3 in. thick) with native bismuth, etc., at Kingsgate, Glen Innes, N. S. W., Liversidge, Rec. Austr. Mus., 2, 1892.

Monazite, p. 749.—Cryst.—Nil-Saint-Vincent, Belgium, Franck, Bull. Acad. Belg., 21, 40, 1891. Brazil, Hussak, Min. petr. Mitth., 12, 470, 1892. South Lyme, Conn., occurs in distinct crystals, Matthew, School Mines Q. 16, 232, 1895.

Occurrence on New York island. Niven, Am. J. Sc., 50, 75, 1895. Distribution in European rocks, Derby, Min. Mag., 11, 304, 1897. Distribution in U. S., and elsewhere, U. S. G. Surv., 16 Ann. Rept., Pt. IV, p. 667. Occurs rather abundantly in the gold sands of southern Idaho, Lindgren, Am. J. Sc., 4 63, 1897.

Yields helium and other gases, Ramsay, Collie and Travers, J. Ch. Soc., 65, 684, 1895; also Ramsay and Travers, Proc. Roy. Soc., 60, 442, 1897. Also Erdmann, Ber. Ch. Ges., 29, 1710, 1896.

1896.

Mordenite, p. 573.—Relation in composition to ptilolite, Clarke, Am. J. Sc., 44, 101, 1892.

Morenosite, p. 940.—Zermatt, analysis of magnesium variety, Pisani: SO₃ 28.7, NiO 18.5, MgO 6.5, $H_2O 46.5 = 100.2$. Bull. Soc. Min., 15, 48, 1892.

MORONITE.—A mixture of calcium carbonate with the remains of foraminifera, cf. S. Calderon [Anal. Soc. Espagñ. Hist. Nat., 23, 21, 1894], Zs. Kr., 26, 331, 1896.

Mossite. W. C. Brögger, Vidensk Skrift. I. Math.-nat. Klasse, No. 7, Christiania, 1897.

Tetragonal. Axis $\dot{\ell}=0.6438$; 001 \wedge 101 = 32° 46½'. Forms: a (100), c (001), m (110), ϕ (6.9.10), y (305), e (101), v (301), s (111) $ep=42^{\circ}$ 19', $mp=*47^{\circ}$ 41'. Crystals small; commonly twins with tw. pl. e, these often prismatic, clongated parallel a pyramidal edge analogous to twins of rutile (cf. Fig., Min., p. 1047, and Fig. 1 of tapiolite, this Append.), hence simulating orthorhombic forms; also drillings, fourlings. Cleavage none. G. = 6.45. Luster metallic, brilliant.

Composition, Fe(Nb,Ta)2O6, like tapiolite, with probably Nb: Ta = 1:1. Analysis, G.

Thesen:

Nb2O6, Ta2O6 SnO2 FeO 82.92 0.18 16.62 = 99.72

Occurs very sparingly, with yttrotantalite and columbite on feldspar, in a pegmatite vein at Berg near Moss, Norway.

Munkforssite. L. J. Igelström, Zs. Kr., 27, 601, 1896.

Massive, foliated or small granular; the grains apparently monoclinic in crystallization. Cleavage in one direction. H. = 5. Color white or pale reddish.

Near symbergite in composition. Analysis after deducting 10.74 p. c. insol.:

SO₃ 15·12 P2O 16.01 Al₂O₃ 29.23 CaO 36.64 $ign.(SO_3?) 3.00 = 100$

B. B. infusible and does not yield a blue color with cobalt solution; only partially decomposed by acids.

Occurs in the cyanite of a damouritic quartzite at Horrsjöberg, Westanå, and Dicksberg in the Ransät parish, Wermland, Sweden. Named from the Munkforss iron-works.

L. J. Igelström, Zs. Kr., 28, 311, 1897. Near svanbergite in composition, containing P2O5, SO3, FeO, CaO, but not analyzed. Occurs foliated and crystalline; colorless to yellow. From Munkerud, near Dicksberg, Wermland, Sweden.

Muscovite, p. 614.—Percussion-figure shown to deviate from the assumed normal position; thus the angle between the rays opening opposite b (010) was found to be 53° to 56° instead of 60°; similarly in other micas, e.g. in phlogopite (Ceylon) this angle was 63½°. T. L. Walker, Am. J. Sc. 2, 5, 1896.

From Matawatchan, Renfrew Co., Ontario, analysis by Wait (1.26 Cr₂O₃), quoted by Hoff-

mann, Rep G. Canada, 5, 21R, 1889-90.

Fuchsite (2.73 p. c. Cr₂O₃) occurs in Habersham Co., Ga., in emerald-green scales, analysis, Genth, Am J. Sc., 44, 388, 1892. On the occurrence of fuchsite in the Swiss Alps, see J. Erb, Nat. Ges. Zürich, 43, 276, 1898.

Analysis of compact variety, G. Friedel, Bull. Soc. Min., 21, 135, 1898.

On certain new silicates yielded in synthetic experiments, C. and G. Friedel, Bull. Soc. Min., 22, 17, 20, 1899.

See Baddeckite.

NAGYAGITE, p. 105.—Occurs at the Sylvia mine, Tararu creek, New Zealand, J. Park, Austr. Assoc. Adv. Sci., 3, 150, 1891.

NANTOKITE, p. 154.—From the Broken Hill mines, New South Wales, Liversidge. Occurs in indistinct crystals in a matrix of cuprite with native copper and cerussite. G. = 4.7. Analysis by Carmichael: Cl 35.92, Cu 64.28 = 100.20. Also Min. Mag., 10, 326, 1894 (but here Cl = 35.82). [Proc. R. Soc. N. S. W., 28, 96, June 6, 1894.]

See also Marshite and Miersite.

Nasonite. S. L. Penfield and C. H. Warren, priv. contr.

Massive, granular, cleavable and probably monoclinic. Luster greasy. Color white. Composition, (Ca, Pb)10 Cl2Si6O21. Analysis:

PbO CaO MnO ZnO FeO Cl (OH) SiO2 18.47 65.84 11.20 0.90 0.84 0.10 2.80 0.26 = 100.41

B.B. on charcoal, decrepitates, but fuses easily when powdered, giving a lead flame and coating of PbO. In closed tube decrepitates, giving off a little H2O and an abundant sublimate of lead chloride.

Occurs at Franklin Furnace, N. J., associated with brown garnet, yellow axinite, glaucochroite (wh. see) and a little franklinite. Named after Mr. F. L. Nason, formerly of the Geological Survey of the State of New Jersey.

NATROLITE, pp. 600, 1042.—Crystals described, from Puy-de-Dôme, Gonnard, Bull. Soc. Min., 221, 1892. Also, with analysis, Magnet Cove, Arkansas, W. H. Melville, Bull. U. S. G. Surv., 15, 221, 1892. 90, 38, 1892.

Analysis, from the Plauenschen Grund, Dresden, Zschau, Abh. Ges. Isis, p. 100, 1893. Weed and Pirsson conclude from the analysis of a portion (G. = about 2 30) of the leucite rock called by them missourite, from the Highwood Mts., Montana, that it probably consists of analcite and a new potash zeolite, $(K_2, Ca)Al_2Si_3O_{10}.2H_2O$. This would correspond to a natrolite containing potassium and calcium in place of sodium. Am. J. Sc., 2, 319, 1896.

Natronberzeliite, - See Berzeliite.

Natrongranat. - See Garnet.

Natronmelilith. - See Melilite.

Natronmikroklin.—See Anorthoclase.

Natronrichterite. - See Astochite and Richterite.

NEOCHRYSOLITE, p. 455.—Identical with fayalite according to Wichmann, Zs. Kr., 28, 538, 1897.

NEPHELITE, pp. 423, 1042.—Crystals from Vesuvius, with new form (5160), Kaiser, Zs. Kr., 31, 24, 1899. Relation to davyne also discussed.

Discussion of symmetry of crystallization and twinning, etc., as revealed by etching, etc., Traube, Jb. Min., Beil.-Bd., 9, 466, 1895.

Occurrence in New Zealand, Ulrich, Trans. Austr. Assoc. Sc., 3, 127, 1891.

From the nephelite syenite of Dungannon, Ontario, analysis by Harrington, Am. J. Sc., 48, 16, 1894.

Artificial formation of a purely potash compound, Duboin, C. R, 115, 56, 1892.

G. Flink, G. För. Förh., 15, 196, 467, 1893; Zs. Kr., 23, 346, 1894. G. Norden-Neptunite.

**Sk\(\bar{v}\) id. G. F\(\bar{v}\), F\(\ba

d (301): s (111), v (221); o (111); u (612). Angres: mm = 39 40, cs = 30 51, cm = 10 43, $ss' = 55^\circ$ 36'. In prismatic crystals, with c (001) and u (512) prominent. Twins: tw. pl. c. Cleavage: m distinct. Fracture conchoidal. Brittle. H. = 5-6. G. = 3·234. Luster vitreous. Color black; in very thin splinters deep blood-red. Streak cinnamon-brown. Nearly opaque. Optically +. Ax. pl. \pm b. Bx \uparrow b = \pm 18°. Pleochroic; absorption r > b > a. In composition, a titano-silicate of iron (manganese) and the alkali metals; formula

 $\hat{R}_2\hat{R}$ Ti $\hat{S}_4\hat{O}_{12}$, with $\hat{R}=\hat{N}a:K=3:1$ and $\hat{R}=\hat{F}e:Mn=2:1$. Neptunite is therefore related in composition to titanite, and as Flink shows there is also a rather close correspondence in angle. Analyses, 1, Flink. 2, O. A. Sjöström, G. För. Förh., 15, 393, 1893.

SiO2 TiO2 FeO MnO CaO MgO K_2O Na₂O 51.53 18.13 10.91 4.97 4.88 1. 0.49 9.26 = 100.175.32 51.93 17.45 10.23 5.71 9.63 = 100.98

Obtained from Greenland, the locality probably not the well-known Kangerdluarsuk, but rather Narsasik, near Igaliko. It occurs closely associated with ægirite (whence the name), also eudialyte, arfvedsonite, etc.

Nickel-skutterudite.—See Skutterudite.

NITER, p. 871.—Occurs in cavities of the leucite rocks of North Table Butte, Leucite Hills, Wyoming. In the rock of the Boar's Tusk of the same region, soda niter also occurs. Cross, Am. J. Sc., 4, 118, 1897.

Northupite. Warren M. Foote, Am. J. Sc., 50, 480, 1895. J. H. Pratt, ibid., 2, 123, 1896. Isometric, in octahedrons. Cleavage none. Fracture conchoidal. H. = 3.5-4. G. = 2.380. Colorless when perfectly pure; also pale yellow to gray and brown. Index $n_y = 1.5144$ Na. Composition, MgCO3 Na2CO3. NaCl. Analysis, Pratt.

CO₂ 35·43, MgO 16·22, Na₂O 24·90, Cl 14·23, Na $9\cdot22 = 100$.

B.B. fuses at 1 with frothing to a white alkaline mass; colors the flame intense yellow. Easily soluble in acids.

Occurs in a clay at a depth of 450 feet at Borax lake, San Bernardino Co., California. after Mr. Northup, who first obtained the mineral.

This compound has been formed synthetically by A. de Schulten, Bull. Soc. Min , 19, 164, 1896.

OCTAHEDRITE, pp. 240, 1043.—Cryst.—Bourg d'Oisans, new form σ (11·3·44)?, K. Busz, Zs. Kr., 20, 557, 1892. Jämtland, Hamberg. G. För. Förh., 16, 307, 1894. Glacier de la Meije, Hautes Alpes, Lacroix, C. R., 122, 1429, 1896.

Investigation of crystalline structure, Baumhauer, Zs. Kr., 24, 555, 1895.
Occurs with brookite at Placerville, Eldorado Co., Cal., Kunz, Am. J. Sc., 43, 329, 1892. Also at Magnet Cove, Ark., Penfield, Am. J. Sc., 48, 114, 1894. See Halite.

OLIGOCLASE, p. 322.—Cleavage and parting planes, Penfield, Am. J. Sc., 48, 115, 1894. See also Feldspar.

Onofrite, p. 64.—Occurs with cinnabar at Ouen-Shan-Tchiang, Central China, Termier (anal. by Pisani), Bull. Soc. Min., 20, 204, 1897.

OPAL, pp. 194, 1038.—Occurrence in New South Wales, Anderson [Rec. G. Surv. N. S. Wales, 3, 29, 1892], Jb. Min., 2, 221 ref., 1894.

ORPIMENT, pp. 35, 1043.—Obtained in fine crystals in cavities in clay at Mercur, Utah; these are monoclinic (Penfield, priv. contr.) as earlier (1866) deduced for Hungarian crystals by Breithaupt; Groth has also reached this conclusion (Tab. Ueb. Min., 17, 1898; cf. also notes by Hintze, Zs. Kr., 24, 204, 1894). Miers found nothing in the optical characters at variance with orthorhombic crystallization, Min. Mag., 10, 204, 1894.

ORTHOCLASE, p. 315.—Vesuvius, measurement of crystals, Franco, Giorn. Min., 5, 184, 1894. Crystals from Lapland with (370) as tw. plane, Jeremejev, Vh. Min. Ges., 30, 463, 1893. Also twin with tw. pl. \perp plane cm, Goldschmidt and Wright, Zs. Kr., 30, 300, 1898 (earlier noted by Tschermak, Min petr. Mitch., 8, 414, 1887). Sanidine from Monte Cimino, near Viterbo, Italy, Zambonini, Riv. Min. Ital, 20, 20, 1898.

Noted as a gangue mineral in a fissure vein in the Silver City district, Idaho, Lindgren, Am.

J. Sc., 5, 418, 1898.

Parisite.

See also Feldspar.

OTTRELITE, pp. 642, 1043.—Analysis, Liberty, Maryland, Eakins, Bull. U. S. G. Surv., 113, **1**11, 1893.

In metamorphic conglomerate in the Green Mts., Vermont, Whittle, Am. J. Sc., 44, 270, 1892. See Chloritoid, Bliabergsite.

Paralaurionite. G. F. Herbert Smith, Min. Mag., 12, 108, 1899.

Monoclinic. Forms: a (100), c (001), m (110), d (101), h (201), k (401), l (601); p (111). Angles * $ac = *62^\circ 47'$, $am = *67^\circ 25'$, $ap = *58^\circ 28'$, $cm = 79^\circ 53'$, $cp = 52^\circ 37\frac{1}{2}'$. In prismatic ($\parallel \bar{b}$) or tabular ($\parallel a$) crystals; twins with a as tw. pl. and thus pseudo-orthorhombic. Cleavage, basal. G. = 6.05. Sections $\parallel a$ show in monochromatic light a double interference-figure. Refractive index $\beta = 2.1463$.

Composition as for laurionite, PbClOH. Analysis, Cl 14.9, O [3.6], Pb 78.1, H₂O 3.4 = 100.

The water is given off at 180°; laurionite loses its water at 142°.

Occurs in lead slags from Laurion, Greece.

Parisite, p. 290.—Crystals (rhombohedral, with new forms) from Igaliko, Greenland, described, also analysis, G. Nordenskiöld, G. För. Förh., 16, 338, 1894.

Obtained from Ravalli County, Montana, in striated hexagonal crystals (Fig. 1), with pyramidal terminations, embedded in a white siliceous matrix. Analyses, 1, by C. H. Warren; also 2, from Muso, id.:

F gangue = 5.90 [8 07]=102.48 6.82 0.50 =102.65 Ce2O3 (La,Di)2O3 CaO O = FCO2 10.98 10.70 4.128 Montana, 22 93 26.14 28.46 2.48 0.50 = 102.65 2.8729.74 Muso Valley, 4.302 24.22 30.67 6.82

These analyses lead to the formula [(Ce, La, Di)F]2Ca(CO3)2. Penfield and Warren, priv. contr.

Pearceite. S. L. Penfield, Am. J. Sc., 2, 17, 1896.

Monoclinic. Axes $\hat{a}: \hat{b}: \hat{c}=1.7309:1:1.6199, \beta=*89°51'$. Observed forms: v (332), s (221), u (331), o_0 (114), q_0 (113), r_0 (112), p_0 (111), v_0 (332), s_0 (221), u_0 (331), x (311), y (313), z (3·1·12). Angles: mm' (110 \wedge 110)=*60° 2′, cd=*25° 3′, cn=43° 2′, cr= 43° 3′, cp= 61° 49′.

In pseudo-rhombohedral crystals, tabular | c; basal faces with triangular

^{*} The author gives the axes, $a: \vec{b}: \vec{c} = 0.8811:1:0.6752$ ($\beta = 62^{\circ} 47'$), which, however, do not correspond with the angles quoted.

markings (Fig. 1). Twinning probable as with the micas and chlorites, but not definitely determined; this would explain the occurrence of some of the forms in the list above. Also massive.

Figs. 1, 2, Marysvale, Montana.

Fracture conchoidal. Brittle. H. = 3. G. = 6.125-6.166. Luster metallic. Cleavage none.

Color and streak black. Opaque.

Control Stream Stream Conduct.

Composition, Ag₀AsS₀ or 9Ag₂S.As₂S₃, hence an arsenical polybasite. Analyses: 1, F. C. Knight, quoted by Penfield, l. c. 2, S. H. Pearce, Am. J. Sc., 44, 16, 1892, after deducting 28 18 p. c. impurities (siderite, galena). 3, Penfield, l. c., deducting 12 81 p. c. (chiefly galena). Here belongs also an analysis by H. Rose of a Schemnitz mineral (No. 2, Dana Min., p. 146).

			S	As	Sb	Ag	Cu	Zn	
1.	Marysvale, Mo	ont.	17.71	7.39	-	55.17	18.11	— Fe 1.05,	insol. $0.42 = 99.85$
2.	Aspen, Colo.	mass.	17.73	6.29	0.18	59.73	12.91	3.16 = 100	
3.	ii ii	cryst.	18.13	7.01	0.30	56.90	14.85	2.81 = 100	

B.B. decrepitates slightly and fuses readily. On charcoal in O.F. a slight arsenical coating; with soda a silver globule. In the open tube fumes of sulphur dioxide and sublimate of arsenic

trioxide. In the closed tube fuses, gives a yellow sublimate of arsenic trisulphide and above a faint deposit of sulphur. Readily oxidized and dissolved in powder by nitric acid.

Occurs with quartz and calcite, also chalcopyrite, in a cavity at the Drumlummon mine, Marysvale, Montana. Also at the Mollie Gibson mine, Aspen, Colorado, both massive in large quantity disseminated through a pink barite; also in tabular crystals embedded in siderite, in both

cases associated with galena. Also in good crystals from the Tintic district, Utah. Named after Dr. Richard Pearce of Denver.

Pectolite, p. 373.—Torosay in Mull, Scotland, analyses, Heddle, Trans. G. Soc. Glasgow. 241, 1892.

Pelionite. A name suggested by W. F. Petterd for a bituminous coal (Pelion Coal) resempling the English cannel coal, from near Monte Pelion, Tasmania. Catalogue of Minerals of Tasmania, 1893.

Pencatite, p. 271.—Investigated (also predazzite), Leneček, Min. petr. Mitth., 42, 429, 447. 1892.

Penfieldite. F. A. Genth, Am. J. Sc., 44, 260, 1892. S. L. Penfield, ibid., 48, 114, 1894.

Hexagonal. Axis $\dot{c}=0.8967$; $0001 \land 01\bar{1}1=39^{\circ}~26\frac{1}{4}'$. In hexagonal prisms (Fig. 1) with c (0001), m (1010) and p (1122); also undetermined acute pyramids of the unit series forming tapering crystals. Angle $cp=*41^{\circ}~53'$.

Cleavage: basal, distinct. Luster vitreous, inclining to greasy. Color white. Transparent to translucent. Double refraction, strong, positive. Composition, a lead oxychloride, PbO.2PbCl₂ = Chlorine 18.2, lead 79.7,

oxygen 2.1 = 100. Analysis, Genth:

Pb 1. Tapering cryst. 18:55 78.25 17.94 2. Opaque cryst. undet.

B.B. in the closed tube decrepitates and yields a sublimate of lead chloride

but no water. Easily soluble in nitric acid.

Found in the ancient lead slags from Laurion, Greece, in which it has resulted from the action of sea-water. Other lead oxychlorides occuring at Laurion are: laurionite, fiedlerite and paralaurionite (this Append., p. 50).

Penfieldite.

Penninite, p. 650.—Analysis of kämmererite, from Tampadel, Zobtengebirge, Lower Silesia. Traube, Zs. G. Ges., 48, 53, 1894. See Clinochlore.

Pentlandite, p 65.—Shown by Penfield (Am. J. Sc. 45, 493, 1893) to coord intimately mixed with pyrrhotite at Sudbury, Ontario. It is non-magnetic, has a lighter color and is isometric as shown by the octahedral parting G. = 4.946-5.006. Analysis gave S: 33.42, Fe 3.25, Ni 34.23, Co 0.85, gangue 0.67 = 99.42. It is also shown that the folgerite of Emmens (ref., p. 26) from the Worthington mine, 30 miles southwest of Sudbury, is only pentlandite.

Occurs at Beiern, Norway, (analysis), J. H. L. Vogt, G. För. Förh., 14, 325, 1892.

See also Heazlewoodite.

Percylite, pp. 172, 1028.—Synthetic experiments by C. Friedel lead to the composition before suggested for the species, viz. PbCuCl₂(OH)₂ or Pb(OH)Cl. Cu(OH)Cl. This is the composition of boléite (Min., p. 1028) except that it contains a small amount of silver chloride (\$\frac{1}{4}\text{AgCl}\). Bull. Soc. Min., 15, 96, 1892. Friedel has also obtained crystals with the latter composition (boléite), bid., 17, 6, 1844.

The locality at Boléo, Lower California has yielded not only the cubes of boléite to which belong the formula PbCuCl₂(OH)₂ + ½ AgCl (see Min., p. 1028, and Mallard and Cumenge, Bull. Soc. Min., 14, 283, 1891), but also octahedral or pyramidal crystals, sometimes in pseudo isometric groupings of six crystals. They are referred to the tetragonal system by Cumenge, C, R, 116, 898, 1893. Analyses, 1, Fourment, quoted by Cumenge; 2, Friedel, Bull. Soc. Min., 16, 187, 1893.

G.	Cl	Pb	Cu	Ag	H_2O	0
1. 4.675	18.53	52.99	15.20	0.15	9.00	4.13 = 100
2. 4.71	19.04	52.85	17.95		5.44	$4.55 \text{ SiO}_20.39 = 100.26$
			a I	gnition.		

Analysis 2 (1 being incorrect in the H₂O) corresponds to PbCuCl₂(OH)₂, the composition above given for percylite. These crystals are called cumengeite by Mallard, Bull. Soc. Min., 16, 184, 1893. He obtained $001 \land 101 = 58^{\circ} 44'$; c = 1.6469; optically negative, uniaxial; indices

 $\omega = 2.026, \ \epsilon = 1.965, \ \omega - \epsilon = 0.061.$

The relation of percylite to boléite and cumengite has also been discussed by Lacroix (Bull. Mus. d'Hist, Nat., Paris, p. 39, 1895), but his conclusions rest on insufficient data. He would recognize a series passing from cumengite containing no silver (PbCuCl₂(OH)₂, through pseudoboléite with less than ½AgCl and boléite with ½AgCl, to percylite in which still more AgCl is present (but see Friedel above). He would also find a progressive increase in specific gravity, viz. for the four substances named: 4.71, \$\times 5.08\$, 5.254; also a decreasing birefringence, viz. 0.061 (cumengite), 0.03, (pseudoboléite), 0.01 (boléite), to 0 or nearly 0 in percylite. The substance called pseudoboléite forms part at least of the cubic crystals with re-entrant angles (001 \Lambda 102 = 63° 44') referred to cumengite and percylite by Mallard.

A mineral from the Broken Hill mines, New South Wales, is referred to boléite by Liversidge, Proc. R. Soc. N. S. W., 28, 94, 1894. In cubic crystals with o and d. H. = 3.5. G. = 5.02, Analysis by Carmichael and Armstrong: Cl 13.50, Pb 47.20, Cu 19.20, Ag 8.25, O calc. [6.10].

 H_2O calc. [5.44] = 99.69. H_2O determined by Liversidge 6.39 p. c.

Obviously these supposed distinct minerals need further examination, especially on the chemical side.

Periclase, p. 207.—Occurs in small grains at Långban, Hj. Sjögren, G. För. Förh, 17, 288,

Discussion of method of origin at Långban and Nordmark, Hj. Sjögren, G. För. Förh., 20, 25, 1898.

Artificial production, A. de Schulten, Bull. Soc. Min., 21, 87, 1898.

Perovskite, p. 722.—Further investigation of crystallographic and optical characters, Des Cloizeaux Bull. Soc. Min., 16, 218, 1893.

Occurs with magnetite as a rock at Catalão, Goyaz, Brazil, Hussak, Jb. Min., 2, 297, 1894.

Petalite, p. 311.—Occurs near the source of the Amanaur river, Caucasus, C. Jeremejev (anal., Antipov), Bull. Ac. St. Pet., 5, 1896, Proc. Verb., p. viii.

PETZITE, p. 48. - Occurs in the Yale district, Br. Columbia, Hoffmann, Rep. G. Canada, 8, 12R, 1895. Also at the Nordenfeldt mine, Thames gold-field, New Zealand, J. Park, Austr. Assoc. Adv. Sci., 3, 152, 1891.

PHARMACOLITE, p. 827.—Analysis by Church gives 12:37 p. c. as loss of water in vacuo (3 = H₂O), and 3·11 between 100° and 200° (H₂O). Min. Mag., 11, 7, 1895.

PHENACITE, p. 462. — Crystals described (anal. by Preis) from Ober-Neusattel, Vrba, Zs. Kr., 24, 119, 1894.

Crystals occur at Kragerö of prismatic habit, the usually tri-rhombohedral symmetry not disthe third third twins of both contact and penetration types, with m (1010) as tw. plane, Bäckström, G. För. Förh., 20, 295, 1898, and Zs. Kr., 30, 352, 1. 1898.

Pseudomorphous crystals (Fig. 1) of very large size (one weighed 28 lbs.) occur at Greenwood, Me., C. H. Warren, Am. J. Sc., 6, 119, 1898.

Occurrence at St. Christophe-en-Oisans, Dauphiné, Des Cloizeaux and Lacroix, C. R., 116, 1231, 1892. Also at Striegau, Silesia, Hintze, Zs. Kr., 28, 174, 1897.

Philipstadite. R. A. Daly, Proc. Amer. Acad. Sc., 34, 433, 1899.—See Amphibole.

PHILLIPSITE, p. 579.—Analysis by G. H. Edwards of crystals from Bass Strait, Australia, gave:

Phenacite.

G.	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	(Ba,Sr)O	CaO	Na ₂ O	K ₂ O
2 20	47.94	21.72	4.44	0.77	2.25	2.73	9.87 = 100.65

This leads to the formula $RAl_2Si_4O_{12}$ $4H_2O$, where $R = K_2$, Nu_2 and Ca. That phillipsite should contain $4H_2O$, instead of $4\frac{1}{2}H_2O$ as generally accepted (Min., p. 580), was indicated by Pratt and Foote in their discussion (Am. J. Sc., 3, 448, 1897) of the wellsite-phillipsite-harmotome stilbite series. S. L. Penfield, priv. contr.—See Wellsite.

PHLOGOPITE. - See Mica.

PHENICOCHROITE, p. 914.—Synthesis, Ludeking, Am. J. Sc., 44, 57, 1892. Also Lachaud and Lepierre, Bull. Soc. Chim., 6, 232, 1891.

Phosgenite, p. 292.—Crystals from Monteponi, Sardinia, studied by Goldschmidt, are referred to the trapezohedral group of the tetragonal system, Zs. Kr., 21, 321, 1893; 23, 139, 1894; 26, 9, 1896. Traube concludes, however, that etching-figures are not at variance with crystallization in the normal (holohedral) group, Jb. Min., Beil.-Bd., 10, 456, 1896. On crystals from Latitus Carres (C.R. Henbert Strith, Min., Med. 120, 1890. Laurion, Greece, G. F. Herbert Smith, Min. Mag, 12, 107, 1899.

Formation of artificial crystals also of PbCO₃. PbBr₂, A. de Schulten, Bull. Soc. Min., 20,

191, 194, 1897.

Picromerite, p. 948.—(Schoenite.) Relation to other sulphates, etc., J. K. van der Heide, Zs. phys. Ch., 12, 416, 1893.

Piedmontite, p. 521.—Shown by G. H. Williams to occur at South Mountain, Pa., in an ancient rhyolite with scheelite, etc.; analysis by W. F. Hillebrand, after deducting quartz assumed to be present to the amount of 10 p. c.: SiO₂ 37·37, Al₂O₃ 22·07, Ce₂O₃ 0·89, R₂O₃* 1·52, Fe₂O₃ 4·78, Mn₂O₃ 8·15, MnO 2·285, CaO 18·825, MgO 0·30, K₂O 0·81, Na₂O 0·27, H₂O 2·48, CuO 0·13, PbO 0·17 = 100 05. (*Other rare earths.) Am. J. Sc., 46, 50, 1893.

Occurs in rhyolite in Province of Shinano, Japan, Yamasaki, J. Coll. Sc. Japan, 9, 117, 1897.

PINAKIOLITE, p. 877.—A related mineral from Långban has been analyzed by Bäckström, G. För. Förh, 17, 257, 1895.

PINITE, p. 621.—Breage, Cornwall, analysis, Collins, Min. Mag., 10, 8, 1892.

Pirssonite. J. H. Pratt, Am. J. Sc., 2, 126, 1896.

Orthorhombic hemimorphic. Axes $\check{a}: \bar{b}: \dot{c}=0.5662:1:0.3019$. Forms: b (010), m (110), p (111), p (111), p (131), x (311). Angles: $mm'''=*59^{\circ}$ 2', $pp''=*63^{\circ}$ 0', $pp'=54^{\circ}$ 6', $pp'''=29^{\circ}$

50'. Habit prismatic (Figs. 1 to 4).

Cleavage none. Fracture conchoidal. Brittle. H. = 3-3·5. G. = 2·352. Luster vitreous. Colorless to white, sometimes dark from impurities. Pyroelectric. Optically +. Ax. pl. [c. Bx_a \pm b. $2E_y = 48^\circ$ 14′. Indices (Na): $\alpha = 1 \cdot 5043$, $\beta = 1 \cdot 5095$, $\gamma = 1 \cdot 5751$ (. · · 2V = 32° 48′). Composition, CaCO₃.Na₂CO₃.2H₃O. Analysis:

	CO ₂	CaO	Na ₂ O	K ₂ O	H ₂ O	
2/2	36.07	23.38	25.70	0.15	14.73	Al_2O_3 , SiO_2 0.32 = 100.45

B.B. decrepitates, fuses at 2-2.5, coloring the flame deep yellow; alkaline reaction after heating. Soluble in cold acids with effervescence,

Occurs sparingly with gay-lussite and northupite at a boring near Borax lake, San Bernardino Co., California. Named after Prof. L. V. Pirsson of New Haven. This mineral has been obtained artificially by A. de Schulten, C. R., 123, 1023, 1896.

PLAGIOCLASE.—See Feldpar.

PLAGIONITE, p. 118.—Description of crystals from Wolfsberg, Luedecke, Min. d. Harzes, 125, 1896; also with new forms, L. J. Spencer, Min. Mag., 11, 192, 1897, and 12, 56, 1899 (see further Semseyite).

Planoferrite. L. Darapsky, Zs. Kr., 29, 213, 1897.

In rhombic or hexagonal tabular crystals (probably orthorhombic) with basal cleavage and faces on the edges. Brittle. H. = 3. Color yellowish green to brown (Grünling) streak chromeyellow. Composition Fe₂O₃.SO₃.15H₂O. Analysis:

 SO_3 15.57, Fe_2O_3 31.20, H_2O 51.82, insol. 1.41 = 100.

Occurs in druses in copiapite at the Lautaro mine near Morro Moreno, Antofagasta, Atacama,

PLATINUM, pp. 25, 1044.—Venable concludes that the reported occurrence of platinum in North Carolina is very do:btful, Am. J. Sc., 43, 540, 1882; J. Elisha Mitchell Sc. Soc., 8, 1892.

Occurs with gold in the sand of the N. Saskatchewan river, near Edmonton, Alberta, Hoffmann, Rep. G. Canada, 5, 65R, 1889-90. Also on Rock creek, Kettle river, Yale district, Br. Columbia, ib., 6, 14R.

PLATTNERITE, p. 239.—Mullan, Idaho, analysis (Yeates) and cryst. description (Ayres) as given in Syst. Min., p. 240. Am. J. Sc., 43, 407, 1892.

PLUMBOCUPRITE.—See Cuproplumbite.

Plumboferrite, p. 228.—Sjö mine, Örebro, Sweden, analysis of impure material, Igelström, G. För. Förh., 16, 594, 1894, and Zs. Kr., 24, 129, 1894.

Polianite, p. 236.—Analyses, Gorgeu, Bull. Soc. Min., 16, 96, 1893.

POLLUCITE, pp. 343, 1044.—Rumford, Me., analysis by H. W. Foote confirming formula of Wells, Am. J. Sc., 1, 457, 1896.

Na.O Li₂O Al₂O₃ Cs₂O K₂O H₂O SiO2 $G. = 2.984 \frac{2}{3} 43.64$ 16.84 36.14 0.37 2.09 0.08 1.58 = 100.74.

POLYBASITE, pp. 146, 1045.—Crystals from the Yankee Boy mine, Ouray, Colorado, are shown by Penfield to be monoclinic

and pseudo-rhombohedral (Fig. 1). Axes: \dot{a} : \dot{b} : \dot{c} = 1.7309: 1: 1.5796, β = 90° 0′. Forms: cForms : c (001), l (310), m (110), n (101), A $(\bar{2}03)$, n_0 $(\bar{1}01)$, π $(\bar{4}03)$, t_0 (201); o (114), r (112), p (111), s (221), u

Angles $cm = *90^{\circ} 0'$, $mm' = *60^{\circ} 2'$, $cn = *42^{\circ} 23'$, $cr = 42^{\circ} 22'$, $co = 24^{\circ} 31'$. Crystals tabular

c, Figs. 1, 2. The form is very near that of pearceite, p. 50, Fig. 2 shows a crystal from the Himmelfahrt mine, Freiberg, perhaps a twin. Am. J. Sc., 2, 23, 1896. See also Pearceite. Also occurs in fine crystals at the Big Seven Mine, Neihart, Montana (Pfd.).

Analysis from Quespisiza, Chili, by Bodländer: S 16·37, Sb 5·15, As 3·88, Ag 67·95, Cu 6·07, Pb 0·76 = 100·18. This gives the ratio of Ag₂(Cu₂)S: Sb₂(As₂)S₃ = 7·74:1 instead of 9:1 as commonly accepted, Jb. Min., 1, 98, 1895.

Polycrase, p. 744.—Occurs in the township of Calvin, Nipissing, Ontario, Canada, Hoffmann, Am. J. Sc., 7, 243, 1899.

POLYLITE, p. 1045.—Thomson's supposed mineral is shown to be a mixture containing fayalite derived from an iron furnace, Lacroix, Bull. Soc. Min., 20, 308, 1897.

Powellite, p. 989.—Occurs at the South Hecla copper mine, Houghton Co., Michigan, (WO₃ 1.65 and 4.50 p. c.,) Koenig and Hubbard, Am. J. Sc., 46, 356, 1893. The same locality has afforded some fine crystals described by C. Palache, *ibid.*, 7, 367, 1899. G = 4.356, color bluish green. Habit as in Fig. 1. Observed forms: e (101), p (111), h (133), j (3.11.11); also narrow and doubtful, k (155), l (1.11.11). Angles near those of scheelite. Cleavage e interrupted. One specimen showed a dark, nearly black exterior and bluish-green interior presumably due to variation in composition.

Crystals, with e (001), e (101), p (111), have been obtained artificially by L. Michel; analysis gave MoO₃ 62 37, WO₃ 10 23, CaO 26 41 = 99 01. Bull. Soc. Min., 17, 612, 1894.

Powellite.

PREHNITE, p. 530.—Occurs in crystals at Friedensdorf near Marburg, Brauns (anal. by A. Nau), Jb. Min., 2, 6, 1892.

Crystals described and investigated pyroelectrically; new forms (301), (601), (10.0.1); crystals hemimorphic and twinned (tw. pl. a (100)). Traube, Jb. Min., Beil.-Bd., 9, 134, 1894. Crystals described from Tulferthal, Tyrol, Habert, Zs. Kr., 28, 258, 1897. Anal., Fassa, Tyrol,

Schneider, Bull. U. S. G. Surv., 113, 112, 1893. Identification in rocks, Lacroix, Bull. Soc. Min., 21, 277, 1893.

Prolectite. Hj. Sjögren, Bull. G. Inst. Upsala, 1, 40, 1892; 2, 99, 1894.

A new member of the Humite Group, thus far only known from two fragments of crystals obtained with humite, chondrodite, and clinohumite at the Ko mine at Nordmark, Sweden. In appearance and physical characters like other members of the group. Crystallization, monoclinic. Axes \hat{a} : \hat{b} : \hat{c} = 1.0803: 1:1.8862, β = 90°. Forms: (001), (010); (110); (103), (503), (409); (012), (011); (121), (367), (362); (227), (223), (111); (121), (249). Ax. plane (α = Bx₀) inclined 44° to 47° 15′ to (001), that is, 46° to 42° 45′ to \hat{c} . 2K_{a,y} = 79° 45′ (n^y = 1.6703).

Not yet analyzed, but the composition is probably Mg[Mg(F,OH)]SiO4, the member of the group predicted by Penfield and Howe as noted under the Humite Group, p. 35. Hence named

from $\pi \rho o \lambda \dot{\epsilon} \gamma \epsilon i \nu$, to foretell.

Prosopite, p. 178.—Analysis of a pale green variety from Utah, Hillebrand, Am. J. Sc., 7, 53, 1899.

Pseudoboléite. A. Lacroix, Bull. Mus. d'Hist. Nat. Paris, p. 39, 1895.—See Percylite.

PSEUDOBROOKITE, p. 232.—Crystals from Aranyer Berg have been examined by Traube, Zs. Kr., 20, 327, 1892. Doss has described crystals obtained as a furnace product, *ibid.*, p. 566. He deduced the composition Fe₂O₃.TiO₂ and urges isomorphism with and alusite; Frenzel, however, has confirmed the accepted formula, 2Fe₂O₃.3TiO₂, Min. petr. Mitth., 14, 126, 1894.

Pseudogaylussite.—Discussion as to the origin of the barley-corn pseudomorphs of calcium carbonate (see Min., pp. 907, 271) with description of forms occurring in Holland, F. J. P. van Calker, Zs. Kr., 28, 556, 1897.—See also Jarrowite.

Pseudomalachite, p. 794.—Analysis of ehlite, from Semipalatinsk, Antipov, Vh. Min. Ges., 28, 527, 1891.

Pseudopyrophyllite. F. Loewinson-Lessing, Vh. Min. Ges., 33, 283, 1895. Zs. Kr., 28, 516. -See Pyrophyllite.

PTILOLITE, p. 572.—A new locality near Silver Cliff, Custer Co., Colorado, is described by Cross and Eakins, Am. J. Sc., 44, 96, 1892. Occurrence similar to that of Green Mountain. Analysis, Eakins: SiO₂ 67.83, Al₂O₃ 11.44, CaO₃ 30, K₂O₀ 64, Na₂O₂ 63, H₂O_{13.44} = 99.28. The relation in composition between ptilolite and mordenite is discussed by Clarke, ibid., p. 101.

Pyrargyrite, p. 131.—Crystals from Mexico with new form (1126), Busz, Zs. Kr., 20, 557, 1892. From the Harz described by Luedecke, Min. d. Harzes, 134, 1896.

Occurs in galena near Bear Lake, West Kootanie, Br. Columbia, Hoffmann, Rep. G. Canada,

6, 27R, 1892-93.

Pyrite, pp. 84, 1045.—Crystals described from Bélabánya, Hungary; new forms (11.5.0), (13.8.0), (13.9.0), (10.7.0) (15.11.0), (8.13.0), (7.11.0), (11.15.0), (16.9.1). A. Franzenau, Ber. aus Ungarn, 16, 198, 1898. Also from Ketterbach, with new forms (21.1.0), (17.1.0), etc., Zimanyi, Földt. Közl., 28, 192, 1898.

Monte della Riva, Valle del Dardagna, description of peculiar crystals, Bombicci, Mem. Accad.

Sci. Bologna, Jan. 8, 1893.

A twinning of tetartohedral crystals (similar to ullmannite) is suggested by Miers for a specimen from Gilpin Co., Colorado, Min. Mag., 12, 112, 1899.
Twin crystal with (320) as tw. plane, G. D'Achiardi, Att. Soc. Tosc., Proc. verb., March 14,

From Müsen, containing 4:13 Ni and 1:97 Co, Laspeyres, Zs. Kr., 20. 553, 1892. Also from Sudbury, Ont., (Murray mine,) containing 4:34 p. c. Ni, Walker, Am. J. Sc., 47, 312, 1894.

Action of alkaline reagents on pyrite compared with that on marcasite, Doelter, Jb. Min.,

273, 1894. The same subject has been fully studied by A. P. Brown, Proc. Am. Phil. Soc., 33,

June 19, 1894.

Penfield has shown that the uncertain blueite and whartonite of Emmens (J. Am. Ch. Soc., 14, No. 7, 1892), both from the Sudbury region, are (even if the analyses are trustworthy) only nickeliferous varieties of pyrite. Am. J. Sc., 45, 496, 1893.

Pyroaurite, p. 256.—Described by Hj. Sjögren from the Moss mine, Norway. Occurs in hexagonal or rounded tabular crystals (Fig. 1). Forms: c (0001), mexagonal or rounded taboliar crystals (Fig. 1). Forms: e (0001), $m (10\overline{10})$, $h (21\overline{30})$, $f (10\overline{11})$; $ef^* = 76^\circ$ 30', hence e = 36073. Crystals apparently show pyramidal hemihedrism in the development of h. H. = 2-3. G. = e^* 20'. Luster pearly to greasy. Color yellow to yellowish brown. Translucent. Optically —; birefringence low. Analysis (on 0.03 gr.) by R. Mauzelius: Fe₂O₃ 22.0, MnO 4.5, MgO 34.8, H₂O 36.1, insol. 0.5 = 97.9. Associated with pyrochroite in manganiferous dolomite. Bull G. Lust Upgala, 2.50, 1805. 1. (often altered to manganite) in manganiferous dolomite. Bull. G. Inst. Upsala, 2, 59, 1895.

Pyrochlore, p. 726.—From Alnö, analyses and discussion of composition (also of related minerals), Holmquist, G. För. Förh., 15, 588, 1893. From the Ural, analysis, Khrushchov, Vh. Min. Ges., 31, 415, 1894.

Pyrolusite, pp. 243, 1045.—Analyses, Gorgeu, Bull. Soc. Min., 16, 96, 1893.

Pyromorphite, p. 770.—Crystals from New Caledonia with new forms (15.0.15.4), (9091). Lacroix, C. R., 118, 553, 1894, and Bull. Soc. Min., 17, 120, 1894.
Crystals described from Nil-Saint-Vincent, Belgium, G. Cesàro, Mem. Acad. Belg., 53, 1897.

Pyrophyllite, p. 691.—F. Loewinson-Lessing concludes from his investigations of the mineral of Pyshminsk that it represents a mixture of pyrophyllite, $3H_2O.3Al_2O.11SiO_2$, and pseudo-pyrophyllite, $3MgO.4Al_2O.9SiO_2.8H_2O$. These were separated by the Thoulet solution. Both are assumed to be orthorhombic with $Bx_1 \perp base$ (cleavage); the former is optically negative, the latter positive. Vh. Min. Ges., 33, 283, 1895, and Zs. Kr., 28, 516, 1897.

Pyrostilpnite, p. 135.—Discussion of crystalline form, Luedecke, Min. d. Harzes, 133, 1896.

Pyroxene, pp. 352, 1045.—Crystals from New York State described, with optical investigation and analyses, H. Ries, Ann. N. Y. Acad. Sc., 9, 124, 1896.

Diopside, Achmatovsk, new form H (551), Busz, Zs. Kr., 20, 558, 1892. Crystals from several localities described, also augite. new forms **K** (10·1·0), **G** (710), **S** (750), **K** (140), **W** (160), **Y** (0·11·5), **E** (414), **W** (421), **W** (531), A. Schmidt, Zs. Kr. 21, 1, 1892. From Graubtunden, Baumhauer, *ibid.*, p. 200. From Zöptau, optical and chemical description, Graber, Min. petr. Mitth., 14, 265, 1894.

Forms a saccharoidal rock of an azure-blue color, on the Gila river, 40 miles from Silver City, New Mexico. Analysis by Merrill and Packard gave: SiO₂ 54·30, MgO 18·33, CaO 25·00, FeO 1·11 = 98·74. Am. J. Sc., 43, 279, 1892.

Violan, p. 357.—Analysis of original material by Penfield shows it to be essentially a diopside, Ani. J. Sc., 46, 293, 1893. Color light blue. G. = 3.227-3.272.

MgO CaO Na₂O K₂O Al₂O₃ Fe₂O₃ Mu₂O₃ MnO 53.94 1.00 0.86 0.88 0.36 16.63 23.80 1.22 0.05 0.66 = 99.40

Salite, from Sala, optical exam. and analysis, Hovey, Min. petr. Mitth., 13, 218, 1892.

Hedenbergite, Su Poru, Sardinia, analysis by Fasolo, quoted by Lovisato (10.92 p. c. MnO and no Al₂O₃); also epidote, etc., Rend. Accad. Linc., 4 (1), 111, 1895. From Renfrew Co., Ontario, optical characters, analysis, etc., Wülfing, Min. petr. Mitth., 15, 29, 1895.

Iron-schefferite, Långban, analysis by Mauzelius, Hj. Sjögren, G. För. Förh., 14, 251, 1892. See Urbanite.

Jeffersonite, from Franklin Furnace, N. J., analyzed by Hillebrand, Am. J. Sc., 7, 55, 1899.

Augite, on crystals, see diopside above.

Analysis, Italian Peak, Gunnison Co., Colo., Eakins, Bull. U. S. G. Surv., 113, 112, 1893, From Highwood Mts., Montana, L. V. Pirsson, Bull. G. Soc. Am., 6, 410, 1895. In analcite-basalt, Colorado, Hillebrand, quoted by Cross, J. Geol., 5, 687, 1897. In analcite-

On the pyroxene (ægirite-augite, augite) from the volcanic rocks (leucitite, etc.) of the Ernici, Province of Rome, Italy, see Viola, Jb. Min., 1, 101 et seq., 1899. Crystals often show zonal structure with varying extinction; twins noted with m (110) as tw. plane. The name federovite is suggested by Viola for a pyroxene from this region, which falls between ægirite-augite and ægirite, containing 9 to 13 p. c. alkalies and about 24 p. c. FeO; pleochroism strong, \mathbf{r} yellow, $\mathbf{b} = \mathbf{a}$ olive-green; $\mathbf{c} \wedge \dot{\mathbf{c}} = 65^\circ$ to 75° , $2\mathbf{V} < 50^\circ$.

On the extinction-angles in the vertical zone, see R. A. Daly, Proc. Amer. Acad., 34, 311, 1890; else the same are calking figures.

1899; also the same on etching-figures, ibid., p. 374.

Many petrographical papers (in Jb. Min. et al.) contain analyses, optical determinations, etc.; a summary of some of these is given by Viola, Jb. Min., 1, 115-120, 1899.

Conditions of formation in a magma, Morozewicz, Min. petr. Mitth., 18, 113, 1898.

The meteorite of Vaca Muerta, Sierra de Chico, contains an unidentified silicate, in some respects resembling augite.

Weinschenk, Min. petr. Mitth., 17, 567, 1897.

Pyrrharsenite, p. 753.—See Berzeliite.

Pyrrhotite, p. 73.—Crystals from Andreasberg, described with t (1012), r (7071), Busz, Jb. Min., 1, 124, 1895. From Frontenac Co., Canada, with (2021), (4041), etc., W. Nicol, Zs. Kr., 31, 53, 1899.

Investigation of magnetic properties, Abt, Wied. Ann., 57, 135, 1896. From Sudbury, Ont., containing nickel, Vogt, G. För. Förh., 14, 315, 1892.

Linck shows reason for not regarding pyrrhotite and troilite as heteromorphic modifications of the same compound (FeS), Ber. Ch. Ges., 32, 895, 1899.

Quartz, pp. 183, 1046.—Cryst.—Monograph for crystals from Val Malenco, Rossignoli, Riv. Min. Ital., 10, 3, 1892. No. Carolina, A. Capen Gill, Inaug. Diss., Leipzig, 1893, reproduced in Zs. Kr., 22 97, 1893; also H. A. Miers, Am. J. Sc., 46, 420, 1893. Jämtland, Hamberg. G. För. Förh., 16, 307, 1894. Wurmthal, Harz, cryst. described, Luedecke, Abh. Nat. Ges. Halle, 20, 1894; Min. d. Harzes, 196, 1896. Devil's Lake, Wisconsin, Hobbs, Bull. Univ. Wisconsin, 1, 109, 1895. Switzerland, Termier, Bull. Soc. Min., 18, 443, 1895, and C. R., 121, 842, 1895. Phys., 2, 393, 1893; effect of pressure on optical phenomena, id., ibid., pp. 459, 472; see also Wiechmann. Sch. Mines Q., 20, 267, 1899. Measurement of rotatory power, Gumlich, Zs. Instrumentenkunde, 16, 97, 1896. Tenacity investigated, Sella and Voigt, Wied. Ann., 48, 663, 1893.

Piezo-electric property discussed, Lord Kelvin, Phil. Mag., 36, 331, 1894.

Refractive indices measured, Wülfing, Min. petr. Mitth., 15, 59, 1895.

Investigation of coloring matter of smoky quartz (titanium), Weinschenk, Zs. G. Ges., 48, 704, 1896; Zs. anorg. Ch., 12, 375, 1896.

Observations on the solvent power of water at elevated temperatures (153° to 323°) and after long duration, G. Spezia, Att. Accad. Sc. Torino, 33, June 16, 1898; also ibid., 31, Dec. 29, 1895. Stated to occur in the Toluca meteoric iron, Laspeyres, Zs. Kr., 24, 485, 1895.

A supposed cubic form of silica from Guanabacoa, Cuba, has been called cubaite by F. Vidal y Careta [Cron. Cient. Barcelona, 13, 497, 1890]; shown by L. F. Navarro to be rhombohedrons of ordinary quartz, Anal. Soc Españ. Hist. Nat., 21, Actas p. 120, 1893. Later (ibid., 14, 268, 1891) the first author proposed to substitute the name guanabaquite (guanabacoite); this includes also pseudomorphous chalcedony (analogous to that from Hungary) as further shown by Navarro, l. c.

Quartzine. Lutécine, Lutecite. Michel-Lévy and Munier-Chalmas, C. R., 110, 649, 1892, and Bull. Soc. Min., 15, 159, 1892. Wallerant, Bull. Soc. Min., 20, 52, 1897.

The forms of anhydrous silica having a fibrous structure differ from quartz in slightly lower density (G. = $2\cdot5-2\cdot6$) and more distinctly in optical characters. They are optically +, but biaxial with a small axial angle, 20° to 35° ; birefringence $0\cdot009$ to $0\cdot010$. Three varieties have been distinguished, according to the direction of elongation of the fibers. (1) In chalcedony the elongation coincides with the axis π (= Bx_{\circ}), in other words the direction of the fibers is sometimes said to be negative. (2) In quartzine it coincides with t_{\circ} , and in lutécine with a plane of symmetry (= Bx_{\circ}) to the axes t_{\circ} and t_{\circ} , the fibers making an angle of 29° with t_{\circ} and of 61° with t_{\circ} .

As interpreted by Michel-Lévy and Munier-Chalmas the regular arrangement of the fibers of chalcedony give rise to spherulites with concentric zones of like extinction; regular ternary (120°) aggregates of quartzine are regarded as producing ordinary quartz; the regular hexagonal (60°) arrangement of the elementary lutécine gives the double hexagonal pyramids of lutécite, aggregates about an axis inclined 45° to c and 74° to the elongation of the fibers in the plane b and c. According to Wallerant (l. c.) all quartz is to be regarded as formed by regular intergrowths of

minute elements of quartzine.

It is obvious that these three forms of fibrous silica are essentially identical, and all their various aggregates seem to have been derived from original colloidal concretions. Groth (Tab. Ueb., 42, 1898) uses quartzine as a general term to embrace them all.

On quartzine from Herman Mestec, Barvir, Ber. Ak. Böhm., March 10, 1893.

Christobalite (p. 193) has been shown to result from the action of water and hydrofluoric acid (at 200° and 26 atmospheres) upon amorphous silica, Khrushchov, Bull. Acad. St. Pet., 2, 27, 1895.

On the peculiar form of silica obtained from heulandite, with G. = 2.14 and optically negative, see Rinne, Jb. Min., 147, 1896.

QUENSTEDTITE, p. 957.—A ferric sulphate having the composition of quenstedite has been observed by O. Kuntze as a yellow incrustation in sandstone near Montpelier, Muscatine county, Iowa. H. = 2.5. G. = 2.212. Analysis gave: SO₃ 39.01, Fe₂O₃ 26.86, Al₂O₃ 0.27, H₂O 32.32, insol. (SiO₂) 1.79 = 100.25. Amer. Geol., 23, 119, 1899.

Quirogite. L. F. Navarro [Anal. Soc. Españ. Hist. Nat., 24, Actas p. 96, 1895] Zs. Kr., 28, 202, 1897. A supposed tetragonal mineral of metallic luster and lead-gray color, often tarnished dull. H.=3. G.=7.22. Analysis on material containing particles. 28, 202, 1897. A supposed tetragonal mineral of metallic luster and lead-gray color, often tarnished dull. H.=3. G.=7.22. Analysis on material containing pyrite gave: S 17.51, Pb 63.89, Sb 9.69, Fe 6.30, Ag tr.=97.39. From the mines San Andrés, Georgina, etc., Sierra Almagrera, Spain. Named after the Spanish mineralogist, F. Quiroga. Probably only an impure galena (cf. remarks credited to Schrauf, Zs. Kr., l. c.).

L. J. Igleström, G. För. Förh., 18, 41, 1896.—See Garnet.

Raspite. C. Hlawatsch, Ann. Mus. Wien, 12, 38, 1897; Zs. Kr., 29, 137, 1897; 31, 8, 1899. Monoclinic. Axes $d: \vec{b}: \vec{c} = (1.3358:1:1.1112; \beta = 72^{\circ} 19' = 100 \land 001 = ac$. Angles $ce = 46^{\circ} 41'$, $cd = 46^{\circ} 38'$. Observed forms: a (100), b (010), c (001), c (101), d (011). Crystals small, elongated $\parallel \vec{b}$ and tabular $\parallel a$ with this face as twinning plane; a striated horizontally.

Cleavage: a perfect. H. = 2.5. G. undetermined. Luster adamantine, brilliant. brownish yellow. Transparent. Ax. pl. b. An axis and negative bisectrix oblique to a. Index

= 2.6 approx.

Composition, lead tungstate, PbWO4, like stolzite. Analysis, Treadwell:

> WO, 49.06 PbO 48.32 Fe_2O_3 , MnO 1.43 = 98.81

Occurs with reddish stolzite on limonite at the Broken Hill mines, New South Wales. Named after Mr. Rasp, the discoverer of the Broken Hill mines.

Rathite. Baumhauer, Zs. Kryst., 26, 593, 1896.

Orthorhombic. Axes $\check{a}: \check{b}: \dot{b}: = 0.6681: 0: 1.0579.$ $100 \land 110 = 33^{\circ}444^{\circ}.$ $001 \land 101 = 57^{\circ}431^{\circ}.$ $001 \land 011 = 46^{\circ}363^{\circ}.$ Also $001 \land 203 = *46^{\circ}33^{\circ}.$ $001 \land 045 = *40^{\circ}141^{\circ}.$ $001 \land 021 = 64^{\circ}42^{\circ}.$ Observed forms: (001), (107), (106), (209), (207), (103), (205), (102), (203), (405), (101), (403), (302). (201), (401), (601); (045), (0.11.10), (021), (0.16.3); also other forms in part vicinal.

d

m

In crystals, prismatic $||\tilde{b}|$, with numerous macrodomes finely striated || an undetermined brachydome. Twins: tw.-plane an obtuse brachydome. In luster and color not to be distinguished from dufrenoysite.

In composition allied to dufrenoysite and jamesonite, but formula uncertain. Analysis, Bömer:

S 23.72 As 17.24 Sb 4.53 Pb 52.98 Fe 0.56 = 99.03

From the dolomite of the Binnenthal, Switzerland, with other related species. Named after Prof. G. vom Rath (1830-1888).

Realgar, pp. 33, 1046.—Crystals from Allchar, Macedonia, described (new form 5 (450)), Hackman, Zs. Kr., 27, 608, 1896; also Vrba, Ber. Ak. Böhm., Dec. 7, 1894.

Retzian. Hj. Sjögren, Bull. G. Inst. Upsala, 2, 54, 1894; G. För. Förh., 19, 106, 1897.

Orthorhombic. Axes $\check{a}:\bar{b}:\dot{b}=0.4414:1:0.7269$. Forms: b (010), m (110), n (130), d (101), k (071). Augles: $mm'''=47^{\circ}$ 38', $bm=*66^{\circ}$ 11', $cd=*58^{\circ}$ 44'. Crystals prismatic, sometimes tabular $\|b\|$. The axial ratio is near that of flinkite (Min., p. 802).

Cleavage none. Fracture conchoidal to uneven. H. = 4. G. = 4·15. Luster vitreous to greasy. Color dark chocolate-brown to chestnut-brown. Streak light brown. Subtranslucent. Strongly pleochroic. Ax. pl. || b. Ax. angle large. $a, b, c = c, \bar{b}, \dot{a}$.

In composition, a basic arsenate of manganese, calcium and undetermined rare metals; formula uncertain. Analysis, on 0.08 gr., R. Mauzelius:

Xª MnO FeO PbO CaO MgO As₂O₅ 24.4 10.3 30.2 1.7 0.2 19.2 2.7 8.4. SiO, 0.5. insol. 4.3 = 101.9* X = rare earths.

B.B. almost infusible; yields water. With soda on charcoal gives arsenical fumes; reacts for manganese and iron. Soluble in acids.

Found sparingly in small drusy cavities in the manganiferous limestone of the Moss mine, Nordmark, Sweden; it is associated with jacobsite. Named after the Swedish naturalist, Anders Jahan Retzian (1742-1821).

RHABDITE, p. 31.—See Schreibersite.

Rhodoarsenian. L. J. Igelström, Zs. Kr., 22, 469, 1893. A partially described mineral from the Sjö mine, Örebro, Sweden. Occurs in small rose-red spherules embedded in arseniopleite. H. = 4. Luster vitreous. An analysis (after deducting CaCO₃) yielded: As₂O₄ 12·17, MnO 49·28, CaO 21·53, MgO 5·37, H₂O 11·65, Pb, Cl tr. = 100. Regarded as the arsenic compound corresponding to ferrostibian (Min., p. 804).

Rhodochrosite, p. 278.—Artificial formation, A. de Schulten, Bull. Soc. Min., 20, 195, 1897.

Rhodolite. Hidden and Pratt, Am. J. Sc., 5, 294; 6, 463, 1898.—See Garnet.

Rhodonite, pp. 378, 1046.—Etching-figures investigated, T. L. Walker, Am. J. Sc., 5, 182, 1898.

Rhodophosphite. L. J. Igelström, Zs. Kryst., 25, 433, 1895. A mineral occurring in a quartzite carrying cyanite with svanbergite, lazulite, etc., at the Hörrsjöberg Mts., Wermland, Sweden. Occurs crystalline (hexagonal), cleavable; color white or pale red; translucent. Analysis: P₂O₈ 36·42, CaO 45·17. MnO. FeO 8·80, Cl 2·92, SO₃ 1·34, F undet. = 94·65 (author gives 97·93). It is probably simply apatite.

Rhodusite. H. B. Foullon, Ber. Ak. Wien, 100 (1), 176, 1891.—See Glaucophane.

RICHTERITE, pp. 386, 391.—Hj. Sjögren has shown that the original mineral of Breithaupt is identical with that examined by Michaelson, Igelström and Flink. His astochite (Min., p. 1027) is simply a soda-richterite, see astochite, this Append., p. 6). Sjögren also refers here the marmairolite of Hulst, Min., p. 391. G. För. Förh., 13, 604, 1891; ib., 14, 253, 1892; Bull. G. Inst. Upsala, 2, 71, 1894; also Hamberg, G. För. Förh., 13, 801, 1891.

RIEBECKITE, pp. 400, 1047.—Occurs in pebbles in the glacial drift of the east coast of Ireland; crystals found at Portrane have been measured by Sollas. Observed forms: b (010), m (110), x (150), t (101), p (101), r (011), z (121). Angles: $mm'''=56^\circ$, $pm'=77^\circ$ 50', $pt=54^\circ$ 20', hence d: b: b=0.5558:1:0.2927, $\beta=73^\circ$ 4'. A partial analysis gave: SiO₂ 42.69, Al₂O₃, Fe₃O₃ 41.71. Na₂O 10.00, K₂O 0.87. Proc. R. Irish Acad., 3, 516, 1895.

Heddle has noted on crystals from the micro-granite of Ailsa Craig, Scotland, the additional forms: a (100), c (001), e (130), i (031), o (021). Trans. Edinb. G. Soc., 7, 265, 1897.

Occurs in an intrusive rock in slates between Song and Tikobu, Southern Sikkim, India, Holland, Rec. G. Surv. India, 25, 159, 1892. Extinction-angle 7° 30′ to 10° with c. Also reported by A. Osann as occurring in the nephelite-syenite of Paisano Pass, Davis Mountains, Texas, Geol. Surv. Texas, 4th Ann. Report, 1892, p. 28. Occurs in trachytic rocks from Abyssinia, Prior, Min. Mag., 12, 92, 1899.

See Crossite.

RITTINGERITE, p. 136.—Shown by Miers to be identical with xanthoconite, wh. see. Min. Mag., 10, 185, 1893.

Roeblingite. S. L. Penfield and H. W. Foote, Am. J. Sc., 3, 413, 1897.

Massive; closely compact; consisting of aggregates of prismatic crystals. H. = 3.25. G. = 3.433. Color white. Extinction parallel; birefringence low.

Composition, probably H10Ca7Pb2Si6S2O28, which is regarded as a combination of five molecules of the silicate, H2CaSiO4, and two of the basic sulphite, CaPbSO4. This requires: Silica 22·1, sulphur trioxide 9·4, lead protoxide 32 9, lime 29 0, water $6\cdot 6 = 100$. Analysis:

Fuses B. B. at 3 to a gray globule giving the pale blue flame of lead. With soda on charcoal yields metallic lead and a lead coating. In the closed tube yields water. Dissolves readily even in dilute acid, yielding gelatinous silica on evaporation.

Found at a depth of 1000 feet in the Parker shaft at Franklin Furnace, N. J.; occurs at or near

the contact of the granite and limestone with garnet rock; associated with titanite, axinite, zircon, Named after W. A. Roebling of Trenton, N. J. willemite, rhodonite, etc.

- ROUMANITE.—See Rumanite, Min., p. 1005.

Rowlandite, p. 1047.—Further described by Hidden with analysis by Hillebrand, Am. J. Sc., 46, 208, 1893.

RUTILE, pp. 237, 1047.—Crystals from the Valais, twins, etc., described, Baumhauer, Cong. Sc. Catholiques, Fribourg, 1897.

Parting | (902) (cf. Min., p. 238) observed on crystals from Prägratten and Georgia, Mügge, Jb.

Min., 2, 82, 1897.

Occurs at West Cheyenne Cañon, El Paso Co., Colorado, in iron-black distorted crystals containing 6 68 p. c. Fe₂O₃; G. = 4 249, Genth and Penfield, Am. J. Sc., 44, 384, 1892.

Shown by spectroscopic examination to often contain vanadium in small amount, Hasselberg, Astrophysical Journal, 6, 22, 1897; 9, 143, 1899. Ak. H. Stockh., Bih., 23, (1), No. 3, 1898. Cf. also Hillebrand, Am. J. Sc., 6, 209, 1898.

Artificial formation, Michel, Bull. Soc. Min., 15, 37, 1892.

See Dicksbergite.

opina Version

SAFFLORITE, p. 100.—A related mineral occurs at the Ko mine, Nordmark, Sweden, with chondrodite, tremolite, etc. Usually massive, rarely in prismatic crystals elongated, $\parallel \bar{b}$; e (101) prominent. Forms: a (100), m (110), e (001), d (011), o (111). Angles $ee'''=59^\circ$ 14', $oo'=105^\circ$ 20'. Axial ratio $\check{a}:\bar{b}:\bar{e}=0.5086:1:0.8945$ or $0.6782:\frac{4}{3}:1.1927$, the latter showing the relation to arsenopyrite, etc. G. = $7\cdot41$. Analysis by R. Mauzelius: As $71\cdot13$, S $0\cdot68$, Fe $15\cdot28$, Co $12\cdot99$, Ni $0\cdot20$, Pb(Cu) $0\cdot33=100\cdot61$. This gives the formula (nearly) FeAs₂.CoAs₂. Hj. Sjögren, Bull. G. Inst. Upsala, 2, 68, 1894.

Sal-Ammoniac, p. 157.—Observations on crystals, Wolff, Ber. Ak. Berlin, 1085, 1895.

SALITE, p. 356.—See Pyroxene.

Salvadorite. W. Herz, Zs. Kryst., 26, 16, 1896.

Monoclinic. In aggregates of rough prismatic crystals, with m (110), also b (010); mm' = 48Crystals often twins united by a plane inclined 30° to c.

Cleavage: b perfect. Luster vitreous. Color green to blue, bluish green. Ax. pinclined 52° to c for Na (on same side as tw. plane), 46½° for Tl; ax. angle 76° for Na. Composition like pisanite (Min., p. 943), (Cu, Fe)SO₄ + 7H₂O with Cu: Fe = 2:1.

27440	SO ₃	CuO	FeO	H_2O
1. Green	27.87	18.77	8.49	44.65 = 99.78
2. Blue	28.16	17.57	9.59	44.31 = 99.63

From the Salvador mine, Quetena near Calama, Chili. Differs from pisanite in optical orientation and apparently in form.

SAMARSKITE, pp. 739, 1037.—Contains germanium in small amount (1.5 p. c); this is also true of tantalite, fergusonite, gadolinite, columbite, etc., Khrushchov, Zs. Kr., 24, 516, 1895. Analysis from the Ural by the same, Vh. Min. Ges., 31, 415, 1894.

Examination of gases (helium, etc.), Ramsay, Proc. Roy. Soc., 59, 325, 1896. Ramsay and Travers, ib., 60, 443, 1897.

Sartorite, p. 113.—Description of complex crystals (new forms) from the Binnenthal with analysis, Baumhauer, Ber. Ak. Berlin, 243, 1895.

SCAPOLITE, p. 466.—Crystals from Eel lake, Frontenac Co., Ontario, described, G. O. Smith, Johns Hopkius Circ., No. 112, May, 1894. Analysis of a "paranthite" from Clay Co., N. C., Berkley, Am. Ch. J., 14, 628, 1892.

See also Wernerite.

Scheelite, p. 985.—From Marlow township, Beauce Co., Quebec, analysis by Johnston quoted by Hoffmann, Rep. G. Canada, 5, 21R, 1889-90; also from the Ballou mine, Queens Co., Nova Scotin, ibid., 7, 14R.

Occurs at South Mountain, Pa., with piedmontite in an ancient rhyolite, Williams, Am. J. Sc.,

44, 50, 1893.

SCHEFFERITE, p. 357.—See Pyroxene.

SCHNEEBERGITE, p. 862.—See Garnet.

SCHOENITE, p. 948.—See Picromerite.

Schreibersite, p. 31.—Cohen, as the result of an investigation of many meteoric irons, has shown that the tetragonal iron-nickel phosphide, called rhabdite (Min., p. 31), is identical with schreibersite; the relative amounts of the metals vary widely. Ann. Mus. Wien, 9, 97, 1894.

"Rhabdite" occurs in tetragonal crystalline forms (with (001), (110), (111)) in the meteoric iron of Bendegó, Brazil; 110 \(\Lambda \) 111 = 39°-40° Hussak. Cf. Derby, Arch. Mus. Nac., Rio de Janeiro,

9, 171, 1896.

Schulzenite. P. Martens [Act. Soc. Sci. Chili, 5, 87, 1895], Bull. Soc. Min., 19, 211, 1896. A doubtful substance of uncertain origin, related to asbolite. Found in the collection of J. Schulze H. = 3.5. G. = 3.39. Color and streak black. Gives off chlorine when treated with hydrochloric acid. Analysis gave: Co 46.76, Cu 12.65, SiO₂ 1.76, Fe₂O₃ 0.29, H₂O (comb.) 14.08, H₂O (hygr.) 4.92, O [19.54] = 100. From this the formula is deduced: CuO.2CoO.Co₂O₃ + 4H₂O. and supposed to have come from northern Chili. Amorphous with conchoidal fracture.

Scolecite, p. 604.—Referred to the clinohedral group of the monoclinic system by Rinne, who gives the results of investigation by etching, pyroelectricity, etc. Jb. Min., 2, 51, 1894. Moderate heating causes a partial loss of water, and this is accompanied by molecular changes, the new form being called metascolecite, viid., p. 60; also Ber. Ak. Berlin, 46, 1163, 1890. Crystals from the Tulferthal, Tyrol, described by Habert, Zs. Kr., 23, 252, 1897. Analysis, from granite on the Struth, Thuringia, Fomme [Ber. phys.-med. Soc. Erlangen, 25, 1893], Zs. Kr., 25, 616. Also from Italian Peak, Gunnison Co., Colo., Eakins, Bull. U. S. G. Surv., 113, 112, 1898.

Scorodite, p. 821.—Crystals from the Lölling show the forms h (101), f (011), Busz, Zs. Kr., 20, 555, 1892.

Seelandite. Brunlechner [Jb. Nat. Land.-Mus. Klagenfurt, 22, 192, 1893], Bull. Soc. Min., 19, 121, 1896. A variety of pickeringite forming an efflorescence on the siderite of Lölling, Carinthia. Composition, $MgAl_2(SO_4)_4 + 27H_2O$, deduced from the analysis: SO_3 34·03, Al_2O_3 10·54, MgO 4·07, H_2O 51·22 = 99 86.

Semsevite, p. 123.—L. J. Spencer has described (Min. Mag., 12, 60, 1899) crystals from Wolfsberg similar to Krenner's mineral and yielding: S 19.42, Sb 28.62, Pb 51.84 = 99.88, G = 5.92; calculated formula 21PbS.10Sb₂S₃. The form is near that of plagionite. The author also discusses the relations of plagionite, heteromorphite and semseyite, and the suggestion is made that they may form a morphotropic series from 5PbS.4Sb₂S₃ (through 7PbS.4Sb₂S₃, etc., heteromorphite) to 9PbS.4Sb₂S₃. The complex formulas often obtained (cf. plagionite) may be explained by assuming that the crystals analyzed in a given case are compounded of smaller crystals. tals in nearly parallel position but differing among themselves slightly in angle and composition.

Senaite. E. Hussak and G. T. Prior, Min. Mag., 12, 30, 1898.

Tri-rhombohedral like ilmenite (phenacite type). Axis 0 997. $cr = 49^{\circ}$ 4'. In crystals with the forms c (0001); r (1011), S (2021), z (4041). Twins common, tw. pl. a (1120). Cleavage none. Fracture conchoidal. H. = 6 or slightly above. G. = 5:301 unchanged cryst.; 4:78 fresh grains; 4:22 altered cryst. Luster submetallic. Color black. Streak brownish black. In very thin splinters oil-green to greenish brown. Optically uniaxial; birefringence low. Not magnetic.

Composition uncertain; if the iron is all FeO and the manganese MnO2, the approximate for-

mula is (Fe, Pb)O.2(Ti, Mn)O₂. Analysis, Prior:

TiO2	Fe_2O_3	PbO	FeO	MnO	MgO	SnO ₂	
57.21	20.22	10.51	4.14	7.00	0.49	0.11 = 99.68	

Occurs in rounded fragments and rough crystals in the diamond-bearing sands of Diamantina, Minas Geraes, Brazil. Named after Prof. Joachim da Costa Sena of Ouro Preto, Brazil.

SENARMONTITE, p. 198.—Occurs at Nieddoris, Sardinia, Brugnatelli, Rend. Accad. Linc., 3(1). 78, 1894.

SEPIOLITE, p. 680.—Optical structure investigated, also of other compact "amorphous" minerals (glauconite, celadonite, halloysite, nontronite), which are shown to be crystalline with minute mica-like scales, Lacroix, C. R., 121, 737, 1895; Bull. Soc. Min., 18, 426, and Min. France, Vol. 1.

Analysis from Eskishehir, Asia Minor, Weinschenk, Zs. Kr., 27, 574, 1896.

SERPENTINE, pp. 669, 1047.—Anal.—Kynance Cove, Lizard, England, aluminous var. (pseudo phyte), Fox, Min. Mag., 9, 275, 1891. Binnenthal, Duparc and Mrazec, Bull Soc. Min., 17, 210, 1894. Elzivir, Ontario, antholite, Coleman, Am. J. Sc., 48, 281, 1894. Serpentine and serpentine rocks of northern Syria, formation from gabbros and associated peridotites, Finckh, Zs. G. Ges., 50, 113 et seq., 1898.

Comp.—Discussion of composition with experiments and analyses, R. Brauns, Jb. Min., 1, 205, 1894; Zs. anorg. Ch., 8, 348, 1895, Schneider, *ibid.*, 8, 98, 1895; A. Lindner [Inaug. Diss., Breslau, 1893], Zs. Kr., 25, 589, 1896.

Occurrence and associated minerals in the Austrian Alps, Weinschenk, Zs. Kr., 26, 337, 27,

559, 1896.

SERPIERITE, p. 963.—Laurion, Greece, analysis by Frenzel: (G. = 2·52), SO₃ 24·29, CuO 36·12, ZnO 13·95, CaO 8·00, H₂O 16·75 = 99 11. The formula deduced is $3(Cu,Zn,Ca)SO_4 + 3H_2O$. Min. petr. Mitth., 14, 121, 1894.

SIDERITE, pp. 276, 1047.—Description of crystals from France with the new forms (0332), (1012), (3034), Gonnard, Bull. Soc. Min., 18, 382, 1895.

From Neunkirchen, Siegen, containing 3.85 p. c. CoO, Bodländer, Jb. Min., 2, 236, 1892.
Occurrence and origin in the Province of Drenthe, Holland, G. M. van Bemmelen, Arch. Néerland, 20, 25, 1807. Occurrence in the Markhamburg Moore, A. C. States, Arch. Van Bemmelen, Arch. Néerland, Arch. Van Bemmelen, Arch. Néerland, Arch. Van Bemmelen, Arch. Néerland, Arch. Van Bemmelen, Arch. Van Bemmele land., 30, 25, 1897. Occurrence in the Mecklenburg Moors, A. Gärtner, Arch. Ver. Meckl., 51, 1897.

The "clay-ironstone" of Yorkshire, England, contains gallium, Hartley and Ramage, Proc. Roy. Soc., 60, 35, 393, 1896.

Siderotil. A. Schrauf, Jb. G. Reichs., 41, 380, 1892. A rare iron sulphate occurring in groups of divergent needles with melanterite at Idria, Carniola. Composition, FeSO4.5H2O, deduced from the approximate analysis: SO₃ 34.3, Fe₂O₃ 31.7, FeO 30.0, H₂O [34.0], MgO tr. = 100.

SILICATES.—Discussion of constitution, F. W. Clarke, Bull. U. S. G. Surv., 125, also 113.

SILLIMANITE, p. 498.—Experimental investigation of conditions of formation in a magma. Morozewicz, Min. petr. Mitth., 18, 22, 1898.

SILVER, p. 19.—Occurs at Silver Hill, near Livingston, Davidson Co., N. C., Kunz, Am J. Sc., 7, 242, 1899. Also in groups of minute crystals at the Elkhorn mine, Jefferson Co., Montana (Pfd.).

Sjögrufvite. Igelström, G. För. Förl., 14, 309, 1892. A partially investigated mineral from the Sjö mine, Orebro, Sweden. Occurs in cavities and minute veins with jacobsite. Crystalline. Color yellow; blood-red in thin layers. Streak yellow. Dissolves completely in cold hydrochloric acid without evolution of gas. Analysis gave: As2O, 49.46, Fe2O, 11.29, MnO 27.26, CaO 3.61, PbO 1.74, H_2O 6.81 = 100.17. It is related to arseniopleite (Min., p. 803).

SKUTTERUDITE, p. 93.—Crystals from the Turtmannthal, Switzerland, show the forms: a (100). o (111), d (110), e (210), n (211). Analysis: As 74:45, S 0.72, Bi 4:40, Co, Xi 20:47, Fe 2:90, gangue 0:28 = 100:22. Staudenmaier, Zs. Kr., 20, 468, 1892.

Bismutosmaltite is a skutterudite containing bismuth. Occurs in small crystals, a and o or a and d. Brittle. H. = 6. G. = 6.92. Luster metallic. Color tin-white. Streak black. Composition, Co(As,Bi)₃₅ Analysis: As 61.59, Bi 20.17, Sb 0.16, Co 10.70, Cu 0.69, Fe 3.71, S 0.05 = 100.07. Occurs with other bismuth minerals at Zschorlau, near Schnecherg, Saxony. Frenzel, Min. petr. Mitth., 16, 524, 1896.

Nickel-skutterudite is a variety occurring in granular form in the Bullard's Peak distr., Grant Co., New Mexico. H. = 5; color gray; streak black. Analysis, after deducting 4.56 SiO₂ and 8.38 Ag (native silver), yielded: As 78.10, Ni 12.80, Co 5.95, Fe 0.00 = 100. This corresponds to RAs, with R = Ni: Co: Fe = 4:2:1. Waller and Moses, Sch. Mines Q., 14, 49, 1892.

SMITHSONITE, p. 279.—A variety from Bolco, Lower California, has a delicate pink color. G. = 3.874, and contains 39.02 p, c. ZnO, 10.25 OoO, 2.36 MnO, 7.22 MgO. C. H. Warren, Am. J. Sc., 6, 123, 1898.

Analysis of the "turkey-fat ore" of Marion Co., Arkansas, gave H. N. Stokes, CdS 0.25,

CdO 0.63, etc., Bull. U. S. G. Surv., 90, 62, 1800.

On the occurrence of lead and zinc ores in Iowa, A. G. Leonard, Iowa Geol. Surv., 6, 1896.

Soda-Berzeliite.—See Berzeliite.

Soda-niter, p. 870.—On the morphology, see Wolff, Ber. Ak. Berlin, 715, 1895; 135, 1896.

SODA-RICHTERITE. - See Astochite and Richterite.

Sodalite, p. 428.—Anal.—Hastings Co., Ontario, etc., Luquer and Volckening, Am. J. Sc., 49, 465, 1895. Dungannon, Hastings Co., Ontario, Harrington, *ibid.*, 48, 17, 1894. From the trachyte of Montesanto, Italy, Franco, Zs. Kr., 25, 332, 1895.

Reported by Osann as occurring in the nephelite-syenite of Paisano Pass, Davis Mts., Texas, Geol. Surv. Texas, 4th Ann. Rep., 128, 1892.

On the formation of some twenty-five analogous compounds, Thugutt [Inaug. Diss., Dorpat,

1891], Zs. anorg. Ch., 2, 65, 113, 1892, also Jb. Min., 2, 10 ref., 1893.

Experimental investigation of conditions of formation in a magma (also for related species), Morozewicz, Min. petr. Mitth., 18, 128, 1898.

Spangolite, p. 919.—Associated with connellite, clinoclasite, tiroconite from Cornwall (probably the St. Day distr., Redruth?); in hemimorphic, hexagonal crystals, pyroelectric Nature, 48, 426, 1893, and Min. Mag., 10, 273, 1894.

Sperrylite, p. 92.—Crystals from the Vermillion mine show the diploid (10.5.2), T. L. Walker, Am. J. Sc., 1, 110, 1896.

Occurrence and crystals (Fig. 1 by G. H. Edwards) described, from

Macon Co., N. Carolina, Hidden, Am. J. Sc., 6, 381, 467, 1898.

SPHÆROSTILBITE, p. 583.—Prior shows that the supposed mineral of Bendant probably has no existence. Specimens from various localities called by this name proved to be thomsonite, not stilbite. Min. Mag., 12, 26, 1898.

SPHALERITE, pp. 59, 1048.—Cryst.—Binnenthal, new form 316, Cesâro, Bull. Acad. Belg., 25, 88, 1893; also earlier 618 (or 618), idem, Ann. Soc. G. Belg., 17, 237, 1890. Kis-Almás, Hungary, new form (10·10·1), Franzenau, Zs. Kr., 27, 95, 1896 Galena, Ill., new form (775), Hobbs, Bull. Univ. Wisconsin, 1, 134, 1895, and Zs. Kr., 25, 268
Harz Mts., Luedecke, Min d. Harzes, 53 1896. Val Trompia, Bóvegno, Artini, Rend. Ist. Lombardo, 30, 1526, 1897.

Analysis of "schalenblende" from Mies, Bohemia, with 1 02 p. c. cadmium, Becke, Min. petr. Witth. 14, 278, 1894.

Mitth., 14, 278, 1894. Peelwood, N. S. W., contains gallium and indium, Kirkland, Austr. Assoc. Adv. Sci., 4, 266,

1892. A variety (Cornwall?) containing 9.29 p. c. Fe has perfect metallic luster, Miers, Min. Mag., 12, 111, 1899.

SPINEL, pp. 220, 1048. - Experimental investigation of the conditions of formation in a magma, Morozewicz, Min. petr. Mitth., 18, 22, 1898

Spodiosite, p. 777.—Crystals from Nordmark, Sweden, examined by G. Nordenskiöld were orthorhombic with the forms: a (100), b (010), c (001), m (110), d (102), e (021), p (111), q (254)?, r (854)?. Axes deduced $\tilde{a}:\tilde{b}:\tilde{c}=0$:8944:1:1:7836; $bm={}^{+}48^{\circ}$ 11'-4, $cp={}^{+}67^{\circ}$ 10'-2. Analysis on material much decomposed gave (cf. anal., p. 777): P_2O_3 29 62, CaO 45.84, CaO MgO 8.56, CaO 41.03, CaO 45.84, CaO 8.74, CaO 49.856, CaO 45.84, CaO 8.76, CaO 49.856, CaO 40.856, CaO 40.85

STANNITE, p. 83.—Tetrahedral crystals are mentioned by vom Rath, Vh. Ver. Rheinl., 41,

295, 1884; also Stelzner (from Bolivia), Zs. G. Ges., 49, 97, 1897.

Shown by Headden to occur at the Peerless and Etta mines, Black Hills, S. Dakota, Am. J. 8c., 45, 105, 1893. Analysis (Peerless mine) gave: S $28\cdot26$, Sn $24\cdot08$, Cu $29\cdot81$, Fe $7\cdot45$, Zn $8\cdot71$, Cd $0\cdot33$, Sb tr., insol. I $51=100\cdot15$. G $=4\cdot534$; color grayish black. Largely altered by exidation to a greenish earthy mass; this substance has been made by Ulke (Trans. Am. Inst. Mng. Eng., 21, 240. Feb., 1892) the basis of a new species, cuprocassiterite, supposed (as the result of a partial analysis) to have the formula, $4SuO_2 + Cu_2Sn(OH)_2$. Headden shows, however, that the composition varies widely.

STAUROLITE, p. 558.—Penfield and Pratt, on the basis of new analyses (below) on pure material, have established the formula HAl₆FeSi₂O₁₈, or (AlO)₄(AlOH)Fe(SiO₄)₂. Sections of crystals from Lisbon, N. H., show a regular arrangement of carbonaceous inclusions, thus Figs. 1 to 4, cut from the same crystal.

The composition has also been discussed by Rammelsberg, Jb. Min., Beil.-Bd., 9, 480, and Ber. Ak. Berlin, 435, 1893.

Steenstrupine, p. 415.—Further examined by Moberg (Zs. Kr., 29, 386, 1898) with the following results: Crystallization rhombohedral, axis $\dot{c}=1.0842$, $cr=*51^{\circ}$ 23', $rr'=85^{\circ}$ 10'. Forms: c (0001), a (1120), ρ (5059), r (1011), z (4041), ϵ (0113), ϵ (0112), f (0445), d (0221), ξ (0881). Habit rhombohedral, r predominating. Cleavage none. Fracture conchoidal. H.=4. G.=3.40 -3.47 cryst.; 3.19 massive. Luster resinous. Color dark brown to nearly black. Streak brown. Optically—Birefringence low. By alteration isotropic. Analyses by Blomstrand, 1 on crystals and 2, 3 on massive material; all somewhat altered, the crystals least so. About onethird of the water goes off at 100° to 110°.

 ${\rm SiO_{2}~(Ta,Nb)_{2}O_{5}~P_{2}O_{5}~ThO_{2}~Ce_{2}O_{3}~(La,Di)_{2}O_{3}~Y_{2}O_{3}~Fe_{2}O_{3}~Mn_{2}O_{3}~MnO~~Al_{2}O_{3}~BeO~~CaO~~PbO~~Na_{2}O_{3}~Ne_{2$ 15.90 2.55 5.81 3.03 14.40 4.55 1.83 2.35 4.03 0.46 8.34 K2O 0.50, H2O 7.58 = 99.07 $\mathrm{SiO_2} \ (\mathrm{Ta}, \mathrm{Nb})_2\mathrm{O_5} \ \mathrm{P_2O_5} \ \mathrm{ThO_2} \ \mathrm{CeO_2} \ (\mathrm{La}, \mathrm{Di})_2\mathrm{O_3} \ \mathrm{Y_2O_3} \ \mathrm{Fe_2O_3}$ Mn2O3 Al2O3 BeO CaO PbO Na₂O H₂O

Stephanite, pp. 143, 1025, 1048.—Cryst.—Sarrabus, Sardinia, crystal monograph, new forms noted: (510)?, (230), $(0.5\cdot11)$?, (818), $(18\cdot5\cdot5)$, $(13\cdot4\cdot4)$, $(7\cdot11\cdot9)$, (372), (141), $(2\cdot10\cdot1)$, (161). Artini, Giorn. Min., 2, 241, 1891. Přibram, cryst. memoir, new forms: N (522), r_3 (441), h_2 (9·13·18)?, t_3 (8·33·16)?, Nejdl, Ber. Böhm. Ges., Feb. 8, 1895. Harz Mts., Luedecke, Min. d. Harzes, 168, 1896. Chili, new forms (551), $(10\cdot10\cdot3)$, L. J. Spencer, Min. Mag., 11, 196, 1897.

Stevensite.—See Talc.

Stibiotantalite. G. A. Goyder, J. Ch. Soc., 63, 1076, 1893. A mineral substance, occurring in water-worn fragments in the tin bearing sands of Greenbushes, West Australia. Analysis on nearly pure material gave: Ta_2O_b 51 13, Nb_2O_3 7 56, Sb_2O_3 40 23, Bi_2O_3 0 82, NiO 0 08, H_2O 0 08=99 90. G. = 7 37. H. = 5-5 5. Luster adamantine to resinous. Color pale reddish yellow to greenish yellow and yellow. Fracture subconchoidal to granular. Structure crystalline.

STIBNITE, pp. 36, 1048.—Cryst.—Cetine, Italy, Artini, Rend. Accad. Linc., 3 (2), 416, 1894. Allchar, Macedonia, Vrba, Ber. Ak. Böhm. Dec. 7, 1894. Schlaining, Hungary, new forms b (034), A (10.9.15), b (12.19.3), s (40.19.10), r (563), A. Schmidt, Zs. Kr., 29, 196, 1897. Brixlegg, Tyrol, Worobieff, Zs. Kr., 31, 52, 1899.

Heat conductivity measured, F. B. Peck, Zs. Kr., 27, 316, 1896.

STILBITE, p. 583.—Crystals from the Tulferthal, Tyrol, described, Habert, Zs. Kr., 28, 243, 1897.

Change in physical and chemical characters brought about by the action of sulphuric acid, Rinne, Jb. Min., 1, 41, 1897. The name metadesmine (p. 58) is given to the forms resulting from more or less complete dehydration; the chemical and physical changes are found to go on together See Sphærostilbite.

STILPNOMELANE, p. 658.—Occurs at the Wallbridge mine, Madoc, Hastings Co., Ontario; Also on Partridge Is., Nova Scotia. Hoffmann, Rep. G. Canada, 7, 15R.

STOLZITE, p. 989.—Crystals from Loudville, Mass., described by Emerson are hemihedral with

the forms: (120), (130), (101), (111), (131), (342). Bull. U. S. G. Surv , 126, 163, 1895. Crystals from the Broken Hill mines, New South Wales, described by C. Hlawatsch, show the new forms: a (100), Ω (1·0·10)?, ω (109), τ (103), o (102), η (203), h (304), e (201), π (133), A (155). Axis e=1.5606. Optically —. Indices $\omega_y=2.2685$, $e_y=2.182$. Analysis by Treadwell. Zs. Kr., 29, 1:0, 1897.

On rounded faces, etching-figures, etc., Hlawatsch, Zs. Kr., 31, 1, 1899.

STRIGOVITE, p. 659.—Analysis, Grand Marais, Minn., Berkey 23d Ann. Rep't Minn. G. Surv., p. 197.

STROMEYERITE, pp. 56, 1048.—Occurs at the Silver King mine, Toad Mt., Yale district, Br. Columbia (anal. by Johnston), Hoffmann, Rep. G. Canada, 8, 13R, 1895.

STRONTIANITE, pp. 285, 1048.—Occurs in Nepean township, Carleton Co., Ontario, Hoffmann. Rep. G. Canada, 6, 22R, 30R, 1892-93 At Lubna, near Rakonitz, Bohemia, Eichleiter, Vh. G. Reichs., 297, 1898.

Succinite, p. 1004 —See investigations on succinite and related resins by Dahms, Schrift. Ges. Danzig, 8, Nos. 3-4, p. 97, 1892; 9. No. 2, 1, 1895. Also Aweng [Arch. f. Pharm., 232, 660, 1894], Jb. Min., 2, 254 ref., 1896; Helm [ibid., 233, 191, 1895], Jb. Min., 2, 255, 1896. Also Monograph. d. baltisch. Bernsteinbäume, H. Conwentz, Danzig, 1890.

See also allingite, burmite, cedarite, etc.

Sulfoborite. See Sulphoborite.

Sulphoborite. Sulfoborit, H. Naupert and W. Wense, Ber. Ch. Ges. 26, 874, 1893. H. Bücking, Ber. Ak. Berlin, 967, 1893.

