MARCH MDCCCXLII.

A SERIES  
OF  
ENCYCLOPEDIAS  
AND  
DICTIONARIES,

FORMING  
SPECIAL AND INDEPENDENT WORKS, EDITED BY WRITERS  
DISTINGUISHED IN THE VARIOUS DEPARTMENTS.

Contents.

No.		
1.	BLAINE'S ENCYCLOPÆDIA OF RURAL SPORTS . . . .	5
2.	BRANDE'S DICTIONARY OF SCIENCE, LITERATURE, AND ART (In course of publication.)	3
3.	COPLAND'S DICTIONARY OF PRACTICAL MEDICINE . . . (In course of publication.)	8
4.	JOHNSON'S FARMER'S ENCYCLOPÆDIA . . . . . (In course of publication.)	3
5.	LOUDON'S ENCYCLOPÆDIA OF AGRICULTURE . . . . .	8
6.	LOUDON'S ENCYCLOPÆDIA OF ARCHITECTURE—RURAL . . (With Supplement to end of 1841.)	7
7.	LOUDON'S ENCYCLOPÆDIA OF GARDENING . . . . .	6
8.	LOUDON'S ENCYCLOPÆDIA OF PLANTS . . . . . (With Supplement.)	6
9.	LOUDON'S ENCYCLOPÆDIA OF TREES . . . . . (In course of publication.)	7
10.	M'CULLOCH'S DICTIONARY OF COMMERCE . . . . . (New Edition.)	4
11.	M'CULLOCH'S DICTIONARY OF GEOGRAPHY . . . . . (In course of publication.)	4
12.	MURRAY'S ENCYCLOPÆDIA OF GEOGRAPHY . . . . . (New Edition.)	5
13.	SAVAGE'S DICTIONARY OF PRINTING . . . . . (Just completed.)	8
14.	URE'S DICTIONARY OF ARTS AND MANUFACTURES . . . .	4

MESSRS. LONGMAN AND CO. INTEND CONTINUING THIS SERIES UNTIL IT EMBRACES

EVERY BRANCH OF KNOWLEDGE.

LONDON :

PRINTED FOR

LONGMAN, BROWN, GREEN, AND LONGMANS.

**Notice of a Series of Encyclopædias**

**OPINIONS OF THE PRESS ON THE SERIES.**

**The Athenæum.**

“A series of encyclopædical volumes, wherein a great quantity of information is condensed into a small compass, and arranged in a form the most convenient for frequent reference. Such a series will, when completed, form a valuable library of practical knowledge. The specimens we have already seen of these works are such as do great credit to the publishers who formed the design, and to the authors who have executed the respective divisions. Loudon’s Encyclopædia of Agriculture has now given proof of its value by a third edition; his Encyclopædia of Gardening is to be seen open on the table of every scientific gardener, and of every man who values his garden, from one end of this garden-covered island to the other—from the region of the heath to that of the myrtle! M’ulloch’s Dictionary of Commerce and Commercial Navigation is to be found in the library equally of the merchant and the man of general information. Of the Dictionary of Practical Medicine, by Dr. Copland, we heretofore expressed our approbation. Taken as a whole, and judging by the specimens already published, we consider this series of works to be one of the most valuable produced for many years; and we look forward to the publication of the Dictionary of Science, Literature, and Art, with confidence and special pleasure, as a work much wanted. None can conceive, who have not witnessed them, the difficulties encountered in the attempt to get up sterling substantial works of this kind; few are aware of the extent of knowledge, of reading, and of sustained effort, in collecting, writing out, and digesting such works.”

**Examiner.**

“We think it a worthless, because an impracticable design, to aim at embodying in any one work an epitome of every branch of human knowledge. All the general encyclopædias that we know of are general failures. Some portions of them have been admirably done, but at some point or other in all of them the necessary alternative has forced itself on the projectors—to leave the design unfinished, or the book unfinished.—This is a better plan of the Messrs. LONGMAN and Co. and deserves all encouragement and support. They purpose to publish a series of encyclopædias and dictionaries, each edited by a competent person, each in itself complete, condensed into as small a compass as possible, and arranged for the utmost convenience of simple and easy reference.”

**The Statesman.**

“The authors and publishers of most of the great Dictionaries and Encyclopædias that have hitherto appeared in this and other countries, have endeavoured to concentrate into a single work all the scattered elements of universal knowledge. But success in such an undertaking could not rationally be looked for; in such works it is uniformly found that those departments with which the editors and principal contributors are best acquainted, are treated at great length, and often with much care and research; while those equally important, and far more numerous, departments, with which they are less familiar, or in which they take less interest, are dispatched in a comparatively brief and slovenly manner. It is clear, too, that if all the various branches of human knowledge were treated in a single work, with that completeness which the interest attached to the greater number demands, it would be of the most gigantic dimensions, and could not be afforded, except at a price that would preclude the great bulk of readers from becoming its purchasers. We have, therefore, always approved of the valuable encyclopædias which have issued, or are in the course of publication, by Messrs. Longman. They seem to form a series of SPECIAL AND INDEPENDENT DICTIONARIES, each being the work of persons distinguished by their attention to, and proficiency in, the departments of which it treats. The advantages of this arrangement are obvious. Each subject must have the best chance of being well and carefully treated. The publication of a series of independent Dictionaries is farther advantageous, by its giving individuals the option of purchasing such only as they may have occasion for, without encumbering themselves with the others. The success of the works already published on this plan, shows that it has been fully approved of by the public.”

**Times.**

“These books are not only full of information of the best kind, arranged and presented in the best manner, but are kept current in all cases with the latest discoveries in their various departments of knowledge, by the help of Appendices and Supplements. They promise to realise a more complete Library of Practical Knowledge on the various subjects of human inquiry than we have yet seen attempted with success, and they have the manifest advantage of giving each reader his option of selecting the subjects that will be useful to him, and of rejecting those that would merely encumber his book-shelves.”

Printed for Longman, Brown, and Co.

## BRANDE'S DICTIONARY OF LITERATURE, SCIENCE, &c.

A Dictionary of Literature, Science, and Art; comprising the History, Description, and Scientific Principles, of every branch of Human Knowledge; with the Derivation and Definition of all the Terms in general use. General Editor, W. T. BRANDE, F.R.S.L. & E.; of Her Majesty's Mint; Professor of Chemistry in the Royal Institution; Professor of Chemistry and Materia Medica to the Apothecaries' Company &c. &c. Assisted by JOSEPH CAUVIN Esq.

ARCHITECTURE, MUSIC, AND THE FINE ARTS .....	JOSEPH GWILT, F.S.A. & F.R.A.S.
BOTANY .....	{ J. LINDLEY, Ph. D. F.R.S. L.S. &c. Professor of Botany in London University College, and in the Royal Institution.
CHEMISTRY, GEOLOGY, MINERALOGY, MEDICINE, AND THE ARTS AND SCIENCES DEPENDING ON CHEMICAL PRINCIPLES .....	{ W. T. BRANDE, Esq.
GARDENING AND AGRICULTURE .....	J. C. LOUDON, F.L.S. H.S. &c.
LAW .....	{ HERMAN MERIVALE, A.M. Late Fellow of Balliol College.
GENERAL LITERATURE .....	{ J. R. M'CULLOCH, Esq.; and JOSEPH CAUVIN, Esq.
MATHEMATICS, AND THE ARTS AND SCIENCES DE- PENDING ON MATHEMATICAL PRINCIPLES .....	{ THOMAS GALLOWAY, M.A. F.R.S.
POLITICAL ECONOMY, STATISTICS, & COMMERCE.....	J. R. M'CULLOCH, Esq.
THEOLOGY .....	THE REV. CHARLES MERIVALE, M.A.
ZOOLOGY, ANATOMY, AND PHYSIOLOGY .....	RICHARD OWEN, F.R.S. &c.

In 1 very thick volume 8vo. containing nearly 1400 closely printed pages, illustrated by engravings on wood.

\* \* \* Will be ready in April.

"A general encyclopædia in miniature. The reader will find the elements of nearly all branches of science and art and human enquiry embraced in these compact and laborious pages; and given, too, in so popular a style, as to place him at once in possession of the information he seeks. He will also be gratified at discovering a variety of minor topics explained in this Dictionary, which would not, or more properly could not, be admitted into an Encyclopædia."

"A concise, well-written, and comprehensive article, is given upon all subjects, each containing quite as much as any person could be desirous of reading for the purpose of acquiring a thorough knowledge of the principles of a science without the labour of working out all the minutæ."—*Observer*.

"This Dictionary is one of the most satisfactory and generally useful books of the kind that have come under our observation."—*Monthly Review*.

## JOHNSON'S FARMER'S ENCYCLOPÆDIA.

The Farmer's Encyclopædia and Dictionary of Rural Affairs. By CUTHBERT JOHNSON, Esq., Barrister at Law, Editor of the Farmer's Almanack, &c. &c. Illustrated with wood engravings of the best Agricultural Implements. 8vo. Parts 1 to 6. To be completed in 10 monthly parts, 5s. each.

Many years have now elapsed since an alphabetically arranged work, of easy reference, has been produced for the service of the English farmers and country gentlemen; and yet, within the present century, agricultural discoveries, and rural improvements of all kinds, have been making progress with a rapidity and to an extent which has long rendered obsolete the greatest portions of all the existing Agricultural Dictionaries. The present work is the result of many years' careful and laborious experimental researches, observations, and collections, by an author whose successful public efforts have long been favourably received by the English farmers. It is proposed to be chiefly devoted to the details of practical agriculture, and to the results of those scientific inquiries by which this important pursuit is assisted and illustrated. It will include, also, many other details interesting to the farmer: such as the law with regard to certain parish and other public and private duties, which he is often called upon to fulfil—the kitchen and flower garden—a herbal of native plants, &c. &c. The endeavour will, in short, be made to produce a new and useful book of reference, to which the farmer may readily resort under all ordinary circumstances.

"We have no hesitation in stating that it will become one of the first of our standard works on British Agriculture. . . . It will be an agricultural library of itself, and will add to Mr. Johnson's already well-acquired reputation as an agricultural writer."—*Mark-Lane Express*.

"Promises to be one of the most useful works for agriculturists which has been issued from the Press for many years past. . . . Should be found in the library of every one connected with the soil."—*The Farmer's Journal*.

"A work which promises to be of great practical value to the farmer. Every intelligent farmer is certain to possess himself of this book, and no private gentleman, of inquiring turn of mind, can be without it."—*Mirror*.

"The execution of it has been confided to Mr. Cuthbert Johnson, a well-known and very respectable writer on agricultural subjects. The design is good; the execution is admirable."

"Great care appears to have been taken to bring down the information to the present time."  
*Salopian Journal*  
*Birmingham Herald*.

"Replete with practical information."—*Sporting Magazine*.

"Remarkable for perspicuity of style, and lucid treatment of the minutest points."  
*Sporting Review*.

Notice of a Series of Encyclopædias.

---

## M'ULLOCH'S GEOGRAPHICAL DICTIONARY.

A Dictionary, Geographical, Statistical, and Historical, of the various Countries, Places, and principal Natural Objects in the World. Illustrated with Maps. In Two Volumes.

The first Volume is now ready, containing excellent Maps of the World on Mercator's Projection; the Navigable Rivers, the completed and proposed Canals, and Railroads, of Great Britain and Ireland, with the Coal Fields, Light-Houses, &c.; of the British Possessions in North America, with part of the United States, compiled from official sources, and with Plans of the Cities and Harbours of Montreal and Quebec; and of Asia, carefully constructed by Messrs. Walker, from the most recent information. (This present Map of Asia is the most recent Map of that Continent, and is the only Map containing the recent Discoveries.) Price £2, handsomely bound in cloth lettered.

"The fulness with which each article is written, the clearness of the arrangements throughout, and the vast surface traversed under each head, and in every department of inquiry essential to the undertaking, contribute to the production of the most luminous body of information concerning Geography, Statistics, and History, and all matters necessary to their elucidation, that has ever been brought together in a shape so perspicuous and accessible. Such a publication—which can be referred to, on the instant, for any subject embraced in its pages—is indispensable to all libraries, and must completely supersede every previous attempt to popularise and reduce within convenient limits these various classes of information."—MONTHLY CHRONICLE.

"Reflects great honour on all parties concerned in it, Mr. M'ulloch himself and the respectable firm who have seconded him in his conscientious endeavours to redeem the literature of his country from the disgrace stamped on it by numerous compilations, made without knowledge or industry, in which no notice is taken of changes and improvements, and old errors are carefully repeated."—MORNING CHRONICLE.

\*\* The concluding Volume will be ready in April.

---

## M'ULLOCH'S DICTIONARY OF COMMERCE.

A Dictionary, Practical, Theoretical, and Historical, of Commerce and Commercial Navigation. Illustrated with Maps and Plans. New edition, 50s. boards.

In this Edition all the more important returns and accounts as to the TRADE, NAVIGATION, and CONSUMPTION of this and other countries, have been brought down to the latest period. In some instances, too, the form of the returns has been changed, and new ones, drawn up on a more comprehensive plan, and embracing various additional particulars, have been substituted for those previously embodied in the work. In illustration of this the reader is referred to the tables now given under the articles IMPORTS and EXPORTS: they will, it is believed, be found to contain, within a brief space, the completest view hitherto laid before the public of the recent trade of the British Empire. A few new articles have also been inserted; among which may be specified those on Bombay, Malta, &c.

The present Supplement has been greatly enlarged, and, it is hoped, materially improved. It contains as much matter as would fill, if printed with types of a medium size, a large octavo volume, and embraces a good deal of important information not elsewhere to be met with. We can assure the reader that neither labour nor expense has been spared to render it instructive and trustworthy. It embodies the substance of the former Supplements, and has, among others, articles on the following subjects, viz. :—

AUSTRIAN TARIFF, AND NEW COMMERCIAL TREATY WITH AUSTRIA.

JOINT-STOCK BANKS; with a complete list of these establishments, and an examination of the principles on which they should be founded.

AMERICAN BANKING SYSTEM; with Remarks on the liabilities of the Foreign Holders of the Stock of the United States' Bank.

NEW CUSTOMS ACT FOR BENGAL.

COTTON TRADE OF GREAT BRITAIN, from 1816 to 1839, both inclusive.

TABLES OF IMPORTS AND EXPORTS, comprising a full Account of the Foreign Trade of the United Kingdom during the Ten Years ending with 1838, with Remarks on the probable consequences of Foreign Competition, &c.

COINAGE OF AMERICA AND INDIA. NAVIGATION OF THE DANUBE.

TRADE WITH PRUSSIA, PRUSSIAN COMMERCIAL LEAGUE, TARIFF, &c.

OPIUM TRADE; with Remarks on the State of our Relations with China.

RAILWAYS AND RAILWAY LEGISLATION.

NEW POST-OFFICE ARRANGEMENTS.

ALTERATIONS IN THE BRITISH TARIFF.

RUSSIAN TARIFF.

CLASSIFICATION OF SHIPS.

SUGAR TRADE—Growth of Beet-Root Sugar, &c.

COMMERCIAL TREATY WITH TURKEY, with Notices of Civita Vecchia, Galacz, Guayaquil, Port Lamar, Montevideo, Moulmein, Rostock, &c.

---

## LOUDON'S ENCYCLOPÆDIA OF TREES.

Arboretum et Fruticetum Britannicum, Abridged; or, the Hardy Trees and Shrubs of Britain, Native and Foreign, scientifically and popularly described: with their Propagation, Culture, and Uses in the Arts; and with Figures of nearly all the Species. Abridged from the large Edition in 8 volumes, and adapted for the use of Nurserymen, Gardeners, and Foresters. By J. C. LOUDON, F.L.S. &c. Conductor of the "Gardener's Magazine." To be completed in 10 monthly parts, at 5s. each, of which 3 are published.

Printed for Longman, Brown, and Co.

## MURRAY'S ENCYCLOPÆDIA OF GEOGRAPHY.

An Encyclopædia of Geography; comprising a complete Description of the Earth, exhibiting its Relation to the Heavenly Bodies, its Physical Structure, the Natural History of each Country, and the Industry, Commerce, Political Institutions, and Civil and Social State of all Nations. By HUGH MURRAY, F.R.S.E.: assisted in Astronomy, &c. by Prof. Wallace; Geology, &c. by Prof. Jameson; Botany, &c. by Sir W. J. Hooker; Zoology, &c. by W. Swainson, Esq. New Edition, brought down to 1840, with 82 maps, drawn by Sidney Hall, and upwards of 1,000 other engravings on wood, from drawings by Swainson, T. Landseer, Sowerby, Strutt, &c., representing the most remarkable objects of Nature and Art in every Region of the Globe. Containing upwards of 1,500 pages. £3. cloth lettered.

### EXTRACT FROM INTRODUCTION.

This important and extensive subject seems to divide itself naturally into three parts:—  
The *First Part* treats of the "History of Geography;" the origin and progress of the Science; and the steps by which man, who seemed fixed by nature in a local and limited position, has made himself acquainted with the immense circuit of the globe. This part is divided into—  
I. Ancient Geography;—II. Geography of the Middle Ages;—III. Modern Geography.

The *Second Part* comprises the *Principles of the Science*. These are—  
I. *Mathematical*: those which relate to the form of the earth, its movements, its place in the Solar System, the great circles by which it is divided, the operations by which it is surveyed, and the modes in which its spherical outline can be represented on the plane surface of a map. II. *Physical*: those which treat of the substances which cover the earth's surface, the elements which compose and surround it; rock, earth, water, air, as they appear under the various forms of mountain, plain, river, sea, and present all the changing phenomena of the atmosphere. III. *Geography* may be considered in its relation to other objects and sciences. 1. To Zoology, or the distribution of animals over the globe. 2. To Botany, or the diffusion of vegetable productions. 3. To the human race, and the various branches into which it has been formed, considered in relation to numbers, wealth, political union, social, intellectual, and moral condition.

The *Third Part* considers Geography in detail, as it applies to the various quarters and countries into which the world is divided, the outline and extent of each, its natural features, the revolutions through which it has passed, its political constitution, the industry and wealth, the civil and social condition of its inhabitants. The description of each country will conclude with a local and topographical survey of its districts, cities, and towns.

This part will divide itself into five general heads: I. Europe. II. Asia. III. Africa. IV. America. V. Australia.

An Index is added, which, being extremely copious, and containing references to all the places mentioned in the work, will answer in a great degree the purposes of a Geographical Gazetteer.

## BLAINE'S ENCYCLOPÆDIA OF RURAL SPORTS.

An Encyclopædia of Rural Sports; or, a complete account, Historical, Practical, and Descriptive, of Hunting, Shooting, Fishing, Racing, and other Field Sports and Athletic Amusements of the present day. By DELABERE P. BLAINE, Esq. Author of "Outlines of the Veterinary Art," "Canine Pathology," &c. &c. Illustrated by nearly 600 engravings on wood, by R. Branston, from drawings by Alken, T. Landseer, Dickes, &c. £2. 10s. handsomely bound in fancy cloth, lettered.

### CONTENTS.

#### PART I.—The Origin, Progress, and Present State of Field Sports.

- |  |   |
|--|---|
| Book 1.—History of the Chase.  | Book 3.—The History of British Field Sports, accompanied with occasional Notices of such other Rural and Active Exercises as are common among the Sporting Classes of our Countrymen. |
| Book 2.—The Progress of Field Sports after Mankind had Peopled the Four Quarters of the Globe. |   |

#### PART II.—The Philosophy of Field Sports.

- |  |  |
|--|--|
| Book 1.—The Moral Character of Field Sports, and the Benefits derived from them. | Book 2.—The Natural History of the Living Objects of Field Sports. |
|--|--|

#### PART III.—Horse Racing, &c. &c.

- IV.—Hunting.
- V.—Coursing.
- VI.—Hawking.

#### PART VII.—Shooting.

- VIII.—Fishing.
- IX.—Cock Fighting.
- X.—Boxing.

"This book is a perfect library for all lovers of country sports, for all country gentlemen, and for all persons who delight in the manly and healthy recreations which are afforded to the inhabitants of no country in such perfection as to the inhabitants of the British Isles. It is true the book treats of the field sports, and the sports by flood, of all the countries in the world; and is, for that reason, so much the more valuable: but its principal value with Englishmen will be the great accuracy with which it describes the sports of which they can partake in their fields, woods, and waters, and the plain and agreeable manner in which intelligence on subjects with which they want to be acquainted is conveyed. The book is a large one, and so filled—indeed, so crammed—with information, that it becomes a matter of conjecture as to how the whole can have been brought together. It is, what it professes to be, 'an Encyclopædia of the Amusements of the Country.' The book is illustrated by an immensity of engravings on wood, by Mr. R. Branston, from drawings by Alken, T. Landseer, Dickes, and other artists. It is at once a manual and library for all sportsmen."—*Times*.

"The study of a sportsman would be incomplete without it."—*Sporting Magazine*.

"The three great heads of 'guns, dogs, and horses,' could not be treated in a fuller, more complete, or more effective manner, than they have been by Mr. Blaine in this publication."

*Observer.*

Notice of a Series of Encyclopædias,

## LOUDON'S ENCYCLOPEDIA OF GARDENING.

An Encyclopædia of Gardening; comprising the Theory and Practice of Horticulture, Floriculture, Arboriculture, and Landscape Gardening, including all the latest improvements, a General History of Gardening in all Countries, and a Statistical View of its Present State, with suggestions for its Future Progress in the British Isles. By J. C. Loudon, F. L. S., H. S., &c. &c. New Edition, greatly enlarged and improved, with nearly 1000 Engravings on Wood. £2. 10s. boards.

The object of this Encyclopædia is to present, in one systematic view, the History and present State of Gardening in all countries, and its Theory and Practice in Great Britain. Under the term Gardening, we include Horticulture, or all that relates to the kitchen-garden and the orchard; Floriculture, or all that relates to the flower-garden, the botanic garden, the shrubbery, and the culture of flowers and ornamental shrubs and trees; Arboriculture, or the formation of useful and ornamental plantations, and the culture of the most valuable timber trees; and Landscape Gardening, or the art of laying out grounds.

"No gardening book so comprehensive, and containing such an immense mass of matter, has ever been submitted to the public more free from errors of the pen or the press."—*Monthly Review*.

### CONTENTS.

**PART I.**—Gardening considered in respect to its Origin, Progress, and Present State, among different Nations, Governments, and Climates.

Book 1. History of Gardening among Ancient and Modern Nations.

- 2. Gardening considered as to its Progress and present State under different Political and Geographical Circumstances.

**PART II.**—Gardening considered as a Science, and as an Art.

Book 1. On the Study of the Vegetable Kingdom.

- 2. On the Study of Natural Agents of Vegetable Growth and Culture.  
— 3. Mechanical Agents employed in Gardening.  
— 4. Of the Operations of Gardening.

**PART III.**—Gardening as Practised in Britain.

Book 1. Horticulture.

- 2. Floriculture.  
— 3. Arboriculture, or Planting.  
— 4. Landscape-Gardening.

**PART IV.**—Statistics of British Gardening.

Book 1. Of the present State of Gardening in the British Isles.

- 2. Of the Future Progress of Gardening in Britain.

### CALENDARIAL INDEX.

### GENERAL INDEX.

## URE'S DICTIONARY OF ARTS, MANUFACTURES, &c.

A Dictionary of Arts, Manufactures, and Mines; containing a clear Exposition of their Principles and Practice. By ANDREW URE, M. D. F. R. S. M. G. S. &c. New Edition, illustrated with 1,241 engravings on wood, £2. 10s. cloth lettered.

The following are the objects which the author has endeavoured to accomplish:—

First—To instruct the manufacturer, metallurgist, and tradesman, in the principles of their respective processes, so as to render them in reality the masters of their business, and to emancipate them from a state of bondage to operatives—too commonly the slaves of blind prejudice and vicious routine.

Secondly—To afford to merchants, brokers, drysalter, druggists, and officers of the revenue, characteristic descriptions of the commodities which pass through their hands.

Thirdly—By exhibiting some of the finest developments of chemistry and physics, to lay open an excellent practical school to students of these kindred sciences.

Fourthly—To teach capitalists, who may be desirous of placing their funds in some productive branch of industry, to select judiciously among plausible claimants.

Fifthly—To enable gentlemen of the law to become well acquainted with the nature of those patent schemes which are so apt to give rise to litigation.

Sixthly—To present to our legislators such a clear exposition of our staple manufactures, as may dissuade them from enacting laws which obstruct industry, or cherish one branch of it to the injury of many others.

And lastly—To give the general reader, intent chiefly on intellectual cultivation, a view of many of the noblest achievements of Science, in effecting those grand transformations of matter to which Great Britain owes her paramount wealth, rank, and power, among the kingdoms.

\* \* \* The latest Statistics of every important object of Manufacture are given, from the best, and usually from Official Authority, at the end of each article.

Printed for Longman, Brown, and Co.

## LOUDON'S ENCYCLOPÆDIA OF PLANTS.

An Encyclopædia of Plants; comprising the Description, Specific Character, Culture, History, Application in the Arts, and every other desirable particular, respecting all the Plants indigenous to, cultivated in, or introduced into, Britain; combining all the advantages of a Linnæan and Jussieuan Species Plantarum, an Historia Plantarum, a Grammar of Botany, and a Dictionary of Botany and Vegetable Culture. The whole in English, with the Synonymes of the commoner Plants in the different European and other languages; the scientific names accentuated, their etymology explained; the classes, orders, and botanic terms illustrated by engravings; and with figures of nearly 10,000 species, exemplifying several individuals belonging to every genus included in the work. Edited by J. C. Loudon, F.L.S. H.S. &c. The Specific Characters by Professor Lindley; the Drawings by J. D. C. Sowerby, F.L.S.; and the Engravings by R. Branston. 2d Edition, corrected, £3. 13s. 6d.

In this Encyclopædia are included all the indigenous, cultivated, and exotic Plants which are now found in, or have been introduced into, Britain. The object of this work is to give a Natural History of these Plants, accompanied by such descriptions, engraved figures, and elementary details, as shall enable a beginner, who is a mere English reader, to discover the name of every Plant which he may find in flower, refer it to its proper place, both in the natural and artificial Systems of Classification, and acquire all the information respecting it which is useful or interesting.

The work is divided into Two Parts. The First Part contains the Linnean or Artificial Arrangement of all the genera and species, with all the details comprehended in botanical description, and natural and artificial botanical history, and with engraved portraits of one or more species of each genus. The Second Part contains the Jussieuan or Natural Arrangement of all the genera, without repetition of the species or any details connected with them: but as the names of the natural orders are added after each genus in the Artificial System, and as each genus in both arrangements is numbered, a direct reference may be had from the second arrangement to the first, and from the first to the second; reference may also be had indirectly, through the medium of the Contents or Index.

An Introduction is given to each system of arrangement, and a General Introduction to the whole work, in which its uses are explained. When the beginner has a plant in flower and would ascertain its name, he will turn to the Linnean System, as explained in the Introduction to that system; and, when he has but a small part of any plant, he will turn to the Natural System, as directed in the General Introduction.

All the Technical Terms, or words not usually found in an English Dictionary, are explained in the Glossary, and engravings are given of such of the objects designated as might occasion any difficulty to a beginner. This Glossary and the two Introductions form together a complete Grammar of Botany.

The Table of Synonymes in various languages may, to a certain extent, be considered as presenting the Popular Floras of the various countries where these names are used; since it is only to the remarkable plants of a country that vernacular names are given.

"The most useful and popular botanical work that has ever appeared in the English Language."  
*Jameson's Philosophical Journal.*

## LOUDON'S COTTAGE ARCHITECTURE.

An Encyclopædia of Cottage, Farm, and Villa Architecture; with about 1,100 pages of letter-press, and upwards of 2,000 wood engravings; embracing designs of Cottages, Farm Houses, Farmeries, Villas, Country Inns, Public Houses, Parochial Schools, &c.; including the interior Finishings and Furniture; accompanied by Analytical and Critical Remarks illustrative of the Principles of Architectural Science and Taste, on which the Designs for Dwellings are composed, and of Landscape Gardening, with reference to their Accompaniments. By J. C. Loudon, F.L.S. &c. New Edition, corrected, with above 100 of the Plates re-engraved, with a Supplement, bringing down the Improvements in Domestic Architecture, Furniture, and in Landscape Gardening, to the end of 1841, £3.

The main object of this Encyclopædia of Cottage, Farm, and Villa Architecture, is to improve the dwellings of the great mass of society, in the temperate regions of both hemispheres: a secondary object is to create and diffuse among mankind, generally, a taste for architectural comforts and beauties.

The means by which we propose to accomplish these objects are the following:—

By submitting a series of Designs for human dwellings, embracing every appropriate comfort and the greatest variety of beauty; and by accompanying these designs with analytical and critical remarks, pointing out in what this comfort and beauty consist, and on what principles both are founded.

By submitting a series of Designs for the finishing, fittings up, fixtures, and furniture, suitable to the different descriptions of Cottage, Farm, and Villa Buildings; and by accompanying these with remarks on their fitness for the end in view, such as lighting, heating, ventilating, &c., as well as with analytical and critical remarks on their style or beauty; thus showing the necessity of Architects including the study of furniture in that of their profession, so as to be able to give designs for furnishing a house, as well as for building one.

By accompanying many of the Designs with gardens, as well small kitchen and flower gardens for the cottager, as pleasure ground and park scenery for the occupant of the villa; and by explaining the connection of Villa Architecture with Landscape Gardening, and pointing out the necessity which exists for Villa Architects possessing a considerable knowledge of the art of laying out grounds.

By avoiding, when it is not absolutely necessary, the use of terms peculiar to Architecture; by explaining all such as are used, when they first occur; and by adopting such a style as will render the work easily understood by the uninitiated reader, as well as subservient to the purpose of educating young persons, especially those of the female sex, in Architecture as an art of taste.

"From the commencement of the present century, a number of works on ornamental cottages, rural villas, and other country dwelling, have been published, and have greatly increased the architectural taste of country gentlemen and retired citizens. One of the best of these is Loudon's 'Encyclopædia of Cottage, Farm, and Villa Architecture and Furniture'; than which, we believe, no single work has ever effected so much good in improving the arrangement and external appearance of country dwellings generally."—*Times.*

Notice of a Series of Encyclopædias, printed for Longman & Co.

## LOUDON'S ENCYCLOPÆDIA OF AGRICULTURE.

An Encyclopædia of Agriculture. By J. C. Loudon, F.L.S. H.S. &c. Comprising the Theory and Practice of the Valuation, Transfer, laying out, Improvement, and Management of Landed Property, and the Cultivation and Economy of the Animal and Vegetable Productions of Agriculture, including the latest Improvements, a General History of Agriculture in all Countries, and a Statistical View of its Present State, with Suggestions for its Future Progress. With nearly 1,500 engravings on wood. 3d edit. with a supplement, containing all the recent improvements, &c. 2. 10s. boards.

"One of the most scientific and justly popular works of the present times."

*Stewart's Planter's Guide.*

### CONTENTS.

PART I.—Agriculture Considered as to its Origin, Progress, and Present State, among different Nations, Governments, and Climates.

Book 1.—History of Agriculture among Ancient and Modern Nations. Book 3.—Agriculture as Influenced by Geographical, Physical, Civil, and Political Circumstances.

PART II.—Agriculture considered as a Science. Book 1.—Of the Study of the Vegetable Kingdom with a View to Agriculture. Book 2.—Of the Study of the Animal Kingdom with reference to Agriculture.

Book 3.—Of the Study of the Mineral Kingdom. Book 4.—Of the Mechanical Agents employed in Agriculture.

PART III.—Agriculture as practised in Britain. Book 5.—Of the Operations of Agriculture.

Book 1.—Of the Valuation, Purchase, and Transfer of Landed Property. Book 4.—Management of Landed Property.

Book 2.—Of the Laying Out, or General Arrangement of Landed Estates. Book 5.—Selection, Heding, and Stacking of Farms.

Book 3.—On Improving the Culturable Lands of an Estate. Book 6.—Culture of Farm Lands.

PART IV.—Statistics of British Agriculture. Book 7.—The Economy of Live Stock and the Dairy.

Book 1.—Of the Present State of Agriculture in the British Isles. Book 2.—Of the Future Progress of Agriculture in Britain.

Calendarial Index.—Glossarial Index.—General Index.

## COPLAND'S DICTIONARY OF PRACTICAL MEDICINE.

A Dictionary of Practical Medicine; comprising General Pathology, the Nature and Treatment of Diseases, Morbid Structures, and the Disorders especially incidental to Climates, to the Sex, and to the different Epochs of Life, with numerous approved Formulae of the Medicines recommended. By JAMES COPLAND, M.D., Consulting Physician to Queen Charlotte's Lying-in Hospital; Senior Physician to the Royal Infirmary for Children; Member of the Royal College of Physicians, London; of the Medical and Chirurgical Societies of London and Berlin, &c.

This work is now in course of publication in Paris, of which seven have appeared. It contains, in an abstract and condensed, yet comprehensive, form, the opinions and practice of the most experienced writers, British and Foreign, so digested and wrought up with the results of the Author's practice, that the Student and Young Practitioner will not be bewildered in the diversity of the opinions and facts adduced for their instruction, but impeded in the difficult path on which they have entered, and enabled, with a due exercise of their powers of observation and discrimination, to arrive at just conclusions and successful practical results. To the experienced Practitioner, also, the work presents a diversified range of opinions, methods of cure, and authorities, which his matured judgment will enable him to apply, in an appropriate manner, to particular cases. It also comprises the complications and modified states of Disease, which are even more frequently met with in practice, than those specific forms too often described by Nosologists as constant and unvarying types, to which morbid actions, occurring under a great variety of circumstances, can never closely adhere. When discussing the methods of Cure, the Author gives Formulae of the Medicines recommended, in the most efficient and improved forms of combination. He likewise furnishes numerous References to the best Works and Treatises on the topics discussed in each article.

In conclusion, the Work will contain the results of many years of laborious study and research, and of twenty years' extensive and diversified experience.

## SAVAGE'S DICTIONARY OF PRINTING.

A Dictionary of Printing. By WILLIAM SAVAGE, Author of "Practical Hints on Decorative Printing," and a Treatise "On the Preparation of Printing Ink, both Black and Coloured." In 1 thick vol. 8vo. with numerous diagrams, &c. 1. 6s. cloth lettered.

It has been the intention to give in this publication a faithful and clear account of the Art of Printing, as now practised in the Metropolis, chiefly derived from the Author's long experience in London, during which period he has executed some of the finest Works that ever issued from the British Press; this has been accompanied with a great mass of information connected with the art, rendering it a Guide to the Apprentice and the inexperienced Young Workman; and a useful Book of Reference to the experienced Workman, to the Master Printer, the Overseer, and the Reader, in the printing-office; and to the Literary Man, and in the Library, for all matters relating to, or connected with, printing.

"Few Printers, we are persuaded, however skilful in their Art, or enthusiastic in its pursuit, are aware of the mass and variety of amusing matter, not to speak of useful hints and information, to be found in this work. (It is) a very useful and curious Dictionary."—*Monthly Review.*

"We heartily recommend the work to all in any way connected with literature, who will find it of great service as a book of reference."—*Literary Gazette.*

## P R E F A C E.

---

ALL the arts of life have had their origin in some simple natural want, supplied, in the first instance, by every man for himself; till, with the progress of civilisation, from these wants sprang those desires and wishes, which gave rise to that division of skill and labour in supplying them, which is one of the characteristics of civilised society. Hence the origin of all the different professions, most of which, in their first existence as such, were practised by distinct associations as mysteries, unknown to, or concealed from, general society.

It is in the nature of all knowledge held as mystery, to remain in a great measure stationary, because the minds which are engaged in it are necessarily few; and because the great object of such associations is, to keep their peculiar knowledge, and the exercise of their craft, among themselves. Hence the little progress which has been made in Domestic Architecture, the science and rules of which have been almost exclusively confined to Architects, from the earliest ages to the present time. On examining into the actual state of this art, it will be found that the improvements which have been made in it in modern times, are chiefly confined to those departments which are open to the understanding, and amenable to the judgment, of mankind generally; we mean, such as relate to comfort and convenience in the arrangement, warming, lighting, heating, &c., of rooms; whereas the department of taste in building is little in advance of what it was two thousand years ago.

To what can this be owing, but to the circumstance, that the knowledge of Architecture, as a fine art, is much less familiar to the public, than it is as an art of utility; or, in other words, that the Architect is under the control of public opinion much more in matters of usefulness, than in matters of taste?

This is a state of things by no means peculiar to Architecture. The greater portion of mankind, in even the most civilised countries, has hitherto been kept in the dark with regard to what constitutes truth and excellence in all arts or professions, the practice of which has been limited to certain associations or corporations of individuals. Hence the sciences of government, law, medicine, theology, education, &c., have been in all countries comparative mysteries, and have, consequently, like Architecture, remained nearly stationary for ages. The profound and exclusive attention, which is requisite to enable the professors of any art to become eminent in it, necessarily precludes them, while engaged in its pursuit, from acquiring a proportionate stock of knowledge upon other subjects. Unless, therefore, this stock of knowledge has been previously laid in by a scientific education in early youth, professional men and artists are very apt to assign an undue importance to the facts and views connected with their professions; and to regard as general truths, those which are, in fact, only particular. Hence, universal principles and extended views are much more likely to be entertained by persons who have studied several arts and sciences, though perhaps none of them profoundly, than by those who have confined their attention to only one. Hence, also, we rarely find great reformatations made in any art by its professors.

Another cause which has retarded the progress of all arts and professions is, the practice, common in most of them, of implicitly following precedents; or of adhering rigidly to rules (made perhaps in a former age, and consequently adapted to a less advanced state of civilisation), instead of testing those precedents and rules by fundamental principles, and adapting the latter to the state of society for the time being. No art has had its progress more retarded by these means than Architecture; whether by the old idea that the whole of its science was included in the knowledge of the five orders; or by the modern one that Architecture, as an art of taste, is one of imitation, like those of sculpture and painting; and that there is no manner of building worthy of the name of Architecture but the Grecian.

According to our views of this subject, all arts, whether of design and taste, or of utility and convenience, like every thing else relative to man, are progressive, and change with the changing condition of society. In like manner, the knowledge of all arts, from being exclusive, is calculated, through the spread of education, ultimately to become universal: and, the art of printing and the use of the steam-engine being discovered, the time will ultimately arrive, in every country, when all knowledge will be common to all

mankind. No art or profession will then be a mystery; but, each being reduced to the comprehension of youth, forming a part of that general education which will ultimately be every where established, and being consequently subject to the criticism of the whole of society, the improvement in it will be great, in proportion to the demand which there may be for its exercise and for its productions. Though scarcely any country has arrived at this stage in social progress, even in any one of the arts or professions, yet all countries are advancing towards it with different degrees of rapidity, according to the circumstances in which they are placed, geographical and political.

In accordance with these views, our intention, in producing the work now submitted to the reader, is, to prepare the way for rendering general, a knowledge of Domestic Architecture; for the immediate purpose of increasing the comforts of the great mass of society; and for the more remote objects of improving the knowledge and the taste of the public in Architecture, and of inducing Architects to study their art on general principles, and on a theory formed on the nature of the human mind, and on the changing condition of society, rather than on the precedents and rules of former ages, or on any hypothesis whatever. The means by which we have endeavoured to effect these objects will be found explained at length in our Introduction, to which we refer the reader.

We have only been enabled to accomplish our purpose by the cooperation of a number of Architects, of scientific men, and of men of taste. Several of these we are proud to call our personal friends; and others, who, before we received their contributions to this work, were known to us only by name, have proved themselves friends by their actions. Before proceeding to return our sincere acknowledgments to the various artists and others, whose names will be found in the list, p. xix., it may be advisable to reply to an objection which has been made to us by some Architects, viz. that, by laying their profession open to the world, we were acting so as to injure their pecuniary interests. The same objection was made to Dr. Buchan many years ago, when he first published his *Domestic Medicine*; and to John Abercrombie, when he wrote his book entitled *Every Man his own Gardener*. Now, without going into details, we shall only ask, what have been the progress of medicine and gardening, and the prosperity of medical men and gardeners, since the time these works appeared, compared to what they were for a similar period previous to their publication? The answer, undoubtedly, is, that their improvement has been great beyond all former example. To what can this be owing, but to the more general diffusion of knowledge on these subjects? The truth is, that public attention can never be turned to any art or science, without benefiting all its professors. A little knowledge of any given subject makes us desire to know more; and, though we first apply to books to acquire this further knowledge, we must ultimately have recourse to living professors to carry it into effect. No book can be framed so as to suit the exigencies of every particular case: all that can be done by any author is, to lay down general principles, and to deduce rules from them. The application of these rules must be learned from experience; and it is evident that a knowledge of the principles from which they are deduced will enable the amateur more thoroughly to appreciate and profit by the skill of the professor.

Among the important uses of this work will be that of pointing out the various capacities for improvement in comfort and beauty, of which each class of building, and each kind of furniture, is susceptible. Now, so far from this having a tendency to injure Architects, it will not only enable those who wish either to build or to furnish, to express more clearly, to the Architect or upholsterer, those wants which they already have; but it will elicit new ones, of which they had previously no idea, and which the Architect, the builder, and the upholsterer will be called upon to supply.

In expressing our acknowledgments to our contributors, it was originally our intention to thank, in an especial manner, those who, by their early contributions, when the work was commenced in monthly parts, in April, 1832, encouraged us to proceed with it; but, on due consideration, lest we might inadvertently appear partial in our acknowledgments, we think it best to return our sincere thanks generally to the whole of our contributors as enumerated in the list, p. xix. to xx. How much we feel indebted to the Architects and others, whose names are included in that list, can be only understood by those who are duly aware that the value of a work consisting principally of graphic designs, depends upon those designs being the production of a number of different minds. For the liberality which has been thus shown us, we have made the best return in our power, by publishing this work at such an unprecedentedly low price, as must insure, to the names and talents of our contributors, an extensive circulation; and, for our own labour, we have earned the consciousness of having produced a book, which must inevitably have an important influence on the rural Architecture of the temperate regions of both hemispheres.

## INTRODUCTION

1

## BOOK I.

### DESIGNS FOR LABOURERS' AND MECHANICS' COTTAGES, AND FOR DWELLINGS FOR GARDENERS AND BAILIFFS, AND OTHER UPPER SERVANTS, AND FOR SMALL FARMERS AND CULTIVATORS OF THEIR OWN LAND.

#### CHAP. I.

Model Designs for Cottages, exhibiting in each Model all the Accommodations and Arrangements for Comfort and Convenience of which the smallest Dwellings of this Class are susceptible	8
I. A Cottage of One Story; combining all the Accommodation and Conveniences of which human Dwellings of that Description are susceptible	9
II. A Cottage of One Story; combining the Accommodations and Conveniences of Design I, differently arranged, and with the Addition of a Veranda	21
III. A Cottage of Two Stories; combining the Accommodations and Conveniences of Design I, differently arranged, and with an additional Bed-room	23

#### CHAP. II.

A miscellaneous Collection of Designs for Cottage Dwellings, with Critical and Analytical Remarks	26
IV. A Dwelling for a Man and his Wife, without Children	27
V. A Dwelling for a Man and his Wife, with Two or more Children, with a Cow-house and Pigsty	31
VI. A Dwelling for a Man and his Wife, with an Apprentice, Servant, or grown-up Son or Daughter	35
VII. A Dwelling of Two Rooms, and a Back Kitchen, for a Man and his Wife	35
VIII. A Dwelling of Two Rooms, for a Man and his Wife	44
IX. A Dwelling in the Swiss Style, for a married Couple and Family, with a Cow-house and Pigsty	44
X. A Dwelling for a married Couple and One Child, with a Pigsty	48
XI. A Dwelling for a Man and his Wife, and One or Two Children, with a Cow-house and Pigsty	52
XII. A Dwelling of Two Stories, for a Man and his Wife, with a Servant and Two or Three Children, with a Cow-house and Pigsty	54
XIII. A Dwelling for a Man and his Wife, with Two or more Children	57
XIV. A Dwelling for a Man and his Wife, with One Servant, and a grown-up Son or Daughter	58
XV. A Dwelling for a Man and his Wife, without Children	63
XVI. A Dwelling for a Man and his Wife, without Children	65
XVII. A Dwelling with Two Rooms and a Bed-closet, for a Man and his Wife, with an Apprentice or Servant	71
XVIII. A Dwelling for a Man and his Wife, without Children	74
XIX. A Dwelling of Two Rooms, for a Man and his Wife, without Children	80
XX. A Dwelling for a Man and his Wife, with	

Children, and having a Cow-house, Pigsty, &c., attached	83
XXI. A Dwelling for a Man and his Wife, without Children	87
XXII. A Dwelling for a Gardener, or other Servant, on a Gentleman's Estate, who has a Wife, but no Children	88
XXIII. A Dwelling of One Story, for a Man and his Wife with a Family of Children; having a Cow-house and Pigsty attached	93
XXIV. A Dwelling for a Man and his Wife, without Children, having Two Rooms, and other Conveniences	94
XXV. A Dwelling for a Working Man, with a Family of Children	97
XXVI. A Cottage Dwelling in the German Swiss Style, for a Man and his Family, with Accommodation for two Horses and a Cow	98
XXVII. A Dwelling for a Man and his Wife, with Children, or a Servant, with the usual Conveniences in a detached Building	101
XXVIII. A Cottage in the Old English Manner, containing a Kitchen, Living Room, and Two Bed-rooms	102
XXIX. A Cottage Dwelling of Three Rooms, with various Conveniences	105
XXX. A Cottage Dwelling with Five Rooms, and various Conveniences	107
XXXI. A Dwelling with Five Rooms, with Conveniences, in the Old English Style, where the building Material is chiefly Stone	108
XXXII. A Cottage Dwelling with Two Sitting-Rooms, in the Old English Manner, where Timber, Brick, and Slate are the Materials used for the Walls and Roof	111
XXXIII. Two Cottage Dwellings, under the same Roof; each having Two Rooms and other Conveniences	135
XXXIV. A Cottage Dwelling of Two Rooms, intended as a Gate Lodge	137
XXXV. A Cottage Dwelling of Three Rooms, with Back Kitchen, Cow-house, and other Conveniences	138
XXXVI. A Dwelling with Four Rooms, a Back Kitchen, and other Conveniences	141
XXXVII. A Dwelling of Four Rooms, with other Conveniences, intended as a Lodge, or a House for a Bailiff or Head Gardener	141
XXXVIII. A Dwelling of Three Rooms, with a Back Kitchen, and other Conveniences, intended as a Porter's Lodge, or Gardener's House	143
XXXIX. Two Dwellings for Country Labourers, under One Roof, with Two Rooms in each, and other Conveniences	144
XL. Two Cottages of Three Rooms each, under the same Roof, with Cow-house, Pigsty, and other Conveniences to each	146
XLI. Six Cottages grouped together, with a view to Economy in building them	147
XLII. A Cottage of Three Rooms, in the Elizabethan Style	157
XLIII. A Cottage of Three Rooms, with Back	

	Page		Page
Kitchen, Cow-house, and other Conveniences	158	LXIX. A Cottage Dwelling, in the Old English Style, with Kitchen, Parlour, Business Room, Three Bedchambers, and other Conveniences	212
XLIV. A Cottage of Three Rooms and a Back Kitchen on the Ground Floor, with various Conveniences	163	LXX. A Cottage Dwelling of Four Rooms, with other Conveniences	214
XLV. A Dwelling of Four Rooms, with Back Kitchen, and other Conveniences	163	LXXI. A Castellated Lodge, as a Dwelling for a Gardener or other Upper Servant, on a Gentleman's Estate	214
XLVI. A Cottage Dwelling of Four Rooms, with a Back Kitchen, Cellar, and other Conveniences	164	LXXII. A Dwelling of Six Rooms, with various Conveniences	223
XLVII. Two Cottages for Country Labourers, under One Roof, with Four Rooms in each, Back Kitchen, Pigsty, and other Conveniences	168	LXXIII. A Dwelling, Three Stories high, with Four Rooms, and various Conveniences	224
XLVIII. A Dwelling of Four Rooms, with a Back Kitchen, and other Conveniences	175	LXXIV. Design for a Cottage Dwelling, in the Old English Style, and of a Construction suitable for having Part of the Walls covered with Weather Tiling	227
XLIX. A Dwelling suitable for a Lodge or Toll-house, having Three Rooms, and other Conveniences	176	LXXV. A Cottage in the Old English Manner, containing on the Ground Floor a Living-Room, Kitchen, and other Conveniences, with Two Bed-rooms over	231
L. A Cottage Dwelling of Four Rooms, with other Conveniences	176	LXXVI. A Cottage Dwelling One Story high, containing Six Rooms, a Wash-house, and other Conveniences	236
LI. A Cottage Dwelling of Six Rooms, with other Conveniences	179	LXXVII. The Model Cottages of the Labourer's Friend Society, as erected at Shooter's Hill, Kent	237
LII. Ideas for altering the Front of an old Cottage, at present in a dilapidated State	181	LXXVIII. Six Cottage Dwellings, built at Abersychan, near Pontypool, in South Wales, with One common Wash-house and Bakehouse	238
LIII. A Cottage for a Village Tradesman	182	LXXIX. Twelve or more Cottages in a Row, with a Kitchen, Wash-house, and other Conveniences in common; the whole heated by the Fires in the Public Kitchen	241
LIV. Two Cottage Dwellings for Labourers, under One Roof	184	LXXX. Eighty Dwellings of the humblest Class, placed together, with a view of being heated by One common Fire, and enjoying other Benefits, on the Cooperative System	244
LV. A Cottage of One Story, with Four Rooms, a Kitchen, and other Conveniences	186	LXXXI. A portable Cottage for the Use of Emigrants and others	251
LVI. A Dwelling of Four Rooms, with other Conveniences, and a large Rustic Portico	190		
LVII. Two Dwellings under One Roof, Two Stories high, with Four Rooms in each, and other Conveniences	191		
LVIII. A Labourer's Cottage of Two Rooms, with other Conveniences	192		
LIX. Two Cottages of One Room and a Back Kitchen each, under the same Roof	196		
LX. Two Dwellings under One Roof, each containing Four Rooms, with a Back Kitchen and other Conveniences	196		
LXI. A Dwelling of Three Rooms on the Ground Floor, with a Back Kitchen and other Conveniences	197		
LXII. A Dwelling of Four Rooms on Two Floors, with various Conveniences	201		
LXIII. Two Dwellings of Two Rooms each, under One Roof	202		
LXIV. Two Dwellings under One Roof, each Three Stories high, and having Three Rooms, and other Conveniences	202		
LXV. A Dwelling of Three Rooms, with other Conveniences	205		
LXVI. A Cottage Dwelling of Two Rooms, with a Smithy, Shoeing-shed, and Three-stalled Stable	205		
LXVII. A Cottage Dwelling of Five Rooms, in Two Floors	211		
LXVIII. A Dwelling of Four Rooms, with other Conveniences	211		

### CHAP. III

Designs and Directions for Exterior and Interior Finishing, as connected with Furnishing, and for the Fittings-up, Fixtures, and Furniture of Cottage Dwellings	258
SECT. I. Designs and Directions for the Exterior Finishing of Cottage Dwellings	259
SECT. II. Designs and Directions for the Interior Finishing of Cottage Dwellings	272
SECT. III. Designs and Directions for Internal Fittings-up for Cottage Dwellings	281
SECT. IV. Designs and Directions for Fixtures for Cottage Dwellings	282
SECT. V. Designs and Directions for Cottage Furniture and Furnishing	298

## BOOK II.

### DESIGNS FOR FARM HOUSES AND FARMERIES, COUNTRY INNS AND PAROCHIAL SCHOOLS.

#### CHAP. I.

Designs for Farm Houses and Farmeries, exhibiting various Degrees of Accommodation, from the Farm of 50 to that of 1000 Acres, suitable to different Kinds of Farming, and in different Styles of Architecture	354
SECT. I. General Principles and Model Designs for Farm Houses and Farmeries	355
1. General Principles and Model Designs for the Arrangement of a Farm House	355
2. Fundamental Principles, Directions, and Model Designs, for the Construction and Arrangement of the various Parts which compose a Farmery	373

#### CHAP. II.

A Collection of miscellaneous Designs for Farm Houses and Farmeries, in different Styles of Architecture, and adapted to	
--	--

different Kinds of Farms; with Specifications, Estimates, and accompanying Remarks	418
SECT. I. Miscellaneous Designs	418
I. A Bailiff's Cottage, in the Old English Style, intended for the Manager of a Farm in the Neighbourhood of London	418
II. A Farmery in the Old English Style, chiefly calculated for Dairy Husbandry, and conducted by a Bailiff, for the Proprietor of the Land	434
III. A Farm House and Farmery suitable for a Farm of 600 Acres of Turnip Soil, executed at Halstone, in Dumfriesshire	441
IV. A Farm House and Farmery suitable for an extensive Turnip Farm, executed at Gatetack, in Dumfriesshire	445
V. A Farm House and Farmery for a Farm of 150 Acres of Arable and Pasture Land in Buckinghamshire	448
VI. A Farm-House and Farmery for a Farm of 600 Acres of Turnip Soil, in Ayrshire, under a Rotation of Five Years, and em-	

	Page		Page
played partly in breeding and partly in feeding Stock	452	Haddingtonshire, consisting of 500 Arable Acres under a Six-course Shift	528
VII. A Farm House and Farmery for Three Ploughs, erected at Ingliston in Dumfriesshire	454	XXXV. A Farm House and Farmery at Elcho Castle, Perthshire, adapted for a Farm of Six Ploughs, under the Turnip Husbandry	537
VIII. A Farm House and Farmery for Three Ploughs, erected at Alton, in Dumfriesshire	457	XXXVI. A Public House and Farmery; the Publican being, at the same time, a small Farmer and a Butcher	544
IX. A Farm for breeding Sheep and Cattle, erected at Holecleugh, in Dumfriesshire	457	XXXVII. A House and Out-buildings for a Cheese Dairy Farm of from 300 to 350 Acres, in Cheshire	545
X. A Farm House and Farmery for a Farm of Two Ploughs, erected on the Grebten Estate, in Dumfriesshire	459	XXXVIII. A Mixed Stock Farm, in a high (hilly) Country, employing only One Pair of Horses	546
XI. A Farm House and Farmery for Four Ploughs, designed, and in Part executed in Dumfriesshire	460	XXXIX. A Farmery for a Garden Farm of 200 Acres, situated near a Town, employed wholly in Tillage, where no Stock is kept but Horses and Family Cows, and where the whole Produce is sold	549
XII. The Villa Residence and Farmery of Ridenwood, in the Parish of Kirkmahoe, Dumfriesshire, in the Occupation of the Proprietor, James Kerr, Esq.	462	XL. A Farmery for a Farm of 500 Acres, kept in a Rotation of Corn Crops and Pasture, producing Turnips, and employed partly in breeding and partly in feeding Stock	551
XIII. A Farm House and Farmery for 100 Acres of Land, to be cultivated on the Norfolk System, with a Flour Mill driven by Wind	471	XLI. A Farmery for a Farm of 500 Acres of Arable Turnip Land, kept under alternate Corn and Pasture, and employed in breeding and in feeding Stock, as well as in sending Corn to Market	552
XIV. A Farm House and Farmery for a Farm of Two Ploughs, in the County of Northumberland	475	XLII. A Dairy Farm of 500 Acres, kept in a Rotation of Corn Crops and Grass; One half being supposed to be in Hay or Pasture	552
XV. The Farm House and Offices at Cocklaw East Farm, on the Beaufront Estate, Northumberland	476	XLIII. A Farmery for a Clay Land Arable Farm of 500 Acres, not producing Turnips, and kept chiefly, or wholly, in Tillage	554
XVI. A Farm House and Farmery for Seven Ploughs, executed at Newnham Barns, in Northumberland	477	XLIV. A Farmery for a Farm of 150 Acres, kept in a Rotation of Crops and Pasture, producing Turnips and Potatoes; and employed partly in feeding and partly in breeding Stock	555
XVII. A Farm House and Farmery for Fourteen Ploughs, suited to the Northumbrian Husbandry	479	XLV. A Farmery for a Cottage Farm of 25 Acres	556
XVIII. A Farm House and Farmery for Ten Ploughs, Ten Cows, Twenty Young Cattle, and other Live Stock, adapted to the Husbandry of Northumberland	482	XLVI. A Farmery for a Cottage Farm of 30 Acres, with Remarks, showing how it may be extended so as to serve for a Farm of 50, 80, or 100 Acres	557
XIX. A Farmery of Five Ploughs, with Cows, Cattle, and other Stock in Proportion, suitable for the Northumbrian Husbandry	484	SECT. II. Examples showing the Manner of displaying Architectural Style in Farm Buildings	560
XX. A Farm House and Farmery for Three Ploughs, adapted to the Northumbrian System of Culture	485	SECT. III. On constructing temporary, portable, and ambulatory Farmeries; and on altering Mansions, Monasteries, Manufactories, and other Buildings, so as to render them fit for Agricultural Purposes	566
XXI. The Farm House and Offices for a Farm of Six Ploughs, called Hallington New Houses, on the Beaufront Estate, in Northumberland	486	SECT. IV. Designs for various Buildings, such as Corn Mills, Kilns, Malt-houses, Cider-houses, &c., connected with Agriculture and Rural Economy	568
XXII. The Farmery at Calley, in Kirkcudbrightshire, suitable for a Galloway Crop and Pasture Farm of 400 Acres	496	I. The Construction of a Building for containing the Machinery of a Corn Mill to be impelled by Water, with introductory Observations on Buildings for Mills generally, on Flour Mills, and on the different Kinds of Water-wheels	568
XXIII. A Farmery for a small French Farm, as given by Morel-Vindé	497	II. The Construction of a Building for containing the Machinery and Apartments belonging to a Vertical Windmill, with Remarks on the different Kinds of Windmills	583
XXIV. A Farm House and Farmery suitable for a Farm of from 300 to 500 Acres in France	499	III. A Malt Kiln, with the requisite Appendages, and Directions for their Use	589
XXV. For a Court of Feeding-houses, built for the late Thomas Hibbert, Esq., at Chalfont Lodge, Buckinghamshire	508	IV. A Hop-oast, or Kiln for drying Hops	592
XXVI. A Farmery for extensive Ironworks, erected at Abersychan, near Pontypool, in South Wales	511	V. A Hop-kiln, or Oast, on an improved Principle, erected in 1832, at Teston, in Kent	595
XXVII. A Farmery for a Farm of 250 Acres, in the Valley of Strathmore, where a Rotation of Seven Crops is followed, the Grass Division being pastured the Second Year	512	VI. An improved Limekiln	600
XXVIII. A Farmery for a particular Situation, suitable for 80 Acres of Arable Land, and 300 Acres of Pasture, in the Carse of Gowrie	514	VII. A Kiln for burning Bricks or Tiles, or other Earthenware used in the Construction of Buildings; and which may also be used as a Kiln for burning Lime or Clay for Manure, or coking Coal or Peat, or charring Wood, impregnating Timber with Pyroligneous Acid, Kiln-drying Corn, or drying Corn in the Sheaf in Wet Seasons, and for other Agricultural Purposes	605
XXIX. The Farm House and Farmery of Starston Place, near Harleston, in Norfolk, suitable for a Farm of 350 Acres under the Norfolk System of Culture	516	VIII. A Cider-house, Mill, and Press, according to the Plan most generally approved of in the Counties of Hereford and Worcester	609
XXX. A Farmery for a Farm of 300 Acres of Arable Land, and 500 of Pasture, in the West Highlands	519	IX. A Cider-house, Mill, and Press, with the different Implements connected with Cider-making	615

# LIST OF ENGRAVINGS.

## MODEL COTTAGES.

*Plans.* Design I. p. 10; fig. 3; II. p. 22; fig. 21; III. p. 24.  
*Elevations.* Figs. 6, 17, 18, 19, 20, 25, 26.  
*Sections.* Figs. 5, 22.

## COTTAGES OF ONE STORY

*Plans.* Design IV. p. 29; V. p. 30; VI. p. 33; VII. p. 34; VIII. p. 45; XI. p. 50; XIV. p. 61; fig. 99; XV. p. 69; XVI. p. 70; fig. 116; XVIII. p. 75; XIX. p. 76; XX. p. 85; fig. 154; XXI. p. 86; XXII. p. 89; XXIII. p. 90; XXIV. p. 95; XXVII. p. 100; XXIX. p. 104; figs. 193, 197, 201; XXXIII. p. 103; figs. 249, 252, 253, 254, 255; XL. p. 140; fig. 258; XLII. p. 159; XLIII. p. 160; fig. 297; LI. p. 178; fig. 315; LV. p. 187; figs. 338, 339, 340, 341, 342, 346; LXVI. p. 204; figs. 366, 377; twelve cottages, 433; college for working men, 440, 441, 442; portable cottages, 445, 477; gardener's house, 1454; for farm labourers' cottages, see p.

*Elevations.* Design IV. p. 29; figs. 29, 30; V. p. 30; figs. 31, 35; VI. p. 33; VII. p. 34; figs. 38, 42, 79; VIII. p. 45; XI. p. 50; fig. 86; XIV. p. 61; figs. 112, 113, 114, 115; XVI. p. 69; XVII. p. 70; figs. 117, 125; XVIII. p. 75; XIX. p. 76; figs. 133, 135, 144, 145, 157; XX. p. 85; XXI. p. 86; XXII. p. 89; XXIII. p. 90; XXIV. p. 95; XXVII. p. 100; XXIX. p. 104; fig. 194; XXXIII. p. 133; XXXIV. p. 134; XXXV. p. 134; XXXVI. p. 134; figs. 250, 251; XXXVIII. p. 139; XL. p. 140; XLII. p. 159; XLIII. p. 160; XLIV. p. 163; XLV. p. 166; figs. 300, 301; LI. p. 178; fig. 316; LV. p. 187; LXVII. p. 194; LXIX. p. 194; LX. p. 194; LXVI. p. 204; LXX. p. 215; LXXVI. p. 226; twelve cottages, fig. 439; college for working men, 444; portable cottages, 454, 456; gardener's house, 1455.

*Sections.* Design IV. p. 29; V. p. 30; VI. p. 33; VII. p. 34; VIII. p. 45; XI. p. 50; fig. 136; XX. p. 85; XXIII. p. 90; XXIV. p. 95; XXIX. p. 104; XXXIII. p. 133; XL. p. 140; XLII. p. 159; XLIII. p. 160; LV. p. 187; LXVI. p. 204.

## COTTAGES OF TWO STORIES.

*Plans.* Design IX. p. 46; X. p. 49; XII. p. 55; XIII. p. 56; fig. 95; XV. p. 62; figs. 98, 105, 106, 107; XXV. p. 96; XXVIII. p. 103; XXX. p. 109; XXXI. p. 110; XXXII. p. 117; figs. 256, 261, 267, 292, 305; XLVI. p. 169; XLVII. p. 170; XLVIII. p. 173; XLIX. p. 174; L. p. 177; figs. 314, 319, 325, 327; LVI. p. 188; LVII. p. 193; figs. 336, 345; LXV. p. 203; LXVII. p. 209; LXVIII. p. 210; figs. 361, 362, 367; LXXII. p. 216; fig. 368; LXXIII. p. 225; figs. 390, 391, 407, 408, 420, 421, 425, 427, 429, 433.

*Elevations.* In the Swiss style, Design IX. p. 46; Old English, X. p. 49; XII. p. 55; XIII. p. 56; figs. 94, 97; XV. p. 62; figs. 102, 108, 109, 138, 139, 140; XXV. p. 96; Old English, XXVIII. p. 103; fig. 203; XXX. p. 109; XXXI. p. 110; XXXII. p. 113; XXXIII. p. 139; XXXIX. p. 139; figs. 268, 291, 293; XLVI. p. 169; XLVII. p. 170; XLVIII. p. 173; XLIX. p. 174; L. p. 177; figs. 317, 318, 320, 326, 328; LVI. p. 188; LVII. p. 193; fig. 337; LXII. p. 199; LXV. p. 203; LXVII. p. 209; LXVIII. p. 210; LXIX. p. 215; castellated, LXXI. p. 215; LXXXI. p. 216; fig. 387; LXXXIII. p. 225; LXXXIV. p. 226; LXXXV. p. 226; figs. 423, 426, 428, 458, 459, 460.

*Sections.* Swiss, fig. 80; XXXII. p. 113 and 114; XLVI. p. 169; figs. 363, 364, 365, 372, 403, 404, 405, 406, 412.

## COTTAGES OF THREE STORIES.

*Plans.* Design XXVI. p. 99; LXIV. p. 200.  
*Elevations.* German cottage, Design XXVI. p. 99; LXIV. p. 200.

## COTTAGES FOR FARM LABOURERS.

*Plans.* Figs. 1203, 1204, 1205, 1207, 1208, 1211,

1212, 1218, 1219, 1223, 1225, 1226, 1228, 1229, 1230, 1236, 1237.

*Elevations.* Figs. 1206, 1209, 1210, 1213, 1214, 1215, 1220, 1224, 1227, 1232, 1235, 1241.

*Sections.* Figs. 1231, 1233, 1234.

## FARM HOUSES AND FARMERIES.

*Plans.* Figs. 749, 754, 757, 758; of ceiling joists, 759, 847, 848, 849, 899, 900, 901, 902, 906, 916, 918, 920, 922, 924, 925, 927, 931, 932, 936, 937, 948, 949, 952, 954, 956, 960, 963, 967, 971, 973, 987, 997, 999, 1000 to 1002, 1008, 1009, 1034, 1045, 1046, 1062 to 1064, 1066, 1070, 1071.

*Elevations, and Perspective and Isometrical Views.*

Figs. 751, 752, 753, 756, 761, 763; Design I.; 850 to 853, 855, 856; Design III. p. 443; IV. p. 444; fig. 944, 917, 919, 921, 923, 926, 928, 929, 930, 933, 934, 935, 938, 939, 940, 943, 955, 961, 962, 966, 970, 972, 988, 996, 998, 1004, 1006, 1012, 1033; with windmill, XIII. p. 473; XIV. p. 474; XV. p. 474; fig. 1041, 1049, 1051; XXXV. p. 535; XXXVI. p. 536; figs. 1065, 1067, 1068, 1069.

*Sections.* Figs. 750, 735, 760, 762, 854, 903, 904, 909 to 911, 914, 915, 946, 950, 951, 953, 974, 1003, 1005, 1007, 1010, 1011, 1013, 1047, 1048.

## FARMERIES ALONE.

*Plans.* Figs. 887, 969, 989, 990, 991, 1020, 1027, 1032, 1041, 1043, 1054, 1055, 1072, 1078, 1079, 1080, 1081, 1088, 1089, 1090, 1092, 1095.

*Elevations, and Perspective and Isometrical Views.*

Figs. 886 to 894, 968, 992, 995, 1018, 1026, 1029, 1031, 1040, 1042, 1043, 1053; Design XXXIV. p. 525; figs. 1077, 1081, 1093, 1094, 1096 to 1098.

*Sections.* Figs. 895 to 897, 993, 994, 1019, 1021, 1022, 1029, 1030, 1034.

## SHEEP HOUSES

*Plan.* Fig. 803.

*Elevation.* Fig. 806.

*Sections.* Figs. 804, 805, 807.

## BARN AND GRANARIES

*Plans.* Figs. 808, 816, 817, 1085.

*Elevations.* Figs. 812, 820.

*Sections.* Figs. 809, 810, 811, 813, 814, 815, 818, 819, 821, 1028, 1082, 1083, 1086.

## PIGGERY AND MEAL HOUSE.

Fig. 912.

## HOVELS.

Circular Hovel for Cattle. Figs. 907, 908.

## MILLS.

*Plans.* Figs., Water, 1108 to 1111; Wind, 1114 to 1118; Cider, 1170, 1173, 1176.

*Elevations.* Figs., Water, 1104 to 1106; Wind, 1113, 1120, 1122, 1123; Cider, 1179, 1181, 1185; Portable Corn Mill, 1288.

*Sections.* Figs., Water, 1107, 1112; Wind, 1119, 1121, 1124; Cider, 1171, 1172, 1174, 1175, 1176, 1177, 1178.

Cider Presses. Figs. 1179, 1185.

Cider Instruments. Figs. 1182 to 1184, 1186 to 1190.

Malt Plough. Fig. 1126. Water Mill Wheels. Figs. 1101 to 1103.

## KILNS.

*Plans.* Figs., Malt, 1129; Hop, 1136 to 1138, 1141, 1142, 1143, 1148, 1152, 1153, 1158; Lime, 1161, Brick, 1164, 1168.

*Elevations.* Figs., Hop, 1139, 1140, 1144, 1147, 1163.

*Sections.* Figs., Malt, 1134; Hop, 1145, 1149, 1150, 1151, 1154, 1155, 1156; Lime, 1157, 1159, 1160, 1162; Brick, 1165, 1166, 1167, 1169.

## POULTRY HOUSES.

*Plans.* Figs. 1191, 1197, 1198, 1199, 1200, 1201, 1723.

*Elevations.* Figs. 1192, 1194, 1195, 1723.

*Sections.* Fig. 1193, 1196, 1198, 1199.

## DAIRIES.

*Plan.* Figs. 741, 1722.  
*Elevation.* Figs. 744, 745, 746, 1721.  
*Sections.* Figs. 742, 743, 1724.

## ICEHOUSE.

*Plan.* Fig. 748.  
*Section.* Fig. 747.

## STABLES.

*Plans.* Figs. 774, 794; of flooring, 798, 1007, 1008, 1009, 1024, 1512, 1583, 1700; circular, 1702.  
*Elevations.* Figs. 777, 778, 759, 1006, 1012, 1023, 1025, 1584, 1613, 1699; Circular Italian, 1703; Gothic, 1704.  
*Sections.* Figs. 776, 779, 796, 797, 799, 957 to 959; 1010, 1011, 1013, 1050, 1087.

## RIDING-HOUSE.

*Plan* of that at Monaco. Fig. 1705.  
*Sections of Roofs.* Figs. 1705 to 1717.

## DOG KENNELS.

*Plan.* 1718.  
*Elevations.* 1719, 1720.

## FARM FURNITURE.

Thrashing-machine. Figs. 1285 to 1287.  
 Barley-chopper. Fig. 1289.  
 Turnip-cutter. Fig. 1291.  
 Oat-crusher. Fig. 1290.  
 Apparatus for steaming Potatoes. Fig. 1292.  
 Sheep-racks. Figs. 802, 1036, 1037, 1038, 1283.  
 Racks and Mangers for Stables. Figs. 770 to 773, 780 to 786, 942, 943, 944, 1014, 1015, 1016, 1035.  
 Draining-grating. Fig. 775.  
 Corn Measure. Fig. 1701.  
 Gruel-manger. Fig. 1272.  
 Pig-troughs. Figs. 801, 913, 1281, 1282.  
 Rick-stands. Figs. 825 to 837, 1039.  
 Rack for Cattle. Fig. 1279.  
 Tethering Stake. Fig. 1280.  
 Rabbit-trough. Fig. 1284.  
 Cow Trough. Fig. 1273.  
 Cow Ties and Brechin. Figs. 1274 to 1278.  
 Fodder Cribs. Fig. 965.  
 Saddle and Harness Pegs. Figs. 1269 to 1271.  
 Gates. Figs. 359, 360, 841 to 846, 871 to 873, 898, 1076.  
 Cheese-press. Fig. 1261.  
 Weighing-machine. Fig. 1260.  
 Sparrow-pot. Fig. 468.  
 Pumps. Siebe's, figs. 9, 10; Cottam's, 1294.  
 Liquid Manure Tanks. Figs. 840, 1073 to 1075.  
 Posts, &c. for Drying Clothes. Figs. 166 to 171, 1353.

## INNS AND PUBLIC HOUSES.

*Plans.* Figs. 1296, 1297, 1298, 1300, 1301, 1303, 1304, 1310, 1312, 1313, 1314, 1319, 1322, 1323, 1324.  
*Elevations.* Figs. 1295, 1299, 1302, 1309, 1311, 1318; Italian, 1321; Swiss, 1326.  
*Section.* Fig. 1320.  
 Interior of a Liquor Shop. Figs. 1315, 1316.

## SCHOOLS.

*Plans.* Figs. 1374, 1375, 1376, 1377, 1380, 1382, 1383, 1384, 1385, 1387, 1389, 1395, 1399, 1403.  
*Elevations.* Figs. 1386, 1390, 1391, 1392, 1393, 1394, 1398.  
*Sections.* Figs. 1378, 1388, 1396, 1397.  
*School Furniture.* Figs. 1379, 1381, 1400 to 1411.

## VILLAS.

*Maps and Plans.* Figs. 1435, 1439 to 1442, 1444 to 1448, 1450, 1451, 1453, 1456, 1457, 1459 to 1463, 1470, 1471, 1473, 1474, 1480 to 1482, 1488 to 1491, 1496, 1498, 1501, 1504, 1505, 1506, 1509, 1510, 1511, 1538, 1540, 1541, 1543, 1545, 1548 to 1550, 1565, 1567, 1571, 1573, 1580 to 1582, 1585, 1590, 1591, 1592, 1597, 1598, 1600, 1601, 1602, 1603, 1606, 1608, 1609, 1645, 1652, 1653, 1662.  
*Elevations and Views.* Figs. 1412 to 1434, 1436 to 1438, 1443, 1449, 1452, 1458, 1464 to 1467, 1469, 1472, 1475, 1479, 1485, 1486, 1487, 1492, 1493, 1497, 1503, 1508, 1513 to 1516, 1539, 1544, 1546, 1547, 1551, 1552, 1566, 1568 to 1570, 1572, 1574, 1586, 1587, 1588, 1589, 1599, 1604, 1605, 1607, 1610, 1611, 1612, 1646, 1658, 1659, 1660, 1661, 1663.  
*Sections.* Figs. 1483, 1484, 1494, 1495, 1507, 1553, 1593, 1614.

*Illustrations of Gothic Architecture.* Figs. 1593 to 1596, 1615 to 1644, 1647 to 1651.  
*Illustrations of Italian Architecture.* Figs. 1670 to 1698.

## CONSERVATORIES

*Plan.* Fig. 1725.  
*Elevations.* Figs. 1729, 1730, 1731, 1732, 1733  
*Sections.* Figs. 1726, 1727.

## COTTAGE GARDENS.

*Gardens.* Design XIII. p. 56; XIV. p. 61; XVI. p. 69; XVII. p. 70; XVIII. p. 76; XXI. p. 86; XXII. p. 69; XXVII. p. 100; figs. 247, 260, 289, 290; LI. p. 178; public house, figs. 1298, 1301.

## VILLA GARDENS AND SCENERY.

*Villa Scenery.* Figs. 1441, 1445, 1480, 1489, 1800, 1543, 1571, 1585, 1653.  
*Gardens.* Figs. 1448, 1452, 1456, 1496, 1652.  
*Architectural Gardens.* Figs. 1734, 1735, 1736.

## TEMPLES AND COVERED SEATS.

Figs. 1758, 1759, 1760.

## CASCADE.

Fig. 1761

## FOUNTAINS.

Figs. 1762, 1763, 1764, 1765, 1766, 1767, 1768.

## RUINS AND ANCIENT CASTLES.

Figs. 1769, 1770.

## SUNDIAL.

Fig. 1771.