Orthorhombic. Axes $\check{a}: \check{b}: \dot{c}=0.6196:1:0.8100$. Observed forms: b (010), c (001), m (110), r (101), o (111). Angles: $mm'''=63^{\circ}$ 34', $oo'=*90^{\circ}$ 53', $oo'=*66^{\circ}$ 4', $oo''=113^{\circ}$ 56', $oo'''=52^{\circ}$ 24'. In small prismatic crystals of varying habit.

Cleavage: m rather perfect; c less so. Brittle. H. = 4. G. = 2·38-2·45 Naupert and Wense; 2·416 Thaddeeff, also clear cryst. 2·440. Luster dull on c. Colorless or reddish on the exterior (Fe₂O₃). Transparent. Optically – . Ax. pl. \parallel b. Bx_a \pm c. $2H_{ay} = 79^{\circ}$ 36′, $2H_{o,y} = 85^{\circ}$ 4′ Na. . . $\beta_y = 1.5396$, also $\alpha_y = 1.5272$. $\gamma_y = 1.5443$. Composition, $2MgSO_4$. 4MgHBO₃.7H₂O Thaddéeff; Naupert and Wense obtained 3MgSO₄.

2Mg_{*}B₄O₉ + 12H₂O. Analyses, 1, Naupert and Wense; 2 Thaddéeff, Zs. Kr, 28, 264, 1897.

H₂O B_2O_3 MgO

19 79 33.48 23.43 (ign.), H_2O 0.10 (110°-170°), Fe_2O_3 0.11, insol. 0.32 = 99.6922.46

B.B. fuses with intumescence, coloring the flame green; reacts for sulphur with soda on charcoal. Dissolves rather readily in mineral acids.

From the salt mines of Westeregeln, where it occurs with anhydrite, carnallite, kieserite, celestite, eisenboracite, etc.

SULPHOHALITE, p. 917.—Van't Hoff and Saunders suggest doubts as to the existence of this species on the insufficient grounds: (1) since they failed to obtain it synthetically; and (2) since specimens furnished as sulphohalite by a dealer proved to be simply halite. Ber. Ak. Berlin, p.

392, 1898. Penfield, however, has examined (priv. contr.) the original specimen and finds it to be homogeneous and to contain both sulphate and chloride of sodium. A new analysis will be made.

Sulphur, pp. 8, 1048.—Cryst.—Milo; Roisdorf, new form f (151); Bassick, η (553); Comil, near Cadiz, twins, tw. pl. (101), Busz. Zs. Kr., 20, 558 et seq., 1892. Allchar, Macedonia, new form k (122), Pelikan, Min. petr. Mitth., 12, 344, 1892; also Vrba, Ber Ak. Böhm., Dec. 7, 1894. Schlaining, Hungary, occurring with stibnite, Schmidt, Zs. Kr., 29, 207, 1897. Buggeru, Sardinia, new forms, φ (305), μ (319), λ (155), Millosevich, Riv. Min. Ital., 21, 43, 1898. Occurs in the Upper Helderberg limestone of Monroe Co., Mich., Sherzer, Am. J. Sc., 50, 246, 1895. Occurrence in Texas, E. A. Smith, Science, 3, May 1, 1896. Method of formation of the third allotropic form (monoclinic), Salomon, Zs. Kr., 30, 605, 1899.

Sundtite. W. C. Brögger, Zs. Kr., 21, 193, 1893.—See Andorite,

SVABITE, p. 1052.—Further described by Hj. Sjögren, G. För. Förh., 13, 789, 1891; 17, 313, 1895; Bull. G. Inst. Upsala, 1, 50, 1892. Occurs well crystallized at the Harstig mine, Pajsberg; also in minute crystals, but usually massive, at the Jakobsberg mine, near Nordmark, Sweden. Compositive of the Composition of t tion essentially Ca₄(CaF)As₃O₁₂, or analogous to that of apatite, with which it agrees in form; F partly replaced by Cl and (OH), Ca partly by Pb, Mg and alkalies. Analyses, R. Mauzelius, quoted by Sjögren, Bull. G. Inst. Upsala, 1, 54: 1, G. = 3.77; 2, G. = 3.82.

Svabite.

Svabite appears to belong distinctly to the Apatite Group; its relationship is shown not only in the similarity of angle, but also in the symmetry of the form as indicated by traces of a hexagonal prism of the third order (cf. Fig.).

Sylvanite, p. 103.—From Nagyág, Vrba, Ber. Ak. Böhm, Dec. 7, 1894.

Occurs at Kalgoorlie, West Australia. G. = 8.14, Ag = 3.82 p. c. Frenzel, Min. petr-Mitth., 17, 288, 1897.

Occurs at Cripple Creek, Colorado. See Calaverite, Krennerite, and Goldschmidtite.

SYLVITE, pp. 156, 1036, 1049.—Refractive indices for long waves, Rubens and Snow, Wied. Ann., 46, 529, 1892.

Dispersion and absorption in infra-red, Rubens and Trowbridge, Wied. Ann., 60, 724, 1897. and Am. J. Sc., 5, 33, 1898.

Stassfurt, analysis by W. Schimpff, Zs. Kr., 25, 92, 1895.

SYNGENITE, p. 945.—Optical constants determined, Mügge, Jb. Min., 1, 266, 1895.

TACHHYDRITE, p. 178.—Discussion of conditions of formation and of alteration, van't Hoff and Meyerhoffer, Ber. Ak. Berlin, 508, 1897.

On the synthesis of isomorphous compounds, A. de Schulten, Bull. Soc. Ch., 17, 165, 1897.

Talc, p. 678.—From the dolomite of Canaan, Conn., rose-colored, analysis by L. Kahlenberg: SiO₂ 61.48, Al₂O₃ 3.04, MgO 25.54, CaO 4.19, FeO 0.77, MnO tr., H₂O 5.54 = 100.56. See Hobbs, Am. J. Sc., 45, 404, 1893.

On the origin (from enstatite and tremolite) of the fibrous talc of northern New York, C. H.

Smyth, Sch. Mines Q., 17, 333, 1896; see Am. Geol., 10, 44, 1892.

Talc, pseudomorphous after pectolite, has been called *stevensite* by Leeds, cf. Chester, Dictionary Names Minerals, 257, 1896.

A fibrous variety perhaps pseudomorphous has been called beaconite by L. W. Hubbard, Rep't State Bd. Geol. Surv. Michigan, 1891–92, p. 171 (Lansing, 1893). Resembles asbestus; $\beta=1.5-1.6$; $2V=60^{\circ}$ (Lane). G. = 2.74-2.88. Analysis gave Packard: SiO₂ 59.72, Fe₂O₃,FeO 8.67, MnO 0.64, MgO 26.42, ign. 4.13 = 99.58; formula deduced H₂(Mg,Fe)₃(SiO₄)₃. From the Champion mine, Beacon P. O., Michigan.

A magnesium silicate near talc in composition occurs in irregular veins and streaks of a bright blue color in silver bearing limestone near Silver City, New Mexico. As separated it is dull, earthy, resembling vivianite. An analysis gave: SiO₂ 62·43, MgO 28·53, ign. 6·47, Al₂O₃ 0·25, FeO 0·99, Na₂O 0·14, K₂O 0·16 = 98·97. R. L. Packard, Proc. Nat. Mus., 17, 19, 1894. This mineral has been called native ultramarine.

Talkknebelite, Talc-knebelite. L. J. Igelström, Jb. Min., 1, 248, 1890.—See Knebelite.

a d

TANTALITE, pp. 731 et seq.—Crystals from Paris, Me., with G. = 7.26, agree closely with columbite in angles (Fig. 1); forms a, b, c, m, d (730), g (130), o (111), n (163), C. H. Warren, Am. J. Sc., 6, 123, 1898. These results show the correctness of the position taken in Dana's Min. (l. c.) in regard to the relation of true tantalite and columbite, as also of the former to "skogbölite" and "ixiolite."

Brögger has now proved, further, that the supposed orthorhombic iron tantalite (skogbölite of Nordenskiöld), which most authors have vainly tried to bring into correspondence in form with columbite, is in fact tetragonal and identical with tapiolite. The crystals (Figs. 1, 2, Min., p. 736) are twins elongated parallel to e (101) as tw. plane (r = 111, etc.). In axial ratio and habit they correspond to mossite (this Append., p. 48). Vid. Skrift. I, Math.-nat. Klasse, No. 7, 1897, Christiania. See also Tapiolite.

Analysis from Finland, Khrushchov, Vh. Min. Ges., 31, 415, 1894.

See also Mossite.

Tapiolite, Topsham, Me.

Tapiolite, p. 738.—Crystals, in part twins (Figs. 1, 2), with G. = 7.67-7.68, occur at Topsham, Me., C. H. Warren, Am. J. Sc., 6, 121, 1898. The twins are elongated & (tw. pl.), similarly to some rutile, cf. Min., p. 1047. Similar twins exist with the tapiolite of Norway formerly called tantalite (skogbölite), see Tantalite.

> Taraspite.—A variety of dolomite from Tarasp, Switzerland, apparently the same as miemite (Min., p. 271), cf. C. v. John, Vh. G. Reichs., 67, 1891.

> Taylorite.—This name (already in use, Min., p. 895) has been given by W. C. Knight (Eng. Mng. J., 63, 600, 1897) to an unctuous, greenish-yellow to cream-colored clay with G. = 2.132; composition variable. Forms beds in the Cretaceous shales of Rock Creek, Albany Co., Wyoming.

TENNANTITE, pp. 137, 1049.—A massive variety occurs at the Mollie Gibson mine, Aspen, Colorado, associated with polybasite (see p. 54, this Appendix). Analysis. Penfield: (G. = 4.56), S 25.04, As 17.18, Sb 0.13, Cu 35.72, Ag 13.65, Zn 6.90, Fe 0.42, Pb 0.86 = 99.90. Also stated to occur near Central City and at the Freeland lode and Crocett mine, Idaho Springs, Colorado. Penfield and Pearce, Am. J. Sc., 44, 18, 1892.

Occurs in Barrie township, Frontenac Co., Quebec, Hoffmann, Rep. G. Canada, 6, 28R, 1892-3. Also at the Avoca claim, Bonaparte river, Lillooet distr., Br. Columbia, *ibid.*, 9, 13R, 1896. See also *Binnite*; which is stated to be identical with tennantite.

TETRADYMITE, p. 39.—Analyses by W. Muthmann and E. Schröder, of specimens from Orawitza and Schubkau give the same composition, Bi₂(Te, S)₃ or 2Bi₂Te₃. Bi₂S₃. Zs. Kr., 29, 140,

1897. Analyses below after deducting gangue, in 1, 11 p. c.; in 2, 0.5 p. c.
Occurs with altaite and hessite near Liddell creek, Kaslo river, West Kootanie, Br. Columbia, Hoffmann, Rep. G. Canada, 8, 10R, 1895. Analysis by Johnston (3 below after deducting 3.5 p. c.

quartz).

Te Se S Ri Orawitza 35.43 4.49 59.14 = 99.062. Schubkau 35.43 60.23 = 99.974.31 tr. Br. Columbia 37.29 53.69 Pb 3.63, Ag 0.94, Tl tr. = 100. 4.45 tr.

Tetragophosphite. L. J. Igelström, Zs. Kryst., 25, 433, 1895. A supposed new phosphate resembling lazulite, occurring at Horrsjöberg in a quartzose rock carrying cyanite. In four-sided tabular crystals; color bright blue; transparent. Two analyses gave somewhat discordant results:

P2O6	Al ₂ O ₃	FeO, MnO	Mg, CaO	H ₂ O
36.92	40.00	9.51	7.50	5.96 = 99.89
33.64	41.81	9.51	6.24	$8\ 30 = 100$

TETRAHEDRITE, p. 137.—Crystals from Framont described with new forms, (771), (11-11-2), (21-20-20), Brunlechner [Inaug. Diss., Strassburg, 1892], Zs. Kr., 24, 628, 1895.

A variety containing lead (9-38 p. c. Pb) occurs at the Antelope claim, West Kootanie, Br. Columbia (anal. by Johnston), Hoffmann, Rep. G. Canada, 7, 12R, 1894. Occurs also (3-09 p. c. Ag) near Sicamons, Shuswap Lake, Br. Columbia, Hoffmann, Rep. G. Canada, 5, 65R, 1889-90. With gold ores of California, Turner and Lindgren, Am. J. Sc., 49, 379, 1895.

Specific heat determined, also of other sulphur compounds, A. Sella. Nachr. Ges. Göttingen,

311, 1891.

Thalénite. Benedicks, G. För. Förh., 20, 308, 1898.

Monoclinic. Axes $\dot{a}:\dot{b}:\dot{c}=1.154:1:0.602$; $\beta=80.2^{\circ}$. Forms: a (100), b (010), c (001), m (110), f (021), e (111), d ($\bar{1}\bar{1}1$), d (311). Angles: $am=48.7^{\circ}$, $a'd=73^{\circ}$ 0', $bd=55.7^{\circ}$. Crystals tabular | a, in part prismatic | c.

Cleavage none. Fracture uneven to splintery. Brittle. H. = 6·5. G. = 4·227. Color flesh-red. Optically—. Ax pl. nearly \pm c. Bx_a \pm a (100). Indices for Na, α = 1·7312, β = 1·7375, γ = 1·7436. $2H_{a \cdot y} = 81^{\circ}$ 36′, \therefore $2V_{a \cdot y} = 67^{\circ}$ 35′. Composition, $H_2Y_4Si_4O_{15}$ or $H_2C.2Y_4O_3.4SiO_2$. Analyses: 1, of fresh material; 2, of weathered

material.

Y₂O₃* Fe₂O₃ Al₂O₃(BeO) CaO Na₂O SnO H₂O CO2 Xp MgO SiO2 0.45 0.49 0.21 0 26 0.23 2.08 1.04 1.40 = 99.6929.88 63.35 0.30 1. 2.70 2.19 1.07 0.22 27.69 58.58 1.51 0.35 0.403.33 2.50 = 100.53 ${}^{1}R_{2}O_{3} = 245.3$ bHelium, etc.

The numbers given are the mean of two to five determinations.

Occurs with fluorerite at Österby in Dalecarlia, Sweden. Named after Prof. R. Thalén. Related to yttrialite (Min., p. 512), rowlandite (p. 1047), etc.

THALITE, p. 682.—Examined by N. H. Winchell (anal., Pease), Amer. Geol., 23, 41, 1899.

THAUMASITE, p. 698.—From West Paterson, N. J., described by Penfield and Pratt. Occurs in trap associated with pectolite, apophyllite, and various zeolites. Forms a loose aggregate of prismatic crystals (hexagonal). G. = 1.875-1.887. Color white. Index $n_y = 1.5125$ Na. Analysis:

CO₂ SO₃ CaO H₂O Na2O K₂O SiU, $(\frac{3}{3})$ 9.26 6.82 13.44 27.13 42.77 0.39 0.18 = 99.99

As regards the water, 13 molecules go off at 150° and This agrees closely with earlier results. are regarded as being water of crystallization, hence the formula [(CaOH)CO₂].[(CaOH)SO₃]. [(CaOH)HSiO₄] + 13H₂O. Am. J. Sc., 1, 229, 1896.

Also described by Bäckström from Skottvång, Nyköping, Sweden; associated with apophyl-

lite, G. För. Förh., 19, 307, 1897.Sec also note by Pisani, Bull. Soc. Min., 19, 85, 1896.

THENARDITE, p. 895.—Pseudomorphs after mirabilite from Aussee in the Salzkammergut are described by Pelikan; also pyramidal crystals r (111) with the new forms v (113) and u (130); these yield the mean axial ratio, $\check{a}: \check{b}: \dot{c} = 0.5970:1:1.2541$. Min. petr. Mitth., 12, 476, 1891.

THOMSONITE, pp. 607, 1050.—Crystals from the Tulferthal, Tyrol, described, Habert, Zs. Kr., 28, 254, 1897.

See also Bagotite and Lintonite.

THORITE, pp. 488, 1050.—Crystals from Arendal, described with c (001), Hamberg, G. För. Förh., 16, 327, 1894.

Occurs in granite of the Trotter mine, Franklin Furnace, N. J., Kemp, Trans. N. Y. Acad. Sc., 13, 76, 1893.

Tiffanyite. G. F. Kunz, Trans. N. Y. Acad. Sci., 14, 260, 1895. A name proposed for a hydrocarbon assumed to be present in certain diamonds, namely, those which, on this account, exhibit fluorescence and phosphorescence. The substance apparently has a bluish-white color.

Tilasite, Fluor-Adelite. H. Sjögren, G. För. Förh., 17, 291, 1895. Massive, granular. Cleavage in one direction (A) distinct, in three others (B, C, D) less so. G = 3.28. Luster resinous, m cleavage-surfaces vitrous. Color gray with a tinge of violet. A section ||A| and Bx, shows the ax. plane inclined 19° to B and 28° to C.

Composition (MgF)CaAsO₄, or analogous to adelite (p. 1) with fluorine instead of hydroxyl.

Analysis, Mauzelius:

Occurs at Långban, Sweden, with berzeliite and calcite in veins in the manganiferous (hausmanaite) dolomitic limestone. Named after the Swedish mining engineer, Daniel Tilas.

TITANITE, p. 712.—Crystals from Lauvitel, Isère, France, show the new forms (3.3.20) and (883), Termier, Bull. Soc. Min., 19, 81, 1896. Crystals from Tyrol, Weinschenk, Zs. Kr., 26,

Pyroelectricity investigated, Traube, Jb. Min., Beil.-Bd., 11, 209, 1897.

Occurs as a prominent constituent of the "titanite-gneiss" from near the Brenner Pass in Tyrol, Rodewyk, Min. petr. Mitth., 17, 544, 1897.

Artificial formation, Michel, C. R., 115, 830, 1892.

See also Neptunite.

Topaz, p. 492.—Cryst.—Alabashka, new form (338), Jeremejev, Vh. Min. Ges. St. Pet., 27, 439, 1891, and Zs. Kr., 22, 74, 1893. Ilmen Mts., new forms (290), (580), (415), (10-3-13), (8-7-15), (116)?, and others doubtful, Southeur, Zs. Kr., 20, 232, 1892. Japan, Matthew, Sch. Mines Q., 14, 53, 1892. Köhlerloh quarry near Reenersreuth, Fichtelgebirge, forms (9'9'20), (1'11'12)?, Bücking, Ber. Senckenberg. Ges., 147, 1896. Crystals in collection of U. S. National Museum, Eakle, Proc. U. S. Nat. Museum, 21, 361, 1898.

Investigation of inclusions, Tolstopiatov, Vh. Min. Ges., 33, 289, 1895.

Ilmen Mrs. and Adun Chalon, optical characters determined, Thaddeeff, Zs. Kr., 23, 536, 1894.

Occurs abundantly in colorless crystals in alluvial sands of district of Batang Padang, Perak, Lacroix and Sol, C. R., 123, 135, 1896. Occurs near Palestine, Texas, in rolled crystals, Kunz, Trans. N. Y. Acad. Sc., 13, 144, 1894, and Am. J. Sc., 47, 403, 1894.

Synthetic experiments, A. Reich, Ber. Ak. Wien, 105 (2), 105, 1896; Monatsh. f. Chemie, 17,

149, 1896.

By a series of accurate analyses, Penfield and Minor (Am. J. Sc., 47, 387, 1894) have shown that the ratio for $SiO_2: Al_2O_3: F + OH$ is constant, viz. = 1:1:2, but the amounts of fluorine and hydroxyl vary widely. This ratio gives the formula $[Al(F,OH)]_2SiO_4$ or $Al(F,OH)_2AlSiO_4$. With the change in the relative amounts of fluorine and water vary also the specific gravity, crystallographic axes, and optical characters. Crystals from the Thomas Range, Utah, contained almost no water (0·19 p. c. with 20 37 F); they have G. = 3·565, $2E_y = 125^{\circ}$ 53' and $\gamma - \alpha = 0.0104$. Crystals from Minas Geraes, Brazil, gave 2·45 H₂O and 15·48 F; for them G. = 3·532, $2E = 84^{\circ}$ 28' and $\gamma - \alpha = 0.0081$. Between these extremes fall crystals from Colorado, Japan, Siberia, Saxony, Maine. The presence of water has also been determined by Jannasch and Locke, Zs. anorg. Ch., 6, 168, 321, 1894, and Am. J. Sc., 47, 386, 1894.

Torbernite, p. 856.—Etching-figures indicate monoclinic symmetry T. L. Walker, Am. J. Sc., 6, 41, 1898.

Tourmaline, pp. 551, 1050.—From Elba, monographs on the crystallization (new forms (2.0.2.11) and (5.1.6.1) and physical characters, especially the refractive indices, also pleochrolsm, specific gravity, hardness, etc. G. D'Achiardi, Att. Soc. Tosc., Mem., Pisa, 13, 229, 1894, also Proc. Verb., March 4, 1894, and 15, 1896. Isola del Giglio, investigation of sections | c, showing zou-| structure, idem, Annal. Univ. Tosc., 22, 1897.

Etching-figures investigated, Traube, Jb. Min., Beil.-Bd., 10, 460, 1896; also Walker, Am. J.

Sc., 5, 178, 1898. Secondary enlargement in itacolumite, Derby, Am. J. Sc., 5, 190, 1898.

Dichroism for infra-red waves, E. Merritt, Wied. Ann., 55, 49, 1895.

Anal.—Urulga, Siberia, Prendel, Zs. Kr., 20, 93, 1892. Kuhrau, Bohemia, Katzer; also from Benitz, Formánek, Min. petr. Mith., 12, 420, 1892. Nevada Co., California, W. H. Melville, Bull. U. S. G. Surv., 90, 39, 1892. Caprera, Fasolo quoted by Lovisato, Rend. Accad. Line., 4 (1), 84, 1895.

Occurrence of tourmaline schists, Belcher Hill, Colorado, H. B. Patton, Bull. G. Soc. Amer.,

10, 21, 1899.

Comp.—Penfield and Foote (Am. J. Sc., 7, 97, 1899), on the basis of two new analyses of widely different varieties (quoted below) which were carried through with great care on material of absolute purity, and also after a discussion of many other trustworthy analyses, arrive at the conclusion that all varieties of tourmaline can be referred to the aluminium-borosilicic acid $H_0Al_3(B\ OH)_2Si_4O_{19}$. More simply put, the acid derived is $H_{20}Bi_2Si_4O_{21}$, the ratio of $H:B_2O_3:SiO_2$ being 20:1:4. The constant relation between the boron and silicon deduced by other analysts is fully confirmed. Of the analyses of others (for the most part quoted in Min., pp. 554, 555) the series by Riggs agree closely with the above ratio; this is also true of those by Januarch and Kalb; the analyses by Rammelsberg are (as stated by him) low in water and require correction for the oxidation of the iron. Corrected in these points they also conform to the above ratio. new analyses by Penfield and Foote are:

SiO₂ TiO₂ B₂O₃ Al₂O₃ FeO MnO MgO CaO Na₂O K₂O Li₂O H₂O F .05 — 2.98 0.93=101.11 deduct (F=O) 0.39=100.73 — 1.64 3.10 1.13=101.09 deduct (F=O) 0.48=100.61 1. DeKalb, colorless 3·049 \(\frac{2}{3}\) 36·72 0·05 10·81 29·68 0·22 — 14·92 3·49 1·26 0.05 2. Haddam Neck, green 3.089 \$ 36.96 0.03 11.00 39.56 2.14 2.00 0.15 1.28

The composition has been also discussed by Kenngott, Jb. Min., 2, 44, 1892, and by Rheineck, Zs. Kr., 22, 52, 1893.

TRIPHYLITE, p. 756.—The influence of varying amounts of iron and manganese in triphylite and lithiophilite has been minutely investigated by Penfield and Pratt, Am. J. Sc., 50, 387, 1895.

Tripuhyite. E. Hussak and G. T. Prior, Min. Mag., 11, 302, 1897

In fragments in gravel, these are micro-crystalline aggregates. G.=5 82. Color dull greenish low. Streak canary-yellow, Translucent. Refringence and birefringence high. Biaxial. vellow. Streak canary-yellow, Composition, probably 2FeO.Sb2O5. Analysis, Prior :

> CaO SiO. Al₂O₃ TiO, Sb2Os FeO 27.70 0.82 1.35 0.86 undet. 1.19 = 10066.68

From the cinnabar-bearing gravels of Tripuhy near Ouro Preto, Minas Geraes, Brazil. Associated with the new species lewisite and derbylite; also xenotime, monazite eyanite, rutile, hematite, magnetite, etc.

TROILITE, pp. 72, 1051.—See Pyrrhotite.

TSCHEFFKINITE, p. 718.—On the occurrence in India, see Mallet, Rec. G. Surv. India, 25, 123. 1892. The original locality is shown to be Kanjamalai Hill in the Salem district, Southern India.

Turquois, p. 844.—Analyses from New Mexico and Persia, Carnot, Bull. Soc. Min., 18, 119, 1895.

Occurs in the Jarilla Mts., Doña Ana Co., N. M., Hidden, Am. J. Sc., 44, 400, 1893.

Tyrolite, p. 839.—Church, working again upon material examined in 1873 (J. Ch. Soc., 27, 108) seems to prove that the mineral (from Falkenstein or Libethen?) in fact contains CaCO₃ (11 p. c.) as an essential ingredient; of the total water (15.68 p. c.) 5.23 p. c. was lost in vacuo and 2.40 at 100° C. Min. Mag., 11, 5, 1895.

Tysonite, p. 166.—Analysis, Colorado, Hillebrand, Am. J. Sc., 7, 51, 1899.

A partially described yttrium-calcium fluoride occurs with the astrophyllite of W. Cheyenne Cañon, El Paso, Colorado, Genth and Penfield, Am. J. Sc., 44, 386, 1892. Granular, crystalline, cleavable. H. = 4. G. = 4'316. Color white, grayish or reddish white. Analysis (Genth) gave; (Y, Er)₂O₃, 47.58 (at. wght. 126), CeO₂ 0.83, (La, Di)₂O₃ 1.55, CaO 19 41, ign. 1.57, Fe₂O₃, F, etc., undet. The formula suggested is CaF₂.(Y, Er, Ce, La, Di)F₃.

UINTAITE, p. 1020.—For description of the occurrence and properties of this hydrocarbon (also called gilsonite), see Locke, Trans. Am. Mng. Eng., 17, 162, 1888, and Eldridge, U. S. G. Surv., 17th Ann. Rep., Part. I, pp. 915-945, 1896.

URANINITE, p. 889. — The varieties cleveile and bröggerite yield helium (and other gases), Ramsay, Proc. Roy. Soc., 58, 65, 81, 1895; 59, 325, 1896. Also Ramsay and Travers, ibid., 60, 443, 1897. Lockyer, ibid., 58, 67, 113, 116, 192, 193; 59, 4, 1895; 59, 342, 1896; (and other minerals) 60, 133, 1896. Tilden, ibid., 59, 218, 1896 Langlet, Oefv. Ak. Stockh., 52, 211, 1895. Regarded as containing the new substances polonium and radium, M. and Mde. P. Curie and G. Belmont, C. R., 127, 175, 1215, 1898.

Analyses, Llano Co., Texas; Marietta, S. C., Villeneuve, Quebec, Johanngeorgenstadt, W. H. Hillehrand Bull, U. S. G. Surv., 90, 22, 1892.

Hillebrand, Bull. U. S. G. Surv., 90, 22, 1892.

URANOTIL, p. 699.—On the crystalline form (triclinic), Pjanitzky, Zs. Kr., 21. 74, 1892, also Jb. Min., 2, 249 ref., 1896.

Urbanite. Hj. Sjögren, G. För. Förh., 14, 251, 1892; Bull. G. Inst. Upsala, 2, 77, 106, 1894. Lindesite, L. J. Igleström, Zs. Kr., 23, 590, 1894. 1.

Monoclinic, belonging to the Pyroxene Group. Axes (Sjögren), $\hat{a}:\hat{b}:\hat{c}=1.1009:1.0.6058$, $\hat{\beta}=72^{\circ}$ 7. Forms: a (100), b (010), m (110), p (101), r (053), u (111), n (221), s (111), o (221); also

doubtful, x (322 or 433), y (614). Angles: $mm'''=92^\circ$ 40', $uu'=48^\circ$ 28', $mu=44^\circ$ 5', $m's=59^\circ$ 6' (calc., Sj.). Habit pyramidal, u, s prominent (Fig. 1). Cleavage, prismatic (m) distinct; c less so. H=.5-6. G=3.52 (L.), 3.53 (G.). Luster vitreous. Color brownish black (L.), chestnut-brown (G.). Streak light brown. Faintly translucent. Strongly pleochroic. a brown, b yellow-brown, c yellow. Ax. pl. | b (010). $a \wedge b =$ + 16° (L.) to 22° (G.).

In composition a metasilicate corresponding to (Ca, Mg)SiO₂

(diopside) + 2 NaFe(SiO₃)₂ (acmite). Analyses, R. Mauzelius, quoted by Sjögren (Bull. G. Inst. Upsala, l. c.):

SiO₂ TiO₂ Al₂O₃ Fe₂O₃ FeO MnO CaO MgO K₂O Na₂O H₂O

1. Långban 51.61 27.24 0.74 0 54 1.73 4.90 2.75 0.36 10.59 0.90 = 101.362. Glakarn 49.21 0.06 1.27 25.35 0.50 6.71 5.68 1.39 0.40 8.95 1.05 F 0.20=100.77

B.B. fuses with difficulty to a magnetic slag. Only slightly attacked by acids.

Occurs at Långban, Sweden, in cavities in granular hematite. This mineral was apparently earlier (1865) mentioned by Breithaupt and analyzed by Winkler (cf. Sjögren). It had been confounded with schefferite (iron-schefferite). Also found at Glakärn, province of Örebro, as idiomorphic grains in a mixture of yellowish-white feldspar and rhodonite. This mineral was partly investigated by Igelström (l. c.) and called lindesite. Named after the Swedish investigator Urban Hjärne.

Utahlite. - See Variscite.

VALERIITE, p. 108.—Shown by Petrén to be a mixture of covellite, pyrrhotite, hydrotalcite, siderite, spinel and probably limonite, G. För. Förh., 20, 183, 1898.

Valléite. G. Cesàro, Bull. Acad. Belg., 29, 508, 1895; 32, 536, 1896. A colorless or pale red orthorhombic amphibole accompanying the violet tremolite of Edwards, N. Y. In prismatic crystals with a (100), m (110), x (920)?, (021)?; $mm''' = 54^{\circ}$ 30'. Cleavage m, also (according to the author) parallel to the pinacoids, and several brachydomes. H. = 4.5. G. = 2.88. Optically negative. Ax. pl. | b (010). Bx 1 a (100). 2E = 90° 28', 2V = 51° approx. $\gamma - \beta = 0.0036$. Composition RSiO₂ or that of anthophyllite, deduced from the analysis by Renard: SiO₂ 58.02, MgO 27.99, CaO 5.04, Fe₂O₃ 1.28, MnO 2.88, K₂O 0.89, H₂O 3.13 = 99.23. Easily fusible to a white opaque bead. Named after De la Vallée-Poussin.

VARISCITE, p. 824.—From near Lewiston, Cedar Valley, Tooele Co., Utah, compact, nodular or crypto-crystalline, color bright green; analysis, R. L. Packard G. 2.62: P.O. 44.40, Al₂O₃ [32.65], H₂O 22.95 = 100. Am. J. Sc., 47, 297, 1894. This variscite has been called utahlite, see G. F. Kunz, 16th Ann. Rep't. U. S. G. Surv., 1894-5, Part IV, p. 602.—See also Wardite.

VERMICULITES, p. 664.—A hydro-mica, largely but not wholly altered to vermiculite, from Rocky Hill, N. J., has been analyzed by F. W. Clarke and N. H. Darton. It is unusual in containing a large percentage of iron (Fe $_2$ O $_3$), and a ferric muscovite is suggested as part of the unaltered compound. Am. J. Sc., 7, 365, 1899.

VESUVIANITE, p. 477.—Cryst.—Mte. Somma and Zermatt, new forms (observed, except E, once only): T (106), S (229), V (552), W (14·14·5), D (18·5·5), K (722), E (11·4·4), also (13·13·4)? Boecker, Zs. Kr., 20, 225, 1892. Vesuvius, P. Franco, Giorn. Min., 4, 185, 1893; also in full in Boll. Soc. geol. Ital., 11, No. 2, 1893. Monograph with optical determinations, analyses, discussion of composition, etc., Weibull, Zs. Kr., 25, 1, 1895. Friedeberg, Silesia, Graber, Min. petr. Mitth., 17, 384, 1897.

Optical characters fully discussed, Klein, Jb. Min., 2, 106, 1895.

Comp.—Ural, analysis of a chromium-bearing variety (2.31 p. c. Cr₂O₃), Sofia Rudbeck, G. För. Förh., 15, 607, 1893. Harstig (4.81 p. c. MnO) and Vaticha (anal. by Mauzelius), discussion of the composition of the species in general, Hj. Sjögren, G. För. Förh., 17, 267, 1895. Analyses and discussion of composition, Jannasch and Weingarten, Zs. anorg. Ch., 11, 40, 1895. Composition discussed, Rammelsberg, Jb. Min., 2, 157, 1896. See also Weibull, above.

Violan, p. 356.—See Pyroxene, p. 57.

VIVIANITE, p. 814.—Occurrence, origin, etc., in province of Drenthe, Netherlands, G. M. van Bemmelen, Arch. Néerland, Harlem, 30, 25, 1897.

Occurrence in the Mecklenburg moors, A. Gärtner, Arch. Ver. Meckl., 51, 1897 (and Inaug. Diss., Rostock).

Wardite. J. M. Davison, Am. J. Sc., 2, 154, 1896.

Massive, encrusting; with concretionary structure, in part colitic. H. = 5. G. = 2.77. Luster vitreous. Color light green, bluish green. Streak white.

Composition, $2Al_2O_3$. P_2O_4 . $4H_2O$ or $Al_2(OH)_3PO_4 + \frac{1}{2}H_2O$. Analysis, Davison, l. c.:

 P_2O_5 Al_2O_5 CuO FeO MgO Na_2O K_2O H_2O $34\cdot46$ $[38\cdot25]$ 0.04 0.76 2.40 5.98 0.24 17.87 = 100

Occurs encrusting cavities in nodular masses of the variscite from Cedar Valley, Utah (see above). Named after Prof. Henry A. Ward of Rochester, N. Y.

WAVELLITE, p. 842.—Crystals described from Arbrefontaine, Belgium, G. Cesàro, Mem. Acad. Belg., 53, 1897.

Analyses by Carnot, C. R., 118, 995, 1894.

Occurs at the Dunellen phosphate mines, Marion Co., Florida, Moses and Luquer, Sch. Mines Q., 13, 238, 1892.

Webnerite. Stelzner, Zs. Kr., 24, 125, 1894.—See Andorite.

Weldite. F. M. Krause [Proc. R. Soc. Tasmania, 1884] quoted by Petterd, Catalogue of Minerals of Tasmania, p. 94, 1896. A white, amorphous substance, containing chiefly silica, alumina and soda, but of undetermined composition. H. = 5.5. G. = 2.98. Occurs with bands of quartzite and is probably derived from the alteration of a felsitic rock. From the Weld river, Upper Huon, Tasmania.

Wellsite. J. H. Pratt and H. W. Foote, Am. J. Sc., 3, 443, 1897.

Monoclinic Axes $a: \dot{b}: \dot{c} = 0.768: 1: 1:245; \beta = 53^{\circ} 27$ = 001 \wedge 100. Measured angles: $ac = 53^{\circ} 27', bm = 58^{\circ} 19', aa = 73^{\circ} 6', bb = 90^{\circ}$. In complex twinned crystals (Figs. 1, 2) analogous to familiar forms of harmotome and phillipsite, but without striations on the b-faces.

Cleavinge none. Brittle. H.= $4.4^{\circ}5$. G.=2.278-2.366. Luster vitreous. Colorless to white. Optically +. Bi refringence low. Bx_a \perp b (010). Bx_o \wedge b = -52° . Ax.

angle large.

Composition, RAl₂Si₃O₁₀.3H₂O where R = Ba: Ca: K₂ = 1:3:3. This requires: Silica 42:8, alumina 24:3, baryta 6:6, lime 7:3, potash 6:1, water 12:9 = 100. Wellsite thus falls into the Phillipsite Group, containing less water than the other members (cf. Min., p. 571). It is shown further that it is to be expected that phillipsite should contain $4H_2O$, not $4\frac{1}{2}H_2O$ as usually accepted (see *Phillipsite*).

Analysis:

MgO K₂O Na2O SiO2 Al203 BaO CaO H₂O 24.96 5.07 0.62 3.40 1.80 43.86 1.15 5.80 13.35 = 100.01

About one molecule of water is given off between 100° and 200°, a second between 200° and 300°, and the remainder at a red heat.

B.B. exfoliates slightly and fuses at 2.5-3 to a white bead. Yields water readily in the closed tube. Easily decomposed by hot hydrochloric acid with separation of silica.

Found in Buck Creek corundum mine in Clay Co., N. C.; occurs in small crystals with chabazite on feldspar, also on corundum. Named after Prof. H. L. Wells of New Haven, Conn.

Wernerite, p. 468.—As a contact mineral in the Adamello Group and discussion of composition (anal.), Salomon, Min. petr. Mitth., 15, 159, 1895. It is argued that *dipyre* is to be regarded not as a definite scapolite type but as belonging in part to wernerite, in part to mizzonite.

Westanite (Vestanite), p. 499.—Weibull has confirmed Groth's suggestion that the mineral is an altered and alusite. A specimen examined by him showed a nucleus of and alusite surrounded by pyrophyllite. G. För. Förh., 20, 57, 1898.

Whartonite. S. H. Emmens, J. Am. Chem. Soc., 14, No. 7. See Pyrite.

Whewellite, p. 993.—Obtained at the Venus mine, near Brux, Schubert (optical determinations), Min. petr. Mitth., 18, 251, 1898.

WICKELKAMAZITE. E. Cohen, Ann. Mus. Wien, 6, 157, 1891.

WILLEMITE, p. 460.—Penfield has described colorless prismatic crystals from the Merritt

mine, New Mexico, with the new forms $z(01\overline{1}1)$, $u(2\overline{1}\overline{1}3)$, $v(\overline{1}3\overline{2}5)$ (Fig. 1): colorless rhombo. hedral crystals (Fig. 2) from the Scdalia mine, Salida, Colo.; also pale green prismatic crystals from Franklin Furnace, N. J. (Figs. 3, 4) with h (3120), s (1123), x (3121). Am. J. Sc., 47, 305, 1894

Etching-figures investigated, Traube, Jb. Min., Beil.-Bd., 10, 463, 1896.

Willyamite. E. F. Pittman, Proc. R. Soc. N. S. W., 27, 366, 1893.

Isometric: massive. Cleavage: cubic, perfect. Fracture uneven. Brittle. H. = 5.5. G. = 6.87. Luster metallic. Color between tin-white and steel-gray. Streak grayish black. Composition a sulph-antimonide of cobalt and nickel, CoS₂.NiS₂.CoSb₄.NiSb₂. Analysis, J. C. H. Mingaye:

S	Sb	Co	Ni	
1. 15.64	56.85	13.92	13.38	Fe, Cu Pb $tr. = 99.79$
2. 15.92	56.71	13.84	13.44	Fe, Cu, Pb $tr. = 99.91$

In the closed tube yields a dark red sublimate, orange on cooling; in the open tube sulphurous and antimonial fumes; also the latter on charcoal fusing to a globule. Decomposed by nitric acid with separation of antimony trioxide.

Found at the Broken Hill mines (in Willyama township), New South Wales, associated with dyscrasite in a gangue of calcite and siderite.

Winebergite, p. 970 —Bod enmais, Bavaria, analyses, Thiel, Zs. Kr. 23, 295, 1894.

WITHERITE, p. 284.—In parallel growth with barite, Mügge, Jb. Min, 1, 252, 1895.

Wolframite, p. 982.—Occurrence in Bolivia, described by Frenzel, analysis by Sipöcz, Min.

a ÿ

petr. Mitth., 16, 256, 1896.
Occurs (C. H. Warren, priv. contr.) in Lawrence Co., South Dakota, in small brilliant black crystals (Fig. 1) in a highly siliceous matrix. Observed forms: a (100), c (001), b (010), l (210), m (110), i (7·11·0) new, t (102), y (101), f (011), Δ (112). The angles show a close agreement with those given for ordinary wolframite. B.B. the crystals show no reaction for manganese; they are hence inferred to be the pure iron tungstate.

WOLFSBERGITE. - See Chalcostibite.

WOLLASTONITE, pp. 371, 1052.—Crystals from near Harrisville, N. Y., described, Ries, Trans N. Y. Acad. Sc., 13, 146, 207, 1894.

New Hartford, Oneida Co., N. Y., shows strong greenish-yellow phosphorescence, Hillebrand, Am. J. Sc., 1, 323, 1896.

Occurs, with gehlenite and hexagonal CaSiO₃, in slags from Přibram, Heberdey, Zs. Kr., 26,

19, 1896. An essential constituent in aplite from Quérigut, Ariège, Lacroix, Bull. Soc. Min., 21, 272,

Crystals altered to pyroxene, Diana, Lewis Co., N. Y., C. H. Smyth, Jr., Am. J. Sc., 4, 309,

1897.

WULFENITE, p. 989.—Cryst.—Jarilla Mts., Doña Ana Co., New Mexico, crystals hemimorphic (Figs. 1-3) with p (201) below only, while c (001), u (102), e (101), n (111), π (313) occur

both above and below; p and π are new forms, C. A. Ingersoll, Am. J. Sc., 48, 193, 1894. Loudville, Mass., habit varied, in part hemimorphic; new forms θ (1·1·12), γ (443), λ (131), Emerson,

Bull. U.S. G. Surv., 1 Min. Ital., 16, 25, 1896. 126 176, 1895. Gorno, Val Seriana, Italy (with (5:1:75)?), Artini, Riv.

Etching-figures do not show hemimorphic symmetry, Traube, Jb. Min., Bell -Bd., 10, 457, 1896. Observations on optical anomalies, A. de Gramont, Bull. Soc. Min., 16, 127, 1893.

WURZITE. pp. 70, 1051.—Artif. cryst. described, Traube, Jb. Min., Beil.-Bd., 8, 151, 1894.

Xanthoconite, p. 149.—Shown by Miers (Min. Mag., 10, 185, 1893, and Zs. Kr., 22, 433) to be monoclinic with the axial ratio, \dot{a} , \dot{b} ; \dot{c} = 1 9187 : 1 : 1 0152, β = 88° 47′. Here belongs also rittingerite from Joachimsthal. Common forms: c (001), m (110), d (501), D (501), p (111), q (551), P (111), Q (551); also a (100), n (053), r (112), t (223), h (334), and on rittingerite f (115), g (443), g (332), g (112), g (443). Angles g (112), g (443), g (382), g (112), g (443). $cm = 80^{\circ} 26'$.

Crystals tabular | c, usually stout, again very thin; also massive, earthy. Twins: tw. pl. c,

Cleavage c, distinct. Fracture subconchoidal. Brittle. H. = 2-3. G. = 554. Luster adamantine to pearly. Color brown, orange-red; by transmitted light, lemon-yellow. Streak orange-yellow. Transparent. Optically –, Birefringence strong. Ax. pl. \pm b (010). Bx_a nearly \pm c (001). \pm 2E = 125° approx.; ρ < σ .

Composition same as for proustite, Ag3AsS3 or 3Ag2S.As2S3. Analysis, Prior (corrected):

Freiberg, G. = 5.54 As 14.93 S 19.07 Ag 65.15 = 99.15

Xanthoconite occurs in calcite at Freiberg, Saxony, the original locality; also at Johanngeorgenstadt, Markirch in Elsass, Rudelstadt and Chañarcillo.

Xanthophyllite, p. 639.—Waluewite, Zlatoust, anal. and discussion of composition, Clarke and Schneider, Am. J. Sc., 43, 379, 1892.

XENOTIME, p. 748.—Cryst.—Brazil, Hussak, Min. petr. Mitth., 12, 465, 1892.

Anal.—El Paso Co., Colorado, Penfield obtained: P₂O₆ 32·11, (Y,Er)₂O₆ 67·78, ign. 0·18 = 100·07 (at. weight of Y,Er, 118); G. = 5·10C, Am. J. Sc., 45, 398, 1893. Analyses (Eakins) from the Brindletown gold district, Burke Co., N. C., greeu and brown var., Hidden, Am. J. Sc., 46,

Occurrence on New York island, Niven, Am. J. Sc., 50, 75, 1895. In Calvin township, Nipissing distric Ontario (mass of 312 grams), Hoffmann, Rep. G. Canada, 9, 13R, 1896. Distribution in European rocks, Derby, 11, 304, 1897.

Xiphonite. G. Platania, Accad. Sc. Acireale, 5, 1893.—See Amphibole, p. 3.

ZEOLITES, pp. 570-610.—Discussion of the composition of the species, F. W. Clarke, Am. J. Sc., 48, 137, 1894. Bull. U. S. G. Surv., 125. Also as to the part played by the water, G. Friedel, Bull. Soc. Min., 21 5, 1898.

See also Analcite, etc.

ZINCITE, p. 208.—Franklin Furnace, N. J., hemimorphic crystals with m (10 $\overline{10}$), c (0001) and a pyramid o probably (20 $\overline{23}$), measured $co=55^{\circ}$ 38'; analysis by Schütz gave: ZnO 96·20, MnO 3·33, Fe₂O₃ 0·43 = 99·96. Grosser, Zs Kr., 20, 354, 1892. Crystals from Franklin measured by Moses show two pyramids, interpreted as (40 $\overline{45}$) and (50 $\overline{54}$) if c=1·6219. School Mines Q., 16, 226 1895.

On artificial crystals, in part twins, Cesàro, Ann. Soc. G. Belg., 19, 271, 1892 (abstr Zs. Kr., 24, 618). Also Rics, Am J. Sc., 48, 256, 1894; Traube, Jb. Min., Beil.-Bd., 9, 147, 1894

ZINKENITE, p. 112 — Crystals from Wolfsberg in the Harz show the form: a (100), c (001), e (102), Spencer, Min. Mag., 11, 188–1897. He notes also relation in form to chalcostibite and other similar species. Cf. also Luedecke, Min. d. Harzes, 121, 1896.

Occurs at Cinque Valle, Val Sugana, Tyrol, Sandberger, Jb. Min., 1, 196, 1894. Also at Oruro, Bolivia (anal. by Mann), Stelzner, Zs. G. Ges., 49, 86, 1897.

Zinkmanganerz. — A. Brunlechner, [Jb. Nat. Land.-Mus., Klagenfurt, 22, 194, 1893,] Zs. Kr., 25, 432. A hydrated compound of ZnO and MnO₂. Massive, compact; color dark brown or gray. Occurs with calamine at Bleiberg, Carinthia.

ZIRCON, p. 482.—Crystals described from the nephelite-syenite of Dungannon, Ont., Pratt, Am J. Sc., 48, 214, 1894. From Ilmen Mts, new forms (501), (643), (766), (545), Jeremejev, Vh. Min. Ges., 33, 429, 1895.

Crystals from the Meredeth Freeman mine in Henderson Co., N. C., are cruciform-twins with the following twinning planes: e (101) Fig. 1, p (111) Fig. 2, d (553) Fig. 3, ϕ (774), v (221), u (331), Hidden and Pratt, Am. J. Sc., 6, 323, 1898.

Occurs in the Toluca meteoric iron, Laspeyres, Zs Kr, 24, 485, 1895. Synthesis, Khrushchov, Jb. Min., 2, 232, 1892. Analyses of cyrtolite from Mt. Antero, Colorado, Genth, Am. J. Sc., 44, 387, 1892.

Zirkelite. E. Hussak and G. T. Prior, Min. Mag., 11, 86, 1895; G. T. Prior, ibid., 11, 180, 1897. E. Hussak, Min. petr. Mitth., 14, 408, 1894.

Isometric. In octahedrons, sometimes with cubic faces; crystals flattened and striated | o,

due to polysynthetic twinning. Spinel twins common, also fourlings.

Cleavage none. Fracture conchoidal. Brittle. H. = 5.5. G. = 4.706-4.741. Luster resinous.

Color black. Nearly opaque; dark brown and isotropic in thin splinters. Non-magnetic. Composition, RO.2(Zr,Ti,Th,O₂. Analysis, G. T. Prior, l. c., p. 180 (also an approximate analysis in p. 88):

ZrO2 TiO2 ThO2 Ce2O3 Y2O3? UO2 FeO MgO ign. CaO $G. = 4.741 \quad 52.89$ 14.95 7.31 2.52 0.21 1.40 7.72 10.79 0 22 1.02 = 99.03

Found with baddeleyite, perovskite, etc., in the decomposed magnetite-pyroxenite of Jacupiranga, S. Paulo, Brazil.

Named after Prof. F. Zirkel of Leipzig. The same name was earlier given (1887) to a rock by M. E. Wadsworth, cf. Am. J. Sc., 5, 153, 1898.

Zoisite, pp. 513, 1035.—Relation to epidote discussed with description of crystals from Zermatt and Prägratten, Weinschenk, Zs. Kr., 26, 156, 433, 1896; see also *Clinozoisite*. On the optical characters of ordinary zoisite (ax. pl. $\parallel b$ (010), dispersion $\rho < v$ large), also

those of " β -zoisite" (ax. pl. $\|c\|$ (001), dispersion $\rho > v$ small, variable), and the relation of these

varieties to each other, see Termier, Bull Soc. Min., 21, 148, 1898.

Occurs at Flat Rock mine, Mitchell Co., N. C., with monazite and allanite, analysis by Eakins, W. E. Hidden, Am. J. Sc., 46, 154, 1893 (in Bull. U. S. G. Surv., 113, 111, 1893, same anal. credited to James's mica mine, Yancey Co., N. C.)

ZONOCHLORITE, p. 610.—See Chlorastrolite.

ZUNYITE, p. 436.—Occurs in minute tetrahedrons in an altered porphyrite near Red Mountain, Ouray Co., Colorado, Penfield, Am. J. Sc., 45, 397, 1893. The mean of two analyses gave: SiO₂ 24·11, Al₂O₃ 57·20, Fe₂O₃ 0·61, Cl 2·62, F 5·81, H₂O 11·12, P₂O₅ 0·64, CaO 0·11, Na₂O 0·48 = 102.70 (deduct O 3.03) = 99.67. This confirms Hillebrand's results and the formula given in Min., p. 436.

PREFATORY NOTE

This Second Appendix to the Sixth Edition of the System of Mineralogy issued in 1892 is designed to make the work complete up to the beginning of 1909. Its preparation was begun by the Senior Editor soon after the publication of the First Appendix in 1899, and carried forward at intervals down to 1906, when he was finally compelled to relinquish it. The work was resumed by the Junior Editor in 1907 and carried through to completion.

During the ten years of mineralogical investigation which this appendix covers, a large amount of material has been published. An evidence of this is to be found in the two hundred new names which are given in the classified list in the Introduction. About sixty of these new names on account of the completeness of their descriptions seem to have a warrant for their acceptance as new species. The other names are either of imperfectly described minerals or variety names of well-recognized species.

The descriptions of the new species included in this book are given concisely but completely. It was found, however, impracticable to follow the plan adopted in the System and the First Appendix of recalculating all the angles and crystal constants of the new species. This has been done in a few cases, but in the majority of the descriptions the figures of the authors have been accepted without verification. In the cases of some of the new species with complex crystals it has been impossible to give the complete lists of the forms identified upon them. The method followed has been to give the more common and prominent forms and to indicate the number of those not listed.

For an explanation of the *Abbreviations* made use of in the case of periodicals, also of the crystallographical, optical and chemical symbols employed, reference is made to the Introduction to the System (1892), pp. xlv-li and pp. xiii-xl. General abbreviations are explained on pp. lxi-lxiii.

The bibliography, while not intended to be exhaustive, contains, it is thought, the titles of all the important volumes published between 1899 and 1909.

YALE UNIVERSITY, NEW HAVEN, CONN., July 1, 1909.

PREFATORY NOTE

1300

This Second Appendix to the Sixib Meltion of the Statem of Allowance residence in the designed to easie the work complete up to reach her and the sease of the problem of the State Appendix in 1806, and certical factor of the problem of the State Appendix in 1806, and certical factor of the problem of the State Appendix in 1806, and certical accounted to the problem of the problem of the problem of the statement
Our ing the ten years of inhoratories in a which this appendix of set a large apartic of macinity has been published. All evidences in this found in the loss times as a same which are given in the characted list in the fulnomerous on. A half sixty or show one a graines on second of the completeness of their descriptions, seem to have a sharper in their strengther as second or the character of their strengthers, seem to have a sharper or variety or research or variety sources. It

The descriptions of the new species included in this case ser given conclude that controlled the first transfer to the tentral process of the new species. The feeling the was found to the first first form and the first form to a first first form the first fi

those not listed.

Were an explanation of the Riberrimiens cashe are of in the case of regionized a clear of the formal of the Riberrimiens and description to the formal symbols amplitude, remained in the formal altered the System (1972), up. xiv-ii and pp. xiii-f). General altered indicate are explained to a region of the listed of the Principle, while principles, while principled to be explanative, contains, it is shought, the tukes of the

the important volumes published between 1809 and 1909.

CLASSIFIED LIST OF NEW NAMES.

I. NATIVE ELEMENTS, Min. pp. 2-32.

Arsensulfurite (p. 9). Var. Sulphur, Min. p. 8.

Quisqueite (p. 87). Chiefly C and S.

Souesite (p. 11). Nickel-iron alloy, near Awaruite, Min. p. 29.

II. SULPHIDES, TELLURIDES, ARSENIDES, ETC., Min. pp. 33-108.

Arsenschwefel (p. 9), As₂S₃ + H₂O.

PATRONITE (p. 79), VS₄ (?).

Keweenawite (p. 59), (Cu,Ni,CO)₂As.

Stibiodomeykite (p. 97). Var. of Domeykite, Min. p. 44.

Mohawkite (p. 70), (Cu,Ni,CO)₃As.

LEDOUXITE (p. 62), Cu₄As.

Rickardite (p. 89), Sanfordite (p. 90), Cu, Te,

KALGOORLITE (p. 58), HgAu₂Ag₆Te₆.

Coolgardite (p. 31). Telluride of Au, Ag, Hg. Probably a mixture.

Chalmersite (p. 27), Cu₂S.Fe₄S₅. Near Chalcocite, Min. p. 55.

Teallite (p. 104), PbS.SnS₂.

Bravoite (p. 19). Nickeliferous Pyrite, Min. p. 84.

BADENITE (p. 12), (Co,Ni,Fe)₂(As,Bi)₃.

Speculite (p. 95). A silver, gold telluride near Sylvanite, Min. p. 103.

Von Diestite (p. 110). Telluride of silver and bismuth.

· III. SULPHO-SALTS, Min. pp. 109-151.

HISTRIXITE (p. 52), 7Bi₂S₃.2Sb₂S₃.5CuFeS₂.

Hutchinsonite (p. 53), (Tl,Ag,Cu)₂S.As₂S₃ + PbS.As₂S₃ (?).

Trechmannite (p. 107), Ag₂S.As₂S₃, rhombohedral.

Smithite (p. 95), Ag₂S.As₂S₃, monoclinic.

LIVEINGITE (p. 64), 5PbS.4As₂S₃.

Baumhauerite (p. 13), 4PbS.3As₂S₃.

SELIGMANNITE (p. 92), Cu₂S.2PbS.As₂S₃ (?) Near Bournonite, Min. p. 126.

LENGENBACHITE (p. 62), 6PbS.(Ag,Cu)₂S.2As₂S₃ (?)

Antimon-luzonite (p. 7). Var. Enargite, Min. p. 147.

SULVANITE (p. 101), 3Cu₂S.V₂S₅.

IV. CHLORIDES, BROMIDES, IODIDES, Min. pp. 152-182.

1. ANHYDROUS CHLORIDES, ETC.

Kleinite (p. 59). Mercury ammonium chloride.

Chlornatrokalite (p. 28). A mixture of Halite, Min. p. 154, and Sylvite, Min. p. 156.

Chlormanganokalite (p. 28), 4KCl.MnCl₂.

Chloragryrite (p. 28). Same as Cerargyrite, Min. p. 158.

Bromargyrite (p. 20). Same as Bromyrite, Min. p. 159.

Iodembolite (p. 55), Ag(Cl,Br,I).

Rinneite (p. 89), FeCl₂.3KCl.NaCl.

Villiaumite (p. 110), NaF.

Cryolithionite (p. 33), Li₃Na₃Al₂F₁₂. To follow Cryolite, Min. p. 166.

2. Oxychlorides.

Terlinguaite (p. 104), Hg₂ClO.

Egglestonite (p. 37), Hg₄Cl₂O.

Rafaelite (p. 87). Same as Paralaurionite, App. I, p. 50.

Paratacamite (p. 79), CuCl₂.3Cu(OH)₂. Near Atacamite, Min. p. 172.

KOENENITE (p. 60). Justite (p. 58). Oxychloride of Al and Mg.

V. OXIDES, Min. pp. 183-260.

Pseudochalcedonite (p. 87). Var. of Chalcedony, Min. p. 188.

Montroydite (p. 71), HgO.

CADMIUMOXYD (p. 21), CdO.

MELANOCHALCITE (p. 67), Copper oxide with SiO2, CO2 and H2O.

CORONADITE (p. 32), (Mn,Pb)Mn₃O₇.

HOLLANDITE (p. 52), $m(Ba,Mn)_2MnO_5 + nFe_4(MnO_5)_3$.

Нуркодотніте (р. 54), 3Fe₂O₃.4H₂O.

Esmeraldaite (p. 40), Hydrous ferric oxide.,

Brostenite (p. 20). Manganite of Mn and Fe.

VI. 1. CARBONATES, Min. pp. 261-309.

Glendonite (p. 46). Calcite pseudomorphs after Glauberite.

KUTNOHORITE (p. 61), (Ca,Mn,Mg,Fe)CO₂.

Manganospherite (p. 66). Manganiferous Siderite, Min. p. 276.

Lacroisite (p. 61). Mixture of Rhodochrosite and Rhodonite.

Conchite (p. 31). Same as Aragonite, Min. p. 281.

Zeyringite (p. 114). Var. of Aragonite, Min. p. 281.

Leesbergite (p. 62), 2MgCO₃.CaCO₃ (?).

Cordylite (p. 31), (BaF)(CeF)Ce(CO₃)₃. Related to Parisite, Min. p. 290.

Synchisite (p. 102), CeFCa(CO₃)₂.

Rutherfordine (p. 90), UO₂CO₃.

Ancylite (p. 5), 4Ce(OH)CO₃.3SrCO₃.3H₂O.

Tychite (p. 108), 2MgCO₃.2Na₂CO₃.Na₂SO₄. Related to Northupite, App. I, p. 49.

Rosasite (p. 89), 2CuO.3CuCO₃.5ZnCO₃.

BLEIMALACHITE (p. 16), 2CuCO₃.PbCO₃.Cu(OH)₂.

OTAVITE (p. 77), basic cadmium carbonate.

Artinite (p. 9), MgCO₃.Mg(OH)₂.3H₂O.

Giorgiosite (p. 45), 4MgCO₃.Mg(OH)₂.4H₂O.

Brugnatellite (p. 21), MgCO₃.5Mg(OH)₂.Fe(OH)₃.4H₂O.

VI. 2. SILICATES.

A. Anhydrous Silicates, Min. pp. 310-562.

Leucosphenite (p. 64), Na₄Ba(TiO)₂(Si₂O₅)₅. Related to Eudidymite, Min. p. 313.

Isorthose (p. 57). Var. of Orthoclase, Min. p. 315.

Paracelsian (p. 78), Ba₃Al₈Si₈O₃₁. Probably var. of Celsian, App. I, p. 15.

Clinoenstatite (p. 30). Magnesium pyroxene.

Pigeonite (p. 81), Violaite (p. 110), Ægirine-hedenbergite, Blanfordite (p. 16). Var. of Pyroxene, Min. p. 352.

Kunzite (p. 61). Var. of Spodumene, Min. p. 366.

Torrensite (p. 107). Probably a mixture of Rhodonite, Min. p. 378, and Rhodochrosite, Min. p. 278.

Pseudowollastonite (p. 83).

Alamosite (p. 1), PbSiO₃. Near Wollastonite, Min. p. 371.

Schizolite (p. 92), HNa(Ca, Mn)₂(SiO₃)₃.

Soretite (p. 95), Széchenyiite (p. 102), Tschernichéwite (p. 108), Osannite (p. 77), Winchite (p. 111). Var. of Amphibole, Min. p. 385.

Rhönite (p. 88), (Ca,Na₂,K₂)₃Mg₄Fe₂Fe₃Al₄(Si,Ti)₆O₃₀. Related to Ænigmatite, Min. p. 403.

Oehrnite (p. 76), 6(Mg,Fe,Ca)O.6SiO₂.H₂O.

Weinbergerite (p. 111), NaAlSiO₄ + FeSiO₃ (?).

Taramellite (p. 103), Ba₄Fe Fe₄Si₁₀O₃₁.

Hackmanite (p. 48), Na₄ [Al(NaS)] Al₂(SiO₄)₃. Member of Sodalite Group.

Viellaurite (p. 110). A mixture of Tephroite, Min. p. 457, and Rhodochrosite, Min. p. 278.

Pseudomeionite (p. 83). Var. of Meionite, Min. p. 467.

Howdenite (p. 53). Var. of Chiastolite, Min. p. 496.

Californite (p. 24). Var. of Vesuvianite, Min. p. 477.

Naëgite (p. 72). Zircon (Min. p. 482) containing UO₃, ThO₂, Nb₂O₅, Ta₂O₅, Y₂O₂.

Johnstonotite, Landerite (p. 61), Xalostocite, Rosolite (p. 90). Var. of Garnet, Min. p. 437.

BITYITE (p. 16), $7(R_2O + RO).4Al_2O_x.5SiO_2$; R = H,Li,Na,K; R = Ca,Be,Mg.

Hibschite (p. 52), H₄CaAl₂Si₂O₁₀.

Spurrite (p. 97), 2Ca₂SiO₄.CaCO₃.

Cerepidote (p. 25). Same as Allanite, Min. p. 522.

Leucophænicite (p. 63), Mn₅(MnOH)(SiO₄)₃.

Hellandite (p. 50), $\operatorname{Ca}_{2}\operatorname{R}_{3}[\operatorname{R}(\operatorname{OH})_{2}]_{3}(\operatorname{SiO}_{4})_{4}$.

Molybdophyllite (p. 70), $RSiO_4 + H_2O$; R = Pb, Mg.

Stokesite (p. 100), H₄CaSnSi₃O₁₁

Beckelite (p. 14), Ca₃(Ce,La,Di)₄Si₃O₁₅.

Grandidierite (p. 47), 7SiO₂.11(Al,Fe)₂O₃.7(Mg,Fe,Ca)O.2(Na,K,H)₂O.

SILICOMAGNESIOFLUORITE (p. 94), a fluosilicate of Ca and Mg.

SERENDIBITE (p. 93), a basic silicate of Al, Ca, Mg.

B. Other Silicates, Chiefly Hydrous Species, Min. pp. 563-711.

Bakerite (p. 12), $8CaO.5B_2O_3.6SiO_2.6H_2O$

Hillebrandite (p. 52), Ca₂SiO₄.H₂O.

REYERITE (p. 88), Ca, Al silicate with H₂O.

ZEOPHYLLITE (p. 113). Calcium silicate with H₂O. Near Gyrolite, Min. p. 566.

Agnolite (p. 1), H₂Mn₃(SiO₃)₄.H₂O.

Pseudophillipsite (p. 83), Var. Phillipsite, Min. p. 579.

Astrolite (p. 10), (Na,K)₂Fe(Al,Fe)₂(SiO₃)₅,H₂O (?).

Pseudomesolite (p. 83). Var. of Mesolite, Min. p. 605.

Bavenite (p. 14), $Ca_3Al_2Si_6O_{18}$. H_2O .

MELITE (p. 68), 2(Al,Fe)₂O₃.SiO₂.8H₂O.

LOTRITE (p. 65), 4SiO₂.2R₂O₃.3RO.2H₂O.

Lasallite (p. 61), MgO.Al₂O₃.5SiO₂.3 $\frac{1}{2}$ H₂O (?).

Irvingite (p. 57). Var. of Lepidolite, Min. p. 624.

MORAVITE (p. 71), H₄Fe₂(Al,Fe)₄Si₇O₂₄.

Pycnochlorite (p. 84). Var. of Chlorite, Min. p. 643.

Brunsvigite (p. 21), 6SiO₂.2Al₂O₃.9MgO.8H₂O.

Stilpnochloran (p. 99). Alteration product of Thuringite, Min. p. 657.

SPODIOPHYLLITE (p. 96), (Na₂K₂)₂(Mg,Fe)₃(Fe,Al)₂(SiO₃)₈.

Tæniolite (p. 102), (K,Li)₂O.MgO.3SiO₂.2H₂O (?).

Radiotine (p. 87), Hampdenite (p. 49), Hampshirite (p. 49), Ricolite (p. 89), Nemaphyllite (p. 74). Var. of Serpentine, Min. p. 669.

NEPOUITE (p. 75), 3(Ni,Mg)O.2SiO₂.2H₂O.

Greenalite (p. 47). Near Glauconite, Min. p. 683.

TERMIERITE (p. 105), a hydrated Al silicate.

Hyaloallophane (p. 54). Var. of Allophane, Min. p. 693.

Dubuissonite (p. 36). Near Montmorillonite, Min. p. 690.

Planchéite (p. 81), 15CuO.12SiO₂.5H₂O.

MÜLLERITE (p. 72), Fe₂Si₃O₉.2H₂O.

Morencite (p. 72), a silicate of ferric iron with H₂O.

Aloisite (p. 3), a hydrous silicate containing FeO, CaO, MgO, Na₂O.

TITANO-SILICATES, TITANATES, Min. pp. 711-724.

Carlosite (p. 24). Same as Neptunite, App. I, p. 49.

Narsarsukite (p. 73), acid titano-silicate of ferric iron and sodium.

Benitoite (p. 14), BaTiSi₃O₉.

Lorenzenite (p. 65), Na₂(TiO)₂Si₂O₇.

Yttrocrasite (p. 112), a hydrous titanite of the yttrium earths and thorium.

Delorenzite (p. 34), 2FeO.UO₂.2Y₂O₃.24TiO₂ (?).

Davidite (p. 34), TiO₂ with Fe, U, V, Cr and rare earths.

VI. 3. NIOBATES, TANTALATES, Min. pp. 725-746.

Marignacite (p. 66). Var. of Pyrochlore, Min. p. 726.

Chalcolamprite (p. 26), RNb₂O₆F₂, RSiO₃. Allied to Pyrochlore, Min. p. 726.

Neotantalite (p. 74). Near Tantalite, Min. p. 731.

STRÜVERITE (p. 100), FeO.(Ta,Nb)₂O₅.4TiO₂ (?).

Loranskite (p. 65), Ta₂O₅, Y₂O₃, Ce₂O₃, CaO, FeO, ZrO, H₂O.

ENDEIOLITE (p. 38), RNb₂O₆(OH)₂.RSiO₂ (?).

Epistolite (p. 39), Nb₂O₅,SiO₂,TiO₂,Na₂O,H₂O,F (?).

ERIKITE (p. 39), SiO₂, P₂O₅, ThO₂, (Ce, Le, Di)₂O₃, Al₂O₃, Na₂O, H₂O (?).

Britholite (p. 19). Silicate and phosphate of Ce metals and Ca.

Blomstrandine-Priorite (p. 17): Niobate and tantalate of Y, Er, Ce, U.

Robellazite (p. 89). Contains Va, Nb, Ta, W, Al, Fe and Mn.

VI. 4. PHOSPHATES, ARSENATES, ETC., Min. pp. 747-861.

Hussakite (p. 53). Var. of Xenotime, Min. p. 748.

Graftonite (p. 47), $R_3P_2O_8$; R = Fe, Mn, Ca.

Bowmannite (p. 19). Same as Hamlinite, Min. p. 762.

Florencite (p. 42), $3Al_2O_3.Ce_2O_3.2P_2O_5.6H_2O$. Near Hamlinite, Min. p. 762.

Georgiadésite (p. 45), Pb₃(AsO₄)₂.3PbCl₂.

Petterdite (p. 80). Same as Mimetite, Min. p. 771.

Tarbuttite (p. 103), Zn₃P₂O₈.Zn(OH)₂.

SCHERTELITE (p. 91), Mg(NH₄)₂H₂(PO₄)₂.4H₂O.

Parahopeite (p. 78), Zn₃P₂O₈.4H₂O. Near Hopeite, Min. p. 808.

Anapaite (p. 5), Tamanite (p. 103), (Ca, Fe)₃(PO₄)₂.4H₂O.

Paravivianite (p. 79). Var. Vivianite, Min. p. 814.

Purpurite (p. 83), 2(Fe,Mn)PO₄.H₂O.

GORCEIXITE (p. 46), BaO.2Al, O3.P2O5.5H2O.

STOFFERTITE (p. 99), 2CaO.P₂O₅.6½H₂O. Near Brushite, Min. p. 828.

PALMERITE (p. 78), HK₂Al₂(PO₄)₃.7H₂O.

Kertschenite (p. 59). A hydrated basic ferric phosphate.

CERULEITE (p. 25), CuO.2Al2O3.As2O3.

Podolite (p. 82), 3Ca₃(PO₄)₂.CaCO₃.

HARTTITE (p. 50), (Sr,Ca)O.2Al₂O₃.P₂O₅.SO₃.5H₂O.

VI. 5. BORATES, URANATES, Min. pp. 874-893.

Thorianite (p. 106), ThO₂, U₃O₈.

HULSITE (p. 53), 10(Fe,Mg)O.2Fe₂O₃.1SnO₂.3B₂O₃.2H₂O.

Paigeite (p. 78). Probably same as Hulsite, above.

VI. 6. SULPHATES, CHROMATES, Min. pp. 894-981.

Palmierite (p. 78), 3(K,Na)₂SO₄.4PbSO₄ (?).

Vanthoffite (p. 109), 3Na₂SO₄.MgSO₄.

Bellite (p. 14). Lead chromate containing arsenious oxide, etc.

ARZRUNITE (p. 9), (Pb₂O)SO₄.3(CuCl₂.H₂O).Cu(OH)₂(?).

DOUGHTYITE (p. 36), Al₂(SO₄)₃.5Al₂(OH)₆.21H₂O.

Stelznerite (p. 97), CuSO₄.2Cu(OH)₂.

FERROPALLIDITE (p. 42), FeSO₄.H₂O.

Scleropasthite (p. 92). A hydrous sulphate of ferrous iron and chromium.

Cuprogoslarite (p. 33). Var. Goslarite, Min. p. 939.

Boothite (p. 18), CuSO₄.7H₂O.

Natrochalcite (p. 73), Na₂SO₄.Cu₄(OH)₂(SO₄)₂.2H₂O.

Ferrorömerite (p. 42), Zinkrömerite (p. 114). Var. of Römerite, Min. p. 959.

Janosite (p. 57). Same as Copiapite, Min. p. 964.

Palacheite (p. 78). Var. of Botryogen, Min. p. 972.

Natrojarosite (p. 73). Var. of Jarosite, Min. p. 974.

Plumbojarosite (p. 82). Var. of Jarosite, Min. p. 975.

Moissanite (p. 70), CSi.

reported (p. 40. Mar. C. Mar.

APPENDIX II.

ACMITE, Min., pp. 364, 1046; App., p. 1. — Crystals of ægirite from Narsarsuk, Greenland, have been described by Flink, Medd.Grönl., 24, 70, 1901; from Kororsuak, Greenland, with new form (221); Böggild, Min. Grönl., 379.

Ægirite occurs as a constituent of mariupolite (elæolite-syenite) on the shore of the Sea of Azov (anal.), Morozewicz, Min. petr. Mitth., 21, 240, 1902. Anal. of acmite from nepheline-syenite, Montreal; Harrington, Trans. Roy. Soc. Canada, 11, (3), 25, 1905.

Ægirite and riebeckite rocks occur in the neighborhood of Adowa and Axum, Abyssinia;

Prior, Min. Mag., 12, 255, 1900.

Adamite, Min., p. 786. — Description of crystals (with anal.) from Monte Valerio, Campiglia Marittima, Italy; Aloisi, Proc. Soc. Tosc., Nov. 17, 1907.

ENIGMATITE, Min., p. 403; App., p. 2. — Occurs as an essential constituent of certain basalts (ænigmatite-basalts) especially in the southern Rhon; Soeliner, Centralbit. Min., 206, 1906. Widespread occurrence of cossyrite in pantellerites in Choa, in Afar and on the plateaus of Somali and Abyssinia, East Africa; Arsandaux, C. R. Sci. de la Mission Duchesne-Fournet, Paris, 1906.

Agnolite, Agnolithe: — E. Breussig, Jb. Min., Beil. 13, 265; Bull. Min. Soc., 23, 36, 1900.

A mineral from Schemmitz called mangano-calcite by Breithaupt, was later proven to consist of a mixture of a rhombohedral carbonate and a silicate (cf. Min., p. 278). The silicate has been studied and named agnolite.

Triclinic. In radiating fibrous masses. Cleavage | length of fibers. H.=5. G.=3.054-3.067.

Luster vitreous. Color flesh red to rose.

Comp. $H_2Mn_3(SiO_3)_4.H_2O.$

* After deducting carbonates of lime and magnesia and recalculating.

Associated with carbonates of calcium, magnesium, manganese and iron, with quartz, sphalerite and pyrite. Name derived from άγνοεω (not recognized).

AIKINITE, Min., p. 129. — Anal. of material from Beresowsk, Urals; Guillemain, [Inaug.-Diss., Breslau, 1898], Zs. Kr., 33, 75.

AKERMANITE, Min., p. 476. — Double refraction studied by Hlawatsch, Min. Mitth., 23, 420 1904. An attempt to synthesize it in a melt consisting of only CaO and SiO₂ failed; Day and Shepherd, Am. J. Sc., 22, 280, 1906.

Alamosite. C. Palache and H. E. Merwin, Am. J. Sci., 27, 399, 1909.

Monoclinic. $\dot{a}: \dot{b}: \dot{c} = 1.375:1:0.924$. $\beta = 84^{\circ} 10'$. Forms: c (001), a (100), b (010), m (110), v (101), g (011), p (121), r (121). Angles: $cv=32^{\circ}$ 02'; $cg=42^{\circ}$ 36'; $am=53^{\circ}$ 50'.

In radiating fibrous aggregates, occasionally in minute slender

crystals, elongated parallel to \overline{b} . Cleavage perfect $\parallel b$ (010). G. = 6.488. H. = 4.5. Luster adamantine. Colorless or white. Ax. pl. | b (010). Refraction and double refraction high.

Comp. — PbSiO₃; PbO, 78.68; SiO₂, 21.32. Anal. (Merwin) = SiO₂, 21.11; PbO, 78.13; CaO, tr.; FeO, .09; Insol., .08; Undet., .53; total, 99.94.

U

Fuses at 3 to greenish yellow bead, colorless when cold.

Lead reactions on charcoal. Sol. in HNO₃, yielding silica jelly.

Found associated with quartz, iron oxide, cerussite, leadhillite and wulfenite on specimens from an undeveloped prospect near Alamos, Sonora, Mexico.

Closely related to wollastonite in crystal forms and composition.

Albertite, Min., p. 1020. — On an asphalt from McGee Creek valley and Impson valley in Indian Territory; Taff, Am. J. Sc., 8, 219, 1899.

Albite, Min., pp. 327, 1025; App., p. 2. — Cryst. — Melczer (Zs. Kr., 40, 571) gives in tabular form the results of the crystallographic studies on albite by previous investigators, describes and figures crystals from Nadahula and from his measurements derives the following: a:b:c

= 0.6350 : 1 : 0.5578; $\alpha = 94^{\circ}$ 6′, $\beta = 116^{\circ}$ 36 $\frac{1}{3}$ ′, $\gamma = 87^{\circ}$ 52′.

Dreyer and Goldschmidt (Medd. om Grönland, **34**, 1907) give a description of fine crystals from Greenland, with an exhaustive discussion of the forms and elements of the mineral. their measurements the authors derive the following: a:b:c=0.6373:1:0.5599, $\alpha=94^{\circ}18'$, $\beta = 116^{\circ} 41'$, $\gamma = 87^{\circ} 37'$. They give a new table of angles for the faces of albite, using these fundamentals. The following new forms were identified on the Greenland crystals: (350), $(0\overline{4}1)$, $(0\overline{5}1)$?, $(\overline{3}32)$, $(\overline{2}11)$, $(\overline{3}12)$, $(\overline{2}91)$?, $(\overline{1}\overline{5}1)$, $(\overline{1}52)$; on Greenland crystals see also

fundamentals. The following new forms were identified on the Greenland crystals: (350), (041), (051)?, (332), (211), (312), (291)?, (151), (152); on Greenland crystals see also Böggild, Min. Grönl., 460, 1905.

Crystals from Zöptau figured, Min. Mitth., 21, 348; Neuwirth, Min. Mitth., 23, 263, [Zs. d. mähr. Landmus. Brüm, 39, 1904], Zs. Kr., 42, 411. Crystals from Lake Baikal; Jeremejew, Zs. Kr., 32, 494. Twins from Schirm, and Rettenegg; Milch, Jb. Min., 1, 152, 154, 1900. Crystals from Haddam Neck, Conn., show the forms Z (120), W (111), X (241), Y (311). Bowman, Min. Mag., 13, 115, 1902; from Comba Perægüe, Piedmont; Zambonini, Centralblt. Min., 117, 1903. Crystals from marble of Carrara with chem. and opt. study; D'Achiardi, Att. Soc. Tosc. Sc., Mem. 22, 1906; from L. Como; Repossi, Rend. Acc. Linc., 15, (1), 508, 1906; from Lyon Mt., Clinton Co., N. Y.; Whitlock, N. Y. State Mus. Bull., 107, 66, 1907. Crystallographic and optical study of albite from Morro Velho and Greenland; Grosspietsch, Min. Mitth., 27, 353, 1908.

Pseudomorphs after laumontite from Evje, Sätersdalen, Norway; Schei, [Nyt. Mag., 43, 137,

Pseudomorphs after laumontite from Evje, Sätersdalen, Norway; Schei, [Nyt. Mag., 43, 137,

1905]; Zs. Kr., 43, 639.

Opt. — Studies by Viola, Albite from Carrara, Zs. Kr., 32, 113; from Wallhomthörl, Amelia, albite-oligoclase from Bakersville. pericline from Weidalp and Kramkogl, Zs. Kr., 32, 305. Optical orientation discussed with measurements on albite from Amelia; Becke, Min. Mitth., 19, 321; Viola, Zs. Kr., 32, 318; Min. Mitth., 20, 199; Optical studies on albite from amphibole diabase in Murra dist., Sardinia (with anal.); Viola, Zs. Kr., 43, 202; Boll. Com. Geol. d'Italia, 6, 106, 1905; from granites of Sardinia (with anal.); Riva, Att. Acc. Sc., Napoli, 12, No. 9, 1905.

Anal. — From San Pablo, Calif.; Blasdale, Uni. Calif. Bull. Dept. Geol., 2, 11, 327, 1901; from Amelia, Va.; Erben and Ceipek, Min. Mitth., 20, 85.

Occ. — From Mokrusche Mt., near Mursipke, Buscie, Warshieff, IV.

Occ. — From Mokruscha Mt., near Mursinka, Russia; Worobieff, [Verh. russ. min. Ges., 42, Prot. 52, 1905]; Zs. Kr., 43, 71; in granite from Montorfano; Tacconi, Rend. Acc. Linc., 14, (2), 88, 1905; in chalk from Ortola, Massa, Italy; Aloisi, [Proc. Soc. Tosc., 15, 42, 1906]; Zs. Kr.,

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull. 207, 1902; Zs. Kr.,

38, 697.

ALGODONITE, Min., p. 45. — A specimen from the Pewabic mine, in the Quincy amygdaloid

bed, L. Superior, analyzed by Koenig, Am. J. Sc., 10, 447, 1900, gave:

G. = 8.383 As 16.08, Cu 83.72, (Fe, Ni, Co) 0.08 = 99.88. On the fresh fracture has the color and texture of razor-steel, tarnishes chocolate-brown, tough. The specific gravity obtained is near the calculated value and much higher than the value given by Genth (7.62). Another specimen from the Champion mine gave Koenig: As 16.55, Cu 83.53 = 100.18, Am. J. Sc., 14, 414, 1902.

Mohawk-algodonite, Koenig, Am. J. Sc., 14, 414, 1902, is regarded as an intimate mixture of

these two species.

An artif. material containing some silver, named argento-algodonite; Koenig, Proc. Am. Phil. Soc., 42, 229.

Alith. — Portland cement clinkers show in microscopic sections several crystalline mineral substances called *alith*, *belith*, *celith*, *felith*. Of these alith is the most common; its probable composition is given as x (3CaO.SiO₂).9CaO.Al₂O₃. See Törnebohm, Zs. Kr., **32**, 610, 1900 [Stockholm, 1897].

ALLANITE, Min., p. 522; App., p. 2. — Crystals in granite of Sardinia; Riva, Att. Acc. Sc., Napoli, 12, No. 9, 1905; from biotite-granite on Hiei mountain, Japan; Hiki, Mem. College of Sci and Eng., Kyoto Imperial Uni., 1, 1, 1903.

Anal. of bucklandite from the Achmatovsk mines in the Urals; Antipoff; Vh. Min. Ges. St.

Pet., 37, Prot. 45, 1899.

Occurrence at Avigait and Kara Akungnait, Greenland; Böggild, Min. Grönl., 259, 1905.

Aloisiite; Luigi Colomba, Rend. Acc. Linc., 17, (2), 233, 1908.

A hydrous silicate acting as a cement in tuff found at Fort Portal, Uganda. Amorphous, brown to violet in color. Anal.: *

> SiO₂ 24.52 FeO H.O CaO MgO Na2O 20.56 11.08 9.96 6.95 = 99.5726.50

* After deducting impurities and CaCO₃.

The water is considered as basic and the general formula given as (R", R₂')₄SiO₆. Name derived from Aloisius, a Latin form of Luigi.

Altaite, Min., p. 51; App., p. 2. — In crystals, octahedrons with a (100) and β (322) with gold in the Birney pocket mine, Tuolumne Co., Cal. (anal. by Schaller); Eakle, Bull. G. Univ. Cal., 2, 324, 1901.

Occurs sparingly with other tellurides at Kalgoorlie, West Australia; Spencer, Min. Mag., 13,

278, 1903.

ALUM, Min., p. 951. — On the growth of crystals; Weyberg, Zs. Kr., 31, 510; ibid., 36, 40; also Chevalier, Min. Mag., 14, 134; Becker and Day, Proc. Wash. Acad. Sci., 7, 283, 1905; on variation of angles on alum crystals; Miers, Zs. Kr., 39, 220.

ALUMYTE.—G. H. Kinahan, [Jour. R. Geol. Soc. Ireland, 8, 66, 1889]; [Trans. Manchester Geol. Soc., 23, 165, 1895]; Min. Mag., 12, 378. Alum clay ("bauxite") of Co. Antrim, Ireland.

ALUNITE, Min., p. 974; App., p. 2. — On the relation of alunite to jarosite, natrojarosite, plumbojarosite, see *jarosite*. Varieties of alunite containing soda (natroalunite, Hillebrand and Penfield, Am. J. Sc., 14, 218, 220, 1902) have been described by Cross (4.32Na₂O) from Rosita Hills, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 1891), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 41, 472, 418), and Hurlburt (4.41Na₂O) from Red Mountain, Colorado (ib., 4 48, 130, 1894, App., p. 2).
Occ. with anal. from Réalmont, Tarn, France; Ternier, Bull. Soc. Min., 31, 215, 1908.

ALUNOGEN, Min., p. 958. — Anal. from Cripple Creek, Colo.; Hobbs, Amer. Geol., 36, 185, 1905; Zs. Kr., 43, 394. Found as a deposit at the Doughty Springs and at Alum Gulch in Colorado; anal.; Headden, Proc. Col. Sc. Soc., 8, 62, 1905. See also doughty te. Anal. of material from Zolfo Grotto, Mesino, Italy; Zambonini, Rend. Acc. Sci., Napoli, Dec., 1907.

Amalgam, Min., p. 23. — Sjögren has described two varieties from Sala, Sweden; var. A in crystals is Ag₂Hg₃, var. B, massive, is Ag₅Hg₆; analyses by R. Mauzelius, G. För. Förh., 22, 187, 1900.

Amblygonite, Min., p. 781. — Two analyses of material from Montebras are given by Lasne, C. R., 132, 1191, 1901. Occurs massive (anal.) at the lepidolite mine near Pala, San Diego Co., Cal.; Schaller, Am. J. Sc., 17, 191, 1904. Occurrence near Sumjám in Pádar district, Kashmir; Mallet [Rec. Geol. Sur. India, 32, 228, 1905]; Zs. Kr., 43, 620.

Амривось, Міп., рр. 385, 1026; Арр., р. 3.

Cryst. - Small crystals found associated with pyroxene, biotite, chrysolite, leucite, apatite, sodalite, hauyn, titanite, in volcanic bombs from Cappuccini di Albano, Italy; Zambonini, Zs. Kr., 37, 369. Twelve forms were observed and the following axial ratio calculated: a:b:c=0.55051: 1: 0.29470; $\beta=74^{\circ}$ 35' 24". Small crystals from the cavities in syenite near Biella; idem; ib., 40, 231. The crystals are complex in habit, showing 13 different forms, one being new, B (132). Angle (110): (132) = 79° 38', meas., 79° 45' 33", calc. The calculated constants for these crystals are a:b:c=0.54501:1:0.29439; $\beta=75^{\circ}$ 4' 13". An analysis is given and the relation between chemical composition and the crystallographic constants discussed. Crystals formed at eruption of Vesuvius in 1906; see under Vesuvius. Crystals fom Lyon Mt., Clinton Co., N. Y.; Whitlock, N. Y. State Mus. Bull., 107, 66, 1907.

Opt. — Refractive indices of hornblende in inclusions of Augite-Andesite lava from Bellen-

berges near Mayen; Gaubert, Bull. Soc. Min., 28, 187, 1905; Optical study of amphiboles occurring in glaucophane schists of California with discussion of classification of group; Murgoci, Bull. Uni. Calif., 4, 15, 359, 1906. Var. pargasite from Grenville, Canada, and Pargas, Finland (with new anal.), studied optically with discussion of variation in optical constants of amphiboles of different composition. Kreutz, Min. Mitth., 27, 247, 1908. Optical constants of rock forming amphiboles and hornblendes from various localities; Duparc and Pearce, Bull. Soc. Min., 31, 109, 1908.

Chem. Comp. — Penfield and Stanley, Am. J. S., 23, 23, 1907; Zs. Kr., 43, 233, give new analyses (1) tremolite, Richville, N. Y., (2) Lee, Mass., (3) actinolite, Greiner, Tyrol, (4) Russell, N. Y., (5) Kragerö, Norway, (6) Pierrepont, N. Y., (7) hornblende, Renfrew, Ontario, (8) Edenville, N. Y., (9) Cornwall, N. Y., (10) Monte Somma, Italy, (11) Bilin, Bohemia, (12) Grenville, Quebec. The authors' conclusions as to the composition of amphibole are (1) that it is a metasilicate, (2) that fluorine and hydroxyl are isomorphous with the protoxides, (3) that the presence of sesquioxides is available by the introduction into the molecular in the form of various highest redicals. is explained by their introduction into the molecule in the form of various bivalent radicals.

New analyses (see below) of amphibole resembling kaersutite from island of Linosa (for which name linosite is suggested) and of kaersutite from Kaersut, Umanak Fjord, Greenland, with optical study; Washington and Wright, Am. J. Sc., 26, 187, 1908. Discussion of chem. comp. of amphiboles given. Anal. by Washington.

I. Linosa 40. II. Kaersut 39	85 8.47	$\begin{array}{ccc} {\rm Al_2O_3} & {\rm Fe_2O} \\ 9.89 & 8.85 \\ 11.22 & 1.22 \end{array}$	3.96	MnO NiO 0.12 0.10 0.06 —	12.47 12.16

* Corrected for presence of 0.77% of apatite.

Study of the rôle of water in tremolite with new analyses of material from Ham Island, Alaska; Ossining, Gouverneur, Russell and Edwards, N. Y. Also analyses of kupfferite from Edwards, N. Y., and diopside from Ham Island. Conclusion reached that water is not chemically combined in tremolite but is to be regarded rather as dissolved water in a solid solution. Allen and

bined in tremolite but is to be regarded rather as dissolved water in a soud solution. Amen and Clement, Am. J. Sc., 26, 101, 1908.

Anal. — Tremolite from Bistrau, Bohemia; Kovàř [Abh. Böhm Ak., 28, 1899]; Zs. Kr., 34, 704: — from Pisek, Bohemia; Krejci, Ber. böhm. Gess. Wiss., xliv, 1899; hornblende from volcanic bomb found on the island of St. Christopher; Fels., Zs. Kr., 37, 460; from Granatilla, Cabo de Gata; Pfeil, [Inaug. Diss. Heidelberg, 1901]; Centralbl. Min., 143, 1902; amphibole from Grenville, Quebec, containing 2.8% fluorine; Harrington, Am. J. S., 15, 392, 1903; from near Easton, Pa.; Eyerman, Amer. Geol., 34, 43, 1904; hornblende from Lukow, Bohemia; Hibsch, Min. Mitth., 24, 271, 1905; also Hampel, ib., 27, 271, 1908; "grammatite" from Statoúst in southern Urals; Smirnoff, [Travaux Soc. Imp. Nat. St. Pétersbourg, Sect. géol. et min., 33, 5, 45, 1905]; Zs. Kr., 44, 93; dannemorite from Macskamezö, Hungary; Kosmat and v. John, Zs. prakt. Geol., 13, 305-325, 1905; amphibole, with anal., from Cevadaes, Portugal; Hlawatsch, Festschrift zum siebzigsten Geburtstage von Harry Rosenbusch, p. 68, 1906. siebzigsten Geburtstage von Harry Rosenbusch, p. 68, 1906.

A blue amphibole is described by L. L. Fermor [Rec. Geol. Sur. India, 31, 235, 1904], Zs. Kr., 42, 390, as occurring in a schist associated with quartz, calcite and a black oxide of manganese. Prismatic crystals 6mm in length. Pleochroic, a pale reddish lilac, b paler lilac, c blue. Shows zonal structure evidently due to varying composition, with corresponding variation in extinction angle a: c from 16° to 70°. G. = 2.86. Secondary blue amphibole occurring in a kersantite in Co. Down, Ireland, noted by H. J. Seymour, Geol. Mag., 7, 257, 1900. Occurrence of fibrous amphibole (with anal.) in spinel rock on island of Elba; P. Aloisi, Proc. Soc. Tosc., July, 1908.