## VASES.

Figs. 1240, 1772 to 1777.

## URNS.

Figs. 1778, 1779, 1780.

## PEDESTAL.

Fig. 1781.

## CENOTAPHS AND TOMBS.

Figs. 1782, 1783, 1784.

## ENTRANCE LODGES AND GATES.

*Plans of Lodges.* Figs. 1786, 1788, 1790, 1792, 1794, 1796, 1798.  
*Elevations of Lodges and Gates.* Figs. 1785, 1787, 1789, 1791, 1793, 1795, 1797.  
 Gates and gateways. Figs. 1799 to 1805.

## DETAILS OF CONSTRUCTION.

*Roofs.* Figs. 33, 54, 121 to 124, 226, 227, 229; of corrugated Iron, 348 to 354, 1670; for Riding-houses, 1705 to 1717, 1726, 1727, 1821, 1822.  
*Eaves of Roofs and Gutters.* Figs. 27, 36, 40, 55, 56, 59, 63, 77, 101, 103, 120, 127, 142, 155, 159, 160, 173, 174; Design XXXI. p. 118; figs. 248, 263 to 265, 304, 335, 371, 388, 389, 800, 864, 945, 1125, 1216, 1217, 1306, 1468, 1670, 1672.  
*Barge-boards and Gables.* Figs. 181, 185, 299, 321, 378 to 385, 863, 865, 1476 to 1478, 1627.  
*Pinnacles.* Figs. 78, 1626.  
*Water Trunks, or Spouts.* Figs. 60, 61.  
 Thatching. Fig. 89.  
*Tiles, Quarries, and Slating.* Figs. 23, 24, 43, 146, 163, 164, 434, 885, 947; Slating, 1099, 1100; Kiln, 1135, 1238, 1239, 1242, 1517 to 1529, 1670 to 1673, 1809 to 1813.  
*Modes of Joining Pieces of Timber.* Figs. 49, 50, 57, 238, 239, 376, 422, 447, 448, 450 to 453, 455, 595, 1180.  
*Walls.* Figs. 7, 39, 44, 48, 216, 306 to 312, 329 to 334, 463, 975, 976, 1056, 1057, 1674.  
*Partition Walls.* Figs. 46, 58, 266.  
*Weather Tiling.* Figs. 392 to 402, 466.  
*Mathematical Tiling.* Figs. 461 to 465, 467.  
*Chimney-tops.* Figs. 32, 33, 84, 88, 91, 92, 100, 104, 131, 132, 141, 165, 172, 176, 190, 196, 202, 294, 303, 324, 343, 347, 373, 409 to 411, 435, 436, 879 to 882, 1305, 1308, 1531 to 1537, 1579, 1675 to 1682; Slates for ditto, 430 to 432.  
 Tessellated Pavements. Figs. 1517 to 1529; 1809 to 1813.  
 Watchtowers and Bell-turrets. Figs. 1692 to 1695.  
*Windows.* Figs. 28, 45, 73, 85, 90, 180, 188, 191, 192, 235, 237, 257, 262, 283 to 288, 322, 323, 344; Storm-head, 386, 478 to 489, 787, 876, 976, 977, 1307, 1595, 1616, 1617, 1619 to 1624, 1628 to 1635, 1647, 1684 to 1688, 1723.

Canopies for Windows. Figs. 496 to 500.  
 Mullions. Figs. 87, 177.  
 Sash-bar. Fig. 126.  
 Doors and Porches. Figs. 64, 232; Corrugated  
 Iron, 355 to 358, 469 to 476, 519, 875, 1575, 1576,  
 1593, 1594, 1596, 1616, 1689 to 1691, 1696 to 1698.  
 Door Bracket. Fig. 34.  
 Sills. Figs. 216, 218, 981.  
 Gauge-box for hollow Walls. Figs. 1221, 1222.  
 Curb for a Well. Figs. 229, 230.  
 Verandas. Figs. 128 to 130.  
 Stairs and Staircases. Figs. 137, 241, 242, 1643, 1644,  
 1648.  
 Chimneys and Chimney-pieces. Figs. 47, 210 to 214,  
 219, 220, 245, 518, 541, 542, 1542, 1578, 1650, 1817,  
 1847, 1848.  
 Chimneys for Steam-engines. Figs. 1267, 1268.  
 Floors. Figs. 52, 62, 231, 446; Parquetted, 1814 to  
 1816.  
 Modes of Heating Floors, &c. Figs. 4, 11, 276 to  
 282, 295, 296, 313, 1202.  
 Ventilator. Fig. 1381.

## FINISHINGS, FITTINGS-UP, AND FIXTURES.

Panels for Rooms. Figs. 518, 519, 1849, 1850.  
 Ceilings. Figs. 1640 to 1642, 1651.  
 Mouldings and Skirtings. Figs. 71, 195, 200; De-  
 sign XXXI. p. 118; figs. 233, 234, 240, 418, 514  
 to 517, 859 to 861, 877, 1554 to 1564, 1618, 1625,  
 1636 to 1639, 1649.  
 Window-fasteners. Figs. 72, 236, 985.  
 Plaster Ornaments for Ceilings. Figs. 511 to 513.  
 Cornices. Figs. 41, 93, 178, 179, 182, 183, 186, 204;  
 Design XXXII. p. 118; figs. 302, 501 to 510,  
 869, 1683.  
 Filters. Figs. 8, 119, 275.  
 Tanks for Water. Figs. 1, 118, 822 to 824.  
 Water-closets. Figs. 13 to 16, 269, 413 to 415, 437,  
 438, 1325, 1336 to 1338.  
 Stink-traps. Figs. 215, 222 to 224, 838, 839, 1499,  
 1500.  
 Door-spring. Fig. 274.  
 Cranks and Pulleys. Figs. 270 to 273, 520, 1818  
 Blinds. Figs. 788 to 793, 1806 to 1808.  
 Breweries. Figs. 1830 to 1833.  
 Kitchen and different Apparatus. Figs. 1819 to  
 1829; Sinks for, figs. 416, 544, 1259, 1332; Roll-  
 ers for Towels, figs. 546, 547; Dressers for,  
 figs. 557 to 566; Cupboards, figs. 567 to 572.  
 Gas-pipes for Cooking. Figs. 1317, 1373, 1825 to  
 1829.  
 Gas-pipes for Lighting. Figs. 1835 to 1837.  
 Movable Cupboards. Figs. 1327 to 1329.  
 Nails and Wall-hooks. Figs. 51, 76, 221, 244, 246.  
 Brackets. Figs. 81, 82, 161, 162, 553, 554, 556, 983,  
 1249, 1250, 1333, 1339 to 1341, 1865, 1866, 1867.  
 Balusters. Fig. 184; Design XXXII. p. 118; figs.  
 584, 858, 870, 874.  
 Parapets. Figs. 83, 134, 147 to 154, 175, 189; De-  
 sign XXXII. p. 119; figs. 862, 1330, 1577, 1737  
 to 1757.  
 Ornamental Nails. Figs. 477, 1854, 1855.  
 Ornamental Shutters. Figs. 490 to 493.  
 Locks. Figs. 69, 70.  
 Bolts. Figs. 68, 494.  
 Hinges. Figs. 37, 65, 66, 187, 298, 495, 606, 731,  
 982, 1058, 1059, 1060, 1061, 1851.  
 Latch. Fig. 67.  
 Handles for Doors. Figs. 1832, 1833.  
 Modes of hanging Pictures. Figs. 1856, 1857.  
 Grates. Figs. 521 to 527, 533 to 539, 978, 979, 1243,  
 1244, 1245, 1252 to 1255, 1256, 1257; American,  
 1258; Folding, 1330, 1331, 1843 to 1848.  
 Heating-Stoves. Figs. 1838 to 1842.  
 Cooking-Stoves. Figs. 520 to 530, 1354 to 1360.  
 Ovens. Figs. 531, 532, 1361 to 1372.  
 Ash-pan. Fig. 540.  
 Register. Fig. 543.

## INTERIORS.

Dining-rooms, Grecian. Fig. 1900; Gothic, fig.  
 2009; Elizabethan, fig. 2037.  
 Drawingrooms, Grecian. Fig. 1980; Gothic, 2021;  
 Elizabethan, 2038.  
 Library, Gothic. Fig. 2012.

## KITCHEN FURNITURE.

Sinks. Figs. 544, 545, 1259, 1332.  
 Rollers, &c. for Towels. Figs. 546, 547.

Tables. Figs. 550 to 556, 596, 601, 1348 to 1350.  
 Dressers. Figs. 557 to 565.  
 Cupboards. Fig. 567 to 572.  
 Kneading-trough. Fig. 593.  
 Settles. Fig. 636, 1346.  
 Chairs. Figs. 643 to 650.  
 Stools. Figs. 623 to 630, 1379.  
 Clocks. Figs. 729, 730, 1247.  
 Stand for brushing Clothes. Fig. 733.  
 Washing-machines. Fig. 1262, 1335.  
 Wringing-machines. Fig. 1262, 1858.  
 Mangles. Figs. 1263, 1264, 1265, 1834.  
 Knife-cleaner. Fig. 1266.  
 Napkin-press. Fig. 1334.  
 Cooking Apparatus. Figs. 1354 to 1373, 1822 to  
 1829.

## HALL FURNITURE.

Hat and Cloak Pins and Stands. Figs. 548, 549,  
 724 to 727.  
 Benches. Figs. 632 to 635, 637 to 639, 1863, 1864,  
 2003.  
 Table. Fig. 2034.  
 Chairs. Figs. 640 to 642, 651, 718, 1343 to 1347,  
 1859 to 1862, 2004.  
 Mats and Scrapers. Figs. 719 to 723.

## DINING-ROOM FURNITURE.

Sideboards. Figs. 573 to 575, 1868 to 1877, 1880,  
 2005, 2035.  
 Tables. Figs. 602, 613 to 615, 1882 to 1890, 2006.  
 Castors. Fig. 603; Table Flap-cases, 1878 to  
 1881.  
 Screens. Figs. 732, 1896, 1899.  
 Window-curtains. Figs. 705, 708, 710, 711.  
 Chimney-glasses. Figs. 712, 713.  
 Chairs. Figs. 1891 to 1895, 2007, 2008.  
 Leg-rest. Fig. 1897; Candlestick-stand, 1898.

## LIBRARY FURNITURE.

Bookcases and Writing-tables. Figs. 576 to 582,  
 1901 to 1904, 1906, 1907, 2010, 2011.  
 Library-table. Figs. 1905, 2014.  
 Book-stands. Figs. 583, 584.  
 Window-curtains. Figs. 705, 708, 710, 711.  
 Chimney-glasses. Figs. 712, 713, 1914.  
 Desks. Figs. 610, 1908, 1909.  
 Chairs. Figs. 1911, 1912, 1913, 2013, 2029, 2033.

## DRAWINGROOM FURNITURE.

Chimney-glass. Fig. 1975.  
 Curtains. Fig. 1976 to 1979  
 Stool. Fig. 2020.  
 Tables. Fig. 604 to 609, 611, 612, 1938 to 1941, 1943,  
 1944, 1947 to 1958, 2019.  
 Footstools. Figs. 631, 1921, 1922.  
 Chairs. Figs. 652 to 660, 1923 to 1937, 2015 to 2018,  
 2023 to 2025, 2030 to 2032.  
 Fire-screens. Figs. 1972 to 1974.  
 Chiffonier. Fig. 1942.  
 Sofas, Couches, Ottomans, and Sofa Bedsteads.  
 Figs. 674 to 680, 1915 to 1920.  
 Devonports. Figs. 1945, 1946.  
 Piano-fortes, Music-stands, &c. Figs. 1961 to 1966,  
 1968.  
 Book-stands. Figs. 583, 584, 1959, 1960.  
 Portfolio-stand. Figs. 1967, 1969.  
 Flower-stands. Fig. 1970, 1971.

## NURSERY FURNITURE.

Figs. 734 to 740, 1997 to 2002.

## SCHOOL FURNITURE

Figs. 1404 to 1411.

## BEDROOM FURNITURE.

Bedsteads. Figs. 681 to 699, 1981, 1982, 1984, 2022.  
 Bed Pillars. Figs. 1983, 2036.  
 Cribs, &c. for Children. Figs. 700 to 703, 1997.  
 Wardrobes. Figs. 585 to 591, 1987 to 1989.  
 Looking-glasses. Figs. 714 to 717, 1991 to 1994.  
 Chest of Drawers. Fig. 592.  
 Towel-stands. Figs. 723, 1351, 1352.  
 Chairs. Figs. 661 to 673.  
 Tables. Fig. 619 to 622, 1986.  
 Washhand-stands. Figs. 616 to 618, 1910, 1995,  
 1996.  
 Bed-steps. Fig. 1985.  
 Dressing-table. Fig. 1990.

## LIST OF BOOKS QUOTED.

*The Abbreviated Title, or the Name of the Author, is given, with the Number of the Paragraph where the work, or the Author, is first mentioned, and afterwards the Title of the Books at length. All the Works in this List, with the exception of one or two which are out of print, may be had of Messrs. Priestley and Weale, Architectural Booksellers, High Street Bloomsbury, London, to whom we beg thus publicly to acknowledge our obligations for the loan of several of the volumes enumerated.*

# ENCYCLOPÆDIA

OF

## COTTAGE, FARM, AND VILLA ARCHITECTURE.

---

---

### INTRODUCTION.

**T**HE main object of this ENCYCLOPÆDIA OF COTTAGE, FARM, AND VILLA ARCHITECTURE, is to improve the dwellings of the great mass of society, in the temperate regions of both hemispheres: a secondary object is to create and diffuse among mankind, generally, a taste for architectural comforts and beauties.

The means by which we propose to accomplish these objects are the following:—

By submitting a series of Designs for human dwellings, embracing every appropriate comfort and the greatest variety of beauty; and by accompanying these Designs with analytical and critical remarks, pointing out in what this comfort and beauty consist, and on what principles both are founded.

By submitting a series of Designs for the finishing, fittings up, fixtures, and furniture suitable to the different descriptions of Cottage, Farm, and Villa Buildings; and by accompanying these with remarks on their fitness for the end in view, such as lighting, heating, ventilating, &c., as well as with analytical and critical remarks on their style or beauty; thus showing the necessity of Architects including the study of furniture in that of their profession, so as to be able to give Designs for furnishing a house, as well as for building one.

By accompanying many of the Designs with gardens, as well small kitchen and flower gardens for the cottager, as pleasure ground and park scenery for the occupant of the villa; and by explaining the connexion of Villa Architecture with Landscape Gardening, and pointing out the necessity which exists for Villa Architects possessing a considerable knowledge of the art of laying out grounds.

By avoiding, when it is not absolutely necessary, the use of terms peculiar to Architecture; by explaining all such as are used, where they first occur; and by adopting such a style, as will render the work easily understood by the uninitiated reader, as well as subservient to the purpose of educating young persons in Architecture as an art of taste, especially those of the female sex.

To attain the end proposed, we commence our work with Designs, as rendering it more attractive to a general reader, as well as of more immediate practical utility to persons intending to build or furnish, than it would be if commenced with abstract principles; and because, in the analytical and critical remarks, with which we mean to accompany these Designs, we intend to develop, as it were, incidentally, and by little and little, all the principles of Architecture, and also those of Landscape Gardening as connected with Buildings. We consider this mode of instruction best calculated for those practical men who have not had a sufficient education, or have not pursued such a course of reading in early youth, as to enable them to enter at once on the perusal of discussions, which must necessarily be, to a considerable extent, metaphysical. We also consider this mode by far the best adapted for initiating the general reader in the principles of architectural taste; and for enabling young persons, especially ladies, to educate themselves in Architecture as an elegant art.

The improvement of the dwellings of the great mass of society throughout the world, appears to us an object of such vast importance, as to be well worth attempting, even though

we may not all at once succeed to our utmost wishes. In ameliorations necessarily involving considerable expense, much cannot be expected to be performed immediately; yet, by making known the various particulars in which these ameliorations consist, to those who are to derive important benefits from them, we may rest certain, that, sooner or later, they will be effected. The efforts of Architects, in all ages and countries, have hitherto been, for the most part, directed to public buildings, and to the mansions of princes, noblemen, and men of wealth; and what have hitherto been considered the inferior orders of society, have been, for the most part, left to become their own architects. Hence the tardiness with which the improvements made in the accommodation, arrangement, and exterior beauty of the mansions of the wealthy, have found their way to the dwellings of the poor. The great object of this work is, to show how the dwellings of the whole mass of society may be equalized in point of all essential comforts, conveniences, and beauties.

By implanting in the minds of general readers, and especially of the youth of both sexes, some knowledge of the good and bad of Architecture, as an art of Design and Taste, it is evident that this main object will also be promoted. Teach the young what architectural beauty is, and they will admire it; show them how it may be produced in their dwellings, and they will desire to possess it. Whatever is generally and ardently desired, and unremittingly pursued, is certain of being ultimately obtained.

Independently of the usefulness of the study of Architecture, its pursuit, as a fine art, recommends itself, like the study of painting and sculpture, as a rational source of intellectual entertainment; easily indulged in, since buildings occur every where, and form one of the principal sources of interest in all towns and cities, and in travelling. The great use of the study of any of the fine arts is, to polish and refine the taste, and divest the mind of vulgar and common-place feeling. Architecture is the only fine art open to the inspection of all, and interesting to all; and could we only succeed in raising the taste of the mass of society in this art, we should not only effect an universal improvement in Architecture, but materially contribute towards the universal adoption of correct and elegant habits of thinking and acting generally.

As the buildings of every country are open to all its inhabitants, it may be asked, why all have not already a correct and elegant taste in this art? To this we answer, by asking how it happens that all persons have not a correct knowledge of their native language; or a good taste in written compositions? The truth is, that but a very slight knowledge of any subject can be obtained without studying its first principles. There is a grammar in Architecture which must be taught, no less than the grammar of language; and when that grammar is mastered empirically, there remains to be acquired the principles of human nature, upon which its rules are founded. It is on Architecture, as founded on these principles, that we chiefly rest our hopes of creating a general taste for the art, and of rendering architectural criticism as common among all classes of society, as the criticism of general literature.

"It is not," says a clever architectural writer, (*Foreign Quarterly Review*, April, 1831,) when advocating the study of Architecture by women, "in order that they may be able to draw columns, for that is merely the means, not the end of the pursuit, that we would suggest the propriety of ladies applying themselves to what has hitherto never been included within the circle of female acquirements; but that they may thereby cultivate their taste, and ground it on something less baseless and shifting than mere feminine likings and dislikings. And when we consider how wide is the province, how influential the authority, which the sex are apt to claim in such matters; how much, in all that regards ornamental furniture and interior embellishments, depends on the refined or trivial taste of our fairer halves; it must be acknowledged that to initiate them into such studies would not be an act of perfect disinterestedness." Independently of its subsequent advantages, the study of the Grammar of Architecture, or, in other words, "the elementary practice of architectural drawing, would be highly beneficial to the youthful pupils, inasmuch as it affords an immediate application of the simpler principles of geometry; as it forms the hand to correctness, the eye to a scrupulous examination of forms, and, consequently, implants habits of careful deliberation and attention, as well as the seeds of taste."

We entirely agree with this writer in his opinions of the influence which women would have on the public taste in Architecture; believing, as we do, that the improvement which, within the last fifty years, has taken place in landscape gardening, is, in a great measure, owing to the more general adoption of the art of sketching landscapes from nature, as a branch of female education. If the study of landscape drawing, by ladies, has led to the improvement of landscape gardening, why should not the study of architectural drawing, on their part, lead to the improvement of domestic Architecture?

The influence of Architecture on taste and morals has been argued, in a masterly manner, by Dr. Dwight, when speaking of what he saw of its influence in the towns of New England. Speaking of a city which had, when he saw it, in the beginning of the present century, been twice ravaged by fire, this admirable author observes, that though the tenants of the houses which were burned were, in many instances, sufferers, yet the town and the proprietors gained much. "The town," he says, "has already been improved not a little in its appearance, and will probably be much more improved hereafter. There are persons who will imagine this to be a matter of little consequence. I wish them to consider for a moment the following hints:—

"There is a kind of symmetry in the thoughts, feelings, and efforts of the human mind. Its taste, intelligence, affections, and conduct, are so intimately related, that no preconception can prevent them from being mutually causes and effects. The first thing powerfully operated on, and, in its turn, proportionally operative, is the taste. The perception of beauty and deformity, of refinement and grossness, of decency and vulgarity, of propriety and indecorum, is the first thing which influences man to attempt an escape from a grovelling, brutish character; a character in which morality is effectually chilled, or absolutely frozen. In most persons, this perception is awakened by what may be called the exterior of society, particularly by the mode of building. Uncouth, mean, ragged, dirty houses, constituting the body of any town, will regularly be accompanied by coarse, grovelling manners. The dress, the furniture, the equipage, the mode of living, and the manners, will all correspond with the appearance of the buildings, and will universally be, in every such case, of a vulgar and debased nature. On the inhabitants of such a town, it will be difficult, if not impossible, to work a conviction, that intelligence is either necessary or useful. Generally, they will regard both learning and science only with contempt. Of morals, except in the coarsest form, and that which has the least influence on the heart, they will scarcely have any apprehensions. The rights enforced by municipal law they may be compelled to respect, and the corresponding duties they may be necessitated to perform; but the rights and obligations which lie beyond the reach of magistracy, in which the chief duties of morality are found, and from which the chief enjoyments of society spring, will scarcely gain even their passing notice. They may pay their debts, but will neglect almost every thing of value in the education of their children.

"The very fact, that men see good houses built around them, will, more than almost anything else, awaken in them a sense of superiority in those by whom such houses are inhabited. The same sense is derived, in the same manner, from handsomer dress, furniture, and equipage. The sense of beauty is necessarily accompanied by a perception of the superiority which it possesses over deformity; and is instinctively felt to confer this superiority on those who can call it their own, over those who cannot. This, I apprehend, is the manner in which coarse society is first started towards improvement; for no objects, but those which are sensible, can make any considerable impressions on coarse minds. On these grounds I predicted to my friends in this town a speedy change for the better in its appearance, and in the character and manners of its inhabitants. I have since seen this prediction extensively fulfilled."—(*Travels in New England*, vol. ii. p. 202.)

"The connexion of Architecture with the other fine arts," says the critic, in the *Foreign Quarterly Review*, "and the convenience of knowing at least as much of it as will enable us to judge how far the accessories in a picture are correct, where buildings are introduced, are too obvious to be insisted upon; neither is it necessary to expatiate on the superior advantages possessed by the traveller who has qualified himself, by a competent study of the subject, for enjoying the local beauties of the cities he visits. It might be conceived that the additional interest which an acquaintance with the various styles of Architecture imparts to historical studies, and the kind of *memoria technica* furnished by the various reminiscences connected with celebrated buildings, would alone form a sufficient reason for directing the attention of the youthful pupil to such studies."—*Foreign Quarterly Review*, April, 1831.

"He who criticises every fine building which he sees," observes one whom we consider the most philosophical of British architectural authors, "with a sincere desire to find out whatever in it is excellent, bringing everything to the test of his own unbiassed feelings and judgment, will form to himself a habit, profitable, not only when applied to Architecture, but to every subject on which the human understanding is exercised."—*Wood's Letters of an Architect*, Preface.

By the principles of Architecture, many persons understand nothing more than certain established rules and precedents, drawn from the ancient buildings of Greece and Rome; and, for the greater part, comprehended in the study of the orders used in Grecian and Roman temples. 'Are not those orders everything—the all in all of Architecture?' say such persons. "The whole science," observes the critic before quoted, "is commonly

thought to consist in knowing a few cabalistic words derived from the Greek, and a few mechanical rules for the proportioning of columns; while, for those who would wish to acquire such a knowledge of Architecture, as would enable them to appreciate its beauties as they do those of its sister arts, there is hardly a single elementary work, that is not either too superficial, or merely technical. Instead of anything like generalization of principles, or originality of views, we meet with insulated rules, and the dull quackery of monotonous routine: while peurile trifling, or anile superstition, is suffered, in many cases, to exclude even a glimpse of common sense. In almost every other branch of knowledge, the student is able to provide himself with theoretical and critical, as well as practical, works; but here, he ought to be endued with more than ordinary ardour and perseverance, if he would collect for himself the insulated scraps of criticism, and the few really useful, original remarks that, 'few and far between,' are scattered over a wide expanse of almost unvaried sameness."—*Foreign Quarterly Review, April, 1831.*

But a knowledge of the rules of Grecian Architecture, can no more be considered the principles of the science, than the art of mixing colours can be called the principles of painting. "The great object of an Architect," says Wood, "is to determine in what manner, with means always in some degree limited, either by the nature of the material to be employed, the customs of the country, the expense, or the taste or no taste of the employer, he can combine beauty with utility. The connexion of beauty, as an effect, with the composition of the parts of buildings, as the cause of that effect, is the great end and object of the Architect."—*Letters of an Architect, Preface.*

After studying with care all the various opinions delivered by different architectural writers on the subject of the principles of their art, and divesting ourselves, as much as possible, of all accidental associations and temporary prejudices, we have arrived at the following conclusion:—that the leading principle of Architecture, as a useful art, is fitness for the end in view; as an art of design, expression of the end in view; and, as an art of taste, expression of some particular Architectural style. Those beauties or effects which are the result of the first and second principles, are in their nature permanent; those which are the result of the third principle, are in their nature temporary and accidental.

All the various principles which come into operation, in the design and construction of buildings, easily range themselves under these three fundamental principles. The fitness of a design for the end in view, comprehends, not only the fitness of the size, shape, number, relative position, and other particulars of the interior divisions of a building, for the uses for which they are intended; but the fitness of the materials and construction, with reference to the strength and durability which may be required; and the fitness of the expenditure for the means at the command of the builder. In like manner, the principle of the expression of the purpose, or end in view, applies not only to unity of expression in a building as a whole, but to the separate expression of all the different parts of a building for the purposes for which they are intended. So also the expression of architectural style applies, not only to the building taken as a whole, which must be in the same style throughout, but to all its component parts, which, even to the most minute details, must belong to that style, and exhibit its characteristics.

Thus, as there are various uses to which buildings are devoted, so are there various kinds of beauty of which they can be rendered expressive. But, as all the uses to which buildings can be applied, all the arrangements which are requisite for convenience or luxury, and all mechanical or chemical processes which enter into their construction, are referable to the principle of fitness; so all the different kinds of beauty of which they are susceptible, are referable either to the expression of purpose, or to the expression of style. A cottage or a barn, which are recognized to be such at the first glance, are so far perfect, as to the expression of purpose; but they may also be specimens of Grecian or Gothic Architecture, in which case, to the expression of purpose is added the expression of style.

As fitness and the expression of purpose are principles applicable to all buildings whatever; so fitness, the expression of purpose, and the expression of architectural style, comprehend all the beauties of which buildings are susceptible.

The principle of expression of purpose, is of universal application in Architecture; and whatever building will bear the test of examination according to it, cannot but prove satisfactory to every unprejudiced mind, though it may not possess any of the beauties of architectural style. The minds of all men, however, are more or less subject to the prejudices of the age and country in which they live; and the prejudices of European Architects and their employers, seem long to have been in favour of the expression of architectural style in building, rather than of the expression of use or purpose. This circumstance has influenced the general taste; and hence it is, that the critical observer,

when looking at what is considered a fine building, instead of first examining whether it is expressive of the purpose for which it is applied, considers only whether it is intended to be in the Grecian, Roman, or Gothic style; and, having determined to which of these styles it belongs, he next examines whether the details of the building are in strict conformity with the best practice and precedents in that style. But according to the principles we have laid down, it will be seen that the Grecian and Gothic styles are mere accidents in Architecture; and are nothing more than the language which the Architect makes use of to convey his ideas. The expression of the purpose, for which every building is erected, is the first and most essential beauty; and should be obvious from its Architecture, altogether independently of any particular style; in the same manner as the reasons for things, are altogether independent of the language in which they are conveyed. As in literary compositions, no beauty of language can ever compensate for poverty of sense; so, in architectural composition, no beauty of style can ever compensate for the want of expression of purpose. Every reasonable mind must feel this; for, as we have said before, the foundation of all true and permanent beauty is utility.

But though it is necessary to study the expression of purpose, as the first and fundamental beauty in all Architecture, it is by no means either necessary or advisable to neglect the study of style; on the contrary, the judicious artist will take advantage of the prejudices in favour of this kind of beauty already fixed in the minds of mankind, and will employ it, so as to co-operate with and heighten the expression of purpose; because there are many persons who can admire the beauty of style, by whom the more simple and universal beauty of expression of purpose, would neither be relished nor understood.

Most authors, from Vitruvius to the present time, divide the subject of Architecture into use and decoration; and, by decoration, it is evident that they mean what we denominate style; though scientifically considered, style and decoration are essentially different. Any building may be decorated, by fixing on it ornamental objects of different descriptions; but for a building to be in a particular style, all its principal parts must be characteristic of that style, and must co-operate in producing one effect, or expression.

Another class of architectural writers, Laugier, John Wood, Milizia, and especially Quatremère de Quincy (whose opinions have been adopted by a number of English writers, without the slightest acknowledgment), maintain, that Architecture, in so far as it is an art of taste, is to be considered an art of imitation. According to this doctrine, the type of the Egyptian Architecture is a cavern; of the Chinese, a tent; of the Gothic, a grove of trees; and of the Grecian, a rectangular hut. An opinion of this sort, adopted by such a profound metaphysical author as Quatremère de Quincy, deserves to be examined with the utmost attention. That there is truth in it, cannot be denied: man, whether in a state of barbarism or of civilisation, is alike an imitative animal; that is, he cannot act otherwise than according to general laws, which have influenced all his predecessors from the earliest ages, and which will control all his posterity to the latest period. To say, however, that Architecture is an imitative art, like the arts of Painting or of Sculpture; that is "purely imitative," as Mr. Elmes calls it in his Lectures, strikes us to be by no means a correct use of language. That the more ancient of the different manners of building have had their origin in certain rude types, there is very little doubt; at all events, this is sufficiently clear with respect to Grecian Architecture, all the principal members of which may be traced to the props and roof of a hut constructed of timber: but where is the type for the semicircular arch? But why should a people, living in a country where stone was almost the only building material, be induced, by the instinct of imitation, to adopt a mode of building suited only for a material altogether different? May not a stone or mud hut serve as a model, as well as a wooden one? If Egyptian or Indian Architecture may have had its origin in caves or excavations in the face of an upright rock, and Grecian Architecture have taken its rise from a rectangular hut, why may not Gothic Architecture have had its type in the conical huts of turf and stone, or of sticks and mud, formed by the northern nations of Europe? We think this, at all events, just as likely to have given rise to Pointed Architecture, as a tent to that of the Chinese.

The origin, however, of the different styles of art, appears to us a matter of very trifling importance. All Architecture may be reduced essentially to two kinds; viz. that where the openings are covered with horizontal planks or blocks; and that where they are covered with arches, either curved or pointed. Now, provided a system founded on any of these three principles be developed in a uniform, harmonious, and consistent manner, with reference to strength, durability, and fitness for the end in view, and to the general laws which govern all compositions of lines and forms, what objection can there be to it, in any reasonable mind? On the other hand, supposing an Architect to take any of the alleged

types as the foundation of his system, to what kind of result would he attain, without the exercise of reason at every step? Without reason, indeed, and that too continually exercised, Architecture would be an art of absurdity. As well, in our opinion, might agriculture and gardening be called imitative arts, as the art of Architecture; because there must have been some origin for cultivation as well as for building. The truth seems to us to be, that, viewed with reference to their origin, all arts are imitative; and, with reference to their adaptation to the state of man for the time being, all arts are founded on reason or human improvement.

How far Architecture is to be considered one of the fine arts must, as it appears to us, (and our opinion is in consonance with that of Alison, Dugald Stewart, Sulzer, and other writers) depend, not on its being either an imitative or an inventive art, but on its powers of creating in the mind, emotions of sublimity or beauty.

Notwithstanding the seeming difference of opinion on this subject among architectural writers, it appears to us in the highest degree probable, that, if the language of each writer were explained with reference to one fixed standard, they would all be found nearly to agree; the expressions, "art of imitation," and "art of imagination," being used by many of them as synonymous. At all events, hypothetical differences of this kind should never prevent us from profiting by the excellent works of such writers as Quatremère de Quincy and Milizia.—But it is time to turn from a speculative digression to the main purpose of this introduction, which is, to explain the general nature of our work.

1. *Our grand object being to introduce improvement into Cottage, Farm and Villa Architecture*, in the temperate regions of both hemispheres, by numerous examples of Designs, with different degrees of accommodation, and in different styles of Architecture, we have adopted, as the first term in our ascending series, a simple dwelling of two rooms, suitable for a man and his wife, without children; and, as the last term, the villa or country house of an English gentleman of wealth and refinement. We have fixed on the English villa, as combining more of the comforts and luxuries of life than the villa of a man of wealth and taste in any other country in the world.

2. *The first step towards the introduction of improvements in the practice of any art*, is to familiarize the minds of the practitioners with the deviations from usual practice which constitute these improvements. In rural Architecture, almost the only means of doing this is by published Designs; for no local builder can be supposed to have had either leisure or opportunities to inspect the various improvements which have taken place throughout his own country, and in other countries. Unless he has recourse to books of Designs, therefore, he can do little more than repeat himself, or copy what he has seen; probably with some improvement—possibly with deterioration. To supply the country builder, therefore, with numerous Designs, at a moderate price, must be rendering him an acceptable service.

3. *The use of published Designs to an experienced Architect* is to furnish him with ideas for composition; that is, with different modes of connecting the various parts of which a building is composed; of varying the forms of those parts; of devising new forms from them; and, finally, of composing the exterior as well as the interior details; subject always to the guiding principle of unity of expression, whether of purpose or of style.

4. *The same use of published Designs may be made by a young Architect*; but in order that he may profit to the fullest extent, either from viewing buildings actually executed, or from studying published Designs, he should be able to analyze them, and to trace the cause of whatever they may display of the beauties of fitness, of expression, or of style, to first principles of composition. To assist him in doing this is the object of the analytical remarks which we have made on each Design. The amateur Architect, and general reader, will also find these remarks useful as a means for improving their taste, by enabling them to refer the beauties or defects of buildings to their true causes. This is, indeed, the chief use of Designs to a general reader; but an Architect or builder may profit much from the careful inspection of a book of Designs, merely as a collection of models, without being able to analyze them; or to trace the causes of the pleasure or dislike, which he may receive from them, to first principles. Such an Architect, or builder, however, though he may be a very efficient empirical practitioner, can never be considered as possessing a scientific knowledge of his art. "The uneducated Architect," says Wood, "judges by his feelings; the half-educated, by rule; but the master, from feelings, trained and purified by study and reflection."

5. *In delineating these Designs*, we have, instead of geometrical elevations, given in every case, correct perspective views; and we have not accompanied these views by trees, or landscape scenery of any kind, considering the practice of doing so as of no real use; and, on the contrary, as calculated to mislead the inexperienced eye. For, as the beauty of every whole, is necessarily made up of the beauties of all its component parts; and as the size and shape of the trees, and the style of the scenery which form conspicuous parts in pictorial views

of Designs for buildings, are beyond the power of the Architect, whatever part of the effect of the picture depends on them, cannot be realized in the execution. In every landscape composed of a house surrounded by verdant scenery, the beauty or deformity of the house may easily be heightened or obscured, at the pleasure of the artist, by the management of the other parts of the picture; but where a building is exhibited in perspective by itself, its beauties or deformities are more easily detected; and the latter can be corrected before proceeding to carry the Design into execution. If, indeed, the introduction of verdant scenery in the picture, would serve as a guide for planting and arranging the ground about the house, then, indeed, it would not only be allowable, but advantageous; but every landscape gardener knows that instruction in this department can only be conveyed graphically, by plans and sections of the surrounding grounds, showing the disposition of the trees and shrubs to be planted, and enumerating their kinds.

6. *The Details of Construction, or Specifications*, as they are technically called, which accompany some of these Designs, are for the purpose of assisting the young Architect in making out similar Specifications for all the rest; and also for instructing the employers of Architects and builders, as to the sort of details which ought to be entered into and settled, before any building, however small, is undertaken to be executed. Engravings on wood, of the details on a large scale, are given with each Design, for the like purpose of facilitating execution.

7. *The Estimates*, with the exception of those cases, in which detailed Specifications are made out, can only be considered as approximations; but as, in every case, the data are given from which the estimate has been made, an experienced builder, who knows the difference between the price of labour and materials in his own locality and that of London, will always be able to calculate from these data, so as to form an estimate sufficiently accurate for general guidance. Every builder, or even carpenter, when he has laid before him a plan, a perspective or isometrical elevation, and a section, such as we shall give, can make out a specification of the details of construction, on which he can form an estimate suitable for contract and actual execution.

8. *In the Analytical and Critical Remarks on each Design*, we have illustrated all the different kinds of construction, and all the principles of architectural composition. In doing this, we have preferred, as the most useful mode, and as the one least likely to restrain the freedom and extent of our remarks, to give such details, and offer such criticisms, as naturally arose out of the subjects as they came successively under review, without much regard to the order of their succession.

9. *In illustrating the Principles of Landscape Gardening, as connected with Buildings*, we have, in like manner, limited ourselves to the development of one principle at a time; showing, in some cases, how the ground ought to be disposed in the neighbourhood of a building; in others, how it ought to be approached by roads or walks; sometimes, how fences ought to be disposed; and, in various cases, not only how the trees or shrubs ought to be arranged, but the particular situations for different sorts, with the different heights to which they grow, the soils they require, their suitableness for particular climates, and their character as ornamental, useful, or fruit-bearing plants.

10. *Plans of small Gardens* have been given along with several of the humbler Designs; and, in describing these, we have not only shown how they may be planted, with fruit and ornamental trees and shrubs, to most advantage; but, in some cases, we have given courses of cropping, labouring, and manuring. But as this subject is likely to be much more generally understood than Landscape Gardening, as connected with Architecture, we have taken care to restrain our remarks, so as to keep them within due limits.

11. *In our Designs for Farm Buildings*, we have always taken care to state the extent of the Farm, and the kind of culture, for which they are adapted; taking chiefly, as precedents, the climate and farming of the best districts of Great Britain; but partly, also, the circumstances of France, Holland, Belgium, and Germany. The same countries have been kept in view, in arranging our Designs for Country Inns and Public Houses, and for the Workshops of Country Tradesmen and Mechanics.

12. *The Order in which we have arranged these Designs, is as follows:—*

Book I.—Designs of Cottages for Labourers, Mechanics, Country Tradesmen, and Small Farmers; of Lodges for Gardeners, Bailiffs, Land Stewards, and other Superintendants on Landed Estates.

Book II.—Designs for Farm Houses and Farmeries; Country Inns, with Farm Buildings attached; Fermes Ornées, and Villa Farms.

Book III.—Designs for Cottage Villas, and Villas of the highest class, with their accompanying Offices, and other Buildings.

## BOOK I.

DESIGNS FOR LABOURERS AND MECHANICS' COTTAGES, AND FOR DWELLINGS FOR GARDENERS AND BAILIFFS, AND OTHER UPPER SERVANTS, AND FOR SMALL FARMERS AND CULTIVATORS OF THEIR OWN LAND.

13. *The Designs of this Book* are calculated for what, in countries having a privileged aristocracy, are called the lower and middling classes of society; but which, in self-governed democracies, like North America, or in newly-colonized countries, like Australia, constitute nearly the whole rural population. We have arranged these Designs in two chapters: the first contains three Designs of what may be called Model Cottages, as each combines all the accommodations and arrangements for comfort and convenience of which buildings of the lowest class are susceptible. Each of these Designs contains the same quantity of accommodation, but differently arranged to suit different situations and climates. The second chapter includes a miscellaneous assemblage of Designs, each combining more or less of the comforts and conveniences of the Model Designs, joined to various kinds of architectural beauty and style.

---

 CHAP. I.

*Model Designs for Cottages, exhibiting in each Model all the accommodations and arrangements for comfort and convenience of which the smallest dwellings of this class are susceptible.*

14. *The Accommodations and Arrangements of these Designs* are presented as the beau ideal of what we think every married couple, having children of both sexes, and living in the country, should possess; while, at the same time, we have included in them all that is essentially requisite for health, comfort, and convenience, to even the most luxurious of mankind. In such dwellings every labourer ought to live, and any nobleman might live. All that in any dwelling exceeds the accommodation and arrangements here given, must either be required for a larger family and extended hospitality, or for the display of either superfluous wealth or highly refined taste. The necessaries, and even comforts of life, are contained in a small compass, and are within the reach of a far greater portion of mankind than is generally imagined. But one room can be used at a time, by either the poor man who has no other, or the rich man who has several; and that room can only be rendered comfortable by being warm, dry, light, well ventilated, and convenient: qualities which depend not so much upon the materials used in its construction, as on the manner of applying them. All that is wanting is knowledge; first, of what is necessary and desirable; and, secondly, of the means of obtaining it at a small expense. To communicate this knowledge is the main purpose of the present Book; but more especially of the Designs contained in this chapter.

15. *In the composition of these Designs*, we have, in every case, adopted the following arrangements:—First, We have placed every dwelling-house, or the floor containing its living-rooms, upon an elevated platform, with a view of keeping it drier, and consequently, warmer and healthier; as well as to procure greater dignity of effect, as an object in landscape, and as a station for the eye to survey the surrounding scenery. Secondly, We have placed the chimnies in the interior walls, rather than in the exterior ones; because when the chimnies are so placed, a greater portion of heat is retained within the house; and because, from the greater degree of heat contained in the mass of masonry through which the flues are carried up, the smoke always ascends faster, or, in common language, the flues draw better. Thirdly, We have, in every Design, kept in view the practicability of the most economical application of fuel; of the collecting, filtering, and preserving the water which falls on the roofs; and of the collecting and economizing the liquid and other manure produced in or about the cottage. We have shown the various details for effecting these objects in plans, sections, and perspective elevations, with copious descriptions and various graphic illustrations; and we wish the Architect to keep them continually in view in judging of the Designs in Chapter II., and to imagine them applied, more or less, to each Design given in that chapter, as circumstances may admit or require. We have before published these Model Designs of Cottages in our tract entitled, *A Manual of Cottage Husbandry, Gardening, and Architecture*; but we consider the details which they exhibit as of so much importance, and all the Designs which are to follow in this work as depending so entirely upon many of

them for their chief excellencies in a useful point of view, that we have felt we should not be doing justice to our readers if we did not repeat these Designs, with their descriptions, in the present work. This we have now done in a much more clear and systematic form than was compatible with the plan of the pamphlet alluded to, and with very considerable additions both of descriptive matter and engravings.

Design I.—*A Cottage of One Story, combining all the Accommodation and Conveniences of which human Dwellings of that description are susceptible.*

16. In the Ground Plan of this Design, marked I. in page 10, *a* represents the kitchen, or living room. The floor of this apartment may be of tiles; or paved; or laid in a composition of lime, sharp sand, and Roman cement; or of lime, sharp sand, and scoria from a smithy. Composition floors of this kind are much warmer than those of stones or tiles. In the ceiling, nearly over the hearth, is a trap-door to the loft; which door may, in summer, be partially opened to promote ventilation, there being a false flue in the chimney for that purpose, which will hereafter be described.

*b*, A small parlour, with a fire-place and boarded floor: as it will receive a good deal of heat from the kitchen fire, it will seldom require a fire made on purpose for it. It ought to have a small ventilator in the ceiling, near the stack of chimneys, communicating with the false or air flue, for summer use.

*c*, Family bed-room; the floor of tiles, or paved, or of the same material as that of the kitchen.

*d*, Bed-room for girls; the floor boarded.

*e*, Bed-room for boys; the floor boarded. There may be a door in the partition between these small rooms, which it may be convenient in some cases to use instead of the door between the girls' bed-room and the family bed-room.

*f*, Water-closet for the mother, girls, and females, supplied by water as to be hereafter described. The basin may be of brown earthenware or of cast iron, so as to cost very little; the door ought to open inwards, and the small window outwards, so that every movement of the door may act as a ventilator. There might also be a water-cock and wash-hand-basin.

*g*, Tool-house, and man and boy's water-closet, with an opening to the loft for ventilation: supplied with water from the same source as the other water-closet. The basins of both closets communicate with an earthen pipe, which empties itself into the reservoir of the cess-pools for liquid manure. The liquid manure thus gained will be of so much value to the garden, as alone, independently of cleanliness and decency, to justify the expense of two closets, and both of these water-closets.

*h*, Cow-house, with a tying-post and trough for food in one corner, and a loft for hay and straw over: this loft may be got at through a trap-door, by the use of a common ladder.

*i*, House for fuel, lumber, or for various other purposes, such as roots or other food for the cow and pigs. In cases where the cottager grows corn, it may be made his barn; and if it were desired to have this barn larger, it could easily be made so, by projecting the whole lean-to two or three feet farther from the main body of the house.

*k*, Place for ducks or geese, with a small poultry-stair or ladder to hen-loft formed over *f* and *g*. This loft ought to be lined with straw on the top and sides, in order to keep the poultry warm in winter and cool in summer.

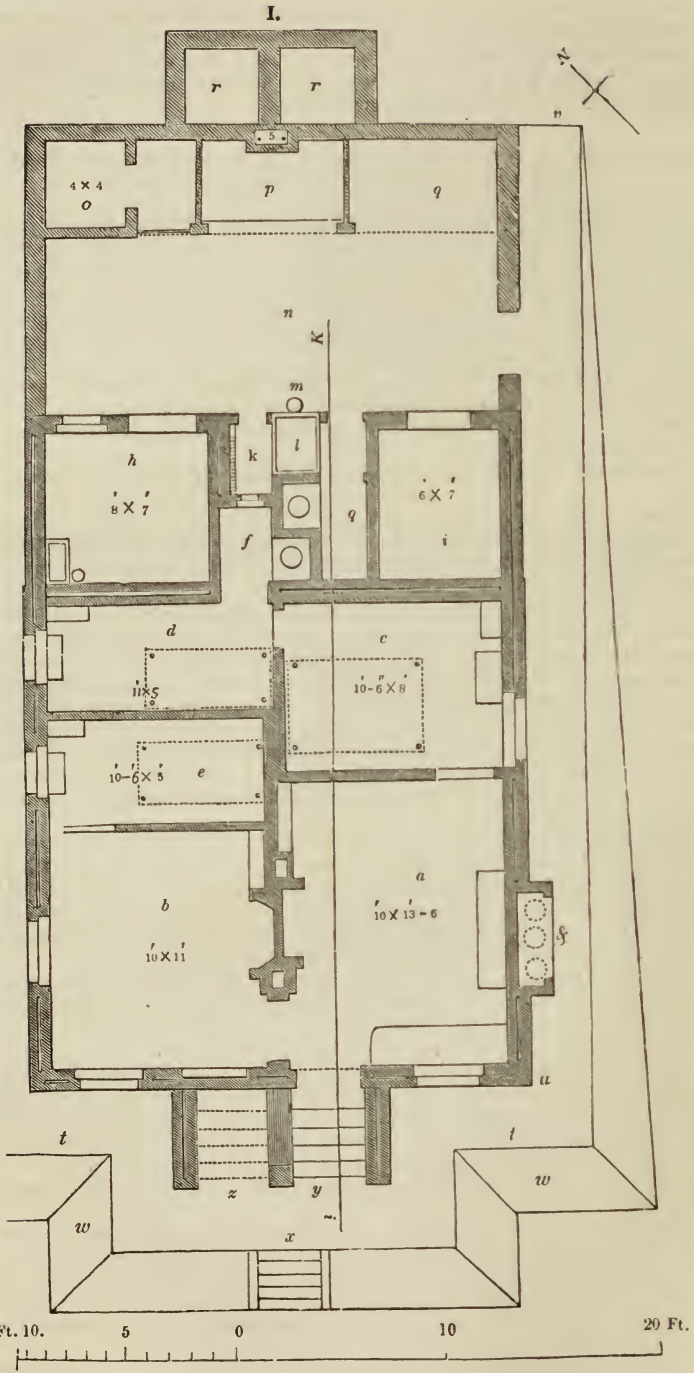

*l*, Cistern for receiving half of the water which falls on the roof.

*m*, A pump for pumping water from the tank below, either for use in the back yard or in the house, or for raising the water into the water-closet cistern above. Siebe's rotatory pump is the best adapted for these different purposes, being at once a lifting-pump and a forcing-pump. It costs no more than a common pump, may be worked in far less room, and with greater ease, by a female or a boy, and is much less likely to go out of order.

*n*, The open yard, which should have a gentle inclination from all sides towards the dung-pit (*p*).

*o*, Pigsty, with a rubbing-post in the open area or feeding-place. Two old barrels, for pigs' food, will require to be placed under cover, where they can be kept from freezing in winter, and from being extremely hot in summer. One of these ought to be filling while the other is emptying, and the contents should not be made use of before fermentation has commenced. The fuel-house, *i*, will be a very good situation for these tubs in summer, and a corner of the cow-house, *h*, in winter.

*q*, Shed for faggot-wood. *o*, *p*, and *q*, may be roofed with one lean-to, or pavilion roof of uniform height and width; or, if corn be grown by the cottager, then, instead of a roof of slates, tiles, &c., may be substituted a floor of joists of the same width as required for the

roof; and on this floor may be laid, first, a layer of faggots, and on these built the corn or hay as a stack or stacks, and thatched in the usual manner. This would save the expense of tiles or slates, and also the ground that would otherwise be requisite as a rick-stand.

*r r*, Two cesspools for liquid manure, i. e. for all the drainings of the open yard after they have passed through the dung-pit, *p*, for the water of the two closets, and that proceeding from the sink to be described hereafter, including soap-suds and all waste or foul water made on the premises. As it is found advantageous that liquid manure should undergo fermentation before it is used, two cesspools become necessary, and also an arrangement by which the supplies from the different sources can be turned into either cess-pool at pleasure.

*s*, The situation of two plug-holes, for regulating the admission of water to the cesspools. The well containing these plug-holes is, in horizontal dimensions, one foot square, and in depth, three feet. The sides are built of brick or stone, and the bottom is formed of one stone, containing the two holes, each of which is three inches in diameter; the left hand hole communicating with the left hand cesspool, and the right hand hole with the other cesspool. A plug, with a handle four or five feet long, is to be used for stopping the communication with the cesspool which is filled and undergoing fermentation: and as these pools are alternately filled and emptied, the plug can be removed from the one hole in the regulating well to the other. These pools are placed without the open yard, in the supposed garden, for the greater convenience of emptying them.

*t t*, The level part of the platform, or terrace, on which the house appears to stand, and which will be better understood by referring to figs. 6 and 17, or to Designs IV. and V.

*u*, Point at which this platform commences to incline gradually till it terminates at *v*.

*w*, Sloping sides of the platform; the slope being  $45^\circ$  in stiff loamy soils, and  $30^\circ$  or less, in loose soils. The platform may be covered with turf, or ornamental plants, and finished with a parapet or low hedge, as will be afterwards described.

*x*, Steps for ascending the platform, opposite the principal door of the cottage.

*y z*, Entrance porch: *y* represents the steps leading up to the living floor, and *z* the steps leading down to the cellar floor. If the front of such a porch were to any other quarter than the south-east, the porch should be larger, with an exterior door; if it fronted the south-west, the entrance to the porch ought to be on its south side, for the sake of protection from the weather.

*§*, Shelves for bee-hives; the upper part of which may be fitted up as a dove-cote, and the lower part as a dog-kennel.

17. *The Section A B of fig. 3*, is represented in fig. 1. It shows the reserve tank, *a*; the opening for inserting the cock for drawing supplies from it, *b*; and the sink, *c*.

18. *The Section C D of fig. 3*, is represented in fig. 2. It shows the cellar window, *d*, with the open area before it, *e*, covered with a grating, *f*.

19. *The Plan and Section of the Cellar floor*, shewing the heating flue, and the foundations, are given in figs. 3 and 4.

*a*, Steps of descent to the cellar. These steps are represented in Design I. by the letter *z*.

*b*, Apartment serving as a back-kitchen, wash-house, brew-house, bake-house, &c., as well as for boiling or scalding food for the cow, pigs, and poultry.

*c*, Store cellar and larder for potatoes, beer, home-made wines, fresh and salt meat, and similar articles of provision.

*d*, Milk-house and pantry; in the farther corner in the ceiling ought to be a small grated opening, communicating the air-flue in the wall, to promote ventilation; the exterior window ought to be of wire or hair cloth; which both excludes air and heat or cold.

*e*, Copper for brewing, washing, heating water for the bath, &c., unless a copper pot or iron box is fixed over the oven, when a separate copper becomes unnecessary.

*f*, Oven for baking, and also for heating the floor of the living-room and family bed-room.

*g*, Termination of the double covering of the flue, commencing at the oven, *f*. (See also letter *g*, in fig 4.)

*h*, Brick-on-edge work, for strengthening the sides of the flues.

*i*, Loose round stones between the flues, for the purpose of retaining heat.

*k*, Sunk area, before the cellar windows.

*l*, A situation in which a bath may be placed, to be supplied with hot water from the boiler, *e*, or the cast-iron box over the oven, *f*, or with cold water from the reserve tank, *q*.

*m*, The receiving tank, which, in addition to the pipe from the roof, has another pipe from the inside, with a funnel, into which a supply may be poured for filtration, from the pump (*m*, in Design I.), in times of great drought, or at any time when the reserve tank is exhausted.

*n*, Waste pipe from this tank, communicating with the drain pipe.

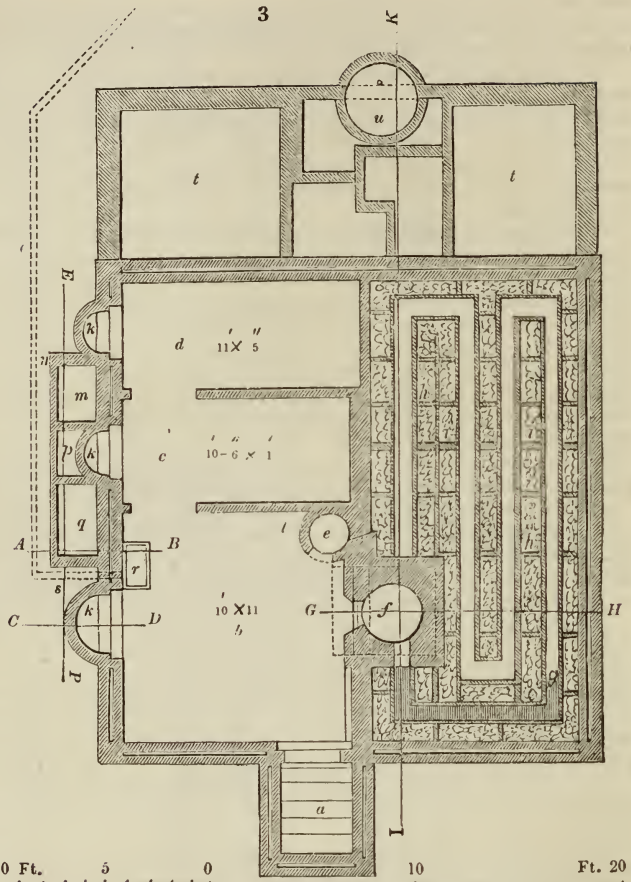

*o*, Drain pipe, communicating with the well, with plug-holes connected with the cess-pools (*s*, in Design I.).

*p*, Filtering tank, consisting of sand and charcoal, placed on a false bottom, raised three or four inches above the bottom of the tank.

*q*, Reserve tank for the filtered water, communicating by a cock with the sink, *r*, and the sink having a stink-trap (see fig. 13, *d*, in p. 18.), connected with a waste pipe, *s*, which joins the drain pipe, *o*.

*t*, Foundations of the out-buildings, shown in Design I. by *f*, *g*, *h*, *i*, *k*, *l*, and *m*.

*u*, Tank, or well of water for general purposes, and for supplying the filtering tank in times of extraordinary drought.

20. The Section showing the depth of the flues and the cast-iron box over the oven for heating water, is represented in fig. 4. This section is taken in the line G H, in fig. 3, and the object is to show the depth of the flues; the double cover and vacuity between the covers at *g*; the cast-iron box of hot water, *k*; the cock for drawing water from it, and for emptying and cleaning it, *l*; the situation of the small lid for filling it, *m*; the oven, *n*; the copper, *o*; the natural surface of the ground, *p*; and the surface of the platform, or terrace, *q*.

21. The Section showing the height of the rooms, and other particulars, is given in fig. 5. This section is taken in the direction of the line I K, in Design I, and it shows the following particulars:—

- z*, Natural surface of the ground.
- b*, Surface of the platform.
- c*, Level of the foundation of the cellar.
- d*, Foundations of the other walls.
- e*, Foundation of the oven.
- f*, Foundation of the partition wall between the living room and family bed-room.
- g*, Well or tank.
- h*, Siebe's pump, with an ascending pipe into the cistern, *i*.
- i*, Cistern for the water-closets, and for supplying the yard.
- k*, Place for ducks or geese beneath.
- l*, Hen-house, with tool-house and man's water-closet under.
- m*, Family bed-room.
- n*, Loft, with ventilator, or trap-door, from the kitchen, and opening near the air or ventilating flue.

- o*, Kitchen.
- p*, Porch.
- q*, Cover to the air flue, which is only kept open during summer to prevent excessive heat at that season: it is simply a square paving tile supported by an iron shank, in order to exclude rain.
- r*, Oven.
- s*, Water-box over.
- l*, Commencement of flue from oven.
- u*, Continuation of flue.
- v*, Cornice to chimney top, made large for the purpose of encouraging swallows to build their nests there; these birds being of great importance to cultivators or possessors of gardens, as destroyers of winged insects, on which they live entirely.

22. *The perspective elevation of the entrance front and south-east side of Design I. is shown in fig. 6. The object of this elevation is to show the general appearance of this description of cottage. The steps to the level part of the platform are seen on the left, and the gradual inclination of the surface from the south corner to the south-east corner to the yard-wall. The shelves for bee-hives are shown with the dog-kennel under, but the dove-cote is placed over the entrance porch.*

23. *General Form.* The most economical form in which a house can be built, is well known to be the cube. Not only does this form afford the greatest quantity of accommodation, with the least quantity of walling and roofing, but it is easier warmed; and, when warmed, it retains the heat better than any other form, more especially when the chimneys are placed in the interior walls, the reason being that a smaller extent of surface is exposed to the exterior atmosphere.

24. *Aspect.* With reference to Britain, and to the flat countries of most parts of Europe, the mildest aspect is the south-east, and, therefore, the door of a cottage should, if possible, be placed on that side. The next best side is the south; and the two worst are the north-east and the south-west. It is very desirable, in a cold moist climate, that the sun should

shine on all the exterior walls of the cottage, and also in at all the windows, every fine day in the year, for the sake of keeping the walls dry, and the interior warm and cheerful. This object may be accomplished by placing any building, which is, or can be, resolved into a square, or parallelogram, on the ground plan, so as that a north and south line will form the diagonal figure. This being done, the out-offices should be placed on the north-west side of the square, or parallelogram, as in Design I. The dairy and the pantry should always, if possible, be placed on the same side, or with a north-east aspect, for the sake of coolness. Tanks for water should also be on the same side, and under ground, for the same reason.

25. *Construction.* The walls of this cottage may be built of stone, or brick, or earth; but either of the two former are, undoubtedly, preferable to the latter, both in point of strength and durability. In situations, however, where these materials are too expensive, or cannot be obtained, every part of the walls here shown above the platform, may be formed of earth, either in the *pisé* manner, by compressed blocks, or by lumps of loam or mud mixed with straw. Each of these modes will be described hereafter. In Design I. we have shown the walls as if built of brick, eleven inches wide, with a vacuity in the centre. This we propose to be done by keeping the width of the wall at eleven inches, working the outside fair (even); and, on the inside, keeping the headers or cross bricks, fig. 7, *a*, one inch within the line of the stretching or lengthway bricks, *b*, and keeping these lengthway bricks two inches apart along the centre of the wall, *c*. Walls built in this way are much handsomer on the fair side; at least equally strong with solid walls;

always dry, and less easily penetrated by the cold in winter, or the heat in summer. The inner surface, being uneven, is peculiarly favourable for receiving and retaining the plaster. Hollow cottage walls may also be built by placing the bricks, both headers and stretchers, on edge, as first practised by Mr. Silverlock, of Chichester. They may be also built with bricks halved lengthways, by cutting with a knife or wire before burning, as recommended by Mr. Dearne. (*Hints on an improved Method of Building*, &c. London, 8vo. 1821.) Both these modes will be afterwards described. The roof may be covered with tiles, slates, thatch, &c., at pleasure or convenience. Other ordinary particulars of construction and arrangement have been incidentally mentioned in describing the ground plan, § 16, and in figs. 1 to 5, § 17 to 22. Some which are less common follow.

26. *Platform, or Terrace.* The principal use of this part of our plan, is to keep the living floor of the cottage dry, and to prevent the necessity, in moist situations, of much excavation for the sunk apartments. Secondary advantages are, that it furnishes a neat and comfortable walk round the house, and adds to the dignity and stability of its appearance. To have the walls of so artificial and important an object as a house, rising abruptly from a plain flat surface, whether that surface be dug or covered with turf,—in short, whether it be a garden or a field, cannot be considered as either in harmony with nature or reason. Every work of art is recognised as such by the appearance which it displays of design; and the

preparatory terrace may be considered as enhancing this appearance, and raising its character. Independently, therefore, of the platform being useful, its importance on the principle of enhancing the character and dignity of the design to be raised upon it, ought, in our opinion, to ensure its almost universal adoption in buildings erected in the country. The platform, in Design I, is five feet broad, and includes a border of one foot for wall-trees and flowers next the house, and a margin of one foot, which should be of turf, on the outer edge, leaving a walk between of three feet, which ought to be gravelled. The exterior sides of the platform may have different degrees of slope, according to the nature of the soil, and the culture or application of the slope. For a loamy soil, the platform may be covered with turf, with a furze or a box hedge, about two feet high, along its upper angle, and the slope may be  $45^{\circ}$ ; where a loamy soil is to be cultivated as a flower border, the slope may be from  $35^{\circ}$  to  $30^{\circ}$ ; a sandy soil should have a still greater slope. Where stones are abundant, the slope may be formed into rock-work, with a small hedge at top, or a dwarf wall, or a row of rough stones. In some situations, it might be worth while to form a rough trellis over the roof, about a foot above it, and on this trellis to train either apples, pears, plums, or vines, for their fruit; or, in severe climates, ivy, for the sake of retaining heat, by its evergreen leaves, in winter. On the side walls of the cottage there might be trained fruit trees, or vines, together with ever-flowering roses, honeysuckles, and a variety of climbing shrubs and flowers; but, at the same time, there is danger of indulging in these to such an extent as to keep the walls damp, and to encourage flies, and other insects, which are disagreeable in the house. The small border of one foot wide, under the wall, may always be planted with low flowers, and great might be their variety and beauty, if the taste of the occupant lay in this way; but the number and kind of shrubs and trees to be planted among these, with a view of training up the walls, must depend on the climate, aspect, and other circumstances. We shall afterwards give a list of climbing shrubs, and fruit trees, suitable for the purposes in view, in different climates.

27. *The outer margin of the platform* may either be finished with or without a low hedge, or by a low parapet, or other fence of wood or iron. If with a hedge, the sameness of the line may be broken by small standard trees, four or five feet high, at the angles; and we see no reason why these standards should not be cut (not clipped,) into shapes, as well as the hedge, if the cottager's taste inclines him to do so. The standards may either be of the same species of tree as the hedge, but in a state of variegation,—say a green box hedge, with variegated box standards,—or of a different species. Green, and variegated box, are among the best shrubs for this purpose, in point of utility; because every time the box is pruned, the twigs may be used as a substitute for hops, in brewing. But, in most cases, an architectural parapet will have a better effect than a dwarf hedge, and this may always be made an object of great beauty at very little expense. We shall afterwards show in how many different ways common bricks and tiles, and stones, rough or hewn, may be formed into these parapets. We shall also show various forms of iron and wooden parapets for the same purpose.

28. *Entrance Porch.* No edifice whatever, in our opinion, is complete, unless some distinctive mark is placed on the opening by which it is entered. What a portico is to a palace or a public building, a porch is to a cottage. A porch is not only the distinctive mark of the entrance door, but, being a protection to it from the inclemency of the weather, it must tend to preserve the warmth of the apartment within. No cottage, therefore, ought to be without its porch. In many cases, the porch may be a wooden structure superadded to the cottage; in others, a vestibule within may serve the same purpose; but, for stability, durability, and dignity of effect, the porch should always project from the main body of the edifice, and be built of the same materials, and in the same taste or style as the cottage itself.

29. *Chimney Tops.* In every human dwelling, these ought to be conspicuous objects, because they are its essential characteristics. They distinguish apartments destined for human beings from those designed for lodging cattle. They also distinguish a dwelling-house from a manufactory or workshop, by their size, form, number, and disposition. Independently of these qualities, they ought, in dwellings, to be dignified by a greater attention to design, than the less important parts of the edifice. On this subject we shall have much to say in describing succeeding Designs, but we have deemed it necessary thus early to state our guiding principle with respect to this part of the cottage, in order that it may never be supposed, for a moment, that we approve of concealing chimney tops, or of leaving them in their present mean and trivial form.

30. *Collecting and Filtering Water.* Considering it to be desirable that every cottager should be perfectly independent in respect of water, and also that rain-water is the purest of all water, we propose to show the manner in which all the water which falls on any dwelling may be collected; how to filter and preserve one part of it, in a tank, for *cooking purposes*;

and to preserve the other part unfiltered, in a cistern and in a large tank, for the purposes of the water-closets, for the use of the cow and pigs, for washing and cleaning, and for the garden. It is calculated by Waistell, that the average quantity of water which falls on a square yard of surface in Britain, in a year, is 126 gallons; which, for this building, containing upwards of 100 square yards of roof, will give 12,600 gallons; an ample quantity for the purposes mentioned. A cottage constructed on this principle, therefore, may be set down in any situation, without reference to a natural supply of water. The cistern, *l*, in Design I, may be of cast-iron; or of slabs grooved into each other, and made water-tight with Roman cement; or of plates of Welsh slate; or of large flat paving tiles set in cement; or it may be made of wood, plastered inside with cement; or of bricks set in cement, and plastered within with the same material; or in countries where timber is abundant, as in America, or Australia, it may be formed of thick planks, well pitched; or it may be simply an old liquor cask. However constructed, it must have a waste-pipe; which, when the cistern is full, will flow over into the tank or well below, shown in fig. 5. This well or tank is to be considered as the grand reservoir of the premises; and if there should be a natural spring in it, so much the better. Should the culinary, or filtering tank, fig. 8, *f*, fail at any time, water may be drawn from this tank, and introduced into the filtering tank.

31. *The mode of filtering is very simple, and will be easily understood from the section E F, of Design I. In this section, fig. 8, a, represents a vacant space of three inches from the bottom to b; b, is a slate, stone, or board, pierced with numerous holes, say at the rate of three to an inch, of about the eighth of an inch in diameter; c, is a mixture of clean coarse sand and powdered charcoal, or coarse burnt clay, without either sand or charcoal; d, a filtering stone; or in default of a stone of this porous nature, a plate of lead thickly pierced with holes, of one twentieth of an inch in diameter; e, an opening by which the water of the receiving tank, *f*, communicates with a, at the bottom of the filtering tank; g, an opening by which the water after it has ascended through the filter, runs over into the reserve tank, *h*. The filtering of the water may be effected in a more simple manner, by placing a layer, about six inches thick, of round burnt stones, about the size of eggs, in the bottom of the filtering tank, and over this either burnt clay, or sand and charcoal, covered by a pierced leaden plate, as before; or by a stratum of sponge, which may be substituted for the plate. It must be evident by inspecting the section (fig. 8), that when the water supplied from the roof to the receiving tank, *f*, rises above the level of *d*, it will run over, by *g*, into the reserve tank, *h*; and that the water in all the three tanks will always stand at the same level, provided the water in the tank, *f*, be above the level of *d*.*

32. *The filtering material may be cleaned by having a large cock in the bottom of the receiving tank, communicating with the waste drain; by opening which, when the reserve cistern is full, the water in that cistern will rush through the filter in a contrary direction to what it did before; and will carry off all the impurities, either in the filter, or in the space at the bottom, *a*. The filtering might also be effected by placing the filter in the tank *f*, instead of in the centre tank; and by introducing the water from the roof, direct to the space, *a*, by a pipe, through the filter; the water would then rise through the filter, and fill the tanks, *e* and *h*. A larger reserve of filtered water would thus be obtained; but the filter would require cleaning oftener. The great advantage of the mode we have recommended is,*

*that the water will deposit the greater part of its impurities in the bottom of the tank, *f*.*

33. For pumping up the water from the main tank or well, *g*, in fig. 5, we have recommended Siebe's rotatory pump. This pump, fig. 9, operates by the rotation of a roller, on its axis, *a*, having paddles or pistons, *b, b, b*, by which, when the roller is turned, a vacuum is produced within the barrel, *c*. In consequence of this vacuum the water flows up the rising trunk, *d*, into the barrel, and as the paddles go round they force it into an opening which conducts it wherever it may be wanted, and by that means produces a continual stream. By having an ascending tube, *e*, this water may be forced to any height, and, by having a horizontal tube with a cock, *f*, it may be let out at pleasure, as in a common pump. By having several pipes branching from *e* as many cisterns or reservoirs might be supplied. The appearance of this pump is very neat and simple, fig. 10; but, as in the case of other pumps, the tubes must be covered with straw or matting, during frosty weather, otherwise the freezing of the water will make them burst.

10

34. The mode of heating by a flue below the kitchen floor we consider a most valuable plan for ensuring and economizing heat, particularly in cold countries, where fuel is scarce. Indeed, we shall afterwards show how, with this arrangement, and an extra quantity of land, say an acre, besides garden ground, every cottager may grow all his own fuel. Whenever there is a back kitchen adjoining the principal kitchen, or cottager's living room, and both are on the ground floor, this mode of heating the floor by a flue may be adopted. All that is necessary is to have a sunk area in the back kitchen for the oven, as will be shown in Design IV. When there are two rooms on the ground floor, and one of these rooms is over

a cellar, as in Design I., then the oven or furnace can be made in the cellar. In either case the courses of the flue are to be so contrived, as to allow the covers, supposing them to be one-foot tiles, to form the floor of the two rooms which it heats. The flues may be of any convenient depth exceeding eighteen inches, their sides built of brick-on-edge not plastered, and the intervals between the flues filled up with loose stones or rough gravel. If the flues are made deep, which in some cases may be found cheaper than preparing a raised solid basis on which to build shallow flues, then the side walls may be tied together by brick-on-edge work, (Design I., *h*.) and the foundation of the partition wall, which separates the family bed-room from the kitchen, will contribute to the same end. To equalize the heat given out by the flue, and to prevent the kitchen floor from being too hot where the flue proceeds from the oven, a double covering is there shown, with a vacuity of six inches between the under cover and the floor, from the oven, *f*, to *g*; a section of which may be seen in fig. 4, at *g*.—As faggots are intended to be burnt in the oven, the soot produced will be very trifling; but the flues may be cleaned once a year by taking up a tile at each end of the different courses of the flue. Except when there is a fire in the oven, its door must be kept perfectly close, and a damper in the upright flue, nearly so. In many cases, instead of a flue, a vault may be made under the kitchen, and the smoke from the oven or furnace allowed to spend the principal part of its heat in this vault, and afterwards ascend a flue proceeding from near its bottom, fig. 11, *a*. As the walls, from the superincumbent weight, would form abutments of very great stability, the arch might be made very flat, and would thus cost less in execution than the flues.

11

35. The immense superiority of this mode of heating the air of a room, over any other whatever, will be obvious to every one acquainted with the nature of heat. By open fire-places, by stoves, steam-pipes, or water-pipes, (unless indeed these are in the floor,) and, by heated air, the coldest

stratum of air is always found immediately on the floor, where, for the sake of the feet and the legs, the air ought to be hottest; by the method of under-ground flues, or a smoke vault, as in fig. 11, the lowest stratum is necessarily the hottest, which must be preferable for the feet and legs of grown persons, and for the whole bodies of little children. The heat being diffused over the whole surface of the floor, must contribute greatly to the equality of the temperature throughout the apartment, and the mass of loose stones, or the materials of the arch will continue to give out heat for a day or two, according to the season of the year, after every time that the oven is heated. The heat from the floor, in its ascent to the roof, will warm whatever it meets with; but this is not the case with either raised stoves or open fires. In heating

by open fires or common stoves, the heat ascends directly to the ceiling, and is there in a great measure wasted, as far as it respects the persons in the apartment; but by this mode the ceiling will not in general be hotter than the floor.

36. *Hot water for domestic purposes* may always be obtained by a very simple arrangement connected with the oven and flues. Over the oven, and as a cover to it, instead of brick-work, might be placed, or built in, a cast-iron box or iron pot for heating water, as shown by the dotted lines in the plan fig. 3, and by *k*, in fig. 4. The upper surface of this box or pot might form a part of the kitchen floor, as at *e*, in fig. 22; and might have a properly secured flat lid on that side, to admit of putting in and taking out water; or the box might be entirely buried in masonry, as in fig. 4, and in that case a part of it should project from the wall into the back kitchen, or cellar, and should have a lid to open, for the purpose of filling and cleaning out, and a cock, *l*, in fig. 4, for the purpose of drawing off the water. If this box were two feet, or two and a half feet square, and nine inches or ten inches deep, it would supersede the necessity of the copper, fig. 3, *e*, and in summer, when the heat of the flue was not wanted, a damper withdrawn would admit the smoke to ascend directly through a flue to the chimney top. A family with a pot or box of this kind over their oven, the box or pot either opening only from the kitchen above, or both from above and from the back kitchen, would, throughout the year, scarcely require any other fire than what was made in the oven; all their roasting and baking would be done in the oven, and all their boiling in the pot or box over it. As it might not be always convenient or desirable to boil the large box or pot full of water, there might be a well of six inches diameter, and nine inches deep, cast in its bottom, and the small quantity of water which this well would contain would be boiled with very little fuel; for tea, or any similar purpose, a tin jug of water might be set in among the water in the well, which would keep the former perfectly pure. A very small quantity of fuel consumed in such an oven will have a powerful effect in heating the water above it, from the difficulty of the heat escaping by the sides. By this mode of heating and cooking a smaller quantity of fuel may be made to suffice for the wants of a family than by any other method that we are aware of; since no more can escape by the chimney than is absolutely necessary to carry up the soot. Water might easily be drawn out of the well, or out of the box or pot when in common use, from the upper kitchen, without stooping, by inserting a long tube, like a trumpet, fig. 12, made of tin, and open at both ends. When plunged in the water, if the thumb be placed on the upper orifice, *a*, and retained there, the water in the lower part, *b*, may be transferred to any other vessel.

37. *Water-closets and tanks for liquid manure.* A water-closet or privy ought to be attached to every human dwelling, and in all cold countries it should form part of the edifice, and be approachable under cover. No cottage is, therefore, in our eyes, complete without this appendage under the same roof, or under a lean-to. The well or tanks for liquid manure connected with it, are as advantageous, in point of profit, to every cottager who has a garden, as the water-closet or privy itself is essential to cleanliness and decency.