Hornblende occurring in a hornblende gabbro, From Pavone, near Ivrea, Piedmont, Italy, is

described and an analysis given by Van Horn, Amer. Geol., 21, 370, 1898; Zs. Kr., 32, 600. Hornblendes occurring as rock constituents in the coast range near Berkeley, California; Blasdale, Uni. Calif. Bull. Dept. Geol., 2, 11, 327, 1901. Tremolite from Campo longo, Tessin; Mann, [Inaug. Diss., Leipzig, 1904]; Zs. Kr., 42, 666.

Actinolite as pseudomorph after diopside from Kragerö, Norway, with anal.; S. Hillebrand,

Min. Mitth., 27, 272, 1908. Derived from pyroxene, which see.

Nephrite from New Zealand with analyses, Dieseldorff; Centralbl. Min., 334, 1901; from Bodensee, Kalkowsky, Ber. Abh. Naturwiss. Ges. Isis, 28, 1907. Historical with bibliography; Berwerth, Min. Mitth., 24, 228, 1905.

See Asbestus.

Edenite. — Occ. in upper Vallone delle Rovine, Italy, with anal.; Roccati, Riv. min. cristall.

ital., 32, 12, 1905.

Hudsonite from Cornwall, N. Y., formerly classed as a pyroxene, is proven by Weidman, Am. J. Sc., 15, 227, 1903, to be an amphibole. An optical description and a new analysis are given.

Soretite is an aluminous amphibole from the anorthite-diorite rocks of Koswinsky in the north Ural; Dupare and Pearee, Mem. Soc. Phys. Genève, **34**, 1902; Bull. Soc. Min., **26**, 126, 1903. Occurs in short prismatic crystals with b (010), m (110) but not terminated. G. = 3.223. Refraction indices: $\alpha = 1.6627$, $\beta = 1.6765$, $\gamma = 1.6856$. Birefringence negative. $\gamma - \alpha = 0.0228$. 2 V = 82° 30′ obs. Extinction of γ on b = 17°. Pleochroism deep green, green, pale greenish vellow.

Analysis, Gabaglio:

Fe₂O₃ TiO2 SiO, Al₂O₃ FeO Na₂O MnO CaO MgO K_2O Ign. 10.99 40.52 1.71 9.64 11.82 0.68 9.83 tr. 12.33 2.38 0.50 = 100.40

Crossite. The blue amphibole occurring at Silver Cliff, Colo., and thought by Palache (Bull. G. Univ. Calif., 1, 181, 1894) to be the same as crossite, is said to be crocidolite, instead: Murgoci, Am. J. Sc., 20, 143, 1905.

Széchenyüte is an amphibole occurring with jadeite from Central Asia, collected by Count

Széchenyi (1877–1880) and examined by J. Krenner, Zs. Kr., 31, 502, 1899.

G. = 3.033. Color light greenish brown to brownish or blackish green; pleochroism feeble. Extinction on m (cleavage) 14° 12′, on b (010) 16° 16′. An analysis by Loczka gave:

 ${
m K_2O} \\ 1.52$ SiO. Al₂O₃ Fe₂O₃ FeO MgO CaO Na,O H₂O 0.51 = 100.9755.02 4.53 1.04 3.28 20.36 8.00 6.71

Tschernichéwite is the name given by Duparc and Pearce, Arch. Sci. Phys. Nat., Genève, 23, 1, 1907; C. R. 144, 763, 1907; to an amphibole found in a magnetite bearing quartzite in northern Urals. It shows very strong pleochroism, a = deep violet, b = pale greenish yellow, c = intense

blue green. Probably near riebeckite or arfvedsonite.

Osannite, name given by Hlawatsch, Festschr. H. Rosenbusch, 76, 1906, to a soda-amphibole between riebeckite and arfvedsonite in which ax. pl. is ± to (010) and Bxac nearly coincides with axis c. Found in amphibole-gneiss at Cevadaes, Portugal. Named after Prof. A. Osann of

Freiberg, Baden.

Winchite; name given to a blue amphibole near tremolite from manganese mines of Central India. Named after H. J. Winch. Fermor [Trans. Min. Geol. Inst. India, 1, 79, 1906]; Min.

Mag., 14, 413, 1907.

Artificial. In investigating the synthetic production of a series of minerals of the composition MgSiO₃, E. T. Allen, F. E. Wright and J. K. Clement, Am. J. Sc., 22, 385, 1906, succeeded in making microscopic crystals which they determined to be amphibole. Preparation of Nordenskioldine; Ouvrard, C. R. 143, 315, 1906.

Analcite, Min., p. 595; App., p. 3.—Crystals from basalt of East Greenland; Böggild, [Medd. om Grönl., 28, 99]; Zs. Kr., 43, 636; from Scottish localities; Goodchild, [Trans. Geol. Soc., Glasgow, 12, Suppl., 1–68, 1903]; Zs. Kr., 45, 307; (with anal.) from Ben Lomond, N. S. W.; Anderson, Rec. Aus. Mus., 6, 418, 1907.

Effect of low temperatures on optical properties; Panichi, [Mem. Acc. Linc., 4, 389, 1902];

Zs. Kr., 40, 88.
Anal. of material from nepheline-syenite, Montreal; Harrington, Trans. Roy. Soc. Canada,
11, (3), 25, 1905; composition discussed; Clarke and Steiger, Am. J. Sc., 8, 251, 1899. Chem. constitution; McNeil, Jour. Amer. Chem. Soc., 28, 594, 1906. Anal. of material from Seisser

Alp in Tyrol with discussion of composition; Baschieri, Att. Soc. Tosc., 24, 1908.

Occurrence in rocks. J. W. Evans, Quar. Jour. Geol. Soc., 57, 38, 1901, describes analcite as forming the isotropic base to a monchiquite from Mount Girnar Junagarh, Kathiawar. A. Pelikan, Mitth., 25, 113, describes analcite as a primary constituent of an analcite-nephelite-phonolite from Schönfeld near Kamnitz, Bohemia, and of an analcite phonolite from Kubatschkaberge, northwest from Praskowitz. Noted by H. Proboscht, Centralbl. Min., 79, 1904, as occurring in the center of altered olivine crystals in an analcite-melaphyre from Pizmeda.

Anapäite. A. Sachs, Ber. Ak., Berlin, 1902, p. 18. Tamanite, S. P. Popoff, Zs. Kr., **37**, 267, 1902. Tschirwinskij, [Ann. Géol. Min. Russ., **7**, 28, 1904]; Zs. Kr., **43**, 77.

Triclinic. Axis $\bar{a}:\bar{b}:\bar{c}=0.8757:1:0.5975;\ \alpha=132^{\circ}\ 22',\ \beta=106^{\circ}\ 47',\ \gamma=83^{\circ}\ 28'$

Forms: a (100), c (001), m (110), M (110), o (111). Angles: $ac = 73^\circ$ 10', $am = 44^\circ$ 55', $aM = 52^\circ$ 20', $co = 52^\circ$ 35'. Crystals tabular. $\parallel a$ (100). Cleavage a, perfect. H. = 3.5. G. = 2.81–2.85. Color green white. Extinction on a(100), 15° with c. Ax. angle about 127°.

Composition (Ca,Fe)₃(PO₄)₂.4H₂O. Analyses: 1. Sachs, l. c.; 2. Popoff, l. c.; 3. Loczka, Zs. Kr., **37**, 438, 1902.

G	P _o O _s	FeO	CaO	H ₂ O	
1. 2.81	P_2O_5 35.51	18.07	27.77	18.47	= 99.82
$2. 2.812 \frac{2}{3}$	34.50	20.00	27.72	18.33	= 100.55
3. 2.85	34.36	17.49	28.32	18.64	Fe.O. 0.84 . CO. $0.62 = 100.27$.

From the limonite mines of Zelesnyj Rog near Anapa on the Taman peninsula, Kuban Province, occurs in crusts lining cavities at the junction of the limonite and siderite-bearing schist.

Ancylite. Ankylite. G. Flink, Medd. om Grönl., 14, 235, 1899; [ibid., 24, 49, 1901].

Orthorhombic. Axes $\vec{a}: \vec{b}: \vec{c}=0.916:1:0.9174$. Forms: d (101), e (011), Angles: $dd'''=90^\circ$ 5', $ee'''=85^\circ$ 4'. In small rhombic pyramids, de, with curved faces and edges; also

occasionally in small groups or druses and in crusts.

Cleavage not observed. Fracture splintery. Brittle, rather tough. H. = 4.5. G. = 3.95. Luster on crystal faces vitreous, on the fracture greasy. Color light yellow to orange, also brownish or grayish, resin-brown, yellowish green. Subtranslucent. Ax. pl. || (001). Bxa \(\pm \) (010). Birefringence strong, optically positive.

Composition, 4Ce(OH)CO₃.3SrCO₃.3H₂O. Analysis, R. Manzelius on 0.3 gram:

ThO, Ce2O3 FeO SrO CaO H,O CO (La,Di)2O3 insol 23.28 0.20 22.22 24.04 0.35 21.03 1.52 6.52 0.60 = 99.76** Traces of Y,O, MnO, F.

B. B. infusible, loses CO₂ and becomes brown; moistened with hydrochloric acid gives an intense red flame. In the closed tube yields water freely. Readily soluble in acids with evolution of CO2.

Occurs at Narsarsuk, southern Greenland, with ægirite and albite; also in crusts on corroded

feldspar crystals. Ancylite is related to weibyeite (Min., p. 291).

Named from ἀγκυλος, curved, in allusion to the rounded character of the crystal faces.

A mineral found in a pebble in West Russia, related to ancylite (spelled, ansilite) and parisite, is described by G. Tschernik, Vh. Min. Ges. St. Pet., 41, 43, 1903; Zs. Kr., 41, 184. In minute octahedrons in part dark brown (anal. 1), in part brownish yellow (anal. 2) with rounded faces. Luster vitreous. H. = 4 - 5, dark crystals harder. G. = 4.298 dark var., = 3.962 light var. Analyses:

Andalusite, Min., p. 496; App., p. 4. — Crystals from Pisek, Bohemia; Krejči, Ber. böhm. Ges. Wiss., xxxv, 1902; chiastolite crystals remarkable for their size and complex structure occur at Mt. Howden, ten miles north of Bimbowrie, South Australia. C. Anderson, Records Austr.

Mus., 4, 298, 1902; see also Am. J. Sc., 24, 183, 1907.

Refractive indices; Taubert, [Inaug.-Diss., Jena, 1905]; Zs. Kr., 44, 313.

Analyses of material from various localities in the neighborhood of Flücla and Scaletta in Switzerland, are given by A. Grammann, [Inaug.-Diss., Zürich, 1899; Viertelj. — Schrift d. Naturf. Ges. Zürich, 44, 302, 1899]; Zs. Kr., 35, 407. Author also discusses the probable cause of the varieties in color in the Alvice registron. of the variation in color in the Alpine specimens; Chem. constitution of; Zulkowski, Ber. Ak. Wien, 109, (IIb), 851, 1900; conversion at high temperature into sillimanite, which see.

Andesine, Min., p. 333; App., p. 4. — Crystals from Ekaluit, Greenland; Böggild, Min. Grönl., 467.

Andreite, App., p. 4. The following new forms were observed by Spencer, Min. Mag., 14, 316, on crystals from Oruro: ω (035), η (041), ξ (312), A (321), B (441), C (243)?, D (241), E (261). The chemical and crystallographic position is also discussed, and orite being considered as the first member of a series with diaphorite and freieslebenite.

Anglesite, Min., p. 907; App., p. 4. — Crys.: from Malfidano, Sardinia; Millesovich, Rend. Acc. Linc., 9, (1), 153, 1900; Eureka, Utah; Rogers, Sch. Mines Q., 23, 135, 1902; from Laurium and from the Tintic distr., Utah, the latter with several new forms; Hulyák [Term. Füz., 23, 187, 1900] in Zs. Kr., 36, 201; from Monte Poni, with new forms and a critical summary of all known forms with literature, etc., also a table of angles (after Gdt.); Hermann, Zs. Kr., 39, 463, 1904; from Broken Hill, S. Australia; Toborffy, Zs. Kr., 44, 601; from Mies., Slavík, [Abh. böhm. Akad. No. 19, 1905]; Zs. Kr., 44, 83; from Gaeta, L. Como; Repossi, Att. Soc. Milano, 43, 430, 1905; from ore bodies of province of Messina, Sicily; Traina, Rend. Acc. Linc., 14, (1), 220, 1905; from Dundas, Tasmania, mine Meretrice, New Caledonia and Lewis Ponds near Orange, N. S. W. C. Anderson, Rec. Austr. Mus., 6, 90, 1905; Zs. Kr., 43, 621–622; from Broken Hill, N. S. W., with new forms Y (187), X (3.4.12), v (598); Anderson, Rec. Aus. Mus., 7, 1, 63, 1908; Tintic dist., Utah; Farrington and Tillotson, Field Col. Mus., Geol. Series 3, No. 7, p. 131, 1908, Etching figures, see under barite.

ANHYDRITE, Min., p. 910; App., p. 4. — Crystals from the Simplon Tunnel and the etching figures on the three cleavage faces studied by Preiswerk, Jb. Min., 1, 33, 1905. Twin from Aussee, Styria, with new form p (151); Bascom and Goldschmidt, Am. J. Sc., 24, 487, 1907; Zs. Kr., 44, 65.

Effect of low temperatures upon optical properties, Panichi, [Mem. Acc. Linc., 4, 389, 1902]; Zs. Kr., 40, 89. Pleochroism was noted in a crystal of anhydrite from Stassfurt by Görgey, Min. Mitth., 26, 141, 1907, giving α violet, β colorless, γ violet; absorption $\gamma > \alpha > \beta$.

Analysis of anhydrite from Frontenac County, Ontario, by Nicol., [Can. Rec. of Sci. 1896–

1897, 7, 61], Zs. Kr., 31, 293.

Studies in the genesis of anhydrite and its associated minerals were made by van't Hoff with Armstrong, Hiurichsen, Weigert, Farup, d'Ans; Ber. Ak. Berlin, 559, 1900; 570, 1140, 1901; 1000, 1903; 218, 1906; [Arch. Neërland d. sc. exact. et nat. Harlem, 6, 471, 1901]; reviewed in Zs. Kr., 38, 525; Jb. Min., 2, 5, 1902; and by Vater, Ber. Ak. Berlin, 269, 1900.

Inclusions of liquid carbon dioxide in anhydrite from Simplon Tunnel; Spezia, Att. Acc. Torino, 39, 521, 1904. Occurrence at Wilhelmsglück; Lenze [Ber. ub. d. Versamml. d. oberrhein. geol. Vereins, 32, 23, 1899]; Zs. Kr., 35, 411. In a phonolite at Hammer-Unterwiesenthal, Saxony, blue anhydrite; Bergt, Abh. naturwiss. Ges. Isis, Dresden, 88, 1899; in a micaceous dolomite from Simplon Tunnel; Spezia, Att. Acc. Sci. Torino, 38, June, 1903.

Micro-determination in rocks; Berg, Centralbl. Min., 688, 1907.

Ankerite, Min., p. 274. — Analysis of normal var. from Phelps Co., Mo.; Rogers, Kans. Univ. Bull., 8, 183, 1899.

Annabergite, Min., p. 818. — Artif.; de Schulten, Bull. Min. Soc., 26, 87, 1903. Occurrence at Cobalt, Ont.; Miller, Rep. Can. Bureau Mines, 2, 1905.

Annerödite. — See under Uraninite.

ANORTHITE, Min., pp. 337, 391, 1027; App., p. 5. — Cryst. — From Vesuvius figured by Viola, Zs. Kr., 31, 484. From Aranyi-Berg described by V. Hulyák, [Földt. Közl., 33, 54, 1903], Zs. Kr., 40, 504. Following new forms given, $G(\bar{4}05)$, F(205), $V(\bar{1}31)$, H(421), $K(\bar{2}43)$, $L(\bar{2}\bar{4}3)$. Crystals from a volcanic bomb found on the island of St. Christopher described by Fels, Zs. Kr., 37, 450. From Franklin, N. J., by Warren, Am. J. Sc., 11, 369, 1901. Twins from Rochenoire, Puydon, Vicing Pull See Min. 21, 142, 1008 de-Dôme; Vigier, Bull. Soc. Min, 31, 142, 1908.

Opt. — Studies of optical constants and orientation on anorthite from Vesuvius by Becke,

Ber. Ak. Wien, 108, 434, 1899, Min. Mitth., 19, 201, 1899; by Viola, Zs. Kr., 31, 484, and Klein,

Ber. Ak. Berlin, 346, 1899.

 $\alpha_{\rm p} = 1.57524$, Viola; 1.57556, Klein. " 1.58348, $\beta_{\rm p} = 1.58327$ 66 66 $\gamma_{\rm D} = 1.58840,$ $2V = 76^{\circ} 56',$ 1.58849, 76° 30′,

One of the optic axes lies in c (001) and makes the angle $26^{3\circ}$ (Becke) with pole to b (010), the

other optic axis makes a small angle with the \dot{c} axis.

Anal. — From Phippsburg, Maine, by Hillebrand, U. S. G. S., Bull. 167, 1900; from the island of St. Christopher by Fels, Zs. Kr., 37, 460; from Franklin, N. J., by Warren, Am. J. Sc., 11, 371, 1901; discussion of chemical constitution by Tschermak; Ber. Ak. Wien., 112, (1), 355, 1903; 114, 455, 1905; **115**, 217, 1906.

Anorthoclase, Min., p. 324; App., p. 5. — Portoscuso, Sardinia, determination of refractive indices; Riva, Riv. Min. Ital., 26, 21, 1901; Zs. Kr., 35, 274, 1901. Anal. of phenocrysts from granite of Port Victor, S. Australia; Gartrell, [Trans. Roy. Soc. S. Aus., 27, 256-260, 1903]; Zs. Kr., 45, 315.

Ansilite, see under Ancylite.

Anthophyllite, Min., p. 384; App., p. 5. — Occurs with fayalite at Rockport, Mass., (Opt.) Warren, Am. J. Sc., 16, 339, 1903, 17, 179, 1904; also at Saint-Germain-l'Herm, France (Anal. Opt.) G. Friedel, Bull. Soc. Min., 25, 102, 1902. Occurrence at Fonte del Prete, Elba; Cornu and Himmelbauer, [Mitth. Nat. Ver. Wien, 3, 9-19, 1905]; Zs. Kr., 44, 299.

Artif. formation of kupfferite; Allen, Wright and Clement, Am. J. Sc., 22, 385, 1906.

Antimon-luzonite. S. Stevanović, Zs. Kr., 27, 239, 1902. — See Enargite.

APATITE, Min., pp. 762, 1027; App., p. 5. - Cryst. - Complex crystals of rich purple color are described from Minot, Maine, by Palache, occurring with tourmaline, lepidolite, cookette, etc., in described from Minot, Maine, by Palacne, occurring with fourmaine, lepidolite, cookette, etc., in pegmatite; optical properties (biaxial) are also described and analysis given by Wolff, Proc. Amer. Acad., 39, 517, 1902; crystals from granite of Baveno; Artini, Rend. Acc. Linc., 11, (2), 362, 1902; crystals, pink, also green occur at Haddam Neck, Conn.; new forms noted l (7430), W (7520), W (7250); Bowman, Min. Mag., 13, 111, 1902. Crystals described from Rautenkrantz in the Erzgebirge; Hermann, Centralbl. Min., 433, 1904; from Biella, Italy, by Zambonini with new pyramid f (1014), Zs. Kr., 40, 220, 1904; from Gellivara in Norbotten, Sweden, with new forms e (7.0.7.11), f (2023) g (7079), f (7078), also refractive indices measurements; Zimányi, Zs. Kr., 39, 505, 1904; Apn. Mus. Nat. Hung., p. 288, 1904. Needle-like crystals in volcanic bomb from e (7.0.7.11), f (2023) g (7079), f (7078), also retractive indices measurements; Zimányi, Zs. Kr., 39, 505, 1904; Ann. Mus. Nat. Hung., p. 288, 1904. Needle-like crystals in volcanic bomb from Cappuccini di Albano, Italy; Viola, Zs. Kr., 37, 370. Crystals rich in faces of a clear pale amethyst color from Gletsch, Switzerland; Busz, Centralblt. Min., 753, 1906. The following new forms noted, λ (4.0.4.21), β (5057), δ (4045), γ (8089); Lyon Mt., Clinton Co., N. Y.; Whitlock, N. Y. State Mus. Bull., 107, 72, 1907. Chemical, optical and crystallographic study of apatite from Epprechtstein, Bavaria (new forms; B (5490), K (10.9. $\overline{19}$.0), K₁ (19.9. $\overline{10}$.0), D (13.0. $\overline{13}$.4)), and Luxullian, Cornwall. — Walter, Inaug. Diss., Univer. Münster, 1907.

Opt. — Refractive indices of fluorapatite from Pisek; K. Zimányi, Zs. Kr., 40, 281, 1904; Ann. Mus. Nat. Hung., 562, 1904; also of crystals found in inclusions in augite andesite lava from Bel-Mus. Nat. Hung., 562, 1904; also of crystals tound in inclusions in augite andesite lava from Beilenberges near Mayen; Gaubert, Bull. Soc. Min., 28, 186, 1905. Optically anomalous crystals from amphibole diabase from Nurra, Sardinia; Viola, Boll. Com. Geol. Ital., 6, 106, 1905. Optical constants for crystals from Gletsch, Switzerland; Busz, Centralbl. Min., 760, 1906. Refractive indices; Gaubert, Bull. Soc. Min., 30, 108, 1907. Optical study of material from various localities; Baumhauer, Zs. Kr., 45, 555, 1908.

Anal. — Gordonbrook, New South Wales, analysis; Mingaye, Trans. Austr. Ass. Sc., 1898.

An apatite from Narsarsuk, Greenland, containing 3.36 p. c. Y₂O₃ has been described by G.

Flink, Medd. Grönland, 14, 235, 1898; 24, 173, 1901. Analysis of crystals from Gletsch, Switzer-

land; Busz, Centralbi. Min., 760, 1906.

Pseudomorph of "osteolite" after calcite from near Prausnitz, Kreis Jauer, Silesia; Schwantke, Centralbl. Min., 641, 1905.

On the apatite deposits of Canada; A. Osann, Geol. Surv. Canada, 12, Pt. O, 1899.

Phosphorite. — Various Swedish phosphorites contain fluorine in the same ratio to the phosphoric acid as in apatite; Andersson and Sahlbom, Bull. G. Inst. Upsala, 4, 79, 1899. Occurrence in Europe; Kruft, Jb. Min., Beil, 15, 1, 1902.

APHTHITALITE, Min., p. 897; App., p. 5.—See B. Gossner on the crystallographic relations of the sulphates and chromates of potassium and sodium, Zs. Kr., 39, 155, 1903; also van't Hoff on the formation of isomorphous mixtures of K₂SO₄ and Na₂SO₄, Ber. Ak. Berlin, 359, 1903. The latter concludes that glaserite (K₂SO₄), aphtalose or aphtalite (75% K₂SO₄) and arcanite (62% K₂SO₄) are probably identical.

Probable occurrence in fumaroles of Mt. Pelée, Martinique; Lacroix, Bull. Soc. Min., 28, 60,

1905. Formed at eruption of Vesuvius in 1906; see under Vesuvius.

Apophyllite, Min., p. 566; App., p. 5. — Cryst. — Crystals with optical study and anal. from Sulitelma, Sweden: Hennig, Geol. För. Förh., 21, 391, 1899; From Seiser-Alp with (013); Zambonini, Zs. Kr., 34, 561; in tabular crystals from Rézbánya, Hungary; Zimányi, Zs. Kr., 36, 256, 1902; from Gross-Priessen, east of Aussig, showing t (103); Pelikan, Ber. Ak. Wien, 111, 334, 1902. From Scottish localities; Goodchild, [Trans. Geol. Soc. Glasgow, 12, Suppl., 1-68, 1903]; Zs. Kr., 45, 305. From following Swedish localities, Nordmarken, Taberg, Utö, Skottvång, Långbaushyttan, Hällestad; Flink, G. För. Förh., 28, 423, 1906. From basalt of East Greenland; Böggild, [Medd. om Grönl., 28, 99]; Zs. Kr., 43, 636; also in Min. Grönl., 546, 1905. From Traversella with anal. and discussion of chem. comp.; Colomba; Rend. Acc. Linc., 16, 966, 1907. Quartz pseudomorph after apophyllite occurs with datolite and pectolite near Fort Point, San Francisco. Cal., see under martz.

San Francisco, Cal., see under quartz.

Studies on apophyllite free from fluorine and on those which contain fluorine show that the first variety is + with higher index of refraction, the second — and with lower index of refraction; Cornu, Centralbl. Min., 79, 1906.

Occurrence (with anal.) at Asmara and Sciket, Eritrea; Manasse, Proc. Soc. Tosc., July, 1906. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 124, 1908. Anal. of material from Seisser Alp, Tyrol, with discussion of composition; Baschieri, Att. Soc. Tosc., 24, 1908. Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull. 207, 1902; Zs. Kr.,

38, 696.

Aragonite, Min., pp. 281, 1027; App., p. 5. — Crystals described by Jeremejew from Karkaralinsk distr., Khirgise Steppes, Vh. Min Ges. St. Pet., [35, 75, 1897]; Zs. Kr., 31, 507; by Zimányi from Dognácska with new forms and list of forms for the species with references to authors, etc., Zs. Kr., 31, 353, 1899. From Herrengrund, new forms, discussion of twins and measurement of refractive indices; Melczer, Zs. Kr., 38, 249, 1903; Ber. aus Ungarn, 23, 272, 1905; from East Greenland; Böggild, Medd. om Grönl., 28, 108, 1905; from Plauen in Vogtland; Henglein, Centralbl. Min., 372, 1908.

Symmetry that of the holosymmetric class; Melczer, Zs. Kr., 39, 279, 1904. See also Becken-

kamp, Zs. Kr., 32, 24, 1899.

The crystalline structure of the members of the Aragonite group has been exhaustively studied

by Westhoff, Inaug. Diss., 1899. See also absts. in Zs. Kr., 35, 188.

Investigation of structure of mimetic crystals, Mügge, Jb. Min., Beil. Bd., 14, 247, 1901.

Fluorescence in; Schincaglia, [Il Nuovo Cimento, Pisa, 10, 212, 1899]; Zs. Kr., 34, 312.

On the relations of aragonite to calcite see H. W. Foote, Zs. phys. Ch., 33, 740, 1900.

Conchite of Agnes Kelly, Ber. Ak. München, 30, 187, 1900; Min. Mag., 12, 363, 1900, the material of molluscan shells supposed to be a new form of CaCO₃ is shown by Vater, Zs. Kr., 35, 140, and Braune Centrally Min. 124, 1001, to be identical with a regonite.

149, and Brauns, Centralbl. Min., 134, 1901, to be identical with aragonite.
 Mossottite from Montieri is shown by G. D'Achiardi; to be a mixture of calcite and aragonite,
 [Att. Soc. Tosc., Proc. Verb., 11, 1898]; Zs. Kr., 32, 522.

Aragotite, Min., p. 1013. — Occurrence in Ætna mercury mine, Napa Co., Calif., Hanks, [Jour. Roy. Microsc. Soc., 673, 1905]; Zs. Kr., 43, 615.

ARDENNITE, Min. p. 542. — Analysis by W. Prandtl of the arsenical variety:

CaO As2O5 Al₂O₃ 25.25 Fe₂O₃ 0.53 FeO SiO, MnO MgO Ign. 5.24 = 99.500.65 27.77 22.70 5.20 1.44 9.91

This leads to the formula H₆Mn₅Al₅(As, V)Si₅O₂₈, Zs. Kr., 40, 392, 1904.

Arfvedsonite, Min., p. 401; App., p. 6. — Crystals from Narsarsuk, Greenland; Flink, Medd. Grönl., 24, 77, 1901.

ARGENTITE, Min., p. 46. — Occurrence at Cobalt, Ontario; Miller, Rep. Can. Bureau of Mines, 14, Pt. 2, 1905. Occurrence (with anal.) at California mine on Glacier Mt., Montezuma, Summit Co., Colo.; Van Horn, Am. J. Sc., 25, 508, 1908.

ARGENTODOMEYKITE, see under Domeykite.

ARGENTOPERCYLITE, Chem. Zeit., 16, 1952, 1892, same as Boleite, which see.

ARGYRODITE, Min., p. 150; App., p. 6. — Occurrence in Bolivia; Canfield, Am. J. Sc., 23, 20, 1907. Crystallographic and chemical study of material from Colquechaca, Bolivia; V. M. Goldschmidt, Zs. Kr., 45, 548, 1908. Anal. of material from old specimen from "Bescheert Glück" mine, Freiberg; Kolbeck, Centralblt. Min., 331, 1908.

See Plusinglanz.

ARSENIC, Min., p. 11; App., p. 6. — Occurs near Montreal with calcite in a vein cutting nephelitesyenite, G. = 5.74, contains 1.65 Sb and 0.16 S; Evans, Am. J. Sc., 15, 92, 1903. Also occurs in reniform masses at Washington Camp, Santa Cruz Co., Arizona; Warren, Am. J. Sc., 16, 337, 1903.

ARSENOPYRITE, Min., p. 97; App., p. 6. — Crystals from the Lengenbach quarry in the Binnenthal have been measured by Lewis, Min. Mag., 13, 291, 1903. Crystals from Brosso and Traversella with new form (221); Colomba, Rend. Acc. Linc., 15, 642, 1906. Crystals from Ivigtut, Greenland; Böggild, Min. Groenland, 49, 1905.

The cobaltiferous variety, danaite, from the Sulitjelma mines in northern Norway, contains 1.15 p. c. Co and gives an axial ratio near that of glaucodot, according to Fletcher, Min. Mag., 14, 54, 1904. Crystals from the same locality earlier described by Stelzner gave 6.81 p. c. Co, cf. Fletcher, l. c., also Vogt, Zs. prakt. Geol., 2, 43, 1894, and Hintze, Min., 1, 863, 1901. Occurrence (with anal.) at Cobalt, Ont.; Miller, Rep. Can. Bureau Mines, 14, Pt. 2, 1905.

Arsenschwefel, E. Monaco, [Ann. Scuola Agricolt. Portici, 1902], Zs. Kr., 40, 297, 1904. A blue-gray mineral with metallic luster occurring in granular crystalline (tetragonal?) aggregates, mixed with realgar, at the Solfatara of Pozzuoli, near Naples. An analysis, yielding the formula $As_2S_2 + H_2O$, gave: S, 35.92; As, 56.90; H_2O , 7.00 = 99.82.

ARSENSULFURITE, see Sulphur.

Artinite. L. Brugnatelli, [Rend. R. Ist. Lomb, Mailand, 35, 869, 1902; 36, 824, 1903]; Centralblt. Min., 144, 663, 1903; Zs. Kr., 40, 103; 41, 257.

Orthorhombic. Fibrous, radiating, in spherical aggregates. H. = 2. G. = 2.028. Color white. Optically – . Length of fibres usually \parallel b. Ax. pl. usually \perp to length of fibers. β = about 1.537. γ – α = about 0.055. 2E over 90°. Comp. — MgCO₃,Mg(OH)₂,3H₂O = MgO, 40.82; CO₂, 22.45; H₂O, 36.73.

Anal. on material from Val Laterna:

MgO 41.34 CO₂ 22.37 H_2O (36.39) = 100.00

Obs. Found in an asbestus quarry associated with a peridotite at Val Brutta in the Val Laterna. Later observed with magnesite at Emarede in the Aosta valley. Named in honor of Prof. Ettore Artini of Mailand.

Arzrunite. A. Arzruni and K. Thaddéeff, Zs. Kr., 31, 230, 1899.

Orthorhombic. In druses of small hexagonal prisms with basal planes and minute pryamidal faces; these are interpreted as being orthorhombic with a prismatic angle sensibly 60°, and showing the forms b (010), c (001), m (110), also (021) and (111). Color blue or bluish green, but the light transmitted through the prism is in part blue, in part nearly colorless. Biaxial, an axis nearly $\perp m$.

Composition highly uncertain, as the material for analysis was scanty (0.2, 0.19 gr.) and very

impure; further the only completed analysis shows a loss of 2 p. c.

Analyses, Thaddéeff:

	SO,	Cl ·	PbO	CuO	H,O	Fe,O,	CaO	ZnO	SiO.
1.	8.07	14.39	31.41	21.39	undet.	0.70	1.70	undet.	13.60
2.	13.06	9.46	33.38	14.54	11.01	1.81	1.87	4.08	8.88 = 98.09

Of the above the SiO, is assumed to be present as quartz, Fe,O, as limonite, ZnO as goslarite. furthermore the mineral graduates into lanarkite; deducting the impurities a formula is deduced which would make arzunite a double salt of basic lead sulphate and a basic copper chloride, (Pb₂O)SO₄.3(CuCl₂.H₂O).Cu(OH)₂; the result, however, has little value.

Observed as a drusy crystalline incrustation lining eavities in the cellular gangue rock at the mine Buena Esperanza, Challacollo, Tarapaca, Chile. Named after Prof. A. Arzruni of Aachen.

Asbestus. — Occurrence, Exploitation and Uses is the title of a pamphlet (pp. 169, 19 plates) by Fritz Cirkel, published at Ottawa in 1905 by the Mines Branch of the Dept. of the Interior, Canada. It gives an account of the amphibole asbestus occurring in Hastings Co., Ontario, and elsewhere, which has, however, only limited applications in the arts; also, more fully of the serpentine asbestus, or chrysolite, mined extensively in Canada, particularly south of Quebec at Thetford, etc.

The occurrence and origin of asbestus (chrysotile) is discussed at length in the geological

reports of Vermont for 1903-1904 and for 1905.

ASCHARITE, App., p. 6. — Formation discussed; van't Hoff, Ber. Ak. Berlin, 652, 1907.

ASPHALT, etc., Min., pp. 1017-1020. — The asphalt and bituminous rock deposits of the United States, with description, occurrence, etc., of asphaltum, albertite, impsonite, grahamite, nigrite, uintahite (gilsonite), wurtzilite, ozocerite; Eldridge, 22nd Ann. Rep. U. S. G. S., 1, 211-452, 1900-1901.

ASTRAKAMITE, Min., p. 946. — See Blödite.

Astrolite. Astrolith, R. Reinisch, Centralbl. Min., 108, 1904.

Orthorhombic (?). In globular forms with radiated or stellate structure. Under the microscope foliae are noted, in part showing sections of irregular outline without cleavage lines and non-pleochroic, to these $Bx_a(-)$ is normal with $2E = 48^\circ$, dispersion $\rho > v$; sections of foliae are also in part elongated, pleochroic, and showing cleavage cracks.

H. = 3.5. G. = 2.78. Luster vitreous to pearly. Color siskin-green. Streak grayish white.

Composition somewhat uncertain, the material being impure from inclusions; the formula deduced is that of a metasilicate: (Na,K)₂Fe(Al,Fe)₂(SiO₃)₅·H₂O. Analysis, after deducting 3.88 p. c. CaCO₃:

SiO ₂ 52.14	Al_2O_3	$\mathrm{Fe_2O_3}$	FeO	K_2O	Na ₂ O	$H_{2}O$
52.14	8.15	13.05	12.01	5.20	$6.\overline{62}$	2.83 = 100

Fuses B. B. at 3.5 quietly to a gray enamel; reacts for iron with the fluxes; not sensibly attacked

Occurs inclosed in a diabase tuff near Neumark in masses of black siliceous schist, of granular limestone and of calcareous alum schist in Saxon Voigtland. Named in allusion to the stellated structure.

ASTROPHYLLITE, Min., p. 719. — From Narsarsuk, Greenland; Böggild, Medd. om Grönl, 33, 103, 1906.

Atacamite, Min., p. 172; App., p. 6. — **Cryst.** From the Brilladora mine, Paposo, Atacama, show the new forms β (210), γ (150); Moses, Am. J. Sc., **12**, 100, 1901; from same locality; Keller, Proc. Amer. Phil. Soc., **47**, 84, 1908; from Sardinia; Pelloux, Att. Acc. Linc., **13**, (2), 34, 1904; from Bimbowrie, S. Australia, with anal.; Mawson, Frans. Roy. Soc. S. Aus., **30**, 67–70, 1906]; Roy. May **45**, 215; from Chapter Operatory Associated Proc. Apr. May **7**, (4), 67, 1906. Zs. Kr., 45, 315; from Gloneurry, Queensland; Anderson, Rec. Aus. Mus., 7, (1), 67, 1908.

Atopite, Min., p. 861. — Occurs at the manganese mines of Miguel Burnier, Minas Geraes, Brazil, (anal.); Hussak, Centralbl. Min., 240, 1905.

AUERBACHITE, see under Zircon.

AUGELITE, Min., p. 847; App., p. 6. - Found in small amount in the silver ores of Tatasi and Portugalete, in the province Sud-Chichas, Potosi, and from Oruro, Bolivia. New face g (910) observed. Indices of refraction for Na light = 1.5752 and 1.5893. 2E = 82½°. $G_{\rm s} = 2.69$. Spencer, Min. Mag., 12, 1; ibid., 14, 323.

AUTUNITE, Min., p. 857.—Study of absorption spectrum and the changes through loss of water by heating into "metakalkuranite;" Rinne, Centralbl. Min., 709, 1901.

Occ. in Madagascar and at Tinh-Tuc, region of Cao-Bang, Tongking, China; Lacroix, Bull.

Soc. Min., 31, 245, 259, 1908.

AWARUITE, Min., pp. 29, 1043. — Native nickel-iron alloys, near the awaruite from New Zealand, have been described by Sella from Biella, Piedmont, see Min., p. 1043; also by Melville from Josephine Co., Oregon, and called *josephinite*, see App., p. 38; by Hoffmann from the auriferous gravels of the Fraser river, British Columbia, and called by him souesite, Am. J. Sc., 19, 319, 1905; by Jamieson from Josephine Co., Oregon (see above) and from South Fork, Smith river, Del Norte Co., California, ibid., 19, 413, 1905.

The alloy called *souesite* (after Mr. F. Soues) is obtained from the gold washings of the Fraser

river near Lillooet, with platinum, iridosmine, magnetite, chromite, etc. It occurs in small, irregular, rounded grains, not exceeding 1.5 mm. in diameter, in part microscopic. Strongly magnetic and malleable. G. = 8.215. Slowly dissolved in hot hydrochloric acid, readily in hot nitric acid. Analysis 1 below by Wait, after deducting 1.16 p. c. silica.

The nickel-iron from Oregon (earlier described by Melville, and named josephinile, Am. J. Sc.,

43, 509, 1892, App., p. 38) occurs in water-worn, bean-shaped pebbles, from a few millimeters to several certimeters in diameter; these consist of a sponge-like mass enclosing particles of a silicate resembling serpentine; analysis, 2 below, after deducting impurities.

The Smith river iron is in nearly uniform grains, from 0.15 to 1.5 mm. in diameter; it is obtained with magnetite and chromite as a residue from gold washings. G. = 7.85 (corrected for admixed

magnetite).

Analyses: 1. Wait, l. c.; 2,3. Jamieson, l. c.

The second second	Ni	Fe	Co	Cu	P	S
1. Fraser R., souesite	76.48	22.30		1.22		= 100
2. Josephine Co., Oregon	² / ₂ 74.23	25.18	0.46		0.04	0.09 = 100
3. Smith R., California	$\frac{2}{2}$ 76.69	21.37	1.20	0.64	0.04	0.06 = 100

The above approximate to Ni₃Fe which requires Ni 76.0, Fe 24.0 = 100. Skey obtained for awaruite Ni 67.63 and Mattirolla for the Biella mineral described by Sella Ni(Co) 75.20.

AXINITE, Min., p. 527; App., p. 7. — Crystals from Obira, Japan, described by Zimányi, Zs. Kr., 32, 125, 245, 1899; also by Ford, Am. J. Sc., 15, 200, 1903, and by Wada, Minerals of Japan, p. 114, Tokyo, 1904; crystals from Biella, Italy; Zambonini, Zs. Kr., 40, 259, 1904; from Bowling Alley Point, near Mundle, N. S. W.; from Moonbi, N. S. W., and from Colebrook mine, Dundas, Tasmania: Anderson, Rec. Aus. Mus., 6, 133-137, 1906; from Tremore, Bodmin, Cornwall; Barrow and Thomas, Min. Mag., 15, 119, 1908.
Ford (l. c.) gives the analyses 1 and 2 below, from which, and with other reliable earlier

analyses, the formula $R_7 R_4 B_2 (SiO_4)_8$ is deduced; here R = Ca chiefly, also Fe, Mn, Mg, H₂ and

R = Al, also Fe.

1. Bourg d'Oisans 2. Obira, Japan 3.028 3. Bonsall, San Diego Co., 42.61 6.04 17.43 0.38 7.53 $4.10 \ 19.74 \ 0.44 \ 1.56 = 99.83$

4. Consumers Mine, Amador $42.79 [6.70] 16.38 \dots 4.22 8.76 19.21 0.09 1.85 = 100.00$ Co., Calif.

Anal. 3 and 4 by Schaller (priv. contr.), who finds that axinite consists of isomorphous mixtures of ferroaxinite, 8SiO2, 2Al2O3, 2FeO, H2O, 4CaO, B2O3, and manganoaxinite, 8SiO2, 2Al2O3, 2MnO, H₂O, 4CaO, B₂O₃.

AZURITE, Min., p. 295; App., p. 7. — Crystals from Rosas, Sardinia; Riva, Zs. Kr., 31, 534, 1899; from Chessy with new forms (261), (I.10.2), also crystal from Broken Hill; Cesaro, Bull. Ac. Belg., 130-143, 1905.

Occurrence at Castello di Bonvei, near Mara, Sardinia; Millosevich, Rend. Acc. Linc., 15, (2), 732, 1906; from Timpone Rosso, near Lagonegro, Basilicata; Zambonini, ibid., 16, (2), 737, 1907.

Babingtonite, Min., pp. 381, 1027; App., p. 7. — Palache and Fraprie have described crystals from Somerville and Athol, Mass., Proc. Amer. Acad., 38, 382, 1902. At Somerville it occurs with prehnite in veins and pockets in diabase, the crystals are complex and show several new forms. An analysis by Fraprie gave:

SiO₂ TiO₂ Al₂O₃ Fe₂O₃ FeO MnO CaO MgO (Na, K)₂O H₂O
$$52.25$$
 0.18 5.27 7.49 11.05 1.94 20.36 0.46 0.22 0.29 = 99.51

Shepard's identification of babingtonite at Athol is confirmed. The crystals are less complex than those from Somerville.

Baddelevite, App., p. 8. — Three crystals found in the gem gravels from Balangoda, Ceylon. The axial ratio calculated from measurements on these crystals was a:b:c= $0.9905:1:0.5110; \beta = 80^{\circ} 32'$. Anal. 1. Blake and Spencer, Min. Mag., 14, 378.

Occurs in rolled masses in the Rio Verdinho near Caldas, Minas Geraes, Brazil; E. Hussak, Min. petr. Mitth., 18, 339, 1899; Hussak and Reitinger, Zs. Kr., 37, 566, 1903, have described other occurrences of "zirkonfavas" from the same region, including light brown specimens with G. = 4.639-4.983 (anal. 2) and slate-gray to blackish, G. = 5.102-5.402 (anal. 3).

"zirkonfavas" are probably alteration products of silicates containing zirconium.

The same authors also describe "zirkonoxydfavas" occurring in reniform crusts, fibrous and concentric; they contain 97.19 p. c. ZrO₂ and are regarded as an independent modification of the native ZrO₂, not as fibrous baddeleyite.

0.28 = 100.251. Crystals, Ceylon G. = 4.8581.75 15.49 0.50 1.06 0.85 tr. MnO 2. Light brown, Brazil 0.63 = 100.283. Slate-gray, Brazil G. = 5.24593.18 1.94 0.61 2.76 0.64

* Including FeO.

Badenite. P. Poni, Min. Roumanie, p. 17, 1900 (Ann. Sci. Univ. Jassy, 1, 29). — Massive granular to fibrous. G. = 7.104. Luster metallic. Color steel-gray, becoming dull on exposure to the air.

Composition, (Co,Ni,Fe)₂(As,Bi)₃. Analysis: As Bi Analysis: As Fe 61.54 0.27 20.56 7.395.98 = 100.50

B. B. on charcoal gives arsenical fumes and fuses to a magnetic bead; with borax a cobalt bead. In the closed tube yields metallic arsenic and in the open tubes a crystalline sublimate of As₂O₃. Dissolves easily in nitric acid.

From Roumania, occurring in the valley of Neguletzul, opposite the village Badeni-Ungureni,

district of Muscel; associated with erythrite, annabergite, malachite in siderite.

W. B. Giles, Min. Mag., 13, 353, 1903.

In compact masses resembling unglazed porcelain; under the microscope feebly birefringent. H. = 4.5. G. = 2.73; 2.7-2.93, Spencer. Color white with sometimes a faint tinge of seagreen. In composition a hydrated calcium borosilicate. Analyses yield the formula 8CaO.5B2O3. 6SiO2.6H2O.

CaO Al₂O₃,Fe₂O₃ 8.30 White 28.4534.88 0.63 = 100Faint greenish 28.0535.22 8.60 = 100

Fuses B. B. to a white transparent bead, coloring the flame green. Readily soluble in dilute

hydrochloric acid, the solution on evaporation yielding gelatinous silica.

Occurs in veins and nodules in the mines of the Consolidated Borax Company situated in the Mohave desert, sixteen miles N. E. of Daggett in San Bernardino Co., Cal. Named after Mr. R. C. Baker of Nutfield, Surrey, director in the Borax company, who discovered the mineral.

BARITE, Min., pp. 889, 1027; App., p. 8.—**Cryst.**—From Tetschen.-Bodenbach, Bohemia, with K (267); Polak, [Lotos, 77, 1897], Zs. Kr., **31**, 528; from Auvergne, with (11.3.8); Buttgenwith K (267); Polak, [Lotos, 77, 1897], Zs. Kr., 31, 528; from Auvergne, with (11.3.8); Buttgenbach, Ann. Soc. G. Belg., 25, xxx, 1898; Is. Artificial formation; de Schulten, Bull. Soc. Min., 26, 103, 1903.

Barylite, Min., p. 562. — M. Weibull, G. För. Förh., 22, 33,1900, has extended the examination of Blomstrand (1874) as follows: Crystallization orthorhombic; axes $\check{a}:\bar{b}=0.4084:1$. Crystals imperfect, tabular $\parallel a$ but showing no other faces; cleavage a good, also b, c, and m, cleavage angle $am=22^{\circ}$ 13' (22° 6'-22° 21'), $mm'''=44^{\circ}$ 26'. Color milk-white. Optically +. Ax. pl. $\parallel c$, Bx_a \perp a. Dispersion $\rho > \nu$ small. $2V_{Na}=65^{\circ}$. $\beta_{Na}=1.685$, $\gamma -\alpha =0.014$. A relation to the chrysolite group (knebelite) as well as iolite is suggested.

Barysilite, Min., p. 421. — Occurs at Långban, Sweden, as described by Hj. Sjögren, G. För. Förh., 27, 458, 1905. Crystals rhombohedral, tabular in habit, with the forms c (0001), s (10 $\overline{1}$ 1), r (90 $\overline{9}$ 7), n (27 $\overline{9}$ 4); $cs=29^{\circ}$ 19'; $ss'=129^{\circ}$ 51'; $rr'=119^{\circ}$ 4'; c=0.4863, G. Flink. G. = 6.72 (corrected). Optically uniaxial. Analysis by R. Mauzelius:

SiO, PbO FeO MnO MgO CaO . Na₂O H₂O(100°) CI 16.42 79.51 0.04 3.34 0.03 0.60 0.08 tr. = 100.040.02

Discussion of chem. comp.; Cesàro, Mem. Soc. Liège, 5, No. 6, 16, 1904.

BARYTA-ORTHOCLASE, see under Celsian.

Baumhauerite. R. H. Solly, Min. Mag., 13, 151, 339; Zs. Kr., 37, 321; 38, 652. Monoclinic. à : \dot{b} : \dot{c} = 1.1368 : 1: 0.9471. β = 82° 42′ 45″. Forms: a (100), b (010), c (001), (702), (301), (502), (201), (302), (101), (102), (103), (104), (106), (301), (502), (201), (704), (302), (101), (102), (104), (120), (110), (320), (210), (520), (111), (111), (122), (122), (011). These are the most common forms observed, there being one hundred and twenty forms listed in the original articles.

Angles: $100 \land 101 = 50^{\circ} \ 27'^{*}$, $101 \land 001 = 32^{\circ} \ 15\frac{3}{4}'^{*}$, $010 \land 11\overline{1} = 50^{\circ} \ 33'^{*}$, $010 \land 111 = 53^{\circ} \ 51\frac{1}{4}'$.

Crystal habit varied, (1) with large development of (010), (2) tabular | (100), (3) prismatic || à axis, (4) with rhombic shape.

Cleavage: a perfect. Fracture conchoidal. H. = 3. G. = 5.330. Luster metallic. Color

lead to steel-grey, with sometimes an iridescent tarnish.

Composition, 4PbS.3As₂S₃= sulphur 24.61, arsenic 26.64, lead 48.75.

Anal. by Jackson:

As 24.39 26.42 48.86 = 99.67

Obs. — from the Binnenthal in Switzerland. Named in honor of Prof. H. Baumhauer, of Freiburg.

BAUXITE, Min., p. 251; App., p. 9. — Analyses of bauxite from Adairsville, Ga., which correspond to Al₂O₃.3H₂O. Watson, Amer. Geol., 28, 25, 1901; Zs. Kr., 37, 79; from Italian localities; Formenti, (Gazz. chim. ital., 31, 455, 1901; 32, 453, 1902), Zs. Kr., 37, 406, 40, 109; Aichino; D'Achiardi, Lotti, (Rass. Min., 15, 1902, 18, 1903), Zs. Kr., 40, 296, 41, 261, 279; Novarese, Zs. prakt. Geol., 11, 299, 1903.

Occ. Does not occur at Calabre as stated in Sys., p. 251; Salmoiraghi, Rend. Inst. Lomb.

Milano, 33, 252, 1900.

Bavenite. E. Artini, Acc. Linc., 10, (2), 139, 1901.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c} = 1.1751:1:0.7845; \beta = 89^{\circ} 17' 19''$. Forms: a (100), m (110).

g (210), (103), (101).

In fibrous-radiated groups of pseudo-orthorhombic prismatic crystals, flattened parallel

a (100). Faces a striated \parallel edge a/c. Cleavage b easy. H. = 5.5. G. = 2.72. Color white. Ax. pl. nearly normal (2°) to a. Bx_a \perp cleavage (b). 2Ey = 78° 30′, β = 1.580. Composition, Ca₃Al₂Si₆O₁₈. H₂O. Analysis: SiO₂ Al₂O₃ CaO MgO Na₂O H₂O

 Al_2O_3 15.42 56.93 24.47 0.12 0.29 2.49 = 99.72

Occurs in pegmatitic druses in the granite of Baveno, Italy.

BECHILITE, Min., p. 888. — Occ. in Argentina of var. hayesine which author considers as identical with bechilite; Buttgenbach, Am. Soc. géol. Belg., 28, 99, 1900-1901.

Formation discussed; van't Hoff, Ber. Ak. Berlin 652, 1907.

Beckelite. J. Morozewicz, Min. Mitth., 24, 120, 1905; Bull. Inter. de l'Acad. des Sci. de Cracovie, 485, 1905.

Isometric. Observed forms: a (110), o (111), d (110). In small crystals, often miscroscopic, the smaller crystals showing combinations of cube and octahedron, the larger being dodecahedral. Cleavage cubical. Fracture conchoidal. H. = 5. G. = 4.15. Luster nonmetallic. Color yellow.

Composition, Ca₃(Ce,La,Di)₄Si₃O₁₅. The analysis gave:

Sol. in phosphorus salt, giving a pale yellow-green bead that is not changed in the Infus. reducing flame. Easily sol. in acids.

Occurs in connection with nepheline syenite rocks near Mariupol, on the north shore of the Sea of Azov, Russia, and is associated with nepheline and magnetite.

Named after F. Becke.

Beckerite. E. Pieszczek, [Arch. Pharm. (3), 14, 433, J. Ch. Soc., Abstracts, 40, 687, 1881]. Spencer, Min. Mag., 12, 379, 1900. — A brown resin occurring with Prussian amber.

Belith. - See Alith.

W. F. Petterd, Notes on Tasmanian Minerals, priv. publ., John Vail, Gov't printer, Tasmania, 1904.

In aggregates of delicate tufts and in thin velvety coatings, rarely showing

minute acicular crystals; sometimes pulverulent.

H. = 2.5. G. = 5.5. Luster adamantine. Color bright crimson-red in the mass, also yellow to orange especially when distinctly crystallized. Streak pale yellow. Transparent to translucent.

In composition lead chromate containing arsenious oxide, etc.

An analysis by J. D. Millen gave:

 $\begin{array}{c} P_2O_5\\0.04\end{array}$ Al₂O₃ SiO₂ SO3 CrO, As₂O₃ PbO V2O5 Cl 22.61 0.11 0.01 0.520.05 7.59 = 99.1661.68

B. B. fuses readily, yielding a lead globule with lead and arsenic coatings and arsenical odor:

reacts for chromium with salt of phosphorus.

From the upper workings of the Magnet silver mine, Magnet, Tasmania, associated with a chromiferous cerussite, also with crocoite and mimetite; forms a lining to druses of a soft iron-Named after Mr. W. R. Bell of Tasmania. manganese gossan.

Benitoite (Palache)

Benitoite. G. D. Louderback, Uni. Cal. Pub., **5**, 9, 149, 1907; Rogers, Science, **28**, 676, 1908; Palache, Am. J. Sc., **27**, 398, 1909.

Hexagonal, ditrigonal-bipyramidal. $\dot{c} = 0.7319$ (Palache). Forms: m (1010), μ (0110), a (1120), c (0001), p (1011), π (0111), e (0112), x (2241). Angle: (0001): (1011) = 40° 12′.* In crystals with p prominent. Occasionally tabular.

Cleavage $\parallel p$, imperfect; fracture conchoidal. H. = 6.25–6.5. G. = 3.64–3.65. Color sapphire blue to lighblue and colorless. Transparent. Strongly dichroid Color sapphire blue to light parent. Strongly dichroic, ε = deep blue, ω = colorless. Refractive indices,

1.77; $\varepsilon = 1.80$. Absorption $\varepsilon > \omega$.

Comp. BaTiSi₃O₉; SiO₂, 43.71; TiO₂, 19.32; BaO, 36.97. Anal. by Blasdale:

	I	II	Av.
SiO ₂	43.56	43.79	43.68
TiO,	20.18	20.00	20.09
BaO	36.34	36.31	36.33
	100.08	100.10	

Fuses to a transparent glass at 3. Insol. in HCl but easily attacked by HF and sol. in Pvr. fused Na₂CO₃.

Found associated with neptunite (carlosite) and natrolite near the head waters of the San Benito River, in San Benito County, California. Used as a gem mineral.

Bentonite. Non-Metallic Minerals, Merrill, p. 243.

A peculiar soapy clay found in Albany, Crook, Weston and Natrona counties, Wyoming. Considered to have been derived from labradorite found in the rocks of the Laramie Mountains.

Berthierite, Min., p. 114; App., p. 9. — Loczka has confirmed the usual formula FeS.Sb₂S₃ by analysis of the Bräunsdorf mineral, variations from this are due to impurities, Zs. Kr., 37, 379, 1902.

Occurs rather abundantly near Charbes, Val de Villé, Alsace, in the veins of Honilgoutte and Trou-du-Loup; analysis agrees with the usual formula, Ungemach, Bull. Soc. Min., 29, 266, 1905.

Bertrandite, Min., pp. 545, 1028; App., p. 9. — Crystals from Albany, Maine, with new form l (203); Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 136, 1908.

Beryl, Min., pp. 405, 1028; App., p. 9. — Crystals from Russian localities; von Jeremejew,

Vh. Min. Ges. St. Pet., 35, 58, 1897; also by E. Romanovsky, ibid., p. 63; from Pisek, Bohemia; Kreiči, Ber. böhm. Ges. Wiss., xxxv, 1902; from Emmaville, N. S. W.; Anderson, Rec. Aus. Mus., 5, 300, 1904; Elba, described by G. D'Achiardi, Soc. Tosc., Proc. Verb., March 13, 1004. 1904. Crystals of rose-pink color in modified short prismatic crystals from San Diego Co., Cal. (at Mesa Grande and Pala) (fig.); Ford, Am. J. Sc., 22, 217, 1906; Zs. Kr., 43, 12; the same author describes unusual crystals from Mt. The emerald locality known as Cleopatra's emerald mines has been investigated by D. A.

The emerald locality known as Cleopatra's emerald mines has been investigated by D. A. MacAlister, Geol. Jour., 16, 537, 1900; it is situated near Jebel Sikait in northern Etbai nearly due east of Edfu; the extensive workings date back some two thousand years. Star emerald from Muso; Prinz, Bull. Ac. Belg., 283, 1903. Occurrence at Heidelbach, Saxony; Bergt, Ber. Abh. Naturwiss. Ges. Isis, Dresden, 23, 1903. From Vall' Autoliva and Cosasca; Lincio, Att. Acc. Sc., Torino, 40, 870, 1905; at Torrington and Emmaville, N. S. W.; Anderson, Rec. Aus. Mus., 7, 1, 62, 1908.

Beryllonite, Min., p. 758. — Refractive indices; Gaubert, Bull. Soc. Min., 30, 108, 1907.

BEUDANTITE, Min., p. 868. — Composition discussed in detail by Hartley, Min. Mag., 12, 234, 1900 (cf. Miers, ibid., p. 242). The formula deduced is 4Fe₂O₃.3P₂O₅.3SO₃.As₂O₅.9H₂O, from the analysis of dark green crystals.

P₂O₅ 9.35* SO. Fe₂O PbO CuO H.O Gangue 12.72 34.61 32.33 1.35 8.45 0.56 = 99.37* With trace of As2O5.

BINNITE, Min., p. 118; App., p. 10. — The identity of binnite with tennantite, early announced, is discussed in detail by Prior and Spencer in Min. Mag., 12, 184, 1899. Crystals are isometric-tetrahedral, highly modified, and analysis gives the formula 3Cu₂S.As₂S₃; see discussion of comp. under Tetrahedrite.

BIOTITE, Min., p. 627; App., p. 10. — Meroxene with unusual axial angle from andesite of

Assos in Troas, Asia Minor; Johnsen, Centralbl. Min., 620, 1908.

Anal. from Easton, Pa.; Eyerman, Amer. Geol., 34, 43, 1904; Zs. Kr., 42, 304. Chemical constitution discussed; Dalmer, Centralbl. Min., 51, 1907.

Bischofite, Min., p. 176. — Sp. G.; Przibylla, Centralbl. Min., 234, 1904.

BISMITE, Min., p. 200. — Minute pearly scales of this mineral have been found in the oxidized zone of the veins of Goldfield, Nevada. The scales have a brilliant luster and a silvery-white color. The mineral is proven to be uniaxial, negative, with perfect basal cleavage. From triangular markings on the basal planes and the occasional presence of striated faces corresponding to rhombohedrons it appears to be hexagonal, rhombohedral and not orthorhombic as usually stated. Measurements of crystals gave $\dot{c}=0.5775$. The following forms were determined: c (0001), o (10 $\overline{1}6$), q (10 $\overline{1}5$), u (10 $\overline{1}4$), k (10 $\overline{1}3$), (20 $\overline{2}5$)?, (10 $\overline{1}2$)?. Anal. of impure material gave $\frac{1}{3}$ Insol., 78.94; Bi_2O_3 , 17.04; H_2O , 3.96; Fe_2O_3 , 0.36; total, 100.30. W. T. Schaller (priv. contr.).

BISMUTH, Min., p. 13. — Occurs, also bismite, at Pala, San Diego Co., Calif.; Kunz., Am. J. Sc., 16, 398, 1903. Occurrence at Cobalt, Ontario; Miller, Rep. Can. Bureau Mines, Pt. 2, 1905; Zs. Kr., 43, 395.

BISMUTHINITE, Min., pp. 38, 1028; App., p. 10.—Occurs with hematite at the Paulina mine, Nacozari, Mexico; analyzed by Headden, Proc. Col. Sc. Soc., 8, 67, 1905.

The supposed tetradymite from Bastnäs, Riddarhyttan, Sweden, has been shown by G. Lind-

ström to be bismuthinite containing 0.95 p. c. Te, G. För. Förh., 28, 198, 1906.

BISMUTITE, Min., p. 307. — A basic bismuth carbonate occurring as a botryoidal incrustation showing minute square plates, uniaxial and tetragonal, has been described by A. Arzruni, K. Thaddeeff from Schneeberg, Saxony, Zs. Kr., 31, 238, 246, 1899. The composition 5Bi₂O₃, CO₂, H₂O is deduced by Thaddeeff from the analysis (after deducting impurities): Bi₂O₃, 97.38; CO₂, 1.83; H_2O , 0.78 = 99.99.

À bismuth carbonate from the Sierra de S. Luis, Argentina, has given Bodenbender 0.54Ce₂O₂,

Zs. prakt. Geol., 7, 322, 1899.

BITUMEN, Min., p. 1017. — A fossil egg, found in a large pebble in the placer gravels of the Gila river, Arizona, contained crystalline colemanite associated with a tar-like substance in contact with the shell; Morgan and Tallmon, Am. J. Sc., 18, 363, 1904.

Bityite. A. Lacroix, C. R., 146, 1369, 1908; Bull. Min. Soc., 31, 241, 1908.

Pseudo-hexagonal. Occurs in minute hexagonal plates which in polarized light show division into six sectors. Crystals often in parallel grouping with basal planes in common. Color yellowish white. Cleavage parallel to base, showing slight pearly luster. $H_{\rm c}=5.5$. $G_{\rm c}=3.05$. Under microscope each sector shows the emergence of an acute negative bisectrix. Indices of refraction between 1.62 and 1.64.

Comp. — A silicate of calcium and aluminium with water. Formula suggested 7(R₂O + RO),

4Al₂O₂,5SiO₂. Anal. by Pisani:

 H_2O 6.50 = 100.19SiO, Al₂O₃ 41.75 CaO BeO MgO Li₂O Na₂O K_2O 31.95 14.30 2.27 0.13 2.73 0.40 0.16

Found as crusts of crystals coating tourmaline, quartz, etc., in pegmatite veins at Maharitra, Madagascar.

Name derived from Mt. Bity where the mineral occurs.

Blanfordite. See Pyroxene.

BLEIMALACHITE. S. F. Glinka and I. A. Antipov, Vh. Min. Ges. St. Pet., p. 468, 1901; Glinka,

Centralbl. Min., 281, 1901.

Acicular crystals occurring in druses in the Syrjanovsk mine in the Altai have, according to Antipov, the composition 2CuCO₃.PbCO₃.Cu(OH)₂. The crystals are monoclinic, twins, showing three cleavages; strongly pleochroic (yellow, green).

BLÖDITE, Min., p. 946; App., p. 11.—Simonyite from Hallstadt proven to be identical with blödite (astrakamite) from Astrakhan; Jaeger, Min. Mitth., 22, 103, 1903. Optical investigation gave: for Na light, $\alpha = 1.4825$, $\beta = 1.4839$, $\gamma = 1.4866$; 2V (calc.) = 71° 45½. Anal. and description of crystals from Hallstadt. Axial ratio derived = à : b : c = 1.3492 : 1 : 0.6717;
β = 100° 48½'. Koechlin; Ann. Hofmus., Wien, 15, 103, 1900; Zs. Kr., 36, 637.
Anal. of material from Chuquicamata, Prov. Antofogasta, Chile; Palache and Warren, Am.
J. Sc., 26, 347, 1908; Zs. Kr., 45, 536, 1908.
Formation discussed; van't Hoff and Meyerhoffer, Ber. Ak. Berlin, 678, 1903.

Natronkalisimomjite, name given to crystals agreeing with blödite in form but differing slightly in chemical comp. From the salt deposits of Kalusz, Galicia; Koechlin, Min. Mitth., 21, 356, 1902; formation discussed; van't Hoff and Barschall, Ber. Ak. Berlin, 359, 1903.

Blomstrandine-Priorite. W. C. Brögger, Die Mineralien der Südnorwegischen Granitpegmatitgänge, 98, 1906.

Orthorhombic. Axes & : \tilde{b} : $\tilde{c} = 0.4746$: 1 : 0.6673. $110 \wedge 1\bar{1}0 = 50^{\circ}$ 47′, $120 \wedge 1\bar{2}0 = 87^{\circ}$ 1′, $130 \wedge 1\bar{3}0 = 109^{\circ}$ 50′, $140 \wedge 1\bar{4}0 = 124^{\circ}$ 32′ 30″, $100 \wedge 101 = 35^{\circ}$ 26′, $021 \wedge 0\bar{2}1 = 106^{\circ}$ 19′, $110 \wedge 111 = 32^{\circ}$ 44′ *, $111 \wedge 1\bar{1}1 = 42^{\circ}$ 17′ *, $010 \land 121 = 52^{\circ} 17'$

Forms: a (100), b (010), c (001), m (110), r (120), n (130), t (140), x (021), d (101), p (111), π (121) Crystals tabular $\parallel b$, the most prominent combination being b, n and c. b is horizontally striated. Brittle. $G_{\cdot} = 4.82 - 4.93$. Fracture conchoidal. Luster submetallic. Color brownish black.

Comp. — Niobates and titanates of yttrium, erbium, cerium and uranium similar to the euxenite-polycrase series.

Formula contains (Br.) the following molecules: (R,R2).[(Nb,Ta)O3]2, [(U,Th)O].[(Nb,Ta)O3], (U,Th).[TiO₃]₂, (Y,Ce)₂[TiO₃]₃. Blomstrandine and priorite are the end members of a series which give the following ratios of Nb₂O₃: TiO₂ = 1:2 (Priorite), 1:4(Blomstrandine from Arendal), 1:6 (Blomstrandine from Hitterö).

Anal. — I and II, Blomstrand (loc. cit.); III Prior, ibid., and Min. Mag., 12, 97.

	Nb ₂ O ₅ Ta ₂ O ₅	TiO, SnO,	SiO ₂ ZrO ₂	UO2	UO ₃	ThO2	$(Y,Er)_2O_3$
I. Hitterö	17.99 0.89	32.91 0.12	0.38 tr.	4.01		7.69	28.76
II. Arendal	23.35 1.15	27.39 0.18	0.40 1.33	5.35		4.28	25.62
III. Swaziland (Priorite)	36.68	21.89 0.29	2.12	0.49	2.14	0.61	17.11

(Ce,La,Di)2O2 FeO MnO CaO ZnO PbO MgO Na₂O K,0 H,O 0.27 1.97 1.48 1.02 0.06 0.04 0.22 0.19 1.88 = 99.882.48 1.43 0.30 1.80 0.09 0.84 0.15 0.900.18 2.56 = 99.784.32 4.12 5.63 0.19 0.22 3.69 = 99.50

Brögger considers that the euxenite-polycrase and the priorite-blomstrandine series are

dimorphous.

Obs. Originally found in a pegmatite vein at Urstad on the island of Hitterö, also observed from the neighborhood of Arendal and in other localities in southern Norway. Blomstrandine named from Prof. C. W. Blomstrand. The name is not to be confounded with blomstrandite. Priorite was named from G. T. Prior of the British Museum.

[Brögger (l. c.) shows that blomstrandine could be referred to the euxenite axes, but because of their difference in habit and because in one case a crystal of blomstrandine was observed on a crystal of polycrase in parallel position and orientated according to the position adopted above he

considers that blomstrandine and euxenite should have distinct axes.]

Bobierrite, Min., p. 817. — On the artificial reproduction of crystals; A de Schulten, Bull. Soc. Min., 26, 81, 1903.

BOLEITE, PSEUDO-BOLEITE, CUMENGITE. These closely associated and related species have been studied by G. Friedel, Bull. Soc. Min., 29, 14, with the following results.

Boleite. Tetragonal, pseudo isometric. Axis, $\dot{c} = 3.996$. $001 \wedge 101 = 75^{\circ} 57'$. Forms

(001), (101).

Twinning: Each crystal is made up of three individuals, the caxis in each case being parallel to a cubic axis. The basal planes of each individual form the pseudo cubic faces. Cleavages (1) (001) perfect, (2) (100) poor, (3) (101) good. G. = 5.054. Luster pearly on cleavage (001). Color pure Prussian blue, in thin section somewhat more green than with cumengite. Powder blue with a greenish tint.

Optically -. Strength of birefringence = 0.020. In thin sections crystals show isotropic interior surrounded by a birefringent border. Isotropic center considered to be caused by a mixture of the three individuals. The two zones were proven identical chemically (see below).

Comp. -9PbCl₂.8CuO,3AgCl,9H₂O = Pb 49.93, Cl 17.13, AgCl 11.54, CuO 17.05, H₂O 4.35. Anal. — I of interior isotropic zone, II of exterior birefringent zone.

	Pb	Cl	AgCl	CuO	H_2O	Insol.
I.	49.16	17.04	12.03	17.17	4.35	0.21 = 99.96
II.	49.52	17.28	11.16	17.20	4.35	0.25 = 99.76

Pseudo-boleite. Tetragonal. Axis $\dot{c}=2.023.~001 \wedge 101=63^{\circ}$ 42'. Forms (001), (100), (110), (101), (112). Always observed in parallel growth on boleite, with face (001) of pseudo-boleite in contact with (001) of boleite. Frequently occurs as raised crystalline masses on the different pseudo cubic faces of boleite, leaving reëntrant angles along the cubic edges, or it may completely envelop the latter.

Cleavage (1) (001) perfect, (2) (101) perfect. G. = 4.85 (?). Pearly luster on cleavage (001). Optically—. Strength of birefringence = 0.032. Comp. — 5PbCl₂, 4CuO, 6H₂O = PbCl₂ 76.52, CuO 17.51, H₂O 5.97.

PbCl₂ 77.5 CuO Anal.: * 5.5 = 100.0016.9

* After deducting 1.6AgCl and corresponding amounts of other constituents to form boleite molecule.

Cumengite. Tetragonal. Axis $\dot{c}=1.625$. $001 \wedge 101=58^{\circ}$ 24'. Forms (001), (101), (110). Occurs in parallel position with boleite and pseudo-boleite, sometimes completely enveloping them.

Cleavage (101) very good, (110) good, (001) poor. Distinguished from the other members of the group by lack of pearly luster on cleavage faces, and by a purer blue color in thin section and in powder. G. = 4.67. Optically – . Strength of birefringence = 0.1. Comp. — 4PbCl_2 , 4CuO, $5\text{H}_2\text{O}$ = Pb 54.46, Cl 18.68, CuO 20.93, H₂O 5.93.

Anal.:

Cl CuO Insol. H,O 19.03 20.27 0.19 5.90 = 99.8654.47

These three minerals occur in intimate association and in parallel orientation with each other. Boleite is always the first to form, while pseudo-boleite and cumengite are deposited subsequently and often simultaneously.

Boothite. W. T. Schaller, Bull. G, Univ. Cal., 3, 207, 1903.

Monoclinic. Axes à : \dot{b} : \dot{c} = 1.1622 : 1 : 1.500. β = 74° 24′. Forms: a (100), c (001), m (110), t ($\bar{1}$ 01), z ($\bar{3}$ 01), π ($\bar{1}$ 12), e ($\bar{1}$ 11), σ ($\bar{1}$ 21).

Usually massive, crystalline, also fibrous. Cleavage basal, imperfect. Fracture uneven. Brittle. H. = 2-2.5. G. = 1.94. Color blue, paler than chalcanthite.

Ax. pl. \parallel (010). Bx_a nearly $\perp c$.

Composition, CuSO₄ + 7H₂O, or since 1 molecule H₂O goes off only at a high temperature, CuSO₄.H₂O + 6H₂O. Analyses 1, 2, l. c.; 3, Am. J. Sc., **17**, 192, 1904.

	SO ₃					H ₂ O (above 105°)	
1. Leona Heights	28.87	27.83	tr.	tr.	36.64	7.42	=100.26
2. " "	28.65	28 53	0.28	tr.	43.	.76	=101.22
3. Campo Seco	27.25	26.13	0.81	0.64	36.76	4.91 3.96 (Inse	ol.) = 100.46

Occurs as a secondary mineral at the Alma pyrite mine, near Leona Hetghts, Alameda Co., and at copper mine near Campo Seco, Calaveras Co., Cal. Chalcanthite is intimately associated with massive boothite. Named after Mr. Edward Booth of the University of California.

BORACITE, Min., p. 879; App., p. 11. — F. Rinne shows that the green colored boracites containing iron lose the greater part of their double refraction only when heated to a somewhat higher temperature (285°) than is the case with ordinary boracite (265°). Author also discusses the internal structure of boracite, with the effect of heat upon variously oriented thin sections. Jb. Min., 2, 108, 1900.

Borickite, Min., p. 852. — Analysis of material from Trpin, near Beraun, Bohemia; P₂O₅, 20.22; Fe₂O₃, 42.43; CaO, 8.63; H₂O, 28.72; giving for the formula, Ca₂(PO₄)₂.3Fe₃(OH)₆PO₄. 20H₂O; Preis [Ber. d. k. Böhm. Ges. d. Wiss., **19**, 1897], Zs. Kr., **31**, 526.

BORNITE, Min., p. 77; App., p. 11. - Variation in streak, from gray with bluish tinge (fresh mineral) to greenish (slightly altered); Schroeder van der Kolk, Centralbl. Min., 78,

519, 1901.

Analyses of pure specimens of the massive mineral from Canadian localities (G. = 5.055-5.085) and of crystals from Bristol, Conn. (G. = 5.072), agree with the formula $\mathrm{Cu}_{5}\mathrm{FeS}_{4}$, while the usually accepted formula $\mathrm{Cu}_{3}\mathrm{FeS}_{3}$ was probably deduced from analyses of impure material. Harrington, Am. J. Sc., 16, 151, 1903.

Botryogen, Min., p. 972. — Comp.: Analysis by Cleve of botryogen from Falun, Sweden, gave for the formula 2RO.Fe₂O₃.4SO₃.15H₂O, or as suggested Mg(FeOH)(SO₄)₂ + 7H₂O; Sjögern, G. För. Förh., 17, 268, 1895; Zs. Kr., 28, 507. Analysis of material from Val de Villé, Alsace; Ungemach, Bull. Soc. Min., 29, 270, 1906.

A variety of botryogen from Knoxville, California, has been called palacheite (after Dr. Charles

A variety of botryogen from Khoxvine, Camorina, has been caned patachetic (after Di. Charles Palache of Harvard University) by Eakle, Bull. G. Univ. Cal., 3, 231, 1903; its true relations were later recognized by the same author, Am. J. Sc., 16, 379, 1903.

Found somewhat abundantly at the Redington mercury mine (now the Boston mine), Knoxville, Cal., in loosely coherent aggregates of minute crystals. Habit prismatic, m (110), f (120) both vertically striated with c (001); also subordinate b (010) and rare a (100), t (450), d (403)

v (023), o (043), p (223), s (243). Axial ratio deduced: $\dot{a}:\dot{b}:\dot{c}=0.6554:1:0.5994,$ $\beta=62^{\circ}$ 51'. Cleavage b perfect, m distinct. Brittle. H. = 1.5 - 2. G. = 2.075. Luster vitreous. Color deep brick-red. Streak pale yellow. Ax. pl. $\perp b$. $\dot{c} \wedge c$ (Bxa) = -12°. Indices: $\alpha=1.544,$ $\beta=1.548,$ $\gamma=1.572$. $2V=40^{\circ}$ 54' for Na. Dispersion $\rho < v$. Pleochroism strong: c deep orange-red, b pale red, a bright yellow. The composition deduced is the same as that deduced by Cleve as above noted, viz., 2MgO.Fe₂O₃.4SO₃ + 15H₂O. Analysis:

> SO3 MgO 9.35 H₂O (100°) H₂O (above 100°) Fe₂O₃ 38.37 19.51 19.53 12.75 = 99.51

Boulangerite, Min., p. 129; App., p. 11. — Analyses of material from various localities; Guillemain (Inaug.-Diss., Breslau, 1898), Zs. Kr., 33, 74.

Occurrence at Voûte Chilhac Canton, Haute-Loire; Gonnard, Bull. Soc. Min., 28, 23, 1905.

BOURNONITE, Min., p. 126; App., p. 11. — Crystals from Ally, Haute-Loire, France; Richard, Bull. Soc. Min., 27, 218, 1904; from Pulacayo, Bolivia, with new form g (601); Mauritz, [Ann. Mus. Nat. Hung., 3, 461 or 470, 1905]; Zs. Kr., 44, 78; from Sarrabus, Sardinia; Millosevich, Rend. Acc. Linc., 15, (1), 457, 1906.

Analyses of material from Liskeard, Cornwall, and Wolfsberg, Harz; Guillemain, (Inaug. — Diss., Breslau, 1898), Zs. Kr., 33, 75. Occurs at the mine Argentiera della Nurra, Portotorres, Sardinia (anal., Rimatori); D. Lovisato, Rend. Acc. Linc., 11, (2), 357, 1902.

BOWENITE, see Serpentine.

Bowlingite, Min., p. 682. — A related mineral occurs at Beaver Bay and other points on the north shore of L. Superior, derived from the alteration of chrysolite; N. H. Winchell, Am. Geol., 23, 41, 1899.

Bowmannite, see Hamlinite.

Braunite, Min., pp. 232, 1029; App., p. 11. — Crystals from Brazil with following new forms: r (013), d (111), v (122), w (344), f (121), z (353), g (153); Koechlin, Min. Mitth., 27, 266, 1908.

Bravoite. W. F. Hillebrand, Am. J. Sc., 24, 142, 1907. In small grains and crystal fragments, apparently octahedral. Pale yellow, whiter than pyrite, with a faint reddish tarnish. An iron nickel sulphide carrying vanadium, siliceous and titaniferous matter. The analysis gave:

S Fe Ni CO V* Mo C H₂O TiO₂ SiO₂ Al₂O₃ 45.06 25.38 15.70
$$tr$$
. 4.31 0.09 0.47 1.38 0.93 1.93 2.45 = 97.70 * V_2O_3 6.33 or V_2O_5 7.66.

Considering the mineral as simply an iron nickel sulphide and calculating to 100% gives S 52.31, Fe 29.46, Ni 18.23, which gives the formula (Fe, Ni)S₂ with Fe to Ni nearly as 5 to 3. It is evidently a highly nickeliferous pyrite.

Occurs disseminated through the vanadium ore in which patronite was found, at Minasragra, Peru. The name suggested is from J. J. Bravo who described the occurrence.

Breislakite, Min., pp. 386, 391; App., p. 11. — Probably identical with ilvaite (lievrite); Weinschenck, Zs. Kr., 37, 442, 1902. Occurs as a product of the eruptions of Vesuvius of 1895—99; R. V. Matteuci, Centralbl. Min., 48, 1901, cf. Zambonini, ibid., p. 401.

Breithauptite, Min., pp. 72, 1029; App., p. 11. — Reference in App. I to anal. of arite from Sardinia should read "quoted by Lovisato" etc.

Breunnerite, Min., p. 274. — Occurrence near Avigliana, Italy, with anal.; Piolti, Att. Acc. Torino, 41, 1066, 1906.

Britholite. Chr. Winther, Medd. om Grönland, 24, 190, 1901. Orthorhombic. In pseudo-hexagonal prisms, formed by twinning parallel to the prism m, mm''' = 63° 34', six individuals unite with their optic axial planes meeting in the vertical axis.

Forms: b (010), m (110), z (130), d (021), p (111).

Angles: $bm = 58^{\circ}13'^{*}, bd = 49^{\circ}48'^{*}$, hence the approx. ax. ratio, $\underline{a}: \overline{b}: \underline{b} = 0.620: 1: 0.423$. Cleavage not observed. Fracture uneven. Brittle. H. = 5.5. G. = 4.446. Luster greasy to vitreous. Color brown. Opaque. Optically negative. Birefringence weak. Ax. plane || (100). $Bx_a \perp c$.

Composition; a complex silicate and phosphate of the cerium metals and calcium, formula uncertain.

Analysis, Chr. Christansen:

Fe₂O₃ SiO2 P2O5 (Ce,La,Di)2O3 CaO MgO Na₂O H₂O 1.27 16.77 60.54 0.43 11.28 0.13 1.85 1.33 = 100.08.

Brought from the nephelite-syenite region of Julianehaab, South Greenland, by G. Flink in 1897 (Medd. om Grönland, 14, 245, 1898); found at Nanjakasik in pegmatitic veins with arfved-sonite, eudialyte, streenstrupite, nephelite, sodalite, ægirite.

Named from βρίθος, weight, in allusion to the high specific gravity.

BROCHANTITE, Min., p. 925. — Crystals from Utah show the new form (532); Zambonini, Zs. Kr., 34, 238, 1901. Occurs rather commonly in prismatic crystals, often intergrown with malachite, at various points in the Clifton-Morenci copper district; most abundant in fissure veins in porphyry. Lindgren and Hillebrand, Am. J. Sc., 18, 458, 1904.

Analysis of specimen from Chile; Arzruni and Thaddéeff, Zs. Kr., 31, 245, 1899. Containing

2.35% As₂O₅ from Copaquire, Province of Tarapacá, Chile; Keller, Proc. Amer. Phil. Soc., 47, 82,

1908.

Occ. at Rosas, Sardinia; Riva, Rend Acc. Linc., 8, (1), 347, 1899.

BRÖGGERITE, see Uraninite.

BROMARGYRITE, see Cerargyrite.

BROMYRITE, see Cerargyrite.

BROOKITE, Min., pp. 243, 1029; App., p. 12.—Crystals from the Piattagrande, near Sondalo, Veltlin, with (324); Brugnatelli, Zs. Kr., 32, 355, 1899; Rend. R. Inst. Lomb., 32, 1405, 1899;

complex crystals from Tremadoc with θ' (5.13.17); habit hemihedral but etching figures normal orthorhombic; Busz, Jb. Min., 2, 135, 1901. From Brindletown, N. C., prismatic in habit, often complex. with new forms, τ (101), σ (324), β (5.4.10), v (146) (fig.); Robinson, Am. J. Sc., 12, 182, 1901. Crystals in gneiss at Freiberg; Kolbeck, Centralbl. Min., 547, 1908; from Somerville, Mass.; Palache, Festschr, siebzigsten Geburtstage, H. Rosenbusch, p. 314, 1906.

Effect of low temperatures upon optical properties; Panichi, [Mem. Acc. Linc, 4, 389, 1902]; Zs. Kr., 40, 88. Refractive indices; Taubert, [Inaug.-Diss., Jena, 1905]; Zs. Kr., 44, 313.

Anal. from Magnet Cove, Ark.; Pfeil, [Inaug.-Diss., Heidelberg, 1901]; Centralbl. Min., 144, 1902. Discussion of formula, see Rutile.

Occurrence in quartzite, Shankille, Co. Dublin, Ireland; O'Reilly, [Proc. Roy. Dublin Soc., 8, 691, 1898]; Zs. Kr., 32, 293; from the Bristenstock, near Amsteg, Switzerland; Pearce and Fornaro, Arch. Sc. Phys. Genève, (4), 10, 435, 1900; with octahedrite in minute crystals in the Claudion in the Charlenge England, Linddow, Min. May 14, 96 in the Cleveland ironstone, England; Lindsley, Min. Mag., 14, 96, 1905.

Brindletown, N.C.

Brostenite. P. Poni, Min. Roumanie, p. 41 (Am. Sci. Univ. Jassy, 1, 53, 1900); Zs. Kr., 36, 199. A decomposition product of rhodochrosite occurring in crystalline schists at several points near Brosteni, Roumania. Occurs in dull black friable and compact

masses, with submetallic luster on the fresh fracture.

In composition a manganite of manganese and ferrous iron, but variable in specimens from different localities.

Analyses:

	MnO ₂	MnO	FeO	CaO	MgO	H,O	Gangue
1. Holda	52.40	6.16	11.47	3.05		11.97	14.75 = 99.80
2. Dorna							5.51 CaCO, 1.97 = 100.18
3. Dealul-Ferului	61.95	3.11	12.02	2.70	0.72	10.90	$8.20 = 99.60^{\circ}$

BRUCITE, Min., 252; App., p. 12. — Crystals from the Nikolaje-Maximilianovsk mine, Russia, described by Jeremejew, Vh. Min. Ges. St. Pet., 36, 19, 1899.

Effect of low temperatures upon optical properties; Panichi, [Mem. Acc. Linc, 4, 389, 1902];

Occurrence (with anal.) from Lyssogorsk, Caucasus; Karpinsky, [Verh. russ. min. Ges., 42, Prot. 21, 1905]; Zs. Kr., 43, 70. In chalk from Teulada, Sulcis, Sardinia; Peruzzi, Rend. Acc. Linc., 14, (2), 83, 1905.

Brugnatellite. E. Artini, Rend. Acc. Linc., 18, (1), 3, 1909.

Micaceous, lamellar. Perfect cleavage. Color flesh pink. Faint pearly luster. Uniaxial, rative. Opt. axis \perp to cleavage plane. $\omega = 1.533_{\rm Na}$. Absorption $\omega > \epsilon$; $\omega = {\rm yellow\ red}$, $\epsilon =$ colorless.

Comp. MgCO₃.5Mg(OH)₂.Fe(OH)₃.4H₂O.

Anal.:

Fe₂O₃ MgO MnO Insol. 1.80 42.791.03 = 100.37

Found in an old asbestos mine at Torre Santa Maria, Val Malenco, Lombardy. Named in honor of Professor Luigi Brugnatelli of the University of Pavia.

Brunsvigite. J. Fromme, Min. Mitth., 21, 171, 1902.

In cryptocrystalline and small foliated masses sometimes forming spherical radiated aggregates. The folia under the microscope (Tschermak) have a hexagonal outline, are cleavable and show a uniaxial figure and negative double refraction; normal to the cleavage the color is olive-green, parallel to it yellow-green. $H_1 = 1-2$, $G_2 = 3.01$.

Luster vitreous to greasy, on cleavage folia of the mass dull.

Color green to dark leek-green. Translucent.

In composition not far from the metachlorite of the Büchenberg and like it classed with the leptochlorites. Calculated formula: 6 Si O₂.2Al₂O₃.9MgO.8H₂O.

Anal.:

 ${\rm Fe_2O_3}\atop 1.77$ SiO. MnO CaO H₂O Al₂O₃ FeO MgO 27.88 31.92 0.20 9.52 11.97 15.81 0.51 H_2O [hygr.] 0.15 = 99.73.

In powder easily decomposed by acids with the separation of pulverulent silica.

Occurs in the gabbro of the Radauthal in the Harz, filling crevices and coating quartz and calcite.

Brushite, Min., p. 828. — Optical characters of crystals from the island of Mona, W. Indies; Klein, Ber. Ak. Berlin, 720, 1901. Artificial formation of crystals; A. de Schulten, Bull. Soc. Min., 26, 11, 1903.

CABRERITE, Min. p. 819. — Crystals from Laurium; Sachs, Centralbl. Min., 198, 1906, with the forms: a (100), b (010), m (110), w (101) v (111); axial ratio \dot{a} : \dot{b} : \dot{c} = 0.82386: 1: 0.77672, β = 73° 31′ deduced from the angles: aw = 55° 30′, vv' = 65° 15′, mv = 44° 53′; also calc. mb = 51° 42'.

Analysis:

As₂O₅ 40.45 NiO CoO FeO MgO H₂O $G_{\cdot} = 3.01$ 26.97 1.10 25.26 = 99.94tr. 6.16 Artif.; de Schulten, Bull. Soc. Min., 26, 87, 1903.

CACOXENITE, Min., p. 848; App., p. 12. — Occurs at Ober-Rosbach, Taunus Mts., Prussia, with manganese ores; Wittich and Neumann, Centralbl. Min., 656, 1902. Optical character; Mann, [Inaug. - Diss., Leipzig, 1904]; Zs. Kr., 42, 665.

Cadmiumoxyd. E. Wittich and B. Neumann, Centralbl. Min., 549, 1901.

Isometric, in minute octahedrons, sometimes with cubic faces, also as penetration twins; forms a very thin coating, of black color and brilliant metallic luster, upon calamine from Monte Poni, Sardinia; also in part pulverulent. H. = 3. G. = 6.146.

Easily soluble in hydrochloric acid. Analysis gave: Cd 87.5, O 12.5 = 100. The associated

calamine contains no cadmium.

The artificial mineral has been noted in the muffles of zinc furnaces (cf. Werther, J., pr. Ch., 55, 1852) in octahedrons with a, d, n. Also obtained (Wittich and Neumann) by burning cadmium in an atmosphere of oxygen; crystals cubic, cleavable, probably || o.

CALAMINE, Min., p. 546; App., p. 12. — The supposed new form (311) from Moresnet (App. I, p. 12) is really identical with (211); Buttgenbach, Ann. Soc. G. Belg., 26, cliii, 1899. Crystals from Leadville, Colo.; Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 138, 1908. Composition discussed; Clarke and Steiger, Am. J. Sc., 8, 249, 1899. Rôle of water and discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 35, 1908.

Occurrence at Broken Hill, N. W. Rhodesia; Spencer, 15, 34, 1908.

CALAVERITE, Min., p. 105. — Cryst. — Crystals of fine quality have been found at Cripple Creek and have been the subject of study by Penfield and Ford, (figs.), Am. J. Sc., 12, 225, 1901; Zs. Kr., 35, 5, and by Smith, Min. Mag., 13, 122; Zs. Kr., 37, 209. The crystals are prismatic, being deeply striated in this zone; they show monocline symmetry, the striated prism zone being parallel to the ortho axis; the terminal faces are many, often very small; they are arranged in a number of prominent zones but with few exceptions only very complicated symbols can be assigned to them; by selecting certain prominent and frequently recurring faces and assigning simple indices to them and using their angles as fundamentals Penfield and Ford derived the axial ratio

as $\dot{a}:\dot{b}:\dot{c}=1.6313:1:1.1449$; $\beta=89^{\circ}$ $47\frac{1}{3}'$, values very close to those assigned to sylvanite. Twins according to two laws are described by same authors and according to the same laws and two more by Smith. The complexity of the symbols necessarily assigned to the majority of the faces makes the problem a very unusual one, there being no evidence of any twinning that could solve it. Smith suggests that it is to be explained by a very intimate twinning and that the different faces are to be referred to five distinct lattices which are incongruent but not independent and which have the prism zone in common.

Calaverite, Cripple Creek.

Analyses of material from Cripple Creek by Penfield, Am. J. Sc., 12, 246, 1901, by Prior, Min. Mag., 13, 149; from Kalgoorlie quoted by Spencer, Min. Mag., 13, 271, prove the formula to be AuTe,. Occurs abundantly at Kalgoorlie in the East Coolgardie gold district, West Australia, cf. Spencer, Min. Mag., 13, 270, 1903; Carnot, Bull. Soc. Min., 24, 362, 1901 (anal.); C. R., 132, 1301, 1901; Krusch, Centralbl. Min., 199, 1901.

CALCIOVOLBORTHITE, Min., p. 790.—A mineral occurring in bright yellow scales found at Little Baby copper prospect 25 miles N. E. of Baker City, Oregon, is provisionally referred to this species. It is a vanadate of copper with some sodium. 22d Ann. Rep. U. S. G. S., II, 644.

CALCITE, Min., pp. 262, 1029; App., p. 13. — Cryst. — Over 50 forms described as new are to be found in the following papers.

Crystals from Jarow near Wran (south of Prag); Polak, Lotos, Prag, 77, 1897; Zs. Kr., 31, 528; in coral chalk at Bremke; Fromme, (10, 11, Jahresber. d. Ver. f. Naturw., Braunschweig, 1897-1898), Zs. Kr., 32, 192; Villers-en-Fague; Buttgenbach, Ann. Soc. Geol. Belg., 25, 73, 1898; Lake Superior with lists of 81 forms, 31 new; Palache, Geol. Sur. Mich., 6, 161, 1898; Iceland; Jeremejew, [Bull. Acad. Sc., St. Pétersbourg, 9, 5, 1898]; Zs. Kr., 32, 428; Nordmark, Sweden; Moberg, Geol. För. Förh., 21, 349, 1899; crystals of different types in parallel growth from Ofner mountains; Melczer, (Föld. Köz., 29, 160, 217, 1899); Zs. Kr., 34, 709; also Argentine, Kan., and Kansas City, Mo.; Rogers, Am. J. Sc., 9, 365, 1900; twins and study of crystal forms from Joplin, Mo.; Farrington, Bull. Field Mus. Geol. Series No. 7, 1, 221, 1900; Zs., Kr., 36, 78; Gräsberg, Dalarne, Sweden; Weibull, Geol. För. Förh., 22, 19, 1900. Twins, Union Springs, Cayuga Co., N. Y. (figs.); Egremont and Pallafat, Cumberland; Stank mine, Lancashire; from elæolite-syenite, Montreal; Penfield and Ford, Am. J. Sc., 10, 237, 1900; Zs. Kr., 33, 6; Tharandt, Saxony; Sachs, Zs. Kr., 45, 628; crystals from Lyon Mountain, Clinton Co., N. Y., Whitlock, N. Y. State Mus., Bull. 107, 58, 1907; Zs. Kr., 43, 321. West Paterson, N. J.; Whitlock, Am. J. Sc., 24, 426, 1907; "Kis Strázsahegy," near Esztergom, Hungary; Franzenau, Zs. Kr., 43, 468; Bojcza, and Salgótarján, Hungary, from "Kühlen Tal" near Budapest; Toborffy, Zs. Kr., 44, 604, 605, 607; from Piszke, Tatabánya and Torockó, Hungary; Toborffy, Földt. Közl., 37, 308, 1907. Andreasberg, Harz; England: San Francisco. 308, 1907. Andreasberg, Harz; England; San Francisco, Calif.; Hillsboro, N. M.; Lincoln, R. I.; Terlingua, Texas; Schaller, Zs. Kr., 44, 321; Terlingua, Texas; Zeller, Centralbl. Min., 18, 1907; stalactite of rhombohedral crystals, Potter Creek cave, Shasta Co., Calif., small crystals from Terlingua, Texas; Eakle, Uni. Calif. Pub., 5, 6, 89, 91, 1907; associated with dioptase from Mindouli, French Congo; Lacroix, Bull. Soc. Min., 31, 258, 1908; crystals in a marble inclusion in basalt at Weitendorf in Styria; Leitmeier, Centralbl., Min., 257, 1908; figures of various twins, etc.; Lewis, Min. Mag., 15, 62, 1908; crystals from Joplin, Mo., and Bellevue, Ohio; Farrington and Tillotson, Field Col. Mus., Geol. Series 3, No. 7, 140, 144, 1908.

Union Springs.

spar; Carvallo Jour. de physique, 9, 465, 1900], Zs. Kr., 35, 629; phosphorescent calcites from Fort Collins, Colo., and Joplin, Mo.; Headden, Am. J. Sc., 21,

Studies of solution and etching figures, etc.; Gaubert, Bull. Soc. Min., 24, 326, 1901; also Goldschmidt and Wright, Jb. Min., Beil. 17, 355, 1903; ibid., 18, 335, 1904; pits produced by polishing basal planes; Samojloff, Zs. Kr., 39, 19.

Experiments with compression of marble at varying pressures and temperatures; Adams and Nicholson, [Proc. Roy. Soc. London, 67, 228, 1900]; Zs. Kr., 36, 82; also Rinne, Jb. Min., 1, 160, 1903.

Siliceous calcites, Penfield and Ford, Am. J. Sc., 9, 352, 1900, from Washington Co., $CaCo_2$, 40%, quartz sand, 60%, apparently rounded pyramids, near the form γ (8.8.16.3) (the sand stone crystals from near Heidelberg, Ger., considered to have the same form; Cohen, Zs. Kr., 37, 610); from S. Dakota and Goshen Hole region, Wy., showing combinations of acute and obtuse rhombohedrons; Barbour and Fisher, Am. J. Sc., 14, 451, 1902; siliceous calcites; Delkeskamp, Zs. für Naturwiss., Halle, 75, 185, 1902; sand-calcite concretions from Salton, Calif.; Nichols, Field Columbian Mus., No. 111; Zs. Kr., 44, 539.

Studies as to whether calcite or aragonite is formed under varying conditions when CaCO, is precipitated from solution; Meigen, (Ber. Naturfors. Gesellsch., Freiburg, 13, 40, 1902), Zs. Kr., 40, 524.

Fetid calcite from Chatham, Canada, analyzed by Harrington, Am. J. Sc., 19, 345, 1905,

showed the presence of H2S in small amount.

Containing Co, from Traversella; Spezia, Att. Acc. Torino, 42, 409, 1907. Studies concerning origin, structure, physical properties and associated minerals of marble by Vogt, Zs. pr. Geol., 6, 4-16, 43-52, 1898. The minerals of the marble of Carrara; D'Achiardi, Att. Soc. Tosc., 21, (1), 49; (2), 236, 1905; 22, 94, 1906; Giampaoli, sep. pub.; Zs. Kr., 43, 492. Calcite and aragonite in coral rock; Sep. Pub., The Atoll of Funafuti, Roy. Soc., 1904. Portland cement clinkers have been minutely studied by Törnebohm. See alith.

CALCIUM ORTHOSILICATE. Artif. formation; Day and Shepherd, Am. J. Sc., 22, 280, 284, 1906.

CALCIUM OXIDE. — Crystalline form and density of fused lime; Day and Shepherd, Am J. Sc. 22, 271, 1906.

CALEDONITE, Min., p. 924; App., p. 13. Occurs in crystals at the Stevenson-Bennett mine, Organ Mts., New Mexico; O. C. Farrington, Bull. Field Col. Museum, Geol., 1, 224, 1900; also at the Alice mine, near Butte City, Montana; Rogers, Am. J. Sc., 12, 47, 1901. In deep sky-blue crystals at the silver mines of Mt. de Challacollo, Atacama, Chile; G. Berg, Min. petr. Mitth., 20, An analysis by Brunk, after deducting 2.31 insol., gave:

SO ₃ 14.15	PbO	CuO	CO,	H,O
14.15	69.18	9.73	CO ₂ 3.16	H_2O $3.78 = 100$

CALAVERITE, Min., p. 105. — Cryst. — Crystals of fine quality have been found at Cripple Creek and have been the subject of study by Penfield and Ford, (figs.), Am. J. Sc., 12, 225, 1901; Zs. Kr., 35, 5, and by Smith, Min. Mag., 13, 122; Zs. Kr., 37, 209. The crystals are prismatic, being deeply striated in this zone; they show monocline symmetry, the striated prism zone being parallel to the ortho axis; the terminal faces are many, often very small; they are arranged in a number of prominent zones but with few exceptions only very complicated symbols can be assigned to them; by selecting certain prominent and frequently recurring faces and assigning simple indices to them and using their angles as fundamentals Penfield and Ford derived the axial ratio as $\dot{a}:\dot{b}:\dot{c}=1.6313:1:1.1449;\;\beta=89^{\circ}$ 471, values very close to those assigned to sylvanite. Twins according to two laws are described by same authors and according to the same laws and two more by Smith. The complexity of the symbols necessarily assigned to the majority of the faces makes the problem a very unusual one, there being no evidence of any twinning that could solve it. Smith suggests that it is to be explained by a very intimate twinning and that the different faces are to be referred to five distinct lattices which are incongruent but not independent and which have the prism zone in common.

Calaverite, Cripple Creek.

Analyses of material from Cripple Creek by Penfield, Am. J. Sc., 12, 246, 1901, by Prior, Min. Mag., 13, 149; from Kalgoorlie quoted by Spencer, Min. Mag., 13, 271, prove the formula to be AuTe.
Occurs abundantly at Kalgoorlie in the East Coolgardie gold district, West Australia, cf.
Spencer, Min. Mag., 13, 270, 1903; Carnot, Bull. Soc. Min., 24, 362, 1901 (anal.); C. R., 132, 1301, 1901; Krusch, Centralbl. Min., 199, 1901.

CALCIOVOLBORTHITE, Min., p. 790.—A mineral occurring in bright yellow scales found at Little Baby copper prospect 25 miles N. E. of Baker City, Oregon, is provisionally referred to this species. It is a vanadate of copper with some sodium. 22d Ann. Rep. U. S. G. S., II, 644.

CALCITE, Min., pp. 262, 1029; App., p. 13. — Cryst. — Over 50 forms described as new are to be found in the following papers.

Crystals from Jarow near Wran (south of Prag); Polak, Lotos, Prag, 77, 1897; Zs. Kr., 31, 528; in coral chalk at Bremke; Fromme, (10, 11, Jahresber. d. Ver. f. Naturw., Braunschweig, 1897–1898), Zs. Series No. 7, 1, 221, 1900; Zs., Kr., 36, 78; Gräsberg, Dalarne, Sweden; Weibull, Geol. För. Förh., 22, 19, 1900. Twins, Union Springs, Cayuga Co., N. Y. (figs.); Egremont and Pallafat, Cumberland; Stank mine, Lancashire; from elæolite-syenite, Montreal; Penfield and Ford, Am. J. Sc., 10, 237, 1900; Zs. Kr., 33, 6; Tharandt, Saxony; Sachs, Zs. Kr., 36, 449; Shullsburg, Wis., and other neighboring localities, Saguache Co., Colo., Frizington, Eng., from Eudora, Kan., Kansas City, Mo.; Rogers, Am. J. Sc., 12, 42, 1901; Dortmund; Beykirch, Centralbl. Min., 494, 1901; from Pradalunga, Val Seriana, Italy; Artini, Att. Soc. Milano, 40, 269, 1901; from Trapp-Region of N. J.; Rogers, Sch. of Mines Quart., 23, 336, 1902; Zs. Kr., 38, 693; twins, Somerset; Bowman, Min. Mag., 13, 329; twins, Joplin, Mo.; Sterrett, Am. J. Sc., 18, 73, 1904; Rákó and Szentandrás, Hungary; Zimányi, [Föld. Köz., 35, 491 or 544, 1905]; Zs. Kr., 34, 72; Guggiate, Lake Como; Repossi, Att. Soc. Ital. Sc. Nat., Milano, 44, 106, 1905; Grand Rapids, in coral chalk at Bremke; Fromme, (10, 11, Jahresber. d. Ver. f. Naturw., Braunschweig, 1897-1898),

Mich., Hobbs, Amer. Geol., 36, 179, 1905; Zs. Kr., 43, 394; Rondout, Ulster Co., and Union Springs Cayuga Co., N. Y.; Whitlock, N. Y. State Mus., Bull. 98, 1905; East Greenland; Böggild, Medd. om Grönl., 28, 106, 1905; Narsarsuk, Greenland; id., ibid., 33, 98, 1906; Simplon Tunnel; Abraham, Mem. Soc. Liége, 6, 11, 1906; twins from marble of Carrara; D'Achiardi, Proc. Soc. Sc. Tosc., Mem. 21, 1905; also Mar. 11, 1906; Rikuchu Province, Japan; Jimbō, Beitrage Min Japan, 2, 26, 1906;

21, 1905; also Mar. 11, 1906; Rikuchū Province, Japan; Jimbō, Beitrage Min Japan, 2, 26, 1906; twin crystals; St. Kreutz, [Denkshr. Wien Akad, 80, 15, 1906]; Zs. Kr., 45, 628; crystals from Lyon Mountain, Clinton Co., N. Y., Whitlock, N. Y. State Mus., Bull. 107, 58, 1907; Zs. Kr., 43, 321. West Paterson, N. J.; Whitlock, Am. J. Sc., 24, 426, 1907; "Kis Strázsahegy," near Esztergom, Hungary; Franzenau, Zs. Kr., 43, 468; Bojcza, and Salgótarján, Hungary, from "Kühlen Tal" near Budapest; Toborffy, Zs. Kr., 44, 604, 605, 607; from Piszke, Tatabánya and Torockó, Hungary; Toborffy, Földt. Közl., 37, 308, 1907. Andreasberg, Harz; England; San Francisco, Calif.; Hillsboro, N. M.; Lincoln, R. I.; Terlingua, Texas; Schaller, Zs. Kr., 44, 321; Terlingua, Texas; Zeller, Centralbl. Min., 18, 1907; stalactite of rhombohedral crystals, Potter Min., 18, 1907; stalactite of rhombohedral crystals, Potter Creek cave, Shasta Co., Calif.; small crystals from Terlingua, Texas; Eakle, Uni. Calif. Pub., 5, 6, 89, 91, 1907; associated with dioptase from Mindouli, French Congo; Lacroix, Bull. Soc. Min., 31, 258, 1908; crystals in a marble inclusion in basalt at Weitendorf in Styria; Leitmeier, Centralbl., Min., 257, 1908; figures of various twins, etc.; Lewis, Min. Mag., 15, 62, 1908; crystals from Joplin, Mo., and Bellevue, Ohio; Farrington and Tillotson, Field Col. Mus., Geol. Series 3, No. 7,

140, 144, 1908.

Opt. — Fluorescence; Schincaglia, [Il Nuovo Cimento, Pisa, 10, 212, 1899]; Zs. Kr., 34, 312; dispersion of iceland spar; Carvallo [Jour. de physique, 9, 465, 1900], Zs. Kr., 35,

Union Springs.

629; phosphorescent calcites from Fort Collins, Colo., and Joplin, Mo.; Headden, Am. J. Sc., 21, 301, 1906.

Studies of solution and etching figures, etc.; Gaubert, Bull. Soc. Min., 24, 326, 1901; also Goldschmidt and Wright, Jb. Min., Beil. 17, 355, 1903; ibid., 18, 335, 1904; pits produced by polishing basal planes; Samojloff, Zs. Kr., 39, 19.

Experiments with compression of marble at varying pressures and temperatures; Adams and Nicholson, [Proc. Roy. Soc. London, 67, 228, 1900]; Zs. Kr., 36, 82; also Rinne, Jb. Min., 1, 160,

1903

Siliceous calcites, Penfield and Ford, Am. J. Sc., 9, 352, 1900, from Washington Co., S. D., CaCo., 40%, quartz sand, 60%, apparently rounded pyramids, near the form γ (8.8.16.3) (the sand stone crystals from near Heidelberg, Ger., considered to have the same form; Cohen, Zs. Kr., 37, 610); from S. Dakota and Goshen Hole region, Wy., showing combinations of acute and obtuse rhombohedrons; Barbour and Fisher, Am. J. Sc., 14, 451, 1902; siliceous calcites; Delkeskamp, Zs. für Naturwiss., Halle, 75, 185, 1902; sand-calcite concretions from Salton, Calif.; Nichols, Field Columbian Mus., No. 111; Zs. Kr., 44, 539.

Studies as to whether calcite or aragonite is formed under varying conditions when CaCO, is precipitated from solution; Meigen, (Ber. Naturfors. Gesellsch., Freiburg, 13, 40, 1902), Zs. Kr.,

Fetid calcite from Chatham, Canada, analyzed by Harrington, Am. J. Sc., 19, 345, 1905,

showed the presence of H2S in small amount.

Containing Co, from Traversella; Spezia, Att. Acc. Torino, 42, 409, 1907. Studies concerning origin, structure, physical properties and associated minerals of marble by Vogt, Zs. pr. Geol., 6, 4-16, 43-52, 1898. The minerals of the marble of Carrara; D'Achiardi, Att. Soc. Tosc., 21, (1), 49; (2), 236, 1905; 22, 94, 1906; Giampaoli, sep. pub.; Zs. Kr., 43, 492. Calcite and aragonite in coral rock; Sep. Pub., The Atoll of Funafuti, Roy. Soc., 1904.

Portland cement clinkers have been minutely studied by Törnebohm. See alith.

CALCIUM ORTHOSILICATE. Artif. formation; Day and Shepherd, Am. J. Sc., 22, 280, 284, 1906.

CALCIUM OXIDE. - Crystalline form and density of fused lime; Day and Shepherd, Am J. Sc. 22, 271, 1906.

CALEDONITE, Min., p. 924; App., p. 13. Occurs in crystals at the Stevenson-Bennett mine, Organ Mts., New Mexico; O. C. Farrington, Bull. Field Col. Museum, Geol., 1, 224, 1900; also at the Alice mine, near Butte City, Montana; Rogers, Am. J. Sc., 12, 47, 1901. In deep sky-blue crystals at the silver mines of Mt. de Challacollo, Atacama, Chile; G. Berg, Min. petr. Mitth., 20, An analysis by Brunk, after deducting 2.31 insol., gave: 390, 1901.

CuO SO. PbO 3.78 = 10069.18 9.73 3.16 14.15

The CO, here belongs to the caledonite and is not due to impurity (cf. Min., p. 925); the formula deduced is $5[4PbSO_4.3Pb(OH)_2] + 2[4CuCO_3.3Cu(OH)_2]$. From Sardinia; Pelloux, Att. Acc. Linc., 13, (2), 34, 1904.

Californite, see Vesuvianite.

CALOMEL, Min., p. 153; App., p. 13.—Occurs in square prisms and in tabular crystals with other mercury minerals at Terlingua, Texas; Moses, Am. J. Sc., 16, 262, 1903; crystals from same locality showing δ (016) and d (031) as new forms, and from Avala, Spain; Goldschmidt and Mauritz, Zs. Kr., 44, 393; Schaller (priv. contr.) on crystals from Terlingua gives new form K (553) and deduces c = 1.7234.

CANCRINITE, Min., pp. 427, 1029. — A cancrinite-syenite has been described (anal.) by Sundell, Bull. Comm. G. Finland, No. 16, 1905. Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull., 207, 1902. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 48, 1908.

CANFIELDITE, App., p. 13. — The true locality of the specimens described by Penfield (Am. J. Sc., 47, 451, 1894) is shown by Canfield to be Colquechaca, Bolivia, not La Paz. Am. J. Sc., 23, 21, 1907; spinel twins are noted.

Carbapatite; P. Tschirwinsky, [Ann. Géol. et min. Russie, 8, 8, 1906]; Centralbl. Min., 283, 1907. Name suggested through an error for a supposed crystalline type of podolite, 3Ca₃(PO₄)₂.CaCO₃. Name withdrawn.

CARBORUNDUM, see Moissanite.

Carlosite = neptunite, which see.

Carnallite, Min., p. 177; App., p. 13. — Large crystals $(8 \times 6 \text{ cm.})$ from Beienrode near Königshutter gave the new forms: n (103), g (012), h (032), u (118), t (114), w (126), v (136). Optical determinations also given and analysis (by Kleinfeldt); Bücking, Ber. Ak. Berlin, 539, 1901. Also, Busz; Ber. Naturhist. Ver., Bonn, 1, C, 2, 1906; Ber. Med.-naturwiss. Ges. Münster, June, 1906. Sp. G. and artif. formation; Przilylla, Centralbl. Min., 234, 1904; of related compounds of iodine; de Schulten, Bull. Soc. Min., 23, 5, 1900. Isotrimorphism of carnallite and bromcarnallite; Boeke, Centralbl. Min., 710, 1908.

Deformation under pressure; Rinne, Festschr. siebzigsten Geburtstage, Adolf v. Koenen,

369, 1907.

CARNOTITE, App., p. 13. — Description of occurrence in western Colorado with analyses; Hillebrand and Ransome, Am. J. Sc., 10, 120, 1900. The material is shown to be impure, so that no definite formula can be assigned.

Ratio of radium to uranium; Boltwood, Am. J. Sc., 18, 97, 1904. Examination by E. P.

Adams has shown the absence of helium, Am. J. Sc., 19, 321, 1905.

Carpholite, Min., p. 549. — Occurs in quartz pebbles found in the diluvial deposits of the region of Bernburg, probably derived from the southeastern Harz Mts., near Wippra; Cornu, Centralbl. Min., 77, 1906.

Cassiterite, Min., pp. 234, 1030, 1037; App., p. 14. — Crystals from Pitkäranta with complex new forms; Borgström, Zs. Kr., 40, 1, 1904; İvigtut, Greenland; Böggild, Min. Grönl., 91, 1905. Small crystals resembling hexagonal pyramids by repeated twinning on 101, from near La Paz, Bolivia; Spencer, Min. Mag., 14, 332; pseudomorphs after some unknown monoclinic mineral from Tres Cruces, Bolivia; Pearce, ibid., 345. Crystals from Emmaville; Elsnore; Hognis Creek, near Dundee; The Glen, New England, all in N. S. W., and from Stanthorpe, Queensland; Anderson, Rec. Aus. Mus., 6, 404, 1907. Secondary twinning lamellæ in crystals from Selangor, Malacca; Johnsen, Centralbl. Min., 426, 1908.

Hidden notes cleavage (or parting) $\parallel e$ (101) on crystals from the Ross tin mine, near Gaffneys,

So. Carolina, Am. J. Sc., 40, 410, 1905.

From tin gravels, Embabaan district, Swaziland, S. A.; Prior, Min. Mag., 12, 100; also see Molengraaff, [Trans. G. Soc. S. Africa, 4, 141, 1898], Zs. Kr., 32, 301. On the deposits of Mt. Bischoff, Tasmania, see von Fircks, Zs. G. Ges., 51, 431, 1899; of the Carolinas; Pratt and Sterrett, Bull. 19, G. Surv. No. Carolina, 1904; discussion as to formation of tin deposits of Campiglia Marittima, Tuscany; Bergeat, Jb. Min., 1, 135, 1901.

CATAPLEHTE, Min., p. 412; App., p. 14. — Crystals from Narsarsuk, Greenland; Flink, Medd. Grönland, 24, 93; also see Böggild on optical and crystallographic relationships; ibid., 33, 106, 1906.
Rôle of water in; Zambonini, Mem. Acc. Sci. Napoli, 14, 54, 1908.
A catapleiite-syenite occurs in central Sweden, near the Wettersee; Törnebohm, Sveriges

Geol. Und., C, No. 199, 1906.

CELESTITE, Min., p. 905; App., p. 14. — Cryst. — From the Marienstein mine, near the Tegemcelestric, Mill., p. 505; App., p. 14. — Gryst. — From the Marienstein line, hear the Tegemsee, Bavaria, (anal.); Sustschinsky, Zs. Kr., 34, 563, 1901; with (124) prominent, near Mentor, Saline Co., Kansas; Rogers Am. J. Sc., 12, 48, 1901; from Wymore, Nebraska, id., Sch. Mines Q., 23, 134, 1902; from Boratella, Romagna, with (017), by Zambonini, Rend. Acc. Linc., 13, (1), 37, 1904; from Monte Viale, Vicentine Alps; new forms (214), (0.1.16), (119), (117); Billows, Riv. Min. Ital., 31, 3, 1904; from the Djebel Kebbouch and Djebel Bezine, Tunis (anal. Pisani); Termier, Ital., 31, 3, 1904; from the Djebel Kebbouch and Djebel Bezine, Tunis (anal. Pisani); Termier, Bull. Soc. Min., 25, 173, 1902, also see Samojtoff (pseudemorph after barite?), Centralbl. Min., 33, 1905; from Haring, Tyrol; Koechlin, Min. petr. Mitth., 24, 114, 1905; from Lyssaja gora near Theodosia, Crimea; Popoff, [Bull. Nat. Moscow, p. 180, 1906]; Zs. Kr., 46, 221; from Maybee, Michigan, with discussion of occurrence, crystals, natural etching figures and anal.; Kraus and Hunt, Am. J. Sc., 21, 237, 1906; crystals from sulphur caves near Lornano, Siena, with new forms (327), (019); Manasse, Att. Soc. Tosc., 23, 1907; from Mokattam and Abou Roach, Egypt, with optical determinations; Couyat, Bull. Soc. Min., 31, 264, 1908; from Kresty, Saratow, Russia, with new form (177); Surgunoff, Bull. Soc. Nat. Moscow, 435, 1904; Zs. Kr., 43, 76.

Effect of low temperatures upon optical properties: Panichi [Mem. Acc. Line. 4, 389, 1902]:

Effect of low temperatures upon optical properties; Panichi, [Mem. Acc. Linc., 4, 389, 1902];

Zs. Kr., 40, 89. Etching figures, see under barite.

Occurrence near Syracuse, N. Y.; Kraus, Am. J. Sc., 18, 30, 1904; the general occurrence and distribution of celestite-bearing rocks; id., ibid., 19, 286, 1905. Occurrence noted at Longue Pointe, Island of Montreal, ibid., 21, 188, 1906.

Celith, see Alith.

Celsian, App., p. 15. — Further investigation proves it to be monoclinic with $\dot{a}: \dot{b}: \dot{c}=0.657$: 1:0.554; $\beta=115^{\circ}2'$. Angles 001: $110=68^{\circ}41'$; 010: $110=59^{\circ}14'$; 001: $201=79^{\circ}23'$. Forms: P(001), M(010), K(110), Y(201), T(110), (114), G(112), o(111), (311), (311). Twinning general according to Carlshad law: mamphab and beyond twing also found. general according to Carlsbad law; mamebach and baveno twins also found. Opt. positive. Ax. pl. \parallel (010); c: $a=28^{\circ}$ 3' in obtuse angle β . $2V_a=86^{\circ}$ 22'. $\alpha=1.5837$, $\beta=1.5886$, $\gamma=1.5940$. Anal. given. Strandmark, G. För. Förh., 25, 289, 1903; 26, 97, 1904; Zs. Kr., 43, 89. Also discussion of mixtures of orthoclase and celsian molecules with anal. of a barium potassium feldspar from the Binnenthal. Name baryta-orthoclase given to mixtures of celsian and orthoclase.

CERARGYRITE, Min., p. 158. — Prior and Spencer (Min. Mag., 13, 174), as the result of an investigation of the isometric-normal (holosymmetric) silver haloids, conclude that while they should be included under the common group name, cerargyrite, sub-species should be recognized as follows: chlorargyrite, AgCl; bromargyrite, AgBr; embolite, Ag(Cl,Br); iodembolite, Ag(Cl,Br,I). Isomorphous mixtures of AgCl, AgBr, AgI exist in varying proportions. New analyses (Prior) are as follows:

	G	Cl	Br	I	Ag
1. Chañarcillo	6.17	7.11	22.35	10.39	$60.\overline{37} = 100.22$
2. Broken Hill, N. S. W.	6.31	1.96	32.22	8.77	56.93 = 99.88
3. " " "	5.82	14.36	15.85	2.35	67.28 = 99.84
4. " " "	5.66	13.20	19.71	0.16	66.91 = 99.98

In addition to the above group, there is also the rhombohedral-hemimorphic AgI, iodyrite, and the isometric-tetrahedral 4AgI.CuI, miersite.

Cerepidote; synonym for allanite. Rosenbusch, Mikrosk. Phys. Min., 1, 2, 286, 1905.

Ceruleite, Cæruleite. H. Dufet, Bull. Soc. Min., 23, 147, 1900.

Massive, compact and resembling clay but made up of excessively minute crystals, which polarize in the mass. G. = 2.803. Color turquoise-blue.

Composition: CuO.2Al2O3.As2O5.

Analysis:

 As_2O_5 34.56 H_2O 22.32 = 99.94 CuO 11.80

The water goes off only at a high temperature, the loss at 180° being only 1.45. p. c. Soluble in acids, leaving a slight residue consisting of a white clay.

From the Emma Luise gold mine at Huanaco, Taltal province, Chile (cf. Möricke, Zs. pr. G., 1, 143, 1893). A white clay associated with the ceruleite, contained 1.8 p. c. As₂O₅ but no copper.

CERUSSITE, Min., pp. 286, 1030; App., p. 15. — Cryst. — Accurate measurements of angles and optical constants on crystals from localities in Westphalia; Ohm, Jb. Min. Beil. 13, 1, 1899; crystals from Altai, with anal.; Jeremejew [Verhandl. d. kais. russ. miner. Gesellsch., 1898. St. Petersburg, 36, Protok. 12, 1899], Zs. Kr., 32, 429; from Malfidano, Sardinia, with pseudomorphs after anglesite and phosgenite; Millosevich, Rend. Acc. Linc., 9, (1), 153, 1900. Twins from Sardinia described by Hubrecht, with bibliography of mineral, a list of the observed forms and combinations with the relative frequency of occurrence of each form. The following new

forms also given: T (034) and Q (054), Zs. Kr., 40, 147; from Mies with the new forms (0.22.1), (0.29.1), (0.33.1), (0.37.1); Barvir, Ber. böhm. Ges. Wiss. xxxvi, 1900; ibid., xvii, xxxiii, 1901; from Santa Rosalia, Peru, with new forms (150) and (310); Buttgenbach, Ann. Soc. géol. Belg., 29, 103, 1902; from the Alice mine, Butte, Montana, and Phenixville, Pa.; Rogers, Sch. Mines Q., 23, 136, 1902; multiple twins from Mapimi, Mexico, with new form A (304); Goldschmidt, Jb. Min. Beil. 15, 562, 1902; crystals from Valle di Contra, Valsassina, Italy; Artini, Att. Soc. Milano, 42, 107, 1903; from Djebel-Ressas mine, Tunis; Jecker, C. R., 140, 1410, 1905; Gaeta, L. Como; Repossi, Att. Soc. Milano, 43, 425, 1905; Magnet mine, Tasmania; C. Anderson, Rec. Austr. Mus., 6, 93, 1905; Traversella; Colomba, Rend. Acad. Linc., 15, 643, 1906; Broken Hill, N. S. W.; Zeehan, Whyte River and Dundas, Tasmania; Anderson, Rec. Aus. Mus., 6, 407, 1907; Broken Hill; Spencer, Min. Mag., 15, 36, 1908; with dioptase from Mindouli, French Congo; Lacroix, Bull. Min. Soc., 31, 257, 1908; Rézbánya with new forms, M (0.13.2); D (0.11.2); C (072); B (095); Löw, Földt. Közl., 38, 205, 1908; Laurium, Greece; Lacroix and de Schulten, Bull. Soc. Min., 31, 89, 1908

Effect of low temperatures upon optical properties; Panichi, [Mem. Acc. Linc., 4, 389, 1902];

Zs. Kr., 40, 88. Luminescence; Pochettino, Rend. Acc. Linc., 14, (1) 505, (2) 220, 1905.

Analysis of cerussite containing 3.15% SrO from Isle, Custer Co., Colo., Warren, Am. J. Sc., **16**, 343, 1903.

Chabazite, Min., p. 589; App., p. 15. — Cryst. — Description of crystals from near Rome (with anal.); Zambonini, Jb. Min., 2, 93, 1902; crystals from Scottish localities; Goodchild, [Trans. Geol. Soc., Glasgow, 12, Suppl., 1-68, 1903]; Zs. Kr., 45, 307; from East Greenland; Böggild, Medd. om Grönl., 28, 123, 1905; also Min. Grönl., 571, 1905. Petersdorf, near Zöptau, Mähren; Kretschner, Centralbl. Min., 609, 1905; Ben Lomond (with anal.) and Inverell, N. S. W., and from Bell Mount, Tasmania; Anderson, Rec. Aus. Mus., 6, 416, 1907; from basalt of Montresta, Sardinia; Deprat, Bull. Min. Soc., 31, 189, 1908; also Millosevich, Rend. Acc. Linc., 17, (1), 270, 1908; and (with anal.): Pelacani, ibid., (2), 68, 1908.

(with anal.); Pelacani, ibid., (2), 68, 1908.
From Golden, Colo.; Patton, Bull. Geol. Soc. Amer., 11, 461, 1900; Zs. Kr., 36, 74; from the Buck Creek corundum mine, Clay Co., N. C., (with anal.); Pratt, Jour. Elisha Mitchell Sc. Soc., 14, 61, 1897], Zs. Kr., 32, 603; anal. of chabazite from Maddalena and Montresta, Sardinia; Rimatori, Rend. Acc. Linc., 9, (2), 146, 1900. Anal. of mineral from syenite from Biella; Zambonini, Zs. Kr., 40, 263. Occurrence in basalts (with anal.) at Asmara, and Sciket in Eritrea;

Manasse, Proc. Soc. Tosc., July, 1906.

Concerning "herschelite" from Palagonia, Sicily, and its relations to other similar zeolites; Gonnard, Bull. Soc. Min., 29, 283, 1906. Also see Di Franco, Att. Acc. Sci. Nat. Catania, 15, 3, 1902.

Chem. constitution; McNeil, Jour. Amer. Chem. Soc., 28, 597, 1906.

Chalcanthite, Min., p. 944; App., p. 15.—Crystals from the Alma pyrite mine, Leona Heights, Alameda Co., Cal., showed the new forms l (120), g (141); analysis gave the formula CuSO₄,H₂O + 4H₂O; Schaller, Bull. G. Univ. Cal., 3, 212, 1903. Twinning in artif. crystals. Also new form (131); Boeris, Att. Soc. Milano, 44, 73, 1905.

From Copaquire, Province of Tarapacá, Chile (with anal.), and associated with it a light blue material in rounded masses which proved to be a double sulphate of copper and magnesium, CuSO₄ being to MgSO₄ nearly as 1:2. Anal. gave: SO₃, 35.70; CuO, 12.43; MgO, 11.39; FeO, 1.01; MnO, 0.32; NiO, 0.06; H₂O, 38.38; total = 99.29; Keller, Proc. Amer. Phil. Soc., 47, 81, 1908.

CHALCOCITE, Min., p. 55. — Twin, with twinning plane (201), from Cornwall; Milch, Jb. Min., 1, 155, 1900. Pseudomorphs after galena from Osaruzawa, Prov. Rikuchu, Japan; Wada, Beitr. Min. Japan, 1, 17, 1905; after barite (?), from Grab near Koštunići; Stevanović, Zs. Kr., 45, 60.

A pulveriform variety occurs at the Champion mine, in the Keweenaw copper region, Michigan; Koenig, Am. J. Sc., 14, 415, 1902. A prominent mineral in the copper district of Clifton, Arizona; it is of secondary origin, occurs only massive and commonly shows a sooty aspect on the surface. Lindgren and Hillebrand, Am. J. Sc., 18, 451, 1904; Bull. U. S. G. S., 262, 45.

CHALCODITE, see Stilpomelane.

Chalcolamprite. G. Flink, Medd. om Grönland, 14, 234, 1898; 24, 160, 1901.

Isometric, only in small octahedrons, sometimes hollow or otherwise irregular. No cleavage observed. Fracture splintery or subconchoidal. Brittle. H. = 5.5. G. = 3.77; Mauzelius. Luster greasy; crystal faces show a copper-red metallic iridescence. Color dark grayish brown, inclining

to red, streak ash-gray. Opaque, translucent in thin splinters. or allied to pyrochlore. Analysis, Mauzelius: Composition, RNb,O,F, RSiO,

Nb₂O₅ SiO₂ TiO₂ ZrO₂ Ce₂O₃, etc. Fe₂O₃ MnO CaO K₂O Na₂O H₂O F

59.65 10.86 0.52 5.71 3.41 1.87 0.44 9.08 0.38 3.99 1.79 5.06 = 102.76 less O (2.13) =100.63

Occurs very sparingly at Narsarsuk, southern Greenland, associated with ægirite. Named from χαλκός, copper, and λαμπρός, luster.

CHALCOPHYLLITE, Min., p. 840. — Analysis of material from Cornwall (?); Hartley, Min. Mag., 12, 120.

Chalcopyrite, Min., pp. 80, 1030; App., p. 15. — Cryst. — Twins from Burgholdinghausen; Baumhauer, Zs. Kr., 31, 269. Crystals of unusual habit and twin crystals from Cornwall; Lewis and Hall, Min. Mag., 12, 324. From Visé, Belgium, showing new form (115); Buttgenbach, Ann. soc. géol. Belg., 25, civ, 1898. Small crystals, rich in forms, from Pulacayo, Bolivia; Toborffy, Zs. Kr., 39, 366. New forms, x (113), η (771), τ (509). Twins; twinning planes (111) and (101). Crystal, $4^{\rm cm}$ diam., from Somerville, Mass., with m (110) and e (101); Richards, Am. J. Sc., 17, 425, 1904. From Botes, from Kapnik, rich in forms, from Schemnitz; Mauritz, Zs. Kr., 40, 588. Traversella, with new forms, Y(515), $\mu(11.11.1)$; Colomba, Rend. Acc. Linc., 15, 639, 1906;

Val de Villé, Alsace; Ungemach, Bull. Soc. Min., 29, 213, 1906; crystals of unusual habit from Arakawa, Japan, (figs.); Ford, Am. J. Sc., 23, 59, 1906; the same with a general discussion of the crystal structure of the mineral; Beckenkamp, Zs. Kr., 43, 43; from Besano, Italy; Repossi, Att. Soc. Milano, 47, 89, 1908; Bréole, Basses-Alpes, France; Lacroix, Bull. Soc. Min., 31, 353, 1908.

Etching figures; Himmelbauer, Min. Mitth., 27, 327, 1908. Anal. — From Wheal Towan, St. Agnes, Cornwall, on crystals with cubic appearance, probably

twins; Prior, Min. Mag., 13, 190.

Artif.: formed by sublimation in a furnace at Butte, Mont., analyses given; Winchell, Amer. Geol., 28, 244, 1901; Zs. Kr., 37, 80.

CHALCOSTIBITE, Min., pp. 113, 1030; App., p. 16. — Crystals from Oruro, Bolivia; Spencer, Min. Mag., 14, 322.

Chalmersite (Palache)

Chalmersite. E. Hussak, Centralbl. Min., 69, 1902; 332, 1906. F. Rinne, ibid., p. 207, 1902; Palache, Am. J. Sc., 24, 255, 1907; Zs. Kr., 44, 14.

Orthorhombic. Axes $\check{a}: \dot{b}: \dot{c} = 0.5734:1:0.9649$ (Hussak) near chalcocite. Forms: c (001), b (010), a (100), m (110), l (130), f (012), g (011), g (111), g (122), g (123), g (123), g (124), g (125), g (127), g (128), g (129), (021), y (103), p (111), o (236), r (233), s (263), t (136), u (1.9.12). $mm''' = 59^{\circ}$ 40', $cp = 62^{\circ}$ 44', $pp''' = *52^{\circ}$ 29', $pp' = *100^{\circ}$ 54'. Angles:

In thin, elongated prisms, with vertical faces strongly striated; rarely Twins common with m as tw. plane, resembling chalcocite; tabular | b. also contact and penetration twins probably with tw. plane v (112). Fracture conchoidal. H. = 3.5. G. = 4.68. Luster metallic. Color brass- to bronze-yellow, resembling millerite, often with iridescent tarnish. Opaque. Strongly magnetic.

Composition, CuFe, S, or Cu, S.Fe, S,

Analysis by G. Florence, (1) on 0.016 gr., (2) on 0.0896:

	S	Cu	Fe
1.	35.30	17.04	46.95 = 99.29
2.	35.11	22.27	43.13 = 100.51.

From the Morro Velho gold mine, Minas Geraes, Brazil, with chalcopyrite and dolomite on a limonite derived from the alteration of pyrrhotite. Named after G. Chalmers, superintendent of the mine.

CHAMOSITE, Min., p. 658. — From Thuringia, with anal; Zalinski, Jb. Min., Beil. 19, 40, 1904; Zs. Kr., 42, 602.

CHILDRENITE, Min., p. 850. — Occurrence in granite of Greifenstein near Ehrenfriedersdorf in Saxony; Kolbeck, Centralbl. Min., 333, 1908.

Chloanthite, Min., p. 88. — Occurrence (with anal.) at Cobalt, Ontario; Miller, Rep. Can. Bureau Mines, Pt. 2, 1905; Zs. Kr., 43, 395.

CHLORALUMINITE, Min., p. 165. — In colorless obtuse rhombohedrons in blocks ejected from Vesuvius in April, 1906. Optically negative. High birefringence, agreeing with artificially prepared AlCl₃·6H₂O (Dennis and Gill, Zs. f. An. Ch., 9, 340, 1895), which gave $r \wedge r' = 125^{\circ}$ 48'. Lacroix, Bull. Soc. Min., 30, 254, 1907.

CHLORARGYRITE, see Cerargyrite.

Chlorites, Min., pp. 643-664; App., p. 16. — Colorless chlorite from Zlatoust, Russia, description with analysis; Zemiatčenskij, Zs. Kr., 35, 357. Studies on chemical constitution of chlorite group; Dalmer, Centralbl. Min., 627, 1901.

Chloritoid, Min., pp. 640, 1031; App., p. 16. — Occ. (with anal.), at Strettoia, Tuscany; Manasse, Proc. Soc. Tosc., Jan., 1906.

H. J. Johnston-Lavis, Nature, 74, 103, 1906; A. Lacroix, C. R., Chlormanganokalite. 142, 1249, 1906; Bull. Soc. Min., 30, 219, 1907; H. J. Johnston-Lavis and L. J. Spencer, Min. Mag.,

15, 54, 1908.

Hexagonal-rhombohedral c = 0.5801. $r \wedge r' = 57^{\circ} 36'$. Crystals simple obtuse rhombohedra with $r(10\bar{1}1)$ with occasionally small truncations of $a(11\bar{2}0)$. Conchoidal fracture. H. = 2.5. G. = 2.31. Vitreous luster. Color pale wine-yellow. Optically +. Double refraction very low. Mean index of refraction = 1.59 (approx.). Deliquescent.

Comp.: Probably 4KCl.MnCl2.

MnCl₂ KCI MgCl, Na2SO4 H₂O Insol. 1.52 Anal.: 69.42 26.45 0.16 1.19 0.71 = 99.45

Found in fragmentary material ejected from Vesuvius in April, 1906. [Considered by Lacroix to be monoclinic, pseudo-rhombohedral.]

Chlornatrokalite. H. J. Johnston-Lavis, Nature, 74, 174, 1906. — See Sylvite.

CHLOROMELANITE, see Jadeite.

Chloropal, Min., p. 701.—Anal.—Variety nontronite, from Gross-Tresny, Mähren; Kovář, [Abh. böhm. Akad. No. 15, 1, 1896]; Zs. Kr., 31, 524; from Strehlerberg near Markt Redwitz in the Fichtel Mountains, as an alteration product of an amphibolite; Stadlinger (Sitz.-Ber. phys.-med. Soc. Erlangen, 31, 1, 1899; Zs. Kr., 35, 313; from Gdossau and Pulitz, Mähren; John [Verh. geol. R.-Anst. Wien, 50, 335, 1900; Zs. Kr., 36, 641; from Palmetto Mountains, Esmeralda Co., Nev.; Turner, Am. J. Sc., 13, 344, 1902.

CHONDROARSENITE, see under Sarkinite.

Chromite, Min., pp. 228, 1031; App., p. 17. — Occ. in meteorites with anal.; Tassin. Proc.

U. S. Nat. Mus., 34, 685, 1908.

Var. chrompicotite. Occurs in veins in volcanic rocks on Scottie Creek, east of Mundorff, district of Lilloet, B. C.; mineral is massive, granular; velvet black; G. = 4.239. Analysis:— Cr_2O_3 , 55.90; Al₂O₃, 13.83; FeO, 14.64; MgO, 15.01; SiO₂, 0.60; total, 99.98. Associated with serpentine. Hoffmann, Am. J. Sc., **13**, 242, 1902.

Chrysoberyl, Min., pp. 229, 1031. — Cryst. — Twins from Smaragd, Urals, in addition to the common habits of twinning show a new law with (111) as twinning plane; Jeremejew [Bull. d. l'Acad. Imp. d. Sc., St. Petersburg (V), 8, 5, 1898]; Zs. Kr., 32, 427. Crystals from Ceylon with l'Acad. Imp. d. Sc., St. Petersburg (V), 8, 5, 1898]; Zs. Kr., 32, 427. Crystals from Ceylon with following new forms: l (210), q (140), f (10.1.10), g (515), h (313), p (232). From measurements on these crystals following axial ratio was derived: $\ddot{a}: \dot{b}: \dot{c}=0.4707:1:0.5823$. Also optically investigated; Melczer, Zs. Kr., 33, 240.

Also from Ceylon the additional new forms: η (113), ψ (11.20.20), ω (7.10.8), π (131), τ (277),

 Q (142), φ (1.18.9); Liffa, Zs. Kr., 36, 606, 1902.
 Twins from Ceylon discussed with tables of angles (after Goldschmidt) both with the usual orientation and also when (001) is made to occupy position of (010); Goldschmidt and Preiswerk, Zs. Kr., 33, 455, and Goldschmidt, ibid., 468. Crystal from New York City; Moses, Am. J. Sc., 12, 104, 1901; Marschendorf in Mähren; Slavik, Zs. Kr., 39, 303.

Anal. of material found on the Rivière du Poste in the county of Maskinonge, Province of

Quebec, Canada; Evans, Am. J. Sc., 19, 316, 1905. Occ. at Veltlin, near Sondalo, Switzerland; Brugnatelli, Zs. Kr., 32, 81.

CHRYSOCOLLA, Min., p. 699. — Palmer found that chrysocolla from Pinal County, Arizona, would lose from 12 to 20 per cent of water by drying over sulphuric acid and would regain it all and even more by allowing it to stand over water for a few hours. The loss and regaining of the water was unaccompanied by change of color. Analyses given. Am. J. Sc., 16, 45, 1903. Anal. of material from copper mine, Bena Padru, near Ozieri, Sardinia; Lovisato, Att. Acc. Linc., 12, (2), 81, 1903; from Campiglia, Tuscany; Manasse, Proc. Soc. Tosc., 15, 20, 1906.

Common in the oxidized portions of the mineral deposits at the Clifton-Morenci copper district

in Arizona. It forms cryptocrystalline to microcrystalline aggregates of particles, also in fibrous and felted aggregates and in fibrous crusts; extinction parallel, birefringence strong, negative. Lindgren and Hillebrand, Am. J. Sc., 18, 453, 1904. Cf. Jannettaz, Bull. Soc. Min., 9, 211, 1886.

Chrysolite, Min., pp. 441, 1031; App., p. 17. — **Cryst.** — Latium with new forms, t (230), u (141); Zambonini, Zs. Kr., 32, 152; ibid., 34, 227; Montefiascone, Italy, with derivation of axial ratios; Fautappiè, Rend. Acc. Linc., 14, 17, 1905; villarsite from Traversella; Colomba, Rend. Acc. Linc., 15, 636, 1906; complex crystals of fine quality from St. Jean island in the Red Sea; Michel, Bull. Soc. Min., 29, 360, 1906; also with anal. and opt. study; Couyat, ibid., 31, 344, 1908.

Opt. — Relation existing between optical angle and the variation in composition; Stark, Min.

Mitth., 23, 451, 1904; Zs. Kr., 42, 496. Refractive indices of crystals from inclusions in augiteandesite lava from Bellenberges near Mayen; Gaubert, Bull. Soc. Min., 28, 188, 1905; optical con-

stants of rock forming olivine; Duparc and Pearce, ibid., 31, 108, 1908.

Anal. of mineral; from Latium; Zambonini, Zs. Kr., 32, 156. Anal. and description of crystals from meteorites from Pawlodarsk; Jeremejew and Antipoff, [Bull. Acad. Imp. d. Sc., St. Petersburg, 8, 4, 9, 1, 91, 1898], Zs. Kr., 32, 424. Anal. of material from Flysch near Višegrad in Bosnia; Schiller, Min. Mitth., 24, 315, 1905.

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull. 207, 1902; Zs. Kr.,

38, 697.

Occurrence in serpentine at Chester and Middlefield, Mass., with discussion of the original mineral of the "hampshirite" pseudomorphs, which was undoubtedly olivine, although Roe and Parsons, Bull. Minn. Acad. Sci., 4, 2, 268, 276, 1906, have assigned them to humite; Palache, Am. J. Sc., 24, 491, 1907.

Intergrowth of olivine with ilmenite in a dolerite near Homberg on the Ohm; Schwantke, Jb.

Min., Beil.-Bd. 18, 460, 1904; Zs. Kr., 42, 527.

Hyalosiderite:—Occurrence in a basic dike rock at Iron Mine Hill, Cumberland, R. I., with analysis; Johnson and Warren, Am. J. Sc., 25, 17, 1908.

Titanolivine.—Occurrence in the Piedmontese Alps; Boeris, Riv. Min., 26, 1901; also L. Brugnatelli, Zs. Kr., 36, 151, 1902, gives anal. and following description: Color cherry red. G. = 3.20-3.26. Pleochroism strong, bright yellow to orange. $\beta = 1.680$. $2V_{Na} = 57^{\circ} 56'$. Opt. +. In section | (010) shows strong crossed dispersion, from which it is concluded that titanolivine is monoclinic with ax. pl. \perp (010) and b axis = Bx_a. Intergrown with olivine with (100) of olivine || to (010) of titanolivine. Alteration products of titanolivine, same as for olivine.

CIMOLITE, Min., p. 689. — Anal. of material from Argentiera with discussion of chemical composition; Smirnoff, [Trav. d. l. Soc. Imp. Natur. de St. Pétersbourg, 33, 214, 1902], Zs. Kr., 39, 625.

CINNABAR, Min., pp. 66, 1031; App., p. 17. — Crystals from Alsósajó, Hungary, with following new forms: j (5058), A (8089), X (9098), V (8085), Y (11.0. $\overline{11}$.4), I (11 $\overline{22}$); Zimányi, Zs. Kr., 41, 439; from Sonoma County, California; Sachs, Centralbl. Min., 17, 1907. Large twinned rhombohedrons from Province of Kweichow, China; Petereit, Am. J. Sc., 26, 517, 1908.

Following indices of refraction on cinnabar from Almaden determined:

Li;
$$\omega = 2.8189$$
; $\epsilon = 3.1461$, $\epsilon - \omega = 0.3272$
 H_a ; $\omega = 2.8306$; $\epsilon = 3.1615$, $\epsilon - \omega = 0.3309$

Zimányi, Zs. Kr., 41, 439.

Occ. - At Terlingua, Brewster Co., Texas; Uni. of Texas, Min. Sur. Bull., 4, 74; Am. J. Sc., 14, 464; also Hill, ibid., 16, 251, 1903; at Gratwein near Graz, Styria; Cornu, Centralbl. Min., 279, 1908.

Radioactivity of; Losanitsch, Berichte, 37, 2904; Am. J. Sc., 18, 462, 1904. Relations to metaginnabarite; Weber, Zs. Kr., 44, 231.

CLAUDETITE, Min., p. 199. — Anal. of material from Szomolnok; Loczka, Zs. Kr., 39, 523.

CLIFTONITE, Min., p. 6. — Internal structure; Davison, Am. J. Sc., 13, 467, 1902. Limited distribution in the meteoric iron found in 1884 in Youndegin, West Australia; Fletcher, Min. Mag., 12, 171.

CLINOCHLORE, Min., p. 644; App., p. 17. — Effects of heating upon optical character; Klein, Ber. Ak., Berlin, 118, 1902.

Anal. from Paringu; Munteanu-Morgoci, [Bull. Soc. Sc. Bukar, 9, 568, 764, 1900], Zs. Kr., 36, 653. Analysis of var. leuchtenbergite from Slatouster Bezirk, Russia; Zemiatschensky, Centralbl. Min., 215, 1901. From Calci and Verruca near Monti Pisani, Tuscany, and from Affaccata, Elba,

with anal.; Manasse, Proc. Soc. Tosc., 15, 20, 1906.

Occurrence of pseudophite (Min., p. 652) in granite at Strehlerberg near Markt Redwitz in Fichtelgebirge, with anal.; Stadlinger, [Ber. phys.-med. Soc. Erlangen, 31, 1, 1899]; Zs. Kr., 35,

313.

Olinoenstatite. Name suggested by Wahl; Min. Mitth., 26, 121, 1907, for the magnesium pyroxene. Concerning its artif. formation see Allen, White, Wright and Larsen, Am. J. Sc., 27, 1-47, 1909.

CLINOHUMIT, Min., p. 535. — Description of occurrence in crystalline limestone near Kandy, Ceylon, with anal.; Coomára-Swámy, Q. J. G. Soc., 58, 399, 1902.

CLINOZOISITE, App., p. 18. — Measurements on crystals from Goslerwand gave the axial ratio: $\dot{a}: \dot{b}: \dot{c} = 1.5853: 1: 1.8117; \beta = 64^{\circ} 30.4';$ Westergård, Zs. Kr., 42, 279.

COBALTITE, Min., p. 89; App., p. 18. — From Northern Ontario, Canada; description of crystals with anal.; DeLury, Am. J. Sc., 21, 275, 1906.

COCCINNITE, Min., p. 161. — Crust of microscopic scarlet colored crystals on specimen from Broken Hill were proved to be mercuric iodide. Crystals were evidently cubes with occasional octahedral truncations. Does not agree with previous descriptions of this mineral. Moses, Am. J. Sc., 12, 98, 1901.

COLEMANITE, Min., p. 882; App., p. 18. — Crystals from the Calico district, San Bernardino Co., Cal., described with following new forms: l(310), $\rho(301)$, $g(\bar{5}02)$, $f(\bar{8}01)$, $\phi(\bar{5}22)$, p(142), n(141), u (164), μ (165), η (232), P ($\bar{1}$ 23), w ($\bar{1}$ 82), s ($\bar{3}$ 41). The following axial ratio was derived: $a:\bar{b}:\bar{c}=0.7768:1:0.5430;$ $\beta=110^{\circ}$ 7'. Eakle, Bull. Dept. Geol. Uni. Cal., 3, 31, 1902; Zs. Kr., 38, 691. Occ. of var. pandermite in Argentina. Anal.; Buttgenbach, Am. Soc. géol. Belg., 28, 99, 1900— 1901.

Artif. formation; van't Hoff, Ber. Ak. Berlin, pp. 566, 689, 1906.

Color in minerals; study of coloring matter in fluorite, apatite, barite, celestite, anhydrite, halite, calcite, zircon, topaz, amethyst, microcline, tourmaline; Kraatz-Koschlau and Wöhler, Min. Mitth., 18, 304, 447, 1899; Weinschenk, ibid., 19, 144, 1900; Koenigsberger, ibid., 148; Nabl, ibid., 273; in zircon, amethyst, smoky quartz, tourmaline; Simon, Jb. Min., Beil., 26, 249-295, 1908.

Coloradoite, Min., p. 64.— Occurs somewhat abundantly at the Kalgoorlie gold district in Western Australia. Described by L. J. Spencer, Min. Mag., 13, 274, 1903. In massive form with conchoidal fracture; rather brittle; H. = 2.5; G. =8.07; luster metallic and color iron-black; composition HgTe as shown by the analyses 1, 2, the latter incomplete.

	Te	Hg
1.	39.38	60.95 = 100.33
2.	35.8	59.4

Also earlier mentioned by Rickard, Trans. Am. Inst. Mining Eng., 30, 708, 1900, and Simpson, Geol. Sur. W. Austr., '97-'98, 44; '98-'99, 57; the latter (quoted by Spencer) gives G. = .9.21 and deduces the composition Hg₂Te₃. See also *Coolgardite* and *Kalgoorlite*.

Probable occurrence at Norwegian mine, Mother Lode region, Calif.; Hillebrand, Am. J. Sc.,

8, 297, 1899.

COLUMBITE, Min., p. 731; App., p. 18. — Crystal from tourmaline mine near Ramona with new form r (141). Eakle, Uni. Cal. Pub., 5, 6, 87, 1907.

Occurrence (anal.) in bed of river Tschoroch, Batum, Caucasus mts.; Tschernik, [Jour. phys.chim. Russe, 34, 684, 1892]; Zs. Kr., 39, 627. From Sonikedal near Kragerö; Milch, Jb. Min., 1, 159, 1900. Occurs in large masses, up to 600 lbs., in pegmatite with red and green tourmaline seven miles west of Cañon City, Colorado. Analysis. W. P. Headden, Proc. Col. Sc. Soc., 8, 57, 1905. 1905:

Nb2O5 SnO2 Ta_2O FeOMnO Ign. G. = 5.66156.48 22.12 0.45 0.15 = 99.830.11 8.07 12.45

Two other analyses (ibid., pp. 58, 59) of material from the Black Hills, So. Dakota, agree very closely with the above. Study of crystals from southern Norway and Greenland, with new analyses by Blomstrand and a general discussion of chemical and crystallographic relations with other species; Brögger, Min. Süd-Nor. Granitpeg., 53, 1908.

Crystals of manganotantalite from Mt. Apatite, Maine, showed new form, j (320). Partial anal.;

Schaller, Am. J. Sc., 24, 154, 1907; Zs. Kr., 44, 3.

Conchite, see under Aragonite.

Coolgardite. A. Carnot, Bull. Soc. Min., 24, 357, 1901; C. R., 132, 1300, 1901; L. J. Spencer, Min. Mag., 13, 282, 1903.

Described by Carnot as a sesquitelluride of gold, silver and mercury, essentially (Au, Ag, Hg), Te, from Kalgoorlie in the East Coolgardie gold field, West Australia. The material analyzed (1, 2, 3, below) was massive with conchoidal fracture, rarely showing traces of cleavage; of an iron-gray or yellowish gray inclining to bronze. Analyses:

	Te	Au	Ag	Hg	Cu	Fe	Sb '
1.	56.55	23.15	16.65	3.10	0.10	tr.	0.20 = 99.75
2.	53.70	27.75	13.60	3.70	0.25	· tr.	0.15 = 99.15
3.	51.13	37.06	4.71	3.70	0.88	0.90	1.20 = 99.58

These analyses vary widely, and Spencer shows that the material analyzed was unquestionably far from homogeneous and that "coolgardite" is probably to be regarded, not as a distinct species, but as a mixture of coloradoite with sylvanite (1) or with calaverite (3), or both (2); petzite may also be present.

Coorongite, Min., p. 1019. — Anal. of material from Coorong district, South Australia, corresponded to $C_{10}H_{16}O$; Cumming, [Proc. Roy. Soc. Victoria, 15, 134, 1903], Zs. Kr., 41, 407.

COPIAPITE, Min., p. 964. — A ferric sulphate originally described as new and named janosite (from Dr. János Böckh, Director of the Geol. Sur. of Hungary) is proven after considerable discussion to be identical with copiapite. H. Böckh and K. Emszt, [Föld. Köz., 35, 76, 139, 1905; ibid., 36, 186, 228, 404, 455]; Weinschenk, [ibid., 36, 182, 224, 289, 359, 1906]; controversy reviewed, etc., by Toborffy, [ibid., 37, 122, 173, 1907]; Zs. Kr., 43, 369. A yellow ferric sulphate occurring with pyrite near Leona Heights, Alameda, Cal., is referred here by Schaller (anal.), Bull. G. Univ. Cal., 3, 214, 1903.

Artif. formation; Scharizer, Zs. Kr., 43, 124.

COPPER, Min., p. 20; App., p. 19. — New structure faces on; Mügge, Jb. Min., 2, 60, 1899. Occ. in diabase, São Paulo; Hussak, Centralbl. Min., 333, 1906. Occ. at Flatschach near Knittelfeld; Cornu, Centralbl. Min., 279, 1908; in basalts of lower Rhine; Brauns, ibid., 705, 1908.

COQUIMBITE, Min., p. 956. — A green ferric sulphate from the Redington mine, Knoxville, Cal., described by Eakle and analyzed by Schaller is perhaps a mixture of coquimbite with the iron about one-half replaced by aluminium. Bull. G. Univ. Cal., 2, 322, 1901.

Artif. formation and constitutional character of its water; Scharizer, Zs. Kr., 43, 113.

Cordylite. Barium-parisite. G. Flink, Medd. om Grönland, 14, 236, 1898; ibid., 24, 42, 1901; Böggild, ibid., 33, 101, 1906.

Hexagonal. Axis $\dot{c} = 3.3865$.

Forms: c (0001), m (10 $\overline{1}$ 0), q (10 $\overline{1}$ 3), p (4.0. $\overline{4}$.15), r (20 $\overline{2}$ 3), s (40 $\overline{4}$ 3). Angle: $cp = *46 \circ 12'$.

In minute prisms with p, or less often c, p, q; also with club-shaped termina-

tion upon a slender prism.

Cleavage c, distinct. Fracture uneven. Brittle. H. = 4.5. G. = 4.31. Luster vitreous to adamantine; on c pearly. Color pale wax-yellow and transparent when fresh but often ocher-yellow and dull by surface alteration. Birefringence negative, weak. A zonal structure is seen in sections | c. Pleochroic, $\omega =$ greenish yellow, $\epsilon =$ brownish yellow. Refractive indices $\omega = 1.7640$; $\epsilon = 1.5762.$

Composition, a fluocarbonate of the cerium metals and barium, cf. parisite (Min., p. 290), Ce₂F₂BaC₃O₉ or (BaF)(CeF)Ce(CO₃)₃. Analysis, R. Mauzelius:

CO, ThO, Ce₂O₃ (La,Di)₂O₃ Y₂O₃ FeO BaO CaO H₂O F Insol. 23.47 0.30 23.72 25.67 tr. 1.43 17.30 1.91 0.80 [4.87] 2.58=102.05, deduct 2.05 = 100

The material for analysis was scanty, not perfectly pure and perhaps not quite fresh.

B. B. decrepitates, becomes brown but does not fuse; moistened with hydrochloric acid colors the flame green. Easily soluble in hydrochloric acid with effervescence.

Occurs very sparingly in loose blocks and partly in pegmatite in situ at Narsarsuk in southern Greenland. Associated particularly with parisite, neptunite and ancylite; often implanted on ægirite crystals, on neptunite and on lepidolite. Named from κορδύλη, club, in allusion to a common form of the crystals.

Cordylite.

Coronadite. W. Lindgren and W. F. Hillebrand, Am. J. Sc., 18, 448, 1904; U. S. G. S., Bull.,
262, 42, 1905; Zs. Kr., 43, 380.
Massive, with delicate fibrous structure; in general aspect resembling psilomelane. H. = 4.

G. = 5.246. Luster metallic, dull. Color black. Streak black with brownish tinge. Opaque. Composition (Mn, Pb)Mn₃O₇, assuming the water to be due to alteration. Analysis, W. F. Hillebrand:

MnO₂ PbO MnO ZnO 56.13 26.48 6.56 0.10 0.45 = 100

* With TiO₂, P₂O₅, V₂O₅ tr. † Oxidation undet. | 0.89 above 200°. \ Loss with CaO, MgO, Alk, Occurs somewhat abundantly at the west end of the Coronado vein of the Clifton-Morenci copper district, Arizona; it is intimately mixed with quartz and is obviously of secondary origin. Named after Coronado, the explorer.

Discussion of relations to hollandite, with suggestion that both are manganates of the acid

H₄MnO₅; Fermor, Rec. Geol. Sur. India, 36, 295, 1908.

CORUNDUM, Min., pp. 210, 1031; App., p. 19. — Cryst. — Twin crystal of sapphire with (1010) as twinning plane and showing new forms; Bowman, Min. Mag., 12, 355. Study of the crystallographic and optical constants by Melczer, Zs. Kr., 35, 561, 1901, and Ber. aus Ungarn, 19, 373, 1901, on Burma ruby crystals, on some Ceylon crystals and on artificial ruby crystals gave for value of caxis=1.3652. A large number of vicinal and somewhat doubtful forms in the rounded zones are given and the indices of refraction for sodium, blue and red light for crystals of different colors, are compared. Twin from Coler Fork of Cowee Creek, Macon Co., N. C.; Hidden, Am. J. Sc., 13,474, 1902. Large crystals of sapphire and ruby from Australia and Ceylon; Brauns, Centralbl. Min., 588, 1905. Pseudomorph after corundum, Perth, Ontario; Graham, Am. J. Sc., 1905. **22**, 52, 1906.

Anal. of ruby from Siam and Burma; Pfeil [Inaug.-Diss., Heidelberg, 1901]; Centralbl. Min.,

145, 1902.

lina; Lewis, N. C. Geol. Sur., Bull. 11. In syenite rocks from Ontario, Canada; Miller, Amer. Geol., 24, 276, 1899; from Hungary; Szadeczky, Földt. COVELLITE, Min., p. 68; App., p. 20. — Study of crystals from Bor in Timoker Kreis, Servia, showed that they were pseudohexagonal through twinning and in reality were monoclinic or tri-

m

m

clinic, probably the first. Angles: $(001):(111)=50^{\circ}$ 40'; $(001):(\bar{1}11)=51^{\circ}$ 30'; $(1\bar{1}1):(111)=45^{\circ}$ 20', from which the monoclinic constants à: $\ddot{b}:\dot{c}=0.5746:1:0.6168;\;\beta=90^{\circ}$ 46' were derived. The more important forms are c (001), p (111), k (012), r (034), s (011), t (043), g (032), l (021), d (031), f (041), h (092), i (051), y (0.15.2), z (081), v (091), w (0.16.1); 15 other forms listed. Anal. given. Stevanovic, Zs. Kr., 44, 349. Artif; Cornu, Jb. Min., 1, 30, 1908.

CRISTOBALITE, Min., p. 193. — Occurrence at Mayen, Eifel, with optical study; Gaubert, Bull. Soc. Min., 27, 242, 1904.

CROCOITE, Min., p. 913; App., p. 20. — Crystals from Tasmania show following new forms: a (100), x (301), θ (331); Moesz [Math. és term. tud. Értesitó, 17, 436, 1899]; Zs. Kr., 34, 707; f_1 (470); Slavik, Zs. Kr., 39, 302; J (032); Van Name, Am. J. Sc., 13, 339, 1902, (fig.); also see Anderson, Rec. Aus. Mus., 6, 141, 1906; Zs. Kr., 45, 314.

Artif. formation; Cesàro, Bull. Ac. Belg., 327, 1905.

CROSSITE, see Amphibole.

Crocoite, Tasmania CRYOLITE, Min., pp. 166, 1032; App., p. 20. — On heating to 570° changes to isotropic material and reverse change takes place on cooling; Nacken, Centralbl. Min., 38, 1908; Cornu, ibid., 546.

Cryolithionite. N.-V. Ussing, Overs. Dansk. Vid. Selsk. Forh., No. 1, 1904.

User vitreous. Colorless. Perfectly transparent. Optically isotropic, indices $n_r = 1.3382$ (Li), $n_y = 1.3395$ (Na), $n_{gr} = 1.3408$ (Tl).

Composition Li, $Na_3Al_2F_{12}$; or similar to a cryolite with half the sodium replaced by lithium.

Analysis, Chr. Christensen:

F Na Li Ign. 60.79 14.46 18.83 0.36 = 99.79.

B. B. fuses even more easily than cryolite (fusibility 710°, for cryolite 920°). In the closed tubes decrepitates violently and fuses to a colorless liquid; at a red heat decomposes, giving off fumes. Soluble in water, more readily than cryolite (1 gram in 1350 gr. water at 18°).

From the cryolite deposits at Ivigtut, Greenland, where it occurs sparingly, entirely embedded

in the cryolite.

The name is given in allusion to the presence of lithium and the relation to cryolite. Obtained in cubic crystals from the aqueous solution of the mineral; also obtained in crystalline condition in cooling from the fused mineral.

CUBOSILICITE, see Quartz.

CUMENGITE, see under Boleite.

Cuprite, Min., p. 206; App., p. 21. — Artif.: — Crystals found in copper furnace at Åtvidaberg, Sweden; Strandmark, Geol. För. Förh., 24, 80, 1902.

Cuprobinnite. A. Weisbach, Char. Min., 1880, 42. The same as binnite (= tennantite).

CUPRODESCLOIZITE, Min., p. 787. — Occurs at Nogales, Arizona, in layers with fibrous structure, color reddish brown, G. = 6.176. Analysis. Headden, Proc. Colo. Soc., 7, 149, 1903; Zs. Kr., 41, 203.

* State of oxidation not determined.

Obs. Found associated with strüverite in pegmatite at Graveggia, Val Vigezzo, Piedmont. Named in honor of geologist Dr. G. DeLorenzo.

Delorenzite Descloizite, Min., p. 787; App., p. 22. — Crystals from Bena a Padru, Sardinia; Lovisato, Rend. Acc. Linc., 13, (2), 43, 1904; Broken Hill, N. W. Rhodesia, with new form (310); Spencer, Min. Mag., 15, 31, 1908; from near Saïda, Oran, Algiers; Lacroix, Bull. Soc. Min., 31, 44, 1908.

Deweylite, Min., p. 676. — Chem. comp.; Fogy, Ber. Ak. Wien, 115, 1081, 1906; Zambonini, Mem. Acc. Sci. Napoli, 14, 84, 1908.

DIAMOND, Min., pp. 3, 1033; App., p. 22. — New form on crystal from East Indies (531); inclusions of potassium mica; Jeremejew, [Bull. Ac. Sc. St. Pétersbourg, 6, 1897]; Zs. Kr., 31, 508. Electric properties of diamond; Artom, Att. Acc. Torino, 37, 667, 1902. Action of radium emanations on diamond; Crookes, Chem. News, 90, 1.

Origin of; Crookes, Nature, 72, 593, 1905.
Occ. — Bort crystals from Transvaal; Jeremejew, [Verh. russ. min. Ges., 36, 34, 1898], Zs. Kr., 31, 115, redd grand Trigge, Lucisciek, Puscipe, Levenger, [Bull. Ac. Sc. St. Pétersbourg, 9, 5, 1905].

32, 431; in gold gravel, Taiga, Jenisseisk, Russia; Jeremejew, [Bull. Ac. Sc. St. Pétersbourg, 8, 5, 1898]; Zs. Kr., 32, 427; in California; Turner, Am. Geol., 23, 182, 1899. Many rich diamond deposits have been located in South Africa recently at points far distant from those earlier developed. Here belong the group of mines of which the Premier is best known. Others occur farther north in Rhodesia, in the Somabula Forest, where the diamond, often of green tinge occurs, rather abundantly in gravels with enstatite, chrysoberyl, cyanite, sapphire, etc.; Mennell, Geol. Mag., (5), 3, 459, 1906; reported by E. David as found in the matrix near Inverell, New South Wales, Nature, 74, 550, 1906. Garnet found embedded in diamond from Wesselton mine, Kimberley, S.A.; Sutton, Nature, 75, 488, 1907. Found in masses of garnet, pyroxene and cyanite occurring as nodules in the "kimberlite" at Roberts Victor Diamond mine, Boshof, Orange River Colony, So. Africa; Corstorphine, Trans. Geol. Soc. So. Africa, 10, 65, 1907; Am. J. Sc., 25, 87, 1908. In a peridotite stock at Murfreesboro, Pike Co., Ark. The stones have been mostly found in the detritus from the stock, but one has been observed embedded in the peridotite. They average about 1 carat in weight, but one weighing 6½ carats was found. They vary in color from clear and colorless to brown, yellow and almost black.. The crystals are chiefly distorted hexoctahedrons, and frequently twinned. Kunz and Washington, Am. J. Sc., 24, 275, 1907; Trans. Am. Inst. Min. Eng., March, 1908.

The discovery of an extensive alluvial diamond field in Luderitzbuchte, German Southwest

Africa, is reported.

Artif. — Formed in a silicate fusion; Friedländer, [Verh. Ver. Beförd. Gewerbfleisses, Berlin, 1898]; Zs. Kr., 33, 490; also Hasslinger and Wolf, Ber. Ak. Wien, 112, (26), 507, 1903; and Hasslinger, Monatshefte, 23, 817; Ludwig, Chem. Zeit., 25, 979; Crookes, Proc. Roy. Soc., 76, 458, 1905.

Inger, Monatsherte, 25, 317; Eddwig, Chem. Zeit., 20, 373; Crookes, Floc. Roy. Soc., 10, 453; 1905; Chem. News, 42, 148; in residues obtained by exploding cordite in closed steel cylinders; Burton, Nature, 72, 397, 1905. Moissan on influence of presence of S, Si and P in artif. formation, C. R., 140, 277, 1905; [Ann. Chim. phys., 5, 174, 1905]; Zs. Kr., 44, 522.

Large diamonds. — The "Colenso" diamond, presented to the British Museum by John Ruskin in 1887, weighs 1293 carats, Min. Mag., 13, 193, 1902. The Vienna collection has a diamond weighing 82.5 carats (Vienna), presented by G. von Haas; Min. Mitth., 19, 340, 1900.

The Excelsion diamond found at Larger fontein South Africa in 1903, is now known as the Jubilee The Excelsior diamond, found at Jagersfontein, South Africa, in 1903, is now known as the Jubilee. Weight = 239 carats. "Cullinan" or "Premier" diamond, found at Premier mine, Transvaal, largest yet known, weighing 3024 carats and measuring 4 by 2½ by 2 inches; Hatch and Corstorphine, Geol. Mag., 2, 170, 1905; Am. J. Sc., 19, 395; this stone has been presented to the King of England by the Transvaal Government and has been cut into 9 large stones, the 4 largest weighing 5161, 30916, 92, and 62 carats respectively; and into 96 smaller brilliants; Kunz, Century Mag., June, 1909.

Diaspore, Min., pp. 246, 1033. — Occurs in crystals (new form d (031)) on Övre Arö, Langesund, Norway; Flink, Bull. G. Inst. Upsala, 4,25, 1899. Crystals from Massachusetts; Cesàro, Bull. Ac. Belg., 313, 1907.

Dickinsonite, Min., p. 809. — Probable occurrence at Bokuwka, Kielce, Russia; Glinka [Ann. Geol. Min. Russie, 4, 63, 1900], Zs. Kr., 37, 412.

DIMORPHITE, Min., p. 35. — Study by Krenner, Zs. Kr., 43, 479, of crystals of arsenic sulphide (As, S3) prepared by Schuller by sublimation in vacuum showed them to be orthorhombic with &: \dot{b} : \dot{c} = 0.58787:1:0.88258 with following forms: c (001), p (111), m (110), d (101), t (021), b (010), n (120). Ax. pl. \parallel (010); Bx_{ac} \parallel \dot{a} . Axial angle measured in Toulet solution with n=1.6654 gave $2H_a=108^\circ$ 46'. Optically +. If orientation of type 2 of dimorphite be changed so that its e=m of artif. crystals; m=p; i=d; $o^2=t$; C=c; B=b, the crystals and angles are closely identical as follows:

> Artif. Dimorphite type 2. $ii = 67^{\circ} 15'$ $dd = 67^{\circ} 20'$ $pm = 29^{\circ} 52'$ $mc = 29^{\circ} 40'$ $pc = 60^{\circ} 8'$ $Cm = 60^{\circ} 20'$, etc.

Type 2 of dimorphite may then be considered as a definite species.

Considered by Stenanović, Zs. Kr., 39, 18, to be identical with orpiment, the face e (011) of the former being a (100) of the latter.

DIOPTASE, Min., pp. 463, 1033; App., p. 23. — Anal. of material from Kirghisen-Steppe gave: SiO₂, 38.25; CuO, 50.18; H₂O, 11.39; Fe₂O₃, 0.13; total, 99.95; Zambonini, Zs. Kr., 34, 229; occurs sparingly in crystals at the Stevens mines, near Garfield Gulch in the Clifton-Morenci district, Arizona; Lindgren and Hillebrand, Am. J. Sc., 18, 452. 1904; occ. and associated minerals from Mindouli, French Congo; Lacroix, Bull. Min. Soc., 31, 247, 1908. Loss of water on heating and discussion of chem. comp.; Zambonini, [Mem. Acc. Linc., 5, 344; 6, 102, 1905]; Zs. Kr., 43, 404; Mem. Acc. Sci. Napoli, 14, 44, 1908.

DIPYRE cf. Missonite.

DITTMARITE, Min., p. 807. — In small transparent rhombic crystals from bat guano deposits near Skipton, 30 miles S. W. from Ballarat, Australia. Anal. yields formula: $MgNH_4PO_4.2Mg_2H_4$ (PO_4)_{2.8}H₂O. Anal.:— P_2O_5 , 46.51; MgO, 26.13; (NH_4)₂O, 3.94; H₂O, 23.42; total, 100.00. MacIvor, Ch. News, 85, 181, 1902.

Dognacskaite, Min., p. 111. — New analyses, one giving for formula 3Cu₂S.Bi₂S₃ (wittichenite, Min., p. 128), but a later and apparently more careful analysis (see below) gave Cu. S. 2Bi, S.

> Bi Anal. (Neugebauer): G. = 6.79 17.91, 71.88 10.04 = 99.83

Koechlin, Min. Mitth., 24, 117, and Neugebauer, ibid., 323.

Dolerophanite, Min., p. 924. — Observed as a furnace product at Atvidaberg in Östergötland: Strandmark, Zs. Kr., 36, 456, 1902; Geol. För. Förh., 24, 80, 1902.

DOLOMITE, Min., pp. 271, 1033; App., p. 23. — An exhaustive study of the mineral, chiefly from Alpine localities, with 35 analyses and frequent optical determinations, with the results that it was established that the lime content of the mineral remains constant and that only the magnesia is replaced by other oxides, and that with increase of iron oxide present the angle $r \wedge r$ decreases in value while the density and indices of refraction increase; Eisenhuth, Zs. Kr., 35, 582, 159, 1905]; Zs. Kr., 43, 496.

Domeykite, Min., p. 44. — Mohawkite (G. A. Koenig, Am. J. Sc., 10, 439, 1900) is a variety of domeykite (Cu₃As) from the Mohawk mine in Keweenaw Co., Michigan, containing nickel and Occurs massive, fine granular to compact. Artif. crystals obtained were apparently hexagonal; Koenig and Wright, Proc. Amer. Phil. Soc., 43, 219, 1903. Color gray, with faint tinge of yellow; tarnishes easily, finally to a dull purple. H. = 3.5, brittle. G. = 8.07. Composition (Cu,Ni,Co)₃ As. Analysis, Koenig: As, 28.85; Cu, 61.67; Ni, 7.03; Co, 2.20; Fe, tr. = 99.75. Another specimen, resembling arsenopyrite, showed a much smaller amount of nickel and cobalt, viz.: As, 28.10; Cu, 67.86; (Ni,Co), 3.32 = 99.28, Am. J. Sc., 14, 413, 1902.

Koenig also obtained (Am. J. Sc., 10, 442, cf. also 14, 413, 1902), for domeykile from the Shel-

don-Columbia mine in the Keweenaw region: As, 26.14; Cu, 74.00; (Fe, Ni, Co), 0.06 = 100.20, G.= 7.949. He concludes that earlier determinations of the specific gravity are too low $(G_{\cdot} = 7.2 -$ 7.75). Synthetic experiments yielded a product having the composition Cu_2As with G=7.71; also the domeykite compound, Cu_3As with G=8.05; minute crystals obtained appeared to resemble arsenopyrite. See also Whitneyite.

Another variety of domeykite from the Mohawk mine, containing a small amount of antimony, is called by Koenig (ibid., p. 445) stibiodomeykite. Resembles the domeykite from the Houghton Co. mines. Occurs massive with conchoidal fracture, very brittle, less friable than mohawkite. H. = 4, or a little below. G. = 7.902. Speedily assumes a brass tarnish, finally becoming bluish purple. An analysis gave: As, 26.45; Sb, 0.78; Cu, 72.48; (Fe,Ni,Co), 0.24 = 99.95. Another sample gave 1.29 Sb. Antimony is absent from the Houghton Co. domeykite.

Artif. crystals of domeykite closely resembling chalcocite described by Stevanovic, Zs. Kr.,

37, 245, 1902.

Artif. crystals also described by Koenig and Wright which were hexagonal normal with c = 11.539 and showed following forms; c(0001); a(1120)?; b(1010); z(2023); v(1011); p(2021); x (1122)?; also artif. crystals of argentodomeykite and stibiodomeykite belonging to hexagonal, normal; Koenig and Wright, Proc. Amer. Phil. Soc., **43**, 219, 1903.

Occurrence of domeykite at Flatschach near Knittelfeld, Styria; Cornu, Centralbl. Min., 277,

1908.

Domingite, see Warrenite.

DOPPLERITE, Min., pp. 1014, 1015. — Occurrence in the Fichtelgebirge, North Bavaria, noted; Schmidt, Centralbl. Min., 525, 1901.

Doughtyite. W. P. Headden, Proc. Col. Sc. Soc., 8, 55, 1905.

A deposit formed rather abundantly by the action of alkaline waters of the Doughty Springs in Colorado; it forms a white precipitate sometimes three-quarters of an inch in thickness, over an extensive surface. A sample, after drying in the air five weeks, yielded:

Fe₂O₃ SO. Al₂O₃ ZnO MgO H₂O SiO2 Sand 15.00 0.45 0.44 41.80 39.51 tr. 1.91 1.56 = 100.67

For the above the formula $Al_2(SO_4)_3.5Al_2(OH)_6.21H_2O$ is calculated. Alunogen occurs at the same springs, ibid., 62.

Dubuissonite. C. Baret, [Bull. Soc. Sci. Nat. de l'ouest de la France, 4, 141, 1904]; Spencer, Min. Mag., 14, 398, 1907. — A pink clay from near Nantes resembling montmorillonite but different in its resistance to acids and in its fusibility. Named after M. Dubuisson, mineralogist, of Nantes.

Dufrenite, Min., p. 797.—Occurrence as alteration product of triplite (with anal.) at Cyrillhofer, Mähren; Kovář and Slavik, [Verh. geol. R.-Anst., Wien, 50, 347, 1900]; Zs. Kr., 36, 642.

DUFRENOYSITE, Min., p. 120; App., p. 23. — Proven by Solly to be monoclinic. $\dot{a}:\dot{b}:\dot{c}=0.6509:1:0.6125;$ $\beta=89^{\circ}26\frac{1}{2}$. With the new orientation (001) of vom Rath becomes (010), (100) = (001), (010) = (100) while (111) remains unchanged. Ninety-nine forms are listed, the most prominent being a (100), b (010), c (001), (101), (101), (101), (530), (210), (410), (052), (032), (011), (012). Angles: $100 \wedge 110 = 33^{\circ} 3\frac{3}{4}', 001 \wedge \bar{1}01 = 32^{\circ} 59\frac{3}{4}', 001 \wedge 011 = 31^{\circ} 29\frac{1}{4}', 100 \wedge 101 = 47^{\circ} 2\frac{1}{4}'^{*}, 101 \wedge 001 = 42^{\circ} 31\frac{1}{4}'^{*}, 010 \wedge 111 = 65^{\circ} 51\frac{1}{4}', 010 \wedge 11\bar{1} = 66^{\circ} 3\frac{1}{4}', 010 \wedge 212 = 77^{\circ} 22^{*}.$

Two types of crystals are described, (1) elongated ||a| axis, with b prominent, (2) elongated ||b|axis.

Cleavage: b perfect. Min. Mag., 13, 160; Zs. Kr., 37, 331; also Baumhauer, Zs. Kr., 38, 649. Analyses of material from the Binnenthal; Guillemain, [Inaug.-Diss., Breslau, 1898], Zs. Kr.,

Dumortierite, Min., p. 558. — Analyses of material from Clip, Arizona; San Diego Co., Calif., Harlem, N. Y., by Ford, Am. J. Sc., 14, 426, 1902; Zs. Kr., 37, 417, 1902; and from San Diego Co., and Woodstock, Washington, by Schaller, Am. J. Sc., 19, 211, 1905; Zs. Kr., 41, 19, 1905. Ford considers that the boric oxide and water are basic in character and derives for the formula, (AlO)₁₆Al₄ (SiO₄)₇, while Schaller finds more probable that they are present in definite proportions and gives for the formula 8Al₂O₃.1H₂O_{.6}SiO₂.

A partial analysis on impure material from Val Donbastone, Veltlin; Linck, Zs. f. Naturwiss.,

Jena, 33, 356; Zs. Kr., 35, 319. Color pistache green with strong pleochroism, $\mathfrak{a}=\mathfrak{b}$, colorless, c pistache green. Indices $\alpha=1.678,\ \beta=1.686,\ \gamma=1.689.$

Occurrence with corundum, which see.

Dundasite, App., p. 23. — Petterd in Papers and Proc. of R. Soc. Tasmania, 18, 1902, gives a new locality in Tasmania at Hercules mine, Mt. Read. Prior, Min. Mag., 14, 167, describes its occurrence in Welsh Foxdale mine, near Trefriw, Carnarvonshire. Its characteristics are summarized as: occurs in white spherical aggregates or tufts of minute, radiating needles. H. = 2. G. = 3.25. Vitreous luster. Color white. Transparent. Refraction and double refraction, fairly strong: needles give parallel extinction and are positive.

Chemical formula: — PbO.Al₂O₃.2CO₂.4H₂O; PbO, 45.95; Al₂O₃, 21.07; CO₂, 18.14; H₂O, 14.84. I, Prior, N. Wales, loc. cit. II, Pascoe, Tasmania, loc. cit.:

	PbO	Al ₂ O ₃	Fe ₂ O ₃	CO,	H ₂ O	Insol.	Total
1	43.20	Al_2O_3 21.39	1.61	16.45	15.01	1.80	99.46
II	41.86	26.06	5.50	28.	08		101.50

DYSANALYTE, Min., p. 724.—Crystals showing cube and dodecahedron from Mte. Somma, Italy; Zambonini, Rend. Acc. Sci., Napoli, April, 1908.

Dyscrasite, Min., p. 42; App. p. 24.—Occurrence (with anal.) at Cobalt, Ontario; Miller, Rep. Can. Bureau Mines, Pt. 2, 1905; Zs. Kr., 43, 395.

Ebelmenite, [Coll. Min. Mus. d'Hist. Nat., Paris, Guide du Visiteur, p. 29, 1900]; Spencer, Min. Mag., 14, 398, 1907. A variety of psilomelane containing potassium. Named after Jacques J. Ebelmen (1814-52).

Edingtonite, Min., p. 599; App., p. 24. — Crystals from Kilpatrick, Scotland; Goodchild, [Trans. Geol. Soc. Glasgow, 12, Suppl., 1–68, 1903]; Zs. Kr., 45, 307; crystals from Böhlet, Sweden, and Kilpatrick. Indices of refraction on crystal from Böhlet, for Na light; $\alpha=1.5407$, $\beta=1.5529$, $\gamma=1.5556$. Axial angle = 49° 46′. Sjögren, G. För., Förh., 28, 169, 1906.

Eglestonite. A. J. Moses, Am. J. Sc., 16, 253, 1903. [W. H. Turner, Mng. Sci. Press, July 21, 1900.] Hillebrand and Schaller, Am. J. Sc., 24, 271, 1907.

Isometric. In minute crystals of dodecahedral habit, with also a (100), n (211) and s (321);

crystals sometimes united loosely in a crust. Schaller observes twenty-one forms. none. Fracture uneven. Brittle. H. = 2-3. G. = 8.327. Luster brilliant adamantine to resinous. Color brownish yellow to yellowish Cleavage

brown, darkening on exposure to sunlight and becoming finally black; powder when fresh greenish yellow to canary yellow. Transparent. Composition; mercurous oxychloride, Hg₄Cl₂O (Hillebrand); Hg, 90.21; Cl, 7.99; O, 1.80.

Analyses 1-5 by J. S. McCord; 6-8 by Hillebrand.

	1	2	3	4	5	6	7	8	
Cl	8.72	7.24	7.81	7.68	8.20	8.32	8.23	8.12	W YIII

B. B. in the closed tube decrepitates, becomes orange-red, evolves dense white fumes and yields a white non-crystalline sublimate (chloride); finally volatilizes completely, yielding a ring of chloride and beyond a mercury mirror. Volatilizes completely on charcoal without fusion. Decomposed by HCl and HNO₃ with separation of calomel.

From the mercury locality at Terlingua, Texas, with terlinguaite, montroydite, calomel,

native mercury and calcite.

Named after Professor Thomas Egleston (1832-1900) of Columbia University, New York.

EKMANNITE, Min., pp. 662, 1033. — Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 30, 1908.

Elpidite, App., p. 24. — Crystals from Narsarsuk, Greenland; Flink, Medd. om Grönl., 14, 230, 1898; 24, 146, 1901; optical study. Axial angle $2V_0 = 90^\circ$ 20'. Böggild, ibid., 33, 118, 1906.

Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 59, 1908.

Embolite, Min., p. 159. — See Cerargyrite.

Emmonsite, Min., p. 979. — Possible occurrence at W. P. H. mine at Cripple Creek with analysis; Hillebrand, Am. J. Sc., 18, 433.

Enargite, Min., pp. 147, 1033; App., p. 24.—Crystals of enargite from Caudalosa, Peru, described with new forms S (410), T (430), F (980), N (230), P (250), L (270), R (140), Q (150), D (160), B (205), M (201), G (041); H (061), also analysis; Stevanović, Zs. Kr., **37**, 241, 1902; also crystals (with anal.) from Borin Timoker Kreis, Servia; ibid., **44**, 349, 1907; from Chorolque,

Bolivia; Spencer, Min. Mag., 14, 344.

Analyses of material from San Juan County, Colorado, and Morococha, Peru; Guillemain, [Inaug.-Diss., Breslau, 1898], Zs. Kr., 33, 77; of crystals from the Powers mine, Willis Gulch, Gilpin Co., Colorado; Headden, Proc. Col. Sc. Soc., 8, 61, 1905.

Crystals of "luzonite" from Mancayan, Luzon, Philippine Is., occurring in cavities or on the by Sevanović: $(\frac{1}{2})$ S, 31.01; As, 9.09; Sb, 12.74; Cu, 45.43; Fe, 0.67; residue, 0.65 = 99.59; G. = 4.47.

Zs. Kr., 37, 239, 1902.

Endeiolite. G. Flink, Medd. om Grönland, 24, 166, 1901.

Isometric. Only in minute octahedrons, isolated or forming crusts. Twins common, tw. pl. o. Cleavage none. Fracture subconchoidal to splintery. H. = 4. G. = 3.44, Mauzelius. Luster on crystal faces vitreous inclining to metallic, on the fracture greasy. Color dark chocolate-brown. Streak yellowish gray.