38. *The Water-closets* may be variously arranged; but as one of the best and cheapest modes, and as one the least likely to go out of order, we give the following. The cistern, fig. 13, *a*, may be at any distance from the seat, *b*, provided it be on a higher level, by four or five feet. The basin, *c*, may be an inverted hollow cone, truncated, and joined to a piece of cylindrical tube, inserted in a closed leaden vessel, technically called a stink-trap, *d*. In the side of *c*, at *e*, is a hole, or vertical slit, passing obliquely through the sides of the basin, and communicating with the cistern, *a*, by the pipe, *f*. The water in the cistern is prevented from running off through this pipe, by the valve, *g*, shown in fig. 14, on a larger scale. When it is desired to allow the water to rush down into the basin, it is only necessary to pull the string, *h*; which, if the cistern be at a distance, may pass over several pulleys, according to the number of angles in its course. In order to ensure the descent of a quantity of water to the basin every time it has been used, a cord, *i*, may be joined to

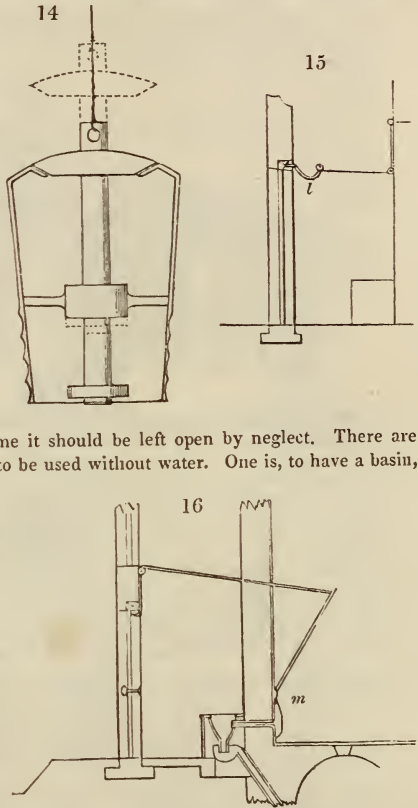

h, and passed over a pulley at k, and the end of this cord may be fixed to the upper part of the door of the water-closet, at such a distance from the hinge, say a foot, as will suffice to lift up the valve, g; or the same purpose might be effected by a lever, fig. 15, l, which would be acted on every time the door was opened.

39. When the cistern is unavoidably placed on a level with the basin, the opening for the admission of water must be much larger than in the first case. This opening may be closed by a valve, similar to that marked g, in fig. 13; but a better mode is to have a lever valve, fig. 16, m, which will also be operated upon by the door every time that it is either opened or shut. In every case in which it is intended that a common or lever valve should be operated on by a door, the latter ought to have a spring bolt (a contrivance for shutting the door, which will be afterwards figured and described), to shut it, lest at any time it should be left open by neglect. There are different methods of constructing a privy to be used without water. One is, to have a basin, as in a water-closet; and to continue down from it, a tube so far into the cesspool below, as to prevent the rising through it of air, and consequently of smell. If all the waste water of the house is, as it ought to be, poured into the basin, neither that nor the tube will ever be choked up; and, in that case, this construction may be considered one of the best for preventing smell. The next mode is to have no basin; but to take care that the surface of the cesspool exposed to the air, is no larger than is necessary; and that no crevices are left in the seat, so as to admit of a current of air passing over the surface of the cesspool. There ought, both in this case and in the other, to be two covers to the hole in the seat; one of a circular form, to fit into the opening, and the other, larger and square, to be affixed by hinges to the back board, so as to shut down over the whole seat. The windows in all water-closets ought to be close to the ceiling; both to prevent the persons within from being seen, and to admit of a more effectual ventilation.

40. *General Estimate.* What is called a general estimate of the expense of a building is calculated at a certain rate per cubic foot, while a specific estimate is made up of the separate estimates of each particular article. The rate or price at which a general estimate is calculated, depends upon a variety of circumstances; but in every situation, the principal points by which it is affected (all others being the same) are,—first, the irregularity of the outline of the ground plan, and of the elevation; secondly, the number of angles in the roof, or the number of separate roofs; and thirdly, the ornamental or carved work, both within and without the building. The nearer the whole mass of a building approximates to the form of a cube, and the nearer all its separate parts approach to that form, the lower will be the rate per foot. One roof of the simplest form may always be calculated at a lower price than a varied roof, or several roofs. In Britain, buildings are divided into three classes: called, first, second, and third-rate buildings. Cottages, and such dwellings as are contained in this Book, belong to the third-rate class, and are generally calculated at from four-pence to six-pence a foot for London. From the amount thus obtained, fifteen or twenty per cent. is generally deducted, and the total thus found is the amount of the general estimate.

41. *The cubic contents of this building* are 16,833 feet; and the following is the manner in which these contents are calculated:—

Length of the front of the main building .....	24 feet.
Width of the main building .....	23 feet.
Height from the bottom of the foundations to the middle of the roof	23 feet.
Then, for the contents of the main building.....	$24 \times 23 \times 23 = 12,696$ feet.
Length of the lean-to building .....	23 feet.
Width of the lean-to.....	9 feet.
Height, including cistern, pump, and well ..	16 feet.
Then, for the contents of the lean-to.....	$23 \times 9 \times 16 = 3,312$ feet.
Length of tanks.....	10 feet.
Width .....	5 feet.
Height .....	5 feet.
Then, for the contents of the tanks, and yard walls ....	$10 \times 5 \times 5 = 250$ feet.
Length of sheds and piggery .....	23 feet.
Width of sheds, &c. ....	5 feet.
Say five feet high, as the sheds have no fronts and include the yard wall.....	5 feet.
Then, for the contents of the sheds, &c. ....	$23 \times 5 \times 5 = 575$ feet.
Whole amount ...	
16,833 feet.	

16,833 cubic feet, at 6d., £420:16s:6d.; at 5d., £350:13s:9d.; at 4d., £280:11s. and at 3d., £210:8s:3d.

17

42. *Expression.* This dwelling has no pretensions to any particular style of Architecture, but it is obviously expressive of the subject or purpose in view; and, as all its details are well adapted for their various uses, whether as respects the convenience of the occupant of the cottage, or as component parts of the structure, it is also expressive of fitness. This Design may be ornamented by the addition of pillars to the porch, by a vase over it, by ornamental chimneys, and by a parapet on the terrace, fig. 17; or, if an architectural parapet is considered too expensive, a low hedge, fig. 18, may be substituted.

18

Design II.—*A Cottage of One Story, combining the Accommodations and Conveniences of Design I. differently arranged, and with the addition of a Veranda.*

43. *Accommodation and Construction.* This Design contains the same number of rooms, and of the same dimensions, as Design I. The communication with the cellar, by means

19

of the stair, *a*, in the lean-to, and the direct entrance to the yard, *b*, is, however, more convenient. The size of the cow-house, *c*, though somewhat diminished, is still large enough for a small cow; the space, *d*, for ducks or geese, and for a ladder to the hen-house, is not quite so commodious as in the other plan; but, on the whole, notwithstanding these drawbacks, this plan exhibits what we think a better arrangement than the preceding one. Exteriously the platform is level as far as the steps to the porch, *e*, and thence it forms an inclined plane to the natural surface. The veranda, *f* (see fig. 19), which is supported by trunks of larch or spruce fir trees, with the bark on, set on plinths of stone, or brick, will add much to the comfort and economical uses of this residence.

44. *Aspect.* The difference in the aspect of this cottage will be ascertained by observing the points of the compass marked in the ground plan; the north and south line being in the direction of from left to right; whereas, in Design I. it is from right to left.

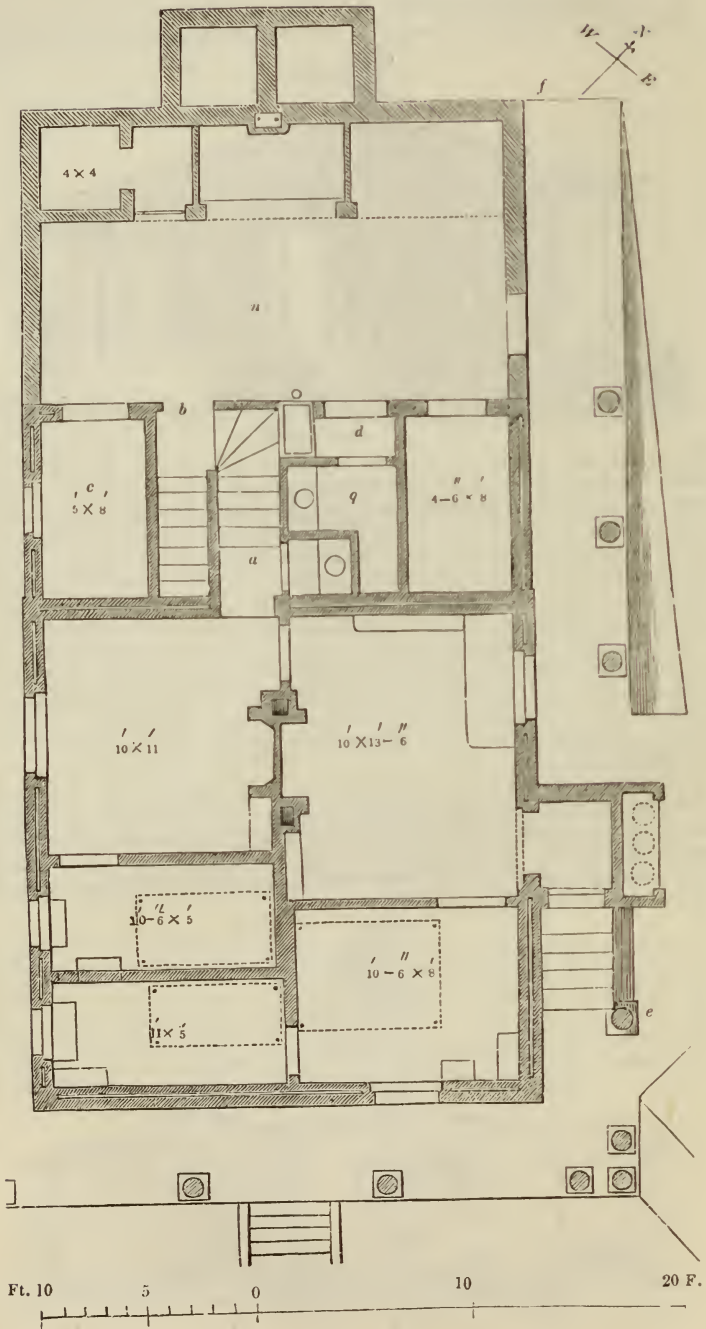

45. *General Estimate.* Cubic contents 17,440 feet, at 6*d.* a foot, £436; at 4*d.*, £290 : 13*s.* 4*d.*; and at 3*d.*, £218.

46. *Expression.* Though no marked features of any style appear in this elevation, yet it must be acknowledged to exhibit something more than the mere expression of purpose; because it would be equally, and to all appearance, as such a human dwelling, without the columns as with them. It may, therefore, be said to exhibit the expression of improved design. This expression would be further heightened by ornamental chimney pots, and a light iron parapet to the terrace, fig. 20.

20

II.

Design III.—*A Cottage of Two Stories, combining the Accommodations and Conveniences of Design I. differently arranged, and with an additional Bed-room.*

47. *Accommodation.* The same general accommodations are here given as in Designs I. and II.; but there is a second story, and this contains four bed-rooms. There is no cellar-floor, but there is a back kitchen, the floor of which is a few steps lower than that of the principal one. Into this sunk kitchen the oven opens, from which the flues proceed which heat the best kitchen and the parlour; unless it be considered desirable to have a boarded floor in the latter apartment; in which case, the courses of the flue will be confined to the floor of the kitchen. The following are the details of the ground plan, as exhibited in Design III. :—

- a, Kitchen.
- b, Parlour.
- c, Back kitchen, the descent to which is by five steps.
- d, Bed-room staircase, under which are the oven and boiler; the former with its flue under the kitchen and parlour floors, which are both paved with tiles or stone.
- e, Sink, supplied as in Design I. from a filtering-tank.
- f, Dairy and pantry.
- g, Women's water-closet.
- h, Tool-house and men's water-closet.
- i, Cistern for water-closets, with tank or well under, place for ducks and geese, and ladder to poultry-house at one side.
- k, Cow-house.
- l, Place for wood, or other fuel.
- m, Open yard.
- n, Pigsty.
- o, Dung-pit.
- p, Faggot-shed.
- q, Well, for the regulating plugs to the manure tanks, or cesspools.
- r r, Cesspools.
- s, Shelves for bee-hives, with dove-cote over, and dog-kennel under.

48. *The Bed-room Floor* is exhibited in detail in fig. 21. In this figure, the bed-rooms, a and b, over the back kitchen and dairy, are on a lower level than the bed-rooms, c and d, over the kitchen and parlour. The positions of the different beds, chests of drawers, and dressing-tables, in the different rooms, are indicated by outlines, as in Designs I. and II.; and the vacuity in the exterior wall is shown as in the ground plan. The vertical profile of the lean-to, containing the cow-house, water-closets, and wood-house, is also shown. By vertical profile, is to be understood a view, looking down vertically upon any object. The walls and ceilings of the bed-rooms are supposed to be finished with two coats of plaster, without cornices, but with the usual fittings and finishings of joiner's work, as given in detail in the specification of Design VII. The bricks used in the exterior surface of the outer walls, should not be of a harsh red colour.

49. *The Levels of the different Floors* are shown by fig. 22, which is a section on the lines A B, in Design III., and in fig. 21. In this section may be seen the level of the open yard,

III.

*a*; passage from the back kitchen, *b*; sunk area under the stair, to give head-room for

attending the oven, *c*; oven, *d*; water-box over it on a level with the kitchen floor, *e*; flues for heating the kitchen, *f*; platform, *g*; natural surface, *h*; lower bed-room, *i*; larger loft over, *k*; closet, *l*; situation of openings to the false flue for ventilation, *m n*; cornice for swallows, *o o*.

50. *Construction.* The walls are shown as of brick, and of the same thickness as in

Designs I. and II. The floors of the kitchen and parlour are formed in the same manner as those in Design I., with flues for heating. The roof may be either covered with Italian tiles, fig. 23, or with Grecian tiles, fig. 24. In putting on either of these tiles, the broad tiles, *a*, are laid side by side, and the semi-cylindrical tiles, *b*, are bedded in mortar, or in cement, over the joints. The advantages of these tiles are, that they admit of a roof being made so flat, that it may be walked on, and used as a terrace; while, at the same time, it is perfectly water-tight, and of great durability, novelty, and characteristic beauty. In Staffordshire, these tiles are made from a stratum of clay, containing a large proportion of iron; and when this clay is burnt, the tiles, or other articles formed from it, are almost as hard and heavy as cast-iron. The articles made from this clay are called *terro-metallic*.

23

51. *Situation and Aspect.* This Design, from having the sleeping-rooms on the second story, is more particularly calculated for low, moist, shady or confined situations; in which, however, cottages should never be built if it can be avoided. By observing the position of the points of the compass in the ground plan (Design III.), it will be seen that the entrance porch is on the south-east; and that the shelves for bee-hives front the north-east.

24

52. *General Estimate.* Cubic contents, 19,040 feet, at 6*d.* per foot, £476; at 4*d.*, £317:16*s*:8*d.*; and at 3*d.*, £238.

53. *Expression.* The tiles and the cornice of the chimney stack, give the elevation of this Design, fig. 25, something of an Italian air; and therefore, in addition to the expression

25

of purpose, this cottage may be said to have something of the expression of architectural style. The beauty of such a dwelling would be greatly heightened by the addition of a terrace parapet, and by ornamental chimney tops, fig. 26; and quite a different character

26

might be given to it, by having the roofing a good deal flatter, and adding cantilevers, (pieces of wood framed into the side of a house, to support such mouldings as may be placed over them,) under the far projecting eaves, so as to form an Italian cornice.

## CHAP. II.

*A Miscellaneous Collection of Designs for Cottage Dwellings, with Critical and Analytical Remarks.*

54. *The Designs which follow* exhibit various modifications of all, or of several of the comforts and conveniences contained in each of the Model Designs, joined to various degrees

of architectural style. The object is to show how some of the improvements in the Model Designs, may be applied to even the smallest dwellings; and, how with all, or with any of these ameliorations, or without them, various degrees of architectural style or beauty may be produced in cottages. For the attainment of these objects, we have accompanied each Design by such remarks, as we think calculated to enable the reader to form an opinion of his own; grounded on sound principles, as to what is, and what is not, beauty in Cottage Architecture. These Designs might have been arranged according to the degrees of accommodation, or their scale in respect to architectural style; but considering that the first appearance of this work will be in periodical portions, we have preferred giving a miscellaneous selection in each portion.

Design IV.—*A Dwelling for a Man and his Wife, without Children.*

55. *Accommodation.* This dwelling, we consider as exhibiting the minimum of accommodation, which ought to exist for a man and his wife without children, even in a country where there is an unequal distribution of civil rights. It contains one room, *a*, in which the cooking and ordinary avocations of the family are carried on, and which serves at the same time as a sleeping-room; a wash-house, *b*, which must also serve as a store-room, pantry, and for various other purposes; a porch, *c*, for wood or other fuel, and for tools of husbandry and out-door work; a privy, *d*, and an enclosed yard, with a dung-pit, *e*, forming a circular basin, and having a well in the centre for liquid manure from the privy.

56. *Description.* The house is placed on an artificial platform, which is ascended by four stone steps, seen on the plan, near the entrance door. The surface of the platform, which may be laid with gravel, or paved, forms a walk, on three sides of the house, leading from the door of the house, to the door of the court-yard. The greater part of this court-yard is on a lower level than the platform; the descent to this level being by an inclined plane from *f* to *g*. The pit, under the seat of the privy, communicates with the well, *e*, four or five feet deep, by an under-ground drain, which may either be formed in the usual manner, by bricks or stones, or by earthenware pipes; so that whenever the well is emptied for the purpose of taking out the manure, (formed by what is thrown in from above, and what is communicated below by the drain from the cesspool, under the privy-seat,) the privy will be emptied also. In consequence of this arrangement, the seat will never require to be removed for the purpose of emptying the cesspool; and the opening in the seat may communicate with the cesspool by means of a tube, either of boards, or earthenware, which, with double covers, will prevent the rising of smell. In the section of this cottage (p. 29), it will be seen that the floor is laid on loose stones; if it be desirable to heat this mass of stones with a view to the economy of fuel, horizontal flues can be built among them, communicating with an oven, in the wash-house, at one end near the boiler, and with an additional flue in the chimney stack at the other, in the manner shown in describing the model cottages. To every dwelling there must be some source for supplying water for the purposes of food and cleanliness. The common resource is a well, from which the water is drawn either by a windlass, or lever and bucket, or a pump; but the water which falls on the roof may be applied to domestic purposes, as described in the preceding chapter.

57. *Construction.* The walls of this cottage are here shown eighteen inches thick, with a view to their being built of rubble stone (stones rough from the quarry); of *pisé* (to be described hereafter); of mud blocks (which is nearly the same thing as building in *pisé*); or of compressed blocks of common earth (also described hereafter). The footings, or lowest parts of the foundations of the walls are shown, in this Design, and most of those which follow, as only a few inches below the surface of the ground, *h*; partly because the footings being covered and surrounded by the platform, are not likely to be afterwards disturbed; and partly because very little depth of foundation is wanted for buildings, generally of one, and seldom of more than two stories high. The roof may be covered with flag-stones, or slates, or Grecian tiles; the eaves being supported by wooden blocks, or cantilevers, as shown more clearly for the purposes of the

carpenter, by the section of a portion of the wall and roof, drawn to a scale of half an inch to a foot, fig. 27, *i*. The wall of the court-yard in countries where flag-stones abound may be formed of a continuous line of these stones fixed in the earth, edge to edge; or it may be constructed of boards, or pales; or built of wood, *pisé*, or blocks of compressed earth. If formed of earth, the wall ought to have a coping either of stone or boards. The raised platform may be made of the earth dug from the dung-pit and well, or from any other convenient source, taking care not to employ any earth for this purpose, rich enough to be used for the garden, if it can possibly be avoided; the entrance door may be formed of what carpenters call bead and batten (bead, a circular moulding, stuck on the edge of a batten, i. e. a scantling or piece of wooden stuff, from two to four inches broad, and one inch thick), with cross back bars inside.

58. *General Estimate.* The cubic contents of this building are 4,000 feet, and the following is the manner in which these contents are calculated :

Length of the front of the main building, 14 feet 4 inches.	
Width of the main building, 14 feet 4 inches.	
Height from the bottom of the foundations of the main building to the middle of the roof, 14 feet.	
Then for the contents of the main building . . . . .	14:4×14:4×14=2,876 2 8
Length of the front of both wings, 8 feet.	
Width of both wings, 11 feet.	
Height of both wings, 10 feet.	
Then for the contents of both wings . . . . .	8×11×10= 880
	3,756 2 0
Add for the wall round the court yard, and to make an even sum	243 9 4
	4,000 0 0
4,000 feet at 6 <i>d.</i> , is £100; at 4 <i>d.</i> , £66: 13 <i>s</i> : 4 <i>d</i> ; and at 3 <i>d.</i> , £50.	

59. *Garden.* The dung-pit and well show that this cottage is intended to have a garden, which ought, if possible, to be around it; but as dwellings like this in Britain are often placed as lodges to entrance gates, and stand on the margin of a plantation or shrubbery, the garden in that case should be on the side of the house which has windows; because that side only in such dwellings is generally left open to the air and light. High trees or shrubs near a house, if on a side which may happen to have no windows, do comparatively little injury in the way of obstructing the ventilation and lighting of the house, to what they do on the windowed side. It is a common practice in Britain to place the kitchen gardens of lodges of this sort in the interior of the plantation or shrubbery, so that they may be concealed from the road; and to have only a flower garden on the front or open side of the house; but in this case the kitchen garden is of very little use to the occupant; the surface being overshadowed by the trees, and the soil exhausted by their roots.

28

Whatever is decidedly contrary to utility and convenience, must be in bad taste, though it may seem to a superficial observer to be otherwise.

60. *Expression.* A plain cottage, like the present, cannot be said to be in any particular style of architecture; though it belongs more to the Grecian than to the Gothic, from the proportions of the windows, and from the blocks or cantilevers, fig. 27, *i*, supporting, or seeming to support, the eaves of the roof. If the door and the two windows had Grecian

29

30

architraves and mouldings (masonry supposed to be in imitation of the original beams

IV.

V.

which, in rude huts, formed the sides and covers to openings, fig. 28), the building would then lay claim to be called a cottage in the Grecian style; but being without these, it has little or no expression of style, but simply an expression of the subject, or purpose, for which it was built; that is, to serve as a cottage, or human dwelling of the humblest kind. The glass windows, the door for security, and the chimney top, clearly show this edifice to be a human dwelling; and its size, as decidedly determines it to be one of the humblest description, or what is called a cottage. Remove the windows and the chimney top, leaving the entrance opening without a door, fig. 29, and it might be taken for a cattle-shed and yard. Remove the roof, and replace the door, fig. 30, and it might pass for a place of burial. Restore the glass windows, increase the height of the principal one, and replace the roof with a little alteration, adding on its summit a turret and bell, fig. 31, and this structure might be mistaken for a chapel. We state these things simply for the purpose of showing what is meant by expression of the subject, in contradistinction to what is meant by expression of architectural style.

Design V.—*A Dwelling for a Man and his Wife with Two or more Children, with a Cow-house and Pigsty.*

61. *Accommodation.* This is a simple, economical, and comfortable dwelling, without pretensions either to ornament or style. It contains an entrance lobby, *a*; kitchen, *b*; back kitchen, *c*; children's bed-room, *d*; bed-room for the father and mother, and the infant children, *e*; tool house, *f*; pantry, *g*; place for fuel, *h*; privy, *i*; cow-house, *k*; and dairy, *l*. There is a yard behind the house containing a pigsty and the manure well. This yard is entered from the back kitchen, *c*; and also by doors in its boundary fence, *m*.

62. *Construction.* The walls may be of stone, brick, or earth; the two former materials will not only be found more suitable in reality, but more satisfactory to the eye: for walls of earth, when not whitewashed, have always a mean appearance, from the inferiority of the material; and when whitewashed, this meanness, though concealed, is still known to exist; for no building was ever whitewashed, but for the purpose of concealing something, and every one must feel, with Wood, that the grandeur or the beauty of any building is never heightened by this operation. "The world in general," says this philosophical artist, "is exceedingly unwilling to acknowledge beauty of form when the material is bad; and, on the other hand, where the materials are good, it is ready to praise the form also; the one is a much more obvious and indisputable merit than the other." (*Letters, &c. Vol. II. p. 96.*) Where white-washing or lime-washing a building, with any colour, contributes to the preservation of the wall, it is justifiable; but no genuine lover of truth will ever admit that this operation can add to the beauty or character of a building. The idea which it conveys of the neatness and cleanliness of the inhabitant is its principal recommendation; and yet it is a fact, that where lime-washing is most employed, as in Wales and Scotland, the interiors of the cottages are less orderly and clean, than in the unwhitened mud and rough stone cottages of England.

63. *The Cow-house* in this Design is placed under the same roof with the dwelling apartments, but with its floor a few inches lower, so as to be on a level with the platform. That part of the platform on which the cow-house opens ought always to be connected with an enclosed yard; and instead of sloping down to the general surface level at an angle of 45° or 50°, it ought to slope, as shown in the Section on the line A B, at an angle not exceeding 15°. The whole of the enclosed yard ought either to be paved, macadamized, or gravelled; and the surface ought to be so inclined as to carry all the water which falls on it, to the manure pit and well. The floor of the cow-house ought to be perfectly level and smooth, so as that it may never be necessary to employ litter. The gutter ought to be formed about a foot broad, and four inches deep, and exactly behind the cow's heels. This will be from seven to eight feet from the feeding-trough at her head, according to the size of the cow; but the details on this subject will be found in our second Book.

64. *The Roof* is shown of a low pitch, and covered with slates. The chimney tops are quite plain; and, in our opinion, they, and most of the other chimney tops in the Designs

hitherto published, are too short. The principle of truth, or a thing appearing to be what it is, and the expression of purpose, alike require that, in all human dwellings in temperate climates, intended to appear as such, the chimney tops should be conspicuous objects. We would, therefore, recommend them, in all cases, to rise boldly into the air above the roof, and to form a conspicuous feature in the outlines of all buildings against the sky. As a palliative for the evil of a stack of chimneys being too short, architectural chimney pots may be employed. Of these there are a great variety of forms made of cement, artificial stone, or earthenware. We shall give numerous specimens in the course of this work, and, in the mean time, present one, fig. 32, which may answer very well for the Design before us, and which was furnished us by Mr. Austin, from his artificial stone manufactory, in the New Road, London. Much of the effect of chimney pots, vases, and all ornaments of this sort, depends on their being raised on suitable plinths (a square plate, originally a square tile, placed under the base of a column, or other object), fig. 33, *n*.

65. *The Door-way* in this Design is protected from the perpendicular rain by what is called a door-bracket, fig. 34, which, considering that there is a lobby or vestibule within, may, perhaps, serve as a substitute for a projecting porch; for, as we have before observed, whenever comfort is the object, there ought either to be a porch, or a lobby; and in every exposed situation, both are desirable. That the porch should always partake of the expression of the main body of the building is sufficiently obvious; and not less so that it should be enhanced in the expression of Design, in order that it may be rendered conspicuous and inviting.

66. *Situation.* This building is not calculated for being placed in a situation where it will be seen from all sides; because the yard-wall, and the irregular size and position of the openings which look into it, have less of the character of architectural design than the front and ends. If it be placed near a road, therefore, the entrance side and end should first meet the eye as in the perspective elevation before us.

67. *General Estimate*, 11,700 cubic feet, at 6*d.* per foot, £292 : 10*s.*; at 4*d.*, £195; and at 3*d.*, £146 : 5*s.*

68. *Expression.* Nothing here can be considered as super-added to the expression of the subject. A degree of ornament and elegance might be conferred by handsome chimney pots as suggested above, and by a low fence round the terrace, fig. 35; but, for the latter, might very well be substituted a box hedge, which the cottager might keep neatly cut and ornamented by verdant figures at the corners, &c.

69. *General Estimate*, 11,700 cubic feet, at 6*d.* per foot, £292 : 10*s.*; at 4*d.*, £195; and at 3*d.*, £146 : 5*s.*

Ft. 10 5 0 10 20 Ft.

VII.

Design VI.—*A Dwelling for a Man and his Wife with an Apprentice, Servant, or grown-up Son or Daughter.*

69. *Accommodation.* This neat little dwelling contains only one large room or kitchen, *a*; a small bed-room for the master and mistress, *b*; and a store closet, *c*. Included under the lean-to at one end, is a privy, *d*, and a place for fuel, *e*, and there is a porch in front, *f*. The servant, or grown-up son, or daughter, is supposed to sleep in the large living room, or kitchen, in which, the situation of a bed is indicated; it being frequently requisite in the case of gate-houses, ferries, or bridges, to have one of the inmates sleeping near the door, for the convenience of rising in the night-time to open the gate, take toll, &c. The use of the space between the ceiling and the roof may be obtained by having a trap door over the porch.

70. *Construction.* The walls may be either of brick or of stone. The roof may be covered with slates, projecting a few inches over the walls, and delivering the water into a gutter, fig. 36. The doors are ledged, and hung with ornamental hinges (fig. 37), to a scale of three quarters of an inch to a foot, fixed on the outside.

71. *General Estimate.* Cubic contents, 5,230 feet, at 6d. per foot, £130 : 15s. ; at 4d., £87 : 3s : 4d. ; and at 3d., £65 : 7s : 6d.

72. *Expression.* There is obviously something more intended here than the mere expression of the subject. The peculiarity of the hinges of the door, the small loop-hole opening over it, and the pinnacle by which the gable end is terminated, are intended to give some character or expression of style to this cottage; though we cannot refer to any known sub-style or manner which may be considered its prototype. The elevation, however, presents a very neat whole, and though not striking, is at least agreeable. It might be enriched by suitable chimney pots, and to be complete, ought to have a parapet on the terrace, fig. 33.

Design VII.—*A Dwelling of Two Rooms, and a back Kitchen, for a Man and his Wife.*

73. *Accommodation.* This dwelling is deficient in closets, which are always more or less useful, either in a small house or a large one; it is, however, substantially built, and comfortable. There is an entrance lobby, *a*; a room, *b*, containing a bed, which may serve also for a working room, and which, in Scotland, very generally serves for a parlour; a kitchen, *c*, well lighted, and with two cupboards; and a back kitchen, *d*, which forms part of a lean-to. One end of this back kitchen may be partitioned off as a pantry. In the lean-to there is also a place for fuel, *e*, and a privy, *f*; which last communicates by a drain with the well of the dung-pit.

74. *Construction.* The walls may be built of rubble stone, with rusticated corners (that is, the joints channelled, or cut in grooves), as shown in the elevation; and as is very generally practised in countries abounding with free stone. There is an obvious propriety in the practice of building the corners with large and square stones; because the corner of a building, from being exposed to the weather, and to accidents from coming in contact with persons or objects on two sides, in order to be equal in durability with the general face of the wall, must be formed of a more solid, homogeneous material. It is not, as some might suppose, that the corners require to be built thicker than

the other parts of the walls in order to be stronger; for the corner, from its very position, is always the strongest part of the wall. Thus, a force applied to the wall, *g*, in the direction of *h*, fig. 39, is resisted only by the thickness of the wall; but a force applied at *i* or *k*, is resisted by the thickness of the wall, backed by its length; and a force applied at *l*, is resisted by the length of both walls. The walls in this Design are finished with what is called a blocking course, fig. 40, *m*, over which the slates of the roof project so as to throw the water into a gutter, formed in the upper surface of what is called the wall head plinth, *n*. This is a very common mode of roofing and finishing stone-built, slate-covered cottages, in Scotland; where it is found both economical and durable. The chimney stacks are formed of hewn stone, finished with a simple cornice (fig. 41, to a scale of one inch and a half to a foot). In the section A B, in Design VII. it will be observed that the part of the platform which is under the house, is formed of stones; the object being to keep the floor dry, and to admit, if it should be thought necessary, of forming a flue in it.

75. *Situation.* A cottage with this description of roof is peculiarly adapted for an elevated situation, much exposed to storms; it being impossible for the wind to get under a roof like this, which has no eaves.

76. *Fitness.* A great fault in this dwelling is, that the fire-places are in the side wall, and though they are in part protected by the lean-to, yet the heat thrown into that part of the building may be considered in a great measure lost, or of no great use. It would be an improvement to transpose *e* and *f*, as the heat given out behind the fire-place of *b*, would then be turned to some account.

77. *Expression.* There is very little more here than the expression of the subject. What there is, belongs to local manner, and that manner being common in Scotland, the dwelling before us may very well be termed a stone cottage in the common Scotch manner. This manner can by no means be commended in point of beauty; but it might be improved both in appearance and usefulness, by the addition of a porch; a parapet to the terrace, and a vase over the porch, to bring those on the parapet, and the chimney pots into harmony, fig. 42. Vases for these purposes, of various forms and dimensions, are to be had from the potters, at a few shillings each.

78. *Specification.* In the following detailed specification, the walls are supposed to be built of stone, with brick coins instead of squared stones. As a number of technical terms are necessarily made use of in these details, we have explained them as they occur; and the engravings which we have made use of in aid of this purpose, are to be considered as merely explanatory, and not drawn to any scale, like those illustrative of the construction of the different Designs.

79. *Specification of Bricklayer's Work.* To dig out the several trenches for the foundations of the respective depth and width required; and to fill in and well ram in the earth round the foundations when built. To dig and steen (to line with brick or stone) in four-inch brick-work, a cesspool for the privy four feet in diameter in the clear, and six feet deep; and to dome (arch over) the same in nine-inch brick-work; and put in four feet of twelve-inch hollow tile drain, fig. 43, with a proper fall to convey the soil to it. To build

all the foundations and the cross-wall under the bed-room floor, and the external walls with stones properly headed (squared at the ends) and prepared (so as to lie flat), laid in random courses (courses of unequal height, fig. 44); the external face with a neat garreted

44

45

46

joint (the joint stuck with small pieces of stone), with brick coins (corners) and common skewback (a bevelled abutment, fig. 45, *o o*), brick arches, set in Roman cement, over the doors and windows. The back kitchen, fuel-house, and privy, to be carried up in four-inch brick-work. To fill in the cross partitions with four-inch brick nogging flat (bricks laid flat, or in bed, fixed between, and flush, i. e. even, with the stud-work, fig. 46). To build nine-inch brick spandrils and steps to the front door, with proper foundations. (The span of an arch is the distance between the two points from whence it springs, and spandrils for door steps are the arches, or the walls, which support the ends of the steps). To build the chimney jambs (sides, fig. 47, *p*), breasts (fronts, *q*), backs, *r*, and shafts, *s*, in brick-work, with flues, nine inches by fourteen inches in the clear; properly gathered and pargetted (plastered in the inside with a mixture of common lime mortar, fresh cow-dung, and loam); and provide an additional flue for a copper (boiler). The fire-places to have each a strong iron chimney-bar (bar for supporting the breast-work, or front side of the flues). All the door and window-frames to be properly bedded (placed in mortar), and pointed (the joints neatly closed) with good lime and hair mortar. To pave the kitchen and entrance with good paving bricks, bedded and jointed in mortar; wheeling in stones and gravel, which are to be well rammed in and consolidated, in sufficient quantity to raise the floor to the level shewn in the section; and to pave the back kitchen, fuel-house, and privy, with common stocks, bedded in sand: the whole to be properly currented (laid to such a slope as to carry off the water). The bricklayer is to find scaffolding and ladders, and to fix and refix the same, as occasion may require; and to cut the chasings (to cut into the brick-work) for lead, and all rakes (to cut a rake, is to reduce to a smooth slope the face of brick-work which has been left in a rough slope, as indicated by the dotted line, fig. 48, *t*), and splays (a splay signifies a return of work deviating from a right angle, and is generally applied to the bevelled jambs of windows and doors, as at *u*, in fig. 48) required; and make good (reinstate what may have been deranged during the operations); and, from time to time, to clear away the rubbish arising from the work during its progress. The bricklayer is to find all materials; lime, sand, tackle, carriage, and labour, for the completion of the foregoing works in a sound and workmanlike manner.

47

48

80. *Specification of Plasterer's Work.* To colour twice over, in a good warm-tinted stone colour, the brick coins, arches, chimney shafts, and the exterior of the back kitchen, fuel-house, and privy. To lathe (to nail on the laths), lay, set, and whiten, the ceilings of the kitchen, bed-room, and entrance; and render set (first and second coats of plaster in two-coat work) the walls and partitions, and lime-white (whitewash) twice over the back kitchen, fuel-house, and privy inside. The plasterer is to find all materials, tools, carriage, and workmanship required for the completion of his work; and to do the same in a workmanlike manner.

81. *Specification of Slater's Work.* To cover the whole of the roofing with Countess slating (the third size of Welch slates, see *Slates*, in *Glossarial Index*), nailed with painted iron nails, and the eaves to be laid double. The whole to be laid with a sufficient lap, and to be carefully sorted in courses (laid so as that the joints may form regular lines), so as effectually to exclude the weather. The slater is to find all materials, tools, carriage, and labour required for the completion of his work, and to do the same in a workmanlike manner.

82. *Specification of Stone-Mason's Work.* To put Yorkshire stone quarry sills, eight inches wide, bevelled (sloped), throated (grooved underneath), and tooled (hewn, but not rubbed afterwards, as is done occasionally to produce a finer surface), to all the windows. To put a Yorkshire stone hearth and slab to the bed-room fireplace; and plain Portland stone mantels (the cross pieces which bear on the jambs), jambs, slips (sides of the jambs), and shelves to both the fireplaces. The mason is to find all materials, carriage, and work, required for the completion and fixing of his work, in a sound and workmanlike manner.