Composition, perhaps RNb₂O₆(OH)₂.RSiO₃. The analysis showed a loss of 11.48 p. c., assumed to be SiO₂ after the analogy of chalcolamprite. Analysis, Mauzelius:

Nb₂O₅ SiO₂ 59.93 * [11.48] TiO2 ZrO2 Ce₂O₃ Fe₂O₃ MnO CaO K_2O H₂O 0.76 3.78 4.43 2.81 0.37 7.89 0.43 3.58 4.14 0.69 =100.29 (less O, 0.29) = 100* Contains Ta₂O₅ in small amount.

Occurs at Narsarsuk in Southern Greenland implanted upon ægirite crystals; associated with

elpidite, leucosphenite, epididymite, etc. Named from ἔνδεια, want, and λίθος, stone, in allusion to the fact that the analysis showed a considerable loss.

ENSTATITE, Min., p. 346; App., p. 24. — Clear green material from the diamond washings, South Africa, determined as enstatite. Prism angle, measured on cleavage faces, $= 88^{\circ}$ 0'. Plane of optic axes $\parallel b$ (010). Bx \perp c (001). $2V = 74^{\circ}$ 5'. $\beta = 1.669$, $\gamma = 1.675$. Dispersion $\rho > \nu$. Pleochroism weak; α , pale yellow; \mathfrak{h} , pale green; \mathfrak{c} , pale yellowish-green. Approximate analysis gave: SiO₂, 56.0; FeO, 5.0; MnO, 0.5; Al₂O₃, 2.5; Cr₂O₃, 0.6; MgO, 36.5; total 101.1. Bowman Min Mag 12, 349, 1900.

Bowman, Min. Mag., 12, 349, 1900.

Anal. of bronzite from Flysch near Višegrad, Bosnia; Schiller, Min. Mitth., 24, 316, 1905.

Artif. Prepared by heating a glass of composition MgSiO₃ to below 1100°, producing enstatite in fibrous aggregates and radial spherulites. Transformed into a monoclinic variety at 1500°.

Allen, Wright and Clement, Am. J. Sc., 22, 385, 1906.

EPIBOULANGERITE, Min., p. 149. — Identity questioned by Guillemain; [Inaug.-Diss., Breslau, 1898], Zs. Kr., 33, 74.

EPIDIDYMITE, App., p. 24. — Crystals from Narsarsuk, Greenland; Flink, Medd. om Grönl., 24, 61, 1901; also, Böggild, ibid., 33, 105, 1906.

EPIDOTE, Min., p. 516; App., p. 25. — Crystals of large size and complex form are described from the Peacock and White Monument mines, Seven Devils mining district, Idaho; Palache, from the Peacock and White Monument mines, Seven Devils mining district, Idaho; Palache, Am. J. Sc., **8**, 299, 1899; association of epidote with zoisite from Mt. Pelvas, with discussion of the crystallographic and optical relations of the two minerals; Termier, Bull. Soc. Min., **23**, 50, 1900; crystals from Eule, Bohemia; Barvíf, Ber. d. k. böhm. Ges. d. Wiss., **12**, 1901; finely crystallized specimens from Sulzer, Prince of Wales island, Alaska; Palache, Proc. Amer. Acad., **37**, 531, 1902; new forms O (544) and X (322) are noted; crystals from Zöptau, Mähren; Neuwirth, Min. Mitt., **22**, 584, 1903; from near Barrisdale, Inverness-shire, England; Thomas, Min. Mag., **14**, 109, 1905. Anal. gave 6.81 per cent Fe₂O₃. $\alpha = 1.714$, $\beta = 1.7196$, $\gamma = 1.725$; $2V = 89^{\circ}$ 35'; crystals from various Greenland localities; Böggild, Min. Grönl., 252, 1905; from Val di Viù, Italy, with new forms m (117), n (119), Y (214); also optical study; Toborffy, Zs. Kr., **43**, 564, 1907; from Lyon Mt., Clinton Co., N. Y.; Whitlock, N. Y. State Mus. Bull., **107**, 70, 1907; Zambonini describes crystals from Sulzbach, Tyrol, with new forms (302), (16.0.15); Jb. Min., 1, 181, 1900; from Colle del Paschietto, Ala; Zs. Linc., 15, (2), 179, 1906. Analysis of material from Phippsburg, Maine; Hillebrand, Clarke, Bull. 167, 70, U. S. G. S., 1900; Zs. Kr., 36, 79; of material from Striegau, Silesia, and Zöptau, Mähren; Pfeil, [Inaug.-Diss., Heidelberg, 1901]; Centralbl. Min., 144, 1902. Rôle of water in; Zambonini, Mem. Acc. Sci. Napoli, 14, 16, 1908.

Epistilbite, Min., p. 577. — Crystals from Nadap, Hungary; Mauritz, Ann. Mus. Nat. Hung.,

546, 1908. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 115, 1908.

Epistolite. O. B. Böggild, Medd. om Grönland, 24, 183, 1900.

Monoclinic. Axes à : \dot{b} : \dot{c} = 0.803 : 1 : 1.206. β = 74° 42′. Forms: c (001), m (110), s (102), r (504), o (011). Angles: $cm = *78^\circ$ 0′; $co = 49^\circ$ 20′; $mm''' = 77^\circ$ 30′ (*102° 30′ angle of prismatic traces on cleavage fragments $\|c$). In rectangular plates, tabular $\|c$, usually enclosed in albite, rarely showing projecting edges; also in massive aggregates of curved folia.

Cleavage: c very perfect, yielding thin leaves; also m (or other face in zone cm) distinct.

Very brittle. H. = 1-1.5. G. = 2.885.

Luster, on c pearly. Color white, grayish or brownish. Transparent to translucent. Optically negative; birefringence strong. Ax. pl. $\parallel b$. $c \wedge a = 7^{\circ}$ approx. Dispersion inclined, $v < \rho$. $2V = 80^{\circ}$ approx. Refractive index 1.67.

Composition, formula uncertain, as the mineral was partly altered.

Analysis, Chr. Christiansen:

From the nephelite-syenite region of Julianehaab, Greenland, both on the Firth of Tunugdliarfik and of Kangerdluarsuk; it occurs partly in pegmatitic veins, partly in a massive marble-like albite, associated with sodalite, arfvedsonite, ægirite, steenstrupite, eudialyte, sphalerite, also with rinkite and polylithionite.

Named from ἐπιστολή letter, in allusion to the flat rectangular form and white color.

Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 69, 1908.

Epsomite, Min., p. 938; App., p. 25. — Occurs crystalline near Wilcox Station, 65 miles N. of Laramie, Wyo.; Farrington, Colum. Mus. Bull. 1, 228, 1900; also id. with Tillotson, ibid., 3, 7, 145, Twins on (110); Johnsen, Centralbl. Min., 728, 1903.

Occurs (anal.) with pyrite near Leona Heights, Alameda Co., Cal.; Schaller, Bull. G. Univ. Cal.,

3, 216, 1903. Anal. from Cripple Creek, Colo.; Hobbs, Amer. Geol., 36, 184, 1905.

O. B. Böggild, Medd. om Grönland, 26, 93, 1903.

Orthorhombic. Axes $\check{a} : \check{b} : \dot{c} = 0.57552 : 1 : 0.75796$

Forms: a (100), b (010), c (001), m (110), n (120), o (130), p (270), r (101), s (201), d (012), e (011), f (032), g (021), h (052), i (031), u (114), t (111). Angles: $mm''' = 59^{\circ}$ 50', $oo' = 60^{\circ}$ 10', $bn = *40^{\circ}$ 59', $cr = 52^{\circ}$ 47½', $dd' = 41^{\circ}$ 31', $gg' = 113^{\circ}$ 10', $bf = *41^{\circ}$ 20'. In prismatic crystals, a, o with c, nearly hexagonal in angle, also

highly modified, a prominent; o faces striated vertically also p.

Cleavage none. Fracture uneven. H. = 5.5-6. G. = 3.493. Color light yellowish brown to dark grayish brown, varying in the same crystal. Streak colorless. Nearly opaque. Thin sections under the microscope show a complex structure: a network of a yellow substance of high birefringence, sometimes porous, but usually enclosing a colorless substance of lower birefringence, which last is uniaxial and positive.

Erikite.

Composition uncertain because the original mineral has obviously suffered alteration; further, it is regarded as probable that the colorless uniaxial substance seen in microscopic sections may be hydronephelite present in unknown amount and not admitting of separation. Perhaps related to britholite. Analysis:

B. B. in the closed tube loses water and becomes white; in the forceps fuses on the edges to a

white enamel. Decomposed by acids without gelatinization.

From the hill Nunarsinatiak at the Tunugdliarfikfjord in Southern Greenland where it occurs in pegmatitic veins in nephelite-syenite, associated with arfvedsonite and ægirite, also analcite and natrolite; found by N. V. Ussing in 1900. The same locality has yielded steenstrupite and epistolite.

Named after Erik the Red, who discovered Greenland in 986 and after whom this fjord was

formerly called Eriksfjord.

ERYTHRITE, Min., p. 817; App., p. 25. — Occurrence at Cobalt, Ontario; Miller, Rep. Can. Bureau Mines, 2, 1905. Refractive indices; Gaubert, Bull. Soc. Min., 30, 107, 1907. Artif.; de Schulten, ibid., 26, 87, 1903.

ERYTHROSIDERITE, Min., p. 176. — Occurrence in fumaroles of eruption of April, 1906, at Vesuvius; Lacroix, Bull. Soc. Min., 30, 252, 1907.

Esmeraldaite. A. S. Eakle, Bull. Geol. Univ. California, 2, 320, 1901.

A hydrous ferric oxide from Esmeralda County, California. In small pod-shaped masses enclosed in a yellowish brown earthy and highly siliceous limonite. Fracture conchoidal. Very brittle. H. = 2.5. G. = 2.578. Luster vitreous. Color coal-black. Streak yellowish brown. Analysis, W. T. Schaller:

If only the iron and water are regarded as essential, the analysis, recalculated, yields: Fe₂O₃, 68.20; H₂O, 31.80=100. This corresponds to Fe₂O₃,4H₂O. The mineral resembles melanosiderite.

Euclase, Min., p. 508; App., p. 25. — Crystals from near Hochnarr, Austria; Koechlin, Min. Mitth., 24, 329, 1905; from Döbschütz near Görletz in Silesia; Kolbeck and Henglein, Centralbl. Min., 335, 1908. Occurrence in granite at Epprechtstein in Fichtelgebirge, Bavaria; Bücking, Centralbl. Min., 425, 1908.

EUDIALITE, Min., pp. 409, 1034; App., p. 25. — Crystals from Greenland with anal. by Christensen; Min. Grönl., 494, 1905; Flink, Medd. om Grönl, 14, 231, 1898; 24, 90, 1901; Ussing, ibid., 16, 145, 1898.

EUDIDYMITE, Min., p. 313. — Crystals from Narsarsuk, Greenland; Flink, Medd. om Grönl., **14**, 230, 1898; **24**, 56, 1901.

Euxenite, Min., p. 744. — The supposed occurrence of an oxide of a new element in euxenite, named "euxenerde," described by Hofmann and Prandtl, with analyses of material from Arendal and Brevig, Berichte Chem. Ges., 34, 1064. Tests for germanium in euxenite and samarskite from various localities gave only negative results; Lincio, Centralbl. Min., 142, 1904. Anal. of material from Transvaal; Aars [Inaug.-Diss., Freiburg i. Br., 1905]; Centralbl Min., 247, 1907.

Probable occurrence in bed of Tschoroch river, Province Batum, Russia, with anal.; Tschernik, [Ann. Géol. Min. Russ., 5, 196, 1902]; Zs. Kr., 39, 625. Found at Karra akungnak, with anal. by Christensen; Böggild, Min. Grönl., 511, 1905. Occurrence of euxenite and polycrase in southern Norway with discussion of their crystallographic and chemical relations; Brögger, Min. Süd-Nor.

Granitpeg., 82, 1908.

Radioactive euxenite (?) from Madagascar; Lacroix, Bull. Soc. Min., 31, 312, 1908.

Evansite, Min., p. 846; App., p. 25. — Anal. of material from Gross-Tresny, Mähren; Kovář, [Abh. böhm. Akad., No. 15, 1, 1896]; Zs. Kr., 31, 524; from Goldburg, Idaho, and coal seam west of Columbiana, Ala.; Schaller, Am. J. Sc., 24, 155, 1907; Zs. Kr., 44, 4.

FAUJASITE, Min., p. 598. — Occurrence with datolite at Daisy mica mine, Derry township, Ottawa County, Quebec; Hoffmann, Am. J. Sc., 12, 448, 1901.

• Favas. — Name given to various minerals occurring as rolled pebbles in the diamond sands of Brazil. Some of them consist almost entirely of TiO₂, others of nearly pure ZrO; Hussak, Min. Mitth., 18, 334; Zs. Kr., 33, 639; Hussak and Reitinger, Zs. Kr., 37, 566; see also Gorceixite.

FAYALITE, Min., pp. 456, 1034; App., p. 26. — Altered material from granulite at Villacidro, Sardinia; Lovisato, Rend. Acc. Linc., 12, (2), 10, 1900. Occurrence in amphibole granite, quartz syenite and nepheline rocks near Wausau, Wis. Analysis given. Weidman; Jour. Geol., 12, 551, 1904; Zs. Kr., 42, 306. Manganiferous fayalite from Agramer Gebirge, Hungary; Kišpatić

[Abh. der Südslavischen Akad., 167, 1906]; Zs. Kr., 45, 404.
Formed by the melting together of the andesite walls and the iron contents of an iron warehouse at St. Pierre, at the time of the eruption of Mt. Pelée, Martinique. The resulting slag consisted of a mixture of fayalite, magnetite and a little glass. In the cavities the fayalite was in isolated crystals; Lacroix, C. R., 136, 28, 1903; Zs. Kr., 41, 106.

FEATHER ORE, see under Jamesonite.

Fedorowite, see Pyroxene.

Feldspars, Min., pp. 314, 1034; App., p. 26.—Analyses of plagioclase from Selischtsche, Province of Wolhynien, and from Gorodischtsche, Russia, are taken to prove that the mineral is a definite compound of the albite and anorthite molecules and not an isomorphous mixture and that no exact relation exists between its chemical composition and specific gravity. Tarassenko, [Schrift. d. Naturf. Ges. Kiew, 16, 2, 365, 1900], Zs. Kr., 36, 182; Bull. Soc. Min., 24, 269, 1901.

Investigations concerning the chemical constitution of the feldspars; Tschermak, Ber. Ak.

Wien, 112, 355, 1903; Zs. Kr., 41, 508, 1905. Chemical study of potash feldspars shows constant presence of small amounts of Li and Rb in monoclinic varieties and their absence in tri-

clinic; Barbier, Bull. Soc. Min., 31, 152, 1908; see also Gonnard, ibid., 303.

Concerning probability of a soda monoclinic feldspar; Barbier and Prost, Bull. Soc. Chim. France, 3, 894, 1908; also Gonnard, Bull. Soc. Min., 31, 303, 1908. Important studies by Day and Allen on the isomorphism and thermal properties of the feldspars; Publication 31, Carnegie Institution, Washington; reprinted in part, Am. J. Sc., 19, 93, 1905. The following mixtures of the albite and anorthite molecules were prepared and their melting points and specific gravities determined.

	An.	Ab ₁ An ₅	Ab ₁ An ₂ 1463°	Ab,An,	Ab ₂ An ₁	Ab ₃ An ₁	Ab
Melting point	1532°	1500°	1463°	1419°	1367°	1340°	
Sp. G.	2.765	2.733	2.710	2.679	2.660	2.649	2.605

Conclusions were that the soda-lime feldspars could be considered as solid solutions and form an isomorphous series. Microscopic investigation of the various products showed that those near the anorthite end of the series commonly crystallized larger than those near the albite end.

the anorthite end of the series commonly crystallized larger than those near the albite end.

Investigations concerning the melting points, the behavior of fused masses, etc., of various silicates including the feldspars; Doelter, Ber. Ak. Wien, 1904, 113, (1), 177, 495.

Optical. — Optical determination of the plagioclases; [Ver. d. k. russ. min. Ges. St. Petersburg, 37, 159, 1899], Zs. Kr., 34, 694, 1901. Optical anomalies in plagioclase; Fedorow, Zs. Felith, see Alith.

FERGUSONITE, Min., p. 729; App., p. 26. — Crystals from Högtveit, Evje, Sätersdalen, Norway; Schei, [Nyt. Mag., 43, 137, 1905]; Zs. Kr., 43, 638.

Mineral referred to fergusonite found in tin gravels, Embabaan district, Swaziland, S. Africa; Prior, Min. Mag., 12, 100, 1899. Occurrence in the Caucasus, Russia, with analysis; Tschernik, [Ann. Geol. Min. Russ., 5, 221, 1902], Zs. Kr., 39, 625; in southern Norway with anal. by Blomtrand; Brögger, Min. Süd-Nor. Granitpeg., 31, 1908; radioactive from Madagascar (with anal.); Lagraig Bull. Sep. Min. 21, 213, 1008 Lacroix, Bull. Soc. Min., 31, 313, 1908.

Ferronatrite, Min., 959.—Scharizer, Zs. Kr., 41, 211, 1905, suggests [(NaSO₄)Fe]₂[NaSO₄] + 6H₂O (cf. suderonatrite) for structural formula. Prepared artificially by mixing acid ferric sulphate and acid sodium sulphate and allowing to stand for a long period in moist air. Author uses ferrinatrite as name for the mineral since its iron is ferric and not ferrous.

Ferrofallidite. R. Scharizer, Zs. Kr., 37, 547, 1903.

A hydrated ferrous sulphate occurring with römerite near Copiapo in Chile. Occurs in clear

grains showing double refraction.

Composition $FeSO_4 + H_2O$. Analysis: SO_3 , 46.66; FeO, 40.94; H_2O , 10.33; Fe_2O_3 , 0.92; insol. 0.87 = 99.72. Difficultly soluble in water; H_2O goes off freely only at 230° . The author remarks upon a possible derivation by dehydration from iron vitriol (melanterite). The compound $FeSO_4 + H_2O$ from Chile was first noted by Mackintosh, Am. J. Sc., **38**, 245, 1889.

Ferroroemerite. Scharizer, Zs. Kr., 37, 546, 1903. See roemerite.

FIBROFERRITE, Min., p. 968. — Occurs thirty miles southwest of Green River, Utah; analyzed by Headden, Proc. Col. Sc. Soc., 8, 60, 1905. Occurrence (with anal.) at Cetine, Siena, Italy; Manasse, Proc. Soc. Tosc., May, 1908.

FICHTELITE, Min., p. 1000. — Review of previous investigations, etc.; Schmidt, Centralbl.

Min., 519, 1901.

Crystals from original locality with new form o (I10) show hemimorphism in the direction of the ortho axis. Crystal constants were calculated à : \dot{b} : \dot{c} = 1.428 : 1: 1.755; β = 126° 57′; Böckh, [Föld. Köz., **34**, 335 or 369, 1904]; Zs. Kr., **44**, 70, 1907; crystals from Borkovic, Bohemia, show following new forms: g (101), e (201), x (304), z (011), y (114). From slightly different angles than those used above were calculated à : \dot{b} : \ddot{c} = 1.4330 : 1: 1.7563; β = 126° 47½′. Chemical analysis gave c = 86.79; d = 13.02; calculated for d = 86.98; d = 13.02. Plzák and Rosický, Zs. Kr., **44**, 332, 1907.

FIEDLERITE, Min., p. 172; App., p. 26. — Crystals from Laurium, Greece, with new form (150) and anal.; Lacroix and de Schulten, Bull. Soc. Min., 31, 83, 1908.

Analysis by de Schulten, C. R., 140, 315, 1905, leads to the formula, 2PbCl₂. Pb(OH)₂.

Florencite. E. Hussak and G. T. Prior, Min. Mag., 12, 244, 1900; Prior, ib., p. 253.

Rhombohedral. Axis $\dot{c}=1.15875$; 0001 \wedge 10 $\overline{1}1=53^{\circ}$ 13 $\frac{1}{2}'$. Observed forms: c (0001), m (10 $\overline{1}0$), r (10 $\overline{1}1$), f (0221). Angles $rr'=87^{\circ}$ 51', $ff'=108^{\circ}$ 26.* In rhombohedral crystals with f and c the prominent forms; r rare, m very rare. Faces r, f bright and smooth, c rough and curved.

* This angle is stated to be given by "very good reflections" and hence is here assumed as fundamental. The author assumes the measured angle rr'=*88° 56′ [misprint for 87° 56?] and calculates c=1.1901 [should be 1.1913], but $rr'=88^{\circ}$ 56′ requires 108° 58′, which is obviously wrong.

Cleavage basal, fairly perfect. Fracture splintery to sub-conchoidal. Brittle. Hardness about 5. G. = 3.586. Luster greasy to resinous. Color clear pale yellow, crystals often spotted black by enclosed tourmaline, or red with iron oxide. Transparent. Optically uniaxial, positive. Birefringence not high.

Comp. A basic phosphate of aluminium and the cerium metals, closely analogous to hamlinite, to which it is related in form. Calculated formula AIPO₄.CePO₄.2AI(OH)₃ or 3AI₂O₃.Ce₂O₃.

2P2O5.6H2O.

Analysis, G. T. Prior, I. c.:

Pyr. etc. Infus. Heated in C. T. gives acid water and leaves signs of etching on the tube.

Only partially sol. in HCl.

A rare constituent of the cinnabar-bearing sands of Tripuhy near Ouro Preto Minas Geraes, Brazil, here associated with monazite, xenotime, lewisite, derbylite. Found more abundantly in larger crystals and rounded grains in diamond-bearing sands from "Matta dos Creoulos" near Diamantina, Minas Geraes, Brazil. Also at Morro do Caixambú near Auro Preto and Tripuhy, as a microscopic constituent of the reddish micaceous schists in the quartz lenticles of which the well known yellow topaz occurs with Laolin and hematite.

FLUORITE, Min., pp. 161, 1034; App., p. 26. — Crystals from Belgium localities, with following new forms, (531), (543); Buttgenbach; Ann. Soc. géol. Belg., 27, 111, 1899–1900. Symmetry of fluorite; Beckenkamp, Zs. Kr., 34, 605, 1901. Complex crystals from Epprechtstein in Fichtelgebirge, showing following new forms: (10.1.1), (17.1.1), (877), (931), (19.9.5); Weber, Zs. Kr.,

Crystals from Gellért-Berg, Budapest, showed the new forms j (15.7.4) and r (24.10.7); Hulyák, [Földt. Közl., 33, 54 and 175, 1903], Zs. Kr., 40, 503, 1905; from marble of Carrara; D'Achiardi, Att. Soc. Tosc. Sc., Mem. 21, 1905; crystals from Ivigtut, Greenland, with anal.; Böggild, Min. Groenland, 104; with new form (20.4.3) from Topělec near Písek, Bohemia; Krejčí, Abh. böhm. Akad., No. 2, 1905.

Determinations of index of refraction and specific gravity of specimens of different colors from different localities were practically identical. Dudenhausen, Jb. Min., 1, 8, 1904.

Fluorescence and thermo-luminescence studied spectroscopically, also chemical examination of gaseous and liquid inclusions; it is concluded that the organic substances, to which the color is at least in part due, have nothing to do with the optical phenomena named. H. W. Morse, Amer. Acad., 41, 587, 1906. Study of cause of phosphorescence under action of cathode rays. due to presence of various rare earths. Phenomenon has been reproduced on artif. prepared material. Urbain, C. R., 143, 825, 1906.

Experiments to determine cause of color; v. Kraatz-Koschlau and Wöhler, Min. Mitth.,

18, 317, Zs. Kr., 33, 632.
Fetid fluorite from Lautignié, Beaujolais; Garnier, C. R., 132, 95, 1901.
Humphreys, Astrophys. Jour., 20, 266; Am. J. Sc., 19, 202, shows that many fluorites con-

tain yttrium and frequently also ytterbium.

Occurrence at Montefano, Italy; Tacconi, Rend. Acc. Linc., 12, (1), 355, 1903; at Heidelbach, Saxony; Bergt, Ber. Abh. Naturwiss. Ges. Isis, Dresden, 23, 1903; Obira, Japan, with enclosed lamellæ of bismuthinite; Wada; Beitr. Min. Japan, 1, 16, 1905; at Chacaltaya mine, Huaina Potosi, Bolivia; Spencer, Min. Mag., 14, 337, 1907; as cementing material in sandstone at Lauth, Königsberg, Prussia; Mügge, Centralbl. Min., 33, 1908; used in artificial stone; Sommerfeldt, ibid., 161. Occ. in natrolite-phonolite at Aussig, Baden; Rimann, Centralbl. Min., 673, 1908.

Foresite, Min., p. 585. — Analysis of material from Elba; Manasse, [Mem. Soc. Tosc. di Sc. Nat., Pisa, 17, 203, 1900]; Zs. Kr., 35, 514.

Forsterite, Min., p. 450; App., p. 26. — Analyses of material from Albaner Mts.; Zambonini, Zs. Kr., 34, 228; from Glenelg, Inverness-shire, Scotland; Clough and Pollard, Jour. Geol. Soc., 55, 372, 1899; from Ceylon; Arsandaux, Bull. Soc. Min., 24, 474, 1901; Coomára-Swámy, Jour. Geol. Soc., 58, 399, 1902.

Kr., 43, 640; from French Creek, Pa.; Middletown, Pa.; Sugar Hill, N. H.; Eyerman, Amer. Geol., 34, 43, 1904. Chemical and mineralogical study of various garnets including galatinization with acids after fusion: the and mineralogical study of various garnets, including gelatinization with acids after fusion; the effect of fusing upon specific gravity and index of refraction. Seebach, Inaug.-Diss. Heidelberg, 1906; Centralbl. Min., 774, 1906.

The alteration of pyrope, "kelyphite," studied optically and chemically by Mrha, Min. Mitth., 19, 111, 1899, showing that it is composed of an iron-poor bronzite or enstatite, a monoclinic pyroxene, picotite and hornblende; on the artificial alteration of garnet to epidote; v. Fedorow, [Ann. géol. et min. Russie, 8, 33, 1905]; Zs. Kr., 44, 91.

Graphitic essonite from Barkhamsted, Conn., Am. J. Sc., 14, 234, 1902.

Occurrence at Heidelbach, Saxony; Bergt, Ber. Abh. Naturwiss. Ges. Isis, Dresden, 24, 1903. Uvarovite. — From Kunsjärvi, Sweden, with anal.; Borgström, Geol. För. Förh., 23, 560, 1902. New localities in the Urals; Worobieff, [Verh. russ. min. Ges., 42, Prot. 52, 1905]; Zs. Kr., 43, 71. A brownish-yellow garnet in trachyte from Port Cygnet, Tasmania, described by Macleod and White [Proc. R. Soc. Tasmania for 1898–1899, 1900, 74]; Jour. Chem. Soc., 78, 663, and named johnstonotite after R. M. Johnston. Anal. given.

A pink grossularite occurring in dodecahedrons in white marble at Xalostoc, Morelos, Mexico, and the strength of the s

has been called variously landerite, xalostocite and rosolite. See Spencer, Min. Mag., 14, 402, 1907.

Garnierite, Min., p. 676; App., p. 28. — Experiments concerning loss of water; Zambonini, [Mem. Acc. Linc., 5, 344; 6, 102, 1905]; Zs. Kr., 43, 401. Occurrence as alteration product in New Caledonia; Deprat, C. R., 140, 1471, 1905.

Gay-Lussite, Min., p. 301; App., p. 28.—Crystals from Sweetwater Valley, Wyoming; Farrington, Bull. Field Columbian Mus. Geol., Series 1, 226, 1900; Zs. Kr., 36, 77.

Gedriff, Min., p. 384.—Crystals from Avisisarfik, Greenland, with anal. by Christensen; Böggild, Min. Grönl., 399, 1905. Occurrence (with anal.) Harcourt Township, Haliburton Co., Ontario; Evans and Bancroft, Am. J. Sc., 25, 509, 1908.

Gehlenite, Min., p. 476; App., p. 28. — Found in granular aggregates in contact zone between limestone and diorite in Velardeña mining dist., Mexico. Anal. gave SiO₂, 26.33; TiO₂, 0.03; Al₂O₃, 27.82; Fe₂O₃, 1.43; FeO, 0.50; MnO, 0.01; MgO, 2.44; CaO, 39.55; Na₂O, 0.21; K₂O, 0.10; H₂O, 1.85; total, 100.27. Wright, Am. J. Se., **26**, 545, 1908.

Geikielite, App., p. 28. — Sustschinsky has described rhombohedral crystals from Ceylon showing the forms: c (0001), also as parting, r (10 $\bar{1}$ 1) only as cleavage, ϕ (50 $\bar{5}$ 8); axis $\dot{c}=1.370$ and $rr' = *94^{\circ} 7'$ or corresponding closely with the species of the Hematite group (Min., p. 210) and pyrophanite (p. 1045); G. = 3.976; analyses by Fr. Kaeppel:

TiO ₂	MgO	Fe ₂ O ₃	FeO
60.00	29.86	6.90	2.03 = 98.79
61.32	28.95	7.75	2.03 = 100.05

Zs. Kr., 37, 57, 1902.

Analyses showing that FeO is always present in considerable amount and that the formula might better be written (Mg,Fe)TiO₃. General relations of ferromagnesian titanates discussed. Crook and Jones, Min. Mag., **14**, 160, 1906. GEOCRONITE, Min., p. 143. — Analyses, Sala, Sweden, by C. Guillemain, [Inaug.-Diss. Breslau,

1898], Zs. Kr., 33, 75.
G. D'Achiardi has studied the crystallized mineral from Val Castello, Tuscany, Att. Soc. Tosc. Mem. 18, 1901, and makes it isomorphous with stephanite. By changing the orientation so that (100) becomes (001) the following axial ratio, near stephanite, is obtained: $\ddot{a}:b:\dot{c}=0.6145:1$:

0.6797. Forms noted c (001), m (110), (058), (067), (011), (032), (021), (225), (111). Angles (001): (032) = *45° 33¼'; (001): (011) = 34° 12′. The analyses do not confirm the relation to jordanite suggested by Solly, Min. Mag., 12, 290, 1899, but yield as formula, Pb_sAsSbS_s,

Sb 7.78 Pb 70.02 S 17.57 As 4.47 Cu, Fe, tr. = 99.84

Prior, Min. Mag., 13, 186, 1902, by a new analysis of "kilbrickinite" from its original occurrence, Kilbricken Mine, County Clare, Ireland; has shown that it is identical with the earlier described geocronite from Sala, Sweden. Analysis follows:

> 9.13 68.49 4.59 17.20 = 99.41

Georgiadésite. A. Lacroix and A. de Schulten, C. R., 145, 783, 1907; Bull. Soc. Min., 31, 86, 1908.

Orthorhombic. $\check{a}:\bar{b}:\bar{c}=0.5770:1:0.2228$. Angles: (100): (010) = 119° 59'; (011): (0 $\bar{1}$ 1) = 154° 53'. Forms; (100), (010), (011), (0.11.4), (451), (16.5.4), (4.15.2). Crystals small with hexagonal outline due to development of prism and brachypinacoid. Striated on top by oscillation of dome faces. Pyramid faces small. H. = 3.5. G. = 7.1. Resinous luster. Color white or brownish yellow. Ax. pl. || (100); Bxac || d. Ax. angle large. Comp. — Pb₃(AsO₄)₂.3PbCl₂; As₂O₅, 13.28; PbO, 38.61; Pb, 35.83; Cl, 12.28.

As₂O₅ PbO Pb Anal.: 12.49 38.86 36.38 12.47 = 100.20

Found on one specimen from lead slags at Laurium, Greece, associated with fiedlerite and matlockite. Named in honor of M. Georgiadès, Director of mines at Laurium.

Gerhardtite, Min., p. 872. — A bright green coating on the granite-porphyry cliffs in Chase Creek Canyon at Metcalf, Arizona, was found to consist of a nitrate and chloride of copper; the presence of gerhardtite with atacamite is inferred. Lindgren and Hillebrand, Am. J. Sc., 18, 460, 1904.

Gibbsite, Min., p. 254; App., 29. — Anal. from Klein-Tresny, Mähren; Kovář Abh. böhm].

Ak., 28, 1899]; Zs. Kr., 34, 705.

Occurs in nodular plates at Kodikanal, Palni Hills, Madras, India. Analysis agrees with accepted formula; Warth, Min. Mag., 13, 172, 1902. Occurs with manganese-ore (pyrolusite and wad) in part radiate-fibrous, in part in minute tabular crystals at Talevadi, Bombay (anal.); also amorphous from Bhekowli, Satara distr. (anal.); L. Leigh Fermor, Rec. G. Surv. India, 34, 167, 1906.

Giorgiosite. A. Lacroix, Bull. Soc. Min., 28, 198, 1905; C. R., 140, 1308, 1905. Saline crusts observed by Fouqué (Santorin et ses éruptions, p. 213, 1879) at the surface of lava at Alphroëssa, Santorin, as a result of the eruption of 1866, have been examined by Lacroix. They consist essentially of sodium chloride, containing small quantities of carbonate, sodium sulphate and magnesium chloride. Magnesium carbonate was observed both as a fine white powder and also as a light white flocculent mass. Dried at 100° they yield water and are hence inferred to be basic carbonates of magnesium. The white powder is made up of minute radiated spherules, isolated and in groups; these yield a black cross in parallel polarized light, with a birefringence of 0.08 to 0.09, positive in the direction of the fibers. This substance is inferred to be identical with a substance obtained by Fritsche and having the composition 4MgCO₃.Mg(OH)₂.4H₂O. This imperfectly investigated mineral is called giorgiosite after the Giorgios.

The white flocculent mass is regarded as probably hydromagnesite.

GISMONDITE, Min., p. 586; App., p. 29. — Analyses of material from Nicolstadt near Liegnitz, Silesia, by Sachs; Centralbl. Min., 215, 1904, and from Vallerano, Capo di Bove and Mostacciano, near Rome, by Zambonini, Jb. Min., 2, 91, 1902, lead to the formula CaAl₂Si₂O₈.4H₂O. Occurs as alteration product (zeagonite) of nepheline from Löbau, Austria; Thugutt, Jb.

Min., 2, 65, 1900.

GLASERITE = aphthitalite, which see.

GLAUBERITE, Min., p. 898; App., p. 29. — Crystals from Hallstatt and from Dürnberge near Hallein described by Koechlin, [Ann. Hofmus., Wien, 15, 103 and 149, 1900]; Zs. Kr., 36, 637. Opal pseudomorphic after glauberite (?) from White Cliffs, N. S. W.; Anderson and Jevons, [Rec. Aus. Mus., 6, 31, 1905]; Min. Mag., 14, 197.

Conditions of formation discussed; van't Hoff with Chiaraviglio, Farup, d'Ans, Ber. Ak. Berlin, 810, 1899; 1000, 1903; 478, 1905; 218, 1906.

Probable occurrence in fumaroles of Mt. Pelée, Martinique; Lacroix, Bull. Soc. Min., 28, 60,

1905.

GLAUCOCHROITE, App., p. 29. — Described by Penfield and Warren in Am. J. Sc., 8, 343, 1899. Optical determination gave: Ax. pl. $\|c(001)$, Bx_a $\perp b$ (010), double refraction negative; $2E_y = 121^{\circ} 30'$, $2V_y = 60^{\circ} 51'$; indices $\alpha = 1.686$, $\beta 1.722$, $\gamma = 1.735$. The above are near the values for monticellite deduced by Penfield and Forbes, Am. J. Sc., 50, 135, 1896.

GLAUCONITE, Min., p. 683; App., p. 29. — General study concerning; Collet and Lee, [Proc. Roy. Soc. Edinburgh, 26, 238, 1906]; Zs. Kr., 45, 302; C. R., 142, 996, 1906.

Anal. from near Grodno, Russia; Smirnoff, [Ann. Géol. Min. Russ., 7, 28, 1904]; Zs. Kr., 43, 77.

GLAUCOPHANE, Min., p. 399; App., p. 29. — Study of crystals, with analysis, from Chateyroux in Gressoney, Piedmont; Zambonini, Rend. Acc. Linc., 11, (1), 204, 1902; from New Jersey; Prather, Jour. Geol., 13, 509, 1905.

Occurrence of var. "rhodusite" from Asskys river, Minassinsk, Siberia, with analyses and discussion of chemical composition; Isküll, Zs. Kr., 44, 370, 1907.

Chemical study of glaucophane schists from many localities; Washington, Am. J. Sc., 11, 35, 1901; from Conandale Range, Queensland; Jensen, Proc. Linnæan Soc. N. S. W., 32, (1), 701, 1907; paragenesis of minerals in glaucophane rocks in California discussed by Smith, Proc. Am. Phil. Soc., 45, 183, 1906; anal. of glaucophane from rocks at Lavintzie, Bagnetal, Wallis, Switzerland; Grubenmann, Festschr. von Harry Rosenbusch, 1906, p. 1.

Glendonite. — Name suggested for calcite pseudomorphs after glauberite in various localities in N. S. Wales, after original locality of Glendon; David, Taylor, Woolnough and Foxall, [Rec. Geol. Sur. N. S. W., 8, 161, 1905]; Zs. Kr., 43, 622.

GMELINITE, Min., p. 593; App., p. 29. — Crystals from Scottish localities; Goodchild, [Trans.

Geol. Soc. Glasgow, 12, Suppl., 1-68, 1903]; Zs. Kr., 45, 307.

Occurrence (with anal.) at Kurzi south of Sympheropol, Taurien, and on Commordor island,

Bering Sea, Russia; Fersmann, Centralbl. Min., 573, 1906.

From Aci Castello; Di Franco, Att. Acc. Linc, 13, (1), 640, 1904.

Gold, Min., p. 14; App., p. 29. — Crystals from Wemyi, Lena gold district, Siberia; Samoiloff, [Ver. russ. min. Gesells., 43, 237, 1905]; Zr. Kr., 44, 87; from Pralorgnan, Val d'Aosta, Italy; Millosevich, Rend. Acc. Line., 15, (1), 320, 1906; from Brusson, Val d'Aosta; Colomba, Att. Acc. Torino, 42, 904, 1907.

Structure planes: Mügge, Jb. Min., 2, 55, 1899.

Nuggets with concentric structure, from New Guinea; Liversidge, Proc. Roy. Soc. N. S. W., 40, 161, 1906; also internal structure of some crystals, ibid., 41, 143, 1907.

Gold in meteorites; Liversidge, Proc. Roy. Soc. N. S W., Sept., 1902.

Goldschmidtite, App., p. 30. — Shown by Palache, Zs. Kr., 34, 542, to be identical with sylvanite, (100) on goldschmidtite becoming (101) on sylvanite. The position of a number of the goldschmidtite forms was due to twinning.

Georceixite. E. Hussak, Min. petr. Mitth., 25, 338, 1906.

Microcrystalline, in rolled pebbles.

H. = 6. G. from 3.036 to 3.123. Luster non-metallic, jasper-like on fresh fracture. Color various shades of brown and white. In thin section appears as an aggregate of small colorless irregular grains, with brown powder between. Optically uniaxial and positive. Index of refraction, 1.6253 (Gaubert, Bull. Soc. Min., 30, 108, 1907). Weak double refraction. Composition, (Ba,Ca,Ce)O.2Al₂O₃.P₂O₅.5H₂O. Analyses (by G. Florence of material from Rio Abaëtè) gave:

SiO ₂	Fe ₂ O ₃	P_2O_5	Al ₂ O ₃	BaO	CaO	CeO	TiO,	H_2O
1. 1.55	4.10	22.74	35.00	15.42	3.55	1.55	0.67	14.62 = 99.20
1a		22.48	37.68	16.60	3.82	1.67		15.74 = 100.00
2. 6.50	1,67	21.47	35.20	15.30	2.24	2.35	0.75	14.73 = 100.21
2a	15	23.52	38.56	16.76	2.45	2.57		16.14 = 100.00

Analyses 1a and 2a are recalculated from 1 and 2 by subtracting the SiO₂, Fe₂O₃ and TiO₂ as impurities. Qualitative tests showed SrO in some specimens. Occurs as rounded pebbles in the diamond sands of Brazil, commonly called favas. Named from H. Gorceix, the first director of the School of Mines, Ouro-Preto, Minas Geraes.

Goslarite, Min., p. 939; App., p. 30. — Cuprogoslarite is a variety containing copper described by Rogers, Kansas Univ. Q., 8, 105, 1899. Occurs as a translucent light greenish blue

incrustation on the wall of an abandoned zinc mine at Galena, Cherokee, Kansas. H. = 2. On exposure to the air loses part of its water and becomes white. Analysis:

ZnO H₂O CuO FeO Insol. [27.02] 23.83 6.68 0.13 41.76 0.58 = 100

Göthite, Min., pp. 247, 1036. — Crystallographic and optical studies; Cesàro and Abraham, Bull. Acad. Roy. d. Belg., 179, 1903.

Graftonite. S. L. Penfield, Am. J. Sc., 9, 20, 1900.

Axes $\hat{a}:\hat{b}:\hat{c}=0.886:1:0.582;\ \beta=66^{\circ}.$ Forms: a (100), b (010), m (110), l (120), n (130), d (011), e (021), p (111). Fundamental measurements only approximate; $b \wedge d = 62^{\circ}$; $b \wedge m = 51^{\circ}$.

In rough composite crystals in which the graftonite is closely interlaminated with a palegreen triphylite, the latter usually dark from alteration. The plane of lamination is parallel to b (010) of the graftonite, the two minerals being intergrown in such a way that the macro-axis of triphylite is parallel to the clino-axis of graftonite and (102) of the former coincides with (010) of the latter.

H. = 5. G. = 3.672. Luster vitreous to resinous. Color when fresh, a delicate salmon-pink, resembling lithiophilite (but usually dark from alteration).

Composition, $R_3P_2O_4$, with R = Fe, Mn and Ca. Analyses, 1, Penfield, on the fresh mineral; 2, Ford, material partly altered and oxidized:

Fe₂O₃ FeO MnO MgO CaO Li,O Na₂O PO. 1. 41.20 17.62 9.23 0.33 * 0.75 = 100.1830.65 0.40 24.28 7.25 1.15 1.17 = 100.332. 40.80 10.16 15.38 0.14

* Containing some Na₂O.

B. B. darkens and fuses at 2 to a slightly magnetic globule; gives a bluish green color to the flame; reacts for manganese with sodium carbonate. Readily soluble in hydrochloric acid.

From the south side of Melvin Mountain five miles west of Grafton, New Hampshire; occurs sparingly in a pegmatite vein with beryl, black tourmaline, garnet, etc.

Grahamite, Min., p. 1020; App., p. 30. — From study of occurrence in Ritchie Co., W. Va., thought to be an oxidation product of petroleum; White, Bull. Geol. Soc. Amer., 10, 277, 1899; Zs. Kr. 34, 205.

Grandidierite. A. Lacroix, Bull. Soc. Min., 25, 85, 1902; 27, 259, 1904; C. R., 137, 582, 1903.

Orthorhombic. In anhedral elongated individuals up to 8 cm. in length; these show two

cleavages in the zone of elongation, a (100) and b (010), the former more perfect.

G. = 2.99. Luster vitreous, on the cleavage surface a somewhat pearly. Color bluish green. Extinction parallel. Ax. pl. $\parallel c$ or transverse to the direction of elongation. Bx_a $\perp a$. Birefringence negative. Indices (Na) $\alpha = 1.6018$, $\beta = 1.6360$, $\gamma = 1.6385$. $2V_{Na} = 30^{\circ}$ 16'. Also by measurement $2 E_{Na} = 49^{\circ}$ 30'. $2 E_{gr} = 52^{\circ}$ (Tl.). Dispersion $\rho < v$. Strongly pleochroic, with $\alpha > \beta > \gamma$. In thin sections colorless in direction of elongation, blue and green transverse to this. Sections normal to an optic axis showing blue brushes on a white ground, belonging to the same type as andalusite.

Composition, a basic silicate, calculated formula 7SiO₂,11(Al,Fe)₂O₃, 7(Mg,Fe,Ca)O, 2(Na,

K,H),O.

Analysis, Pisani:

SiO, Al₂O₃ Fe₂O₃ FeO MgO CaO Na₂O K_2O 2.22 20.90 52.80 6.60 4.86 9.65 2.10 0.40

B. B. infusible; unattacked by acids.

Occurs as an accessory constituent of a pegmatite and an aplite from the faults of Andrahomana, near Fort Dauphin, in the extreme southern part of Madagascar. It is associated with quartz, orthoclase and microcline, almandite, spinel, also biotite and andalusite; encloses the other rock elements in a poikilitic manner. Grandidierite is easily altered, passing into a green fibro-lamellar substance apparently related to kryptotite. Named after M. Alfred Grandidier, who has described the geography and natural history of Madagascar.

Graphite, Min., pp. 7, 1036; App., p. 31. — Description of occurrences in Styria and in Ceylon; Weinschenk, [Abh. bayer. Akad. Wiss., 21, 233 and 281, 1900]; Zs. pr. Geol., 1900, 8, 36 and 174; Zs. Kr., 36, 316. In basalts of lower Rhine; Brauns, Centralbl. Min., 97, 1908.

Greenalite. C. K. Leith, Mon. 43, U. S. G. S., 1903.

Name given to a green hydrated ferrous silicate occurring in the form of granules in the cherty rocks associated with the iron ores of the Mesabi district, Minn. Resembles glauconite (and was originally called so) but shows no potash.

GREENOCKITE, Min., pp. 69, 1036; App., p. 31. — On calcite from Joplin, Mo.; Cornwall. Am. J. Sc., 14, 7, 1902. Occurrence with smithsonite at Montevecchio; Lovisato, Rend. Acc. Linc., 12, (2), 642, 1903.

Guarinite, Min., p. 717; App., p. 31. — Discussion of chem. comp. by Zambonini; Centralbl. Min., 524 and 667, 1902. Crystals studied gave axial ratio: $\ddot{a}:\ddot{b}:\dot{c}=0.99268:1:0.37008.$ G. between 2.9 and 3.3. Double refraction like that of quartz. 2V= near 90°. Axial pl. $\parallel c$. $Bx_a = a$. Strong dispersion $\rho > v$. Pleochroism a = canary yellow; <math>b = colorless; c = verypale yellow. Axial ratio and optical properties agree closely with those of danburite.

Gummite, Min., p. 892; App., p. 31. — Ratio of radium to uranium; Boltwood, Am. J. Sc., 18, 97, 1904.

Gypsum, Min., p. 933; App., p. 31.—Cryst.—Crystals from Lebo, Coffey Co., Kansas; Rogers, Am. J. Sc., 9, 364, 1900; from Tarajungitsok, Godhavn District, Greenland; Steenstrup, [Medd. om Grönl., 24, 294, 1900]; from the Bad Lands, So. Dakota with (13.7.0); Rogers, Sch. Mines Q., 23, 133, 1902; from Ballabio, with new forms (\$\tilde{2}\$12), (\$\tilde{3}\$13); Artini, Rend. Roy. Inst. Lomb., 36, 1181, 1903; sand crystals; Delkeskamp, Zs. für Naturwiss., Halle, 75, 185, 1902; crystals from dolomite limestone, Wietze, Hannover; Höfer, Ber. Ak. Wien, 113, (I), 169, 1904; crystal from Bellisio, with (\$\tilde{3}\$14); Cesáro, Bull. Ac. Belg., 140, 1905; from marble of Carrara; D'Achiardi, Att. Soc. Tosc. Sc., Mem., 21, 1905; unusual crystals from salt springs at Pachpadra, Jodhpur, Rajputana; Fermor, [Rec. Geol. Sur. India, 32, 231, 1905]; Zs. Kr., 43, 620; crystals from Igmand, Hungary; Torborffy, Földt. Közl., 37, 312, 1907; crystals from sulphur caves near Lomano, Siena; Manasse, Att. Soc. Tosc., 23, 1907. Microscopic study of the crystallization of gypsum; Maschke and Vater, Zs. Kr., 33, 57; crystals from Cetine di Cortorniano, Siena; Viola, Rend. Acc. Linc., 17, (1), 501, 1908. Etched crystals; Wiegers, Zs. für Naturwiss., Halle, 73, 266, 1900. Naturally etched crystals from Kommern, Bohemia; Mühlhauser, Min. Mitth., 20, 367, 1901. Etching figures, natural and artificial, fail to show the existence of a plane of symmetry; Viola, Zs. Kr., 35, 220, 1901. Dispersion; König, [Ann. d. Phys., 69, 1, 1899]; Zs. Kr., 35, 1901.

Dispersion; König, [Ann. d. Phys., 69, 1, 1899]; Zs. Kr., 35, 193. Effect of low temperatures upon optical properties; Panichi, [Mem. Acc. Linc., 4, 389, 1902]; Zs. Kr., 40, 88.

Occ. at Cetine di Cortorniano, near Rosia, Siena; Pelloux, Rend. Acc. Linc., 10, (2), 10, 1901;

in Kansas; Grimsley and Bailey, Uni. Geol. Sur. Kansas, 5.

Conditions of formation discussed; van't Hoff with Armstrong, Hiurchsen, Weigert, Ber. Ak. Berlin, 559, 1900; 570, 1140, 1901.

GYROLITE, Min., p. 566. Study of crystals from Niakornat and other Greenland localities by Böggild, Medd. om Grönl., **34**, 93, 1908, gave the following new facts: Crystallization rhombohedral tetartohedral. Axis c = 1.9360. Forms c(0001), $r(10\bar{1}1)$, $u(10\bar{1}2)$. Angles: $r: c = *65^{\circ} 54'$; $u \cdot c = 48^{\circ}$ 11'. Crystals small hexagonal plates, with curved faces giving inexact measurements. Crystals easily etched, figures showing tetartohedral symmetry. Cleavage per. $\parallel c(0001)$.

Six rayed percussion fig. Optically -. $\omega = 1.5645$. $\epsilon = 1.5590$. Anal.: SiO₂, 54.83; Al₂O₃, 4.58; CaO, 31.15; Na₂O, 1.74; H₂O, 8.14; total, 100.44. Discussion of relations to other occurrences of gyrolite and other similar zeolites. mineral from Niakornat has been described as a new species, reyerite, which see.

New occurrences in Scotland; Currie, Min. Mag., 14, 93, 1905. Occurrence (with anal.) in diabase from Mogy-guassu, São Paulo, Brazil; Hussak, Centralbl. Min., 330, 1906.

Thought to be indentical with zeophyllite; Cornu, Centralbl. Min., 80, 1906.

Hackmanite. L. H. Borgström, Geol. För. Förh., 23, 563, 1901; Zs. Kr., 37, 284. Isometric; in dodecahedrons.

H. = 5. G. = 3.32 - 3.33.

Color reddish violet, becoming colorless on exposure to daylight. Transparent and isotropic.

Refractive index (Na) = 1.4868.

Composition: — Member of sodalite group. It may be regarded as a sodalite with 6.23 p.c. of the "white ultramarine compound" Na₄[Al(NaS)]Al₂(SiO₄)₃ of Brögger and Bächström (Zs. Kr., 18, 223, 1890).

Analysis:

SiO₂ Al₂O₃ Fe₂O₃ CaO Na₂O K₂O Cl S $\frac{3}{3}$ 36.99 31.77 0.17 0.05 25.84 0.16 6.44 0.39 = 101.81 less O (= Cl,S) 1.64 = 100.17

Soluble in dilute hydrochloric acid with evolution of H₂S and the separation of a small amount of flocculent silica.

Occurs in the rock called tawite (W. Ramsay) from the Tawa valley in the Lujaur-Urt on the Kola peninsula, Lapland. Tawite consists of hackmanite with ægirite, also, as accessories, nephelite, albite, microcline, eudialyte, etc. Sometimes altered on the exterior to natrolite. Named after Dr. Victor Hackman.

HAIDINGERITE, Min., p. 827. — Artificial production; de Schulten, Bull. Soc. Min., 26, 18, 1903; also of the corresponding barium and strontium compounds; id., ibid., 27, 104, 1904.

Halite, Min., pp. 154, 1036; App., p. 32. — Crystals from Sicily with pseudo-rhombohedral symmetry; Andrée, Centralbl. Min., 88, 1904. Influence of various dissolved salts on the crystal form of sodium chloride; Körbs, Zs. Kr., 43, 451, 1906.

Determination of refractive index from Stassfurt, colorless and blue; Dudenhausen, Jb. Min., 22, 1904. Artificial dichroism of blue halite; Siedentopf, [Verh. deutsch. phys. Ges., 621, 1907];

Jb. Min., 1, 57, 1908.

Cause of blue color; Ochsenius, Centralbl. Min., 381, 1903; Focke and Bruckmoser, Min. Mitth.,

25, 43, 1906; Cornu, Jb. Min., 1, 32, 1908.
Analyses of occurrences in recent lavas from Vesuvius; Casoria, [Ann. R. Scuola sup. di agric. di Portici, 4, 1, 1903]; Zs. Kr., 41, 276; also Brauns; Centralbl. Min., 321, 1906; and Lacroix, Bull. Soc. Min., 30, 239, 1907.

Deformation under pressure; Rinne, Jb. Min., 1, 114, 1904. Cubic crystals found in volcanic ash from Mt. Pelée, Martinique; Lacroix, Bull. Soc. Min., 28, 68, 1905. Occurrence in Bilma oasis, Sahara desert; Lacroix, ibid., 31, 40, 1908.

Halloysite, Min., p. 688. — Anal. from Edwards Co., Texas; var. lenzinite from Ventura Co., Calif.; Merrill, U. S. Nat. Mus. Rep., (2), 330, 1899; Zs. Kr., 36, 73. Chem. constitution; McNeil, Jour. Amer. Chem. Soc., 28, 593, 1906.

Occurs somewhat abundantly as a pink clay (anal.) at the lepidolite mine near Pala, San Diego,

Cal.; Schaller, Am. J. Sc., 17, 191, 1904.

Hamlinite, Min., p. 762. — Suggested by Prior, Min. Mag., 12, 249, 1900, that hamlinite florencite, plumbogummite, beudantite and svanbergite are members of one group, as follows:

		$r \wedge r'$	
Hamlinite	2SrO.3Al ₂ O ₃ .2P ₂ O ₅ .7H ₂ O	87° 2′	$\dot{c} = 1.1353$
Svanbergite	2SrO.3Al ₂ O ₃ .P ₂ O ₅ .2SO ₃ .6H ₂ O	89° 25′	$\dot{c} = 1.2063$
Plumbogummite	2PbO.3Al ₂ O ₃ .2P ₂ O ₅ .7H ₂ O		
Beudantite	$2\text{PbO.3Fe}_{2}\text{O}_{3}.\text{P}_{2}\text{O}_{5}.2\text{SO}_{3}.6\text{H}_{2}\text{O}$	88° 42′	c = 1.1842
Florencite	Ce ₂ O ₃ .3Al ₂ O ₃ .2P ₂ O ₅ .6H ₂ O	88° 56′	c = 1.1901

Identified in the diamond-bearing sands of the Serra de Congonhas, Diamantina, Brazil; Hussak, Ann. Nat. Hofmus., 19, 93, 1904; Am. J. Sc., 19, 202, 1905.

Material from Binnenthal, Switzerland, described originally by Solly; Nature, 71, 118; Min. Mag., 14, 80, 1905, as a new species and named bowmanite, was proven by Bowman; Min. Mag., 14, 389, 1907, to be identical with hamlinite. Occurs in small honey-yeilow crystals forming either hexagonal plates or combinations of rhombohedron and base. Some of the plates show in convergent polarized light a division into six triangular biaxial sectors, showing that the mineral is pseudo-hexagonal. Analyses given.

Hampdenite. Name given to serpentine occurring at Chester, Mass., enclosing serpentine pseudomorphs after olivine (hampshirite); Roe and Parsons, Bull. Minn. Acad. Sci., 4, 2, 268, 276, 1906; and Palache, Am. J. Sc., 24, 491, 1907.

Hampshirite, see under Chrysolite.

HANCOCKITE, App. I, p. 32. — Described by Penfield and Warren, Am. J. Sc., 8, 339, 1899.

Approximate measurements, on crystals elongated $\parallel\vec{b}$, yielded the angles: $ce~(001 \land 101) = 36^{\circ}~15'$, $ca~(101 \land 100) = 30^{\circ}~45'$, $cr~(001 \land \bar{1}01) = 63^{\circ}$, $nn'''~(\bar{1}11) \land (11\bar{1}) = 67^{\circ}$; these are near the corresponding angles for epidote. Analyses by Warren yielded:

The formula is that of epidote, $R(ROH)R_2(SiO_4)_3$; here R = Pb, Ca, Sr, Mn and R = Al, Fe and Mn

HANNAYITE, Min., p. 832. — From guano deposits in Australia, with analysis; MacIvor, Chem. News, 85, 181, 217, 1902.

HARDYSTONITE, App., p. 32. — Wolff has determined the indices of refraction, as follows: $\omega_{\text{Na}} = 1.6691$, $\epsilon_{\text{Na}} = 1.6568$; $\omega_{\text{Li}} = 1.6758$, $\epsilon_{\text{Li}} = 1.6647$. A new analysis gave:

Al₂O₃ CaO Fe₂O₃ ZnO MnO. SiO, 37.78 0.43 23.38 1.26 34.22 0.26 0.91 1.10 0.34 = 100.46.

The alkalies, not shown in an earlier analysis, may be due, at least in part, to impurities. Proc. Amer. Acad., 36, 113, 1900.

HARMOTOME, Min., p. 581; App., p. 33.—Crystals from Sarrabus, Sardinia; D'Achiardi, Mem. Soc. Tosc. 17, 1900; from Scottish localities; Goodchild, [Trans. Geol. Soc. Glasgow, 12, Suppl., 1-68, 1903]; Zs. Kr., 45, 306.

Harttite. E. Hussak, Min. Mitth., 25, 339, 1906. Hexagonal. Occasionally in microscopic crystals with hexagonal cross section. Microcrystalline, in rolled pebbles.

H. = 4.5-5. G. = 3.21. Luster non-metallic. Color flesh-red, seldom yellow or white. In thin section appears as an aggregate of small colorless grains and crystals.

Optically uniaxial and positive. Composition, (Sr,Ca)O.2Al₂O₃,P₂O₅.SO₃.5H₂O.

Analysis by G. Florence of material from Rio Sao Jose gave:

	P ₂ O ₅	SO ₃	Al ₂ O ₃	SrO	CaO	CeO	TiO,	H ₂ O
1.	21.17	11.53	33.36	16.80	2.80	1.02	1.42	12.53 = 100.93*
2.	21.64	11.78	34.40	17.17	2.19			12.81 = 100.00

* Summation of anal. 1 is given by author as 100.27. Probably there is a misprint in case of percentage of CaO which should read 2.14 in order to account for CaO = 2.19 of anal. 2.

Analysis 2 is recalculated from 1 by deducting the CeO and TiO₂ as impurities. Occurs in the diamond sands of Brazil as rounded pebbles, commonly called favas. Named from F. Hartt, the first director of the Geological Survey of Brazil.

HATCHETTOLITE, Min., p. 727. — Possible occurrence on Mt. Bity, Madagascar; Lacroix, Bull. Min. Soc., 31, 246, 1908.

Hauerite, Min., p. 87. — Belonging to tetartohedral class of isometric system; Scacchi, [Rend. Acc. Sci. Napoli, 5, 164, 1899]; Zs. Kr., 34, 294. Crystals from Raddusa with new form, β (477); Goldschmidt and Schröder, Zs. Kr., 45, 214, 1908.

Chemical reactions between hauerite and metals at ordinary temperatures; Strüver, Centralbl. Min., 257, 1901; Rend. Acc. Linc., 10, (1), 124, 1901; study continued with reactions between iron sulphides and various metals; id., Centralbl. Min., 401, 1901; action of potassium chlorate upon; Spezia, Att. Acc. Torino, 43, April, 1908.

HAUSMANNITE, Min., pp. 230, 1036; App., p. 33. — Crystals from Brazil; Koechlin, Min. Mitth., 27, 260, 1908.

HAUYNITE, Min., p. 431; App., p. 33. — Variation of refractive indices with variation in composition; Gaubert, Bull. Soc. Min., 28, 188, 1905.

HAYESINE, see Bechilite.

Hellandite. W. C. Brögger, [Nyt Mag. f. Naturv, Christiania, 41, 213, 1903]; Zs. Kr., 42, 417, 1906.

Monoclinic. Axes à : $\overset{.}{b}$: $\overset{.}{c}$ = 2.0646 : 1 : 2.1570; β = 109° 45′. Forms: a (100), b (010), c (001); m (110), l (120), g (540), n (320), x ($\overline{1}$ 01), d ($\overline{1}$ 02), r ($\overline{1}$ 03), t (205), e ($\overline{2}$ 01), q (301),o (011), p ($\overline{1}$ 22). Angles $mm''' = 125^{\circ}$ 32′, $nb = *37^{\circ} 40'$, $ea' = *28^{\circ} 20'$, $a^{\mathsf{I}}a^{\mathsf{I}\mathsf{I}} = *39^{\circ} 30'$.

Crystals are prismatic in habit, being elongated parallel to c axis. Twins, tw. pl. (1) c, in contact twins, (2) a, shown by twinning striations and lamellæ, best seen in the thin sections.

H. = 5.5. G. = 3.70. Color nut brown to brownish red.

Optically+. Ax. pl. \perp b. c inclined 43½° to \dot{c} in acute angle β . Axial angle about 80°. Birefringence about 0.01.

Composition, 2RO.3R₂O₃.4SiO₂.3H₂O or either Ca₂R₃(R(OH)₂)₃(SiO₄)₄ or Ca₂(R(OH))₆(SiO₄)₄. R = Ca chiefly; R = Al, Fe, Mn, and the cerium metals.

Analyses, 1, O. N. Heidenreich; 2, L. Andersen-Aars.

 SiO_2 Al_2O_3 Fe_2O_3 Mn_2O_3 Ce_2O_3 Y_2O_3 Er_2O_3 ThO_2 CaO MgO Na_2O K_2O H_2O

- 23.55 10.22 2.64 5.69 40.12 10.05 0.26 0.06 7.55 $23.66 \ 10.12 \ 2.56 \ 5.91 \ 1.01 \ 19.29 \ 15.43 \ 0.62 \ 9.81 \ 0.10 \ 0.23 \ 0.06 \ 11.75 * = 100.55$
- * 6.00 p. c. by heating up to 500°, the remainder at red heat. 5.00 p. c. therefore of the water content was considered constitutional and the rest as due to alteration.

Fuses in the Bunsen burner flame. Easily soluble in HCl.

Found in pegmatite veins near Kragerö, Norway, associated with tourmaline, apatite, titanite, phenacite, thorite, and allanite.

Alters readily, chiefly by taking on more water, into a yellow or white earthy material. Pseudomorphs of microcline after hellandite were observed.

HEMATITE, Min., pp. 213, 1037; App., p. 34. — Study of crystals from various localities gave c axis = 1.3654 as an average; Melczer, Zs. Kr., 37, 580, 1903; crystals from Ætna; Franco, Att. Padru, Sardinia; Millosevich, ibid., 16, (1), 632, 1907; artif. crystals; Munroe, Am. J. Sc., 24, 485, 1907; crystals from Vesuvius (eruption of April, 1906); Johnston-Lavis and Spencer, Min. Mag., 15, 60, 1908; from Kakuk Mts., Hungary, with new form, j (4371); Zimányi, Centralbl. Min.,

Optical constants; Försterling, Jb. Min., Beil., 25, 344, 1908.

Eisenrose from St. Gotthard giving black streak; Hogenraad, Zs. Kr., 39, 396. Parting on hematite from Franklin Furnace, N. J.; Moses, Am. J. Sc., 20, 283. Law of parallel growth with rutile, which see. Study of magnetic properties; Westman, [Upsala Uni. Arsskrift, 2, 1896]; Zs. Kr., 31, 309; Abt, [Ann. d. Phys., 67, 474, 1899]; Zr. Ks., 35, 191; Kunz, Jb. Min., 1, 62, 1907.

HERCYNITE, Min., p. 223; App., p. 34. — Occurs in masses in the tin drift, Moorina, Tasmania; Petterd (anal. by Millen), Notes on Tasmanian Minerals, priv. publ., John Vail, Gov't printer, Tasmania.

HERDERITE, Min., p. 760; App., p. 34. — Crystals from Epprechtstein, Fichtelgebirge, Bavaria; Bücking, Centralbl. Min., 294, 1908.

HERSCHELITE, see Chabazite.

Hessenbergite, Min., p. 1037. — By comparison of crystal angles, etc., the identity of hessenbergite (sideroxene) with bertrandite is strongly suggested. Grünling, Zs. Kr., 39, 386.

HESSITE, Min., pp. 47, 1037; App., p. 35. — Crystals from Boulder Co., Colo.; Palache, Am. J. Sc., 10, 426, 1900; Zs. Kr., 34, 547.

Anal. of material from San Sebastian, Jalisco, Mexico; Hillebrand, Am. J. Sc., 8, 298, 1899.

HETEROMORPHITE, see under Plagionite.

Heulandite, Min., p. 574; App. p. 35. — Cryst. — Crystals from Iceland; Jeremejew, [Bull. Acad. Sc. St. Pétersbourg, 9, 5, 1898]; Zs. Kr., 32, 428; from granite of Baveno with opt. study; Artini, Rend. Acc. Linc., 11, (2), 364, 1902; from Scottish localities with following new forms, d (101), w (032), n (111). Mineral considered to be triclinic, pseudo-monoclinic. Goodchild, [Trans. Geol. Soc., Glasgow, 12, Suppl., 1-68, 1903]; Zs. Kr., 45, 306; from Petersdorf, near Zöptau, Mähren; Kretschner, Centralbl Min., 612, 1905; from East Greenland with new form r (501) (Henry Glacier); Böggild, Medd. om Grönl., 28, 120, 1905; from Werris Creek, N. S. W.; Anderson, Rec. Aus. Mus., 6, 422, 1907; from Nadap, Hungary, with anal.; Mauritz, Ann. Mus. Nat. Hung., 550, 1908; from basalt of Montresta, Sardinia; Deprat, Bull. Min. Soc., 31, 181, 1908; also, Millosevich, Rend. Acc. Linc., 17, (1), 267, 1908; and (with anal.); Pelacani, ibid., 17, (2), 70, 1908. 70, 1908.

Anal. of material from Teigarhorn, Iceland, with discussion of composition; Baschieri, Att. Soc. Tosc., 24, 1908. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 96, 1908.

Absorbtion of various liquids on cooling after having been heated; Gaubert, Bull. Soc. Min.,

Absorption of various liquids on cooling after having been heated; Gaubert, Bull. Soc. Min.,

26, 178, 1903.

Hibschite. F. Cornu, Min. petr. Mitth., 24, 327, 1905; 25, 249, 1906. Isometric. In minute crystals, octahedrons and less often dodecahedrons; very rarely isolated, usually grouped in parallel position enveloping dodecahedrons, or grains, of melanite. No cleavage. Very brittle. H. = 6. G. = 3.05. Colorless or pale yellow. Optically isotropic; occasionally shows optical anomalies, analogous to those of garnet. Refractive index 1.67.

Composition as for lawsonite, H₄CaAl₂Si₂O₁₀. This is deduced from analysis of material, (1) consisting of melanite (titanmelanite) and hibschite. The pure garnet gave the results under

(2), leaving (3) as the composition of hibschite, reduced to 100.

		SiO, TiO,	Fe ₂ O ₃	Al_2O_3	CaO	MgO	$H_{2}O$
1.	Melanite + Hibschite	37.70*	8.46	22.38	21.31	1.86	8.59 = 100.30
2.	Melanite (pure)	32.15 6.08	20.99	6.65	32.45	0.68	0.95 = 99.95
3.	Hibschite	37.12		32.82	13.72	2.64	13.70 = 100

^{*} TiO, determined on separate sample 1.76 p. c.

B. B. infusible; yields water freely. Easily attacked by acids and alkalies, somewhat less so after ignition.

From the phonolite of the Marienberg near Aussig, Bohemia, where it occurs enveloping

green crystals of a titaniferous melanite in inclusions in a calcareous marl.

Also occurs in limestone inclusions from the basalt of Aubenas in the Vivarais, Ardêche, cf. Lacroix, Les Enclaves des roches volcaniques, Mâcon, 1893, p. 149, and Cornu, l. c. p. 265. Named after Professor J. E. Hibsch.

HIELMITE, see under Uraninite.

Hillebrandite. F. E. Wright, Am. J. Sc., **26**, 551, 1908. Orthorhombic; radiating fibrous. Cleavage probably after (110). Brittle. H. about 5.5. G. = 2.692. Color pure porcelain white, often with faint tinge of pale green. n about 161. Birefringence weak to medium, negative. 2E medium with strong dispersion $v > \rho$. Comp. Ca₂SiO₄·H₂O; SiO₂, 31.74; CaO, 58.81; H₂O, 9.45. Anal. by E. T. Allen:

In HCl separates some silica but otherwise dissolves. Difficultly fusible to colorless glassy bead, giving calcium flame.

Found in contact zone between limestone and diorite in Velardeña mining district, Mexico, associated with gehlenite and spurrite. Named in honor of Dr. W. F. Hillebrand.

HISINGERITE, Min., p. 702. — From Ritenbeuk or Godhavn district, Greenland, with anal.; Nicolau, [Medd. om Grönl., 24, 215, 1901]; Min. Grönl., 322.

Histrixite. W. F. Petterd, Notes on Minerals Occurring in Tasmania, Proc. Roy. Soc. Tasmania, 18, 1902; Zs. Kr., 42, 393. Occurs in radiating groups of prismatic (orthorhombic) crystals, striated longitudinally and showing indistinct acute terminations: also massive with foliated structure. H = 2, slightly sectile. Luster metallic. Color and streak steel-gray, when massive shows iridescent tarnish. Analyses on material regarded as pure.

	S	Bi	Sb	Cu	Fe
1.	24.05	55.93	10.08	6.86	5.18 = 102.10
2.	23.01	56.08	9.33	6.12	5.44 = 99.98

The formula deduced is 7Bi₂S₃.2Sb₂S₃.5CuFeS₂.

Occurs associated with bismuthinite and pyrite in a massive body of tetrahedrite at the Curtin-Davis mine, Ringville, Tasmania. Named from the Latin hystrix (histrix), a porcupine.

HITCHCOCKITE, see Plumbogummite.

HOERNESITE, Min., p. 817. — Artif.; de Schulten, Bull. Min. Soc., 26, 81, 1903.

Hollandite. L. L. Fermor, [Trans. Min. Geol. Inst. India, 1, 76, 1906]; Rec. Geol. Sur. India, 36, 295, 1908. A crystallized manganate of manganese, barium and ferric iron, m(Ba,Mn), $\mathrm{MnO}_5 + n \ \mathrm{Fe_4(MnO}_b)_3$. Author discusses its relations to coronadite, which see. Found in the Kajlidongri manganese mine, Jhábua State, Central India. Named in honor of T. H. Holland, Director of the Geol. Sur. of India.

HOPEITE, Min., p. 808; App., p. 35. — Crystals from Moresnet, Belgium, with new form (130); also opt. study; Buttgenbach, Ann. Soc. Geol. Belg., 33, M9, 1906; crystals found associated with bone breccia in a cave in the surface lead and zinc ores of Broken Hill mines, northwestern Rhodesia, studied by Spencer, Min. Mag., 15, 1, 1908, gave following new facts concerning the mineral. From measured angles (100): (120) = 49° 10′ and (100): (101) = 50° 34′ was calculated ratio, $\ddot{a}:\ddot{b}:\dot{c}=0.5786:1:0.4758$. Three cleavages a(100) perfect with pearly luster lated ratio, a:b:c=0.3780:1:0.4798. Three cleavages a (100) perfect with pearly russer on cleavage face; b (010), good; c (001) poor but showing in cracks on crystals. H. = 3.25. G. = 3.0-3.1. Cleavage plate parallel to b (010) shows interbanding of two modifications, α -hopeite and β -hopeite. α -hopeite has higher birefringence. Acute negative bisectrix $\perp b$ (010). Ax. pl. ||c| (001). $2E = 58\frac{1}{2}^{\circ}$, approx. β -hopeite lower birefringence. Bisectrix as in α -hopeite. Ax. pl. sometimes ||c| (001), sometimes $\perp c$ (001). In first case $2E = 32\frac{1}{2}^{\circ}$ (approx.) and in latter $2E = 20^{\circ}$ (approx.). When warmed α -hopeite is destroyed at 105° C. while β -hopeite latter $2E = 20^{\circ}$ (approx.). When warmed α -hopeite is destroyed at 105° C. while β -hopeite becomes opaque only at 139° C. β -hopeite has slightly lower Sp. G. than α -hopeite. Analyses prove two modifications to be the same and agree with formula, Zn₃P₂O₅.4H₂O; ZnO, 53.3; P₂O₅, 31.0; H₂O, 15.7.

	ZnO	P_2O_5	H ₂ O
α-hopeite	52.1	31.8	16.1 = 100.00
β-hopeite	51.9	[31.9]	16.2 = 100.00

Artif.; de Schulten, Bull. Min. Soc., 27, 100, 1904.

Hortonolite, Min., p. 455. — Occurs as vein mineral associated with actinolite and clinochlore at Iron Mine Hill, Cumberland, R. I. Analysis; Johnson and Warren, Am. J. Sc., 25, 35, 1908; Warren, Zs. Kr., 44, 209.

Howdenite. — Variety of chiastolite from Bimbowrie, S. Aus; Am. J. Sc., 24, 183, 1907.

Howlite, Min., p. 881. — Occurs in large quantities at the borax mines in the Mohave desert, 16 miles N. E. of Daggett, San Bernardino Co., California. Varies in form from friable aggregates of fine scaly crystals (anal. 1) to hard rocklike amorphous masses (anal. 2). W. B. Giles, Min. Mag., 13, 354, 1903.

	SiO ₂	B_2O_3	CaO	H_2O	MgO, Na ₂ O
1.	15.50	44.38	28.45	11.58	0.09 = 100
2.	15.33	43.78	28.44	11.39	1.06 = 100

HUANTAJAYITE, Min., p. 156. — Synthesis of; Cornu, Jb. Min., 1, 22, 1908.

HÜBNERITE, Min., p. 982. — Anal. from Dragoon, Summit, Ariz.; Hobbs, Amer. Geol., 36, 179; Zs. Kr., 43, 394.

HUDSONITE, cf. Amphibole.

Hulsite. A. Knoff and W. T. Schaller; Am. J. Sc., 25, 323, 1908.

Orthorhombic (?) as small crystals or tabular masses. Prismatic cleavage; $m \wedge m''' = 57^{\circ} 38'$. Twinning frequent with \dot{c} axis as twinning axis; one individual being revolved 120° from the other. Color and streak black. Luster submetallic. H. = 3. G. = 4.28.

Comp. Originally given as a hydrous borate of ferrous and ferriciron and magnesium. Subsequently about 11% of SnO₂ was discovered in the mineral and the revised formula (priv. contr.

W. T. Schaller) is 10(Fe,Mg)O.2FeO₃,1SnO₂.3B₂O₃.2H₄O. Pyr. Readily sol. in HCl and HF. Yields water in C. T. Fuses quietly to a dull black slag

and tinges the flame green. Boron reaction with HKSO, and CaF2.

Occ. Found in metamorphosed limestone at a granite contact at Brooks mountain, Seward Peninsula, Alaska, associated with vesuvianite, magnetite and calcite. Named in honor of Mr. Alfred Hulse Brooks of the U. S. Geol. Sur.

Hureaulite, Min., p. 832. — Artif.; de Schulten, Bull. Min. Soc., 27, 123, 1904.

Hussakite, see under Xenotime.

Hutchinsonite. R. H. Solly, Proc. Cambridge Phil. Soc., 12, 277, 1904; Min. Mag., 14, 72, 1905. G. T. Prior, Nature, 71, 534, 1905. G. F. H. Smith and G. T. Prior, Min. Mag., 14, 284, 1907.

Orthorhombic. Axes $\check{a}: \bar{b}: c=1.6343:1:0.7549$ (\check{a} as given by Solly = 0.8175). (100): (340) = * 47° 28′; (100): (201) = * 47° 16′.

Commonly in flattened rhombic prisms with numerous small faces of domes and pyramids; 7 (140) prominent. Principal forms: a (100), b (010), F (210), l (740), k (320), i (540), m (110), b (340), f (120), g (140), U (102), d (101), W (302), u (201), v (301), w (401), p (111), N (221), n (121), t (342), q (322), o (211), Q (311).

Cleavage a good. Fracture conchoidal. Brittle. H. = 1.5 - 2. G. = 4.6. Luster adamantine. Color and streak, scarlet-vermilion to deep cherry-red. Transparent to translucent. Ax. pl. $\parallel a$ (100). Bx_{ac} \perp to b (010). Negative. Birefringence fairly strong. Pleochroism weak. Composition, (Tl,Ag,Cu)₂S.As₂S₃ + PbS.As₂S₃ (?).

Analyses on small amounts of somewhat doubtful purity. I on crystals; II on variety occur-

ring in needles.

Occurs in the white dolomite of the Lengenbach quarry in the Binnenthal, Switzerland; sely associated with sartorite and rathite. This name is also used by Koechlin for an undeclosely associated with sartorite and rathite. This name is also scribed mineral from the Binnenthal, Min. Mitth., 23, 551, 1904.

Named after Dr. Arthur Hutchinson, of Cambridge, England.

Hyaloallophane. G. D'Achiardi, [Atti. Soc. Toscana Sci. Nat., 12, 32, 1898]. Allophane containing an excess of silica, supposed to be due to the presence of admixed hyalite, from Sardinia. Min. Mag., 12, 384; Zs. Kr., 32, 521.

HYALOPHANE, Min., p. 321. — Crystallographic and optical study of crystals from the Binnenthal, Switzerland; Baumhauer, Zs. Kr., 37, 603, 1903. Crystals from same locality showing new forms (380), (212), (211); Solly, Min. Mag., 14, 17, 1904. Crystallographic and optical study with anal. and discussion of isomorphism of barium and potassium feldspars; Strandmark, G. För. Förh., 25, 289, 1903; 26, 97, 1904.

HYALOSIDERITE, see Chrysolite.

Hyalotekite, Min., p. 422. — Discussion of chem. comp.; Cesáro, Mem. Soc. Liège, 5, No. 6, 26, 1904.

Hydrocerussite, Min., p. 299. — Crystals from Långban are hexagonal with c (0001), o (10 $\bar{1}2$), p (10 $\bar{1}1$); $cp = *58^{\circ}36'$ and c = 1.4188. Flink, Bull. G. Inst. Upsala, 5, 94, 1901.

Hydrogöthite. P. Zemjatschensky [Trav. Soc. Nat. St. Petersburg, 20, 206, 1889], Zs. Kr., 20, 185; [Trav. Soc. Nat. St. Petersburg, 34, 1903], Zs. Kr., 41, 187; J. Samojloff, Zs. Kr., 35, 272, 1901.

Orthorhombic, radiating fibrous. Two cleavages at right angles. H. = 4. G. = 3.7. Color and streak brick red. Optically — Ax. pl. \(\perp\) to best cleavage. Pleochroism strong, orange red to yellow green. Comp. 3Fe₂O₃.4H₂O; Fe₂O₃, 86.9; H₂O, 13.09.

Anal., Samojloff, loc. cit., Fe₂O₃, 86.01; H₂O, 12.95. Occ. associated with limonite near

Lipetzk and Dankow, etc., Gouvernement Tula, Russia.

HYDROMAGNESITE, see Giorgiosite.

HYDROUS CALCIUM CARBONATE. - Occurs as a white fungus-like coating on marl on shore of river Weichsel near Nowo-Alexandria, Poland, in felted mass of thin colorless needles or plates. G. = 2.63. Shows inclined extinction and is monoclinic or triclinic. Analysis gives CaCo₃. with probably 3H₂O = CaCo₃.3H₂O. Iwanoff, [Ann. géol. et min. Russie, 8, 23, 1905]; Zs. Kr., 44, 87.

HYDROUS IRON PHOSPHATE. — Anal. of material from Kutschuk-Eltigen and Nowy Karantin, on Kertsch and Taman peninsulas, Russia, gave Fe₂O₃ 47.71; P₂O₅, 38.87; H₂O, 13.42. Orthorhombic. Cleavage in three directions nearly at right angles to each other. Weak birefringence. Does not correspond to any known mineral. Tschirwinskij, [Ann. géol. et min. Russie. 7, 28, 1904]; Zs. Kr., 43, 77.

Hypersthene, Min., p. 348. — Crystals from a volcanic bomb, St. Christopher; Fels, Zs. Kr.,

37, 455, 1903; from Karra Akungnak, Greenland; Böggild, Min. Grönl., 363.
Optical constants of rock forming hypersthene; Duparc and Pearce, Bull. Soc. Min., 31, 106, 1908.

Ice, Min., p. 205; App., p. 36. — Concerning crystalline structure and its influence on glacial movement; Mügge, Jb. Min., 2, 123, 1899; 2, 80, 1900, and v. Drygalski, ibid., 1, 71, 1900; 1, 37, 1901; Zs. Kr., 37, 635.

Crystals formed in air; Futterer, [Ver. naturwiss. Vereins Karlsruhe, 14, 1, 1901], [Ber. ü. d.

34. Versamml. d. oberrhein. geol. Ver. in Diedenhofen, April, 1901]; Zs. Kr., 38, 509.

IDDINGSITE, App., p. 36. — Occurrence as pseudomorph after olivine in basalt in the Mittelgebirge, Bohemia; Hibsch, Min. Mitth., 19, 98.

Ilmenite, Min., p. 217; App., p. 36. — Crystals from the Eichamwand, Prägraten, Tyrol, described (y (3142) new); Sustschinsky, Zs. Kr., 37, 60, 1902; from near Ofenhorn, Binnenthal, Switzerland, with following new forms: α (0.7.7.20), X (4483), γ (1232), δ (2467), β (5.5.10.24), δ (4150), q (6241); δ (3121); r (4041) and δ (1012); Solly, Min. Mag., 14, 184, 1905.

Study of the relations existing between chemical composition, specific gravity and length of c axis of ilmenites from various localities shows that with increase in percentage of TiO, there is a corresponding increase in the value for c and a decrease in the specific gravity; Doby and Melczer, Zs. Kr., 39, 526.
Anal. from Sundsvale, Sweden; Tschernik, [Jour. phys. Chim. Russe, 36, 457, 712, 1904];

Zs. Kr., 43, 78.

Microscopic intergrowth with magnetite from Brazil; Hussak, Jb. Min., 1, 94, 1904.

Segregation from basic eruptive rocks; Vogt, Zs. pr. Geol., 8, 233, 370, 1900; 9, 9, 180, 289, 327, 1901.

Occurrence in south Norway with anal. by Wallin; Brögger, Min. Süd.-Nor. Granitpeg., 39,

1908

Picrotitanite (Min., p. 218), or picroilmenite, (Groth, Tabell. Übers. d. Min., 4th Ed., 143, 1898). Occurrence in Balangoda district, Ceylon, with analyses; Crook and Jones, Min. Mag., 14, 165, 1906. Small crystals found in albite veins in upper Doria Riparia valley considered to be mohsite which on account of crystallographic differences is thought by author to be an independent species. Colomba, Att. Acc. Torino, 37, 343, 1902.

ILMENORUTILE, Min., p. 238. - New determinations and new analyses (see below I and II) by Prior, Min. Mag., 15, 85, 1908, indicate that the percentages of TiO₂ as recorded were too high and those of Nb2O5 too low. Simplest formula to be derived from new analyses is FeO.Nb2O5. 5TiO₂. Suggested that ilmenorutile is one end of a mineral series while strüverite is the other.

		TiO ₂	SiO ₂	Nb ₂ O ₅	Ta ₂ O ₅	FeO .	MgO	CaO
I.	Ilmen Mts.	53.04		21.73	14.70	10.56		tr. = 100.03
	Iveland, Norway							0.11 = 99.12
III.	Evje, Norway	73.78	0.23	13.74	0.43	11.58	0.04	0.22 = 100.02
IV.	Tvedestrand, Norway	67.68	0.05	20.31		11.68	tr.	0.28 = 100.00
Anal.	III and IV by Heidenry	eich, quo	ted by	Brögger	r, Min.	SüdNor.	Grani	tpeg., 41, 1908.

ILVAITE, Min., pp. 541, 1037; App., p. 37.—Crystals from Siorarsiut, Tunugdliarfik-Fjord, South Greenland; Moesz, [Math. és term. tud. Értesitö, 17, 442, 1899], Zs. Kr., 34, 708; from same locality showing following new forms: γ (160), σ (081), f (041), i (401), m (621), ζ (331), ϵ (431); analysis showing 2.2% MnO; axial ratio $\check{a}:\check{b}:\dot{c}=0.6766:1:0.4499$; etching figures and optical characters described with anal. by Christensen; Böggild, Medd. om Grönland, 25, 45, 1902; crystals (with anal.) from Potter Creek, Shasta Co., Calif.; Prescott, Am. J. Sc., 26, 14, 1908.

Anal. of material from Elba and discussion of chem. comp.; Himmelbauer, Ber. Acad. Wien,

115, 1177, 1906; chem. comp. also; Baschieri, Proc. Soc. Tosc., May, 1907; Mar., 1908.

Impsonite. An asphalt closely similar to albertite but differing in being almost insoluble in turpentine. Found occurring in veins in shales from Impson valley, Indian Territory. Taff, Am. J. Sc., 8, 219, 1899; see under Asphalt.

INESITE, Min., p. 564; App., p. 37. — From near Villa Corona, Durango, Mexico, in tufts of radiating crystals of a flesh color. New forms observed, k ($\bar{11}$.0.12) and s ($9\bar{4}6$). Following analysis:

$$m SiO_2$$
 MnO FeO CaO MgO $m H_2O$ (cryst.) $m H_2O$ (const.) $m G=2.965$ 44.89 36.53 2.48 8.24 tr . 5.99 2.21 = 100.34

giving H₂(Mn,Ca)₆Si₆O₁₉.3H₂O for formula. Farrington, Field Mus., 1, 7, 221, 1900; Zs. Kr., 36, 76. Also in fibrous masses and in crystals in granular hematite at Långban, Sweden; Flink, Bull. G. Inst. Upsala, 5, 92, 1901.

Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 125, 1908.

Iodembolite. G. T. Prior and L. J. Spencer, Min. Mag., 13, 177, 1902. — A name substituted by Prior and Spencer for iodobromite, on the ground that the composition is not definite, as claimed by Lasaulx, and that the name is misleading as to the composition. See Cerargyrite.

A mineral belonging here giving reactions for AgCl, AgBr and AgI occurs in thin seams and crusts of a yellow color in a vein of quartz and calcite near Globe, Pinal county, Arizona; W. P. Blake, Am. J. Sc., 19, 230, 1905.

IODOBROMITE, Min., p. 160; see *Iodembolite* above.

IODYRITE, Min., p. 160.—Crystals from Broken Hill, N. S. W., simple with c and m; twinned, twinning pl. e (3034) giving pseudo-tetrahedral forms. Discussion of behavior when heated and relation to other similar iodides; Spencer, Min. Mag., 13, 45. See also Prior and Spencer, ibid.,

185. Crystal from Broken Hill, N. S. W. showing a (11 $\bar{2}0$); crystals from Tonapah, Nev. (figs.), showing following new forms, r (70 $\bar{4}4$), t (70 $\bar{7}3$), x (70 $\bar{7}1$), y (90 $\bar{9}1$), y' (90 $\bar{9}1$), w (90 $\bar{9}2$), w' (90 $\bar{9}2$), s' (15.0. $\bar{1}5.\bar{8}$), z (3.0. $\bar{3}3.2$). With c (0001): i (20 $\bar{2}1$) = 62° 10′ 30″, c = 0.8204. Crystals varied

in habit but usually distinctly hemimorphic. Twins with tw. pl. e (3034). Etching figures. Sp. G. = 5.5115. Anal.; Kraus and Cook, Am. J. Sc., 27, 210, 1909.

Iolite, Min., p. 419; App., p. 37. — Crystals from Oetzthal and Kaunserthal, Switzerland; Gemböck, Zs. Kr., 31, 248; from Uiordlersuak, Greenland; Böggild, Min. Grönl., 344. Discussion of pseudomorphs of iolite; Gareiss, Min. Mitth., 20, 1, 1901.

Comp. discussed by Weibull (anal. by Ramberg) from Längfalls mine, Grangärde parish, Sweden; G. För. Förh., 22, 33, 1900. Rôle of water in; Zambonini, Mem. Acc. Sci. Napoli, 14, 42, 1908.

Occurrence in North Celebes with analysis; Bücking, Ber. Senckenberg. naturforsch. Ges., Frankfurt, 3, 1900; Zs. Kr., 36, 654; in tourmaline veins of Elba; D'Achiardi, Proc. Soc. Tosc., Jan., 1900; occurrence of iolite and its alteration products with description of crystals from, Physide Dâme, Loire and Rhâne: Gonnard, Bull. Min. Soc. 31, 171, 1908. Puy-de-Dôme, Loire and Rhône; Gonnard, Bull. Min. Soc., 31, 171, 1908.
Origin and association with bibliography; Teall, Proc. Geol. Ass., 16, 61, 1899.

IRON, Min., pp. 28, 1037; App., p. 37. — Crystallization; Osmond and Cartand, [Ann. d. Mines, 17, 110, 1900; 18, 113, 1900]; Zs. Kr., 35, 657, 658. Crystal from meteorite from Laborel measuring 7 × 5 mm. showed cube, octahedron, dodecahedron with small vicinal faces of tetrahexahedron and trisoctahedron; Berwerth, Min. Mitth., 25, 511, 1906. Artif. crystals; Cornu, Centralbl. Min., 545, 1908.

Structure planes; Mügge, Jb. Min., 2, 63, 1899. Mechanical properties of crystallized iron; Osmond and Frémont, C. R., 141, 361, 1905. Physical-chemical observations on meteoric and

furnace iron; Rinne, Jb. Min., 1, 122, 1905.
Composition of iron from Ovifak, Greenland; Winkler, [Vet.-Akad. Förh., 495, 1901]; Zs. Kr.,

37, 286.

Occurrence of native iron enclosed in a rounded basaltic fragment found in a tuff deposit near

Offeiden, on the river Ohm, Germany; Schwantke, Centralbl. Min., 65, 1901.
Studies of meteorites from the following localities: Salt River, Kentucky; Toluca, Mexico; Studies of meteorites from the following localities: Salt River, Rehucky; Toluca, Mexico; Capland, South Africa; Babbs Mill, Tenn.; Illinois Gulch, Deer Lodge Co., Mon.; Deep Springs Farm, Rockingham Co., N. C.; Hammond, Wis.; Cacaria and Nezquital, Durango, Mexico; Bückeberg, Germany; Murphy, Cherokee Co., N. C.; St. Francois Co., Mo.; Cosby's Creek, Cocke Co., Tenn.; Cañon Diablo, Ariz.; Magura, Hungary; Quesa, Spain; Merceditas, Chile; Thunda, Queensland, Australia; San Antonio, Texas; Cohen, [Ann. nat. hist. Hofmus., 15, 74, 351, 1900], [Mitt. d. nat.-wiss. Ver. Neuvorpomm. u. Rügen, 33, 1900], Ber. Ak. Berlin, 1122, 1900; all summarized in Zs. Kr., 36, 644. Meteoric irons from Great Namaqualand, from South Africa and Patagonia; Eletcher Min. Mag. 14, 28, 37, 41, 1904; Jappanse occurrences; Limbo Beitrage Min. Patagonia; Fletcher, Min. Mag., 14, 28, 37, 41, 1904; Japanese occurrences; Jimbo, Beitrage Min. Japan, 2, 30, 1906. See Awaruite.

Irvingite. S. Weidman, Am. J. Sc., 23, 451, 1907. — A mica in crystals up to over an inch in diameter. Basal cleavage. Prismatic parting. Color from grayish to yellowish and pinkish white. Folia tough and elastic. Easily fusible. Axial angle somewhat larger than lepidolite and zinnwaldite.

Comp. A lithia mica corresponding to 6SiO₂.1Al₂O₃.2R₂O.1(F.OH).

Anal. by Lenher:

SiO₂ TiO₂ Al₂O₃ Fe₂O₃ FeO MgO CaO K₂O Na₂O Li₂O F H₂O 57.22 0.14 18.38 0.32 0.53 0.09 0.20 9.12 5.14 4.46 4.58 1.66 [less 1.93, O = F] = 99.91

Found in pegmatite veins near Wausau, Wisconsin. Named after Prof. R. D. Irving, the geologist.

Isorthose, var. of orthoclase, which see.

IVAARITE, Min., p. 448. — Analysis of material from Iiwaara, Finland, gave SiO_2 , 27.35; TiO_3 , 16.44; Al_2O_3 , 1.50; Fe_2O_3 , 20.09; FeO_2 , 2.90; MnO_3 , trace; MgO_3 , 0.82; CaO_3 , 30.99; total = 100.09. Dittrich, Bull. de la Commission Géol. de Finlande, Helsingfors, 11, 1900; Zs. Kr., 36, 196.

Jacobsite, Min., p. 227. — Analysis of material from Bulgaria, Kovář, [Abh. böhm. Akad., Prag, 27, 1900]; Zs. Kr., 36, 202.

Jadeite, Min., p. 369; App., p. 37. — From Bhamo, Burma, with optical properties and analysis; Krenner; [Wissenschaftliche Ergebnisse der Reise des Grafen Béla Széchenyi in Ostasien, Budapest, 3, 285, 1897]; Zs. Kr., 31, 502. Occurrence and optical characteristics in rocks on the Cyclades islands; Ktenas, Min. Mitth., 26, 277.

Analysis of jadeite from Piedmont; Mrazec, [Bull. soc. d. sc. de Bucarest-Roumanie, 7, 187, 1898]; Zs. Kr., 32, 623. Occurrence and analysis from Susa; Piolti, Atti della R. Accad. d. Sc. di Torino, 34, 600, 1899. Analyses of ancient axes made of jadeite from Hungary; Berwerth,

Min. Mitth., 20, 357.

Occurrence in the western Alps and in Liguria; Franchi, Rend. Acc. Lincei, 9, (1), 349, 1900. From Cassine, Italy, with anal.; Colomba, Riv. Min., 27, 1901. Jadeite and chloromelanite in prehistoric objects from Guatemala; Bauer, Centralbl. Min., 65, 1904. Study of jadeite from Upper Burma; Bauer, Centralbl. Min., 97, 1906; Bleeck, Rec. Geol. Sur. India, 36, 254, 1908. Historical; Berwerth, Min. Mitth., 24, 228, 1905.

An elaborate study of chemical composition (with 58 new analyses), structure, microscopical and optical properties, with discussion of origin, included and associated minerals, etc., to be found in book entitled "Investigations and Studies in Jade: The Bishop Collection," by H. R. Bishop, 2 vols., privately printed in New York, 1906. Contributors to the chapter on mineralogy of the mineral include Penfield, Foote, Iddings, Clarke, Palache, Pirsson, Washington and Walden.

Jamesonite, Min., p. 122; App., p. 37. — Analyses of material from various localities; Guillemain, [Inaug.-Diss. Breslau, 1898], Zs. Kr., 33, 74; of material from Campiglia Soana, in Ivrea; Novarese, Boll. Com. Geol. Ital., 23, 319, 1902.

Composition discussed by Spencer, Min. Mag., 14, 207 and 310. A new analysis of crystallized jamesonite from Bolivia does not conform to the formula 2PbS.Sb₂S₃ (see below), and from study of other analyses author concludes that this formula is wrong. All "flexible feather ore" must be removed from this species, as the fibers of jamesonite on account of its basal cleavage are brittle. Cleavages \parallel to m and a were not observed on the Bolivian material. "Flexible feather ore" may be any one of several related species. Warrenite (domingite) should probably be included in jamesonite; the formula given, $3\text{PbS.Sb}_2\text{S}_3$, is the same as the original formula by Rose for jamesonite. The formula deduced from the following analyses by Prior is 7(Pb,Fe)S.4Sb₂S₃.

		S	Sb	Pb	Fe	Cu	Ag
I.	Crystallized, Bolivia	20.52	34.53	41.18	2.76	0.26	0.01 = 99.26
	Massive, Bolivia	21.37	34.70	40.08	2.79	0.22	0.13 = 99.29

Janosite, see Copiapite.

JAROSITE, Min., p. 974; App., p. 37.—Occurrence in Schlaggenwald, Bohemia, in small crystals showing combination of base, low positive and steeper negative rhombohedrons. Some of the crystals in basal cleavage plates showed abnormal double refraction and division into six portions, the two opposite ones being of the same optical orientation and giving a negative biaxial interference figure. The strength of the double refraction and the axial angle varied in different specimens. Slavik, Zs. Kr., 39, 296. Measurement of crystals from Dakota with new axial ratio: Cesaro, Bull. Ac. Belg., 137, 1905.

Analysis of material from Sichotin near Kunstadt in Mähren; Kovář [Progr. d. čechosl. Handels-Akademie Prag, 1903], Zs. Kr., 39, 400.

Occurrence from Chocaya, Potosi, Bolivia; Spencer, Min. Mag., 14, 342.

Natrojarosite (Hillebrand and Penfield, Am. J. Sc., 14, 211, 1902; Turner, ib., 13, 345) is a

variety containing sodium instead of potassium (formula, see below) from the Soda Springs valley, Esmeralda Co., Nevada, on the road from Sodaville to the Vulcan copper mine. As a glistening powder made up of minute tabular crystals, with c (0001), r (1011) and s (0221), $cr = 51^{\circ}$ 53' \therefore c = 1.104. G. = 3.18. Color in the mass yellowish brown, of single crystals

golden yellow. Analysis, after deducting impurities:

 $Fe_{2}O_{3}$ 49.39 SO, Na₂O K₂O 0.37 H₂O 32.94 11.12 = 100

A specimen from Cook's Peak, New Mexico, which yielded 4.49 Na₂O, 0.96PbO (ibid., p. 213) also belongs here. Another form, described by Headden (ibid., **46**, 24, 1893) from the Buxton mine, Lawrence Co., South Dakota, gave after deducting impurities (recalc. by H. and P., l. c.) 4.86 Na₂O, 1.65 K₂O.

Plumbojarosite is a variety containing lead in place of potassium (formula, see below) described by the same authors (ibid., p. 213) from Cook's Peak, New Mexico. Like natrojarosite occurs as a crystalline powder made up of minute tabular crystals with $ss=109^{\circ}\ 20'$ and c=1001.216. G. = 3.665. Color of the mass dark brown, of single crystals golden yellow. Analysis, after deducting impurities:

> SO. $Fe_{2}O_{3}$ 42.44PbO $H_2O \\
> 9.55 = 100$ 28.29 19.72

The relations of the minerals of the alunite-jarosite group in composition, axial ratio and optical character, as developed by Hillebrand and Penfield, is shown in the following table:

	Formula	b	rr'	Birefringence
Alunite.	$K_2Al_6(OH)_{12}(SO_4)_4$	1.252	90° 50′	57 65 + 1 1 1 1 C
Jarosite	$K_2 Fe_6 (OH)_{12} (SO_4)_4$	1.245	90° 45′	e 21 Ones Teamility v
Natrojarosite	$Na_2Fe_6(OH)_{12}(SO_4)_4$	1.104	85° 54′	
Plumbojarosite	$PbFe_6(OH)_{12}(SO_4)_4$	1.216	89° 42′	

Jentschite, Min. Mitth., 23, 551, 1904.—A new mineral not yet described from the Binnental. In thin iron black tables, deeply grooved, with bright tarnish; up to 1 cm. in size. Probably identical with lengenbachite; Solly, Min. Mag., 14, 80, 1905 (footnote).

JORDANITE, Min. pp. 141, 1039; App., p. 38. — Crystal forms and analysis of material from Binnenthal; Guillemain, [Inaug.-Diss., Breslau, 1898], Zs. Kr., 33, 76.

Solly and Jackson, Min. Mag., 12, 282; Zs. Kr., 35, 321, have studied jordanite from the Binnenthal crystallographically and chemically. A list of 115 known forms (monoclinic, see Min., p. 1039), 11 of which are new, is given. Four laws of twinning are given: (1) (101), indicated by numerous twin lamellæ; (2) (301), having law (1) always combined with it; (3) (101) (?); (4), (301) (Baumhauer gives this form by misprint as (103)). Analyses by Jackson:

	Pb	S	As
I.	68.61	18.19	12.32 = 99.12
II.	68.83	18.42	12.46 = 99.71

Study of the zonal relations of crystal faces on jordanite; Baumhauer, Ber. Akad. Berlin, 577, 1900; Zs. Kr., 38, 635.

Occurrence with analysis in the Blei-Scharley mine near Beuthen, Upper Silesia; Sachs, Centralbl. Min., 723, 1904.

Justite = koenenite. Min. Mitth., 23, 97, 1904.

Kainite, Min., p. 918; App., p. 38. — Formation discussed; van't Hoff with von Euler-Chelpin, Meyerhoffer, Ber. Ak. Berlin, 1018, 1900; 424, 1901; 678, 1903; specimens from Wolfenbüttel, Brunswick, Germany, show a blue color and have the following pleochroism: a = violet; b = blue; c = yellow; Baumgärtel, Centralbl. Min., 449, 1905. From Stassfurt, Busz; Ber. Naturhist. Ver., Bonn, 1, C, 2, 1906; Ber. Med.-naturwiss. Ges., Münster, June, 1906.

Kalgoorlite. E. F. Pittman, Rec. G. Surv. New South Wales, 5, 203, 1898. A. Carnot, Bull. Soc. Min., 24, 361, 1901. T. A. Rickard, Trans. Am. Inst. Mng. Eng., 30, 708, 1901. L. J.

Spencer, Min. Mag., 13, 282, 1903.

Described by Pittman from Kalgoorlie, West Australia, as a new telluride having the composition HgAu₂Ag₆Te₆; massive with sub-conchoidal fracture. Color iron-black; G. = 8.79. An analysis by J. C. H. Mingaye (quoted by Spencer) gave: Te, [37.26]; Au, 20.72; Ag, 30.98; Hg, 10.86; Cu, 0.05; S, 0.13 = 100.

Carnot used this name for a mineral from the same source containing but 2.00 or 2.26 p.c. Hg, and essentially, if pure, a mercurial petzite. Rickard, however, urged that the mineral was to be regarded as an impure coloradoite, and Spencer shows that it is undoubtedly a mixture of coloradoite and petzite.

Kaliborite, Min., p. 885. — Formation discussed; van't Hoff, Ber. Ak. Berlin, 1008, 1902.

Kaliumblödite, see Leonite.

Kaolinite, Min., pp. 685, 1039. — Study of crystal plates from National Belle mine, Silverton, Colo., confirms the monoclinic character of the mineral; Milch, Centralbl. Min., 1, 1908. Notes on optical properties; Dick, Min. Mag., 15, 124, 1908.

Observed in minute hexagonal scales (anal.) at the antimony mine of Miramont on the border of Cantal and Haute-Loire, France; Friedel, Bull. Soc. Min., 24, 6, 1901. Analyses of material from Gross-Tresny, Mähren; Kovář, [Abh. böhm. Akad., No. 15, 1, 1896]; Zs. Kr., 31, 524; from Vicz near Bistritz, Mähren; Kovář, [Chem. Blätter, 1899]; Zs. Kr., 34, 706. Chem. constitution; McNeil, Jour. Amer. Chem. Soc., 28, 592, 1906.

KATAPLEIITE, see Catapleiite.

Kentrolite, Min., pp., 544, 1039. — Occurrence in copper mine of Bena Padru near Ozieri, Sardinia; Lovisato, Rend. Acc. Linc., 14, 696, 1905.

Kertschenite. S. Popoff, Centralbl. Min., p. 113, 1906. In fibrous-radiated crystalline aggregates. H. = 3.5. G. = 2.65. Color dark green, nearly black. Streak green.

Comp. — A hydrated basic ferric phosphate.

Analysis:

P₂O₅ 28.20 MgO Fe.O. FeO MnO CaO H₂O 32.93 1.92 1.55 0.47 24.98 = 99.549.49

Occurs in the limonite deposits on the peninsula of Kertsch, Gov't Taurien.

Keweenawite. G. A. Koenig, Am. J. Sc., 14, 410, 1902.

Massive; as a fine granular aggregate, very brittle with flat conchoidal fracture. H. = 4. G. = 7.681. Luster metallic. Color pale pinkish brown resembling niccolite, tarnishing to a deeper brownish red.

Composition, an arsenate of copper and nickel with a small amount of cobalt (Cu, Ni, Co), As.

Analyses:

	As	Cu	Ni	Co	Fe	
1.	36.96	39.12	17.96	0.94	tr.	quartz 4.98 = 99.96
2.	34.18	53.96	9.74	0.94		quartz 0.78 = 99.60
3.	[38.44]	40.72	19.42	0.82	tr.	quartz 0.60 = 100.00

B. B. fuses easily to a globule, yielding arsenical fumes and finally a metallic bead; bead reacts for cobalt, nickel and copper. Dissolves in strong nitric acid.

From the Mohawk mine Keweenaw Co., Michigan, which has afforded domeykite and mohawkite, which see. The author has also obtained synthetically the compound Cu₂As, with the color and crystalline structure of chalcocite, and G. = 7.71, Am. J. Sc., 10, 443, 1900.

Kieserite, Min., p. 932; App., p. 39. — Formation discussed; van't Hoff, Meyerhoffer and Smith, Ber. Ak. Berlin, 1034, 1901.

KILBRICKENITE, Min., p. 145. — Shown by Prior to be identical with geocronite, which see.

Kleinite. Moses, Am. J. Sc., 16, 263, 1903; Hillebrand, Am. J. Sc., 21, 85, 1906; Sachs, Ber. Akad. Berlin, 1091, 1905; Centralbl. Min., 200, 1906; Hillebrand and Schaller, Am. J. Sc., 24, 259, 1907.

Hexagonal. c = 1.6642 (mean of Schaller's and Sachs's values).

Forms: c (0001), m (1010), a (1120), p (1011), x (1012). Crystals short prismatic, seldom

over 1 mm. in length.

Cleavage: c good; m, poor. Brittle. H. = 3.5. G = 7.975-7.987. Color yellow to orange. Darkens on exposure to light but regains original color in the dark. Basal sections show innumerable doubly refracting individuals. Becomes normally uniaxial when heated to 130°.

Comp. — A mercury ammonium chloride of uncertain composition.

Analysis by Hillebrand of orange crystals:

N H.O Hg CI SO. 85.86 7.30 2.57 1.03 = 99.863.10

Pyr. — In closed tube gives a little water, darkens in color and at 260°-280° mercury and calomel sublime. At higher temperature another sublimate is formed. Soluble in warm HCl and HNO₃ without deposition of calomel. Soluble in NH₄Br with evolution of ammonia.

Obs. Found on the properties of the Marfa and Mariposa Mining Co., Terlingua, Texas,

associated with gypsum, calcite and barite and with the other mercury minerals of the locality.

Named by Sachs after the late Prof. Carl Klein of the University of Berlin.

Knebelite, Min., p. 457; App., p. 39. — Anal. of material from Macskamezö in Hungary; Kossmat and v. John, Zs. pr. Geol., 13, 305-325, 1905.

KNOXVILLITE, Min., p. 966. — A pale green granular saccharoidal sulphate from the Victoria gold mine, Salisbury, Tasmania, is provisionally referred here by W. F. Petterd, Notes on Minerals from Tasmania, 1902. An analysis gave:

SO, Al₂O₃ ${
m Fe_2O_3}\ 15.86$ Cr2O3 30.322.48 40.56 = 97.69

Koenenite. F. Rinne, Centralbl. Min., p. 493, 1902. Rhombohedral. In crusts showing, on the rough surface, obscure crystalline faces interpreted as belonging to an acute scalenohedron.

Cleavage highly perfect, yielding thin flexible folia, often triangular in form.

Very soft. G. = 1.98.

Color red, this color due as with carnallite, which it resembles, to minute scales of hematite. Optically uniaxial, negative.

Composition, an oxychloride of aluminium and magnesium, probable formula: Al₂O₃.3MgO₄.

2MgCl₂.8H₂O (or 6H₂O).

Analyses: I, Sundmacher; II, Buchholz; impurities have been deducted.

	$ ext{Al}_2 ext{O}_3 \\ 17.79$	MgO	$\frac{\mathrm{MgCl_2}}{35.70}$	H ₂ O
I.	17.79	21.10	35.70	25.41 = 100
II.	18.25	23.44	36.85	21.46 = 100

Decomposed slowly by boiling water, the scales retain their form but show negative double refraction (metakoenenite, Rinne).

From the potash mine Justus I near Volpriehausen in the Solling; associated with halite, also with anhydrite and carnallite.

Named after Professor A. v. Koenen.

Kröhnkite, Chile.

Krennerite, Min., pp. 105, 1039; App., p. 39. — Highly modified crystals from Nagyág have yielded twenty-seven new forms and the axial ratio $\check{a}: \bar{b}: \dot{c}=0.9369:1:0.5068$; Smith, Min. Mag., 13, 264, 1903. Of possible occurrence, with other tellurides, at Kalgoorlie, West Australia, cf. Spencer, ibid., 272. Kröhnkite, Min., p. 958. — Crystals from Chuquicamata, Prov. of Autofagasta, Chile, described by Palache and Warren; Am. J. Sc., 26, 342, 1908; Zs. Kr., 45, 529, 1908. A new orientation was adopted by which the front and back of the crystals (as given in Sys.) were interchanged. Axial ratio derived = $\dot{a}:\dot{b}:\dot{c}=0.5229:1:0.4357,~\beta=56^{\circ}~17'~20''.$ The observed forms follow: a (100), b (010), m (110), b (120), b (130), e (011), d (021), f (031), t ($\bar{1}01$), u ($\bar{3}02$), v ($\bar{3}01$), p (111), r (121), q ($\bar{1}11$), s ($\bar{1}21$), w ($\bar{2}11$), x ($\bar{2}21$), z ($\bar{3}31$), i ($\bar{5}51$), o ($\bar{1}\bar{0}.10$ 1), y ($\bar{2}32$), n ($\bar{1}32$). Twinning plane c (001). Cleavage perfect $\parallel b$ (010), good $\parallel e$ (011), no prismatic cleavage observed.

Refractive indices; $\alpha = 1.5437$, $\beta = 1.5775$, $\gamma = 1.6013$. $2V_{Na} = 78^{\circ} 36'$ (calc.). Ax. pl. # b (010). Bxac inclined 48° 45' to axis c in obtuse < β. Inclined dispersion. Anal. confirms

formula.

KRUGITE, Min., p. 950. — Artif.; Geiger, Ber. Ak. Berlin, 1123, 1903; van't Hoff, ibid., 566, i 1906.

Ktypeite, App., p. 39. — Concerning the probability of its existence at Carlsbad and its artificial formation; Vater, Zs. Kr., 35, 149.

Kunzite, a var. of spodumene, which see.

Kutnohorite. A. Bukovský [Anz. III Congr. böhm. Naturf. u. Aerzte, Prag, 1901, p. 293]; Jb. Min., 2, Ref., p. 338, 1903. A rhombohedral carbonate with the atomic ratios Ca: Mn: Fe: Mg = 7:5:1:2, occurring as reddish-white cleavage masses at Kutná Hora, Bohemia.

LABRADORITE, Min., p. 334. — Crystallographic, optical and chemical investigation of material found in the anorthosites from Carlton Peak, Minnesota; Winchell, Amer. Geol., 26, 220, 1900. Optical orientation; Luczizky, Min. Mitth., 24, 191, 1905. Anal. from Gleniffer Hills, south of Paisley, Renfrewshire; Houston, [Trans. Geol. Soc. Glasgow, 12, 354, 1906]; Zs. Kr., 45, 304.

Lacroisite = rhodochrosite + rhodonite, Chem. Ztg., 27, (1), 15, 1903.

Landerite, a garnet, which see.

LANGBEINITE, App., p. 40. — From the Punjab Salt Range, India, description with analysis; Mallet, Min. Mag., 12, 159, 1899. Formation discussed; van't Hoff, Meyerhoffer and Cottrell, Ber. Ak. Berlin, 276, 1902. Discussion of crystalline form; Sachs, ibid., 376; Zs. Kr., 40, 646.

LARDERELLITE, Min., p. 882. - New analyses of material from the Tuscan lagoons lead to the formula (NH₄)₂B₁₀O₁₆+ 5H₂O; d'Achiardi, Rend. Acc. Linc., 9, (1), 342, 1900.

	B_2O_2	(NH ₄) ₂ O	H,O	Total.
I.	$_{71.70}^{\mathrm{B_{2}O_{3}}}$	9.87	[18.43]	100.00
II.	72.42	9.78	[17.80]	100.00
III.	72.06	9.83	[18.11]	100.00

Lasallite. G. Friedel, Bull. Soc. Min., 24, 12, 1901; ibid., 30, 80, 1907.

In snow-white masses, showing a fibrous structure.

G. = 1.477.

Composition perhaps 3MgO.2Al₂O₃.12SiO₂.8H₂O or MgO.Al₂O₃.5SiO₂.3½H₂O.

Analysis of the pure material after ignition:

		SiO ₂	Al_2O_3	Fe ₂ O ₃	MgO	CaO
I.	Miramont	69.27	19.42	0.84	10.01	1.30 = 100.84
II.	Can Pey	70.28	21.64	0.38	7.56	0.24 = 100.10

Heated at 100° it loses 16 p. c. H₂O, retaining 14.22 p. c. regarded as belonging to the mineral.

Occurs in sterile levels of the antimony mine at Miramont, France, in the concession of Souliac on the borders of Cantal and Haute-Loire. Associated with kaolinite in minute hexagonal scales, also termierite (which see) and barite. Also at Can Pey near Arles-sur-Tech.

Named after M. Lasalle, proprietor of the mines of Miramont. Author suggests that it may

belong to class of compounds named by Heddle piolite (Min., p. 709).

LAUMONTITE, Min., p. 587; App., p. 40. — Crystals from Henry Land, East Greenland; Böggild, Medd. om Grönl., 28, 128, 1905. Pseudomorph of orthoclase after laumontite from Templeton, Ottawa County, Quebec; Graham, Am. J. Sc., 22, 47, 1906.

Occurrence (with anal.) at Petersberg near Halle, Saxony; Lüdecke, Zs. für Naturwiss., 72, 101, 1899. Occurrence with anal. from Cala Francese, island Maddalena; Rimatori, Rend. Acc. Linc., 11, (1), 542, 1902. In granite from Montorfano, northern Italy; Tacconi, Rend. Acc. Linc., 14, (2), 88, 1905; occurrence (with anal.) at São Paulo, Brazil; Hussak, Centralbl. Min., 331, 1906. Anal. of material from Montecatini, Val di Cecina, and discussion of chem. comp.; Baschieri, Proc. Soc. Tosc., March, 1907.

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull. 207, 1902; Zs. Kr.,

38, 696.

Laurionite, Min., p. 171; App., p. 41. — Crystals from Laurium, Greece, studied by Smith; Min. Mag., 12, 102. Following axial ratio derived: ă : b : c = 0.7385 : 1: 0.8346. New forms: This. Mag., 12, 102. Following axial facto derived: a : b : c = 0.7665 : 1.0.6340. Rew forms. o (112), q (122), r (132), s (142), t (152) and u (232). Indices of refraction: $\alpha = 2.0767$; $\beta = 2.1161$; $\gamma = 2.1580$. Ax. pl. || b. Bx_{ac} $\perp a$. Calc. 2V = 81° 32′.

Doubtful new forms (292), (141), (230) with description of optical characters; Cesàro, Bull. Ac. Belg., 1198, 1904; see also Lacroix and de Schulten, Bull. Soc. Min., 31, 82, 1908. Crystals

from Lake Como; Repossi, Rend. Acc. Linc., 15, (1), 511, 1906.

Lawsonite, App., p. 41. — New forms: r (221), s (331). Analysis:

Fe₂O₃ SiO, TiO, Al₂O₃ FeO MnO CaO MgO Na₂O H,O 0.23 38.45 0.38 31.35 0.86 0.10 tr. 17.52 0.17 0.0611.21 = 100.33

Leadhillite, Min., p. 921; App., p. 42. — Structure of mimetic crystals investigated; Mügge, Jb. Min., Beil.-Bd., 14, 259, 1901. Crystals from Djebel-Ressas mine, Tunis; Jecker, C. R., 140, 141, 1905; from Shultz, Ariz.; Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 146, 1908.

Effect of low temperatures upon optical properties; Panichi [Mem. Acc. Linc., 4, 389, 1902];

Zs. Kr., 40, 88.

Occurs at the Cerro Gordo mines, Inyo Co., Cal.; Rogers, Am. J. Sc., 12, 46, 1901. From Sardinia; Pelloux, Att. Acc. Linc., 13, (2), 34, 1904.

Ledouxite. J. W. Richards, Am. J. Sc., 11, 457, 1901.

A copper arsenide, Cu4As, containing small amounts of cobalt and nickel from the Mohawk mine was analyzed by Ledoux (Eng. Mng. J., April 7, 1900) and called *mohawkite*. This name, however, was given by Koenig (Am. J. Sc., 10, 440, 446, 1900, see mohawkite) to a variety of domeykite (Cu₃As) containing cobalt and nickel. Although Koenig throws doubt on the correctness of Ledoux's analysis, this is confirmed by Richards, who gives the name ledouxite to the compound, Cu,As.

Ledouxite occurs in massive form, resembling algodonite in color and luster. G. = 8.07,

Richards.

Analyses: 1, Richards, l. c.; 2, Ledoux, recalculated by Richards:

	As	Cu	Co	Ni	Fe	S	
1.	[22.8]	70.8	6.4	tr.			= 100.00
2. $G_{\cdot} = 7.8$	22.67	68.60	1.20	6.55	0.23	0.53	= 99.78

Leesbergite. L. Blum; Ann. Soc. Geol. Belg., **34**, B118, 1908. W. Bruhns, Mitt. Geol. Landensanst. Elsas-Lothr., **6**, 2, 303, 1908. A white chalk-like material occurring in magnetite iron ores between Marspich and Hayingen, Lorraine. Comp. originally given as 2MgCo₃.CaCo₃. but shown by Bruhns to contain water as an essential constituent, to vary in composition and to be probably a mixture. Named in honor of Capt. Leesberg of d'Esch-sur-l'Alzette.

Lengenbachite. R. H. Solly, N. Min. Mag., 14, 204; Zs. Kr., 43, 465. R. H. Solly, Nature, 71, 118, 1904; Min. Mag., 14, 78, 1905; Hutchinson,

Probably triclinic. In thin blade-shaped crystals, sometimes curled up like paper.

Cleavage perfect | to large face of crystals. Flexible but not elastic, somewhat malleable. Soft, leaving a trace on paper. G. = 5.80, Solly; 5.85, Hutchinson. Luster metallic. Color steel-gray, often with iridescent tarnish. Streak black. Opaque.

Composition, a sulpharsenite of lead with small amounts of silver, copper and antimony, possibly 7[Pb,(Ag,Cu)₂]S.2As₂S₃ or 6PbS.(Ag,Cu)₂S.2As₂S₃.

Anal. by Hutchinson:

Pb 57.89 2.36 0.17 0.77 19.33 = 99.625.64 13.46

Occurs in the dolomite of Lengenbach quarry in the Binnenthal, Switzerland. Jentschite (Koechlin, Min. petr. Mitth., 23, 551, 1904) may be identical with lengenbachite.

LEONITE (Kaliumblödite), App., p. 42. — Crystals from Leopoldshall show the new forms: b (010), w (101), (211); an analysis of a crystal gave

SO, K CI H₂O 52.50 6.26 21:53 0.24 19.57 =100.10

J. E. Strandmark, Zs. Kr., 36, 461, 1902. The measured angles and analysis confirm the original results of Tenne.

Formation discussed; van't Hoff and Meyerhoffer, Ber. Ak. Berlin, 678, 1903.

Lepidolite, Min., p. 624; App., p. 42. — Crystals from near Ramona, San Diego Co., Calif., studied by Schaller; Am. J. Sc., 19, 225, 1905, showed the following forms: c (001), b (010), a (100), e (023), o (112), u (111), x (131), N (261), z (132), l (130) and doubtful (223), (221), (112).

Anal. of material from Brassac, Tarn, France; Arsandaux, Bull. Soc. Min., 24, 431, 1901.
Occurrence with anal., from Wakefield, Ottawa Co., Province of Quebec; Hoffmann, Am. J. Sc.,

11, 149, 1901. Occurs both of the macrodiagonal and brachydiagonal types at Haddam Neck, Conn.; Bowman, Min. Mag., 13, 103, 1902.

Two var. known as macro- and microlepidolite, one with a large opt. ax. angle and the other with a small angle. Baumhauer, [Eclogæ geol. Helvetiæ, 7, 354, 1903]; Min. Mag., 13, 371, 1903.

Lepidomelane, Min., p. 634; App., p. 42. — Anal. of material from nepheline-syenite, Montreal; Harrington, Trans. Roy. Soc. Canada, 11, (3), 25, 1905.

Leptochlorite, Min., p. 643. — Description of various members of group from shell rock formation in Moravia and Silesia.

See moravite and thuringite. Kretschner, Centralbl. Min., 293, 1906.

LEUCITE Min., pp. 341, 1041; App., p. 42. - Structure of mimetic crystals investigated;

Mügge, Jb. Min., Beil.-Bd., 14, 279, 1901.

Analysis of material from Vesuvius; Casoria [Ann. R. Scuola sup. di agric. di Portici, 4, 1, 1903]; Zs. Kr., 41, 278. Inve Ak. Wien., 112, (1), 355, 1903. Investigation concerning its chemical constitution; Tschermak, Ber.

Occurrence in tufa at Pompeii; Colomba, Boll. Soc. geol. ital., 23, 379, 1904.

Pseudo-leucite from Spotted Fawn Creek, a tributary of Twelve-mile river, Yukon Territory; Knight, Am. J. Sc., 21, 286, 1906.

Attempt to re-form soda-leucite by heating pseudo-leucite crystals; Read and Knight, Am. J. Sc., 21, 294, 1906.

Formation of in igneous rocks; Washington, Jour. Geol., 15, 257, 1907.

LEUCOPHANITE, Min., p. 417. — Crystals from Kangerdluarsuk, Greenland; Böggild, Min. Grönl., 349.

Discussion of chem. comp., Cesàro, Mem. Soc. Liège, 5, No. 6, 8, 1904.

Occurs at the Shepherd and Murphy tin-bismuth mine, Bell Mount, Middlesex, Tasmania; Petterd, Notes on Tasmanian Minerals, priv. publ.

Leucophœnicite. S. L. Penfield and C. H. Warren, Am. J. Sc., 8, 351, 1899.

Monoclinic. Massive, crystalline; fragments parallel to an imperfect cleavage also show indistinct cleavage cracks to which the extinction is slightly inclined.

H. = 5.5-6. G. = 3.848. Luster vitreous. Color light purplish red; slightly pleochroic,

pale rose and colorless.

Composition essentially H₂O.7RO.3SiO₂, with R = Mn chiefly, also Zn and Ca. is expelled at a red heat this may be written as a basic orthosilicate, Mn5(MnOH)2(SiO4)3, which is analogous to a humite with hydroxyl replacing all the fluorine (cf. App. I, p. 36).

Analysis, Warren:

SiO, MnO ZnO MgO K,O CaO Na₂O H₂O FeO 0.21 $\frac{2}{2}$ 26.36 60.63 3.87 5.67 0.39 0.24 2.64 tr. = 100.01

B. B. fuses quietly at 3 to a brownish black globule. Yields a little water in the closed tube; reacts for manganese with the fluxes. Dissolves easily in hydrochloric acid yielding gelatinous silica upon evaporation.

Occurs very sparingly at Franklin Furnace, N. J., intimately associated with clear light green

willemite and crystals of brown vesuvianite.

Named from λευκός, pale, and φοίνιξ, purple-red.

Leucosphenite. G. Flink, Medd. om Grönland, 14, 236, 1898; 24, 137, 1901.

Monoclinic. Axes $\dot{a}: \dot{b}: \dot{c} = 0.5813:1:0.8501; \beta = 86^{\circ} 37'$.

Monoclinic. Axes a: b: c = 0.5515: 1.0.5511; p = 50 0.515Forms: a (100), b (010), c (001), m (110), n (130), d (101), x (011), s (112), p ($\overline{1}11$), r (263) g (133). Angles: $nn''' = *120^{\circ}$ 15', $cn = *88^{\circ}$ 19', $cd = *53^{\circ}$ 21'. In minute wedge-shaped crystals, elongated $\parallel a$ into rectangu

Leucosphenite.

tion and axial relation to eudidymite.

lar prisms with b, c prominent, also n; faces c striated longitudinally, b also vertically. Twins common, contact twins with tw. plane c (001).

Cleavage b, distinct. Fracture uneven. Brittle. H = 6.5G. = 3.05, Mauzelius. Luster vitreous, on b pearly, also on t

(no cleavage detected).

Transparent, ofter Color white, inclining to grayish blue. somewhat opaque from cracks and inclusions. Optically nega

tive. Ax. plane nearly $\parallel c$ and Bx_a $\parallel \dot{a}$. Indices: $\alpha_r = 1.6401$, $\beta_r = 1.6572$, $\gamma_r = 1.6829$, $\alpha_y = 1.6445$ $\beta_y = 1.6609$, $\gamma_y = 1.6878$. \therefore 2V_a = 79° 26′ red, = 77° 4

yellow. Dispersion marked $\rho > v$. Composition, $Na_b Ba(TiO)_2(Si_2O_3)_5$, or somewhat analogous to petalite, related in composition and axial relation to *euclidymite*. Analysis, Mauzelius:

TiO, ZrO, BaO Na₂O K,O H₂O SiO₂ 56.94 13.20 3.50 13.75 11.14 0.56 0.31 = 99.40.

B. B. decrepitates and fuses with difficulty to a dark globule; not attacked by acids. Occurs sparingly in pegmatite at Narsarsuk in southern Greenland; closely associated with ægirite, albite, epididymite, polylithionite. Named from λευκός, white, and σφήν, wedge.

LEVERRIERITE, Min., p. 687. — Further study on purer material gave Termier, Bull. Soc. Min. 22, 27, 1899, the following: G = 2.598; indices, $\alpha = 1.554$, $\gamma = 1.582$, $\gamma - \alpha = 0.028$. A new analysis of the mineral from Rochebelle gave:

SiO₂ Al_2O_3 Fe_2O_3 MgO CaO K_2O Loss on ign. 37.02 3.65 0.30 = 100.6849.90 8.65

Levynite, Min., p. 595. — Crystals from Skye; Goodchild, [Trans. Geol. Soc. Glasgow, 12 Suppl., 1–68, 1903]; Zs. Kr., 45, 307; also Currie, Trans. Edin. Geol. Soc., 8, 341. Crystals from East Greenland with doubtful new forms v (2.10. $\bar{1}$ 2.1), u (10.2. $\bar{1}$ 2.11) (Henry Glacier) \dot{c} = 0.80101; Böggild, Medd. om Grönl., 28, 125, 1905.

LIBETHENITE, Min., p. 786. — Crystallographic study by Melczer, Zs. Kr., 39, 288, 1904 Occurs in small crystals in a quartzite gangue at the Coronado lode of the Clifton-Morenci coppe district in Arizona; Lindgren and Hillebrand, Am. J. Sc., 18, 457, 1904. Crystals from Viel-Salm Belgium; Cesàro, Bull. Ac. Belg, 142, 1905.

LILLIANITE, Min, p. 130. — Occurrence at Mt. Farrell, Tasmania; Petterd, Proc. Roy. Soc Tasmania, 18-33, 1902.

Limonite, Min., p. 250. — Analyses of ores from Great Valley and Nittany Valley, Penn. Hopkins, Bull. Geol. Soc. Amer., 11, 475, 1900; Zs. Kr., 36, 75. Geodes from Muscogie, I. T. Nichols, Field Columbian Mus., No. 111; Zs. Kr., 44, 539.

Linarite, Min., p. 927; App., p. 43. — Crystals from Cerro Gordo mines, Inyo Co., Calif. Rogers, Am. J. Sc., 12, 46, 1901; from Cumberland with new form, ($\bar{1}\bar{2}.2$ 11); Cesàro, Bull. Ac Belg., 328, 1905; from Eureka, Utah, with new forms, δ (10.0.9), ϕ ($\bar{9}.0.10$) f ($\bar{5}23$); Farrington and Tillotson, Field Col. Mus., 3, No. 7, 148, 1908.

Occ. in Sardinia; Pelloux, Att. Acc. Linc, 13, (2), 34, 1904; in County Wicklow, Ireland Russell, Min. Mag., 14, 348, 1907; in the Otavi district, German S. W. Africa, see olavite.

LINNÆITE, Min., p. 78. — Auriferous variety (anal.) from Santa Fé mine, Chiapas, Mexico Collins, Min. Mag., 13, 361.

Liskeardite, Min., p. 846. — Mineral similar in character found at Cape Garonne, near Hyères

France; Lacroix, Bull. Soc. Min., 24, 27, 1901. Liveingite. R. H. Solly and H. Jackson; Proc. Cambridge Phil. Soc., 11, 239, 1901; Min

Mag., 13, 160. Monoclinic.

Monoclinic. $\beta = 89^{\circ} 45\frac{1}{4}$. Comp. 5PbS.4As₂S₃. Anal.: Pb, 47.58; S, 24.91; As, 26.93 = 99.42.

From the Binnenthal.

m

Lorenzenite.

Loaisite. R. L. Codazzi, [Mineralizadores y minerales metalicos de Colombia. Tralajos de la Oficina de Historia Natural. Seccion de min y geol Bogota, 1905]; Centralbl. Min., 183, 1908. A new mineral found at Marmato, Colombia, with following analysis:

As ₂ O ₅	FeO	PbO	H ₂ O
49.6	34.3	0.4	16.9 = 101.2

LORANDITE, App., p. 43. — Analyses 1, 2 by P. Jannasch on material measured by Goldschmidt, (Zs. Kr., 39, 122, 1903), also 3 by J. Loczka, ibid., p. 520.

S	As	Tl	Gangue
1. 19.26	21.65	58.75	0.08 = 99.74
2. 18.75	21.32	59.08	0.12 = 99.27
3. G. = $5.533 \left(\frac{2}{2}\right) 18.99$	22.30	59.76	=101.05

Loranskite. M. Melnikow, [Loranskite a new Mineral, sep. pub., St. Petersburg]; Zs. Kr., 31, 505; Nikolajew [Verh. russ. min. Gesells., 35, 11-13, 1897]; Zs. Kr., 31, 505.

Massive. Metallic. Color black; streak greenish gray. H. = 5. G. = 4.6. Isotropic. Infus. Analysis:

Ta ₂ O ₅ 47.00	Y_2O_3 10.00	Ce ₂ O ₃	CaO	FeO	ZrO ₂	Ig.
47.00	10.00	$\frac{\mathrm{Ce_2O_3}}{3.00}$	3.30	4.00	20.00	$\frac{1g}{8.15} = 95.45$

Occ. Found at Imbilax near Pitkäranta, Finland. Named after A. Loranski.

Lorenzenite. G. Flink, Medd. om Grönland, 14, 250, 1898; 24, 130, 1901.

Orthorhombic. Axes a : b : c = 0.6042 : 1 : 0.3592.

Forms: a (100), b (010), m (110), n (120), x (1.12.0), p (111), o (231). Angles: $120 \wedge 1\bar{2}0 = 100^{\circ} 47'$. $110 \wedge 111 = 55^{\circ} 13'$.

In minute acicular crystals with the prisms n, or m, n, prominent and terminated chiefly by p.

Cleavage n (120) distinct. Brittle. H. = 6-6.25. G. = 3.42, Mauzelius. Luster adamantine brilliant. Colorless or with tinge of violet or brown; also in part with dark ends from enclosed impurities. Transparent to translucent.

Optically +. Ax. pl. $\parallel a$. B $x_a \perp b$. Absorption $\check{a} > \bar{b} > \dot{c}$. Indices: $\alpha_r = 1.7320$, $\gamma_r = 1.7786$; $\alpha_y = 1.7785$, $\gamma_y = 1.7876$. Composition, Na₂(TiO)₂ Si₂O Analysis by Mauzelius:

SiO2 TiO_2 ZrO_2 Na₂O H_2O 0.77 = 99.5934.26 35.15

B. B. fuses easily to a black globule; not attacked by acids.

Occurs in drusy cavities in pegmatite at Narsarsuk, southern Greenland; associated minerals are ægirite, microcline, albite, arfvedsonite, elpidite, etc.

Named after the Danish mineralogist, Johan Lorenzen.

Lotrite. G. Munteanu-Murgoci, [Inaug.-Diss., Munich, 1901]; Zs. Kr., 36, 650; Bull. Soc. Min., 24, 504, 1901.

Massive, in an aggregate of small grains and leaves. Cleavage \parallel to greatest length. H. = 7.5. G. = 3.23. Green. Optically +. n=1.67; $\gamma-\alpha=0.014$ Extinction makes angle

28° to trace of cleavage. Ax. pl. transverse to length of lamellæ and \bot to cleavage. $c \parallel b$. 30°; 2V = 18° (approx.).

Comp. — 4SiO₂.2(Al,Fe)₂O₃.3(Ca,Mg)O.2H₂O. Analysis:

SiO ₂	Al ₂ O ₃ Fe ₂ O ₃	FeO	CaO	MgO	H_2O
38.02	30.90	0.33	23.56	2.80	6.24 = 101.85

Occ. Found in small veins in a chlorite schist associated with epidote, zoisite, clinozoisite, garnet, etc., in valley of the Lotru, Transylvania. Named from locality of occurrence.

LÖWEITE, Min., p. 946. — Conditions of formation discussed; van't Hoff and O'Farelly, Ber. Ak. Berlin, 370, 1902.

Lussatite, Min., p. 197. — Probably a fibrous form of tridymite; Slavik, Centralbl. Min., 690, 1901. Anal. from Bojanovic, Westmähren, Bohemia; Kovář, [Chem. Blätter, Prag, 233, 1901]; Zs. Kr., 37, 500.

LUZONITE, see Enargite.

MACKINTOSHITE, App., p. 44. — Radio-activity from Barringer Hill, Llano Co., Texas; Hidden, Am. J. Sc., 19, 430, 1905; see also under Uraninite.

MAGNESITE, Min., p. 274; App., p. 44. — Analyses of gray and white varieties from Jolsva, Hungary; Loczka, Zs. Kr., 35, 282, 1901. Magnesite deposits of California with anal., etc.; Hess, Bull. U. S. G. S., 355, 1908.

A magnesium carbonate containing isomorphous MnCO₃, FeCO₃ and CoCO₃ from Eiserfeld

near Siegen, Westphalia, having following analysis:

MgO MnO FeO CoO CO₂ 46.77 H_2O 0.31 = 99.61 33.41 7.50 6.50 5.12

Johnsen, Centralbl. Min., 13, 1903.

Also see Dolomite.

Magnesiumpectolite, see under Pectolite.

MAGNETITE, Min., pp. 224, 1041; App., p. 44. — Crystals from Narsarsuk, Greenland; Flink, Medd. om Grönl. 14, 234, 1898; 24, 23, 1901; from Pian Real, Piedmont; Boeris, Att. Acc. Torino,

38, 691, 1903.

Analyses of magnetites containing Ti and V from eastern Ontario, Canada; Pope, Trans. Amer. Inst. Min. Eng., 29, 372, 1899; Zs. Kr., 35, 295; of titano-magnetite from Croustet, near Puy, Haute-Loire; Arsandaux, Bull. Soc. Min., 24, 475, 1901; of magnetite from St. Joseph du Lac, Quebec, Canada, containing 5.32%, TiO₂, 8.46% MnO and 3.24% MgO; also from Magnet Cove, Arkansas; Digby, Nova Scotia, with discussion of isomorphous relations; Harrington, Min. Mag., **14**, 373, 1907.

Formation of; Bruhns, Zs. prakt. Geol., 12, 212, 1904; occurrence in garnet rock at Dasch-

kesan, Caucasus; Jaczewski [Verh. russ. min. Ges., 42, 75, 1905]; Zs. Kr., 43, 69.

MALACHITE, Min., p. 294; App., p. 44. — New form (423) found on crystals from Likasi mine, Katanga, Congo; Cesaro, Bull. Ac. Belg., 1206, 1904; crystals from same locality; Buttgenbach, Ann. Soc. Geol. Belg., 31, M 565, 1905; crystals associated with dioptase from Mindouli, French Congo; Lacroix, Bull. Soc. Min., 31, 253, 1908.

Mamanite, Min., p. 950. — Identical with polyhalite. Analysis given. Van't Hoff and Voerman, Ber. Akad. Berlin, 984, 1904.

MANGANITE, Min., p. 248; App., p. 45.— Crystals from Ilefeld with new forms, E (320), L (940), R (560), U (590); Zambonini, Zs. Kr., 34, 229. From Sandur Hills, India; Fermor, [Rec. Geol. Sur. India, 33, 229, 1906]; Zs. Kr., 45, 308.

MANGANOCALCITE, Min., p. 269. — Anal. from a graphite mine at Gross-Tresny, Mähren, Bohemia; Kovář [Abh. böhm. Akad., 28, 1899]; Zs. Kr., 34, 705. See under Agnolite.

Manganospharite, Manganospherite. K. Busz, Jb. Min., 2, 129, 1901. — See Siderite.

MANGANOTANTALITE, see under Columbite.

MARCASITE, Min., pp. 94, 1041; App., p. 45. — Crystals from Rondout, Ulster Co., N. Y.; Whitlock, N. Y. State Mus., Bull. 98, 1905; Zs. Kr., 43, 393.

Containing small amount of thallium from Galmei mines, Poland; Antipoff, [Jour. russ. phys.

chem. Ges., St. Petersburg, 28, 384, 1896]; Zs. Kr., 31, 515. Anal. of material from sandstone of Calafuria, Italy; Manasse, [Att. Soc. Tosc., 21, 159, 1905]; Zs. Kr., 43, 496.

Method of quantitative determination of amounts of marcasite and pyrite in mixtures; Stokes, Am. J. Sc., 12, 414, 1901; Bull. U. S. Geol. Sur., 178, 1901; Zs. Kr., 37, 81.

Marignacite. S. Weidman and V. Lenher, Am. J. Sc., 23, 287, 1907.

A variety of pyrochlore. Crystals octahedrons. Color light yellowish brown. G. = 4.13., H. = 5-5.5.Analysis:

Occurs in pegmatite 9 miles N. E. of Wausau, Wisconsin. Named in honor of the chemist Marignac.

Marrite. R. H. Solly, Min. Mag., 14, 76, 1905, 188, 1906.

Monoclinic. Axes $\dot{a}:\dot{b}:\dot{c}=0.57634:1:0.47389;\ \beta=88^{\circ}$ 45'. Angles (100):(001) =*88° 45'; (010) : (110) = *60° 3'; (010) : (011) = *64° 39'.

Forms: a (100), b (010), c (001), (720), (310), (210), (320), (110), (230), (120), (130), (140), (150), (170), (201), (013), (012), (023), (011), (021), (073), (083), (031), (072), (041), (111), (112), (223), (111), (312), (212), (211), (121), (131), (151), (271), (121), (123), (121). Habit roughly cubical with a, b, c prominent, modified by numerous domes and pyramids; also

tabular.

Cleavage not observed. Fracture conchoidal. Brittle. H. = 3. Luster metallic, brilliant. Color lead- to steel-gray, often with iridescent tarnish. Streak black with chocolate tinge.

Composition not determined.

Occurs very sparingly in the white dolomite of the Lengenbach quarry, Binnenthal, Switzerland, associated with lengenbachite and rathite.

Named after Dr. John E. Marr of Cambridge, England.

MARSHITE, App., p. 45. — Description of specimens from Broken Hill, N.S.W., give following additional data. Dodecahedral cleavage. H. = 2.5. $n_{\rm Na} = 2.346$. Spencer, Min. Mag., 13, 38. Analysis on material with G. = 5.590; Prior, ibid., 189.

The identification of small quantities of iodine in New South Wales copper ores suggests the probable presence of marshite; A. Dieseldorff, Proc. Roy. Soc. N. S. W., 33, 160, 1899.

Marsjatskite. E. von Fedorow and W. Nikitin, [Ann. Géol. Min. Russie, 3, 90, 102, 1899]; Min. Mag., 12, 387. Glauconite containing much manganese, forming the bulk of a Tertiary sandstone in the Marsjat forest, Urals.

MATLOCKITE, Min., p. 169. — Crystals from Laurium, Greece; Lacroix and de Schulten, Bull. Soc. Min., 31, 85, 1908.

Refractive indices; Buttgenbach, Ann. Soc. géol. Belg., 33, M11, 1906.

Mayberyite. S. F. Peckham, [Jour. Franklin Inst., 140, 382, 1895], Min. Mag., 12, 387. Name proposed in connection with a suggested new classification of petroleum, bitumen, etc., after C. F. Mabery (not Maybery).

MEIONITE, Min., p. 467. — A mineral occurring in amphibole-gneiss from the Black Forest which has the microscopical characters of meionite except that it shows a basal cleavage, has been called pseudomeionite; Rosenbusch, [Mitt. Grossherz. Badisch. geol. Landeanst, 4, 391, 1902]; Min. Mag., 14, 408, 1907.

Melanochalcite. G. A. Koenig, Am. J. Sc., 14, 404, 1902.

Massive, occurring as a pitchy black layer a few millimeters in thickness over a nucleus of cuprite, this kernel being surrounded by a banded green zone of chrysocolla and malachite and this again by quartz, the whole forming nodules having an average diameter of 120 mm. and of much beauty in the cross section. The black mineral when pure has a brilliant luster and is very brittle; H. = 4; G. = 4.141.

Analysis of carefully selected material.

SiO, Fe₂O₃ CuO ZnO 76.88 0.41 0.07

See also analysis of copper pitch ore from Morenci, Arizona; Lindgren and Hillebrand, Am. J. Sc., 18, 454, 1904.

MELANOPHLOGITE, Min., pp. 194, 1041; App., p. 45.—Study of optical properties; Zambonini, Zs. Kr., 41, 48.

MELANTERITE, Min., p. 941; App., p. 46.—Crystals from Falun, Sweden, described and analyzed; Edgren, G. För. Förh., 23, 329, 1901. Occurs in small prismatic crystals, also as an efflorescence with pyrite near Leona Heights, Alameda Co., Cal., new forms noted l (120), d (102), k (203), x (302), q (201), j (904), B (332); Schaller, Bull. G. Univ. Cal., 3, 195, 1903.

Study of chemical constitution and genesis of iron sulphates; Scharizer, Zs. Kr., 35, 345. Occurrence in Baluchistan, India; Hooper [Jour. Asiatic Soc. Bengal, 72, 236, 1901]; Zs. Kr., 42, 391; occurrence at Cetine, Siena, Italy (with anal.); Manasse, Proc. Soc. Tosc., May, 1908.

Melilite, Min., p. 474; App., p. 46. — Indices of refraction for various colors; Hlawatsch, Min. Mitth., 23, 415, 1904.

Study of minerals of melilite group with analyses; Fouqué, Bull. Soc. Min., 23, 10, 1900; chemical composition with analyses; Zambonini, Zs. Kr., 41, 226.

Melinite, Min., p. 695.— From Vicz near Bistritz, Mähren, with anal.; Kovář, [Chem. Blätter, 1899]; Zs. Kr., **34**, 706.

MELIPHANITE, Min., p. 418. — Chem. comp. discussed; Cesàro, Mem. Soc. Liège, 5, No. 6, 11, 1904.

Melite. F. Zambonini, Zs. Kr., 32, 161, 1899; 34, 227, 1901. In imperfect prismatic forms; also stalactitic massive. H. = 3. G. = 2.18. Color bluish brown. Opaque. Composition approximates to 2(Al, Fe)2O3.SiO2.8H2O.

Analysis.

SiO2 Al₂O₃ CaO H₂O Fe₂O₃. 14.90 14.97 0.78 33.75 = 99.64

B. B. infusible, gives off water and the residue becomes brown; iron reactions with the fluxes. Completely soluble in hydrochloric acid with separation of silica.

The specimen examined, originally from the Abbati collection, was labeled allophane from Saalfeld, Thuringia.

Named after Professor Romolo Meli of Rome.

Melonite, Min., p. 76.— Anal. from Worturpa, N. S. W.; Higgin, [Trans. Roy. Soc. So. Aus., 23, 211, 1899]; Zs. Kr., 34, 214.

Analyses by Hillebrand, Am. J. Sc., 8, 295, 1899, from original locality, Stanislaus mine, Melones Co., Calif., and by Dieseldorff, Centralbl. Min., 168, 1901, from Australia, prove that formula should be NiTe₂.

40	I	II	III	IV	V
Te	80.75	81.40	80.17	81.09	81.31
Ni	{ 18.31	18.60	16.73	18.91	18.69
Co	18.51		0.75		
Ag	0.86		Fe 1.33		
	99.92	100.00	98.98	100.00	100.00

I, Hillebrand; II = I recalc.; III, Dieseldorff; IV = III recalc.; V = Theory for NiTe₂. Occurrence at Illinawortina, N. S. W., with analyses; Dieseldorff, Centralbl. Min., 98, 1900.

MERCURIC IODIDE. Minute scarlet-red cubes occurring in limonite at the Broken Hill mines, New South Wales, have been identified as probably mercuric iodide by Moses; its relation to the doubtful coccinite of Castillos (Min., p. 161) is uncertain, Am. J. Sc., 12, 98, 1901.

MERCURY, Min., p. 22. — Occurrence at Erzberg, Styria; Redlich, Centralbl. Min., 280, 1908.

MESOLITE, Min., p. 605.—Optical study of material from Faroe islands; Görgey, Min. Mitth.,

27, 255, 1908.

Anal. — From Table Mountain, Golden, Colo.; Patton, Bull. Geol. Soc. Amer., 11, 461, 1900;
 Zs. Kr., 36, 74; from Ben Lomond, N. S. W.; Anderson, Rec. Aus. Mus., 6, 419, 1907; from basalt of Montresta, Sardinia; Deprat, Bull. Min. Soc., 31, 191, 1908; also, Millosevich, Rend. Acc. Linc., 17, (1), 270, 1908; and Pelacani, ibid., 17, (2), 66, 1908.
 Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 121, 1908.

A zeolite having composition and general physical properties like mesolite but differing optically has been named *pseudomesolite* by A. N. Winchell, [Thèse Fac. des Sc. de Paris, 1900]; Bull. Soc. Min., 24, 506, 1901; Amer. Geol., 26, 275, 1900; biaxial, positive, small axial angle; length of fibers positive; max. angle of extinc. to length of fibers = 20° . Analysis:

SiO,	Al ₂ O ₃	$\mathrm{Fe_2O_3}$	MgO	CaO	Na ₂ O	K,O	H,O
45.25	25.69	1.40	tr.	9.75	4.24	0.47	12.99 = 99.79

Found in the anorthosite of Carlton Peak, Minnesota. Experiments concerning loss of water, etc.; Friedel, Bull. Soc. Min., 22, 84, 1899.

METACINNABARITE, Min., pp. 62, 1041; App., p. 46. — Relations to cinnabar, which see.

Metanhydrite. E. Sommerfeldt, Jb. Min., 1, 140, 1907.

Orthorhombic. Composition, CaSO4.

Prepared artificially in small crystals which show faces that cannot be simply referred to the anhydrite axes. Like anhydrite in cleavage and specific gravity. Differs in showing a distortion of the interference figure. Perhaps to be considered as isomorphous with barite, to the crystal axes of which its faces could be referred.

Metakalkuranite, see Autunite.

Metakoenenite. F. Rinne, Centralbl. Min., p. 498, 1902. — See Koenenite.

Metakupferuranite, see Torbernite.

METAVOLTINE, Min., p. 972. — Formed at eruption of Vesuvius, 1906; anal. given; see under Vesuvius.

Occurrence in a fumarole near Pyromeni on island of Milo, and near Porto di Levante on Vulcano; Lacroix, Bull. Soc. Min., 30, 30, 1907. From Zolfo Grotto, Miseno, Italy; Zanbonini, Rend. Acc. Sci. Napoli, Dec., 1907.

METEORITES, see under Iron.

MIARGYRITE, Min., p. 116. — Crystals from Zacatecas, Mexico, with following new forms: T ($\bar{1}06$), U ($\bar{1}.0.30$), V ($\bar{1}.0.12$), W ($\bar{1}.0.12$), P ($\bar{1}5.2.2$), K ($\bar{1}12$), H ($\bar{4}11$), Z ($\bar{9}13$); Eakle, Zs. Kr., **31**, 209. Description of specimens from Tatasi (anal.), and from Aullagas, Potosi, Bolivia; Spencer, Min. Mag., 14, 339, 340.

MICA GROUP, Min., p. 611; App., p. 46. — Analyses of Canadian micas; Egleson, Trans. Roy. Soc. Canada, 10, (3), 57, 1904; from marble of Carrara; D'Achiardi, Att. Soc. Tosc. Sc., Mem. 22, 1906.

Description of occurrence in the pegmatites of upper Veltlin; Linck, [Zs. f. Naturwiss. Jena, 33, 345, 1899]; Zs. Kr., 35, 317. Occurrence in Canada; Cirkel, Bull., of Mines Branch, Dept. of Interior, Ottawa, Canada; Am. J. Sc., 21, 405, 1906.

MICROCLINE, Min., pp. 322, 1042; App., p. 47. — Occurs in crystals at Haddam Neek, Conn.; Bowman, Min. Mag., 13, 114, 1902. Crystals from various Greenland localities; Böggild, Min; Grönl., 443; from Vizézy near Montbrison, Loire; Gonnard, Bull. Soc. Min., 28, 17, 1905.

Analysis from Ilmengebirge; Sioma, Zs. Kr., 34, 278.

In granites of Sardinia, see under Orthoclase.

MICROLITE, Min., pp. 728, 1042; App., p. 47. — From Narsarsuk, Greenland; Flink, [Medd. om Grönl., 16, 234, 1898; 24, 171, 1901].

Microsommite, Min., p. 428.— Refractive indices of crystals formed during eruption of Vesuvius in 1906; see under Vesuvius.

MIERSITE, App., p. 47. — Description of; Spencer, Min. Mag., 13, 41. Anal. by Prior, ibid., 188, gave Ag, 38.17; Cu, 5.64; I, 56.58 = 100.39, which leads to formula, 4AgI.CuI. G. = 5.64.

MILARITE, Min., p. 312; App., p. 47. — Crystals from Gletsch, Switzerland; Busz, Centralbl. Min., 754, 1906. Chem. comp. discussed; Cesàro, Mem. Soc. Liège, 5, No. 6, 1,

MILLERITE, Min., p. 70; App., p. 47. — Study by Palache and Wood, of crystals from Orford, Quebec, Am. J. Sc., 18, 343, 1904, gave following new facts using as according to Gdt., $\dot{c} = 0.3774$ (Palache); (0112) is a gliding plane and artificial twins can be formed; perfect cleavage \parallel to (1011) and (0112); new forms: (7290), (0221), (2131), (4153) with several doubtful forms.

MIMETITE, Min., p. 771. — Crystals from Bena a Padru, Sardinia; Lovisato, Rend. Acc. Linc., 13, (2), 43, 1904; from Eureka, Utah; Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 150, 1908. Study of refractive indices; Bowman, Min. Mag., 13, 324, 1903.

MINERVITE, App., p. 47. — A white pulverulent phosphate from the Jenolau caves, New South Wales, is analyzed by Mingaye and referred to minervite. Trans. Austr. Assoc. Sci., 7, 1898. Analyses of other phosphatic deposits are also given.

MIRABILITE, Min., p. 931. — Occurrence with gypsum at Puchberg near Schneeberg, Austria; Cornu, Centralbl. Min., 280, 1908.

MISENITE, Min., p. 922. — Anal. of material from Zolfo Grotto, Mesino, Italy, corresponding to formula, K₂SO₄.6HKSO₄; Zambonini, Rend. Acc. Sci. Napoli, Dec., 1907.

Millerite, Orford, Quebec.

MISSONITE, Min., p. 471; App., p. 47. — Variety dipyre occurs altered to forsterite and spinel in lherzolite at Ariège; Lacroix, Bull. Soc. Min., 24, 14, 1901.

Mohawkite. G. A. Koenig, Am. J. Sc., 10, 440, 1900. — A variety of domeykite containing nickel and cobalt. See *Domeykite*; also *Ledouxite*.

Mohawk-Whitneyite. G. A. Koenig, Am. J. Sc., 10, 446, 1900; 14, 414, 1902. — An intimate mixture of mohawkite and whitneyite, see Whitneyite.

Monsite, see Ilmenite.

Moissanite. G. F. Kunz, Am. J. Sc., 19, 396, 1905. — Name proposed for the naturally occurring carbon silicide (CSi) (Carborundum) found by Moissan as small green hexagonal plates in the meteoric iron of Cañon Diablo, Arizona, associated with microscopic diamonds. Moissan, C. R., 139, 778, 1904; 140, 405, 1905.

Crystallization of carborundum. G. B. Negri, Riv. min. crist. ital., 29, 33, 1903; Zs. Kr., 41, 269, 1905. Rhombohedral. Forty-four forms were observed, of which the following are given as the most common: (0001), $(10\bar{1}0)$, $(10\bar{1}1)$, $(40\bar{4}3)$, $(20\bar{2}1)$, $(40\bar{4}1)$, $(01\bar{1}1)$, $(04\bar{4}3)$, $(02\bar{2}1)$,

(0441).

Angles: $0001 \land 10\overline{1}1 = 54^{\circ} 46' 37'', 0001 \land 40\overline{4}3 = 62^{\circ} 5' 53'', 0001 \land 20\overline{2}1 = 70^{\circ} 33' 23'', 0001$

 $\wedge 40\overline{4}1 = 79^{\circ} 59' 31''$

Crystal habit is (1) tabular | (0001), or (2) pyramidal, rhombohedrons of both orders being

present.

Following facts observed under the microscope by Pirsson [priv. contr.]. Cleavage poor, rhombohedral; fracture conchoidal. Uniaxial, positive; double refraction weak. Somewhat pleochroic, & deep indigo blue, \omega light blue. Refractive indices high; both \omega and \epsilon greater than

Moldavite, a glass. — Occurrence in Mähren; Dvorský [Mus. Francisceum-Annalen, Brünn, 1898]; Zs. Kr., 32, 623. Concerning its origin; Suess [Ver. geol. Reichsanst. Vienna, 387, 1898; Rzehak, ibid., 415]; its occurrence in northern Bohemia; Jahn, [ibid., 81, 1899]; all reviewed in Zs. Kr., 33, 649. Chemical composition; John [Verh. geol. Reichsanst. Vienna, 179, 1899]; Zs. Kr., 35, 309.

MOLYBDENITE, Min., pp. 41, 1042; App., p. 47. — Crystallographic study; Moses, Am. J. Sc., **17**, 359, 1904.

Anal. from Biella, Italy; Zambonini, Zs. Kr., 40, 211.

Alpine occurrences; Lincio, Centralbl. Min., 12, 1905. In basalts of lower Rhine; Brauns, Centralbl. Min., 97, 1908.

Molybotte, Min., p. 201. — Analyses by Schaller, Am. J. Sc., 23, 297, 1907; Zs. Kr., 43, 331, of various specimens show that molybdic ocher is not the oxide MoO₃ but rather a hydrous ferric molybdate, Fe₂O₃.3MoO₃.7½H₂O. Results confirmed by Guild, Am. J. Sc., 23, 455, 1907, except his analysis gives formula with 7H₂O. Anal. I, Schaller; II, Guild.

		H_2O	Fe_2O_3	MoO_3	Insol.

* Recalc. after deducting insol. res.

Anal. of material from Hortense, Colo.; Schaller, Am. J. Sc., 25, 74, 1908; Zs. Kr., 44, 12.

Molybdophyllite. G. Flink, Bull. G. Inst. Upsala, 5, 91, 1901.

Hexagonal. In irregular foliated masses with perfect basal cleavage; resembles mica. Somewhat flexible in thin folia; etching figures normal hexagonal (Baumhauer). H = 3-4. G = 4.717. Luster on c pearly, elsewhere vitreous. Colorless in thin folia, in thicker masses pale green. Optically uniaxial, negative. Indices $\omega_y = 1.8148$, $\epsilon_y = 1.7611$. Composition, RSiO₄ +H₂O with R = Pb : Mg = 1 : 1 nearly. Cf. barysilite, Min., p. 421.

Analysis, Flink, l.c.:

SiO2 PbO MgO Al₂O₃ Na₂O K_2O H₂O 18.15 61.09 0.46 0.820.69 $6.\overline{3}2 = 99.24$ 11.71

B. B. fuses with some difficulty to a gray porcelain-like mass, which yields metallic lead with soda on charcoal. Yields water freely in the tube.

Occurs with hausmannite in granular limestone or dolomite at Långban, Sweden.

Named from μόλυβδος, lead, and φύλλον, leaf, in allusion to its structure.

Monazite, Min., p. 749; App., p. 47. — Cryst. — Description of crystals with optical and chemical investigation from Impilaks, Finland; Ramsay and Zilliacus, [Öfversikt af Finska Vetenskaps-Societetens Förhandlingar, 39, 1897]; Zs. Kr., 31, 317; crystals from Tyrol; Cathrein, Jb. Min., 2, 137, 1899; from Pisek, Bohemia; Krejci, Ber. böhm. Ges. Wiss., xliv, 1899; also Bull. Acad. Sci. Bohême, 1904; crystallography with bibliography; Bowman, Zs. Kr., 33, 113,

1900; crystals from Tintagel, Cornwall, with new forms, μ (130), η (132), θ (122); Bowman, Min. Mag., 12, 358, 1900; from Prägratten, Tyrol; Pohl, Min. Mitth., 22, 472, 1903; from Kekertak, Upernivik District, Greenland; Böggild, Min. Grönl., 202; from Emmaville, N. S. W.; Anderson,

Rec. Aus. Mus., 6, 414, 1907.

Opt. study of crystals from Nil-Saint-Vincent, Brabant; Prinz, Bull. Ac. Belg., 313, 1904.

Anal. — From Pisek, Bohemia; Preis, [Ber. böhm. Ges., 19, 1897]; Zs. Kr., 31, 526; Brazil with discussion of composition; Hussak and Reitinger, Zs. Kr., 37, 550, 1903. Concerning presence of thorium; Mann, Inaug.-Diss., Leipzig, 1904; Zs. Kr., 42, 664. Analyses of material from Idaho (?); Tschernik [Verh. russ. min. Ges., 42, 9, 1905], Zs. Kr., 43, 68. Discussion of analyses; Aars [Inaug.-Diss., Freiburg i. Br. 1905]; Centralbl. Min., 247, 1907.

General notes; Derby, Am. J. Sc., 10, 217, 1900. Radioactivity; Barker, Am. J. Sc., 16, 161,

Occ. — In tin gravels, Embabaan district, Swaziland, S. Africa; Prior, Min. Mag., 12, 101, 1899; from Delaware Co., Pa.; Hamilton, [Proc. Phil. Ac. Sc., II, 377, 1899]; Zs. Kr., 34, 206; in iron ore and graphite. Brazil; Derby, Am. J. Sc., 13, 211, 1902; character of monazite sand from Caucasus; Tschernik. [Verh. russ. min. Ges., 41, 43, 1903]; Zs. Kr., 41, 184; occurs in place at Blatherarm Creek, near Deepwater, N. S. W., analysis (1.63ThO₂); Anderson, Records Austr. Mus., 5, 258, 1904; Zs. Kr., 42, 391.

Monetite, Min., p. 784. — Triclinic constants on artif. crystals: $\alpha = 96^{\circ} 40'$; $\beta = 88^{\circ} 44'$; $\gamma = 103^{\circ} 48'$; a:b:c=1.049:1:1.044; de Schulten, Bull. Soc. Min., 24, 323, 1901.

Montmorillonite, Min., p. 690. — Anal. of variety, stolpenite, from Gross-Tresny, Mähren; Kovář, [Abh. böhm. Akad., No. 15, 1, 1896]; Zs. Kr., 31, 524. Anal. of material resembling montmorillonite, from Exeter, N. S. W.; Anderson, Rec. Aus. Mus., 5, 67, 1903.

Montroydite. A. J. Moses, Am. J. Sc., 16, 259, 1903; Hillebrand and Schaller; ibid., 24, 269, 1907.

Orthorhombic. Axes $\check{a} : \dot{b} : \dot{c} = 0.63797 : 1 : 1.1931 \text{ (Moses)}; 0.6375 : 1 : 1.1977 \text{ (Schaller)}.$ Forms: a (100), b (010), m (110), d (101), s (112), o (111), x (331), w (311), r (211), t (212), e (132). Hillebrand and Schaller record 56 forms in all. In minute pris-

matic crystals, highly modified; also forming velvety crusts.

H. = 1.5-2. G. undet. Luster adamantine to vitreous. Color orange-red; streak same but lighter. Transparent. Ax. pl. | (100), $Bx_{ac} \perp (001)$? (Schaller, priv. contr.).

Composition, mercuric oxide, HgO, determined on 0.05 gram; analysis

gave:

Loss on heating (assumed to be O) 7.13, sublimate (Hg) 92.87 = 100. Volatilizes completely in the closed tube, yielding a sublimate of metallic mercury. Dissolves readily in cold nitric or hydrochloric acid.

Associated sparingly with eglestonite and terlinguaite at the mercury deposits at Terlingua, Texas.

Named after Mr. Montroyd Sharpe, one of the owners of the Terlingua mines.

Mooraboolite. G. B. Pritchard, [Victorian Naturalist, 18, 63, 1901]; J. Ch. Soc., 82, (2), 612, 1902; L. J. Spencer, Min. Mag., 13, 373, 1903.— A zeolitic mineral from the Moorabool valley, Victoria. As noted by Spencer the characters given agree closely with those of natrolite, to which it is doubtless to be referred.

Moravite. Franz Kretschmer, Centralbl. Min., p. 293, 1906. A chloritic mineral resembling thuringite. It occurs in lamellar, smallfoliated to scaly and granular forms, with perfect basal cleavage.

H. = 3.5. G. = 2.38. Luster greasy to pearly on the scales. Color iron-black. Streak

dark smoky gray.
Composition, H₄Fe₂(Al,Fe)₄Si₇O₂₄. Analysis of carefully selected material:

 $\underbrace{\frac{\mathrm{Na_2O,K_2O}}{1.10}}$ SiO₂ Al₂O₃ Fe₂O₃ FeO CaO MgO H₂O 4.95 graphite 0.55, P_2O_5 tr. = 99.4649.30 13.99 tr.

A second analysis on less pure, somewhat altered material is not quoted here.

B. B. fuses with difficulty to a black shining bead. Decomposed with hydrochloric acid with the separation of gelatinous silica.

Occurs abundantly at the iron-ore mines of Gobitschau near Sternberg, Moravia, Thuringite is present, also stilpnomelane and stilpnochloran (see also Kretschmer, Centralbl. Min., 195, 1905).

Montroydite.

Morencite. W. Lindgren and W. F. Hillebrand, Am. J. Sc., 18, 455, 1904.

In brownish yellow fibrous seams with silky luster. Under the microscope appears as a nearly homogeneous felted aggregate; the fibers slightly pleochroic with parallel extinction and strong birefringence.

Composition uncertain. Analysis, W. F. Hillebrand:

* 8.84 at 105°, 0.12 at 150°, 4.27 below redness, 0.69 red heat. † FeS₂ 0.66, P_2O_5 0.18, CuO tr.

From Morenci, Arizona; found in a lime shale at the Arizona Central mine, 200 feet below the surface; probably derived from the oxidation of some contact metamorphic mineral.

MORINITE, Min., p. 1042.— Anal. of crystalline massive material from original locality yielded:

* Anal. recalc. after deducting 1.50% SiO₂ and 0.20% H₂O at 120°.

Formula derived may be written as 3AlPO₄.HNa₂PO₄.3CaF₂.8H₂O or HNa₂(AlF)₃(CaF)₅ $(PO_4)_4.8H_2O.$

Relation of composition to that of amblygonite, from which it has been derived, is discussed. Carnot and Lacroix, Bull. Soc. Min., 31, 149, 1908.

Müllerite. F. Zambonini, Zs. Kr., 32, 157, 1899; 34, 225, 1901. Massive; resembling nontronite; in crusts, with rough surface.

Soft. $G_{\cdot} = 1.97$.

Color yellowish green. Streak yellowish, dull. Opaque. Composition, Fe₂Si₃O_{9.}2H₂O.

Analyses: 1, Zambonini; 2, Müller; 3, Uricochea (anal. 2 and 3 quoted; ref. not given).

	SiO ₂	Fe ₂ O ₃ Al ₂ O ₃	MnO	MgO	H ₂ O
1. Nontron	§ 48.82	35.88 4.30	0.63	0.35	9.66 = 99.64
2. Tirschenreuth	47.10	35.75 7.15			10.00 = 100.00
3. Tirschenreuth	47.59	42.49		0.13	9.79 = 100.00

B. infusible, loses water and finally becomes brown. Reacts for iron with borax. Slowly

From Nontron, Dordogne, France, and called "nontronite" (chloropal), but differs chiefly in lower percentage of water. Also stated to occur at Tirschenreuth, Bavaria. The mineral from Starbo, Sweden, analyzed by Weibull (Dana, Min., anal. 9, p. 701) is also near the above. Named after Müller, who analyzed the Tirschenreuth mineral.

MURSINSKITE, Min., p. 1042. — Review of crystal measurements with conclusion that the specimens named as mursinskite were an iron-lime garnet; von Fedorow, Zs. Kr., 43, 36.

Muschketowite. E. von Fedorow and W. Nikitin, [Ann. Géol. Min. Russ., 3, 87, 99, 1899]; Min. Mag., 12, 388. A pseudomorph of magnetite after hematite. Urals.

Muscovite, Min., p. 614; App., p. 48.— Crystals from Mitchell Co., N. C., show following new forms: ε (447); h (556); (29.29.30); ο (111); ε (331); τ (10.10.3); θ (11.11.3); η (23.23.6); ν (551). Baumhauer, Zs. Kr., 32, 164, 1899. In radial crystal groups; Johnsen, Centralbl. Min., 504, 1908. Optical study of material from Monte Orfano, Italy; Viola, Zs. Kr., 32, 118, 1899. With unusual axial angle from the eclogite of the Fichtelgebirge; Johnsen, Centralbl. Min., 620, 1908. Analysis of a pink fibrous variety, associated with lepidolite, from Haddam Neck, Conn.;

Bowman, Min. Mag., 13, 98, 1902.

Fuchsite used as material for prehistoric implements in Guatemala; Bauer, Centralbl. Min., 291, 1900; as decorative stone by the ancients; Miers, Min. Mag., 13, 322.

From upper Veltlin, Italy; Linck, Jena, 33, 349, 1900.

T. Wada, Minerals of Japan, 1904; Beitrage Min. Japan, 2, 23, 1906; Am. J. Sc., Naegite. 19, 90, 1905.

Probably tetragonal and isomorphous with zircon. Occurs in small spheroidal aggregates; rarely in pseudo-dodecahedral crystals. Color varies between dark pistachio-green, greenish gray and brown or reddish brown. Under microscope transparent, grass-green, highly

Narsarsukite.

Marked radioactivity. Analysis by refractive, often nearly isotropic. H. = 7.5. G. = 4.09. Haga:

SiO, Y,O, ZrO. UO, ThO, Nb2O5.Ta2O2 20.58 55.30 3.03 7.69 9.12 = 100.73501

Earlier analyses by Tamura failed to find the zirconia.

Found with fergusonite in placer tin washings near Takayama, Mino province, Japan.

NAGYAGITE, Min., p. 105; App., p. 48. — Anal. and discussion of composition; Přiwoznik, [Oesterreich. Zs. f. Berg-u. Hüttenwesen, 265, 1897]; Zs. Kr., 32, 185.

Narsarsukite. G. Flink, Medd. om Grönland, 14, 234, 1898; 24, 154, 1901.

Tetragonal. Axis $\dot{c} = 0.52352$.

Forms: a (100), c (001), m (110), n (210), p (111). Angles: (210): (100) = 18° 17′; (111): (110) = 53° 29′.

In tabular crystals, c predominating; also rarely cubic. Faces c

uneven, seldom bright; a, m, n bright and vertically striated. Cleavage m, eminent. Fracture uneven. Brittle. H. = 7-7.25. G. = 2.751.vitreous, on m pearly. Color honey-yellow, with tinge of reddish brown; on weathering passes to brownish gray or ocher-yellow. Transparent to translucent. Optically positive. Indices $\omega_y = 1.5532, \epsilon_y = 1.5842.$

Composition, a highly acidic titano-silicate of ferric iron and sodium.

Analysis, Chr. Christensen:

SiO2 TiO, Fe₂O₃ Al₂O₃ MnO MgO Na₂O H.O 61.63 16.12 $0.71 \ 0.29 = 100.04 \text{ less } O (0.30) = 99.74$ 14.00 6.30 0.28 0.47 0.24

B. B. fuses readily to a yellow blebby glass; reacts for titanium with salt of phosphorus. Not attacked by acids.

Occurs at several localities in pegmatite at Narsarsuk, southern Greenland; associated with ægirite, also microcline, albite, elpidite, epididymite, tæniolite.

NASONITE, App., p. 48. — Described by Penfield and Warren, Am. J. Sc., 8, 346, 1899. In massive aggregates, crystallization probably tetragonal with imperfect basal and prismatic cleavage; birefringence rather strong, negative. H. = 4. G. = 5.425. The mean of two analyses by Warren gave:

SiO₂ 18.47 PbO FeO CaO CI ZnO MnO (OH) 65.68 0.10 0.26 = 100.17 deduct 0.63 (O = Cl) = 99.540.82 0.83 11.20 2.81

> The formula deduced is as before given, Pb₆Ca₄Cl₂Si₆O₂₁, or Pb₄(PbCl)₂Ca₄(Si₂O₇)₃. The authors show that nasonite is closely related to ganomalite, the formula of which should probably be written Pb₄(PbOH)₂Ca₄(Si₂O₇)₃.

Natroalunite. W. F. Hillebrand and S. L. Penfield, Am. J. Sc., 14, 220, 1902. — Name suggested for alunites containing considerable soda.

Natrochalcite. C. Palache and C. H. Warren, Am. J. Sc., 26, 345, 1908; Zs. Kr., 45, 534, 1908.

Monoclinic. $\hat{a}: \hat{b}: \hat{c} = 1.423:1:1.214; \beta = 61^{\circ} 17'$ 30". Habit pyramidal, m and p predominating, crystals 1 cm. long. Forms: c (001), b (010), m (110), p (111), v (112), u (221), w (331), q (111), x (221). Cleavage perfect $\|c$ (001). $\|c$ (001). $\|c$ (23). Color bright emerald-Refractive indices, $\alpha = 1.6491$; $\beta = 1.6555$; $\gamma = 2V_{No} = 36^{\circ}$ 52' (calc.). Ax. pl. || b (010). Bx_{ao} 1.7143; $2V_{Na} = 36^{\circ} 52'$ (calc.). Ax. pl. || b (010). inclined 12° to \dot{c} axis in acute angle β . Optically +. Dispersion inclined, strong

Comp. Na₂SO₄Cu₄(OH)₂(SO₄)₂ + 2H₂O; CuO, 42.08; Na₂O, 8.24; SO₃, 42.51; H₂O, 7.17.

Anal. by Warren: CuO, 41.95; Na₂O, 8.44; SO₃, 42.10; H₂O, 7.70; insol. res., 0.70; Cl (from atacamite), 0.05 =100.94.

Occ. Found at Chuquicamata, Province of Autofagasta, Chile, associated with kröhnkite, blödite, brochantite, atacamite, etc.

Natrojarosite. W. F. Hillebrand and S. L. Penfield, Am. J. Sc., 14, 211, 1902. — See Jarosite.

NATROLITE, Min., pp. 600, 1042; App., p. 49. — Cryst. — Iceland; Jeremejew, [Bull. Acad. Sc. St. Pétersbourg, 9, 5, 1898]; Zs. Kr., 32, 428; Langesundfjord, Norway, with following

new forms: g (334); k (335); j (112); p (361); ϵ (836); ξ (16.16.17); Zambonini, Zs. Kr., **34**, 549, 1901; from Leitmeritz, Gross-Priesen, with opt. study and anal.; Pelikan, Ber. Ak. Wien, **11**, (I), 343, 1902; Scottish localities; Goodchild [Trans. Geol. Soc. Glasgow, **12**, Suppl., 1–68, 1903]; Zs. Kr., **45**, 307; Narsarsuk, Greenland; Flink, Medd. om Grönl., **24**, 107, 1901; Kangerdluarsuk; Böggild, Min. Grönl., 531; Katzenbuckels, Odenwald, Baden; Freudenberg, [Mitt. bad. geol. Landes-

Böggild, Min. Grönl., 531; Katzenbuckels, Odenwald, Baden; Freudenberg, [Mitt. bad. geol. Landesanstalt, 5, 185, 1906]; Zs. Kr., 46, 126, 1909.
Anal. — Moore Station, N. J.; Eyerman, Amer. Geol., 34, 43, 1904; from nepheline-syenite, Montreal; Harrington, Trans. Roy. Soc. Canada, 11, (3), 25, 1905; Monte Catini, Tucany; Manasse, Proc. Soc. Tosc., Jan., 1906; and with discussion of chem. constitution; Baschieri, ibid., March, 1907; Inverell, N. S. W.; Anderson, Rec. Aus. Mus., 6, 420, 1907. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 117, 1908.
Association of natrolite (anal.) with datolite at Pokolbin, N. S. W.; Anderson, Rec. Aus. Mus., 5, 2, 1004.

5, 2, 1904.

Action of ammonium chloride upon; Clarke and Steiger, Am. J. Sc., 9, 345, 1900.

Alteration; Cornu and Schuster, Min. Mitth., 26, 321, 1907.

Mooraboolite (which see) from the Moorabool valley, Victoria, is to be referred to natrolite, (Spencer). It occurs in white, radiated aggregates in a decomposed basalt. H. = 6. G. = 2.17. The crystals are elongated orthorhombic prisms terminated by an obtuse pyramid; no cleavage observed. Analysis, E. O. Thiele:

SiO ₂	Al_2O_3	CaO	Na ₂ O	K ₂ O	H ₂ O
48.02	28.68	0.42	11.24	3.00	9.80 = 101.16 *

* Author gives incorrectly the summation as 101.68%.

Following new analysis of "sloanite," Min., p. 610, from Monte Catini proves it to be thomsonite. SiO2 H.O CaO Na₂O

Al₂O₃ 9.76 46.49 25.47 1.10 17.05 = 99.87;

Manasse, [Proc. Soc. Tosc. Sc. Nat., 15, 20-37, 1906]; Zs. Kr., 64, 658.

Natronkalisimonyite, see Blödite.

Nemaphyllite. Friedrich Focke, Min. petr. Mitth., 21, 327, 1902. — A serpentine peculiar in containing 2 p. c. of soda; see Serpentine.

Neotantalite. Pierre Termier, Bull. Soc. Min., 25, 34, 1902.

Isometric, in octahedrons (up to 1 mm.) resembling pyrochlore; dodecahedral faces also occur. H. = 5–6. G. = 5.193. Luster nearly adamantine.

Color clear yellow. Translucent. Isotropic. Refractive index 1.9.

Composition near that of tantalite.

Analysis by Pisani, after deducting small amounts of SiO2, Al2O3, etc., due to admixed mica, and SnO, due to cassiterite, as follows:

Ta2O5 Nb2O5 FeO MnO Alk. H₂O (1200°) 23.10 2.31 60.584.80 3.00 = 100.30.

A little of the iron may be due to enclosed scales of hematite. From the sands yielded by the washing of kaolin of the Colettes and Echassières, Dept. l'Allier, France; these sands carry cassiterite in considerable amount.

Nephelite, Min., pp. 423, 1042; App., p. 49. — **Comp.** — Morozewicz [Bull. de l'Académie des Sciences de Cracovie, p. 958, Oct., 1907] gives new analyses as follows: 2 from Mariupol, 1 from Mias, 2 from Vesuvius. From these and other reliable analyses the author derives two series of empirical formulæ for the mineral.

> Basic Series. Normal Series. (1) K, Na, Al, Si, Ogo

The normal series can be represented by the general formula K_2 Na_n Al_{n+2} Si_{n+3} O_{4n+10} and can be considered as various mixtures of K_2 Al₂Si₃O₁₀ and Na₂Al₂Si₂O₈. The one member of the basic series can be considered as a mixture of K_4 Al₄Si₃O₁₈ with Na₂Al₂Si₂O₈. Any Fe₂O₃ is considered to be isomorphous with Al₂O₃, CaO with Na₂O and MgO with K_2 O. The small amounts of H₂O are considered secondary.

Anal. of material from nepheline syenite at Montreal; Harrington, Trans. Roy. Soc., Canada,

11, (3), 25, 1905.

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull. 207, 1902; Zs. Kr., 38, 696.

Occurrence in syenite near Brookville, N. J.; Ransome, Am. J. Sc., 8, 417, 1899; in Ontario; Coleman, Am. J. Sc., 14, 148, 1902.

NEPHRITE, see under Amphibole.

Nepouite. E. Glasser, C. R., 143, 1173, 1906; Bull. Soc. Min., 30, 17, 1907. Crystals, microscopic plates with hexagonal outline. Cleavage (1) perfect parallel to principal plane of the plates and (2) at right angles to (1) and parallel to the plane of the optic axes; (3) a poor cleavage also perpendicular to the first and inclined at 60° to the second. H 2-2.5. 2.47-3.24, varying with the composition. Pearly luster on best cleavage face. Color from pale to deep green, varying with the per cent of NiO. Plates are slightly dichroic, $\omega =$ yellow green, $\epsilon =$ green. Optically negative. Plane of optic axes perpendicular to principle cleavage and parallel to second cleavage. Axial angle very small. Strength of birefringence about 0.037. $\beta = \text{about } 1.62 - 1.63.$

Composition, 3(Ni, Mg)O.2SiO2.2H2O.

Analyses of material from different localities, New Caledonia:

1. Reis II Mine, Nepoui. 2. Union Mine, Canala.	SiO ₂ 32.84 34.52	NiO 49.05 42.75	MgO 3.64 7.23	FeO 1.90 2.05	CaO 0.50 tr.	Al ₂ O ₃ 0.97 1.21	H_2O $9.64 =$ $10.20 =$	98.54 98.96
2a Union Mine, Canala.*	33.03	46.11	6.47	2.20	tr.	1.39	19.61=	99.81
3. Young-Australia Mine, Comboui River.	35.05	39.99	11.80	1.22	0.58	1.13	10.05=	
4. Paragraphe Mine, Kua River.	40.07	18.21	29.84	0.25	0.53	0.72	11.98 =	101.60
5. Mea Mine, Kouaoua.	32.36		3.00	0.62	tr.	0.69	12,31 =	99.68

* Analysis 2a is of material of heavier specific gravity separated from 2.

Pyr., etc. — In closed tube yields water and blackens. Slowly but completely soluble in HCl. Gives reactions for Ni.

Obs. - Occurs in connection with the nickel deposits of New Caledonia. Named from the locality, Nepoui, where it was first observed.

Neptunite, App., p. 49. — Crystals from Narsarsuk, Greenland, described by Flink, Medd. om Grönl., 14, 232, 1898; 24, 120, 1902; Böggild, ibid., 33, 119, 1906; Wallenström, Geol. För. Förh., 27, 149, 1905. The following new forms are recorded: x (311), f ($\overline{1}01$), i ($\overline{1}12$), r (221), p (311), q (712). Found also at Tutop Agdlerkofia; Böggild, Min. Grönl., 502. Prismatic crystals from San Benito County, Calif., showing a, m, p, s, o and new form g (211) (fig.). Plane of optic axes parallel to b (010), acute bisectrix c making angle of 20° with c axis in obtuse angle β . $2V = 48^{\circ}$, approx. Ford, Am. J. Sc., 27, 235, 1909; Zs. Kr. 46, 321, 1909. The neptunite from California was first thought to be a new species and was named carlosite; Louderback, Uni. Calif. Pub., 5, 9, 152, 1907.

Analyses by Bradley (Am. J. Sc., 28, July, 1909) on California material confirm the formula obtained for the Greenland mineral.

Average of two analyses follows:

NEWBERYITE, Min., p. 830. Occurrence with struvite in tusk of mammoth found in swamp on Quartz Creek, 20 miles south of Dawson City, Yukon territory; Hoffmann, Am. J. Sc., 11, 149, 1901; in bat guano from Australia, (anal.); MacIvor, Chem. News, 85, 181, 217, 1902. Artif. production; de Schulten, Bull. Min. Soc., 26, 24, 1903.

Niccolite, Min., p. 71. — Crystals from Mansfeld, Saxony; Sachs, Ber. Akad. Belin, 856, 1902.

Occurrence at Cobalt, Canada; Miller, Rep. Bureau of Mines,

Toronto, II, 1905.

Neptunite, California.

NICKEL-IRON. Concerning possible existence of Fe, Ni, in meteoric iron of Youndegin and meteoric stone of Zomba; Fletcher, Min. Mag., 15, 147, 1908. See Awaruite.

Nigrite. C. A. Peterson, 20th Ann. Rep. U. S. G. S., 6, 257, 1899. A kind of asphaltum from Utah; also see under Asphalt.

NITER, Min., p. 851; App., p. 49. — Crystals taken as hemimorphic and a new orientation proposed; Wernadsky, [Bull. Soc. Imp. Nat. Moscow, 2, 292, 1897]; Zs. Kr., 31, 518.