83. *Specification of Carpenter's and Joiner's Work.* Carpenter's work. The work to be done with sound, well-seasoned, Quebec red pine timber, except where otherwise specified. The whole to be framed in a workmanlike manner, with the stuff (pieces of timber) sawed square of the several scantlings (dimension of breadth and thickness), and descriptions as follows:—all the carpenter's work, as well as the joiner's work, to hold the several scantlings

(dimensions, see *Glossarial Index*), and thicknesses herein named, when finished. To put oak lintels (correctly, the head pieces over doors or windows, which rest upon the jambs; in brick buildings generally a short beam over the head of a door or window resting on the jambs, to carry work that does not receive support from an arch), three inches and a half thick, to all the openings, of the width of the respective walls, less the thickness of the brick arches, so as to lay nine inches on the walls at each end. Oak wood bricks (pieces of oak timber, cut to the size and shape of bricks, and built into the inner surface of walls for the purpose of nailing joiner's work to them, when finishing the rooms), to be provided in the jambs for fixing the linings (thin boards) where required.

—Bed-room floor. To put oak joists, four inches by three inches, and twelve inches apart, laid on two-inch oak sleepers, four inches wide.—Ceiling floor. To put an oak wall plate, four inches by two inches and a half, dovetailed (see fig. 57) at the angles, and halved and spiked (a mode of joining,

fig. 49) at the laps; and ceiling joists, joggled on (fixed, as shown in fig. 50), and spiked (nailed with spike nails, fig. 51) at each end, to the top of the plate, four inches by two inches, and twelve inches apart; the two end bays (spaces between the girders, or principal timbers in a floor) to be framed at one end into the binding joists, five inches by three inches, fig. 52, r.—Roofing. To put one inch and half yellow deal hip rafters (rafters at the angles of a pavillion roof), and ridge pieces, nine inches deep (fig. 53, w), rounded on the top for lead. Common rafters, four inches by two inches and a half, and thirteen inches apart; with two pair of couplings, five inches by three inches, fig. 54, x,

framed to the binding joists, or tie beams (horizontal pieces of timber, y), and spiked to the face of them at each end, having king-posts (perpendicular posts, z), six inches by two inches and a half. The whole properly trimmed (framed round, leaving a clear opening,) to the chimney shafts. The shed roof over the back kitchen, fuel-house, and privy, to have

rafters, wall plates (pieces of timber on the walls, on which the rafters rest, fig. 54 § §), and ties of the same scantling as above described. The whole of the roofs to be covered with three quarters of an inch thick yellow deal slips (boards), two inches and a half wide, for Countess slates; with proper tilting fillets (tilting fillets are used

inches and a half wide, for Countess slates; with proper tilting fillets (tilting fillets are used

to give a slight inclination to the verge or border-slates, where they butt against brick-work, as at *a*, in fig. 55, in order that the water may be directed from the brick-work; they are

likewise employed to steady and support the lower edges of slates finishing against vallies; the usual size is three inches wide, three-eighths of an inch thick, and feather-edged; and one inch and a quarter feather-edged (thin edged) eaves' board, eight inches wide. Put one inch yellow deal gutters, and bearers (pieces of scantling to support the gutters. fig. 56, *b*), to the chimneys. The internal partitions to be made for nogging flat (the same as in fig. 46, but with the bricks set on edge). Put heads, four inches by three inches, dovetailed, fig. 57, into the plates; sills of oak, four inches by two inches and a half; common quarters, fig. 58. *c*, four inches by two inches, and eighteen inches apart; door-posts, *d*; principal quarters (principal upright pieces of timber in the partition, *e*), and braces (diagonal pieces of timber, *f*), four inches by three inches; nogging pieces, *g*, four by two inches.

84. *Specification of Joiner's Work.* All the inside framing, and all the outside work, to be of sound, well-seasoned, dry, yellow deal. To put one inch and a quarter moulded fascia (fig. 59, *h*), with an inch thick gutter having a false bottom, *i*, to current the water (to slope the bottom, so as to make it run), put together with white lead, all round

the eaves, with two three-quarters of an inch yellow deal water trunks, four inches and a half square (wooden pipes to conduct the water down, fig. 60, *k*), with head, *l*, and shoes, fig. 61, to deliver the water to the ground. To lay in the bed-rooms one-inch folding floors (a particular mode of laying down the boards; but when finished, the appearance presents nothing particular; fig. 62. See folding floors, in *Glossarial Index*), with border to the slab.—[In the specification of the gutter for carrying off the water from the roof, there is a deviation from the section, fig. 40, in p. 36, in which the gutter is formed in stone, being hollowed out of the wall-head plinths. The reason why this deviation has been made, is, that the specification was drawn up with the view of erecting the cottage in the neighbourhood of London, where a stone gutter would have added greatly to its expense. The wooden gutter shown in the section, fig. 63, will produce the same effect, and correspond with the specification.]—Doors. To put proper door-cases (door-cases are called proper, when wrought, i. e. planed, framed, rebated, and beaded,) of fir (fir is generally applied by builders

to Baltic timber; what they call pine generally comes from America, and is of inferior quality). four inches and a half by three inches, and oak sills to all the external doors, with one inch and a half six-panelled bead, butt and square door (a door framed on one side without any moulding; on the other the panel is flush with the stiles, and has a bead run on the edge, butting against the rails, fig. 64, *m, m, m,*) to the entrance, hung with three-inch butts (hinges, fig. 65); and one and a quarter inch proper ledged door (a proper ledged door has the boards planed, tongued into each other, see *Index*, and beaded; they are placed vertically, and nailed to horizontal pieces at the back, called ledges,) to the back kitchen, fuel-house, and privy, hung with sixteen-inch cross garnet hinges (a hinge with a bar, fig. 66); the whole to have Norfolk thumb latches (latches lifted by the thumb, fig. 67), and eight-inch rod bolts, fig. 68; and, except the privy, eight-inch fine plate stock locks (locks with a wooden back, or stock, fig. 69). The internal doors to be one inch and a quarter six-panelled, both sides square, with two inches and a half butt hinges, and a six-inch iron rim brass knob locks, fig. 70.—Windows. To put an oak solid two-light proper frame, three inches by two inches, with cast-iron casements, made to open with strong hinges, latches and spring stay-irons (irons to keep the window open) to the back kitchen.—[We have shown in the elevation, sash windows, greatly preferring them to casements; but as the object was to erect the building at as little cost as possible, casements were substituted in the scullery window, &c.]—The windows in the kitchen and bed-room to have deal cased frames (frames with wooden cases formed at the back of the pulley stiles for the sash weights to hang in) oak sunk sills (the upper part of the sill sunk, or grooved out, in order to prevent the rain from driving under the sash) one inch and a half ovolo sashes (the sash-bars with ovolo mouldings, fig. 71); double hung, with white lines, iron weights, and brass pulleys, with brass spring fastenings, fig. 72. All the windows to have inch wrought and rounded window boards, (a narrow shelf in the interior at the bottom of the sash, fig. 73, *n,*) with three quarters of an inch splayed lining and soffits, *o*, with ogce mouldings, and fillets on the edge, *p*. The doors also inside to have one inch and a quarter single rebated jamb linings, with mouldings to match. To put inch clamped (cross-headed, *q*) folding shutters, with rule joints (joints like those of the common foot rule), and proper hinges to the window, with iron bar fastenings. To put three quarters of an inch square skirting, (a skirting-board

without any moulding at top), four inches high, fig. 74, in the

bed-room, with inch narrow bevelled grounds (slips of wood to fix the skirting to, having the upper edge bevelled back, in order to retain the margin of the plaster, fig. 75, *r*), plugged to the walls (nailed to plugs of wood driven into the walls). To put an inch deal seat riser (the front board on edge), and bearers (cross pieces), with water board hole and a cover, to the privy, and three quarters of an inch skirting at back of the seat, six inches high.—[We have before, in Chapter

I., recommended a hinged flap, or lid, in addition to the round cover which fits into the hole, with a view the more completely to exclude smell; an object which ought, if possible, to be effected, at whatever cost. For this reason, we would always recommend the introduction of a

smooth earthenware basin, with a tube, which may reach down into the soil, under the seat,

in order to diminish the evaporating surface, and prevent the possibility of a current of air rising through the opening.]—To put three tier of inch shelves in each of the recesses in the kitchen. The carpenter and joiner to find all materials, ironmongery, carriage, and labour for the completion of his work, and to do the whole in a sound and workman-like manner.

85. *Plumber's, Painter's, and Glazier's Work.* To put flashings (strips) of milled lead (lead that is pressed out to the required thickness by a machine), eight inches wide, five pounds to the foot superficial, chased (let) into the brick-work, and fixed with wall-hooks, fig. 76, to the chimney shafts, with proper aprons (pieces of lead to overlap the flashings, fig. 77, s), and cover the gutters with lead seven pounds to the foot superficial. To cover the hips and ridges with milled lead, fifteen inches wide, five pounds to the foot superficial, properly lapped, dressed, and nailed with lead-headed nails (nails with their heads enveloped in lead, by dipping them in melted lead, in order to

prevent their rusting). To glaze and back putty, (to remove the putty pressed out of the rebate by the pane), all the sashes and casements with good second (second in quality) Newcastle crown glass. To paint the whole of the external wood-work, and the gutters, and shoots (spouts), inside four times in good white lead and oil; the external doors to be finished in an oak, or in a stone colour. To paint the sashes, frames, shutters, linings, and skirting, inside the house, three times in oil.

The plumber, painter, and glazier, to find all workmanship, materials, and the carriage thereof; and every thing requisite for the performance of his work, and to do the same in a perfect and workmanlike manner.

86. *Well, Pump, and Platform.* The above specification is exclusive of a well and pump, also of a copper boiler, and setting it, and of the bringing of the earth, and forming the platform or terrace round the house.

87. *Estimate.* The following is the form of an estimate, framed on the above specification, as made by surveyors and builders. The architects about London and Edinburgh, as we have before observed, generally estimate by the cubic contents; first making a calculation of what a cube of ten feet square will cost on each separate story; but the surveyor, whose business it is to measure buildings, and to estimate the value of the labour and materials, goes into minute details. He does not, however,

in giving in an estimate, specify to his employer the value which he puts on every particular item; but only the total amounts of the different works generally executed by separate tradesmen, in the following form:

88. *Estimate of Bricklayer's Work.*

- Nine cubic yards of digging, filling, and ramming; seven cubic yards of wheeling in stones and gravel, to level the ground under the kitchen floor.....
- One hundred and ninety-seven feet of reduced brick-work, (in estimating the price of brick-work in Britain, the quantity, of whatever nature and thickness it may be, is always reduced to walls of one and a half brick in thickness, two hundred and seventy-two and a quarter square feet of which form a rod of brick-work).....
- One rod, eighty-two feet of reduced stone-work (the stone walls are reduced to one and a half brick in thickness).....
- Two rods, two hundred and twenty-five feet of reduced stone-work above ground, with brick coins and garreted joints.....
- Twenty-nine yards of brick nogging flat.....
- Ten and a half yards of common stock paving in sand.....
- Sixteen yards of paving bricks bedded and jointed in mortar.....
- Eight feet run (lineal measure) of chasings for lead.....

£ s. d.

Forty feet of cutting splays . . . . .	
Four feet of twelve-inch hollow tile drain. . . . .	
Digging and steening in four-inch brick-work a cesspool, four feet diameter in the clear, and six feet deep. . . . .	
Paved slope to the drain in the privy. . . . .	
Two iron chimney bars. . . . .	
Twelve common brick arches, set in cement. . . . .	
Nine window and door frames, bedded and pointed. . . . .	

---

£70 . 3 : 3

89. *Estimate of Plasterer's Work.*

Thirty-two yards of whitewashing to new work. . . . .	
Sixty-two yards of whitewashing twice over. . . . .	
Forty-five yards of stone-colouring twice over. . . . .	
One hundred and twenty-one and a third yards of render-set plastering. . . . .	
Thirty-two yards of lathlay set plastering. . . . .

£182 : 0 : 2

97. *Estimate from the Cubic Contents.* This dwelling contains 7,305 cubic feet, which, at £182 for the whole, is between 5½d. and 6d. per foot; but, as before observed, contractors about London generally deduct a per centage from their estimates, according to the kind of building to be erected: this per centage, for ornamental buildings, is about ten per cent.; but plain buildings, such as the one above given, may admit of a deduction from the estimate of fifteen per cent., which would reduce the amount to about £155.

Design VIII. — *A Dwelling of Two Rooms, for a Man and his Wife.*

98. *Accommodation.* This dwelling, though small, will be found suitable for those situations where neatness, with some little appearance of improved design, is an object. It contains a kitchen, *a*, well lighted, and with two closets; a bed-room, *b*, with a recess for a cupboard; a porch, *c*; a back-room, *d*, in which there might be a boiler and an oven for baking, and also for heating water, and the flues in the floor; a place for the fuel, *e*; and a privy, *f*. The section, A B, shows that the kitchen floor, and that of the back kitchen and porch, are on a bed of stones. The bed-room floor is of boards laid on joists, and hollow beneath. The whole is surrounded by a platform, which may either be paved or laid with gravel; and along its outer margin, there may be a small parapet, with Gothic ornaments on it at the angles.

99. *Construction.* The walls may be built of stone or brick; and the roof covered with slates or flat tiles, projecting a few inches over the walls, so as to deliver the water which falls upon it into the gutter. The chimney tops are round, terminating with small capitals. The pediment over the entrance terminates in a small ornament or pinnacle, formed of oak (fig. 78, on a scale of half an inch to a foot), characteristic of old English cottages in districts abounding in timber.

100. *General Estimate.* Cubic contents, 7,430 feet, at *6d.* per foot, £185: 15s.; at *4d.*, £123: 18s.; and at *3d.*, £92: 17s.

101. *Expression.* From the pointed top of the entrance-door, from the ornament on the summit of the pediment over it, and from the cylindrical chimney tops, it is evident that something more is intended than mere expression of the subject. Yet there is no great unity of style, for the tops of the windows are square, and there is nothing out of the usual course in the appearance of the roof. All that can be said of this elevation is, that it is pleasing and picturesque; that is, very well calculated to look well in a picture, though it is not in any very marked architectural style. The space between the tops of the windows and the eaves of the roof, is sufficient to admit of a veranda; and this, with a suitable parapet on the terrace, fig 79, would render this cottage a very ornamental object. Placed in a garden, and surrounded by low and round-headed fruit trees, such a building would produce a better effect than in a forest of pines or firs; as the pointed forms of those trees would not contrast so well with it, and they would overpower it by their size. In planting trees near dwellings of any kind, if it be desired to conceal the building, to diminish its importance in the landscape, and to render it an unhealthy abode for its occupants, then tall evergreen shrubs and large trees ought to be planted close to the edifice; but, if on the contrary, it be intended that the cottage should have some dignity of character, and that its occupants should keep their health, no tree, that under any circumstances grows higher than the building itself, should be planted within the distance of several yards of it.

Design IX. — *A Dwelling in the Swiss style, for a Married Couple and Family; with a Cow-house and Pigsty.*

102. *Accommodation.* The rooms in this dwelling are of a good size, and there is a sufficient number of them for the comfort of the occupants. On the ground-floor, there is an entrance lobby, *a*, containing the staircase; a kitchen, *b*; a back-kitchen, or wash-house, *c*; a parlour, *d*; a light closet, *e*; a pantry, *f*; a coal closet, under the stairs, *g*; a cow-shed, *h*; a piggery, *i*; a wood-house, *k*; and a water-closet, or privy, *l*. The windows and doors of all this lower range are protected by a far projecting balcony, which, in point of comfort and effect, is equal if not superior to a veranda. The bed-room floor contains one best bed-chamber, *m*; a light closet, *n*; staircase, *o*; bed-room for boys, *p*; and for girls, *q*.

VIII.

IX.

The balcony is entered from a glass door on the landing of the staircase; and in countries subject to snow and rain, is valuable for the protection which it gives to the windows and the boarded walls; as a place in which children and invalids may take exercise; to hang up corn seeds, herbs, tobacco, and various articles from the eaves; and more especially, to dry clothes on lines during wet weather.

103. *Construction.* The foundations, as high as about two feet above the platform, and the two interior walls containing the flues and the chimney stacks, are of brick or stone. All the rest of the building is of wood, being framed work, covered with boards, outside and in. In Switzerland, the native country of such buildings, these boards are seldom painted, though those on the outside are sometimes tarred, in order to preserve them from the weather. The roofs in that country are generally covered with shingles (wooden tiles), usually of larch or oak, as being the most durable, six or eight inches broad, and a foot or eighteen inches long; but in a country where slates or earthen tiles can be got, they are far preferable, not only on account of their durability, but because the shingles are very apt to be blown off by high winds. The balconies are supported by the continuation of the flooring joists, as appears by the cross section, fig. 80; under which are the further supports of brackets (fig. 81, to a scale of half an inch to a foot). The projecting part of the roof at the sides is

supported by the continuation of the rafters, as may be observed in fig. 80; and the ends are supported by solid brackets (fig. 82, to a scale of half an inch to a foot). The railing is

generally simple, and characterized by perpendicular lines; the ornaments may be notched with the axe and chisel, fig. 83. The chimney has a coping of two broad flat stones or tiles, to exclude the rain; and the openings for the escape of the smoke are consequently lateral. The windows may be sashes hung in the English manner; or they may be hinged, opening inwards, according to the Italian and French taste, and as they most commonly are in Switzerland.

104. *General Estimate.* Cubic contents, 23,026 feet, at 6*d.* per foot, £575 : 13*s.* ; at 4*d.*, £383 : 15*s.* : 4*d.* ; and at 3*d.*, £287 : 16*s.* : 6*d.*

105. *Expression.* This Design assumes a decided character or style, which no one, who has been in Switzerland, can doubt is in imitation of the timber-built dwellings of that country. As a picturesque object, it is most agreeable ; more especially in its native situation on the side of a hill, where it is frequently accompanied by firs, or pines, or other spiry topped trees, which contrast well with the long horizontal line of the roof. It frequently happens that cottages of this sort are placed on the side of a steep slope, so that while the lower end is entirely above the surface the upper end is half sunk into it. In this case, the sloping line of the hill contrasts admirably, both with the horizontal and perpendicular lines of the building, and the appearance of stability is heightened by the one end being sunk or bedded into the hill. The balcony in this case, terminating on the surface, may be entered on the outside. The same cottage placed across the slope would appear much less stable, as well as less picturesque. In imitating the style of any particular country, the Architect ought to take care not to imitate peculiarities or defects. It is common, both in Switzerland and in Kinsighal, in the Duchy of Baden, to see the roofs of dwellings of this sort, loaded with stones, with turves, with planks, or with roots of trees, to keep on the shingles, and even, in some cases, to prevent the roof itself from being blown off by the wind. A landscape painter in taking views in Switzerland or Baden, would, very properly, copy these circumstances, and a moral traveller would describe them ; but for an Architect to introduce them as component parts of a Design in the Swiss style, would display a great want of discrimination, and would be, what Sir Joshua Reynolds, in his *Lectures on Painting*, calls, "imitating a peculiarity." It frequently happens, with such buildings in Switzerland, that being situated in narrow valleys, they are subject to partial inundations from sudden thaws ; and also to have the rain thrown more violently against some parts of the building than against others, when the wind is in a particular direction. To guard against these incidents, barriers of boards are put up in the first case, and an exterior protection of weather boarding (boards overlapping each other), in the latter. For an Architect to imitate these, would be to copy defects in the construction, rendered necessary by an error in the choice of situation, and would remind one of the story of the Chinese tailor, who imitated the patches on a coat sent him for a pattern.

106. *The fitness* of a building of this construction for a human dwelling may deserve some consideration. It is certain that wooden buildings of any kind are never erected (excepting now and then as a matter of fancy), by those who can afford to use stone or brick. Their liability to accidents by fire, is an objection for which no architectural or picturesque beauty can ever compensate. The balcony also surrounding the building, liable to be constantly used, and commanding the bed-room windows, takes away all idea of privacy from these apartments. We, therefore, by no means, recommend this style for any country. For our own part, indeed, rather than bestow so much labour on so perishable and combustible a material as wood, we would prefer walls of earth.

Design X.—*A Dwelling for a Married Couple and One Child, with a Pigsty.*

107. *Accommodation.* This is a dwelling of the lowest class, consisting of three rooms in two stories, and differing only from the commonest cottages in England by the completeness of its appendages, and the architecture of its exterior. It contains, on the ground-floor, an entrance porch or lobby, *a* ; a wash-house, with a place for an oven to heat the kitchen-floor by a flue, *b* ; a kitchen or living room, *c* ; a large closet under the staircase, *d* ; a pantry, *e* ; fuel-house, *f* ; water-closet or privy, *g* ; and pigsty, *h*. The chamber-floor contains a bed-room, *i* ; a clothes or lumber-closet, *k* ; child's bed-room, *l* ; and the staircase, *m*.

108. *Construction.* The walls, as high as the bed-room floor, may be built of stone or of brick, with a vacancy in the centre, as explained in describing Design I. Above, the walls may be of brick nogging ; the principal timbers of which may be like those shown in the elevation. These walls should be plastered within and without. A much better plan of construction, however, is to carry up the brick walls to the roof ; unless the object of the Architect be the imitation of an accident in

X.

XI.

a style, rather than its essentials; or economy, rather than strength, durability, and comfort. The roof may be covered with plain tiles; and some care may be bestowed on the chimneys, fig. 84, (scale, a quarter of an inch to a foot). These chimneys may be built of brick, and covered with cement; or be formed of cement only. The windows may have wooden mullions, fig. 85, and wooden casements; but we cannot recommend these casements being filled in with lattice-work; for that, like exterior walls of brick nogging, is an inferior mode of construction.

109. *Situation.* As this building admits of being viewed on every side, it is suitable for an open space. A few fruit trees are its appropriate accompaniments; and at a distance of a hundred yards, it may have as a back ground, a wood of oak, or other round-headed trees, to contrast with its upright and angular lines. However, either that such a wood should be planted on purpose; or that it is worth while to give up any point of utility or convenience, in order to place a cottage of this character near such a wood. The comfort of the occupant of the cottage should take precedence of every other object, either respecting it, or its accompaniments. It has been too much the practice, hitherto, for Architects and for their employers to set down cottages, more with a view to their effect in the landscape, than to any thing else whatever; but the habitation of a human being, however humble, ought not to be trifled with, either in respect to its accommodations, or its locality.

110. *Aspect.* From what we have already advanced on this subject in Chapter I. it will be understood, that in all practicable cases, we intend that the dwelling should be so placed as to admit of the sun shining on all its walls every fine day in the year, with the exception of a few weeks at the winter solstice. This, we need hardly repeat (were it not for the great importance of the subject), is to be done by imagining the general form of the ground-plan reduced to a square, and letting its diagonal be a north and south line. In most parts of Europe the door should face the south-east. When cottages are detached, and built either singly, or in pairs, and set down in a garden, the adherence to this rule of position, with respect to the sun, will add to the picturesque beauty of a village; whatever may be the direction of the road, along the sides of which the houses and gardens are built and laid out. This fact must never be forgotten; and indeed it should be considered, like the introduction of the platform, as a law, which in building detached cottages, ought never to be violated. In building long lines of connected dwellings of this sort, this law cannot be applied; but if the lines be in the direction of south and north, the same advantages, in point of heat and dryness, are obtained as by the diagonal position of detached cottages; for the sun will shine throughout the year on the east and west sides of every dwelling; and the south and north sides being party-walls (walls of division between different houses), will be necessarily both dry and warm.

111. *General Estimate.* Cubic contents 9,528 feet, at 6d. per foot, £238 : 4s.; at 4d., £158 : 16s.; and at 3d., £119 : 2s.

112. *Expression.* This cottage is in what is called the old English manner, which is characterized by windows not much higher than they are broad, and divided perpendicularly by mullions (vertical divisions); by high, conspicuous, and sometimes ornamented stacks of chimneys; by steep roofs generally covered with plain tiles, projecting at the eaves, and sometimes also at the gable ends; and, finally, by more or less of Gothic forms or mouldings in its details. In this imitation of the old English cottage, an erroneous manner of arrangement is conspicuous in the stacks of chimneys, which ought not to have been in the outside walls; and the introduction into these outer walls of brick nogging, is an inferior

85

It is not meant by this remark,

86

mode of construction, undeserving of imitation. A peculiarity, which in respect to use is a great deformity, is introduced in the principal window, in the form of the head of a Gothic arch supporting the mullion. This Gothic arch crosses the window in such a manner as to intercept the most valuable portion of the light. Nevertheless, we have given this Design a place, from its being characteristic of the style which it affects to exhibit; but we shall afterwards give other Designs in the same style not liable to the same objections. It is also proper to remark, that in new countries, where building materials and labour are scarce and dear, this would be exactly the sort of cottage that would be most suitable for a dwelling in the English cottage style; and in temperate climates rather milder than Britain, such, for example, as many parts of Australia, there could be no objection to the chimneys being in the outside walls. Their effect there, rising boldly into the air, and contrasting with the sloping surface and horizontal line of the roof, is excellent. A low box hedge, with standards at the angles, cut into architectural shapes, would be in perfect harmony with this style of cottage, fig. 86.

Design XI.—*A Dwelling for a Man and his Wife, and One or Two Children, with a Cow-house and Pigsty.*

113. *Accommodation.* This hermitage-looking dwelling contains a porch, *a*; a work-room or parlour, *b*; a bed-room communicating with it, *c*; a kitchen, *d*; and an outer kitchen or wash-house, with an oven, *e*; communicating with a pantry and dairy, *f*. The wash-house has a back door, near which, in the lean-to, is a privy, *g*; a cow-house, *h*; and a place for wood, or for a pig, *i*. In the section the floors are shown as laid over a bed of stones, and a gravelled terrace surrounds the whole building, on a level six inches lower than the floors of the rooms. In the bed of stones may be a flue connected with the oven placed in the angle of the back kitchen, *e*, as before described.

114. *Construction.* The walls are of stone, hewn at the coins (corners), and with the barge stones (a corruption of verge, and signifying the margin of any thing), also hewn. The roof is of a high pitch, in conformity with roofs in the Gothic style, and may be covered with pan (hollow) tiles, or plain tiles; it projects a few inches at the eaves, so as to deliver the water into a gutter. The windows and the door are surrounded by plain architraves; the principal windows have pointed tops, and are divided by mullions (fig. 87, *k*, to a scale of half an inch to the foot). The stack of chimneys, fig. 88, may either be executed in free-stone, or what in Britain will cost much less and yet be sufficiently durable, cement. The door is formed of bead and batten with exterior hinges, similar to those in Design VI. The gable ends are surmounted by crosses, which may either be formed of stone or cement, and if a description of that article, used in forming stone ornaments by Austin, of the New Road, London, be employed, there can be no doubt of their durability.

115. *Situation.* It is evident that a building of this sort is erected chiefly with a view to its ornamental effect, and, therefore, wherever it is placed, it ought not to be obscured by trees. It may be considered as a sort of hermitage, and, in this point of view, it should be placed in a solitary situation.

116. *General Estimate.* Cubic contents, 11,700 feet, at 6*d.*, £292:10*s.*; at 4*d.*, £195; and at 3*d.*, £146:5*s.*

117. *Expression.* This being the first Design in which we have made a great departure from symmetry, that is, a correspondence of parts in the general form, it may be useful to offer a few remarks on the principle of irregularity in Architecture. It is evident that to introduce irregularity of form in buildings, is an architectural refinement of the present age; for, though in ancient buildings of every description, there is much more of irregularity than of symmetry, yet this irregularity has always been the result of accident; of additions made from time to time as they were required, or of subtractions or mutilations, according as certain parts might be done without, or as the ability to keep them in repair diminished. We find no ancient author on Architecture recommending irregularity; and from this we may conclude that no ancient Architect ever designed a building of an irregular form when he could help it. The first in Britain who decidedly recommended irregularity in buildings, was Uvedale Price, in the first edition of his admirable *Essays on the Picturesque*, published in 1794; and he was

soon followed by Mr. Knight, in his poem *The Landscape*; by Malton, in his works on Cottage Architecture, and subsequently by various others. Uvedale Price, who was a great admirer of Sir Joshua Reynolds, and of the works of the great painters of Italy, probably was strengthened in his ideas in favour of irregularity, by the following passage in one of Sir Joshua's *Discourses*:—"Architects may take advantage sometimes of the use of accidents to follow where they lead, and to improve them, rather than always trust to a regular plan. It often happens that additions have been made to houses at various times, for use or pleasure. As such buildings depart from regularity, they now and then acquire something of scenery by this accident, which I think might not unsuccessfully be adopted by an Architect in an original plan, if it does not too much interfere with convenience. Variety and intricacy is a beauty and excellence in every other of the arts which address the imagination; and why not in Architecture?" This passage is quoted by Knight, in his *Analytical Inquiry into the Principles of Taste*, as an authority for the praise which he also has bestowed on irregularity in Architecture. The practice at present needs no recommendation; being, as every one knows, followed in dwellings of every description, of extent, and of every kind of style. All that we are anxious to remark on the subject is, that irregularity can seldom or never be adopted in cottage dwellings where economy is a main object. On this subject we entirely agree with Laing, who, in the preface to his *Hints on Dwellings*, has the following remarks:

118. *The nearer the plan of a building approaches to a square, says Laing, "the greater are its conveniences, and the cost proportionably less. A square, equal in superficial extent to a parallelogram, requires less external walling, and, consequently, less internal finishing. By compactness, convenience is produced, and expense is saved: when the apartments are scattered and lie wide from each other, with long passages between, much unpleasantness must be experienced; and a much larger expense must be incurred from covering a larger space of ground than is absolutely necessary."* This objection, he adds, "may fairly be urged against some schemes, which I have lately seen by an ingenious artist, in which his anxiety to produce variety and want of uniformity, has led him to devise plans void of convenience and economy; how far void of taste, I will not say; yet, surely, uniformity is essential to beauty. I say this merely to oppose a taste which I consider false, and an economy which is profusion." (*Hints on Dwellings. Preface.*)

119. *Irregular Buildings* please their admirers partly with reference to their picturesque effect; and partly as being characteristic of some particular architectural style, as it is found to exist in ancient buildings. The castellated architecture of the present day is evidently more an imitative style, than one of picturesque beauty; and the irregular cottage style depends more on its picturesqueness, than on its being an imitation of any thing that has previously existed. Dugald Stewart, in one of his *Essays on the Beautiful*, has traced the progress of the taste for the several kinds of beauty from that of the rudest appearance of Design, to the greatest irregularities of form. He notices the pleasure which children very early manifest at the sight of regular forms and uniform arrangements. The same love of regular forms and of uniform arrangements, he says, "continues to influence powerfully in the maturity of reason and experience, the judgments we pronounce on all works of human art, whose regularity and uniformity do not interfere with purposes of utility. In recommending these forms and arrangements in the particular circumstances just mentioned, there is one principle which seems to me to have no inconsiderable influence, and which I shall take this opportunity of hinting at slightly, as I do not recollect to have seen it anywhere applied to questions of criticism. The principle I allude to is, that of the sufficient reason, of which so much use is made (and in my opinion sometimes very erroneously made), in the philosophy of Leibnitz. What is it that, in any thing which is merely ornamental, and which, at the same time, does not profess to be an imitation of nature, renders irregular forms displeasing? Is it not, at least in part, that irregularities are infinite; and that no circumstance can be imagined which should have decided the choice of the artist in favour of that particular figure which he has selected? The variety of regular figures (it must be acknowledged) is infinite also; but supposing the choice to be once fixed about the number of sides, no apparent caprice of the artist in adjusting their relative proportions, presents a disagreeable and inexplicable puzzle to the spectator. Is it not also owing, in part, to this, that in things merely ornamental, where no use, even the most trifling, is intended, the circular form possesses a superiority over all others?"

120. *In a house*, which is commonly detached from all other buildings, and which stands on a perfectly level foundation, why are we offended when the door is not placed exactly in the middle; or when there is a window on one side of the door, and none corresponding to it on the other? Is it not that we are at a loss to conceive how the choice of the Architect could be thus determined, where all circumstances appear to be so exactly alike? This

disagreeable effect is, in a great measure, removed, the moment any purpose of utility is discovered; or even when the contiguity of other houses, or some peculiarity in the shape of ground, allows us to imagine, that some reasonable motive may have existed in the artist's mind, though we may be unable to trace it. An irregular castellated edifice, set down on a dead flat, conveys an idea of whim or of folly in the designer; and it would convey this idea still more strongly than it does, were it not that the imitation of something else, which we have previously seen with pleasure, makes the absurdity less revolting. The same, or yet greater irregularity, would not only satisfy, but delight the eye, in an ancient citadel, whose ground-work and elevations followed the rugged surface and fantastic projections of the rock on which it is built. The oblique position of a window in a house, would be intolerable; but utility, or rather necessity, reconciles the eye to it at once, in the cabin of a ship."—*Stewart's Philosophical Essays*, p. 240.

Design XII.—*A Dwelling of Two Stories for a Man and his Wife, with a Servant and Two or Three Children, with a Cow-house and Pigsty.*

121. *Accommodation.* This may be considered a comfortable dwelling for a gardener or bailiff in Britain; or for a small proprietor in America, or Australia. It contains, on the ground-floor, an entrance lobby, *a*; staircase, *b*; kitchen, *c*; parlour, *d*; tool-house or office for paying men, *e*; pantry and dairy, *f*; back kitchen, *g*; shed for wood and fuel, *h*; dusthole, *i*; privy, *k*; and cow-house, with hen-house over, *l*. The cow-house is connected with a court-yard, which contains a shed for hay and straw, piggeries, and dung-pit, with a manure well, connected with the privy. The platform, on three sides of this dwelling, forms a handsome walk, from which there is a door into the court-yard. The bed-room floor contains a best bed-room, *m*; a second bed-room, *n*; a third bed-room, *o*; and a stair, *p*.

122. *Construction.* The walls may be of brick, or stone, or of brick nogging plastered externally, as shown in the elevation; care being taken, whatever material may be used, that the colour is neither a glaring red, nor a glaring white. The roof may be covered with reeds, or with combed wheat straw (straw from which the ears of grain have been cut, or combed off, in consequence of which, the culms are unbruised by the flail). The intersecting lines shown at the ridge of the roof, and which may appear to many, not accustomed to see reed-covered buildings, as a mere ornament at the fancy of the thatcher, are formed by rods, generally of hazel, for the purpose of keeping down the layer of reeds, which are spread across the ridge tree of the roof. The intersecting rods, fig. 89, *g*, are kept in their places by the horizontal rods, *r r*; and these are fastened to the thatch, by staples, or spits, or broaches, *s*, which are nothing more than short pieces of rod, previously well steeped in water, to render them flexible, bent in the form of a staple hook, and stuck in the thatch or reeds. The forked piece of wood represented on the upper part of the gable end, should only be employed if the

90

nothing more than short pieces of rod, previously well steeped in water, to render them flexible, bent in the form of a staple hook, and stuck in the thatch or reeds. The forked piece of wood represented on the upper part of the gable end, should only be employed if the

XII.

XIII.

walls are of brick nogging. The entrance door is ledged; and the bed-room windows, which are broad rather than high, show two perpendicular and fixed bars or mullions; the casements being hinged to open inwards. The small windows in the lean-to are round-headed, with Gothic labels over them, fig. 90. The chimney shafts may be executed in cement, in a decorated style, (fig. 91), to a scale of the fourth of an inch to a foot), such as is sometimes found in the better description of old cottages and farm-houses.

123. *Situation.* This dwelling being intended as an ornamental object, should not be crowded with trees; at the same time it is not calculated for a very exposed situation.

124. *General Estimate.* Cubic contents, 14,904 feet, at 6d. per foot, £372 : 12s.; at 4d., £248 : 8s.; and at 3d., £186 : 6s.

125. *Expression.* The style aimed at here is something of what is called the old English manner. Whatever interest may be excited by associations connected with this style, the specimen here represented, has evidently very little merit, taken by itself as a system of building. When a cottage is throughout in one system or style, all the parts of which it is composed, will seem to be the result of the mode of its construction; and to follow each other so obviously, that the eye and the mind are naturally led from one to the other throughout the whole superstructure. This is Wood's doctrine; and, tried by it, the Design before us will certainly be found wanting. There may be historical or accidental associations between the form of the door and that of the window over it; that is, it may have been usual to have such doors and windows in the same building in some old English cottages; but certainly the form of the one does not naturally arise out of the form of the other. Neither can it be said that the projection of part of the bed-room floor, as shown over the door-way, has anything to do with the mode of construction; on the contrary, to the eye of reason, it appears an inferior method; while, as a projection, it not only has not the merit of real utility, but the pretension which it might have had of forming a shelter to the entrance door, is destroyed, by that door having a small roof of its own; a superfluity which ought to have been avoided, since the walls of the porch evidently do not stand out beyond the line of the projection of the bed-room story. The small wing, or lean-to, shown below this last-mentioned window, seems to be in a different style from the rest of the building; both as regards the projection of its roof, and the labels to its two small windows. On the whole, though we acknowledge the ensemble of this Design to present a picturesque appearance, yet as a piece of Architecture, we consider it a deformity. Where the form of any one part of a building, says Wood, does not seem to depend upon that below it, but might as well be substituted by something different, the principle of arrangement is wanting. In looking at any building we endeavour to trace some simple principle of arrangement, the want of which can never be made up by good parts forced into service, or by superfluity of ornament. Profusion of parts, or of ornaments, without obvious connexion and propriety, produce confusion and absurdity. (*Letters of an Architect &c.* vol. i. p. 6). We have presented this Design for the purpose of showing how easy it is to captivate the eye in matters of this kind, without in any one point completely satisfying the judgment.