NONTRONITE, see Chloropal.

NORTHRUPITE, App., p. 49. — Relations to tychite, which see. An isomorphous mixture of northrupite and tychite obtained artficially by de Schulten, C. R., 143, 403, 1906.

Noselite, Min., p. 432. — Variation in indices of refraction with variation in chem. comp.; Gaubert, Bull. Soc. Min., 28, 188, 1905.

Anal. of material from Vicentino; Maddalena, Rend. Acc. Linc., 17, (1), 802, 1908.

Octahedrite, Min., pp. 240, 1043; App., p. 50. — Cryst. — Piattagrande near Sondalo in Veltlin, Italy; Brugnatelli, Zs. Kr., 32, 355, 1900; Rend. R. Inst. Lomb., 32, 1405, 1899; Scipsius, St. 32, 355, 1900; Rend. R. Inst. Lomb., 32, 1405, 1899; Scipsius, St. Gotthard; Boeris, Att. Soc. Milano, 40, 399, 1901; Riv. min. crist. ital., 28, 75, 1902; complex crystals, Brindletown, N. C., (fig.); Robinson, Am. J. Sc., 12, 180, 1901; Zs. Kr., 35, 425; Prägratten, Tyrol; Pohl, Min. Mitth., 22, 479, 1903; Binnenthal; Solly, Min. Mag., 14, 16, 1904; Harre, Zs. Kr., 42, 282, 1906; with following new forms: R (3.0.10); E (203) (?); H (332); T (11.2.12); L (25.11.5); Millosevich, Rend. Acc. Linc., 14, 92, 1905; Somerville, Mass. showing interpenetration twins (101) as tw. pl. Polache Mass., showing interpenetration twins, (101) as tw. pl.; Palache, Festschr. siebzigsten Geburtstage, H. Rosenbusch, 311, 1906; Nil-Saint-Vincent, Brabant, with new form (449); Prinz, Bull. Ac. Belg., 706, 1907; Kollergraben, Binnen, with new form (338); Cesaro, ibid., 336; Jequitinhonha River, Brazil, with new form (338); Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 150, 1908.

Refractive indices; Taubert, [Inaug.-Diss., Jena, 1905]; Zs. Kr.,

44, 313.

Discussion of formula, see Rutile.

Occurrence in quartzite, Shankille, Co. Dublin, Ireland; O'Reilly, Brindletown, N. C. [Proc. Roy. Dublin Soc., 8, 691, 1898]; Zs. Kr., 32, 293; in the triassic sandstones, Midlands, England; Scrivenor, Min. Mag., 13, 348, 1903; in granite from Montorfano, northern Italy; Tacconi, Rend. Acc. Linc., 14, (2),

.88, 1905.

Ochrnite. E. S. Fedorov, [Gornyi Zhurnal, St. Petersburg, 81, 3, p. 264, 1905]; Spencer, Min. Mag., 14, 405, 1907. A rock-forming mineral from the Caucasus resembling diallage in appearance: it has three rectangular cleavages but is shown by its optical characters to be monoclinic. Formula given as 6(Mg, Fe, Ca)O.6SiO₂. H₂O, but anal. shows also Al₂O₃, 6.74%. Named after A. G. Ern, a Russian mining engineer.

OLDHAMITE, Min., pp. 65, 1043.— Detected by anal. in Allegan meteorite; Tassin, Proc. U. S. Nat. Mus., 34, 433, 1908.

OLIGOCLASE, Min., p., 322; App., p. 50.— Crystals from Biella, Italy, with anal.; Zambonini, Zs. Kr., 40, 253; from Maneetsok, Greenland; Böggild, Min. Grönl., 465.

Optical study of oligoclase in granites of Sardinia; Riva, Att. Acc. Sc. Napoli, 12, No. 9, 1905; refractive indices of crystals from inclusions in augite-andesite lava from Bellenberges near Mayen; Gaubert, Bull. Soc. Min., 28, 196, 1905.

Material from near Lake Baikal known as lazurfeldspar has been proven to belong to oligoclase, (anal.); Jeremejew, Zs. Kr., 32, 493; Bull. Soc. Min., 24, 438, 1901.

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull., 207, 1902; Zs. Kr.,

38, 697.

OLIVENITE, Min., p. 784. — Crystals from Tintic Dist., Utah, showing new forms s (034), d (025); Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 152, 1908.

Oolite. — Siliceous oolite from Tateyama, Etchü Province, Japan; Jimbo, Beiträge zur Min. von Japan, 1, 11, 1905; Am. J. Sc., 19, 399, 1905.

Opal, Min., pp. 194, 1038; App., p. 50. — Study concerning the loss of water at various temperatures and periods of heating; D'Achiardi [Att. Soc. Tosc. Pisa, 11, 114, 1899]; Zs. Kr., **34**, 305.

Microstructure; Bütschli, [Ver. Heidelb. Naturhist. Ver., 6, 287, 1900]; Zs. Kr., 36, 536. Change to quartz; Spezia, Att. Acc. Sc. Torino, 37, 585, 1902.

Gem opal from White Cliffs, Australia, found as filling openings in sandstone, in opalized fossil wood, in the material of various fossil shells and bones and in aggregates of radiating pseudomorphic crystals; Gürich, Jb. Min., Beil., 14, 472, 1901. Pseudomorphs, thought to be after glauberite; Anderson and Jevons, Rec. Aus. Mus., 6, 31, 1905.

ORANGITE, see under Uraninite.

ORPIMENT, Min., pp. 35, 1043; App., p. 50.—Stevanović, Zs. Kr., 39, 14, by etching and crystallographic study of crystals from Allchar, comes to the conclusion that the symmetry of orpiment is monoclinic. Following constants given: $\dot{a}:\dot{b}:\dot{c}=0.5962:1:0.6650;\;\beta=90^{\circ}$ 41'. List of forms and angles given; also anal. Crystals from Mercur, Utah, with following rare forms, e(103) and $K(\bar{1}23)$, and the new forms d(103), l(023) and n(133); Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 154, 1908.

ORTHITE, Min., p. 522. — Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 76, 1908.

ORTHOCLASE, Min., p. 315; App., p. 50. — Cryst. — Monte Cimino near Viterbo, Italy, with anal.; Zambonini, [Riv. Min., Padua, 20, 20, 1898]; Zs. Kr., 32, 533; of adular from Pisek, Bohemia; Krejci, Ber. böhm. Ges. Wiss., xliv, 1899; measurement of crystals from various Italian localities with derivation of crystal constants; Zambonini, Zs. Kr., 34, 243, 1901; Elba with following new forms: (310); (740); (7.20.0); (13.0.12); (16.0.13); (506); (14.0.15); (12.0.1); (737); (11.110); (5.5.11); (14.14.15); (971); optical study also; Bartalini, [Acc. Sc. Med. Nat. Ferrara, 1901]; Zs. Kr., 37, 408; sanidine from Canale Monterano, Province Rome, Italy, with new form m (556); Zambonini, Zs. Kr., 40, 58, 1904; Igaliko, Greenland, with twinning on (201); Böggild, Min. Grönl., 440. Crystallographic and optical study of orthoclase and micro-440. Crystallographic and optical study of orthoclase and microcline in granites of Sardinia; Riva, Att. Acc. Sc. Napoli, 12, No. 9, 1905; study of development of crystals in simple and in twin forms; Neugebauer, Min. Mitth., 25, 413, 1906. Crystals from Corsica; Deprat, C. R., 143, 753, 1906; Bull. Soc. Min., 31, 271, 1908. Twins; — Shinano, Japan; Iwasaki, Am. J. Sc., 8, 157, 1899. On feldspar twinning; Viola, Zs. Kr., 38, 67, 1903; Carlsbad and Baveno twins; Sache Min. Inst. Univ. Breeden, 1903. Sachs, Min. Inst. Univ. Breslau, 1903. Baveno twin from Striegau Sachs, Min. Inst. Univ. Breslau, 1903. Baveno twin from Striegau with (40\(\bar{3}\)); crystal from Isomraudnaiakop, Urals; Gonnard, Bull. Soc. Min., 28, 21, 1905; Baveno twins from Judith Mts., Montana (fig.); Ford and Tillotson, Am. J. Sc., 26, 149, 1908; Zs. Kr. 46, 129; twins from Four-la-Brouque, Puy-de-Dôme; Gonnard, Bull. Min. Soc., 31, 292, 1908; crystals (with anal.) from Valle del Chisone Piedmont; Colomba, Att. Acc. Torino, 43, June, 1908. Optical study of material from Calabria and Cimini, Italy; Viola, Zs. Kr., 32, 121, 124; of sanidine from Flegrea, Italy; Riva, Rend. Acc. Linc., 9, (2), 170, 1900.

Anal., from near Easton, Pa.; Eyerman, Amer. Geol., 34, 43, 1904; adular from Cavour, Piedmont; Colomba, Att. Acc. Torino, 39, 829, 1904.

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull., 207, 1902; Zs. Kr. 38, 697

Occ. in New South Wales at Cockburn Creek (anal.), Oban, Uralla, Bolivia, Inverell; Anderson, Rec. Aus. Mus., 64, 265, 1907; in dolomite from Campolongo, Tessin; Linck, Jb. Min., 1, 21, 1907.

Isorthose. A var. of orthoclase differing in opt. orientation: the Bxac. 1 (010). Positive. Found in granite from northern Urals and at Mont Blanc. Duparc, C. R. 138, 715, 1904.

Osannite, var. of amphibole, which see.

Otavite. Otto Schneider, Centralbl. Min., p. 388, 1906. Forms crusts, showing on both surfaces minute rhombohedral crystals with terminal angle of 80° approx. Luster brilliant, adamantine. Color white to reddish. Dissolves with effervescence in hydrochloric acid. According to qualitative tests by Wölfer, a basic cadmium carbonate (Cd 61.5 p. c.). Found at the Tschumeb mine in the Otavi district, German Southwest Africa; azurite, malachite (dusted with greenockite), aurichalcite, cerussite, pyromorphite, linarite, olivenite, smithsonite occur at the same locality.

OZOCERITE, Min., pp. 998, 999. - From Roumania; Istrati, [Bull. Soc. Sc., Bucarest, 6 61, 1897]; Zs. Kr., 32, 187.

Paigeite. A. Knopf and W. T. Schaller; Am. J. Sc., 25, 323, 1908. A mineral originally described as being a hydrous borate of ferrous and ferric iron with magnesium. It has since been proven to contain a considerable amount of SnO₂ and is probably identical with hulsite, which see. (Priv. contr. from W. T. Schaller.)

Palacheite. A. S. Eakle, Bull. G. Univ. Cal., 3, 231, 1903. — Described as a new ferric sulphate from the Redington mercury mine (Boston mine) at Knoxville, California, and named after Dr. Charles Palache of Harvard University; later shown by Eakle to be a variety of botryogen, which see.

Palladium, Min., p. 28. — Occurrence in Brazil; Hussak, Ber. Akad. Wien, 113, 379, 1904.

Palmerite. Eugenio Casorio, Att. Accad. Georgofili, 1, July 3, 1904.

Amorphous, pulverulent. Color white and unctuous to the touch, resembling purified kaolin. In composition a hydrated phosphate of aluminium and potassium; calculated formula $HK_2Al_2(PO_4)_3 + 7H_2O.$ Analysis:

 Al_2O_3 22.89 ${\rm Fe_2O_3} \atop 1.17$ $_{7.87}^{\mathrm{H_2O(100^\circ)}}$ SiO₂ P₂O₅ 37.10 K_2O Na₂O Ign. 21.29 8.04 0.02 0.36

Insoluble in water but easily in hydrochloric and nitric acids.

Occurs as a stratum in a deposit of guano in a large cavern on the slopes of Monte Alburno, near Controne, in Salerno, Italy. Named after Professor Paride Palmeri.

A. Lacroix, Bull. Soc. Min., 30, 234, 1967; ibid., 31, 261, 1908.

In microscopic micaceous plates, often hexagonal in outline.

G. greater than 3.33. Colorless with pearly luster. Uniaxial, optically -. Strong birefrin-

Composition uncertain, perhaps $3(K,Na)_2SO_4.4PbSO_4 = SO_3$, 33.0; PbO, 52.3; K_2O_7 , 11.1; Na_2O_7 , 3.6 (considering Na: K=1:2). Analysis on small amount of material after subtracting 22.59% impurities, mostly hematite, and 2.64% NaCl. Analyst, Pisani.

> $Na_2O = 3.5 = 100.0$ PbO $\frac{\text{K}_2\text{O}}{12.3}$ 54.8

Pyr., etc. Decomposed by boiling water, leaving an insoluble residue of PbSO4. Easily fusi-

Dissolves in HNO₃.

Artificial. Was prepared synthetically by fusing together the different sulphates, giving

crystal plates larger but identical in their properties with the naturally occurring mineral.

Obs. Found in the fumarole deposits at Vesuvius formed at the eruption of April, 1906. Closely associated with aphthitalite.

Named in honor of the Neapolitan mineralogist, L. Palmieri.

PANDERMITE, see Colemanite.

Paracelsian. E. Tacconi, Rend. Ist. Lomb., Milano, 38, 636, 1905; Zs. Kr., 43, 424.

In grains. Yellow color. $G_{\rm e}=3.325$. $H_{\rm e}=6$. Biaxial, optically +. Birefringence somewhat lower than quartz. $2V=83^{\circ}39'$ (approx.).

Comp. A barium aluminium silicate. Anal., corresponds to formula, Ba₃Al₈Si₈O₃₁. Analysis:

Al₂O₃ BaO Ign. 29.97 34.47 0.45 = 100.26

Pyr. Infus. Decomposed by warm acids.

Occ. Found with quartz and pyroxene in calciphyr at Candoglia, Toce valley, Piedmont. Probably to be considered a variety of celsian.

PARAGONITE, Min., p. 623. — From St. Gotthard with unusual axial angle; Johnsen, Centralbl. Min., 618, 1908.

retrical prisms and pinacoids, base, and traces of domes or pyramids. Tabular ||a|. Good cleavage ||b|. Cleavage planes show parallel banding similar to that of basal cleavage with albite twinning. H. = 3.7. G. = 3.31. Colorless and transparent. On large plane a crystals show bright polarization colors; on b birefringence much lower. Angle of extinction on $a = 30^{\circ}$ to edge ab. Extinction angle on cleavage, b, inclined but varying from 0° to 25° in respect to edge ab. Does not lose water and become opaque until heated to 163°.

Comp. same as for hopeite Zn₃P₂O₈.4H₂O. Analysis:

 H_2O . 15.6 = 100.253.0

Found at Broken Hill mines, N. W. Rhodesia.

Paralaurionite, App., p. 50. — G. F. $Herbert\ Smith$, Min. Mag., 12, 108, April, 1899; ibid., 183; Zs. Kr., 32, 217. Rafaelite. A. Arzruni, Zs. Kr., 31, 229; May, 1899. Monoclinic, usually pesudo-orthorhombic on account of twinning. a:b:c=2.7036:1:1.8019 (Min. Mag., 12, 183, footnote). $\beta=62^{\circ}47'$. Forms: $a\ (100), c\ (001), d\ (10\overline{1}), h\ (20\overline{1}), h\ (40\overline{1}), l\ (60\overline{1}), p\ (111), m\ (110)$ and on rafaelite also $(\overline{1}03), (101), (201), (010), (432)$. The form (111) of paralaurionite was taken as (132) in orig. description of rafaelite.

Angles: $a \land m = \$67.2.5'$; $a \land m = \$59.29'$; $a \land m = \$67.2.5'$; $a \land m = \$6.2.5'$;

Angles: $a \wedge m = 67^{\circ}25$; $a \wedge p = 58^{\circ}28'$; $a \wedge c = 62^{\circ}47'$; $c \wedge m = 79^{\circ}53'$. Crystals of two types, (1) tabular $\parallel a$; (2) prismatic \parallel to edge ac. Twin. pl. a. Refractive index for ray \perp to b for sodium light = 2.1463. G. = 6.05. Color for paralaurionite white; rafaelite, violet red and shows strong pleochroism.

Comp. like laurionite; PbClOH.

Anal. by Prior; Pb, 78.1; Cl, 14.9; H₂O, 3.4; O, [3.6] = 100.

Paralaurionite was found at Laurium; rafaelite from Chile. The close similarity recorded crystal angles proves the two to be identical. No analysis of rafaelite was made. The close similarity of the Crystals from Laurium, Greece; Lacroix and de Schulten, Bull. Soc. Min., 31, 82, 1908.

Paratacamite. G. F. Herbert Smith, Nature, 71, 594, 1905; Min. Mag., 14, 170, 1906; Zs. Kr., 43, 28, 1906.

Axis c = 1.0248. Forms: $a(11\bar{2}0), c(0001), r(10\bar{1}1), w(02\bar{2}5), v(0.7.7.13),$ Rhombohedral. $e(01\overline{1}2)$, $u(04\overline{4}7)$, $f(02\overline{2}1)$, $l(24\overline{6}1)$.

Commonly in rhombohedral crystals (r), crystals often twinned with r as tw. pl.; sometimes in

slender prisms elongated parallel to the zone rfa. Cleavage, r good. Fracture conchoidal. Brittle. H. = 3. G. = 3.74. Luster vitreous. Color bright green. Streak green. Refractive index 1.846. Shows optical anomalies. Composition like atacamite, $CuCl_2.3Cu(OH)_2$. Analysis by Prior gave: $Cl_1.15.97$; Cu, 14.27; $CuO_2.56.10$; $CuO_2.56$

From the Herminia and Generosa mines, Sierra Gorda, Chile; also with native gold from the Bolaco mine, San Cristobal, Chile.

Paravivianite. S. Popoff, Centralbl. Min., p. 112, 1906. — See Vivianite.

Parianite. S. F. Peckham, Jour. Franklin Inst., 140, 381, 1895. — Asphaltum from the Pitch Lake, Trinidad.

Parisite, Min., p. 290; App., p. 50. — The observations of Penfield and Warren given in App. I are published in Am. J. Sc., 8, 21, 1899.

Discussion of crystal constants; Cesaro, Bull. Ac. Belg., 321, 1907. In granite at Montorfano, northern Italy; Tacconi, Rend. Acc. Linc., 14, 2, 88, 1905.

Patronite. Foster Hewett, Eng. Min. Jour., Sept. 1, 1906, p. 385; J. J. Bravo, [Informaciones y Memorias, Soc. Eng., Lima, Peru, 8, 171, 1906]; W. F. Hillebrand, Am. J. Sc., 24, 148, 1907. Amorphous, black material of complex mineral composition containing large amounts of a vanadium sulphide, perhaps VS. Analyses of material extracted by alkalies from the ore gave V 19.16, 18.89, 19.09, 18.46; S 47.74, 47.84, 45.65, 44.74.

The material occurs in a complex mixture of mineral substances among which quisqueite and bravoite were found, at Minasragra, Peru. Named after Antenor Rizo-Patrona, the discoverer

of the ore.

Pectolite, Min., p. 373; App., p. 51. — Crystals from Bergen Hill, N. J., show the new forms y (1.0.25), x (102), h (540); Moses, Am. J. Sc., 12, 99, 1901; from Scottish localities; Goodchild, [Trans. Geol. Soc. Glasgow, 12, Suppl., 1–68, 1903]; Zs. Kr., 45, 305; Niakornat, Greenland, with new forms (201) and (104) with anal. by Christensen; Böggild, Min. Grönl., 388.

Composition discussed, Clarke and Steiger, Am. J. Sc., 8, 245, 1899, 9, 349, 1900. Anal. from Graigenfeoch, near Johnstone, Renfrewshire; Houston, [Trans. Geol. Soc. of Glasgow, 12, 354–361, 1906]; Zs. Kr., 45, 304. Magnesium pectolite with 5,542, MgO from disbase, at Burg.

354-361, 1906]; Zs. Kr., 45, 304. Magnesium pectolite with 5.54% MgO from diabase, at Burg near Herborn, Prussia; Renning, Centralbl. Min., 739, 1907.

Occurs near Fort Point, San Francisco, in serpentine with datolite, etc., (analysis by Schaller);

Eakle, Bull. G. Univ. Cal., 2, 315, 1901.

Pelagosite, Min., p. 1044. — Anal. of material from Capparara, Tremiti Island; Squinabol and Ongaro, Riv. Min. Crist., 26, 44, 1900.

Peninnite, Min., p. 650; App., p. 51. — Optical study; Klein, Ber. Ak. Berlin, 114, 1902.

Penfieldite; App., p. 51. — From Laurium, Greece; Lacroix and de Schulten, Bull. Soc. Min., 31, 83, 1908.

Pentlandite, Min., p. 65; App., p. 52. — Occurrence at Evje, Norway; Stören, [Berg-u. hütten Zeitung, 63, 504, 1904]; Zs. Kr., 42, 633.

Perovskite, Min. p. 722; App. p. 52. — Study of the structure of perovskite from Burgumer-Alp, Pfitschthal, Tyrol, by Bowman, Min. Mag., 15, 156, 1908, confirms results of Baumhauer, that mineral is probably orthorhombic, pseudo isometric.

Crystals from Emersee, Aosta with new form (950) and anal.; Millosevich, Rend. Acc. Linc.,

10, (1), 209, 1901.

Occurrence with anal. from S. Ambrogio, Susa, Piedmont; Boeris, Rend. Acc. Linc., 9, (1), 52, 1900; at Monte Lunella, Piedmont; Boeris, Att. Soc. Milano, 45, 306, 1906.

Petterdite. W. H. Twelvetrees, separate publ., 1902; [Rep. Secy. Mines, Tasmania, 1900, 1; 1901, 356]; [Proc. Roy. Soc. Tasmania, 1900-1901, 51]; Zs. Kr., 42, 392; C. Anderson, Rec. Aus. Mus., 6, 137, 1906; Zs. Kr., 45, 313.

Originally described as a new oxychloride of lead from Britannia mine, Zeehan, Tasmania, but

proven by Anderson to be identical with mimetite.

PETZITE, Min., p. 48; App., p. 52. — Anal. of material from Norwegian mine, Mother Lode Dist., Calif.; Hillebrand, Am. J. Sc., 8, 297, 1899.

Occurs with other tellurides at Kalgoorlie in the East Coolgardie gold district in West Australia, cf. Spencer, Min. Mag., 13, 272, 1903; also Carnot, Bull. Soc. Min., 24, 361, 1901 (anal.), and Krusch, Centralbl. Min., 199, 1901.

Pharmacolite, Min., p. 827; App., p. 52. — Occurrence at Schladming, Styria; Cornu, Centralbl. Min., 279, 1908.

Artif.; de Schulten, Bull. Soc. Min., 26, 18, 1903.

Pharmacosiderite, Min., p. 847. — Refractive index; Gaubert, Bull. Soc. Min., 30, 108, 1907. Analyses of material from Cornwall showed the presence of K2O in varying small amount. One analysis gave:

 As_2O_5 37.16 $P_{2}O_{5}$ 1.20 Fe_2O_3 37.58 K,0 H,O 4.54 18.85 = 99.33

Author suggests following formula: 2FeAsO₄.Fe[O(H,K)]₃.5H₂O. Curious fact noted that a green crystal immersed in ammonia becomes red but recovers its original color on subsequent immersion in hydrochloric acid. Hartley, Min. Mag., 12, 152.

Phenacite, Min., p. 462; App., p. 52. — Crystal from German East Africa with new form (6515); Spencer, Min. Mag., 14, 178, 1906; from tin veins at Ehrenfriedersdorf, Saxony; Kolbeck and Henglein, Centralbl. Min., 365, 1908; also from Döbschütz near Reichenbach, and from Tschirnitz near Jauer in Silesia; ibid., 547; from North Chatham, N. H.; Farrington and Tillotson, Field Mus., Geol. Series, 3, No. 7, 157, 1908.

Anal. from Ober-Neusattel, Bohemia; Preis, [Ber. böhm. Ges. Wiss., 19, 1897]; Zs. Kr., 31, 526.

Analyses; Aars, [Inaug.-Diss., Freiburg i. Br. 1905]; Centralbl. Min., 247, 1907.

Result from alteration of danalite, Gloucester, Mass.; Palache, Am. J. Sc., 24, 252, 1907; Zs. Kr., 44, 17.

PHILLIPSITE, Min., p. 579; App., p. 53. — Crystals from Hareö, Greenland; Böggild, Min. Grönl., 570.

Analyses of various occurrences in the neighborhood of Rome lead to formula, R11Al2Si3O10.4H2O; Zambonini, Jb. Min., 2, 65, 1902. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 114, 1908; anal. of material from Mont Simiouse, Loire, with discussion of chem. comp.; Gonnard, Bull. Soc. Min., 31, 269, 1908.

A zeolite from the leucitite at Casal Brunori and Mostacciano near Rome having composition

and general characters similar to phillipsite but differing in the manner in which it loses water on heating, has been named pseudophillipsite by Zambonini; Jb. Min., 2, 73, 1902; Bull. Soc. Min., 25, 360, 1902. Occurs in pseudo octahedrons, being made up of eight individuals. Analyses given lead to formula R¹¹₂Al₄Si₅O₁₈.9H₂O.

Phlogopite, Min., p. 632. — A crystal found at Sydenham, Frontenac Co., Ontario, had a length of more than 5 meters and a cleavage surface 1.5 × 2 meters. W. H. McNairn, Am. J. Sc., **12**, 398, 1901.

Anal. of material in eruptive rock, "wyomingite," from the Leucite Hills and Pilot Butte, Wyo-

ming; Hillebrand (in article by Cross), Am. J. Sc., 4, 130, 1897.

Hydrophlogopite. Anal. of material from Ceylon; Grünling, Zs. Kr., 33, 218.

Phosgenite, Min., p. 292; App., p. 53. — Crystals from Sardinia; Cesàro, Bull., Ac. Belg.,

328, 1907.

Fluorescence; Schincaglia, [Il Nuovo Cimento, Pisa, 10, 212, 1899]; Zs. Kr., 34, 312. Luminescence; Pochettino, Rend. Acc. Linc., 14, (1), 505, (2), 220, 1905. Determination of refractive indices on crystal from Laurium, Greece, gave: ω = 2.1181; ε = 2.1446; Smith, Min. Mag., 12, 107.

to 6.23.

Occurrence at Terrible mine, Isle, Custer Co., Colo.; Warren, Am. J. Sc., 16, 343.

Phosphorus. Occurrence of free phosphorus in meteorite from Saline Township, Kansas; Farrington, Am. J. Sc., 15, 71, 1903.

Picromerite, Min., p. 948; App., p. 53. — Crystals (with anal.) from Kalusz, East Galicia; Koechlin, Min. Mitth., 21, 356, 1902.
Formation discussed; van't Hoff and Meyerhoffer, Ber. Ak. Berlin, 678, 1903.

PIEDMONTITE, Min., p. 521; App., p. 53. — Crystals from St. Marcel described with the new forms m_x (102), ($\bar{1}07$), l ($\bar{2}01$); measured angles agree more closely with epidote than those of Laspeyres; Zambonini, Zs. Kr., 37, 15, 1902.

PIETRICIKITE. Given as the correct spelling for zietrisikite, Min., p. 999; Istrati, [Bull. Soc. Sci. Bucarest, 6, 65, 93, 1897; Min. Mag., 12, 389.

Pigeonite, var. of pyroxene, which see.

PILOLITE, see Lassallite.

PINNOITE, Min., p. 884. — Formation discussed; van't Hoff and Bruni, Ber. Ak. Berlin, 805, 1902.

PISANITE, Min., p. 943. — Occurs abundantly as a secondary mineral at a pyrite mine near Leona Heights, Alameda Co., Cal. Crystals, prismatic in habit, show the new forms: a (100), h (210), f (320), l (120), v (101), r (111), E (335), D ($\bar{2}21$), σ ($\bar{1}21$). Analyses after deducting in (1) 14.85 insol., in (2) 11.80, in (3) 8.67:

	SO ₃	FeO	CuÓ	MgO	H ₂ O
1.	28.21	12.31	15.73		45.14 = 101.39
2.	29.18	16.47	9.22		45.74 = 100.61
3.	29.25	5.46	17.95	2.82	45.21 = 100.69

In 1 and 2 one-seventh of the water goes off at a high temperature. Hence the formula $RSO_4H_2O + 6H_2O$. In 3 the results were H_2O 34.25 at 110°, 10.96 above 110°. Schaller, Bull. G. Univ. Cal., 3, 199, 1903; Am. J. Sc., 24, 158, 1907. The same author has analyzed massive pisanite from Gonzales, Monterey Co., Cal. A review of all the analyses of the species shows that there is no definite ratio between the Cu and Fe, Am. J. Sc., 17, 193, 1904.

PISSOPHANITE, Min., p. 971. — Thought to be distinct species; Mann, [Inaug.-Diss., Leipzig. 1904]; Zs. Kr., 42, 665.

PITCHBLENDE, see Uraninite.

PITTICITE, Min., p. 867. — Anal. of material from Gross-Tresny, Mähren; Kovář, [Abh. böhm. Akad., No. 15, 1, 1896]; Zs. Kr., 31, 524.

PLAGIONITE, Min., p. 118; App., p. 54. — Discussion of the chemical and crystallographic relations existing between plagionite, heteromorphite and semseyite. New analyses of plagionite from Wolfsberg, Harz; heteromorphite, Arnsberg, Westphalia; semseyite from Wolfsberg, Harz. No simple formulas being derived it is suggested that the three minerals may be members of a morphotropic series, the vertical crystallographic axis increasing in length with increase in the percentage of lead. Spencer, Min. Mag., 12, 55.

Plancheite. A. Lacroix, C. R., 146, 722, 1908; Bull. Min. Soc., 31, 250, 1908. Fibrous, often mammillary. Blue color. G. = 3.36. Shows extinction parallel to length of fibers. Ax. pl. || to same. Strength of birefringence about 0.04. Index of refraction a little greater than that of dioptase. Comp., silicate of copper with water. Formula = 15CuO,12SiO₂, greater than that of dioptase. Comp., silicate of copper with water. Form 5H₂O or H₂Cu₇(Cu.OH)₈(SiO₃)₁₂; SiO₂, 36.04; CuO, 59.46; H₂O, 4.50.

Anal. by Pisani: SiO₂, 37.16; CuO, 59.20; FeO, tr.; H₂O, 4.50 = 100.86.

Differs in reactions from dioptase in that it is only with difficulty attacked by acids and with-

Occ. Found associated with dioptase, etc., at Mindouli, French Congo. Named in honor of M. Planché, who furnished the material.

PLATINUM, Min., pp. 25, 1044; App., p. 54. — Structure of platinum from the Urals; Beck, Ber. Sächs. Ges., Leipzig, 59, 387, 1907.

Distribution and geological relations; Kemp, U. S. G. S., Bull., 193, 1902. Occurrence in Norwegian nickel ores; Vogt, Zs. prakt. Geol., 10, 258, 1902; from Sumatra; Hundeshagen, Chem. News, 90, 77, 1904; Oregon and California; Day and Richards, Min. Resources U. S., 1905; Am. J. Sc., 23, 319; Brazil; Hussak, Ber. Ak. Wien, 113, 379, 1904; Zs. prakt. Geol., 284, 1906; in U. S., Am. J. Sc., 19, 398, 1905.

Plumbogummite, Min., p. 855. — Analyses of material from Roughten Gill mines, Cumberland, and of hitchcockite from Canton Mine, Georgia, prove the two to be closely identical. Plumbogummite from Huelgoat, Brittany, was proven to be a mixture. Hartley, Min. Mag., 12, 223, and Miers, ibid., 239. Prior, ibid., 249, discusses its composition and suggests that it belongs to a group of minerals headed by hamlinite, which see.

Anal. of "fava" from diamond sands in Diamantina, Brazil, which is near plumbogummite;

Hussak, Min. Mitth., 25, 341, 1906.

Plumbojarosite. W. F. Hillebrand and S. L. Penfield, Am. J. Sc., 14, 213, 1902. — See Jarosite.

PLUMOSITE, see under Jamesonite.

Plusinglanz, a name given by Breithaupt to a silver mineral from Freiberg which is proven to be argyrodite; Frenzel, Min. Mitth., 19, 244.

Podolite. W. Tschirwinsky, Centralbl. Min., 279, 1907.

In microscopic prismatic crystals, showing m (10 $\overline{10}$) and c (0001). Also in Hexagonal.

spherulites.

Birefringence $\gamma - \alpha = 0.0075$. $\beta = 1.635$. Shows optical anomalies. Basal section shows division into six sectors of different optical orientation, and a perpendicular section shows an hourglass structure. Color yellow, transparent. G. = 3.077.

Composition, 3Ca₃(PO₄)₂.CaCO₃. Analysis 1 on small amount of crystalline material.

Analysis 2 on a nodule of somewhat impure material.

97.13

= 100.92 - 0.08 = 100.84

Occurs in cavities in the phosphorite nodules found near the Uschitza River in the province of Podolien in southern Russia. Named from the locality.

Pollucite, Min., pp. 343, 1044; App., p. 54. — Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull., **207**, 1902; Zs. Kr., **38**, 695.

Polycrase, see under Uraninite and Euxenite.

POLYHALITE, Min., p. 950. - Artif. formation; Basch, Ber. Akad. Berlin, 1084, 1900; also, van't Hoff with Farup, d'Ans, ibid., 1000, 1903; 412, 1906.

Powellite, Min., p. 989; App., p. 55. — From Barringer Hill, Llano Co., Texas, and from Nye Co., Nevada, with analyses; Schaller, Am. J. Sc., 25, 71, 1908; Zs. Kr., 44, 9.

PREHNITE, Min., p. 530; App., p. 55. — Crystals from Monte Pian Real, Val di Susa, Piedmont; Zambonini, Rend. Acc. Linc., 10, (2), 48, 1901; from Scottish localities with following new forms: g (210), x (104), e (012), f (210); Goodchild, [Trans. Geol. Soc. Glasgow, 12, Suppl., 1–68, 1903]; Zs. Kr., 45, 305; Josvas copper mine, Greenland, with new forms (410) and (301); Böggild, Min. Grönl., 291.

Anal. of material from Radautal, Harz; Fromme, Min. Mitth., 22, 62, 1903; Moore Station, N. J.; Eyerman, Amer. Geol., 34, 44, 1904; Biella, Italy; Zambonini, Zs. Kr., 40, 262, 1904. Rôle of water in; Zambonini, Mem. Acc. Sci., Napoli, 14, 17, 1908. Action of ammonium chloride upon; Clarke and Steiger, Am. J. Sc., 9, 345, 1900.

Occurrence in metamorphic limestone, Bariges valley, Hautes-Pyrénées; Lacroix, C. R., 131, 69, 1900; at Cala Francese, island of Maddalena (anal.); Rimatori, Rend. Acc. Linc., 11, (1), 542, 1902; Faddina, Laka Como; Repossi, Rend. Acc. Linc., 15, (1), 510, 1906.

542, 1902; Fedelino, Lake Como; Repossi, Rend. Acc. Linc., 15, (1), 510, 1906.

Priorite, see Blomstrandine.

Prochlorite, Min., p. 653. — Anal. from near Easton Pa.; Eyerman, Amer. Geol., 34, 43, 1904.

PROUSTITE, Min., p. 134. — Crystals from Sarrabus, Sardinia; D'Achiardi, Mem. Soc. Tosc., 17, 1900; new forms; Lamplough, Min. Mag., 13, 294.

Occurrence (with anal.) at California mine on Glacier Mt., Montezuma, Summit Co., Colo.; Van Horn, Am. J. Sc., 25, 507, 1908.

PSEUDOBOLEITE, see Boleite.

Pseudogaylussite, App., p. 55. — Typical crystals have been obtained from the Clyde at Cardross opposite Greenock; Trechmann, Zs. Kr., 35, 283, 1901; description of these crystals with anal.; Maenair, [Proc. Roy. Phil. Soc. Glasgow, 35, 250, 1904]; Zs. Kr., 43, 616.

PSEUDOLEUCITE, see Leucite.

Pseudomeionite, see Meionite.

Pseudomesolite, see Mesolite.

Pseudophillipsite, see Phillipsite.

Pseudowollastonite. Obtained artificially by heating wollastonite above 1180°. Shows basal cleavage; optically positive; nearly uniaxial and probably monoclinic. Mean refractive index closely the same as with wollastonite; birefringence higher. Allen and White with Wright; Am. J. Sc., 21, 89, 1906; Day and Shepherd, ibid., 22, 290, 1906.

PSILOMELANE, Min., p. 257. — Anal. of copper-bearing psilomelane from Huiquintipa, Province of Tarapaca, Chile, giving: MnO, 69.65; CuO, 6.02; CoO, 0.52; BaO, 0.41; Fe₂O₃, 1.96; Al₂O₃, 1.97; H_2O , 5.21; O, 14.14; total = 99.88; Keller, Proc. Amer. Phil. Soc., **47**, 79, 1908.

PTILOLITE, Min., p. 572; App., p. 55. — Occurrence (with anal.) from San Piero in Campo, Elba; D'Achiardi, Att. Soc. Tosc. Sc. Nat., 22, 150-165, 1906; from Theigarhorn, Iceland, with anal.; Lindström, Geol. För. Förh., 29, 106, 1907.

A zeolite similar to ptilolite found in needles enclosed in calcite from Teplitz Bay, Crown-

prince Rudolf Island. Anal.; Colomba Att. Acc. Torino, 37, 553, 1902.

Pucherite, Min., p. 755. — Optical study of crystals from Schneeberg; Cesàro, Bull. Ac. Belg., 142, 1905.

Purpurite. L. C. Graton and W. T. Schaller, Am. J. Sc., 20, 146, 1905; Schaller, ibid., 24, 152, 1907; Zs. Kr., 44, 1, 1907.

Orthorhombic (?) In small irregular masses. Cleavages: a rather perfect; b less distinct; ab probably 90°. Fracture uneven. Rather brittle. H. = 4-4.5. G. = 3.40. Luster satinlike on fracture surfaces. Color deep red or reddish purple, sometimes with slight bronze-like iridescence; streak purple or deep rose. Transparent in very thin pieces only. Refractive index 1.60-1.65. Pleochroism distinct, ∥ cleavage deep scarlet, ⊥ cleavage purple.

Composition, essentially a ferric-manganic phosphate, 2(Fe,Mn)PO₄ + H₂O. Analyses,

Schaller:

I.	North Carolina	P ₂ O ₅ 247.30		${\rm Fe_2O_3}$ 15.89	CaO 1.48	Na ₂ O Li ₂ O 0.84 tr.	Insol. 0.52=100.54
	South Dakota Branchville, Ct.		2-100	$\frac{38.36}{27.00}$	1.37	tr.	$0.19 = 100.27$ $\dots = 100.00$

B. B. fuses easily; gives off water readily in the closed tube and becomes yellowish brown. Soluble in hydrochloric acid; in nitric acid black oxide of manganese separates.

Occurs at the Faires tin mine at Kings Mountain, Gaston Co., N. C., probably derived from the alteration of lithiophilite, which is sparingly associated with it. Also identified in small quantities with triphylite in the lithium-bearing pegmatite dikes at Pala, San Diego Co., California. At both localities a black or brownish black mineral with pitchy luster is also associated with the purpurite, doubtless derived from its alteration.

Also found near Hill City, S. D., and identified on a specimen from Branchville, Ct.

Named from the latin purpura, in allusion to the color.

Pycnochlorite. Pyknochlorit, J. Fromme, Min. Petr. Mitth., 22, 69, 1903.

A chloritic mineral forming with calcite and quartz a vein of a sort of brecciated rock in the gabbre quarry, "Barenstein II," at the Schmalenberg, Radauthal in the Harz. It occurs in grayish green compact or microcrystalline forms. H. = 1-2. G. = 2.83. Luster dull.

Analysis gave:

Fe₂O₃ FeO SiO₂ 26.55 Al_2O_3 16.91MnO CaO MgO Alk H₂O 25.29 ... 0.46 0.70 12.06 = 99.892.04 15.88 tr.

Pyrargyrite, Min., p. 131; App., p. 56. — Crystals from Sarrabus, Sardinia; D'Achiardi, Mem. Soc. Tosc., 17, 1900; from Andreasberg, Harz, with new twinning plane, W (0118). Klockmann, Zs. Kr., 32, 579; Hiendelaencina, Spain; Mauritz, Zs. Kr., 44, 344.

Occurrence at Cobalt, Ontario; Miller, Rep. Can. Bureau of Mines, 1905, 2; Zs. Kr., 43, 395.

Pyrite, Min., pp. 84, 1045; App., p. 56.— Cryst.— From parisite locality, Ravalli Co., Montana, with new form (541); Zimányi, Zs. Kr., 32, 243, 1899; Muso, Colombia, with new form (11.3.3); Busz, Jb. Min., 2, 139, 1901; Csetras, Hungary, (Γ (215) new) described by Goldschmidt and Philipp, Zs. Kr., 36, 386, 1902; Monzoni with the new forms (754) (643) show unusual distortion; Melczer, Zs. Kr., 37, 268, 1902; Leona Heights, Alameda Co., Cal.; Schaller, Bull. G. Univ. Cal., 3, 193, 1903; Passobreve, Piedmont; Zambonini, Centralbl. Min., 122, 1903; twins according to spinel law, from French Creek, Pa.; Nicol, Am. J. Sc., 17, 93, 1904; Goldschmidt and Nicol, Jb. Min., 2, 93, 1904; Kotterbach in Comitat Szepes, Hungary, with following new forms: I (21.1.0); α (17.1.0) U (15.1.0); H (14.1.0); G (12.1.0); B (810); J (11.2.0); C (16.3.0); A (11.3.0); κ (850); λ (11.10.0); a (11.9.7); ε (14.11.8); δ (852); g (951); δ (13.7.1); r (25.15.6); m (7.11.22); Zimányi, Zs. Kr., 39, 125, 1904; Porkura, Csetrásgebirge, Hungary, showing new forms: (533), (15.14.14), (11.10.0), (17.14.0), (12.5.0), (830), (18.9.2), (10.5.2), (24.15.10), (821), (631), (15.11.7), (11.8.5), (45.36.20), (11.7.5); Mauritz, ibid., 357; Fojnica, Bosnia, with new forms, 2 (18.10.5); % (654); % (456); Mauritz, [Földt. Közl., 34, 484 or 537, 1904]; Zs. Kr., 44, 70; from marble of Carrara; D'Achiardi, Att. Soc. Tosc. Sc., Mem. 21, 1905; Nadabula, Gömör, Hungary, with new form (711); ? Zimányi, Földt. Közl., 35, 546, 1905; Rondout, Ulster Co., N. Y.; Whitlock, N. Y. State Mus. Bull., 98, 1905; Zs. Kr., 43, 393; Ivigtut, Greenland; Böggild, Min. Groenland, 46; Franklin, N. J.; Gilpin Co., Colo., and unknown locality in Colo.; Kraus and Scott, Zs. Kr., 44, 144, lin, N. J.; Gilpin Co., Colo., and unknown locality in Colo.; Kraus and Scott, Zs. Kr., 44, 144, 1907; Major's Creek, N. S. W.; Anderson, Rec. Aus. Mus., 7, 1, 67, 1908.

Crystals described as coming respectively from Porkura, Kis-Almas and Csetras are all from same locality, namely on Zslatyin brook near Porkura and Kis-Almas in the Csetras mountains, Hungary; Goldschmidt, Zs. Kr., 38, 498, 1903.

Quantitative determination in presence of marcasite, which see. Action of potassium chlorate upon; Spezia, Att. Acc. Torino, 43, April, 1908.

Pyroaurite, Min., p. 256; App., p. 56. — Occurs at Långban, Sweden, in thin tabular crystals (c) with the rhombohedron, g (4041), $cg = *82^{\circ}33'$; hence $\dot{c} = 1.6557$ [author gives 81° 33', which his other angles show is a misprint for 82° 33']. Also thick tabular crystals with r (1011), f (0221), $cr = 62^{\circ}23'$, $cf = 75^{\circ}21'$. Flink, Bull. Geol. Inst. Upsala, 5, 81–96, 1900.

Pyrochlore, Min., p. 726; App., p. 56. — From river Tschoroch, Province Batum, Russia, with anal. Tschernik, [Ann. Géol. Min. Russ., 5, 196, 1902]; Zs. Kr., 39, 624. Anal. of material from Sundsvale, Sweden; Tschernik, [Jour phys. chim. Russe, 36, 457, 712, 1904]; Zs. Kr., 43, 78.

Pyrochroite, Min., p 253. — Crystals from Långban, Sweden, described by Flink are long prismatic to thin tabular (c, a) with the rhombohedral forms: $p(10\overline{1}4)$, $q(30\overline{3}4)$, $r(10\overline{1}1)$, Bull. G. Inst. Upsala, 5, 87, 89, 1901. Crystals from same locality with anal. and determination of refractive indices; Sjögren, Geol. För. Förh., 27, 37, 1905.

Pyrolusite, Min., pp. 243, 1045; App., p. 56. — Analyses of manganese ores from Sardinia; Rimatori, Rend. Acc. Linc., 10, (2), 226, 1901; occ. at Narysov, Přibram; Hoffmann, Ber. böhm. Ges. Wiss., xviii, 1903.

Pyromorphite, Min., p. 770; App., p. 56. — Twins with twinning plane (2021), from Friedrichssegen near Ems; Klein, Centralbl. Min., 748, 1902. Crystals associated with dioptase from Mindouli, French Congo; Lacroix, Bull. Soc. Min., 31, 256, 1908. Refractive indices with anal. of material from Braubach, Nassau; Bowman, Min. Mag., 13, 324.

From Braidwood, near Little River, New South Wales, with anal.; Mingaye, Trans. Austr. Assoc. Sc., 1898. Anal. from Broken Hi N. S. W., **8**, 182, 1905]; Zs. Kr., **43**, 623. Anal. from Broken Hill, N. S. W.; Mingaye, White and Greig, [Rec. Geol. Sur.

Occurrence in gold veins on Serebrjanka river, Urals; Karpinsky [Verh. russ. min. Ges., 42, Prot. 20, 1905]; Zs. Kr., 43, 70. Occurrence in small crystals from Broken Hill N. W. Rhodesia; Spencer, Min. Mag., 15, 33, 1908.

Radioactive from near Issy-l'Evêque, Saône-et-Loire; Danne, C. R., 140, 241, 1905.

Pyrophyllite, Min., p. 691; App., p. 56. — Analyses by Baskerville of material from North Carolina; Pratt, N. C. Geol. Sur. Econ. Papers, 3, 1900; Zs. Kr., 36, 81.

Blue mineral similar to pyrophyllite from quartz vein near Kljutschy between Troisk and Tscheljabinsk in Gouv. Orenburg, Russia, with anal.; Morozewicz [Verh. russ. min. Ges., 40, 43, 1903]; Zs. Kr., 39, 611; also in Min. Mitth., 22, 97, 1903.

Composition discussed; Clarke and Steiger, Am. J. Sc., 8, 247, 1899. Chem. constitution; McNeil, Jour. Amer. Chem. Soc., 28, 594, 1906.

Pyrosmalite, Min., p. 465. — Description of crystals from Bjelke mine in Nordmark, Sweden; with new analysis. Discussion of old analyses and formula derived = RCl₂.12RO, 10SiO₂ + 8H₂O. Zambonini, Zs. Kr., **34**, 554. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 22, 1908.

Pyrostilpnite, Min., p. 135; App., p. 56. — Occurs at the Long Tunnel mine, Heazlewood, Tasmania; W. F. Petterd, Notes on Tasmanian Minerals, priv. publ.

PYROXENE, Min., pp. 352, 1045; App., p. 56.—**Cryst.**—Augite from Yoneyama, Province of Echigo, Japan, with new forms (103), (203). Anal.; Iwasaki, Zs. Kr., **32**, 302, 1900; Latium, Italy, with new forms, $\mathfrak{B}(\tilde{1}61)$, $F(\tilde{3}61)$, $G(\tilde{3}.12.1)$, $C(\tilde{1}11)$, $G(\tilde{6}21)$, with anal.; Zambonini, ibid., **33**, 39, 1000 iii. 1900; ibid., 34, 259, 1901. Diopside from Ala, with new forms r (231), v (343), w (14.1.1); Zambonini, ibid., 239; Ducktown, Tenn.; Moses, Am. J. Sc., 12, 105, 1901; augite crystal from the Laacher See with U (431); Busz, Jb. Min., 2, 139, 1901. Augite twins from island of Stromboli; Barvir, Ber. böhm. Ges. Wiss., xlvii, 1902; diopside from Ala, Piedmont; Zambonini, Centralbl. Min., 124, 1903; ponm. Ges. Wiss., xivil, 1902; diopside from Ala, Piedmont; Zambonin, Centralbi. Min., 124, 1903; diopside (with anal.) from Moravicza, Hungary; Weinschenk, Min. Mitth., 22, 363, 1903; augite from Canale Monterano, Province Rome, Italy, with new form \mathfrak{B} ($\tilde{6}05$); anal.; Zambonini, Zs. Kr., 40, 52, 57, 1904; diopside from the eozoon limestone, Côte St. Pierre, Canada, with anal.; Preiswerk, Zs. Kr., 40, 498, 1905; diopside from Maneetsok, Greenland; Böggild, Min. Grönl., 373; augite twins from Vesuvius; Cesàro, Bull. Ac. Belg., 329, 1907; crystals from Lyon Mt., Clinton Co., N. Y.; Whitlock, N. Y. State Mus. Bull., 107, 66, 1907.

Opt. — Diopside crystals with optical measurements from crystalline limestone at Altstadt, Mähren: Pelikan, Min. Mitth. 19, 106, 1900; anal. of same: Pelikan, ibid. 338. Disparsion of

Mähren; Pelikan, Min. Mitth., 19, 106, 1900; anal. of same; Pelikan, ibid., 338. Dispersion of optic axes in orthorhombic pyroxenes; Luczizky, Min. Mitth., 24, 140, 1905. Chemical and optical study of monoclinic pyroxenes with small angle between optic axes and low content of lime; Wahl, Min. Mitth., 26, 1-131, 1907. Optical constants of rock forming pyroxenes from various localities; Duparc and Pearce, Bull. Soc. Min., 31, 96, 1908.

Anal. — Anal. of material in eruptive rock "wyomingite," from the Leucite Hills and Pilot

Butte, Wyoming; Hillebrand (in article by Cross), Am. J. Sc., 4, 130, 1897. Anal. of coccolite from Bistrau, Bohemia; Kovář, [Abh. böhm. Akad., 28, 1899]; Zs. Kr., 34, 705; of augite from Uifak, Godhavn District, Greenland; Nicolau, [Medd. om Grönl., 24, 228, 1901]; Min. Grönl., 377; of diopside from San Pablo, California; Blasdale, Univ. Calif. Bull., Dept. Geol., 2, 11, 327, 1901; of soda-rich pyroxene from Oropa, Piedmont; Zambonini, Rend. Acc. Linc., 10, (1), 240, 1901; of augites containing TiO₂ and Al₂O₃ with discussion of composition; also optical study; Becker, [Inaug.-Diss., Erlangen, 1902], Centralbl. Min., 730, 1902; Zs. Kr., 38, 317. Chromium bearing omphacite with anal., from Lake Brocan, Valle del Gesso di Entraque, Piedmont; Roccati, [Boll. Soc. geol. ital., 24, 659, 1905]; Zs. Kr., 43, 499. Anal. of augite from Paschkopole near Boreslau, June 1967, 1968, 1969. Anal. of augite from Paschkopole near Boreslau, June 1969, 19 Bohemia, with discussion of chem. comp.; Hampel, Min. Mitth., 27, 270, 1908.

Occurrence of a monoclinic pyroxene in meteorite from Zavid, Bosnia; Berwerth, [Mitth. aus Bosnien u. d. Herzegovina, 8, 409, 1901]; Zs. Kr., 38, 320; of orthorhombic and monoclinic pyroxene in meteorite from Peramiho, Dutch East Africa; Berwerth, Ber. Acad. Wien, 112, (1), 739,

Concerning products of weathering of augite, anauxite and cimolite (with analyses); Smirnoff,

Zs. Kr., 43, 338, 1907. Alteration to amphibole; Duparc, Bull. Soc. Min., 31, 50, 1908.

Artif. formation of; Allen, Wright and Clement, Am. J. Sc., 22, 385, 1906; summarized in

Science, Mar. 8, 1907, p. 389.

A zinc schefferite from the Parker shaft at Franklin Furnace, N. J., has been analyzed by Wolff. Proc. Amer. Acad., 36, 115, 1900. It occurs in large foliated masses, with very perfect basal cleavage. $c \wedge c = 40^{\circ} 35'$.

SiO. Fe₂O₃, Al₂O₃ 1.08 MnO ZnO CaO MgO Ign. G. = 3.3152.86 5.31 3.38 13.24 24.48 0.45 100.80 The optical constants have been minutely determined by Melczer, ibid., p. 116.

Occurrence of iron schefferite in Caucasus; Sioma, Zs. Kr., 34, 279.

Fedorowite has been further studied with the following additional determinations. Axial ratio: \dot{a} : \dot{b} : \dot{c} = 1.0927 : 1 : 0.5489; β = 106°. α = 1.680, β = 1.687, γ = 1.709 for Na light.

Analysis: Al₂O₃ FeO SiO, Fe.O. CaO MgO Na.O Total $52.\bar{3}5$ I. 2.24 1.94 2.38 24.63 14.40 2.54 100.48 II. 52.37 4.08 2.46 24.51 14.66 2.05 100.13 Viola and Kraus, Zs. Kr., 33, 36, 1900.

Pigeonite, name given by Winchell, Am. Geol., 26, 204, 368, 1900, to pyroxene with small and

variable axial angle from Pigeon Point, Minn.

Violaite, name given to highly pleochroic pyroxene, occurring in igneous dike (kedabekite) associated with plagioclase and garnet near Kedebek copper mine in the Caucasus; v. Fedorow, [Ann. l'Inst. agronomique Moscou, 1, 43, 1901]; Zs. Kr., 37, 414.

Agirine-hedenbergite, mame given to a pyroxene intermediate in composition between ægirite and hedenbergite; Wolff, Centralbl. Min.; 214, 1902; Rosenbusch uses Hedenbergit-Ägirin, Mikrosk.

Phys. Min., 1, part 2, 218, 1905.

Blanfordite. A monoclinic pyroxene containing some sodium, manganese and iron, occurring with manganese ores in the Central Provinces, India. Strongly pleochroic (rose-pink to sky-blue). Named after Dr. W. T. Blanford (1832-1905). Fermor, [Trans. Min. Geol. Inst. India, 1, 78, 1906]; Spencer, Min. Mag., 14, 395, 1907.

Pyrrhotite, Min., p. 73; App., p. 57. — Crystals from Tollegno, Piedmont; Zambonini, Centralbl. Min., 121, 1903; from Bottino; D'Achiardi, [Proc. Soc. Toscana Sc. Nat. Pisa, 13, 140, 1903]; Zs. Kr., 41, 262; from Igdlokunguak, Greenland; Böggild, Min. Groenland, 39.

Considered by study of magnetic properties, etching figures, etc., to be orthorhombic in symmetry, but pseudo-hexagonal through twinning; Kaiser, Centralbl. Min., 261, 1906; Weiss, ibid.,

338.

Magnetic properties of; Weiss, C. R., **126**, 1099, 1898; [Jour. de phys., **8**, 314, 1898]; Zs. Kr., **34**, 631; [Arc. Sc. phys. et nat., Genf, **16**, 473, 1903]; Zs. Kr., **41**, 110; Kunz, [Arc. Sc. phys. et nat., Genf, **18**, 260, 1904]; Zs. Kr., **42**, 204; Weiss, [Phy. Zs., **6**, 779, 1905]; [Jour. phys., **4**, 469, 829, 1905]; C. R., **140**, 1332, 1587, 1905; Weiss and Kunz, [Jour. phys., **4**, 847, 1905]; C. R., **141**, 182; Zs. Kr., 43, 518-522.

Occurrence at Burgk, Saxony; Bergt, Ber. Abh. Naturwiss. Ges. Isis, Dresden, 20, 1903.

From Sardinia; Serra, Rend. Acc. Linc., 16, (1), 347, 1907.

Quartz, Min., pp. 183, 1046; App., p. 57. — Gryst. — From Opprebais, Belgium; Buttgenbach, Ann. soc. géol. Belg., 25, 111, 1898. Striegau, Silesia; Gonnard, Bull. Soc. Min., 22, 92, 1899; Quenast; van Hove, [Mém. cour. et Mém. des Sav. étrangers, Acad. roy. de Belg., 58, 1, 1900]; Quenast; van Hove, [Mem. cour. et Mem. des Sav. étrangers, Acad. roy. de Belg., 58, 1, 1900]; Zs. Kr., 35, 642; twin from Trarbach, Rhine province, Germany; Kaiser, Centralbl. Min., 94, 1900; crystals from Bourg d'Oisans, Dauphiné; Gonnard, Zs. Kr., 34, 279, 1901; twin from Annaberg in Saxony; Johnsen, Centralbl. Min., 649, 1902; twins from Mies, from Sárka valley near Prag; Barvír, Ber. böhm Ges. d. Wiss., 8, 1902; Zs. Kr., 39, 398; crystals from Brazil; Gonnard, Bull. Soc. Min., 25, 56, 1902; ibid., 59; Valais, Switzerland; id., ibid., 61; crystallographic notes; id., ibid., 90; twin from Japan; Friedel, ibid., 110; crystals from De Aar, Cape Colony, S. Afr.; Barker, Min. Mag., 13, 331, 1903; Hancock, Mich., and Herkimer, N. Y., with several new forms and a "Winkeltabelle" for them: Lincip. Ib. Min. Beil. 18, 155, 1904; moky guartz grystals from Mokruscha Mt. near for them; Lincio, Jb. Min., Beil., 18, 155, 1904; smoky quartz crystals from Mokruscha Mt., near for them; Lincio, Jb. Min., Beil., 18, 155, 1904; smoky quartz crystals from Mokruscha Mt., near Mursinka, Russia; Worobieff, [Verh. russ. min. Ges., 42, Prot. 52, 1905]; Zs. Kr., 43, 71; crystals from Guggiate, Lake Como; Repossi, Att. Soc. Milano, 44, 106, 1905; East Greenland; Flink, Medd. om Grönl., 24, 17, 1901; Böggild, Medd. om Grönl., 28, 104, 1905; twinning; Goldschmidt, Min. Mitth., 24, 157 and 167, 1905; Zs. Kr., 44, 407; crystals from San Diego Co., Calif.; Waring, Am. J. Sc., 20, 125, 1905; Meylan, Isère, France; Gonnard, Bull. Soc. Min., 22, 94, 1899; ibid., 29, 303, 1906; Gletsch, Switzerland; Busz, Centralbl. Min., 753, 1906; Fedelino, Lake Como; Repossi, Rend. Acc. Linc., 15, (1), 506, 1906; Lyon Mt., Clinton Co., N. Y.; Whitlock, N. Y. State Mus., Bull. 107, 56, 1907; Brusson, D'Aosta; Colomba, Att. Acc. Torino, 42, 904, 1907; Simplon tunnel: Bull., 107, 56, 1907; Brusson, D'Aosta; Colomba, Att. Acc. Torino, 42, 904, 1907; Simplon tunnel; Cesàro, Bull. Ac. Belg., 315, 1907; Valle del Chisone, Piedmont; Colomba, Att. Acc. Torino, 43, June, 1908.

Pseudomorph after apophyllite near Fort Point, San Francisco, Calif.; Schaller, Am. J. Sc.,

17, 194, 1904.

Crystallographic symmetry of tridymite, cristobalite and quartz; Beckenkamp, Zs. Kr., 34, 569. Opt. — Dispersion of the infra-red rays in quartz; Carvallo, C. R., 126, 728, 1898; study of effect of compression upon double refraction; Dongier, [Thèse fac. des sc. Paris, 1898]; [Ann. chim. effect of compression upon double retraction; Dongier, [Thèse fac. des sc. Paris, 1898]; [Ann. chim. phys., 14, 448, 1898]; C. R., 124, 26, 1897; Zs. Kr., 32, 541. Optical study; D'Achiardi, Att. Toscana, Pisa, 17, 114, 1899; Viola, Zs. Kr., 32, 551, 1900; optical constants for green mercury light; de Lépinay, [Jour. d. phys., 9, 644, 1900]; Zs. Kr., 35, 630. and artificial etching figures and their relations to optical properties, pyroelectricity, etc.; Martini,

Jb. Min., 2, 43, 1905.

Pyroelectricity; Beckenkamp, Zs. Kr., 32, 9, 1899. Dielectric constants; Fellinger [Inaug.-Diss., München, 1899]; Zs. Kr., 35,186. Electrical double refraction, etc.; Quesneville, Zs. Kr., 33, 102, 1900.

Elastic constants of amorphous quartz; Schulze, [Ann. d. Phys., 14, 384, 1904]; Zs. Kr., 42, 498. Cause of color, Königsberger; Min. Mitth., 19, 148; Nabl, Ber. Acad. Wien, 108, 48, 1899.

Inclusion of organic sulphides in quartz from Salangen, Norway; Sjögren, Geol. För. Förh., 27, 113, 1905; liquid inclusions from Alpine localities; Königsberger and Müller, Centralbl. Min., 72, 1906.

Relationships between quartz, chalcedony and opal; Leitmeier, Centralbl. Min., 632, 1908.

Fibrous silica and its relations to opal and quartz; Hein, Jb. Min., Beil., 25, 182, 1908.
Solubility in sodium silicate; in sodium tetraborate; Spezia, Att. Acc. Torino, 35, 750, 1900; ibid., 36, 631, 1901; also experiments on the growth of quartz crystals, ibid., 40, Jan., 1905; 41, Dec., 1905; 44, Nov., 1908.

Quartz and gelatinous silica in Simplon tunnel; Spezia, Att. Acc. Torino, 34, 705, 1899. Siliceous oolite of Tateyama, Etchū Province, Japan; Jimbō, Bei. Min. Japan, 1, 11, 1905. Artif. formation; Day and Shepherd, Am. J. Sc., 22, 275, 1906; Quensel, Centralbl. Min., 657, 1906; ibid., 728. Synthesis of amethyst; Berthelot, C. R., 143, 417, 1906.

Pseudochalcedonite, a chalcedony-like material, biaxial, optically negative, length of fibers || a. Birefringence = 0.0045. G.=2.5. Chemically=water-free SiO₂. Lacroix, C. R., 130, 430, 1900;

Zs. Kr., 35, 633.

Occurrence of chalcedony on shore of Black Sea, Caucasus; Karpinsky, [Verh. russ. min. Ges.,

42, Prot. 29, 1905]; Zs. Kr., 43, 70.

Quartz glass. — Heraeus, Deutsche Mech. Ztg., Oct. 1, 1903; Am. J. Sc., 16, 469, 1903. Optical properties; Gifford and Shenstone; Proc. Roy. Soc., 73, 201; Am. J. Sc., 17, 399, 1904.

QUARTZINE, App., p. 58. — Occurrence at Mohelmo, Mähren; Barvíř, [Ber. böhm. Ges. Wiss., 14, 1897]; Zs. Kr., 31, 525.

Quisqueite. W. F. Hillebrand, Am. J. Sc., 24, 142, 1907.

A black lustrous material, composed chiefly of C and S. Analysis gave: S (soluble in CS₂), 15.44; S (combined), 31.17; C, 42.81; H, 0.91; N, 0.47; O (by difference), 5.39; H₂O (at 105°), 3.01; Ash, 0.80; total 100.00. Ash analyzed gave: SiO₂, 0.04; Al₂O₃, 0.08; Fe₂O₃, 0.10; NiO, 0.06; V_2O_5 , 0.52. Occurs in a vein adjoining the vanadium ore known as patronite, at Minasragra, Peru. Named from a settlement near place of occurrence.

RADIOACTIVE MINERALS. - Study of the radioactivity and percentages of U3O8, ThO2 and He in the following: uraninite, torbernite, thorianite, aschynite, samarskite, gadolinite, cyrtolite, sipylite, euxenite, carnotite, pyromorphite, microlite, orangite, monazite, thorite, alvite, xenotime, amerôdite, fergusonite, malacon, allanite, yttrotantalite, polyerase, zircon; Strutt, Proc. Roy. Soc., 76, 88, 312, 1905; Chem. News, 91, 299, 1905; radioactivity of uranium minerals, Boltwood, Am. J. Sc., 25, 269, 1908.

Radiotine. R. Brauns, Jb. Min., Beil.-Bd., 18, 314, 1904.
Fibrous, radiating. In very small spherical aggregates.
G. 2.70. Color yellow. Double refraction medium. a parallel to length of fibers. Composition. — $H_4Mg_3Si_2O_9$ like serpentine. Analyses by F. W. Küster, of material from Dillenburg:

	SiO ₂	MgO	$\mathrm{Fe_2O_3}$	CaO	H_2O
1.	41.48	35.84	8.40	1.50	11.96 = 99.48
2.	41.50	35.73	8.50	0.55	12.13 = 98.41

Yields much water in closed tube, mineral becoming brown. Insoluble in HCl. Treated with HF gives magnesium fluor-silicate, which is soluble in water, and solution gives strong reaction for magnesium and weaker reactions for iron and calcium.

Diff. Distinguished from serpentine by its insolubility in HCl and its higher specific gravity. Occurs intimately intergrown with serpentine, from which it has been derived, in an altered picrite near Dillenburg, Nassau. Also observed with serpentine at Steinperf, Rachelshausen, etc. Named on account of its radial structure.

Rafaelite, see Paralaurionite.

RAMOSITE, Min., p. 562. — Proven to be not a definite mineral but a basic volcanic scoria; Luquer, Am. J. Sc., 17, 93, 1904.

Raspite, App., p. 58.—Crystals from gold sands at Sumidouro, Minas Geraës, Brazil, described by Hussak, Centralbl. Min., 723, 1903; Hlawatsch, ibid., 422, 1905; from Broken Hill with new forms m (110), $f(\bar{1}02)$, p (122), δ (1.12.12). New elements given as $\hat{a}:\hat{b}:\hat{c}=1.34497:1:1.11468$. $\beta = 72^{\circ} 23'$. Hlawatsch, Zs. Kr., 42, 587, 1906.

RATHITE, App., p. 58. — A new orientation proposed by Solly so that the well-developed prism zone is vertical and the cleavage plane (001) of Baumhauer becomes (010) to correspond with the cleavage of jordanite, the corresponding forms of the two orientations being:

> 100 010 001 403 095 20.27.0 20.27.15 Baumhauer 001 010 Solly 100 011 111

Axial ratios according to Solly; $\check{a}: \overleftarrow{b}_c: \dot{c}=0.4782:1:0.5112.$ Angles: 010 \land 350 = 51° 27′; 010 \land 111 = 70° 45′. A list of 62 known forms given, 37 of them being new. Twinning; (074) shown in fine twin lamellæ; (0.15.1), rare as a juxtaposed twin. Cleavage \parallel (010); parting \parallel (100). F. conchoidal. H. = 3. G. = 5.412; 5.421. Analyses by Jackson yield formula 3PbS.2As₂S₃; Pb, 51.37; S, 23.82; As, 24.81.

23.41 24.62 = 99.5451.51 23.62 II. 24.91 = 100.15

Solly and Jackson, Min. Mag., 12, 287; Solly, ibid., 13, 77; Zs. Kr., 35, 321.

Realgar, Min., pp. 33, 1046; App., p. 59. — Study of crystals from Allchar, with derivation of new elements; $\dot{a}:\dot{b}:\dot{c}=0.7203:1:0.4858,~\beta=66^{\circ}$ 16'. New winkeltabelle given. Goldschmidt, Zs. Kr., 39, 113; crystals from Mercur, Utah; Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 158, 1908.

Occurs in crystals in the Monte Cristo mining district, Snohomish Co., Washington; Moses, Am. J. Sc., 12, 103, 1901. Crystals formed at eruption of Vesuvius, 1906; see under Vesuvius. Occurrence in morainal material of Zei glacier in Caucasus; Orlowsky, [Proc. Soc. Imp. Nat. Mos-

cow, No. 1-3, 17-18,1897]; Zs. Kr., 31, 518.

REDONITE, Min., p. 807. — Occurrence at Martinique with anal.; Lacroix, Bull. Min. Soc., 28, 13, 1905.

RESIN, MINERAL. — Occurrence of amber in Roumania with discussion of fossil resins, succinite, rumanite, schraufite, simetite, burmite and a new type from Olanesti; Murgoci, Asociatiunea Română pentru inaintarea si respanderea sciintelor Memoriile Congresulăi de la Iasi, Bucarest, 1903.

Reverite. F. Cornu and A. Himmelbauer. Min. Mitth., 25, 519, 1907. Rhombohedral. Crystals in thin hexagonal plates showing combination of base and prism. In radiating aggregates. Cleavage: basal perfect. H. = 3.5. G. = 2.499-2.578. Optically negative. $\omega = 1.564$. Etched with HCl gives triangular figures. Six-rayed percussion figure. Composition. Calcium aluminium silicate with water. An incomplete analysis gave:

> $\frac{\text{Al}_2\text{O}_3}{3.72}$ SiO, CaO 53.31 32.22 6.73 = 95.98

Pyr., etc. — Difficultly fusible B. B. to a white enamel. Yields water in the closed tube. After heating gives an alkaline reaction. Decomposed by HCl.

Obs. on specimens from Greenland. Named after Prof. E. Reyer of Vienna.

Compare Gyrolite.

Rhodochrosite, Min., p. 278; App., p. 59. — Occurrence (with anal.) at St. Barthélemy, Aosta, Italy; Millosevich, Rend. Acc. Linc., 15, (1), 317, 1906.

Rhodonite, Min., pp. 378, 1046; App., p. 59.—Crystals described from St. Marcel, Piedmont, with analysis; Colomba, Accad. Sc. Torino, 39, 664, 1904. Crom Chiaves and other localities in Valli di Lanzo, Italy, with anal.; Roccati, Att. Acc. Torino, 41, 487, 1906; from Broken Hill, N. S. W., with following new forms: A (223), B (225), C (12), D (223), E (667), F (223), G (447), H (241), K (202), L (501), A propers Res. App. App. (202), 1003 H (441), K (403), L (201); Anderson, Rec. Aus. Mus., 7, 129, 1908.

Triclinic crystals lining cavities in a slag similar though not identical to those of rhodonite

named vogtite, after Prof. H. L. Vogt of Christiania. Hlawatsch, Zs. Kr., 42, 590.

RHODUSITE, see Glaucophane.

Rhonite. J. Soellner, Jb. Min., Beil., 24, 475, 1907.

Isomorphous with anigmatite.

Forms: b (010), a (100), m (110), $\tilde{\mu}$ (110), c (001), r (111), k (111), v (131), i (131). Angles, approximately measured under microscope, agree closely with those recorded for anigmatite. Crystal habit, short prismatic or tabular parallel to b (010). Twinning pl. b (010). Cleavage good parallel to m (110) and μ (110). G. = 3.58? Translucent to opaque. Color black to brown black, often showing metallic reflections. Streak red brown. Optically like anigmatite.

Comp Belongs in anigmatite group, with much less amount of ferrous oxide and alkalies and increase in alumina, ferric oxide, lime and magnesia. Formula given is: (Ca, Na2, K2)3Mg4 Fe^{II}₂Fe^{III}₃Al₄(Si,Ti)₆O₃₀.
Anal. by Dittrich of material from nepheline-basanite from Platz near Brückenau, Rhön:

Obs. Found like ænigmatite, as a constituent in basalts. First noted from Rhön, and identified also in similar rocks from Vogelsgebirge, Siebengebirge, Laacher-See, Odenwald, Kaiserstuhl, and in Bohemia. Named after Rhön district, where it was first identified.

Rickardite. W. E. Ford, Am. J. Sc., 15, 69, 1903. Massive. Fracture irregular. Brittle. H. = 3.5. G. = 7.54. Luster metallic. Color deep purple, resembling the color of tarnished surfaces of bornite, of the powder the same. Opaque.

Composition, a copper telluride, Cu₄Te₃ or Cu₂Te.2CuTe. Analysis:

Te,
$$59.21$$
; Cu, $40.74 = 99.95$

B. B. alone on charcoal fuses easily $(F_{\cdot} = 1)$ to a brittle globule of copper telluride, gives a pale azure-blue flame tinged with green and forms a white coating of TeO₂; with sodium carbonate and borax yields with difficulty metallic copper. In the open tube a faint sublimate of TeO₂. Dissolves in nitric acid; heated in concentrated sulphuric acid gives the characteristic reddish-violet color of tellurium.

Occurs at the Good Hope mine, at Vulcan, Colorado, in lens-shaped masses intimately associated with native tellurium, with petzite and berthierite; the vein mineral is chiefly pyrite; native

sulphur is also found in the vein.

Named after Mr. T. A. Rickard of San Francisco.

Ricolite, var. of serpentine, which see.

RIEBECKITE, Min., pp. 400, 1047; App., p. 59. — Crystals from Narsarsuk, Greenland; Flink, [Medd. om Grönl., 24, 80, 1901]; Min. Grönl., 430.

Genesis of; Murgoci, Am. J. Sc., 20, 133.

Occurrence in Roumania with anal.; Mrazek, [Bull. soc. sc. Bucarest, 8, 106, 1899]; Zs. Kr., 34, 710. Occurrence in trachytic rocks from Abyssinia; Prior, Min. Mag., 12, 255, 1900.

RINKITE, Min., p. 722. — New analysis by Christensen of material from Kangerdluarsuk agrees with that of Lorenzen (Min., p. 722), except instead of 13.36% TiO₂ there was found 5.42 TiO₂ and 6.51 ZrO₂. Böggild, Min. Grönl., 269.

Rinneite. H. E. Boeke, Centralbl. Min., 72, 1909. Hexagonal. In coarsely granular masses. Perfect cleavage parallel to prism. Splintery fracture. H. = 3. G. = 2.34. Brilliant luster, often silky. Colorless when fresh and pure, usually rose, violet or yellow; becomes brown on exposure on account of oxidation. Optically +. Weak birefringence. Comp.—FeCl₂.3KCl.NaCl; Fe, 13.67; K, 28.71; Na, 5.64; Cl, 51.99. Analysis:

Fe K Na Cl Br
$$\frac{2}{3}$$
 13.94 28.90 5.61 51.87 0.04 = 100.36

Easily fusible. Taste astringent like ink.

Found in salt beds at Nordhausen, Saxony, associated with carnallite, sylvite, etc. Named after Prof. F. Rinne.

Robellazite. — Preliminary announcement of a new species containing vanadium, niobium, tantalum, tungsten, aluminium, iron and manganese. In black concretions associated with carnotite from Colorado. Named after explorer who collected the specimens; Cumenge, Bull. Soc. Min., 23, 17, 1900.

ROEMERITE, Min., p. 959. — Analyses of natural and artificial material lead to formula, FeSO₄,Fe₂(SO₄)₃,14H₂O. Scharizer, Zs. Kr., 37, 529. Also an artificial roemerite containing 6.60 p. c. ZnO, which is called zinc roemerite in distinction from the ordinary ferroroemerite, ibid., 546; on its decomposition; Scharizer, ibid., 43, 122.

Rosasite. D. Lovisato, Rend. Acc. Linc., 17, (2), 723, 1908.

In compact, fibrous masses, mammillary, of a bright green to sky-blue color. Silky luster on fresh fracture. H. = 4.5. G. = 4.07. Comp., perhaps 2CuO.3CuCO₃.5ZnCO₃. Analysis: CO₂, 30.44; CuO, 36.34; ZnO, 33.57; PbO, tr.; H₂O, 0.21; total, 100.56. Occ. at Rosas mine (whence the name rosasite) at Sulcis, Sardinia.

Roscoelite, Min., p. 635. — The carefully purified mineral from the Stockslager mine, Placerville, Cal., has been analyzed by Hillebrand, Am. J. Sc., 7, 451, 1899; mean result as follows:

The above is shown by Clarke (ibid., p. 454) to correspond to a molecular mixture in a ratio of 1:1:8 nearly, of $H_2KMg_2FeAl(SiO_4)_3$, $H_4K_2Al_2(Si_3O_8)_3$ and $H_2KAlV_2(SiO_4)_3$. Turner (ibid., p. 455) shows that roscoelite occurs at four localities within a small area a few miles northwest of Placerville in Eldorado county, California.

ROSENBUSCHITE, Min., p. 374. — Occurrence in nephelite-syenite-porphyry, Red Hill, Moultonboro, N. H.; Pirsson and Washington, Am. J. Sc., 23, 433, 1907.

Rosolite, a garnet, which see.

Rubrite. — Correct name for the hydrous sulphate of ferric iron and magnesium originally misspelled "kubeit," see App., p. 21; Spencer, Min. Mag., 12, 386, 1900.

Ruby, see Corundum.

Rumänite, Min., p. 1004. — Analyses; Istrati, [Bull. soc. sc. Bucarest, 6, 55, 1897; 7, 272]; Zs. Kr., 32, 187.

Concerning fossil resins from Rumania; name spelled "romanite." Murgoci [Assoc. Română, etc., Bucarest, 1903]; Zs. Kr., 41, 318.

RUMPFITE, Min., p. 661. — Occurrence at Passe von Wald, Austria; in pseudomorph after magnesite. Döll, [Verh. geol. Reichsanst., Wien, 329, 1897]; Zs. Kr., 32, 183.

Rutherfordine. W. Marchwald, Centralbl. Min., 761, 1906.

An ocher resulting from the alteration of uraninite.

Yellow color. Strongly radiocative. G. = 4.82.

Uranyl carbonate, UO2CO3; UO3, 83.5; CO2, 12.3. Analysis: Composition.

UO3 PbO FeO CO_2 CaO H,O Gangue 83.8 12.1 0.8 0.8 = 100.3

Occurs as an alteration product of uraninite associated with mica in the Uruguru Mts., German East Africa. Named from Prof. E. Rutherford.

RUTILE, Min., pp. 237, 1047; App., p. 60.—Crystals from Alpe Veglia, Varzo, Val d'Ossola, Italy; Lincio [Att. Acc. Torino, 39, 995, 1904]; Zs. Kr., 42, 66; from Victor Harbour and Mount Gambier, So. Aus.; Anderson, Rec. Aus. Mus., 7, 1, 66, 1908. Crystal structure; Mügge, Centralbl. Min., 72, 1902; crystals from Jequitinhonha River, Brazil; Farrington and Tillotson, Field Col. Mus., Carl Spins 2, No. 7, 162, 1909.

Geol. Series, 3, No. 7, 160, 1908.

Refractive indices; Taubert [Inaug.-Diss., Jena, 1905]; Zs. Kr., 44, 313.

Anal. from Graves Mt., Ga., and from Tavetsch, Switzerland; Pfeil [Inaug.-Diss., Heidelberg, 1901]; Centralbl. Min., 144, 1902.

Discussion of formulæ of rutile, octahedrite and brookite; Prior, Min. Mag., 13, 220.

Discussion of the regular grouping upon hematite tables from Cavradi; Baumhauer, Sitz.

Akad. Berlin, 322, 1906; Zs. Kr., 43, 61. It is shown that the rutile prisms make angles of 2° 10′ with the hematite diagonals instead of coinciding with them, the actual position being a mean between the latter position and that where a terminal cap of s (111) would coincide with the diagonal; see also Viola, Rend. Acc. Linc., 17, (2), 437, 554.

Sal-ammoniac, Min., p. 157; App., p. 60. — Crystals from Burgk near Dresden; and from Vesuvius; Goldschmidt and Schröder, Zs. Kr., 45, 220, 221; from Vesuvius; Slavik, Bull. Acad. Sci. Bohème, 1907.

From Vesuvius; Matteucci, Centralbl. Min., 45, 1901. Occurrence in volcanic eruptions;

Wegner, ibid., 662, 1907.

SAMARSKITE, Min., pp. 739, 1037; App., p. 61. — Occurrence with anal. in bed of river Tschoroch, Batum, Caucasus Mts.; Tschernik, [Jour. phys.-chim. Russe, 34, 684, 1892]; Zs. Kr., 39, 627. Occurrence in southern Norway with description of crystals and anal.; Brögger, Min. Süd-Nor. Granitpeg., 138, 1908.
Radioactivity; Barker, Am. J. Sc., 16, 163, 1903. Ratio of radium to uranium; Boltwood, Am. J. Sc., 18, 97, 1904; also see under *Uraninite*.

Sanfordite, synonym of earlier name Rickardite, which see.

Sapphirine, Min., p. 561. — Occurrence in rock with hypersthene and hercynite in Vizagapatam, Madras, India; anal.; Middlemiss, [Rec. Geol. Sur. India, 31, 38, 1904]; Zs. Kr., 42, 389.

Sarcolite, Min., p. 474. — Optical study on crystals from Vesuvius gave: $\omega=1.6404$; $\epsilon=1.6566$ for Na; dispersion large, $\rho>v$; birefringence = 0.01626; Opt. +; analyses; Pauly, Centralbl. Min., 266, 1906.

Sarkinite, Min., p. 779. — Crystallographically, optically and chemically species chrondroarsenite (Min., p. 796) is proven to be identical with sarkinite. Sjögren, G. För. Förh., 28, 401, 1906.

Sartorite, Min., p. 113; App., p. 61. — Analyses by Jackson confirm the formula, PbS. As₂S₃; Solly and Jackson, Min. Mag., **12**, 286, 297. Considered to be monoclinic by Solly (loc. cit.) and Trechmann, Min. Mag., **14**, 212; Zs. Kr., **43**, 548, but both give different axial ratios. Trechmann from measurement of small crystals, concerning whose identity with sartorite there is some question, deduces $\dot{a}:\dot{b}:\dot{c}=1.27552:1:1.19487;\;\beta=77^{\circ}48'.$ He makes the brachydomes of vom Rath's orientation the prisms, and transposes the macrodomes into orthodomes. Tables are given including 87 forms and their comparison with the forms observed by earlier

Sassolite, Min., p. 255. — Crystals from Tuscany; D'Achiardi, [Ann. Univ. Tosc., 23, 1, 1900]; Zs. Kr., 35, 519.

Scapolite, Min., p. 466; App., p. 61. — Scapolite rocks from Alaska; Spurr, Am. J. Sc., 10, 310, 1900.

Scheelite, Min., p. 985; App., p. 61. — Crystals from Nordmark; Flink, Bull. G. Inst. Upsala, 5, 96, 1901; from Traversella with the new forms: (885), (714), (735), (756), (232), also less certain (323), (21.1.11); mean value of $\dot{c}=1.53798$; Colomba, Rend. Acc. Linc., **15**, (1), 281, 1906; other new forms from Traversella, (338), (227), (507), (407)?; Zambonini, ibid., 558, 1906; from Hillgrove, N. S. W., and Mount Ramsay, Tasmania; Anderson, Rec. Aus. Mus., **6**, 414, 1907.

Luminescence; Pochettino, Rend. Acc. Linc., 14, (1) 505, (2), 220, 1905. Analyses of material from Traversella gave:

	WO ₃	MoO ₃	CaO	MgO
Colorless	77.03	3.15	19.73	= 99.91
Reddish brown	77.35	2.46	18.33	1.67 = 99.81
Greenish brown	78.75	1.47	19.23	0.55 = 100.00
Orange-yellow	79.68	0.72	19.43	tr. = 99.83

Colomba, loc. cit.

Artif.; de Schulten, Bull. Min. Soc., 26, 112, 1903.

Artif.; de Schulten, Bull. Min. Soc., 26, 112, 1903.
Occurrence with anal., at Villa Salto, Sardinia; Traverso, [Resocconti delle Riunioni d. Soc. Min. Sarda, Iglesias, 6, 8, 1901]; Zs. Kr., 37, 396; from the Mutsch in the Etzlithal, Switzerland (anal. by Hinden); Schmidt, Zs. Kr., 36, 160, 1902; see also ibid., 24, 137, 1895. At Trumbull, Conn.; Hobbs, U. S. G. S., 22d. Ann. Rep., 2, 7, 1902; Zs. Kr., 38, 698; occurrence (with anal.) at Marianna de Itacolumy, Minas Geraës, Brazil; Florence, Centralbl. Min., 727, 1903; near Barkerville, N. C.; Atkin, Geol. Mag., 2, 116, 1905; in eruptive rocks at Predazzo, Tyrol; Block, Ber. Naturhist. Ver. Bonn, 2, A, 68, 1905; at Murri and Orroli, Cagliari, Sardinia; Lovisato, Rend. Acc. Linc., 16, (1), 632, 1907; in pegmatite at Dinan Côtes du Nord, France; Lacroix, Bull. Soc. Min., 31, 349, 1908.

Schefferite, see Pyroxene.

Schertelite. Schertalite. Muellerite. R. W. Emerson MacIvor, Ch. News, 85, 182 and 217, 1902. Zs. Kr., 42, 386, 1906. Comp. $Mg(NH_4)_2H_2(PO_4)_2 + 4H_2O = P_2O_5$, 43.83; MgO, 12.35; $(NH_4)_2O$, 16.05; H_2O ,

27.77. Analysis:

Occurs in small indistinct flat crystals sparsely distributed in the bat guano deposits found in basaltic caves near Skipton, thirty miles southwest of Ballarat, Australia. Originally named from Baron Sir Ferdinand von Mueller, the name being subsequently withdrawn on account of the same name having been previously given to another species. Schertalite is an incorrect spelling. Named from Prof. Arnulf Schertel.

Schizolite. Chr. Winther, Medd. om Grönland, 24, 196, 1901; O. B. Böggild, ibid., 26, 121, 1904.

Triclinic: \Bar{a} : \Bar{b} : \Bar{c} = 1.10613 : 1 : 1.98629. α = 90° 11′; β = 94° 45 \Bar{a} ′; γ = 103° 7 $\Bar{4}$ ′. Forms: a (100), b (010), c (001), c (001), a (530), a (110), a (230), a (110), a (120), a (101), a (101), a (201), a (111), a

In columnar prismatic crystals, elongated $\|\bar{b}\|$ with a, b, c prominent; the habit is like that of pectolite, to which it is related chemically.

Cleavage, a and c both perfect. Fracture uneven. Brittle. H. = 5-5.5. G. = 2.97-3.13. Luster vitreous. Color light red, changing to brown. Semitransparent to opaque.

Optically positive, $c \parallel \overline{b}$. a makes \angle of 9° with normal to c (001). $2E_y = 82^{\circ} 40'$. Birefringence on (100) = 0.0271 (Na).

Composition, HNa(Ca,Mn)₂ (SiO₃)₃. Analysis, Chr. Christiansen:

a

TiO, Ce_2O_3 SiO2 FeO MnO CaO Na₂O H₂O 0.68 1.47 51.06 2.79 12.90 19.48 10.71 1.36 = 100.45

From the nephelite-syenite region of Julianehaab, southern Greenland; found in 1897 by G. Flink (Medd. om Grönland, 14, 257, 1898) at Tutop Agdlerkofia, where it occurs in granular albite with agirite, steenstrupite, sphalerite; also at Kangerdluarsuk embedded in pegmatite with eudialyte, arfvedsonite, etc. Named from $\sigma\chi l\zeta\omega$, to cleave, in allusion to the marked cleavage. A related mineral, obtained by G. Flink from Naujakasik in the same region, is provisionally regarded as a variety of schizolite by Winther. It occurs in small indistinct cube-like crystals,

also in plates.

H. = 5-5.5. G. = 3.084. Luster greasy to vitreous. Color brown.

Analysis, Chr. Christiansen:

ь

SiO2 Y_2O_3 FeO MnO CaO MgO Na₂O H₂O 51.44 2.40 2.01 20.53 0.13 9.50 $2.\overline{25} = 99.95$ 11.69

The percentage composition is closely that of manganopectolite. It is regarded as a partly altered schizolite.

Schneebergite, Min., p. 862; App., p. 61. — The determination of schneebergite to be a garnet. see App. I, p. 28, is proven to be erroneous and that it is an individual species near *alopite* as originally described. The material analyzed by Eakle and Muthmann was a garnet similar in appearance to schneebergite and associated with it. Index of refraction determined, n = 2.10, (Hlawatsch); Koechlin, Min. Mitth., 21, 15, 87, 1902.

Schrötterite, Min., p. 694. — A mineral associated with melite (q. v.) from Saalfeld has been analyzed by Zambonini and shown to belong here, Zs. Kr., 32, 162, 1899; 34, 226, 1901.

Schoenite, Min., p. 948. — See Picromerite.

Schorlomite, Min., p. 447. — Occurrence (with anal.) in nepheline-syenite rocks on Ice River in Rocky Mts., British Columbia; Hoffmann, Am. J. Sc., 11, 150, 1901.

Scleropasthite. W. F. Petterd, Notes on Minerals Occurring in Tasmania, 1902. — Occurs in compact felted masses, very hygroscopic and extremely tough under the hammer; these consist of minute, short, silky white fibers and the surface is often nodular and rough. An analysis gave:

> SO. Fe₂O₃ Cr2O3 Ign. gangue 27.20 14.0 10.64 39.19 10.77 = 101.80

Occurs associated with a sulphate provisionally referred to knoxvillite, q. v.

Scolecite, Min., p. 604; App., p. 61. — Crystals from Karsuanguit-Kakait, Greenland, with

determination of indices of refraction and anal. by Ussing; Böggild, Min. Grönl., 539.

Anal. of material from Werris Creek, N. S. W.; Anderson, Rec. Aus. Mus., 6, 421, 1907.

Action of ammonium chloride upon; Clarke and Steiger, Am. J. Sc., 9, 345, 1900; discussion of

Occurrence with anal. from Cala Francese, Maddalena island; Rimatori, Rend. Acc. Linc., 11, (1), 542, 1902; occurrence on island of Suderö; Görgey, Centralbl. Min., 525, 1908.

Scorodite, Min., p. 821; App., p. 61. — Crystals from Schlaggenwald, Bohemia; Slavik, Zs. Kr., 39, 298, 1904; from Nadabula, Gömör, Hungary; Zimányi, Földt. Közl., 35, 545, 1905.

Seligmannite. H. Baumhauer, Ber. Ak. Berlin, 110, 1901; ibid., 611, 1902; Solly, Min. Mag., 13, 336; ibid., 14, 186.

Orthorhombic. $\delta: \bar{b}: \dot{b}=0.92332:1:0.87338$ (Solly). Angles: (011) \wedge (001) = 41° 8′; (100) \wedge (101) = 46° 35½′; (010) \wedge (120) = 28° 26′. In small complex crystals; 57 forms having been observed. Closely related crystallographically with bournonite. Almost always twinned about (110), also at times (110).

Color lead gray; metallic luster; chocolate streak; conchoidal fracture. H. = 3.

Composition. Qualitative determinations gave copper, lead, sulphur and arsenic. From crystallographic relations to bournonite it is supposed to be isomorphous with it and to have formula Cu2S.2PbS.As2S3.

Occ. in Lengenbach quarry, Binnenthal. Named after G. Seligmann of Coblenz.

Semseyite, Min., p. 123; App., p. 61. — From Oruro, Bolivia, with anal.; Spencer, Min. Mag.,

See under Plagionite.