Design XIII.—*A Dwelling for a Man and his Wife, with Two or more Children.*

126. *Accommodation.* Here we have a colonnade which serves as a porch; a vestibule, *a*; a parlour, *b*; a kitchen, with a stair to two bed-rooms in the roof, *c*; a bed-room on the ground-floor, *d*; a pantry, *e*; two closets, *f*, *g*; and water-closet or pantry, *h*. The two bed-rooms over *c* and *d* may be lighted by dormer windows (windows made in the roof) and by the small opening seen in the upper part of the gable end.

127. *Construction.* The platform on which this dwelling is built, is sustained by masonry; which, on three sides, supports the columns of the veranda or colonnade. These columns may either be of stone, of brick stuccoed, or of timber; in either case, set on stone plinths, and with stone caps. The roof should be slated, with barge courses at the gable ends, terminating in pinnacles. The chimney tops (fig. 92, on a scale of three eighths of an inch to a foot), are plain, like the columns.

128. *The Garden*, containing about three fourths of an acre, is here shown surrounded by a hedge. This hedge might, in many cases, be formed of fruit-bearing shrubs, such as plums, apples, sloes, service or mountain ash, the berries of which afford an excellent spirit; or elders, the berries of which make a well-known wine. Whichever description of fruit-bearing plant is used, the branches must be pruned with a knife, and not clipped with shears; because clipping, by producing an exuberance of weak, young shoots, prevents the plants from forming blossom buds. If it should be desirable to have a very formidable fence, the hedge might consist of two rows; the inner one of fruit-bearing plants, and the outer one of hawthorns or hollies. There is scarcely any situation, either on hills or by the sea-shore, in which the elder will not thrive, and its fruit is always valuable. The same may be said of the sloe, and the mountain ash, and service, in respect to all inland situations. The mode of labouring and cropping the ground may be as follows: trench compartment *i* three spits deep, and plant with the cabbage tribe; manure and dig *k*, and plant with potatoes; trench *l* two spits deep, and sow with root crops, such as turnips, carrots, parsnips, onions, &c.; manure and dig *m*, and crop with peas, beans, and kidney beans. According to this rotation, in the second year, *i* will be manured and dug only, and will be under potatoes; *k* will be trenched two spits deep, and under root crops; *l* will be manured, dug, and under leguminous plants; and *m* will be trenched three spits deep, and under the cabbage tribe. Thus, a new stratum of soil will be brought up to the surface every other year: in the first year, what was the bottom becomes the top; in the second, the top is turned over; in the third, the middle becomes the top; and, in the fourth, this middle is turned over. Manure is applied every second year. This is enough to give a general idea of how a garden ought to be laboured, manured, and cropped; but more minute and accurate details will be found in our *Cottage Manual*; in *Denson's Peasant's Voice*; and in an excellent little work, by Mr. Charles Laurence, entitled *Practical Directions for Cottage Gardens, &c.* The smaller compartments may be cropped as follows: *n*, with gooseberries; *o*, with currants and raspberries; *p*, with strawberries; *q*, with asparagus; *r*, with sea-kale; *s*, with tart rhubarb; *t*, with Jerusalem artichokes; and *u*, with perennial, or what is called Good Henry spinach (*Chenopodium Bonus Henricus*). The border which surrounds the garden may be devoted to the smaller crops, such as salads, herbs, &c.; and to early crops, such as peas and potatoes. The space immediately surrounding the cottage should be ornamented with flowers and flowering shrubs. The trees at the corners of the compartments should be standard apples, pears, cherries, and plums.

129. *Situation.* It is evident that the main purpose of this building is effect; and if placed, as shown, on a raised architectural platform, in the centre of a garden not over planted, it cannot fail to look well from every point of view.

130. *General Estimate.* Cubic contents, 14,568 feet, at 6*d.*, £364 : 4*s.*; at 4*d.*, £242 : 16*s.*; and at 3*d.*, £182 : 2*s.*

131. *Expression.* It can hardly be said that this edifice resembles a cottage dwelling; and, at all events, it is certainly not one of the humble class. There is an obvious desire for display; and as this has produced a comfortable colonnade for the exercise of children, for hanging up Indian corn, tobacco, or seeds, and for drying clothes during rainy weather, it need not be much objected to. As far as respects style, the building is mixed; but, as the mixture is agreeable, a whole of some merit is produced.

Design XIV.—*A Dwelling for a Man and his Wife, with One Servant and a grown-up Son or Daughter.*

132. *Accommodation.* There is a kitchen, *a*; a scullery and sink, *b*; pantry, *c*; closet, *d*; two bed-rooms, *e* and *f*; a closet, *g*; a water-closet for women, *h*; and a water-closet for men, *i*. These accommodations are surrounded by an uninterrupted arcade, for the sake of effect, and for air, exercise, and drying clothes during inclement weather. An arcade necessarily throws a much greater shadow on the windows than square pillars, or round columns; but to compensate for this, it may be executed in brick-work, without the aid of lintels of stone or wood, or of cement.

133. *Construction.* The arcade, which may support the roof independently of the inner wall, should be of brick or stone. The inner walls may be of earth, or brick, or clay nogging, or of stud-work (frame-work), lathed and plastered. The pitch or rise of the roof is low, and the covering is supposed to be of slates of the largest size; the sloping joints being covered with narrow strips of slate, in the manner known in Britain by the term Wyatt's Patent, to be afterwards described. The chimney stack has a far projecting cornice (fig 93, to a scale of half an inch to a foot).

134. *Situation.* This dwelling is calculated for being placed on a platform supported by masonry, in the midst of a garden, on an elevated situation, because it will look well from every point of view.

135. *Garden.* Contents, two roods, thirty-five poles, and fifteen yards. The square in which the house stands is devoted to flowers and other ornamental plants. The compartment to the left of this square, to the perennial crops, such as asparagus, *k*; sea-kale, *l*; rampion, *m*; tart rhubarb, *n*, *n*; strawberries, *o*, *o*; American cranberries, *p*; Jerusalem artichokes, *q*; and common artichokes, or perennial spinach, as may be preferred, *r*. The two squares to the right are devoted, *s*, to gooseberries, and *t*, to currants and raspberries. The two long squares, *u* and *v*, may be subjected to four years' rotation, as described in the preceding Design. There may be a well, or a sun dial, at *w*, and a small court of offices beyond the garden for other conveniences.

93

94

136. *General Estimate.* Cubic contents, 26,824 feet, at 6*d.* per foot, £670 : 12*s.*; at 4*d.* £447 : 1*s.* 4*d.*; and at 3*d.*, £335 : 6*s.*

137. *Expression.* Small dwellings in this manner of architecture are generally considered as belonging to the Italian style. There can be no question of the excellence of the general effect; but we naturally ask how it happens, that in a building so studiously uniform, the entrance stairs should not have been placed in the centre of the front? If the answer be that there is not a central opening, the question occurs, why was not this provided in arranging the plan? Here, then, we have the Architect setting out on a principle, viz., that of uniformity, pursuing it through the main body of the building, and afterwards defeating it in his labours by abandoning it in an important feature. If we consider this

95

building as a human habitation, there is also an obvious absurdity in expending so much for appearance, and yet paying so little attention to internal comfort, as to almost exclude that essential requisite to every dwelling, light. It is evident that all the rooms in this house must be very much darkened; not merely by the arcade, but by the great projection of the roof beyond it. No man, who exercises his reason for a moment, as to what he sees before him, can feel satisfaction on looking at a structure like this; at least with reference to such a climate as that of Britain. Perhaps in Italy, so much shade as this Design would produce may be desirable; and the want of light may not be so great an object in the present state of civilization in that country, since the people are not readers, and are far from being cleanly in either their persons or houses. But even for Italy, this Design is bad; because, in the warmest climates there must be times when more light is desirable than can be admitted into any of the apartments of this dwelling. Still the Design possesses a degree of simplicity and grandeur, and may afford useful hints for something better. The basement raised so as to include a sunk story, fig. 94, would be a great improvement, in point of convenience, and this would admit of lighting the rooms above from two sides instead of one, fig. 95; because, in that case, the back kitchen and store closet would be under ground. Another mode of improving this Design would be to retain the ground-floor in its present state, and to raise a bed-room story over it, roofing the arcade or veranda with glass, concealed by a parapet, and supporting the bed-room story on the inner walls. The removal of the projection of the roof would of itself admit more light; but when to this is added the light which will pass through the glass roof of the veranda, fig. 96, the house will be rendered habitable in any climate. In proportion as the height of the verandas and their openings are increased, the more light will be admitted to the windows beneath them; and if we imagine a veranda raised six or eight feet higher than the tops of the windows which it projects, the rooms would be as light as if there were no veranda at all. In all cases, therefore, of introducing arcades, colonnades, or verandas, before living rooms, they ought either not to project far from the walls, or to have their openings carried up higher than the architraves of the windows. This last arrangement, however, can very seldom be carried into

96

97

effect in buildings of more than one story, without violating some principle of utility or fitness. The arches in the Design before us being somewhat higher than the windows, a balcony might be formed over the veranda, which, by getting rid of the projection of the roof, would admit more light, and this, with a bed-room story added, would produce a good effect, fig. 97. There remains to be noticed another great defect in the expression of this

XIV.

Fig. 40 70 Ft.

XV.

building as a human dwelling, and that is, the want of a porch. Independently of the addition which a porch would make to the expression of purpose, it would add to the actual comfort and propriety of the building; for, surely, there is a great inconsistency in forming so extensive a veranda, and yet leaving the steps of ascent to it not only uncovered, but without any architectural appendage to enhance their interest as a main entrance. To introduce a porch in the best manner in a building so entirely uniform, some alteration would be required in the position of the windows in the ground plan, so as to admit of preserving the character of symmetry, by having a porch in the centre of one side, fig. 98. Were this done, the width of the piers somewhat diminished, and something added to their height, the building would not only have a much better effect, but become more habitable, fig. 99. Edifices of this sort are much better calculated for ornamental purposes, such

as a garden banqueting house; in pleasure-grounds, with a fruit and wine cellar under; or to be placed on a rock or small island, in a lake or river, as a place to fish from under cover.

Design XV.—*A Dwelling for a Man and his Wife, without Children.*

138. *Accommodation.* This cottage, though very small, contains a good many comforts and conveniences. The entrance, *a*, is by a lean-to at one end, which serves as a porch, and at *b*, may also be used as a place for fuel. There is a good kitchen, *c*; a pantry, *d*; back kitchen, *e*, with an oven and a flue to heat the floor of the principal kitchen; a stair-case with a closet under, *f*; water-closet, *g*; and place for poultry, *h*. The upper story contains only one bed-room, *i*. There is a small yard behind, *k*, which may contain a cow-house and a pigsty, and which must include a manure well and dung-pit.

139. *Construction.* The walls are here represented of rough stone plastered, and the roof as covered with Grecian or Italian tiles. The terrace is of masonry, and the chimney tops (fig. 100, on a scale of three-eighths of an inch to a foot), are of brick and cement. The pro-

jection of the roof is considerable, and it is finished with a gutter, supported by short pieces let into the wall, fig. 101, *l*, and by cantilevers, *m*. The blocks supporting the sill of the kitchen window are of stone, and so is the sill. The mullions which divide the window are of wood, and the casements which fit into them are hinged so as to open inwards. The windows of the pantry and back kitchen are sash windows. The principal objection which we have to the construction of this cottage, is the placing the fire-places in the outside walls. For cold climates, this is always with us,

101

a very great objection; though, as this building is in the Italian style, it may be supposed to be adopted for the south of Europe, the most southern parts of North America, or for Australia. With a view to these countries, our objection falls to the ground; and in truth, we have raised it chiefly for the purpose of showing that some objections to buildings of this description, and indeed to all buildings, are relative. Of positive, or absolute objections, which have no relation to either country, climate, or situation, we see none in this Design. It is on a dry foundation, of sufficient strength in construction, and of sufficient durability in its materials. It is securely roofed; the rooms are sufficiently lofty, well lighted, and may be, if the occupant think fit, well ventilated.

140. *Situation.* This building having no windows behind, is calculated for being placed upon the side of a hill, and viewed from below. If surrounded by a good garden, and with no trees within a hundred yards of it higher than fruit trees, it can hardly fail to have a good effect. In general, trees which stand close to any building, more especially to one of small size, should either be decidedly larger or decidedly smaller than the building itself. The chief reason for this is, that objects of the same size, or apparently so, do not co-operate well in forming a whole; which always must consist of one principal or prominent part, and of two or more subordinate ones.

141. *General Estimate.* Cubic contents, 8,206 feet, at *6d.*, £205 : 3s.; at *4d.*, £136 : 15s : 4d.; and at *3d.*, £102 : 11s : 6d.

142. *Expression.* The style attempted is evidently Italian; but why a deviation was made in the wings from the Italian Gothic window, to the common English sash window, is not obvious. The fault is not a great one; because so far from interfering with utility, a superior article is introduced instead of an inferior one. But in respect to appearance, these windows certainly diminish the force of the style. Reduced to their proper form, and a parapet added to the terrace, fig. 102, this dwelling would

102

produce a very good effect, and might serve for one of those which a recent writer in the *Mechanic's Magazine*, recommends to be substituted for mile-stones along the public roads of Great Britain. To the cottages so placed, he proposes to attach large gardens; and those, with the cottage, are to serve as models for neatness and order in their appearance and management to the agricultural labourers in the vicinity. The occupier of the cottage is to sit rent-free, on condition of keeping the sides and fences of one mile of road neat and orderly, and as free from weeds and all obstructions as the approach road in a gentleman's park; a labour which might occupy him fifty or sixty days in the year. *Mech. Mag. Vol. XVI.*

Design XVI.—*A Dwelling for a Man and his Wife without Children.*

143. *Accommodation.* This building contains a commodious kitchen, twelve feet by sixteen feet; and it has two windows, in order to admit of a tailor or shoemaker, with his apprentice, carrying on work at one window, while the woman's work is going on at the other. A large porch, *a*, which is lighted by a fanlight from the upper part of the doorway, forms both the entrance to the dwelling, and the passage of communication from the kitchen, *b*, to the bed-room, *c*. There is a pantry and store-closet, *d*, opening from the kitchen, and a light closet, *e*, partitioned off the bed-room. The privy, and other conveniences, are supposed to be placed at a short distance from the house, and to be concealed by bushes.

144. *Situation.* This building, having one side with only a small window in it, may be placed against a wood, and so that the entrance-door may front the south-east. The roof, being of thatch, indicates that it is not intended for a country subject to high winds.

145. *Construction.* The walls may be formed of stone or mud; or, in a country where bricks are abundant and cheap, they may be built hollow of brick-work (see § 25). The thatched roof will project over the walls, as shewn in the accompanying sketch, fig. 103; in which is shewn the rafter, *f*, placed at an angle of 30°, and also a wooden moulding, *g*, under the projecting thatch. The chimney-stack consists of two circular columns with plain heads, as in the annexed drawing (fig. 104, on a scale of half an inch to a foot).

146. *General Estimate.* Cubic contents, 10,328 feet, at 6*d.*, £258:4*s.*; at 4*d.*, £172:2*s.*:8*d.*; and at 3*d.*, £129:2*s.*

147. *The Garden* contains two roods and a half, and is divided into eight compartments, with a surrounding border; the boundary fence being a wall of mud, brick, or stone, against which may be planted fruit trees, or currants and gooseberries, according to the climate in which the design is executed. The compartment, *h*, is intended for a plantation of gooseberries, surrounded by a row of dwarf apples; *i*, is a plantation of currants and raspberries, surrounded by a row of pears, plums, and cherries; *k*, a grass plot; *l*, strawberries; *m*, perennial spinach; *n*, peas; *o*, beans; *p*, potatoes; *q*, the cabbage tribe; *r*, onions, turnips, carrots, and other surface and fusiform roots. In continuing the rotation, the compartments *n* and *o*, will, of course, be considered as one, and cropped, after (1) the leguminous vegetables, with (2) potatoes, (3) the cabbage tribe, and (4) roots. The borders round this garden may be devoted to small crops, such as salading, annual spinach, pot-herbs, tart rhubarb, which ought never to be omitted in the cottager's garden, a few plants of hops for their tops as asparagus, and their flowers for putting in beer, and, near the house, flowers and flowering shrubs.

148. *Remarks.* This Design may be considered as imperfect in point of accommodation, but we introduce it because there are many persons who may be able or willing to build such cottages for themselves or their dependents, who, from particular opinions or want of means, might be unable or unwilling to build a dwelling of a better description. If at any future time it were desired to enlarge this cottage, two rooms under a lean-to roof might easily be joined to the wall, *s*, *t*, which has but one small window, a communication being opened to such rooms by changing the destination of the kitchen closet. This will give the ground plan, fig. 105, which may be considered a tolerably commodious cottage; not only two additional bed-rooms, *u*, *v*, being obtained, but

105

106

the closet, *w*, as a substitute for *d*, in Design XVI., here, in fig. 105, turned into a passage. If it were desirable to add four rooms instead of two, a passage and staircase might be formed between the two rooms, and two bed-chambers obtained in the floor above. This might be easily effected by turning round the partition wall of *w*, to a line with the door of that closet, and by removing the centre division wall between *u* and *v*, to a line with the door of the right hand bed-room, *v*; a space of seven feet wide would then be left in the middle for the staircase, fig. 106, *x*. Supposing the party who had made these alterations to have increased in prosperity, and to be desirous of one handsome dining-room in which to receive his friends, it might readily be attained by extending the building from the extremity of the staircase passage, as in fig. 107, in which a handsome room, *y*, is obtained; and over this it would be easy to form a corresponding drawing-room, or two additional bed-rooms. As it would be no longer desirable to pass through the kitchen to such apartments, a porch, *z*, might be added, so as to enter the dining-room and the staircase direct from the terrace or platform. The elevation, in the case of such alterations, may very properly be in a somewhat different style of building from the ori-

107

ginal cottage, because the builder may justly be supposed to have become possessed, not only of superior means, but of a higher degree of taste, or of consciousness of deficiency in taste, and consequently have called in professional assistance since his former erection. But

whether he employs another, or proceeds on his own opinion, he will be justified by historical truth, as well as by the natural love of mankind for variety of character, in building two different additions, at different times, in different styles, or substyles of architecture. The elevations in this case will, in our opinion, be in perfect good taste, either as in fig. 108,

which shows only the first addition; or as in fig. 109, which shows the dining-room added, but not a drawing-room; in lieu of this a flat roof is shown, over which an awning may be placed in the summer season, a practice particularly suitable for America and Australia. For the sake of variety, we have shown the centre building in a different style in fig. 109 to what it

is in fig. 108. We have also shewn in fig. 109, three descriptions of terrace parapets, with three styles of ornamental vases; the vases for the original cottage may be stone pots, in shape not materially different from the common flower-pot; those for the first addition may be as in fig. 110, manufactured by Mr. Peake, of Tunstall, in Staffordshire, and sold at 15s. each;

and those for the second addition may be a tazza (cup) vase, like fig. 111, manufactured by the same potter, at 18s. The progressive improvement of cottages in this manner, we consider as particularly suitable for the inhabitants of new and prosperous countries.

149. *Expression.* The lofty proportions of the doors and windows, and the height of the

walls from the platform to the roof, give a certain expression of dignity to the exterior of this dwelling which every one must feel. But this expression is sadly counteracted by the mean, crouching appearance of the thatched roof, which, both as regards the material of which it is made, and the form in which it is disposed, is altogether unsuitable for the walls. In general, the truncated gable ends, such as are seen over the entrance-door, and at both ends of this cottage,

convey the idea of imperfection of form, of restricted resources, and of meanness and tameness of character. If we suppose the pediment of the gable ends completed, even though the building continued to be covered with thatch, the effect (fig. 112) will be superior, and will leave much less to be wished for. But still the expression of a thatched cottage, as such cottages are generally seen and formed in Britain, is not complete; the walls continue to be too high, and the roof too low in the pitch, or not sufficiently steep on the sides; that is, the proportion between the walls and roof to which we are accustomed is violated. Lower

the walls, and increase the surface of the roof, as in fig. 113, and the proportion is restored. the eye satisfied, and the expression of a thatched cottage comparatively complete. Let it not be supposed, however, that we prefer these proportions to those given in fig. 112 with a view to the principle of use; but for the sake of maintaining the beauty of style, we would, with windows of these proportions, introduce the Italian or Grecian roof of low pitch, similar to that of Design XV. Cottages with truncated gable ends, and with roofs, sometimes thatched and sometimes of slates, seem to be

much approved of by many British architects; and many of them have not only been built, but several Designs in this manner have been published. We have no doubt they pleased at the time of their first introduction, from the novelty of the form, and they still please some; but we doubt much if the pleasure they communicate will stand the test of time. There is scarcely any architectural landscape painter who, if he were left to his free choice, would introduce Design XVI. into his composition in preference to fig. 113; at the same time we

XVI.

10 5 0 20 Ft.

## XVII.

allow that the truncated gable ends may occasionally be introduced for the sake of variety. The same ground plan, and general proportion of the different parts, including the door and windows, may be easily adapted to different elevations, according to the circumstances of country, climate, and locality, where it is to be built; and the wealth, good taste, or peculiar taste of the builder. In the suburbs of a country village it may be thought desirable, as a mark of distinction, to give it a highly architectural character, fig. 114; or on an elevated situation some might prefer finishing the walls with Gothic battlements with narrow embrasures, fig. 115, a taste which we have been rather surprised to learn is not uncommon in America. In the south of Europe, the southern parts of the American continent, and in Australia, the great luxury of a portico might lead to a continuation of one all round the structure, fig. 116; the columns being either rude trunks of trees, rude blocks of stone, or worked timber, with square stone plinths as bases, and plain capitals, fig. 117. Indeed a

117

colonnade or veranda, when it does not obstruct light or impede ventilation, is a great source of comfort and enjoyment in all countries; it excludes rain and cold in the north, and a burning sun in the south.

Design XVII. — *A Dwelling with Two Rooms and a Bed-closet, for a Man and his Wife, with an Apprentice or Servant.*

150. *Accommodation.* From the vestibule, *a*, a door leads to the kitchen, *b*, from which is partitioned off the room for the servant or apprentice, *c*, barely sufficient for a bed. The bed-room, *d*, has a dark closet, *e*, and a light one, *f*. There is a closet for fuel, *g*, and some use may be made of the roof, by having an opening in the ceiling, with a trap-door over the porch, and a suitable ladder as will hereafter be described. In the garden are two small yards, surrounded by fruit tree hedges; one of which, *h*, is for wood, poultry, pigs, a privy, and in the centre, a tank for liquid manure; and the other, *i*, is for a drying-ground, wash-house, place for tools, &c. At a short distance from the house, is shown the situation of the spring water well and pump, *k*, it being never desirable to have this near the dung-pit, or liquid manure tank. The pump in the garden may be considered, by some, as too far from the house, but that well is supposed to be of hard water, and principally for use in the garden. For washing, and other domestic purposes, soft water may be collected on the roof, and filtered as described under the Chapter of Model Cottages, Design I. § 31, or below, in § 151. There is a small building in the corner of the yard, *i*, which covers a tank for containing the filtered water, and it may be drawn to the house from that, or from any distance, by Siebe's pump, § 33, fig. 10. Various plans for constructing such a tank may be

given, but the following, by Waistell, is one of the most complete, either for a farm-house or for a substantial cottage.

151. *Waistell's Tank* is circular in the ground plan, with the sides built like a well. "The bottom should be in the form of a flat dome reversed, and the top also domical, with an opening left in the centre of sufficient size to admit a man to clean it out occasionally; the top of this opening should be a little above the surface of the ground, and should be covered with an oak flap, with several holes bored in it for ventilation; or the cover may be an iron grating, horizontal and a little elevated, or conical. These tanks may be constructed of various dimensions; the depth and width should be nearly equal; a hole should also be left for the service-pipe, or that which conveys the water into the tank, and also for the pipe for the pump, if the water be drawn out by that means. The water may be filtered previously to its entering the tank; the hole for the service-pipe ought, therefore, to be near the top, and on that side most convenient for the filtering chamber; this may be about four feet in diameter, and three feet deep; across this, about twelve inches from the side next the tank, as at fig. 118, *l*, a slate partition from the top to within about six inches from the bottom should be fixed; at the bottom of the box should be put clean coarse sand or pounded charcoal, about a foot in thickness. The pipe or opening from the filter to the reservoir should be of ample dimensions, and be made at about eighteen or twenty inches from the bottom, in the small division or space behind the slate. Above this opening, and in any part most convenient, as at *m*, in the large division of the filter, should be an opening or drain to carry off the water when the tank is full. This filter should also have a cover, that it may be cleaned out, and fresh sand, or some other purifier, put in as often as may be found requisite. Of course, the water, as it comes from the roof, is to be first conveyed into the large division of the filtering chamber, on the opposite side to the slate partition, as at fig. 119, *n*, and passing through the sand it rises in the small division purified, when it is fit to pass into the tank by the tube, *o*. If there are two or more of these filtering chambers, or if they are of greater depth, the water may be passed through the greater quantity of sand, &c. in them, and be still more purified. Both the tanks and the filtering chambers should be water tight; if constructed of brick, the inner course may be built in Roman cement, and afterwards the whole of the inside covered with a coat of about three quarters of an inch thick of the same material. Water from drains formed in the ground for the purpose of collecting it for domestic purposes, may be purified by passing it through a sand filter previously to its entering the tank or reservoir. Sponge and flannel may also be used as filters. In constructing tanks of the above description, care must be taken to have the earth closely filled around the brick-work, and to allow sufficient time for the work to get properly settled previously to admitting any great weight of water. Cisterns for water formed of blue slate, or Yorkshire paving stones, are much better than those made of wood, and lined with lead."—*Waistell's Designs for Farm Buildings*.

152. *The Construction of the Walls and Roof* of this dwelling is very similar to that of Design VII. The wall is carried up with a parapet or blocking course, fig. 120, *p*, behind which is the gutter, *q*. This gutter is usually covered with lead; but in countries like Russia, where cast-iron is abundant, it may be very conveniently formed of that metal, in connexion with the entire covering of the roof. A patent was some time ago taken out for this mode of covering roofs in England, by Carter, of Exeter, of which it may be useful here to give the substance.

153. *Carter's Cast-iron Roofs* are formed of three descriptions of cast-iron plates, fig. 121, *r*, *s*, *t*. These forms answer every purpose for flat roofs which have not pavilion ends. One of them, *r*, is formed with three of its sides turned up and one turned down, and is called the roof plate. This plate is tapered narrower towards the lip by twice

118

119

120

121

Fig. 121, *r*, *s*, *t*. These forms answer every purpose for flat roofs which have not pavilion ends. One of them, *r*, is formed with three of its sides turned up and one turned down, and is called the roof plate. This plate is tapered narrower towards the lip by twice

the thickness of the plate. A second, *s*, is called the low ridge plate, and has two of its sides turned up, and the other two turned down. The third, *t*, is the high ridge, or cap plate, having all its sides turned down, and formed with an angle in the middle, so as to slope each way of the roof. This roof may be

made very flat, so much so, that, for a house twenty feet wide, the height of the roof in the middle need not exceed two feet. No boarding is required, but the plates, fig. 122, *u*, may rest without either cement or nails, on the rafters, *v*. The appearance may be considered massive and handsome, fig. 123; and it is evident, from the manner in which the plates overlap each other, as shown in figs. 123 and

124, that there can be no risk of inconvenience from contraction or expansion. If a number of buildings were to be erected, it might become worth while to have plates cast on purpose for hips and angles, so as to complete pavilion roofs on the same principle. Probably, also, especially of the terro-metallic kind, manu-

factured from a stratum of clay almost peculiar to Staffordshire, might be formed of the same shapes as these plates, and be found strong enough, after burning, to serve as substitutes for cast-iron.

154. *The Garden* contains about two roods and a half, and is divided into four large compartments, *w, w, w, w*, for the usual four course rotation; there are several smaller compartments, viz., *x, x*, for grass plats surrounded by flowers; *y, y*, for strawberries; and *z, z*, for gooseberries, currants, and raspberries. The boundary fence is a hedge, which, in suitable climates, may be formed of figs; in more northern latitudes, of apples, quinces, or

plums; and in cold, exposed situations, of sloes, elders, services, or mountain ash. The fruits of the sloe, and the berries of the elder, are valuable for wine and those of the service and mountain ash afford an excellent spirit. The three last named trees must never be clipped, otherwise they will produce but few blossoms. Whenever a cottager has the power of choosing the sort of hedge which shall surround his

garden, he may, in all cases, if he chooses, render it productive of useful fruit; for every climate has its fruit shrubs, and its low edible fruit-bearing trees. It must always be recollected that the ground inside of the fence being under garden cultivation, and well manured, it would be a pity to let any part of this enriched soil be exhausted by barren trees or shrubs. Even where a powerful fence is required, by planting a double row of hedge plants, the outer one of thorns, and the inner one of fruit shrubs, the riches of the soil will not be altogether lost.

155. *General Estimate.* Cubic contents, 1,039 feet, at 6*d.* per foot, £272 5*s.*; at 4*d.*, £181 10*s.*; and at 3*d.*, £136 2*s.* 6*d.*

156. *Expression.* It must be confessed that this, though a substantial looking dwelling, which promises not to be without comfort within, has nothing elegant in its appearance. If it has any character of style, it is that of the Scotch stone cottage, and it might very fitly form a pair with Design VII. What can be done to render such a cottage elegant? A veranda might be added, more especially if it were roofed with glass, otherwise, it would darken the windows. The chimney top might also be enriched by ornamental chimney pots. The greatest improvement would be a substantial porch, fig. 125, which would add to the

interior accommodation and comfort. The veranda may be constructed of wrought iron sash bars, of which fig. 126 is a section full size, cut to the proper length, the upper end let into the wall, and made secure by cement, and the lower ends notched into a cast-iron gutter, fig. 127. The veranda may have an apron in front, formed of cast-iron ornaments, fig. 128, screwed to the under side of the gutter, or to the upper part of the iron props which support it, fig. 129. No simpler or more durable form of veranda can well be constructed; its roof may be glazed with panes of crown glass, from five inches to ten inches wide, according as the country is more or less subject to violent hail storms. In those countries where there is no duty on glass, the bars may be placed a foot or more apart, and plate

glass may be employed; the panes, in that case, being from a foot to eighteen inches in breadth. Where light is not an object, and blue slate abounds, it may be used in plates of any convenient size, stucco, or Roman cement, being employed instead of putty. Sheets of copper, zinc, tinned plates, or rolled iron, may be fixed in the same manner as the glass, or even tarpauling well painted, or oil-cloth, may also be fixed between the bars. The lightness of appearance may be increased,

by bending the bars so as to give a concave form to the upper surface of the roof, fig. 130; concave surfaces, whether of ground or of roofs, reflecting more light, and therefore being always lighter, or more varied to the eye, than plain or convex ones. In this, and in various other cases of a like nature, where the width of the veranda is not more than four feet, it may be supported with cast-iron brackets of elegant architectural design, firmly built into the wall.

126

127

128

129

by bending the bars so as to give a concave form to the upper surface of the roof, fig. 130; concave surfaces, whether of ground

or of roofs, reflecting more light, and therefore being always lighter, or more varied to the eye, than plain or convex ones. In this, and in various other cases of a like nature, where the width of the veranda is not more than four feet, it may be supported with cast-iron brackets of elegant architectural design, firmly built into the wall.

130

#### Design XVIII.—*A Dwelling for a Man and his Wife, without Children.*

157. *Accommodation.* The man, in this case, is supposed to be a working mechanic, a shoemaker or weaver, who works at home in one room, *a*, while the business of the house is carried on by his wife in the other, *b*. There are two small rooms, *c* and *d*, one of which may be used as a bed-room, and the other as a store-room. In the kitchen, *b*, is an oven, which will contribute materially to warm the whole house, when baking is going forward during winter; and in summer, during the same operation, the apartment may be kept cool by opening both the windows. There is a good closet in the work-room, *a*, and also in the kitchen, *b*, so that, on the whole, there seems something like comfort in this dwelling, provided the man and his wife continue without children. In a small yard, which may be seen at *e*, in the plan exhibiting the garden, are contained a privy, pigsty, a place for fowls, a long narrow open shed for fuel, a manure tank and pump, and other conveniences.

158. *Construction.* The great art in building an economical cottage, is to employ the kind of materials and labour which are cheapest in the given locality. In almost every part of the world the cheapest article of which the walls can be made, will be found to be the earth on which the cottage stands, and to make good walls from this earth is the principal art of the rustic or primitive builder. Soils, with reference to building, may be divided into two classes: clays, loams, and all such soils as can neither be called gravels nor sands; and sands and gravels. The former, whether they are stiff or free, rich or poor, mixed with stones, or free from stones, may be formed into walls in one of the three modes already mentioned, viz., in the pisé manner, by lumps moulded in boxes, and by compressed blocks. Sandy and gravelly soils may always be made into excellent walls, by forming a frame of boards, leaving a space between the boards of the intended thickness of the wall, and filling this with gravel mixed with lime mortar; or, if this cannot be got, with mortar made of clay and straw. In

XVIII.

## XIX.

all cases when walls, either of this class or of the former, are built, the foundations should be of stone or brick, and they should be carried up at least a foot above the upper surface of the platform. In the course of this work, we shall describe all the various methods of building earthen walls, and we shall here commence by giving one of the simplest modes of construction, from the work of a very excellent and highly estimable individual, Mr. Denson, of Waterbeach, Cambridgeshire, the author of *The Peasant's Voice*, who built his own cottage in the manner described below.

159. *Mode of building the Mud Walls of Cottages in Cambridgeshire.* After a labourer has dug a sufficient quantity of clay for his purpose, he works it up with straw; he is then provided with a frame eighteen inches in length, six deep, and from nine to twelve inches in diameter. In this frame he forms his lumps, in the same manner that a brickmaker forms his bricks; they are then packed up to dry by the weather; that done, they are fit for use, as a substitute for bricks. On laying the foundation of a cottage, a few layers of bricks are necessary, to prevent the lumps from contracting a damp from the earth. The fire-place is lined, and the oven is built with bricks. I have known cottagers, where they could get the grant of a piece of ground to build on for themselves, erect a cottage of this description at a cost of from £15 to £30. I examined one that was nearly completed, of a superior order; it contained two good lower rooms and a chamber, and was neatly thatched with straw. It is a warm, firm, and comfortable building; far superior to the one I live in; and my opinion is, that it will last for centuries. The lumps are laid with mortar, they are then plastered, and on the outside once rough cast, which is done by throwing a mixture of water, lime, and small stones against the walls before the plaster is dry, which gives them a very handsome appearance. The cottage I examined, cost £33, and took nearly one thousand lumps to complete it. I believe a labourer will make that number in two days: the roofs of cottages of this description are precisely the same as when built with bricks, or with a wooden frame. Cow-house sheds, garden walls, and partition fences, are formed with the same materials; but in all cases the tops are covered with straw, which the thatchers perform in a very neat manner.—*Denson's Peasant's Voice*, p. 31.

160. *The Roof of this cottage is shown as if thatched with reeds or straw; it projects considerably on every side, and forms a truncated pyramid, terminating in the chimney-tops which are of stone, and of a very simple form, (fig. 131, to a scale of half an inch to a foot,) easily executed. Nearly the same form might be produced in well tempered clay, mixed with straw and gravel, and afterwards rough cast; but it is evident that it would not be so durable. When chimney-tops are formed of clay, a shape should be adopted which admits of covering them with a flag stone, or a large slate, or tiles, in the Swiss manner, fig. 132.*

161. *Garden.* The extent is about three-fourths of an acre. There are four large compartments, *f, g, h, i*, calculated for a four-fold succession of crops; viz., potatoes, the leguminous tribe, the cabbage tribe, and turnips and other roots. Two small compartments, *k* and *l*, are devoted to currants, gooseberries, and raspberries; and *m*, to strawberries, asparagus, and sea-kale. The garden is surrounded by a wall, with a border for early and late crops, and for flowers. The rows of shrubs round the compartments, *k* and *l*, are chiefly ornamental, such as roses, honeysuckles, mezereons, *Cydonia japonica*, &c. The single fruit trees at the corners of the compartments are chiefly apples, with some pears, cherries, and plums. There is a small summer house at *n*, from which it may be supposed there is an extensive prospect.

162. *General Estimate.* Cubic contents, 11,362 feet, at 6*d.* per foot, £284: 1*s.*; at 4*d.* £189: 7*s.* 4*d.*; and at 3*d.*, £142: 0*s.* 6*d.*

163. *Expression.* "I imagine," says Newton, in his preface to Vitruvius, "that every building should, by its appearance, express its destination and purpose; and that some character should prevail therein which is suitable to, and expressive of, the particular end it is to answer. To effect this, will require the exertion of the powers of the mind, the fire of genius, and the solidity of judgment; and without this, a composition is but a compilation of parts without meaning or end."—*Preface.* The dwelling now under consideration can hardly be considered as having any other expression than that of the subject. It is a substantial looking cottage dwelling, without any pretensions to either elegance or beauty.