Senaite, App., p. 62. — New analyses of material from near Diamantinas, Brazil, lead to formula (Fe,Mn,Pb)O.TiO_2.

		TiO ₂	ZrO ₂	FeO	MnO	PbO	MgO
I. I	Dattas.	52.11		26.97	10.42	10.86	0.32 = 100.68

Hussak and Reitinger, Zs. Kr., 37, 574.

SENARMONTITE, Min., p. 198; App., p. 62. — Relations to valentinite; Weber, Zs. Kr., 44, 232. Article referred to in App. I should be accredited to Lovisato.

Sepiolite, Min., p. 680; App., p. 62. — Analysis of meerschaum from Gröschelmanth, south of Mährisch-Budwitz, West Mähren, Bohemia; Kovář, [Progr. d. čechosl. Handelsakademie, Prag, 1903]; Zs. Kr., 39, 400. Comp. of; Fogy, Ber. Ak. Wien, 115, June, 1906. Discussion of chem. comp.; Zambonini, Mem. Acc. Sci., Napoli, 14, 77, 1908.

Serendibite. G. T. Prior and A. K. Coomáraswámy, Min. Mag., 13, 224, 1903.

Occurs in irregular grains showing polysynthetic twinning, analogous to the feldspars; probably

triclinic or monoclinic.

Cleavage none. Fracture subconchoidal. H.=6.75. G. = 3.42. Luster vitreous. Color blue, varying from pale sky-blue to deep indigo-blue. Pleochroism marked, in one variety pale yellow (almost colorless) to pale sky-blue, in another pale brownish yellow to deep indigo-blue. Biaxial; birefringence weak. Refractive index about 1.7. Extinction nearly symmetrical and at about 15°, in two sets of twin lamellæ, each of which shows an optic axis nearly central.

Composition a basic silicate of aluminium, calcium and magnesium, perhaps 10RO.5Al,O.

B₂O₃.6SiO₂. Analysis, G. T. Prior:

CaO MgO Na₂O(Li₂O) K₂O P₂O₅ F? Ign. 0.48 undet. 0.69 FeO 0.220.69 = 10014.56 14.91 0.51

B. B. infusible; with calcium fluoride and acid potassium sulphate yields a green boron flame.

Only slightly attacked by acids.

Found on Ceylon at Gangapitiya near Ambakotte and 12 miles from Kandy; occurs in contact zones between bands of granulite and of limestone, associated with diopside, blue spinel, apatite, scapolite and plagioclase. This locality is worked for Ceylon moonstone, which occurs in large porphyritic crystals in the granulite (cf. Q. J. G. Soc., 58, 421, 1902). Named from Serendib, an old Arab name of Ceylon.

SERPENTINE, Min., pp. 669, 1047; App., p. 62.—Analyses of material from Ceylon; Grünling, Zs. Kr., 33, 219, 1900; from near Easton, Pa.; Eyerman, Amer. Geol., 34, 47, 1904; comp. of; Fogy, Ber. Ak. Wien, 115, June, 1906. Analyses of three varieties of serpentine with discussion of chem. comp.; S. Hillebrand, Ber. Ak. Wien, 115, 697, 1906. Loss of water on heating and discussion of chem. comp.; Zambonini, Mem. Acc. Sci., Napoli, 14, 19, 1908.

Microscopic structure; Bonney and Raisin, Jour. Geol. Soc., 61, 690, 1905.

Study of serpentines from Kuttenberg, Bohemia, with anal.; Bukovský [Programm des Realschule in Kuttenberg, 1906]; Zs. Kr. 45, 403.

Occurrence in Vermont; Ver. Geol. Sur. Ann. Rep. 1903–1904; Am. J. Sc., 19, 395. A serpentine rock from Tarnthaler-Köpfe, Tyrol; Young, Min. Mag., 14, 365, 1907.

Variety bowenite from Shigar, Baltistan, Cashmere, with anal.; McMahon [Mem. Geol. Surv. India, 31, 312, 1901]; Zs. Kr., 37, 310.

Pseudocubic antigorite from Persberg, Wermland, and from Kogrube, Nordmarken, with analyses of Fig. Figh. 26, 67, 1004.

analyses; Hamberg, G. För. Förh., 26, 67, 1904.

On the identity of the Amiantos or Karystian stone of the ancients with chrysotile; Evans, Min.

Mag., 14, 143, 1906.

Ricolite, name given to a banded variety of serpentine from Mexico. Name derived from Spanish "rico," in allusion to the rich green color of the stone. Merrill, Stones for Building and Decoration, pp. 365, 366.

Nemaphyllite is a variety containing 2 p. c. soda, occurring in regular intergrowth with dolomite

at Wildkreuzjoch in the Zillerthal, Tyrol; Fr. Focke, Min. petr. Mitth., 21, 323, 1902. In coarse scaly to foliated masses resembling the chlorites; the folia also fibrous in structure, whence the

Cleavage perfect, yielding elastic folia. H. = 3. G. = 2.60. Luster silky or pearly. Color bluish green to greenish gray. Birefringence negative, weak. Axial plane parallel to the direction of fibrous structure. Bxa (a) somewhat inclined to the normal to the folia.

Analysis, R. v. Zeyneck.

Al₂O₃ FeO MgO CaO Na O H₂O 42.490.40 4.63 37.60 0.72 2.11 13.11 = 101.06

See Asbestus.

SIDERITE, Min., pp. 276, 1047; App., p. 62. — Crystals from Traversella; Colomba, Rend. Acad. Linc., 15, 637, 1906; from Frigido near Massa, Italy, (with anal.); Manasse, Att. Soc. Tosc., 22, 81–93, 1906. Scalenohedral crystals with new forms, l (7075); K (5052); y (3251), from near Frostburg, Md.; Schaller, Am. J. Sc., 21, 364, 1906; crystals with danalite, Gloucester, Mass.; Palache, ibid., 24, 253, 1907; Zs. Kr., 44, 18; crystals from Chorolque and Tatasi, Bolivia; Spencer, Min. Mag., 14, 342, 1907; from Cornwall with new forms, Δ (7072), l (3031); Henglein, Zs. Kr., 43, 575, 1907.

Chemical and optical study of material from Camborne, Cornwall; Hutchinson, Min. Mag., 13,

209, 1903.

Containing MgCO₃ to FeCO₃ as 1: 3 (anal.) from Bottino, Tuscany; Manasse, Proc. Soc. Tosc., **15**, 20–37, 1906.

An iron-manganese carbonate related to the oligonite (oligonspath) of Breithaupt (Dana, Min., p. 277) has been called manganospherite by Busz, Jb. Min., 2, 129, 1901. It resembles spherosiderite, occurring in botryoidal or reniform aggregates, the surface spangling with very minute rhombohedral faces; also occurs in fine-fibrous forms resembling chrysotile. H. = 4.5 - 5. $G_{\cdot} = 3.630$. Color brown with tinge of red. The composition corresponds to $3\text{FeCO}_3.2\text{MnCO}_3$ as given by the analysis: CO_2 , 38.34; FeO, 36.72; MnO, 24.76 = 99.82.

This mineral has been found in cavities or in thin cracks in basalt (limburgite) which crosses the siderite deposits at the Louise mine near Horhausen, Westerwald, Germany. The chrysolite (olivine) crystals of the basalt have been in part replaced by manganospherite.

SIDERONATRITE, Min., p. 973. — Artif. formation and discussion of chem. comp.; Scharizer, Zs. Kr., 41, 215.

Silicomagnesiofluorite. P. Zemiattschensky, Zs. Kr., 42, 209, 1906.

In aggregates of half-spherical or spherical forms with fibrous-radiated structure.

H. = 2.5. G. = 2.913 (v. Isküll). Luster silky. Color ash-gray, also light greenish or bluish.

Birefringence weak, positive; extinction parallel.

Composition, a fluosilicate of calcium and magnesium essentially, with perhaps the empirical formula H₂Ca₄Mg₃Si₂O₇F₁₀.

Analysis:

SiO2 Mn₃O₄ CaO MgO H₂O F SO $\mathrm{Fe_2O_3}$ $0.2\mathring{7} = 116.15 \text{ (less O} = 13.06) = 103.09$ 19.86 2.30 38.48 18.27 5.90 31.01 0.06

Disregarding the manganese and a portion of the iron and taking the remainder of the latter as FeO, the following are obtained as the results of the analysis: Si, 9.34; Ca, 27.54; Mg, 11.03; Fe, 1.61; H, 0.33; F, 31.01; O, 18.85 = 99.71.

B. B. fuses rather easily to a clouded greenish glass; yields water in the closed tube, also reacts

for fluorine. Soluble in acids.

From Lupikko, near Pitkäranta, Finland; probably occurs with serpentine.

SILLIMANITE, Min., p. 498; App., p. 62. — Study of crystal from Chester, Conn., gave following forms: (110), (230), (120), (052). Axial rational 1: 0.7046. Taubert, Centralbl. Min., 372, 1906. Axial ratio derived from measurements: $\ddot{a} : \dot{b} : \dot{c} = 0.9696$:

From Ceylon with determination of optical constants; Grünling, Zs. Kr., 33, 253, 1900. Re-

fractive indices; Taubert, [Inaug.-Diss., Jena, 1905]; Zs. Kr., 44, 314.

Conversion of cyanite and andalusite into sillimanite by heating to about 1350°; Beekman, [Veslag Wis-en Nat. Kon. Akad. Wetenschappen te Amsterdam, 11, 1,295, 1902]; Zs. Kr., 39, 395. SILVER, Min., p. 19; App., p. 62. — Structure planes; Mügge, Jb. Min., 2, 59, 1899.

Origin discussed; Vogt, Zs. prakt. Geol., 113, 177, 1899. Occurrence on Lake Temiskaming, Ontario, Canada; Miller, Rep. Can. Bureau of Mines, 2, 1905; Zs. Kr., 43, 395.

SLOANITE, Min., p. 610. — See under Natrolite.

Smaltite, Min., p. 87. — Crystals from Cobalt, Ontario; Miller, Rep. Can. Bureau Mines, 2, 1905; Zs. Kr., 43, 395.

Smithite. R. H. Solly, Min., Mag., 14, 74, 1905. G. F. Herbert Smith and G. T. Prior, ibid.; 14, 293, 1907.

Monoclinic. Axes à: $\dot{b}:\dot{c}=2.2309:1:1.9657;\ \beta=78^{\circ}\ 47\frac{1}{2}'\ (Solly).$ Smith gives slightly different constants. Angles (by Solly): $(100)\ \land\ (101)=42^{\circ}\ 22';\ (100)\ \land\ (10\bar{1})=55^{\circ}\ 0';\ (100)\ \land\ (101)=42^{\circ}\ 22';\ (100)=42^{\circ}\ 22';\ (100)\ \land\ (101)=42^{\circ}\ 22';\ (100)=42^{\circ}\ 22';\$ (111) = 63° 24'. Forms: Fifty-seven observed forms, of which the most prominent are: a (100), c (001), e (101), d ($\overline{1}01$), p (111), P ($\overline{1}11$), r (311), R ($\overline{3}11$), q (211), Q ($\overline{2}11$), l (320). In crystals resembling a flattened hexagonal pyramid, formed by a prominent and the zones

ac, ap, aP equally developed.

Cleavage a highly perfect. Fracture conchoidal. Brittle. H. = 1.5-2. G. = 4.88. Luster adamantine.

Color light red, changing to orange-red on exposure to light. Streak vermilion.

Composition, $Ag_2S.As_2S_3 = AgAsS_2$; Ag = 43.69; As = 30.36; S = 25.95. Anal. yielded Ag_3 , 43.9; As_3 , 28.9; Sb_3 , 0.4; Sb_3 , 0.4; 0.4

Occurs in the white dolomite of the Lengenbach quarry in the Binnenthal, Switzerland; it is associated with hutchinsonite, sartorite and rathite.

Named after Mr. G. F. Herbert Smith of the Mineral Department of the British Museum, London.

SMITHSONITE, Min., p. 279; App., p. 63. — Crystals from San Aniceto, Almaden, Spain, with new form (105); Buttgenbach, Bull. Soc. Min., 29, 190, 1906; pseudomorphs after calcite and anglesite; Millosevich, Rend. Acc. Linc., 9, (1), 153, 1900.

Anal. of material from Morning Star mine, Searcy Co., Arkansas, containing 1.06% CdO;

Min., Reil 26, 151–212, 1908 Beil., 26, 151-212, 1908.

Chemical and spectroscopic study (presence of Cd, In, Ga) of specimens from Sardinia; Rima-

tori, Rend. Acc. Linc., 12, (1), 263, 1903; ibid., 14, 688, 1905. Cadmium content; Biewend, [Bergu. Hütten. Ztg., Leipzig, 61, 401, 413, 425, 1902]; Zs. Kr., 40, 506. With metallic luster from Cornwall (?) with anal.; Miers, Min. Mag., 12, 111; from Binnenthal; Solly, Min. Mag., 14, 81.

Polymorphous relations to wurtzite; Weber, Zs. Kr., 44, 212.

SPINEL, Min., pp. 220, 1048; App., p. 63. — Indices of refraction of blue spinel from Ceylon;

Grünling, Zs. Kr., 33, 259.

Anal. of pleonaste from Unter-Lhota, Mähren; Kovář, [Abh. böhm. Akad., 28, 1899]; from Ceylon and pleonaste from Fassathal, Tyrol; Pfeil, [Inaug.-Diss., Heidelberg, 1901]; Centralbl. Min., 146, 1902. Occurrence of pleonaste accompanied by amphibole in a rock on island of Elba, with anal.; P. Aloisi, Proc. Soc. Tosc., July, 1906.

Manganese spinel in slag from Menyháza, Hungary, with anal.; Krenner, Zs. Kr., 43, 473; chem. comp.; Loczka, Zs. Kr., 43, 571.

Synthetical; Smith, Min. Mag., 15, 153, 1908.

Spodiophyllite. G. Flink, Medd. om Grönland, 14, 232, 1898; 24, 85, 1901.

In rough elongated hexagonal prisms with c resembling chlorite, m faces deeply striated; also

in triangular plates twinned (60° about the vertical axis).

Cleavage, basal perfect, micaceous. Brittle, laminæ not flexible nor elastic. H.=3-3.25. G.=2.633. Luster on cleavage faces pearly, otherwise glimmering or dull. Color ash-gray, on c often pearl-gray. Translucent to transparent. Optically uniaxial, negative; birefringence weak.

Composition, (Na₂, K₂)₂(Mg, Fe)₃(Fe, Al)₂(SiO₃)₈.

Analysis, G. Flink:

Al₂O₃ 4.27 FeO MnO MgO Na₂O SiO₂ Fe_2O_3 53.6110.16 7.80 = 100.40

B. B. fuses slowly to a clear, nearly colorless glass; reacts for iron with the fluxes. Not attacked by acids.

Occurs very sparingly at Narsarsuk in southern Greenland, sometimes embedded in crystals of ægirite; also associated with zircon, ancylite, rhodochrosite, albite.

Named from σπόδίος, ash-gray, and φύλλον, leaf.

Spodumene, Min., p. 366. — Anal. from Čichov, near Trebitsch in Mähren; Kovář, [Zs. chem. Indus., 10, 1900]; Zs. Kr., 36, 204.

Occurrence on Walrus Island, James Bay, Ungava dist., Northeast Territory, Canada; Hoffmann, Am. J. Sc., 11, 152, 1901; in tourmaline-bearing pegmatites in Madagascar; Lacroix, Bull. Soc. Min., 31, 239, 1908.

Kunzite. Kunz; Am. J. Sc., 16, 265, 1903; Baskerville, Science, 18, 304, 1903; Schaller, Univ. Calif. Bull. Geol., 3, 265, 1903; Baskerville and Kunz, Am. J. Sc., 18, 25, 1904; Davis, Am. J. Sc., 18, 29, 1904.—A clear lilac-colored variety of *spodumene* found near Pala, San Diego Co., California. The crystals, some of which weighed from 500 g. to 1000 g., are tabular, lengthened parallel to c axis. The following faces were observed: a (100), b (010), l (320), m (110), n (130), A (350). Shows strong phosphorescence, with an orange-pink light through excitation by oscillating electric discharge, by ultra violet rays, by X-rays or by radium emanations. Analysis by Davis gave:

Used as a gem stone. Named after Dr. G. F. Kunz of New York City.

Spurrite. F. E. Wright, Am. J. Sc., **26**, 547, 1908. Probably monoclinic. In granular masses. Two cleavages, one good, second fair. Cleavage angle = 79°. In thin section twinning noted on two different planes. Fracture uneven to splintery. Brittle. H. = 5. Vitreous to resinous luster. Color pale gray with tints of blue, or yellow to colorless. Transparent to translucent. $2V = 39.5^{\circ}$ approx. Birefringence strong, negative. Crossed dispersion. $\alpha_{\rm Na} = 1.640$; $\beta_{\rm Na} = 1.674$; $\gamma_{\rm Na} = 1.679$. Comp., $2{\rm Ca_2SiO_4.CaCO_3}$; ${\rm SiO_2}$, 27.13; CaO, 62.98; CO₂, 9.89. Analysis by E. T. Allen:

B. B. gives strong calcium flame, loses its glassy luster but does not fuse. Found in contact zone between limestone and diorite in Velardeña mining district, Mexico, associated with gehlenite and hillebrandite. Named in honor of Mr. J. E. Spurr the geologist.

STANNITE, Min., p. 83; App., p. 64. — Spencer (Min. Mag., 13, 54) studying crystals from Oruro, Bolivia, shows them to be tetragonal, sphenoidal, but pseudo isometric through twinning. Following forms identified: c (001), a (100), m (110), e (101), z (201), d (114), n (112), p (111), t (221), -n (112), -p (111), t (221), -n (112), -p (111), t (223). Twinning, (1) always interpenetrant with e (101) as twinning pl., (2) interpenetrant with twin axis \perp to p (111). Anal. given. Regular grouping of crystals on tetrahedrite, from Oruro, Bolivia; id., ibid., 14, 327.

Stantienite. E. Pieszczek [Archiv. f. Pharmacie, [iii], 14, 433], [Jour. Chem. Soc. Abstracts, 40, 687, 1881]; Min. Mag., 12, 392. A black resin occurring with Prussian amber.

STAUROLITE, Min., p. 558; App., p. 64. — Occurrence in the Alps; Weiss, [Zs. Ferd. f. Tirol u. Vorarlberg, 45, 129, 1901]; Zs. Kr., 38, 200. From Campolongo, Tessin; Mann, [Inaug.-Diss., Leipzig, 1904]; Zs. Kr., 42, 666.

Steenstrupine, Min., p. 415; App., p. 64. — Crystals from Julianehaab District, Greenland, with anal. by Christensen; Böggild, Medd. om Grönl., 24, 23, 1901.

Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 64, 1908.

Stelznerite. A. Arzruni and K. Thaddéeff, Zs. Kr., 31, 232, 1899.

Orthorhombic. Axes $\check{a} : \bar{b} : \dot{c} = 0.50368 : 1 : 0.70585$.

Forms: b (010), c (001), m (110), o (011), p (111). Angles: $mm''' = 53^{\circ}$ 28', $po = 48^{\circ}$ 25½'. In prismatic crystals, resembling brochantite, implanted upon a green, crystalline mass. G. = 3.884. Luster brilliant. Color green. Translucent. Ax. plane $\parallel c$, an axes nearly $\perp m$. Composition, CuSO₄.2Cu(OH)₂. Analyses: 1, Thaddéeff; 2, Schröcker.

From Remolinos, Vallinar, Chile. Named after Prof. Stelzner.

STEPHANITE, Min., pp. 143, 1025, 1048; App., p. 64. — Crystals from Přibram with new forms (340), (3.10.0), (140), (160), (087), (031), (833), (553), (11.11.5), (17.17.3), (5.17.9). Slavík, [Abh. böhm. Akad. Prag, 16, 1901]; Zs. Kr., 37, 497. Crystals and twins from Sarrabus, Sardinia, with following new forms: (016), (014), (027), (038), (035), (056), (776), (885), (772), (551), (485). (1.3.19), (1.3.17), (1.4.23), (1.4.20), (1.5.30), (3.27.7); D'Achiardi, Att. Soc. Tosc., Mem. 18, 1901. Crystals, including some of remarkable size, from Arispe, Sonora, Mexico, with anal.; Ford, Am. LSc. 25, 244, 1008; 78, Kr. 45, 231, 1008. J. Sc., 25, 244, 1908; Zs. Kr., 45, 321, 1908.

Stibio-domeykite. G. A. Koenig, Am. J. Sc., 10, 445, 1900. — A variety of domeykite from the Mohawk mine, Keweenaw Co., Michigan, peculiar in containing a small amount (1.29 to 0.78) p. c.) of antimony. See Domeykite.

STIBIOTANTALITE, App., p. 64. — Crystals from California investigated by Penfield and Ford, Am. J. Sci., 22, 61, 1906.

Orthorhombic hemimorphic. Axes $\check{a}:\bar{b}:\dot{c}=0.7995:1:0.8448$.

Forms: a (100), a' ($\bar{1}00$), m (1 $\bar{1}0$), q (130), q' ($\bar{1}30$), q' (209), n' ($\bar{2}09$), h (203), probably h' ($\bar{2}03$), δ (043), w (4.12.9), probably w' (4.12.9). Angles: $mm''' = 77^\circ$ 18', $gg' = *45^\circ$ 16', $ww' = 34^\circ$ 38', $ww''' = 91^\circ$ 6', $\eta\eta$ 26° 26', $ah = 54^\circ$ 50' $\delta\delta' = 96^\circ$ 48', $gw = *39^\circ$ 20'.

Twinning pl. a (100) in polysynthetic twins; often only to be observed by pyroelectric tests, which show intimate and repeated twinning. Crystals usually prismatic in habit, showing vertical striations, resembling columbite. Ends of crystals frequently crossed by ridges parallel to \overline{b} axis, due to twinning. Hemimorphism in direction of ă axis.

Cleavage: a perfect, b indistinct. H. = 5-5.5. G. = 5.98-7.37, varying with the composition.

Luster resinous to adamantine. Color dark brown.

Optically +. Ax. pl. $\|a$. Bx $\perp c$. $\rho < v$. Optical constants vary with the variation in composition.

Refractive indices and axial angles:

I. G. = 6.818, corresponding to about 39% Ta₂O₅ and 17.5% Nb₂O₅.

Pyr. B. B. fuses with difficulty to black enamel. C. T. gives water and blackens. Decomposed by HCl.

As alteration product of thuringite at iron ore mines at Gobitschau, near Sternberg, Occ.

Mähren.

Alter. Alters to chloropal.

Name derived from στιλπνός, shining, and γλωρός, yellow.

Stilpnomelane, Min., p. 658; App., p. 65. — Analysis of *chalcodite* from Harzburg in Radauthal; Fromme [Jahrber. d. Ver. f. Natw. Braunschw., **12**, 31, 1900], Zs. Kr., **36**, 656.

Stoffertite. C. Klein, Ber. Ak. Berlin, June 13, 1901.

A name provisionally given to a mineral similar to brushite but containing a little more water. Monoclinic. Crystals show b (010) and n (011), which agree in their measured angles with the similar forms found on brushite. Cleavage $\parallel b$, perfect. Color faint yellow. Axial pl. $\perp b$. Bx $\perp b$. Extinction on b inclined to c axis in small angle β for Li 9° 15′, Na 10° 15′, Tl 11° 15′. Extinction direction lying in obtuse angle = a, in the acute angle = b, and || b axis = c. Indices of refraction: $\alpha = 1.5509$, $\beta = 1.5455$, $\gamma = 1.5392$, $2V = 85^{\circ}$ 16′. Comp., 2CaO.P.O.5.6½H₂O = CaO, 30.18; P₂O₅, 38.28; H₂O, 31.54.

Analysis by Finkener:

	CaO	P_2O_5	SO,	H _o O
1.	30.83	$\frac{P_2O_5}{37.96}$	0.49	30.88 = 100.16
2.*	30.69	38.22		31.09 = 100.00

^{*} After subtracting sufficient amount of anhydrite molecule to account for SO4. Found in the guano deposits on the island of Mona in the West Indies. Named in honor of Dr. Stoffert, who collected the specimens.

Stokesite. A. Hutchinson, Phil. Mag., 48, 480, 1899; Min. Mag., 12, 274, 1900.

Orthorhombic. Axes: $\check{a}: \bar{b}: \dot{c} = 0.3462:1:0.8037; (100) \land (110) = 19^{\circ} 5^{3}, (001) \land$

 $(011) = 38^{\circ} 47\frac{1}{3}', (001) \wedge (101) = 66^{\circ} 41\frac{3}{4}'.$

Observed forms: b (010), c (001), m (110) cleavage, s (565), t (122), v (121). Angles $bv = *57^\circ$ 33', $vv''' = 64^\circ$ 54', $vv' = 101^\circ$ 37', $vv'' = *141^\circ$ 0'. Known only in a single crystal of acute pyramidal habit (v) with b prominent. Cleavage m perfect; b less so. Fracture conchoidal. Brittle. H. = 6. G. = 3.185. Luster

vitreous, pearly on b. Colorless, transparent. Ax. pl. \parallel b. Bx_a \perp c. 2VN_a = 69½°. β = 1.6125, γ - α = 0.01. Composition, perhaps, H₄CaSnSi₃O₁₁ or CaO.SnO₂.3SiO₂.2H₂O. The most probable results of analysis on a minute quantity gave Hutchinson (l. c.) SiO₂, 43.1; SnO₂, 33.3; CaO, 13.45; H₂O, 8.6 = 98.45.

Associated with axinite from Roscommon Cliff, St. Just, Cornwall; known only in a single speci-

men in the Cambridge Museum.

Named after Sir George G. Stokes, Professor of Mathematics at Cambridge.

STOLPENITE, Min., p. 690, see Montmorillonite.

* Perhaps one-half La, also Di with Prd and Sm. † Earths not precipitated by K₂SO₄. ‡ Or Fe₂O₃ with Ti tr. § Undried material analyzed, 1.56 H₂O expelled at 100°.

B. B. infusible, but glows brilliantly when ignited. Easily dissolved by acids with loss of CO₂. From Narsarsuk, So. Greenland; occurs on surfaces of feldspar or ægirite or in cavities. First described by G. Nordenskiöld as parisite, to which it is closely related.

Named σύγχυσις, confounded, in allusion to its being mistaken for parisite.

SYNGENITE, Min., p. 945; App., p. 66. — Refractive indices; Gaubert, Bull. Soc. Min., 30, 107, 1907.

Conditions of formation discussed; van't Hoff with Wilson, Farup, d'Ans, Ber. Ak. Berlin, 1142, 1900; 1000, 1903; 218, 1906.

Szechenyiite. J. Krenner, Zs. Kr., 31, 503, 1899. — A variety of amphibole, which see.

TACHHYDRITE, Min., p. 178; App., p. 66. — Discussion of conditions of formation; van't Hoff with Dawson, Lichtenstein, d'Ans, Farup; Ber. Ak. Berlin, 557, 1899; 232, 913, 1905; 218, 1906.

Tainiolite. G. Flink, Medd. om Grönland, 14, 234, 1898; 24, 115, 1901. Monoclinic, and belonging to the mica group. Forms: b (010), c (001), θ (027), e (023), μ ($\bar{1}11$), referred to the axial ratio of biotite. Crystals thin strips, elongated \parallel \dot{a} , maximum length 5 mm. Measured angles: $ce=24^{\circ}$ 44', $c\mu=81^{\circ}$ 28', $\mu\mu'=60^{\circ}$ 15'. Twins rare, two crystals in contact

Cleavage c perfect, as in muscovite; laminæ somewhat elastic. H. = 2.5-3. G. = 2.86 (Mauzelius). Color, colorless, with tinge of blue. Transparent. Ax. pl. $\parallel b$. Bxa inclined + 5°

to c. 2E = 50° approx. Birefringence negative, not strong.

Sulphoborite, App., p. 65. — Occurs with anhydrite and boracite in carnallite at the potash mines near Wittmar on the Asse, Brunswick; Bücking, Zs. Kr., 36, 156, 1902.

Sulphohalite, Min., p. 917; App., p. 65. — Analysis by Penfield, Am., J. Sc., 9, 425, 1900, which follows, gives formula as 2Na₂SO₄.NaCl.NaF, with theoretical comp., SO₃, 41.61; Na₂O, 32.25; Na, 11.97; Cl, 9.23; F, 4.94.

Sulphur, Min., pp. 8, 1048; App., p. 66. — Discussion of crystallization from fusion with regard to the various crystalline conditions assumed. Brauns, Jb. Min., Beil.-Bd., 13, 39, 1899. Crystals from Corphalie, Belgium, with following new forms: (201), (102), (043), (227), (229)?, (115), (3.3.16), (116); Buttgenbach, Ann. soc. géol. Belg., 25, 73, 1898; from Girgenti, twins with e (101) and n (011) as twinning planes; Busz, Jb. Min., 2, 132, 1901; from marble of Carrara; D'Achiardi, Att. Soc. Tosc. Sc., Mem. 20, 1905; from Bruchsal, Baden; Beierle, Centralbl. Min., 202, 1906; from near Lornano, Siena; Manasse, Att. Soc. Tosc., 23, 1907.

Study of the different polymorphous crystalline forms of sulphur, Gaubert, Bull. Soc. Min.,

28, 157, 1905.

Concerning microstructure of frozen sulphur; concerning sublimation, superheating and supersaturating of sulphur. Bütschli, sep. pub.; Zs. Kr., 36, 534.

Occ. at Cetine di Cortorniano, near Rosia, Siena; Pelloux, Rend. Acc. Linc., 10, (2), 10, 1901; with celestite, Maybee, Michigan; Kraus and Hunt, Am. J. Sc., 21, 237. Crystals formed at eruption of Vesuvius, 1906, see under Vesuvius.

Specimens of Quaternary clay, from Ortala Lund, Väddö parish, Sweden, which were originally black in color have gradually had developed through the mass and on the surface well-formed crystals (hemihedral in habit) of sulphur, the latter 3 to 3.5 mm. in diameter. E. Erdmann,

G. För. Förh., 23, 379, 1901.

Arsensulfurite is an arsenical sulphur ("sulfurite") occurring in thin brownish-red amorphous crusts on andesite at the volcano of Papandajan in Java; Rinne, Centralbl. Min., 499, 1902. An analysis by Buchholz gave: S, 70.78; As, 29.22 = 100. A similar occurrence was earlier noted by Phipson at the Solfatara near Naples (S, 87.6; As, 11.2; Se, 0.3 = 99.1), C. R., **55**, 108, 1852.

Sulvanite. G. A. Goyder, Jour. Chem. Soc., 77, 1094, 1900.

Massive. H. = 3.5. G. = 4.0. Luster metallic. Color bronze yellow. Streak nearly black. Comp., $3Cu_2S.V_2S_5 = Cu, 51.50; V, 13.88; S, 34.62.$

	Cu	V	S	Fe_2O_3	SiO ₂
1.	47.98	12.53	32.54	0.42	4.97 = 98.44
1 (recalc.)	51.57	13.46	34.97		= 100.00
2.	48.98	12.68	30.80	1.53	5.72 = 99.71
2 (recalc.)	52.96	13.72	33.32	100000000000000000000000000000000000000	= 100.00

Obs. — Found in a mine near the Burra, South Australia, associated with malachite, azurite, quartz, vanadium ocher, gypsum and calcite.

SVANBERGITE, Min., p. 868. — Chemical constitution, see under Hamlinite.

Sychnodymite, Min., p. 1049. — Occurrence from Siegthal, Germany, with anal.; Stahl, Bergu, Hütten. Ztg., 58, 182, 1899; Zs. Kr., 35, 289.

Sylvanite, Min., p. 103; App., p. 66. — Crystals from Cripple Creek, Colo., show following new forms: v (525), w (343), j (521), u (723). Anal. given, Palache, Am. J. Sc., 10, 419, 1900; Zs. Kr., 34, 539; also H (102), T (103), l (203), L ($\bar{2}$ 03); Moses, Am. J. Sc., 20, 282, 1905. Crystals from Nagyág with new forms E (102), G (302), T ($\bar{3}$ 12), π (523), ϵ (543), L (320), U (610); Vrba [Ber. aus Ungarn., 47, 1–5, 1904], [Föld. Közl., 34, 311, 1904]; Zs. Kr., 44, 69. Analysis, Cripple Creek, Colo.; R. Pearce [Proc. Colo. Sc. Soc., 5, 11, 1394]; Zs. Kr., 31, 291:

· Te Au 25.45 $\frac{\text{Ag}}{13.94} = 100$ 60.61

Discussion of chemistry of natural tellurides of gold; Lenher, Jour. Amer. Chem. Soc., 24, 355, 1902.

Occurs at Kalgoorlie in the East Coolgardie gold district, West Australia, much less abundant than calaverite, cf. Spencer, Min. Mag., 13, 271, 1903; Carnot, Bull. Soc. Min., 24, 360, 1901 (anal.); C. R., 132, 1299, 1901; also (with anal.) Krusch, Centralbl. Min., 199, 1901; Zs. prakt. Geol., 9, 211, 1901; Zs. Kr., 38, 302.

Composition, somewhat uncertain; if the loss showed by the analysis (on 0.1 gr.) is calculated as H₂O, the formula obtained is (K,Li)₂O.MgO.3SiO₂.2H₂O; fluorine may also be present. Analysis, Mauzelius:

B. B. fuses easily to a colorless blebby glass, coloring the flame intensely red. Completely but slowly decomposed by hydrochloric acid.

Occurs very sparingly at Narsarsuk, Southern Greenland, in druses with feldspar and ægirite;

narsarsukite and graphite are also closely associated.

Named from ταινία, band or strip, and λίθος, stone, in allusion to the form of the crystals.

TAENITE, Min., pp. 29, 1037. — Occurrence in meteoric iron found in 1884 in the sub-district of Youndegin, W. Australia; Fletcher, Min. Mag., 12, 171.

Talc, Min., p. 678; App., p. 66. — Analyses of steatite from various localities; Merrill, Nonmetallic Minerals. Rep. U. S. Nat. Mus., 1899; Zs. Kr., 36, 73; from North Carolina; Pratt. N. C. Geol. Sur. Economic Papers, 3, 1900; Zs. Kr., 36, 81. Iron-bearing pyrallolite with anal. from Lake Brocan, Valle del Gesso di Entraque, Piedmont; Roccati, [Boll. Soc. geol. ital., 24, 659, 1905]; Zs. Kr., 43, 500; from Kossoi-Brod, Ural Mts.; Iwanoff, [Bull. Nat. Moscow, 1906, p. 156]; Zs. Kr., 46, 221; chemical constitution, McNeil, Jour. Amer. Chem. Soc., 28, 591, 1906.
Occ. in porphyry near Niemberg, Saxony; Haas, Zs. für Naturwiss., Halle, 76, 431, 1903.

Tamanite. S. P. Popoff, Zs. Kr., 37, 267, 1902. — Same as anapäite, which see.

Tamarugite, Min., p. 952. — Anal. of material from Zolfo Grotto, Miseno, Italy; Zambonini, Rend. Acc. Sci. Napoli, Dec., 1907.

TANTALITE, Min., p. 731; App., p. 67. — Occurrence at Wodgina, W. Australia, with anal.; Maitland, Bull. Geol. Sur. W. Aus., No. 23, 65-74, 1906; occurrence of tantalum and niobium minerals in Australia; Simpson, Trans. Aus. Ass. Adv. Sci., Jan., 1907.

Taramellite. E. Tacconi, Centralbl. Min., 506, 1908; Rend. Acc. Linc., 17, (1), 810, 1908. Orthorhombic (?). Fibrous in bundles and radiating aggregates. Color reddish brown. Luster vitreous to silky. H. = 5.5. G. = 3.92. Cleavage perfect parallel to length of fibers, parting perpendicular to cleavage. High birefringence. Positive. Ax. pl. parallel to length of fibers and at right angles to cleavage. Obtuse bisectrix \perp to cleavage plane. $2E_a = 74^{\circ}$ (approx.). Strong pleochroism, c almost black, b and a flesh red.

Comp.: $Ba_4Fe^{11}Fe^{111}_4Si_{10}O_{31}$; SiO_2 , 37.53; Fe_2O_3 , 19.88; FeO, 4.47; BaO, 38.12. Anal.: SiO_2 , 36.56; Fe_2O_3 , 21.54; FeO, 4.47; BaO, 37.32 = 99.89.*

* Traces of TiO₂, Al₂O₃, MnO and MgO not determined.

Found in granular limestone at Candoglia near the contact with a gneiss. Associated with calcite, magnetite, chalcopyrite, pyrite, diopside, actinolite, celsian. Diopside and actinolite altered to ægirine and arfvedsonite.

Named in honor of the geologist Prof. Torquato Taramelli.

Tarbuttite. L. J. Spencer, Nature, 76, 215, 1907; Min. Mag., 15, 22, 1908.

Triclinic. $b:b:c=0.9583:1:1.3204; \alpha=102^\circ$ 37', $\beta=123^\circ$ 52', $\gamma=87^\circ$ 25'. Angles: $(100):(001)=55^\circ$ 50'; $(001):(\bar{1}01)=77^\circ$ 38'; $(100):(010)=84^\circ$ 34'; $(001):(010)=60^\circ$ 31'; $(001):(\bar{2}23)=72^\circ$ 3'. Forms (arranged according to size and frequency of occurrence): c(001), b(010), a(100), $e(\bar{2}21)$, $f(\bar{1}01)$, $g(\bar{2}11)$, $d(\bar{2}23)$, $k(\bar{1}\bar{1}1)$, l(021), $h(0\bar{2}1)$, $i(\bar{1}2)$, $r(\bar{2}43)$, $o(1\bar{2}1)$, $s(\bar{1}02)$, $t(\bar{1}03)$, $u(\bar{0}11)$, $m(\bar{1}10)$. Crystals striated and rounded, frequently in sheaf-like aggregates. Cleavage c(001), perfect with pearly luster on cleavage face. $H.=3\frac34$. G.=4.12-4.15. Luster vitreous. Sometimes colorless and transparent; usually pale shades of yellow, brown, red or green. Acute neg. bisectrix emerges obliquely through cleavage c(001). Double refraction strong. Ax. angle in air 80°-90°. Comp., Basic zinc phosphate, $Zn_3P_2O_3.Zn(OH)_2$; ZnO,67.1; $P_2O_3,29.2$; $H_2O,3.7$.

ZnO Analysis: 3.8 = 99.666.6

Pyr. In C. T. at high temperature decrepitates slightly and gives small amount of water. B. B. readily fusible to clear, yellow bead which becomes dark gray on cooling. Easily soluble in HCl. Pseudomorphs after smithsonite, descloizite and calamine (?) observed. Found at the zinc mines of Broken Hill, N. W. Rhodesia. Named after Mr. Percy Coventry Tarbutt.

Teallite. G. T. Prior, Min. Mag., 14, 21, 1904. Orthorhombic? Forms: c (001), o (111), p (221), also doubtful a (100), d (101), e (201), t (211). Measured angles: $co = 62\frac{1}{2}^{\circ}$, $cp = 75^{\circ}$, $cd = 57^{\circ}$, zone $(co) \wedge (co''') = 86^{\circ}$. In thin flexible folia. Cleavage, c perfect. H. = 1-2. G. = 6.36. Luster metallic. Color blackish gray. Streak black. Opaque. Composition, PbSnS₂ or PbS.SnS₂. Analysis:

$$\frac{2}{2}$$
 S, 16.29; Sn, 30.39; Pb, 52.98; Fe, 0.20 = 99.86

Yields a little sulphur in the closed tube, but does not fuse; readily decomposed by hot hydro-

chloric or nitric acid.

Occurs in thin folia, resembling graphite, embedded in kaolin, upon a dark-gray matrix impregnated with pyrite; also associated with wurtzite and with galena. Brought by Theodor Hohmann from South America, exact locality unknown but probably from Bolivia. Stated by Koechlin, Min. Mitth., 24, 114, 1905, to have come from Santa Rosa, Antequera, Bolivia. From analyses by Prior (loc. cit.) of franckeite and cylindrite the following formulæ, showing

their relationships to each other and to teallite, were derived.

$$\begin{array}{ll} Franckeite = 3PbSnS_2 + Pb_2FeSb_2S_8 \\ Cylindrite = 3PbSnS_2 + SnFeSb_2S_8 \end{array}$$

Tellurite, Min., pp. 201, 1049. — Anal. from Good Hope mine, Gunnison Co., Colo.; Headden, [Proc. Col. Sci. Soc., 7, 141, 1903]; Zs. Kr., 41, 203.

Tellurium, Min., pp. 11, 1049. — Crystals from Babia, Asia Minor; Cesàro, Bull. Ac. Belg., 255, 1908.

Analyses, Gunnison and Boulder counties, Colo.; Headden, Proc. Col. Sci. Soc., 7, 139, 1903. From W. Australia; MacIvor, Chem. News, 82, 272, 1900. Occurs in masses three inches across with pyrite, petzite and rickardite (Cu4Te3) at the Good Hope mine at Vulcan, Colorado.

Tellurwismuth, see under Bismuthinite.

TENGERITE, Min., p. 306. — Possible occurrence with gadolinite at Barringer Hill, Llano Co., Texas. Anal. by Hillebrand shows beryllium carbonate. Hidden, Am. J. Sc., 19, 429, 1905.

TENNANTITE, Min., pp. 137, 1049; App., p. 67. — Binnite identical with; see Binnite.

TEPHROITE, Min., p. 457. — Anal. of material from Bendemeer, N. S. W.; Mingaye, White and Greig, [Rec. Geol. Sur. N. S. W., 8, 182, 1905]; Zs. Kr., 43, 623.

Terlinguaite. A. J. Moses, Am. J. Sc., 16, 255, 1903. Hillebrand and Schaller, ibid., 24, 270, 1907.

Monoclinic. Axes $\grave{a}: \dot{b}: \dot{c}=0.5306:1:2.0335$. Schaller gives 1.6050:1:2.0245. $\beta=74^{\circ}$ $16'; 74^{\circ}$ 23' (Schaller). Forms: 133 forms observed. Schaller (priv. contr.) proposes a slightly changed position to the faces, h. k. l. (Moses) becoming 3 h. k. l. (Schaller).

Terlinguaite.

In small prismatic crystals elongated $\|\hat{b}$ and striated in this direction, rarely doubly terminated. Brittle to subsectile. Cleavage perfect | (101). H. = 2-3. G. = 8.725. Luster brilliant adamantine. Color sulphur-yellow with slight greenish tinge, of powder lemon-yellow, both becoming olive-green on exposure. Birefringent. Extinction parallel.

Composition, an oxychloride of mercury, Hg₂ClO; Hg, 88.65; Cl, 7.85; O, 3.50.

Analyses I, J. S. McCord; II, Hillebrand.

0 $(\frac{3}{3})$ 88.24 = 99.60 $(\frac{2}{2})$ 7.89 3.47 II. 88.61 = 100.197.83 3.75

Occurs with eglestonite at the mercury locality at Terlingua, Texas. The name was first used by W. H. Turner (Mining and Scientific Press, July 21, 1900), but the species was established by Moses; it has also been applied by the local miners to a yellow pulverulent material.

Termierite. G. Friedel, Bull. Soc. Min., 24, 7, 1901.

A clay-like substance resembling halloysite. After exposure to the air for some hours it appears in small compact masses with conchoidal fracture and zonal structure; color clear gray, opaque.

H. = 2 approx. G. = 1.21. In thin sections shows birefringence (= 0.002), perhaps due

to original tension.

Adheres strongly to the tongue, but has no argillaceous odor. Absorbs water in large quantity when placed in it, but does not become plastic; when saturated with water the color deepens and the edges become translucent; refractive index then 1.403 and $G_{\cdot} = 1.549$.

Composition, a hydrated aluminium silicate, corresponding to Al₂O₃.6SiO₂.18H₂O when saturated

with water.

Analysis of pure material gave, after ignition:

SiO2 Fe₂O₃(FeO) Al₂O₃ CaO MgO 15.00 78.290.47 = 100.38

Water to the amount of 6.77 $(\frac{2}{2})$ is lost between 110° and the temperature of ignition. Attacked with difficulty by cold hydrochloric acid. Fuses B. B. with difficulty.

Occurs with kaolinite, lassallite (q. v.) and barite in sterile levels of the antimony mines of Miramont, France, in the concession of Souliac on the borders of Cantal and Haute Loire.

Named after Professor Pierre Termier of Paris.

TETRADYMITE, Min., p. 39; App., p. 67. — See Bismuthinite.

TETRAHEDRITE, Min., p. 137; App., p. 67. — Gryst. — From Pulacayo mine, Huanchaca, Bolivia; Spencer, Min. Mag., 12, 325, 1900; Botes-Berge, Hungary, with new form II (655); Zimányi, Zs. Kr., 34, 78, 1900; anal. of material; Loczka, ibid., 84; from marble of Carrara; D'Achiardi, Att. Soc. Tosc. Sc., Mem. 21, 1905; Traversella; Colomba, Rend. Acc. Linc., 15, 643, 1906. Val de Villé, Alsace (with anal.); Ungemach, Bull. Soc. Min., 29, 219, 1906.

Crystals with anal. from Oisans, Dauphiné; from Horhausen, Rhenish Prussia; from Wolfach, Poder with discussion of manufacture and the presented and the prese

Crystals with anal. from Usans, Dauphine; from Horhausen, Rhenish Prussia; from Wolfach, Baden, with discussion of many analyses and the proposal of a new formula, namely $3R'_2S.R'''_2S_3 + x [6R''S.R'''_2S_3]$, where R' = Cu, Ag; R'' = Fe, Zn; R''' = Sb, As, Bi; and x is a small fraction often $= \frac{1}{10}$ and $\frac{1}{5}$, but rising to $\frac{1}{2}$ in the case of the highly ferriferous tetrahedrite, "coppite." Prior and Spencer, Min. Mag., 12, 184, 1899.

Anal. — Campiglia Soana, Ivrea, Piedmont; Novarese, Boll. Com. Geol. Ital., 23, 319, 1902; [Rassegna Min., 18, 17, 18, 1903]; Zs. Kr., 40, 293; Palmavexi, Sardinia; Rimatori, Rend. Acc. Linc., 12, (2), 471, 1903; Boccheggiano, Fannulla valley, Italy; Tacconi, Rend. Acc. Linc., 13, (1), 337, 1904; var. frigidite from Frigido, near Massa, Italy; Manasse, Att. Soc. Tosc., 22, 81–93, 1906. Concerning its regular intergrowth with galena: Zimányi Zs. Kr. 38, 495 Concerning its regular intergrowth with galena; Zimányi, Zs. Kr., 38, 495.

Occurrence at Cobalt, Ont.; Miller, Rep. Can. Bureau Mines, 1905, 2; Zs. Kr., 43, 395.

THALENITE, App., p. 68. — Hillebrand, Am. J. Sc., 13, 145, 1902, shows that formula given by Benedicks is not borne out by his analyses.

Occurrence (with anal.) at Askagen in Värmland, Sweden; Sjögren, G. För. Förh, 28, 93, 1906.

Thaumasite, Min., p. 698; App., p. 68. — Loss of water on heating and discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 11, 1908.

THELLITE (thelline). Name given to Damour's silicate from Brazil, Chem. News, 21, 13, 1870; see Min., p. 512.

THENARDITE, Min., p. 895; App., p. 68. — Occurrence at Itivdlik-Dal, Holstensborg district, Greenland, with anal.; Pjetursson, [Medd. om Grönl., 14, 337, 1898], Min. Grönl., 1905. Thomsonite, Min., pp. 607, 1050; App., p. 68.—**Cryst.**—Scottish localities; Goodchild, [Trans. Geol. Soc., Glasgow, **12**, Suppl., 1-68, 1903]; Zs. Kr., **45**, 307; Petersdorf near Zöptau, Mähren; Kretschmer, Centralbl. Min., 613, 1905; with new form (601) from basalt of East Greenland; Böggild, Medd. om Grönl., 28, 109, 1905; from Mte. Somma with new form (9.10.0); Cesaro, Bull. Ac. Belg., 334, 1907.

Anal. — North Table Mt., Golden, Colo.; Patton, Bull. Geol. Soc. Amer., 11, 461, 1900; Zs. Kr. 36, 74; Schiket, Erythræa; D'Achiardi, Rend. Acc. Linc., 11, (1), 251, 1902; Monte Catini, Tuscany; Manasse, Proc. Soc. Tosc., 15, 20–37, 1906; Inverell, N. S. W.; Anderson, Rec. Aus. Mus., 6, 420,

1907.

Chem. constitution; McNeil, Jour. Amer. Chem. Soc., 28, 600, 1906; Zs. Kr., 44, 531; Zambonini, Mem. Acc. Sci., Napoli, 14, 122, 1908.

Thorianite. W. Dunstan, Nature, 59, 510, 533, 559, 1904. K. Coomáraswámy, Mineralogical Survey of Ceylon, 1904; Dunstan and Jones, [Proc. Roy. Soc., 77, A, 385, 1906], Zs. Kr., 45, 286; E. H. Büchner, Proc. Roy. Soc., 78, A, 385, 1906.

Isometric; in cubic crystals, usually more or less water-worn. G. = 9.32. Color black. The Composition of Thorianite. — Earlier analyses of the rare mineral thorianite from Ceylon,

remarkable for its radioactive properties, have been more or less incomplete. An exhaustive chemical examination of this species has now been made by E. H. Büchner, loc. cit. The quantity taken for analysis was 24.373 grams; this was divided by treatment with boiling nitric acid into a soluble and an insoluble portion, these having about the ratio of 40:1. The analyses of the soluble portion gave:

ThO ₂ 70.96	U_3O_8 13.12	${ m ZrO_2} \ 0.23$	${ m SnO_2} \ 0.05$	${ m Sb_2O_4} \ 0.11$	$\mathrm{Bi_2O_3}$? 0.21	As_2O_3 ? tr .		
Ce ₂ O ₃ 1.96	${ m Fe_2O_3} \ 2.05$	$Al_2O_3 \\ 0.15$	PbO 2.46	CuO 0.08	HgO tr.	CdO?	CaO 0.13	Residue

The insoluble portion gave:

The amount of helium yielded from 1 gram was 8.2 c.c. under normal conditions.

The radioactivity of the mineral was found to be 83.3 per cent of standard uranium oxide, a sample several years old. This activity belongs almost entirely to the soluble portion, the ratio of activities being about 300: 1. The radioactivity of the several precipitates was minutely studied; nearly all showed activity except the alumina, which was absolutely inactive. Calling the activity of the mineral 100, that of the ThO₂ was 57.2, of the U₃O₈, 6.6 (later, after several weeks, 9.4), of Fe₂O₃, 4.6 (later 5.7), etc.

Obtained from the gem washings of Balangoda, Ceylon, near Kondrugala in Bambarabotuwa, Sabaragamuya, derived from intrusive granitic rocks and associated with thorite, allanite, baddeley-

ite, giekelite and cassiterite.

Also reported from pegmatite at Gampola, Ceylon.

See under Uraninite.

THORITE, Min., pp. 488, 1050; App., p. 68. — See under *Uraninite*.

Anal. from New South Wales; Harker, Jour. Roy. Soc. N. S. W., 33, 193, 1899; Zs. Kr., 34, 213; from Colorado; Tschernik [Verh. russ. min. Ges., 42, 51, 1904]; Zs. Kr., 43, 69.
Occurrence near Ouro Preto, Brazil; Derby, Am. J. Sc., 11, 25, 1901.

TORBENITE, Min., p. 856; App., p. 69. — Etching figures made by cold acid indicate normal tetragonal symmetry, differing from Walker's results (App. I, p. 69). Strong absorption shown. On heating mineral to 60°-65° it loses water and becomes normal tetragonal, optically positive; on further heating to 100° it loss more water and becomes orthorhombic (metakupferuranite). Rinne, Centralbl. Min., 618, 1901.

Analysis by Buchholz, Centralbl. Min., 362, 1903, showed 12 molecules of water instead of 8.

It was found that 4 were lost in desiccator and 8 on heating.

Occurrence near Ambert, Puy-de-Dôme; Boubée, Bull. Soc. Min., 28, 243, 1905.

Torrensite. H. Lienau, Chem. Ztg., 23, (1), 418, 1899.—A compact reddish gray to sepia-colored material occurring with rhodonite at Torrens Mine, Hautes-Pyrénées. Formula given as MnSiO₃.MnCO₃.½H₂O. Lacroix, Bull. Soc. Min., 23, 254, 1900, considers it a mixture of rhodochrosite and rhodonite.

Tourmaline, Min., pp. 551, 1050; App., p. 69. — Cryst. — Twin from Nertschinsk, Siberia; Glinka, [Verh. russ. min. Ges., 35, 75, 1897]; Zs. Kr., 31, 509; chrome-tourmaline from Beresowsk; Wernadsky, [C. R. Soc. Nat. Moscow, 4, 4, 1897]. Exhaustive study of the crystallization, pyroelectricity, etc., of tourmaline with long table of angles. Description of crystals from Ceylon; Dekalb, N. Y.; Lincoln Co., N. C.; Gouverneur, N. Mag., 13, 108, 1902; Montefano, Italy; Tacconi, Rend. Acc. Linc., 12, (1), 355, 1903; in chalcopyrite from Bedovina, Monte Mulatto, Tyrol; Hofmann, Ber. böhm. Ges. Wiss., xvi, 1904; Campolongo, Tessin; Mann, [Inaug.-Diss., Leipzig, 1904]; Zs. Kr., 42, 665; crystals of gem quality on Kangaroo Island, South Australia; Anderson, Rec. Aus. Mus., 5, 302, 1904; Tasna, Potosi, Bolivia; Min. Mag., 14, 333, 1907; Madagascar; Lacroix, Bull. Min. Soc., 31, 218, 1908.

Trechmannite. R. H. Solly, Min. Mag., 14, 75, 1905; 189, 1906; G. F. Herbert Smith and G. T. Prior, ibid., 14, 300, 1907.

Rhombohedral; tetartohedral. Axis $\dot{c} = 0.6530$.

Thirty forms have been observed, the more important being: c (0001), m (1010), D (2570), a (11 $\bar{2}$ 0), e (10 $\bar{1}$ 2), s (20 $\bar{2}$ 1), r (10 $\bar{1}$ 1), α (40 $\bar{4}$ 1), n (14 $\bar{5}$ 3), v (12 $\bar{3}$ 1), z (24 $\bar{6}$ 1), g (35 $\bar{8}$ 4), ζ (35 $\bar{8}$ 1), p (1123).

Crystals very small with prismatic habit, often irregular. Cleavage, $r \operatorname{good}$, $c \operatorname{distinct}$. Fracture, conchoidal. Brittle. H. = $1\frac{1}{2}$ -2. Luster, adamantine. Color and streak scarlet-vermilion. Transparent to translucent. Double refraction, fairly strong; negative. Pleochroism weak.

Composition stated to be AgAsS₂ (G. T. Prior).

Occurs very sparingly implanted upon tennantite (binnite) in the white dolomite of the Lengenbach quarry, in the Binnenthal, Switzerland.

This name is also used by Koechlin for an undescribed mineral from the Binnenthal, Min. petr.

Mitth., 23, 552, 1904.

Named after Dr. C. O. Trechmann.

TRIDYMITE, Min., p. 192. — Crystals from Ishigamiyama, Prov. Higo, Japan; Wada, Bei. Min. v. Japan, 1, 17, 1905; Zs. Kr., 43, 624.

Study of genesis of tridymite in volcanic rocks of Mt. Pelée, Martinique; Lacroix, Bull. Soc.

Min., 28, 56, 1905; from Vesuvius, id., ibid., 31, 323, 1908.

Artif. formation of tridymite and quartz; Day and Shepherd, Am. J. Sc., 22, 273, 1906. Formation by action of lightning on roofing slate; Schwantke, Centralbl. Min., 87, 1904.

TRIPHYLITE, Min., p. 756; App., p. 69. — Intergrown with graftonite from Grafton, N. H.; Penfield, Am. J. Sc., 9, 20, 1900.

TRIPLITE, Min., p. 777.—Anal. of material from Lilla Elgsjöbrottet, Östergötland, Sweden; Nordenskjöld, G. För. Förh., 24, 412, 1902; Skrumpetorp, Östergötland, Sweden; Hamberg, G. För. Förh., 26, 77, 1904.

Occurrence with alteration products at Vienna and Cyrillhof, Mähren, with anal.; John, [Verh. geol. R.-Anst. Wien, 50, 335, 1900, and Kovář and Slavík, ibid., 347]; Zs. Kr., 36, 641, 642.

TRÖGERITE, Min., p. 859. — Study of crystals from Schneeberg shows that they are apparently tetragonal; $\dot{t}=2.16$. Forms: o (001), n (010), Σ (120), y (012), P (011), h (032), i (021), t (111), u (331). Optically it is monoclinic in symmetry. Author considers mineral tetragonal with optical anomalies. Goldschmidt, Zs. Kr., **31**, 468, 1899.

TRONA, Min., p. 303. — Crystals with new form (102) from Vesuvius; see under Vesuvius; from Natroun lakes, Egypt; Couyat, Bull. Soc. Min., 31, 343, 1908.

TSCHERMIGITE, Min., p. 952. — New occurrence in cubes from Brüx, Bohemia, with anal.; Sachs, Centralbl. Min., 465, 1907; from Schellenken, near Dux, Bohemia; Cornu, ibid., 467.

Tschernichewite, an Amphibole, which see.

Tungstire, Min., p. 202. — Tungstic ocher from a gold quartz vein near Salmo, B. C., apparently identical with Silliman's tungstite, gave an analysis leading to formula, WO₃·H₂O. Only minute crystals observed possessing one perfect cleavage with biaxial interference figure when viewed perpendicular to cleavage. Author considers meymacite and tungstite to be identical and as having above formula. Walker, Am. J. Sc., 25, 305, 1908.

Turgite, Min., p. 245. — Occurrence in iron ore mines of central Russia; Samojloff, [Proc. Soc. Imp. Nat. Moscow, Nr. 6-9, 14-24, 1899]; Zs. Kr., 34, 701.

Turquois, Min., p. 844; App., p. 70. — Penfield, Am. J. Sc., 10, 346, 1900, by a new analysis of material from Lincoln Co., Nev. (see below), and a discussion of older analyses, arrives at the conclusion that turquois is a derivative of orthophosphoric acid as follows: [Al(OH)₂,Fe(OH)₂, Cu(OH),H]₂PO₄.

Tychite. S. L. Penfield and G. S. Jamieson, Am. J. Sc., 20, 217, 1905.

Isometric, in small white octahedrons associated with northupite, but very rare. G. = 2.456 (Pratt). Index $n_y = 1.508$.

Artificial crystals, believed to be identical in composition, occur also in octahedrons, with

H. = 3.5; G. = 2.588; index $n_y = 1.510$.

Composition. Qualitative tests showed the natural mineral to be a carbonate and sulphate of magnesium and sodium. Artificial crystals, formed in a manner similar to those by which the associated northupite was obtained (cf. de Schulten, Bull. Soc. Min., 19, 164, 1896), have the formula, 2MgCO₃.2Na₂CO₃.Na₂SO₄, which is doubtless also that of the natural mineral. The formula of northupite (doubled for comparison) is similar, viz., 2MgCO₃.2Na₂CO₃.2NaCl. Cf. Appendix I, p. 49. Analyses of artificial crystals:

SO ₃	CO_2	MgO	Na ₂ O
1. 15.08	33.55	15.83	35.49 = 99.95
2. 15.06	33.45	15.77	35.65 = 99.93

Penfield and Jamieson in addition to the artificial tychite obtained also a third octahedral compound. The probable formula (written to show the relation to the above) is 2MgCO_3 . $2 \text{Na}_2 \text{CO}_3$. The three compounds are thus analogous, with 2CO_3 or 2CO_3 or responding.

From Borax lake, San Bernardino county, California, obtained with northupite (App. I, p. 49) which it resembles in form and composition (cf. above). It is, however, extremely rare. The examination of some five thousand specimens revealed only four crystals of tychite, the remainder being northupite; by a lucky chance the first crystal tested, of a lot of supposed to be northupite, proved to be a different mineral, and this led to the discovery of this new species, hence its name from τυχή, luck or chance.

Isomorphism with northupite, which see.

ULEXITE, Min., p. 887. — Opt. study; Buttgenbach, Ann. Soc. Geol. Belg., 28, 99, 1900-1901. Synthesis of; de Schulten, C. R., 132, 1576, 1901.

URANINITE, Min., p. 889; App., p. 70. — Anal. of bröggerite; Hofmann and Heidefriem, Ber. Ch.

Ges., 34, 914, 1901.

On radioactive substances in; Debierne, C. R., 129, 593, 1899; Am. J. Sc., 9, 143, 1900. Radioactivity of; Barker, Am. J. Sc., 16, 163, 1903. Ratio of radium to uranium; Boltwood, ibid., 18, 97, 1904. Lead and helium as disintegration products of uranium in uraninite, mackintoshite, yttrocrasite, samarskite, annerodite, thorite, orangite, xenotime, hielmite, polycrase and thorianite. Boltwood, ibid., 23, 77, 1907.

Occurrence at St. Joachimsthal, Bohemia; Step, Ber. Akad. Wien, 113, 585, 1904; at Evje,

Sätersdalen, Norway; Schei, [Nyt. Mag., 43, 137, 1905]; Zs. Kr., 43, 639.

Uranophane, Min., p. 699. — Ratio of radium to uranium; Boltwood, Am. J. Sc., 18, 97, 1904. Occurrence at Villeneuve, Ottawa Co., Province of Quebec; Hoffmann, Am. J. Sc., 11, 152, 1901; from Stone Mountain, Ga. (with anal.); Watson, ibid, 13, 464, 1902.

URANOSPINITE, Min., p. 858. — Artif. proven to be optically uniaxial and tetragonal; Goldschmidt, Zs. Kr., 31, 478, 1899.

UTAHITE, Min., p. 966. — Crystals from Santa Rosa Mine, Guanaco, Taltal, Chile. Measured angles not in complete agreement with earlier observations, giving new ratio, c = 1.0576. Anal. Arzruni and Thaddéeff, Zs. Kr., 31, 234, 244.

VALENTINITE, Min., p. 199. — Crystals from S. Suergin, Sardinia; Millosevich, Rend. Acc. Linc., 9, (1), 340, 1900; from Sardinia with new forms, c (001), n (17.7.0), t (4.6.21); Pelloux, Rend. Acc. Linc., 13, (2), 34, 1904; from Tatasi, Bolivia, with discussion of axial ratio; anal.; Spencer, Min. Mag., 14, 328, 1907.

Occ. at Cetine di Cortorniano, Rosia, Siena; Pelloux, Rend. Acc. Linc., 10, (2), 10, 1901; at Procchio, Elba; Cornu and Himmelbauer, [Mitth. Nat. Ver. Wien, 3, 9-19, 1905]; Zs. Kr., 44, 299.

Relations to senarmontite, which see.

Vanadinite, Min., p. 773. — Study of crystals from Hillsboro, N. M., showing following new forms: g (31 $\overline{40}$); f (51 $\overline{60}$), δ (50 $\overline{54}$), γ (40 $\overline{43}$), α (30 $\overline{32}$), β (50 $\overline{53}$), π (40 $\overline{41}$), ξ (41 $\overline{54}$), i (21 $\overline{32}$), e (32 $\overline{53}$), i (32 $\overline{52}$), i (52 $\overline{72}$), i (41 $\overline{52}$)?. Anal.; Goldschmidt, Zs. Kr., **32**, 561, 1900; from near Saïda, Oran, Algiers; Lacroix, Bull. Soc. Min., **31**, 44, 1908.

Refractive indices; Bowman, Min. Mag., 13, 324.

Occurrence (with anal.) from Bena e Padru near Ozieri, Sardinia; Lovisato, Rend. Acc. Linc., 12, (2), 81, 1903; also ibid., 13, (2), 43, 1904.

Botryoidal from Broken Hill mines, N. W. Rhodesia; Spencer, Min. Mag., 15, 33, 1908.

Artif. formation of corresponding cadmium compounds; de Schulten, Bull. Soc. Min., 23, 7, 1900.

K. Kubierschky, Ber. Ak., Berlin, 407, 1902; Bull. Soc. Min., 28, 34, 1905. Vanthoffite. Almost colorless crystalline (without observed faces) material found associated with other salts at Wilhelmshall, near Stassfurt, and isolated by means of heavy solutions.

Comp., 3Na₂SO₄.MgSO₄. Artif. prepared by J. H. van't Hoff, from whom it has been named.

See also for discussion of origin, etc., van't Hoff and others in Ber. Ak. Berlin, 499, 1903; 518, 576,

659, 1904.

Vesuvianite, Min., p. 477; App., p. 71. — Cryst. — Crystals from Monzoni, with new forms (552), (631); Buttgenbach, Ann. soc. geol. Belg., 25, evi, 1898; Pian Real, Piedmont; Boeris, Att. Soc. Ital. Sc. Nat., Milano, 42, 45, 1903; Comba Robert near Avigliani, Piedmont; Boeris, Att. Acc. Napoli, 38, 685, 1903; near Leffe, Bergamo; Tacconi, Rend. Roy. Inst. Lomb., 36, 899, 1903; Alley Point, Nundle, N. S. W.; Anderson, Rec. Aus. Mus., 5, 301, 1904; skeleton-like crystals from Maneetsok, Greenland; Böggild., Min. Grönl. 272; crystals from Barraba, N. S. W.; Anderson, Roy. Mus. Mus. 6, 415, 1907; Serdinia, Polleyr, Pord Acc. Line 17, (2) 70, 2009; exc. intendictions of the company of the com Rec. Aus. Mus., 6, 415, 1907; Sardinia; Pelloux, Rend. Acc. Linc., 17, (2), 70, 1908; associated with bornite from Susa, Piedmont; Zambonini, Zs. Kr., 45, 143, 1908.

Relations between optical character and chemical composition; Klein, Ber. Ak. Berlin, 653, 1904. Anal. of material from the Matterhorn and correction of many old analyses by new water determinations with discussion of chem. comp., formula derived being (Ca,Mn,Mg,Fe)₂,(Al,Fe) (OH,F)Si₂O₇. Weingarten, [Inaug.-Diss., Heidelberg, 1901]; Centralbl. Min., 726, 1902.

Occurrence (with anal.) from Silver Peak quadrangle, Esmeralda Co., Nev.; Turner, Am. J. Sc., 13, 345, 1902; from near Bear Mt., west of Pinos Altos, Grant Co., N. M.; Moses, ibid., 12, 104, 1901.

Californile is a closely compact variety of an olive-green to grass-green color, subtranslucent, luster vitreous to resinous; it resembles jade (nephrite) and like that species takes a high polish; H. = 6.5; G. = 3.286. An analysis by F. W. Clarke gave:

SiO2 $\begin{array}{c} \mathrm{Al_2O_3} \\ 18.35 \end{array}$ Fe_2O_3 FeO MnO CaO MgO TiO. $\frac{P_2O_5}{0.02}$ 33.5 35.85 1.67 0.39 0.05 5.43 0.10 4.47* = 99.85

* 0.29 p. c. H₂O below 100° C. included.

From the South Fork of Indian Creek, 12 miles from Happy Camp and 90 miles from Yreka Siskiyou Co., California; it is associated with precious serpentine. Similar occurrences are reported from Burro valley, Fresno Co., and from Tulare Co. near Selma (in Fresno Co.). G. F. Kunz, Trans. N. Y. Acad. Sci., Oct. 19, 1903; Am. J. Sc., 16, 397, 1903. On a similar variety of vesuvianite from the Engadine, see Min., p. 480.

VESUVIUS. Minerals found at the eruption of April, 1906, include the following; cotunnite, tenorite, gypsum, hematite, aphtithalite, sulphur in crystals, realgar in crystals, galena, pyrite, chalcopyrite, pseudocotunnite, anglesite in crystals, chalcanthite, sylvite, halite, mirabilite, schönite, cyanochroite, metavoltine, amphibole in crystals, sodalite in crystals, microsommite, cavolinite, thermonatrite, trona; Zambonini, Rend. Acc. Linc., 15, (2), 235, 1906; Att. Acc. Sc. Napoli, 13, No. 8, 1906; see also Lacroix, C. R., 143, 727, 1906; Bull. Soc. Min., 30, 219, 1907; ibid., 31, 260, 1908.

 $\begin{tabular}{lll} \hline \textbf{Viellaurite.} & \textit{H. Lienau}, \textit{Chem. Ztg., 23}, (1), 418, 1899. — A massive, dark-gray material from near Vielle-Aure, Hautes-Pyrénées, to which the formula, <math>5 \text{MnCO}_3.2 \text{Mn}_2 \text{SiO}_4$ was assigned. Lacroix examined the material microscopically and proved that it was an intimate mixture of tephroite and rhodochrosite; Bull. Soc. Min., 23, 253, 1900.

Villiaumite. A. Lacroix, C. R., 146, 213. — Isometric. In small grains of a carmine color. Softer than calcite. Sp. G. = 2.79. $n_{\text{Na}} = 1.328$.

Comp.: - Sodium fluoride. Found as a constituent of a nepheline-syenite from the Islands of Los off the coast of Guinea. Named in honor of the explorer Villiaume.

Violaite, see under Pyroxene.

VIVIANITE, Min., p. 814; App., p. 71. — Crystals from Guatemala formed by transformation of bones; Gaubert, Bull. Soc. Min., 27, 212, 1904; from Tatasi and Tasna, Bolivia, with new form h (250) and some doubtful ones. Spencer, Min. Mag., 14, 324, 1907; Silver City, Idaho; Farrington and Tillotson, Field Col. Mus., Geol. Series, 3, No. 7, 163, 1908.

A vivianite containing small quantities of manganese and magnesium has been called paravivianite by S. Popoff (Centralbl. Min., p. 112, 1906). Occurs in radiated acicular crystals with blue color and streak. H. = 2-2.25. G. = 2.66-2.67. Composition, R₃P₂O₈ + 8H₂O with R = Fe,Mn,Mg.

Analysis:

 P_2O_5 FeO MnO MgO CaO H,O 27.01 39.12 2.01 1.92 0.48 [29.46] = 100

Occurs in the limonite deposits of the peninsulas of Kertsch and Taman, Gov't Taurien.

Voglite, Min., p. 308. — A mineral near voglite from Utsch-Kirtan mountain pass, Fergana, Siberia, with anal.; Antipoff, [Verh. russ. min. Ges., 1900, Prot. 38]; Zs. Kr., 36, 175.

Vogtite, see Rhodonite.

E. Cumenge, Bull. Soc. Min., 22, 25, 1899. A telluride of silver and bismuth. Von Diestite. Analysis by Knight:

Bi Te Pb Insol. Au 34.60 4.30 2.25 0.54 0.54 16.31 = 98.79

Occurs in threads associated with copper minerals and auriferous pyrite in the Hamilton and Little Gerald mines, on Mt. Sierra Blanca, Col. Named from Mr. von Diest, director of the Lead Mining Co., San Luis, Col.

WARRENITE, Min., p. 120. — Considered to be identical with jamesonite, which see; Spencer, Min. Mag., 14, 207.

Wavellite, Min., p. 842; App., p. 71. — From Manziana, Province Rome, Italy, with anal.; Zambonini, Rend. Acc. Linc., 11, (1), 123, 1902.

Weinbergerite; F. Berwerth, Min. Mitth., 25, 181, 1906; Zs. Kr., 45, 425.

A silicate occurring in spherical aggregates of radiating fibers found in meteoric iron at Codai al, Palni Hills, Madras, India. Orthorhombic. Black color. Harder than glass. a = c,

A silicate occurring in spirite a aggregates of radiating fives to the state of the small amounts of apatite and chromite. The result is, SiO₂, 45.31; FeO, 39.44; Al₂O₃, 10.04; Na₂O, 5.21. The following formula is proposed: NaAlSiO₄ + 3FeSiO₃.

Named in honor of J. Weinberger in Vienna.

Whewellite, Min., p. 993; App., p. 72. — Crystals from Burgk, near Dresden, showed following new forms: ν (250), a (100), d (032), α (031), g (111), γ (122), A (321), B (341), β (131), C (651), δ (238) and a new twinning plane a (100); on crystals from Grube Himmelsfürst near Freiberg, Saxony, following new forms: ν (250) and ϵ ($\bar{1}14$); and on crystals from Zwickau, ν (250), ξ ($\bar{2}11$), η (211); Kolbeck and Goldschmidt, Centralbl. Min., 659, 1908.

WHITNEYITE, Min., p. 45. — An intimate mixture of whitneyite and mohawkite (mohawkwhitneyite) found in considerable quantities at the Mohawk mine, Keweenaw Co., Michigan, has been described by Koenig, Am. J. Sc., 10, 446, 1900. In tough masses, gray and fine granular to hackly on fresh fracture, tarnishing to dull brown or olive-green. Appears homogeneous to the eye, but different samples gave varying amounts of copper (79.36, 83.61, 84.86, 85.36) and arsenic (13.06 to 15.07). Koenig refers here the mohawkite of Ledoux. See *lédouxité*. Cf. also Koenig, Am. J. Sc., **14**, 416, 1902.

Willemite, Min., p. 460; App., p. 72. — Crystals from Musartut, Greenland, with new forms (5270) and (3121); Böggild, Min. Grönl., 276. Occurs sparingly in stout hexagonal prisms of a grayish color on a garnet rock on Modoc Mt., Clifton-Morenci district, Arizona; Lindgren and Hillebrand, Am. J. Sc., 18, 451, 1904; hemimorphic tetartohedral crystal from Stirling Hill, N. J.; Canfield, Am. J. Sc., 23, 20, 1907. Crystals associated with dioptase at Mindouli, French Congo; Lacroix, Bull. Soc. Min., 31, 257, 1908.

Refractive indices; Gaubert, Bull. Soc. Min., 30, 108, 1907.

From Algeria and the Congo; Lacroix, Bull. Soc. Min., 23, 255, 1900.

Winchite, var. of amphibole, which see.

WITTICHENITE, Min., p. 128. — See under Dognacskaite.

Wöhlerite, Min., p. 376. — Occurrence in syenite at Red Hill, N. H.; Pirsson and Washington, Am. J. Sc., 23, 270, 1907.

Wolchonskoite, Min., p. 696. — Occurrence (with anal.) at Uchtym, Wjatka, Russia; Krotow, [Verh. russ. min. Ges., 40, 1, 1903]; Zs. Kr., 39, 609.

Wolframite, Min., p. 982; App., p. 73. — Crystals from So. Dakota and pseudomorphs after scheelite from Trumbull, Ct.; Warren, Am. J. Sc., 11, 372, 1901; crystals from Wild Kate mine near Deepwater, N. S. W.; Anderson, Rec. Aus. Mus., 5, 303, 1904; from Boulder Co., Colo., with new

occurrence in Yellow Creek, Black Hills, S. D.; Irving, Trans. Amer. Inst. Min. Eng., 31, 683, 1902; from Nurri and Orroli, Cagliari, Sardinia; Lovisato, Rend. Acc. Linc., 16, (1), 632, 1907; from Nagpur Dist., Central Provinces, India; Fermor, Rec. Geol. Sur. India, 36, 301, 1908.

Wollastonite, Min., pp. 371, 1052; App., p. 73.—Anal. (Christensen) of material from Marraks Elv, Greenland; Böggild, Min. Grönl., 386; from Monte Castelli, Tuscany; Manasse, Proc. Soc. Tosc., 15, 20-37, 1906.

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull. 207, 1902; Zs. Kr.,

38, 696.

Effect of radium emanations upon; Baskerville and Lockhart, Am. J. Sc., 20, 95, 1905.

Artif. formation; Allen, White, Am. J. Sc., 21, 89, 1906. Occurrence at Santa Fé Mine, Chiapas, Mexico; Collins, Min. Mag., 13, 356, 1903; with gold and platinum on Singenggoe river, Sumatra; Hundeshagen, Chem. News., 90, 77, 1904.

Wulfenite, Min., p. 989; App., p. 73. — Cryst. — Sarrabus, Sardinia; Tacconi, Zs. Kr., 32, 498, 1900; Rend. Acc. Linc., 9, (1), 22, 1900; Laorca; Artini, Rend. Roy. Inst. Lomb., 33, 1179, 1900; Gaeta, Lake Como; Repossi, Att. Soc. Milano, 43, 432, 1905; Bleiberg, Kärnten, Austria; Cesaro, Bull. Ac. Belg., 331, 1905; with dioptase from Mindouli, French Congo; Bull. Soc. Min., 31, 257, 1908. Study of symmetry points to its belonging to hemimorphic tetartohedral class; Johnsen, Cen-

Artif. formation; Cesàro, Bull. Ac.-Belg., 327, 1905. Occ. at Gennamari, Sardinia; Pelloux, Rend. Acc. Linc., 9, (2), 13, 1900; at the Collioux mine near St. Luc, Val d'Anniviers, Switzerland; C. Schmidt, Ecl. G. Helvetiæ, 7, 139, 1901.

WURTZITE, Min., pp. 70, 1051; App., p. 74. — Relations to sphalerite, which see. Occurs in Tasmania, at the Hercules mine, Mt. Read, and at the Magnet silver mine, Magnet; W. F. Petterd, Notes on Tasmanian Minerals, priv. publ.

Xalostocite, a garnet, which see.

Xanthophyllite, Min., p. 639; App., p. 74. — Discussion of chem. comp.; Zambonini, Mem. Acc. Sci. Napoli, 14, 31, 1908.

Effect of ammonium chloride upon; Clarke and Steiger, U. S. G. S., Bull. 207, 1902; Zs. Kr.,

38, 697.

Xenotime, Min., p. 748; App., p. 74. — Crystals from Pisek, Bohemia; Krejčí, Ber. böhm. Ges. Wiss., xliv, 1899. Crystals from Nil-Saint-Vincent, Brabant; Prinz, Bull. Ac. Belg., 318, 1904.

Analyses of material from Idaho (?); Tschernik [Verh. russ. min. Ges., 42, 9, 1905]; Zs. Kr.,

43, 68.

See under uraninite.

Hussakite. A xenotime from Dattas, Brazil, was described by Kraus and Reitinger, Zs. Kr., 34, 268, 1901, as containing over 6% SO₃ and given the species name hussakite. Later analyses on the same material, Hussak, Centralbl. Min., 533, 1907, failed to confirm the large amount of SO₃, only 0.11% being found, so that the name must be withdrawn. Analyses of octahedral crystals from Bandeira do Mello and Saō Paulo, Brazil, showed only small amounts of SO₃; 2.68% and 1.19%; Hussak and Reitinger, Zs. Kr., 37, 563. Brögger [Nyt. Mag. Naturvid., 42, 1, 1904]; Zs. Kr., 41, 429, discusses composition of xenotime and in anal. of crystal from Arö by Heidenreich no trace of SO₃ could be discovered. Hussakite identified as a rock constituent; Rösler, Zs. Kr., 36, 258, is stated by Hussak, l. c., to have been zircon.

YTTRIALITE, Min., p. 512. — Discussion of chem. comp. with new analysis; Hillebrand, Am. J. Sc., 13, 145, 1902.

Occurrence of eighteen-pound mass at Barringer Hill, Llano Co., Texas; Hidden, ibid., 19, 425,

1905.

YTTROCERITE, Min., p. 182. — Anal. of material from Colorado; Tschernik, [Verh. russ. min. Ges., **42**, **51**, 1905]; Zs. Kr., **43**, 69.

Yttrocrasite. W. E. Hidden and C. H. Warren, Am. J. Sc., 22, 515, 1906; Zs. Kr., 43, 18. Orthorhombic. Rude crystal found showing three pinacoids, unit prism and one orthodome. Resembled fig. of yttrotantalite, Min., p. 738. Fracture uneven and small conchoidal. H. = 5.5-6. G. = 4.8043. Black in color with bright pitchy to resinous luster. In thin splinters of the prisman of the under microscope, rich amber to light yellow color, and with crossed nicols shows a mixture of isotropic and a feebly doubly refracting material.

Comp., a hydrous titanate of the yttrium earths and thorium.

Anal. gives approximately 1R¹¹O, 3R¹¹¹2O₃, 1R¹¹³O₂, 16TiO₂, 6H₂O. Anal. (Warren):

TiO, Nb2O5 Ta2O5 WO3 UO. SiO, CO2 (Yt,Er)2O3 Ce2O3, etc. Fe₂O₃ 49.72 1.87 0.640.68 25.67 2.92 1.44 present tr. tr. UO_2 1.98ThO2 PbO CaO H_2O H₂O MnO MgO 4.36 8.75 0.48 0.13 1.83 0.10 = 100.57tr.

C. T. decrepitates Pyr. B. B. infus., assumes dark gray color and cracks open to slight extent. slightly, gives off H₂O and CO₂. Decomposed by HF. Fine powder sol. with slight effervescence in H₂SO₄; on addition of HCl and Zn a violet color is first obtained, changing to blue gray and deep blue.

Occ. Found in Burnet Co., Texas, three miles east of Barringer Hill. See under Uraninite.

YTTROTANTALITE, Min., p. 738. — Occurrence in southern Norway with anal. by Blomstrand; Brögger, Min. Süd-Nor. Granitpeg., 152, 1908.

ZARATITE, Min., p. 306. — Occ. at Igdlokunguak, Greenland; Böggild, Min. Grönland, 176.

ZEAGONITE, see under Gismondite.

Zeolites, Min., pp. 570-610; App., p. 74. — Chemical constitution; Zambonini, [Mem. Acc. Linc., 5, 344, 6, 102, 1905]; Zs. Kr., 43, 395; Mem. Acc. Sci. Napoli, 14, 88-127, 1908; Ferro, Rend. Acc. Linc., 14, (2), 140, 1905; Baschieri, Proc. Soc. Tosc., March, 1907; Att. Soc. Tosc., 24, 1908; Panichi [Pubbl. R. Ist. Firenze, 1908]; Zambonini, Rend. Acc. Linc., 18, (1), 67, 1909.

Loss of water on ignition as means of identification; Goldschmidt and Hermann; Jb. Min., 1,

Occurrence in Scotland; Goodchild, [Trans. Geol. Soc. Glasgow, 12, Suppl., 1-68, 1903]; Zs. Kr.,

45, 305.

An apparently new zeolite from granite of Baveno, described by Artini; Rend. Acc. Linc., 10, 139, 1901. Monoclinic with apparent orthorhombic symmetry on account of twinning on (100). à : \vec{b} : \vec{c} = 1.1751 : 1 : 0.7845; β = 89° 17¼'. Forms (100), (101), (210), ($\overline{1}$ 01), ($\overline{1}$ 03). Angles: (100) \wedge (110) = 49° 36′; ($\overline{1}$ 00) \wedge ($\overline{1}$ 01) = 56° 46′; ($\overline{1}$ 03) \wedge ($\overline{1}$ 00) = 78° 8′. In radiating aggregates. Color white. Ax. pl. \perp b (010); Bxac \perp b (010). 2VNa = 47° 13′; β = 1.58. Formula given as Ca₃Al₂Si₆O₁₈·H₂O. Analysis:

SiO ₂ 56.93	Al_2O_3	CaO	MgO	Na ₂ O	H_2O
56.93	15.42	24.47	0.12	$0.\bar{2}9$	2.49 = 99.72

Fuses easily with intumescence.

Zeolite mimetica. D'Achiardi, Proc. Soc. Tosc., 14, 150, 1905; 22, 160, 1906; Zs. Kr., 43, 491; 44, 664.

A zeolite from pegmatite at San Piero, Campo, Elba, in small 8 sided prismatic crystals. Easily cleavable parallel to prism faces. Section perpendicular to prism shows a mimetic structure with a division into 8 sectors. White to colorless. H. = 4-4.5. G. = 2.165. B. B. decrepitates, exfoliates and fuses to white enamel. Decomposed by HCl. Formula proposed: $R^{II}_{2}R^{III}_{4}(Si_{2}O_{5})_{9}$, 14H₂O. $R^{II} = Na_{2}$, K_{2} , Ca; $R^{III} = Al$. Analysis:

Author considers it probably a new species, names it for the present "Zeolite Mimetica," but in case future investigation confirms its individuality proposes the name "darchiardite" in honor of his father.

A New Zeolite. A. Pauly, Zs. Kr., 42, 370, 1906. A zeolite occurring associated with quartz, feldspar, and sericite in a rock lying between a dolomite and a granite at Hainburg, Austria, is considered as a new species with the following characteristics. Isometric, in microscopic grains. Colorless and transparent. Cleavage \parallel (100). H. = 3-4. G. = 2.4-2.5. $n_{\rm Na} = 1.507-1.508$. Gives qualitative tests for Na, Ca, Al, SO₄, Si and H₂O. Gelatinizes with HCl. Fuses at 1-2, with intumescence, to a colorless glass. Colors flame yellow.

Zeophyllite. A. Pelikan, Sitz.-ber. Ak. Wien, 111, (1), 334, 1902. F. Cornu, Min. petr. Mitth., 24, 127, 131, 207, 1905. R. Zimmermann, Centralbl., Min., 245, 1905. Rhombohedral. In spherical or half-spherical forms with radiated foliated structure; these show indistinct rhombohedral faces inclined 78° to c.

Cleavage basal, perfect. Dilute hydrofluoric acid yields ditrigonal etching figures; trigonal

contraction figures also appear (Cornu) after etching with hydrochloric acid. H. = 3. G. =

2.764. Luster pearly.

Color white, colorless in thin sections. Translucent. Refractive index $\omega=1.5$ approx., 1.545 (Cornu). Birefringence. A uniaxial center surrounded by a biaxial border (2 E to 27½°); becomes permanently uniaxial on heating.

Analyses Zdarek:

Occurs with natrolite in basalt at Gross-Priessen, Bohemia, north of Leitmeritz and east of Aussig; also (Cornu, Zimmermann) at Radzein, Bohemia, in the amygdaloidal cavities of a leucitetephrite with calcite, apophyllite, etc.

Cornu refers the gyrolite of the Hebrides, Poonah, etc., to zeophyllite, Centralbl. Min., 80, 1906. New localities, Kreibitz near Rumburg, Scharfenstein near Bensen, and Leipa in Bohemia.

Cornu, Centralbl. Min., 80, 1906. See Gyrolite.

Zeyringite. [Pantz, 1811. Taschenb. Min. (Leonhard), 5, 373], Min. Mag., 14, 414. A finely fibrous, greenish-white or sky-blue calcareous sinter containing nickel, from Zeyring, Styria. Placed under aragonite by Zepharovich (Min. Lexicon Österreich, 1, 28, 1859) and Hatle (Die Minerale des Herzogthums Steiermark, 68, 1885); the latter spells zeiringite.

ZINC, Min., pp. 14, 1052. — Crystals formed by electrolysis of zinc chloride; Saposchnikoff, [Jour. soc. physico-chimique russe, 37, 153, 1905]; Zs. Kr., 44, 94.

ZINCITE, Min., p. 208; App., p. 74. — Artif. crystals from furnace at Falvahütte, Schwientochlowitz, Upper Silesia, with discussion of crystal forms and symmetry; Sachs, Centralbl. Min., 54, 1905; see also Weber, ibid., 205. Occurrence (with anal.) from Olkuschsk mine in Poland; Antipoff, [Verh. russ. min. Ges,

Prot. 38, 41, 1900]; Zs. Kr., 36, 176.

ZINCKENITE, Min., p. 112; App., p. 74. — Analyses of material from Wolfsberg, Harz; Guillemain [Inaug.-Diss., Breslau, 1898], Zs. Kr., 33, 73.

Zinkrömerite. R. Scharizer, Zs. Kr., 37, 546, 1903. — See Römerite.

ZINNWALDITE, Min., p. 626. — From Narsarsuk, Greenland, with anal.; Flink, Medd. om Grönl., 14, 232, 1898; 24, 110, 1901. Anal. of material from York region, Alaska; Schaller, Am. J. Sc., 24, 158, 1907; Zs. Kr., 44, 7.

ZIRCON, Min., p. 482; App., p. 74. — Crystals from Comba Robert, near Avigliani, Piedmont; Boeris, Att. Acc. Napoli, 38, 685, 1903; crystals associated with gold from Pisek, Bohemia; Krejčí, Bull. Acad. Sci. Bohême, 1904; from various Greenland localities; Boggild, Min. Grönland, 82; from Lyon Mt., Clinton Co., N. Y.; Whitlock, N. Y. State Mus. Bull. 107, 69, 1907.

Cause of color; Spezia [Atti. R. Acc. d. Sc. Turin, 34, 638, 1899], Zs. Kr., 33, 632, see also Stevanovič, Zs. Kr., 37, 622.

Occurrence in Ceylon. Absorption spectrum. Church, Chem. News, 85, 270, 1902.

Study of variation in specific gravity, index of refraction through heating, etc.; notes on crystals from Rio Doce, Brazil; North Carolina; Rothe Wand, Pfitschthal; artificial from Hautefeuille; Stevanovič, Zs. Kr., 37, 247, 1902; see also Koechlin, Min. Mitth., 22, 368, 1903.

Irregularly developed crystals from Ceylon with description of effect of heat upon their physical

properties; Spencer, Min. Mag., 14, 43, 1904.
Anal. from Sundsvale, Sweden; Tschernik, [Jour. phys. chim. russe, 36, 457, 712, 1904]; Zs. Kr.,

Analysis of a radioactive malacon-like material, containing helium and argon; Kitchin and Winterson; Jour. Chem. Soc., 89, 1568, 1906. Discussion of chem. comp. of malacon; Zambonini, Mem. Acc. Sci. Napoli, 14, 72, 1908.

Different modifications; Spencer, Geol. Mag., (5), 1, 552; Brit. Ass., 562, 1904.
"Cyrtolite" from feldspar quarry at Bedford, N. Y.; Luquer, Am. Geol., 33, 17, 1904.
In granite from Montorfano, Northern Italy; Tacconi, Rend. Acc. Linc., 14, (2), 88, 1905.

Auerbachite from the neighborhood of Mariupol, Gov't Ekaterinoslaw, Russia, has been investigated by Jeremejeff; it agrees with zircon, but is often much altered; the associated rock is not a siliceous schist but consists of a mass of albite crystals. Bull. Acad. Sci. St. Pet., 7, 89, 1897, Zs. Kr., 31, 512.

Zoisite, Min., pp. 513, 1035; App., p. 75. — Crystals from Chester, Mass., show following new forms: g (510), h (410), i (950), j (540), g (221), g (212), g (141) and several others of doubtful nature; Palache, Am. J. Sc., 24, 249, 1907.

Association with epidote and the chem. and crys. relations of the two species, see under epidote. Red zoisite from Mähren with anal.; Slavík, Centralbl. Min., 686, 1901. Anal. of material from Monte Corchia, Tuscany; Manasse, Proc. Soc. Tosc., Jan., 1906. Occurrence (with anal.) from Trace mine, Juarez district, Lower California; Farrington, Field Columbian Mus., No. 112; Zs. Kr., 44, 539.

Occurrence near Baltimore, Md.; Am. J. Sc., 11, 171, 1901.