164. *Alterations and Improvements.*

The first and most obvious mode of ornamenting this cottage, is by surrounding it with a veranda, either glazed, or finished with sheet-iron or copper; and adding a light terrace parapet, and also chimney pots; for example, as in fig. 133. The terrace parapet may be a very simple wooden palisade, fig. 134; and both it and the veranda may be painted of a stone colour. In the suburbs of a town, we should not object to green; but in the country there is green enough; and the colour of stone is, by contrast, a relief to the eye. Another, and a very

134

simple and economical mode of conferring ornament on such a cottage, is by disguising its

roof with a second roof, supported on a screen front; both roof and screen front being formed of light trellis work, for the purpose of being covered with plants, fig. 135. The construction of this trellis roof will easily be understood from the section, fig. 136, in which

*o o* represent the walls of the house, and *p p* the roof, while *q q* and *r r* represent the trellis roof and trellis screen. It deserves to be remarked, that the screen being at the distance of only three feet from the walls, the trellis-work, even when covered with foliage, will throw very little shade on the windows, and therefore not materially darken

the rooms. In warm countries, where it is desirable to sit,

and even to dine, or receive visitors, under the veranda of a house, its distance from the walls should be double or treble what has hitherto been shown in these cottages. At whatever distance the trellis screen and roof may be placed, they ought to be covered with vegetation; and for the industrious cottager, we would recommend apples, pears, or vines, as the most profitable trees. We should even prefer elders for the roof, in climates where the apple would not ripen, rather than to cover the whole with merely ornamental plants, though these would do

very well for the side screen. If heat were the great consideration, no plant could answer the purpose better than ivy; and it may be observed incidentally, that such a trellis-work

137

and screen would form a very handsome covering for any building in a garden or pleasure grounds, which it might be desirable to

138

conceal, though a great objection to all such coverings is their harbouring insects, unless birds are so abundant as to keep them under. The greatest improvement, however, of which a cottage, such as Design XVIII. is susceptible, is by adding another story to it. This might be done in various ways; the cheapest would be by turning the two small closets

139

into one economical staircase, of the kind shown in fig. 137. This description of staircase occupies exactly one half the space of a staircase on the ordinary plan. This may be easily conceived, when it is observed that every step rises twice the usual height. The space occupied by these two closets is four feet by three feet six inches, and supposing the tread or width of each step of the stair to be eight inches, and the rise eight inches, then the depth of the closet being eight feet, it will admit of carrying the stair eight feet high. After this, the stair may project into the kitchen till it gains the height of the surface of the bed-room floor. This height is exactly eleven feet six inches from

140

the surface of the ground floor, none of our ceilings being lower than ten feet. If the projection of the top of the stair into the kitchen were an insuperable objection, then the bottom might either project two double steps into the bed-room below, the door shutting against the riser (perpendicular board) of the third step; or a trap stair, composed of the two lower steps, and made to fold up, might be resorted to. This practice is to be met with in France, and it is remarkable that the celebrated Jefferson, when making a tour in that country, was so struck with the contrivance, that he made a note of it in his journal, which has since been published in his

*Correspondence.* The elevation of this cottage, in the event of a second story being added, will admit of adopting different styles of architecture, and a variety of the decorations or features belonging to each style. The castellated Gothic may be adopted, as in fig. 138; the monastic Gothic, as in fig. 139; the Indian Gothic, the Italian style, with a campanile-like watch tower, or the Elizabethan style, fig. 140. It may appear improbable to some, that a person purposing to build so small a dwelling, should think of applying any of these styles to it; but in particular situations in Britain, it is sometimes considered desirable to render such dwellings striking objects in a view; and in America, we are informed that the proprietors in easy circumstances are commencing not only to build good, comfortable cottages, but to display architectural style in them. Sometimes, also, the object is to create particular associations. It may appear singular to a resident in Britain, that a British emigrant in Van Diemen's Land should wish to build his dwelling in the form of an English church tower; but, duly considered, the feeling will be found to be quite natural. The associations which an object so characteristic of British scenery and civilization is calculated to raise up in the minds of Britons, resident in far distant, and, as yet, scarcely peopled countries, surrounded by primeval forests or wastes, can hardly be conceived by those who have never experienced them.

Design XIX.—*A Dwelling of Two Rooms for a Man and his Wife without Children.*

165. *Accommodation.* This dwelling contains what, in our opinion, ought to be the minimum of apartments for a man and his wife, without children, in any country. It is certain that, without this degree of accommodation in England, no country labourer considers himself at all comfortable; and in new countries, where the first settlers are obliged to put up with huts, or log houses, if they commence with one room, they never rest satisfied till they have obtained, at least, two. The room, *a*, in this design, is supposed to be used as a kitchen, and as the place for sitting and eating in; the bed-room is marked *b*; and from the kitchen are divided off a lumber closet, *f*, and a pantry, *e*. The bed-room has, in like manner, separated from it by partitions, two closets, *c* and *d*; one of which may be used as a store-room, and the other may serve as a place for clothes. The size of all these apartments is comparatively small; but they are all well lighted, and ten feet high from the floor to the ceiling. The privy, dung-pit, and manure tank, to this dwelling, are supposed to be placed at a short distance from it outside the garden; in our opinion, not the best arrangement, but in some particular situations unavoidable. The well for water is also supposed to be placed outside the garden, but in an opposite direction to, or at all events, at some distance from, the tank for manure.

166. *Situation.* This building is well calculated for being placed on the summit of a gentle elevation, in a situation where it will be seen from all sides. The reasons why it is suitable for this purpose, are, first and chiefly, the nearly cubical form of the building, which, from whatever point it is viewed, has a massive, substantial, and secure appearance; secondly, from the chimney being in the centre of the roof, thus giving an expression of symmetry, or of a whole, of which the chimney top is the finishing part; and thirdly, from the number of openings being the same on every side; for though these openings are irregular in size, yet they are regular in number, and mere regularity, though a minor beauty, has the advantage of being recognised and acknowledged by ordinary minds, while, at the same time, it is always more or less satisfactory to those even of the most refined taste. When we add to these particulars, the effect of the elevated platform on which the cottage stands, it being placed on the flattened summit of a knoll, and forming, as it were, an architectural plinth to this little cottage castle, it will not be denied that the result will be a somewhat dignified, though formal expression of purpose. One conspicuous fault

141

in the elevation of this cottage is, that the chimney stack rises from the roof without any preparation, and is far from being sufficiently high. Were this feature properly altered, the effect would be very different, fig. 141.

167. *Aspect.* Much of the comfort enjoyed by the inhabitants of every dwelling will depend on the aspect of the windows. Where a house has only windows on one side, as we have before observed, (§ 24) the best aspect is the south-east, on account of the greater mildness of the wind from that quarter, the infrequency of south-easterly storms, and the cheerfulness of the morning sun. The least desirable aspect for a house having the windows and the door all on one side, is the north; because at such windows the sun will only enter during a few mornings and evenings before and after midsummer: the next worst aspect is, perhaps, the south-west; because the winds from that quarter are frequently boisterous, and are almost always accompanied with rain. If the entrance is unavoidably on the south-west side, then the door should be protected by a close porch, having its door opening to the south; if on the north-west or north-east, the entrance should be similarly protected by porches, having their doors opening to the west or east.

168. *Construction.* The walls are supposed to be of stone, and the roof to be covered with Tuscan or Grecian tiles (figs. 23 and 24, § 50). The windows are surrounded by what are commonly called facings, that is by architraves without mouldings; and the sills are supported by small blocks. The window frames may each be in three parts, opening inwards, with bold perpendicular astragals (from astragalus, the ankle bone; a bar with a round moulding resembling the end of that bone), and lighter horizontal ones. The chimney top may be covered by two pieces of flag-stone, or two large slates, each chimney flue having two holes on the sides of the stack for the smoke to escape. The water which falls on the roof, is collected by a gutter, formed in the manner shown by fig. 142, *g*, which gutter ought to be lined with lead; beneath this is the cantilever, *h*. The end of the wall plate is shown at *i*, on which the binders, *k*, of the rafters, *l*, rest, and to which they are fitted. The poleplate, *m*, is for the purpose of supporting the rafters.

169. *General Estimate.* Cubic contents, 8,316 feet, at 6*d.* per foot, £207 : 18*s.*; at 4*d.*, £133 : 12*s.*; and at 3*d.*, £103 : 19*s.*

170. *The Garden* contains three roods. We have shown the house placed in the middle of a garden, and this garden is divided into seven compartments. The two small ones on the entrance front of the house, *n, n*, may be devoted to flowers, and herbs for seasoning, with a few rhubarb plants for tarts, and one or two hops. These compartments may be surrounded by a line of gooseberries, currants, raspberries, roses, and other useful and ornamental shrubs, three or four feet apart. The compartment, *o*, behind the house, is shown in three equal divisions, and is supposed to be cropped with strawberries, for the sake of selling the fruit. The remaining four compartments, *p, q, r, s*, two on each side of the house, will stand thus:— (1) potatoes; (2) peas, beans, kidney beans, and other leguminous crops; (3) the cabbage tribe; and (4) turnips, carrots, parsnips, onions, and other root crops. These crops may succeed each other in the above order in every compartment, and the rotation may thus go on for ever. The dung should be applied with the first and third crops. The surrounding hedge may be of plums or sloes, pruned, but not clipped, in order that the plants may produce fruit for sale, for tarts, or for wine. The fruit trees shown at the corners of the compartments may be chiefly apples, with one or two pears and cherries. The privy, dung-pit, and well, already noticed, are supposed to be exterior to the garden in the fuel plantation, and therefore are not shown in the plan.

171. *Remarks.* On examining this dwelling, we find that though it is deficient in point of comfort, from having the privy at a distance, it is convenient in respect to in-door enjoyments, from having four light closets in addition to the two apartments which constitute the main part of the dwelling. It must not be forgotten, however, that the living-room, *a*, must also be used as a wash-house, and back kitchen; and that the room, *b*, having a bed in it, can never be considered, by an English labourer, as a comfortable sitting-room. Nothing, indeed, short of three rooms, viz., a kitchen, back kitchen, and bed-room, can be deemed sufficient for the comfort of even a labourer and his wife without children. We know a case in which a cobbler and his wife lived in such a cottage as that represented in the present Design, and

both these persons being under the usual size, they put a bed in the closet, *f*, and used the room, *b*, as the cobbler's work-room, for which, being lighted from two sides, it was very well adapted; but this is what is called, in England, making shift; a thing not to be recommended in any book written with a view to human improvement. We may, notwithstanding, state that a closet may be turned into a makeshift bed-room for persons of even the ordinary size, by projecting the foot of the bed, fig. 143, through a partition, *u*, into the next room, or closet, *v*, enclosing and covering the projection in such a manner as to give it the appearance of a chest of drawers or a press, and making the top serve as a dressing table, *w*. In the space below the bottom of the bed, a large drawer, *x*, for clothes or linen may be obtained, opening into the closet, *v*.

172. *Expression.* It is evident, from inspection, that something more is intended in the elevation of this cottage than mere expression of the subject. The blocks or dentils under the window sills, the projecting roof, and its tiles, the cover to the chimney top, the general

144

form of the windows, and the arched head of the doorway, show something like an attempt at architectural style. What, then, is the style attempted? Those who have viewed the buildings of all the countries of Europe with an architectural eye, or those who have studied the cottage buildings in the pictures of the Italian landscape painters, will best be able to determine this question. All will agree that it seems to belong to the Italian style. This style, as it is called, though in reality it is only a substyle or manner, is founded on the Roman variety of Grecian architecture, with some forms, dispositions, and ornaments belonging to the castelated Gothic, but is by no means definite in its characteristics. In buildings of the humblest class, it may be described as characterised by flat and far projecting roofs, massive walls, and windows broad rather than deep, which are generally carried up close to the eaves, in order to be shaded, as much as possible, from the sun. In adapting the Italian style to England, this last characteristic is generally somewhat modified, as in this Design; indeed no characteristic of any style or manner ought to be servilely

145

imitated, when that imitation would prove inconsistent with utility or convenience. When one age or country borrows the architecture of any other, it must be modified in such a

manner as to suit the new locality to which it is applied; and the hand of the master is shown in effecting this modification in the spirit of the original style.

173. *Ornament or Variation.* A veranda, and a common Italian parapet, would serve to decorate this Design, fig. 144; while, if it were desirable to adapt a different elevation to the same plan, any of the Gothic styles indicated in figs. 138, 139, and 140, § 164, might be adopted; or recourse might be had to the Indian Gothic, fig. 145. The Italian parapet is formed by tiles of any kind, but not longer than six or eight inches, fig. 146, piled

147

148

up between piers, as in figs. 147, 148, 149, 150, 151, and 152. It is easy to conceive that

149

150

numerous other variations of the same kind may be made in the same manner, by tiles of

151

152

these and of other kinds, with or without the aid of bricks and paving tiles. A very hand-

153

154

some parapet may be made by using small hollow draining tiles or tubes as balusters. To the Indian cottage, fig. 145, parapets may be contrived of appropriate Indian forms, figs. 153 and 154.

Design XX.—*A Dwelling for a Man and his Wife with Children, and having a Cow-house Pigsty, &c. attached.*

174. *Accommodation.* The ground plan consists of an entrance, *a*; kitchen, *b*; bed-closet, *c*; wash-house, *d*; bed-room, *e*; dairy, *f*; linen closet, *g*; pigsty, *h*; privy, *i*; pantry, *k*; and cow-house or wood-house, *l*. In the roof, there is one large bed-room, which may be seen in the section A, B; it is lighted from one end, but can only be ascended to by means of a ladder through the trap-door in the ceiling of the entrance lobby, *a*. A hen-house might be formed over the piggery or the cow-house; and rabbits, in hutches, might be kept in the latter building.

175. *Construction.* The inner walls are supposed to be of rubble stone, as being the cheapest material in the given locality; the outer walls are of brick, and hollow; the roof is thatched. The three-quarter columns shown in the front elevation, are supposed to be of wood; and the manner in which they are attached to the walls may be seen in fig. 155, which is a section through the lean-to from back to front.

176. *General Estimate.* Cubic contents, 11,142 feet, at 6*d.* per foot, £278: 11*s.*; at 4*d.*, £185: 14*s.*; and at 3*d.*, £139: 5*s.*: 6*d.*

177. *Expression.* To the eye which looks only at picturesque effect, this cottage will not

be unpleasing; but strictly examined on scientific principles, it is full of faults. The three-quarter columns, supporting nothing but thatch, are absurdities: they are of no use as piers, because the wall is strong enough without them; and they are the more superfluous, because they are attached to the walls at the angles, which, as we have before shown (§ 74), are the strongest parts of the wall. A column is the noblest member of the architectural body, because it effects, of itself, and in a simple and striking manner, by one bold and independent form, what could otherwise be only effected by a great number of petty details of masonry or carpentry. As a support, it may be substituted for a wall; as a monument, it will serve the purpose of either a cone, a pyramid, or a tower; and placed horizontally over an opening, in the form of a beam, it takes the place of an arch. Of what other architectural member can so much be said? A column may be considered in architecture what a timber tree is in the vegetable

kingdom; the first is one of the grandest objects of architectural art, and the second, one of the most imposing in the vegetable creation. It is the part of correct judgment always to adjust the means employed to the end to be attained; and in attempting to gain any end, never to call forth more energy than the occasion requires. When a wall is employed to support a roof, no wise architect will ever join columns to this wall; since, from what has been said of the uses of columns, it must be clear that, to place them there, would, in point of utility, be a mere waste of strength; and in point of order and beauty, it would be to degrade their character. To see a column misapplied in a building, is as offensive to a correct architectural eye, as it is to a well regulated mind to see misapplied wealth or power in the common affairs

of life. Had there been an architrave of any sort over the

capitals of the columns in the front of Design XX. they would have had some pretensions to fitness, by appearing to support it, and having thereby an air of completeness; but merely set against the wall without any conspicuous superincumbent member of the roof, and immediately under the projecting thatch, they show an apparent disregard, not only of the principle of utility, but of that of congruity. A second fault is the placing of two false windows in the wings, which, in the elevation, are so shaded that it is impossible to detect them as such. This, in a drawing, is

155

156

157

XX.

XXI.

liable to be considered as a deception practised on the inexperienced eye, and an architect might thereby mislead his employer. Perhaps the architect may say that he intends glass to be put in these windows, in which case they would not be distinguishable from real ones, either in the drawing, or in the reality. If so, our objections are less strong; but still we disapprove of the expense of false windows in such a building as a cottage. A third objection to this dwelling is, that sufficient consequence is not given to the entrance. So large a cottage, and one of so much pretension, ought surely not to be entered as it were by stealth. One other objection, and we have done:—the window in the roof is too low, and not fit for ventilating sufficiently, so large a room as the one it opens into.

178. *Improvement.* We would remove the three-quarter columns and the false windows; place a porch over the main door, fig. 156, *m*, and extend the roof of the back kitchen in such a manner as to form a covered area for drying clothes, fig. 156, *n*, which might also serve as a play-ground for children, or, in hot countries, for occasionally dining under. We would also enlarge and raise the window in the roof, because there can be no perfect ventilation unless windows reach nearly to the ceiling. This done, the ground plan would be as in fig. 156, and the elevation (chimney pots and a terrace parapet being added), as in fig. 157.

Design XXI.—*A Dwelling for a Man and his Wife, without Children.*

179. *Accommodation.* We have here, in a compact form, and under a pavillion roof, a dwelling of the humblest class; very well calculated for two persons, but not for more. It contains a kitchen, *a*, in which is an oven; a bed-room, *b*; two light closets from the bed-room, *c* and *d*; and two from the kitchen, *e* and *f*. In this, as in most of the preceding Designs, some accommodation for lumber may be obtained in the roof, to which there should be an opening in the ceiling, closed by a door, with a hinged ladder, for ascent and descent. This ladder when not in use, is easily kept suspended to the ceiling, by a hook at one end. By substituting hooks and staples, as in fig. 158, for hinges, the ladder may be taken off at pleasure, and used for other purposes. The cow-house and yard, *g*; and the pigsty, poultry-house, place between them for fuel, liquid manure tank, and privy, *h*, are supposed to be placed in the garden.

180. *Construction.* The walls may be of earth, rough stone, or whatever may be the cheapest material in the particular locality. If they are built of brick, they should be made hollow, either according to the method already mentioned (§ 25), or according to that of Silverlock or of Dearn; both of which will be afterwards described. The roof in this dwelling is shown as covered with large slates. No gutter is added round the eaves, fig. 159, in this, as in many other of the Designs; because this essential accompaniment is of the same form in most buildings of the cottage kind, and is easily added, either as a tinned, zinc, or cast-iron half cylinder. The most durable, the most convenient, and, ultimately, the cheapest gutter, is a segment of a hollow cast-iron pipe, fig. 160; supported by iron brackets, fig. 161. The brackets are nailed to the face of the eaves, as at fig. 159, *k*, and have sometimes rivetted to them tinned iron straps, fig. 162, *l*, the ends of which are folded over the gutter, to hold it in its place. Each length of gutter overlaps the other; and when the slope, for giving a current to the water, is less than one inch in a yard, the one piece of gutter is bedded on the other in putty, or in white lead. If the water is not to be preserved for use, it may be conducted to a drain, by an upright pipe or tube, in one or two places (§ 84, figs. 60 and 61); but, if it is to be collected for filtration, the slope of the guttering, on all the sides of the house, ought to be directed to one point, where a descending tube should conduct the water to a receiving tank (see § 31).

158

159

160

161

162

181. *The Garden* has four main compartments, *m*, *n*, *o*, and *p*, for the usual four year rotation of kitchen crops; two small compartments, *q*, *q*, supposed to be used, the one, as a yard for faggot wood, &c., and the other as a rick-yard; and four small compartments, *r*, *s*, *t*, and *u*, for fruits, shrubs, and flowers.

182. *General Estimate*. Cubic contents, 11,178 feet, at 6*d.* per foot, £279:9*s.*; at 4*d.*, £186:6*s.*; and at 3*d.*, £139:14*s.*:6*d.*

183. *Expression*. This Design, like the preceding one, aims at nothing more than the expression of the subject. To both, might be given a character of elegance, as well as a solid addition in point of comfort, by a surrounding veranda. To fit both these Designs for receiving this addition, the tops of the windows are kept two or three feet under the eaves. If the veranda were formed with an opaque roof, it would merely serve as a shelter, and a cover under which to dry clothes, seeds, Indian corn, and tobacco, and to work or walk under in rainy weather; but, if the roof were glazed, with a trellis under it, grapes and peaches might be grown all round the house (the diagonal of the square being a north and south line), and all the former advantages obtained in equal perfection. The architectural beauty of this Design, as well as its internal convenience, might be greatly heightened by a judicious porch, and by a window in the roof over the entrance door; but these improvements we leave to be contrived by our readers; requesting them to take out their pencils and make the attempt; and assuring them, that nothing will contribute more to their improvement, as architectural designers.

Design XXII.—*A Dwelling for a Gardener, or other Servant, on a Gentleman's Estate, who has a Wife, but no Children.*

184. *The Accommodation* of this cottage consists of a lobby, *a*; a small kitchen, *b*, with an oven; a light closet from the kitchen, *c*; and a bed-room, *d*, with a small light closet, *e*, which may be used as the gardener's library. This closet will be kept sufficiently dry and warm by its proximity to the oven. From the lobby, is portioned off a small closet for fuel, *f*.

185. *Construction*. The walls are supposed to be of common brick, or of flints, with piers and coins, in the form of pilasters, built of brick, of a superior description; or, if brick should not be the material employed, the plain part of the walls may be composed of rubble stone, or random jointed ashlar work (free stone, rough as it comes from the quarry, laid in irregular courses), and the pilasters of tooled stone. The plain parts of the walls may also be of earth, and the pilasters of brick or stone; or both the plain parts and pilasters may be built of earth; the former being rough cast, and the latter covered with cement, scored (lined) in imitation of stone, and lime-whited. The roof is framed at a low pitch (low angle of the sides), and covered with Italian semi-cylindrical tiles, fig. 163, in the manner practised in the neighbourhood of Florence, fig. 164. The chimney top, fig. 165, on a scale of half an inch to a foot, is built with a far projecting cornice, supported by blocks, with intervals between, suitable for swallows' nests. The windows would have been more in character with this manner of building, obviously somewhat Italian, if they had been formed of two frames, lengthways, the whole height of the window, and hinged at the sides, so as to open inwardly; but the comfort of a sash window to a poor man, in a cold climate like that of Britain, is so great, that the British architect may well feel justified in adopting it in preference to the Italian form. In a building of a higher class, or for a warmer country, we should, probably, not so easily have formed an excuse for him, because there is a real advantage in being able to throw open the entire space occupied by the window; and this never can be done in the case of suspended sash-windows, where no more can be opened than one-half.

186. *Situation*. If this dwelling be erected for a gardener, it should, of course, be placed near the garden; and, if the health of the gardener, or that of his wife, be any object to the proprietor, it ought to be in a dry, open, airy situation; and not placed, as such houses very frequently are in Britain, among dug ground, thickly planted with trees and shrubs, where there can be neither good

63

164

165

XXII.

air, nor a free circulation of such air as there is. This Design is also well adapted for a lodge, and is worthy of being exposed to view on three sides, instead of being almost entirely covered with vegetation. The practice of almost entirely covering buildings in the country with creepers, can, by no means, be considered as in good taste: a few may be trained up a plain building, or a ruin; but to cover a handsome piece of architecture in this way, is to defeat the very intention for which that architecture was produced. In the country, all is vegetation: what beauty, therefore, can be expected from clothing with foliage an object, which, to produce any effect at all, must operate by contrast? In the town, all is architecture; and there, the introduction of vegetation of any kind on a building, can, in point of effect, hardly be carried too far. In the country, the white or grey walls of the plainest cottage, are a relief to the eye from the eternal monotony of green, by which such cottages are generally surrounded. In addition to this, it should never be forgotten that all vegetation near a house, especially that of deciduous plants, encourages damp and insects.

187. *Garden.* We have added a garden, on the supposition that this Design might be the right worth adoption, as a gate lodge, or by an independent labourer, or small farmer without children. We have shown in it a building, and yard, for two cows and two horses, *g*; and another yard with a privy, a place for pigs, another for poultry, and a third between them for wood, *h*. It is of great consequence that the floors of these buildings should be raised at least one foot above the surface of the yard, and that their walls should be of such a thickness as to ensure warmth to the animals. The necessity and advantage of this will appear in Book II. There are several small borders and angles, round the house and beneath its terrace or platform, which are supposed to be devoted to flowers and ornamental plants. There are two compartments, *i* and *k*, which, in the case of horses or cows being kept, might be devoted to lucerne, saintfoin, Hemerocallis, (see *Gard. Mag.* Vol. V. p. 451,) Symphytum, or some other perennial forage plant, according to the soil; in order that they may always afford food at a short notice, when it may be inconvenient to send to a greater distance. To a family of two persons without a servant, in Britain, and to small farmers in America and Australia, where servants or helpers, are scarcely to be got at any price, arrangements of this sort should always be kept in view. The four compartments, *l*, *l*, and

*m*, *m*, may be used as a kitchen garden; and the four larger compartments, *n*, *o*, *p*, *q*, for growing corn crops. But if the garden is supposed to be on a smaller scale, and to contain only a quarter of an acre, instead of five acres, then these four large compartments may be devoted to the usual rotation of culinary vegetables; and the four smaller ones to a grass-plot for drying clothes, and to strawberries; either, or both. The two compartments, *r* and *s*, may serve for gooseberries, currants, and raspberries; fruits that ought to be in every cottage garden, where the climate is suitable for them.

188. *In forming Grass-plots for drying Clothes,* where appearance is an object, there ought always to be tubes built in or inserted in the ground, for the purpose of holding the posts, to which lines, for hanging the clothes on, are attached. These

168

tubes, fig. 166, are generally about eighteen inches long and four inches wide inside at top, and three inches at bottom, with a plug, *t*, to cover each when its post is taken out and laid in the dry. Posts for being so used have a shoulder at their lower end, fig. 167, *u*, for preventing them from being wedged too firmly into the receiving box. The top of such a line post has generally two pins, *v*, passed through it in opposite directions, for the purpose of fastening the lines.

167

In some situations, instead of moveable posts, the lines may be tied to fixed posts, ornamented by creepers; or to trees with narrow heads, such as the Lombardy poplar; or for some description of clothes, cords may be stretched under the far projecting eaves of the roof all round the house. One end of the cord in this case is fixed, and the other passes over a pulley, and is made fast to a hook in the wall. The advantage of passing a cord over a pulley, fig. 168, *w*, is, that the line may be lowered to receive the articles to be dried, and then hoisted up again. This mode of drying clothes is very common in Germany

and Switzerland, and has the advantage of never exposing the clothes to perpendicular rain; with the disadvantage of running the risk of having the larger articles blown against the wall, and dirtied and discoloured, in windy weather. Where very long lines are stretched from tree to tree, it is customary to support the line in the middle, or in one or two places by a prop, forked at one end, figs. 169, or 170; the weight of the clothes keeps these props steady. The clothes are kept fast on the lines by what are called clothes' pegs. These are commonly formed of a piece of cleft wood, held together by a fillet of tinned iron; but an elegant improvement on them has lately been made by Mr. Stenning, of Haslemere, under the direction of our highly talented contributor, Mr. Perry, of Godalming, fig. 171, by which the fillet of tin is rendered unnecessary, and all risk of iron-mould on the linen avoided.

189. *General Estimate.* Cubic contents, 9,828 feet, at 6d. per foot, £245:14s.; at 4d., £163:16s.; and at 3d., £122:17s.

190. *Expression.* It is clear that something more is intended in this elevation than mere expression of purpose; else why the pilasters, the far projecting roof with its cantilevers, the semi-cylindrical tiles, and the swallow corniced chimney top? The manner intended to be expressed is evidently of the Italian kind, which is only diminished a little by the English sash window. If it were desired to decorate this cottage, it might be done by placing four ornamental tulip-shaped chimney pots, fig. 172, on the chimney tops, raising a low wall or parapet in the Italian manner, in bricks and tiles, at a very trifling expense, round the outer margin of the platform; and placing vases in harmony with the chimney pots, at the corners. An ornamental water-gutter, fig. 173, ought also to be used instead of a plain one. The dwelling might then be said to be in the enriched Italian style, and if no more trees were placed round it than what are shown in the ground plan of the garden, it could hardly fail to look well from every point of view. We leave our

readers to embody these ideas in geometrical and perspective sketches of their own; and we may further suggest that by increasing the width of the terrace and veranda, and adding a second story, a very handsome elevation, and a tolerably comfortable habitation (the walls still of earth), might be produced. The Italian manner of building cottages must naturally have more charms for such as have been in Italy, or are conversant with the works of the great painters of that country, than for those who have never travelled, or paid much attention to prints or paintings; but even to such persons an Italian cottage may please, when first erected, from its novelty; and afterwards, this satisfaction may be continued on the principle of contrast, or the difference between such a cottage and the generality of cottages in the neighbourhood. It is evident, however, that the great beauty of an Italian cottage, that in which the imagination is engaged, can only be fully realized by those minds in which it will call up associations connected with Italy. An old English cottage has this great beauty to every Englishman, educated or uneducated, that, in addition to all its comforts and conveniences, it operates upon his imagination, and recalls to mind a thousand associations connected with his earlier years, with his parents, his kindred, his school companions, and, in short, with all the vivid feelings of his youth. It ought to be the business of the young architect, therefore, not only to inform himself on all that relates to actual fitness in a building, and to whatever contributes to the expression of purpose, but to those circumstances, in style, which are calculated to operate on the imagination. For this purpose, we recommend to him the careful and repeated perusal of *Allison's Essays on Taste*, *Wood's Letters of an Architect*, and *Dugald Stewart's Philosophical Essays*.

Design XXIII.—*A Dwelling of One Story, for a Man and his Wife with a Family of Children; having a Cow-house and Pigsty attached.*

191. *Accommodation.* The plan consists of a long broad portico, *a*, well adapted for drying clothes under, and protecting the children from the sun or rain while at play; an entrance lobby, *b*; a kitchen, *c*; a wash-house, *d*; three bed-rooms, *e*, *f*, and *g*; a pantry, *h*; dairy, *i*; store-closet, *k*; pigsty, *l*; privy, *m*; cow-house, *n*; and open shed for fuel, *o*.

192. *Construction.* The walls may be of earth; the props of the portico, and of the open shed, trunks of trees with their bark on; the roof is thatched with reeds, heath, straw, or the shavings and dressings of barrel hoops, made from green rods, as practised in various parts of England. In countries where timber is very abundant, and other materials dear, the roof may be covered with shingles; but materials so liable to be consumed by fire, should never be employed if it can be avoided. The rustic columns may be placed on stone plinths, and have square wooden caps, fig. 174, *p*.

In a country having a long winter, and liable to heavy falls of snow, it might be desirable to have the roof of such a cottage considerably steeper; because the melting of snow on flat roofs, or even any roofs which are under an angle, or pitch, as the technical term is, of  $45^\circ$ , is generally attended by water penetrating to the interior. Thatched roofs in snowy countries, unless very steep, are of particularly short duration; and the same may be said of roofs covered with bark, heath, moss, ferns, or spray. These kinds of roof occur often in Sweden and Norway, but they are never resorted to when the builder can afford slate, or flat stone, or iron. One of the best modes of constructing flat roofs in a country liable to heavy falls of snow, would be to employ flat brick arches, tying the abutments together with wrought-iron rods, in the manner which will be afterwards mentioned. In Italy, and in other countries where stucco, puzzulano earth, or any other cement is abundant and cheap, flat roofs are not uncommon. The joists, or rafters, are first covered with boards, then with tiles, or sometimes with reeds; and afterwards, first with a coat of stucco, mixed with gravel, or very coarse sand; and, lastly, with a finishing coat of finer material.

193. *General Estimate.* Cubic contents 14,622 feet, at *6d.* per foot, £365 : 11s.; at *4d.*, £243 : 14s.; and at *3d.*, £182 : 15s : 6d.

194. *Expression.* This cottage pretends to nothing more than what it is; a simple, humble dwelling, but not without comfort. In a cold country, we should propose to heat all the floors by flues conducted

from one fireplace in the back kitchen, *d*; thereby rendering the dwelling, at a mere trifle of expense and trouble, as comfortable as even a first-rate mansion could possibly be (see § 34). This would also greatly diminish the expense of fuel, the labour attendant on keeping up fires, and that of cleaning fireplaces. As a finish to this cottage, the platform may be bordered with a neat hedge of box, or furze, or butcher's broom, or an ivied trellis; or by a rustic fence, composed of the trunks of small pine or fir trees, driven into the ground at equal distances, sawn evenly over at the height of two feet and a half, and finished with a horizontal railing of the same material, or of worked timber painted, fig. 175, to a scale of a quarter of an inch to a foot. Ornamental urn chimney pots, fig. 176, and one or two creepers, would complete all the ornaments proper for such a cottage.

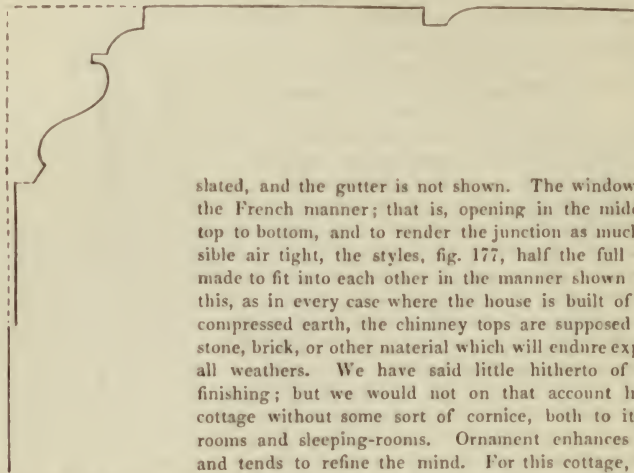

Design XXIV.—*A Dwelling for a Man and his Wife without Children, having Two Rooms and other conveniences.*

195. *Accommodation.* For a small family this may be considered a comfortable cottage. It contains a porch, within which is a lobby, *a*; kitchen, *b*; bed-room, *c*; store-closet, *d*; back kitchen, from which the whole house may be heated, *e*; pantry, *f*; dairy, *g*; privy, *h*; root cellar, *i*; and wood-house, *k*.

196. *Construction.* The walls may be of earth, or of any other convenient material; the roof we have supposed to be

178

slated, and the gutter is not shown. The windows are in the French manner; that is, opening in the middle from top to bottom, and to render the junction as much as possible air tight, the styles, fig. 177, half the full size, are made to fit into each other in the manner shown at *l*. In this, as in every case where the house is built of mud, or compressed earth, the chimney tops are supposed to be of stone, brick, or other material which will endure exposure to all weathers. We have said little hitherto of internal finishing; but we would not on that account have any cottage without some sort of cornice, both to its living-rooms and sleeping-rooms. Ornament enhances comfort, and tends to refine the mind. For this cottage, which is

somewhat in the Italian manner, fig. 178, to the scale of two inches and a half to a foot, may serve as the section of a cornice for the living-rooms, and fig. 179, to the same scale, for the bed-rooms.

197. *General Estimate.* Cubic contents 10,920 feet, at 6*d.* per foot, £273; at 4*d.*, £182; and at 3*d.*, £136: 10*s.*

198. *Expression.* Something more than a common cottage dwelling is here intended; but there are, in our eyes, two conspicuous faults; the first is the hipped or rather truncated angle of the pediment roof; and the second, the want of height and boldness in the chimney tops. These defects supplied, and a window added to show that some use was made of the garret, with a veranda and parapet or balustrade, the effect to us would be satisfactory. We again recom-

mend our readers to attempt to realize these improvements on paper. The benefit they will derive from so doing, is far greater than may at first sight appear. The mere circumstance of familiarizing the mind with orderly arrangement, regular figures, symmetry, means adapted to the end in view, either in buildings, in furniture, or in gardens, must have an influence on conduct. Order is the fundamental principle of all morals: for what is immorality but a disturbance of the order of civilized society, a disturbance of the relations between man and man? We do not say that all kinds of drawing have a tendency to produce an orderly mind, but we do affirm that architectural drawing has that tendency in an eminent degree. Carpenters and stone-masons are a superior class of mechanics in all countries.

XXIV.

Design XXV.—*A Dwelling for a Working Man with a Family of Children.*

199. *Accommodation.* The ground plan exhibits a porch, *a*; staircase and passage, *b*; kitchen, *c*; closet under the stair, *d*; back kitchen, *e*; sitting-room, with small closet, *f*; privy, *g*; and wood-house, *h*. The chamber floor contains a bed-room, *i*; closet, *k*; another closet, *l*; a bed-room, *m*; two closets, *n* and *o*; and the staircase and landing, *p*. The defect in the accommodation here, is the want of a proper pantry; but this might be easily obtained by enlarging *h*, turning its present door into a window, and opening a door to it from the kitchen. A substitute for *h*, may be provided adjoining *g*.

200. *Construction.* This cottage, its designer observes, "may be built of brick stud-

work, plastered outside, the roof to be thatched with reeds or straw. The entrance is to have a ledged door, and the windows are to be filled in with lattice-work, having oak mullions, or mullions of other timber, painted in imitation of stone. The rabbit heads of the windows, fig. 180, *q*, to be back filled, (to project beyond the wall, in the manner of architraves, but without mouldings, as at *r*)." The chimney stacks to be formed of, or ornamented with, Roman cement.

The barge boards and the pendants to be finished as in the working drawing, fig. 181, made to a scale of half an inch to a foot, in which *s, s*, are the barge boards, and *t*, the pendant. Fig. 182, shows a section of a suitable cornice for the living-rooms; and fig. 183, one in the same style for the bed-rooms; both these sections are to a scale of two inches and a half to a foot.

182

183

201. *General Estimate.* Cubic contents, 10,904 feet, at 6*d.* per foot, £272: 6*s.*; at 4*d.*, £181: 10*s.*: 8*d.*; and at 3*d.*, £136: 3*s.*

202. *The Expression* is evidently that of an old English cottage. We should have preferred the chamber windows in the ends, which would have been less picturesque in effect, but cheaper to execute, and much easier to keep in repair. We should also prefer the ground floor windows to have six large panes in each frame, rather than to have them filled in with lattice-work. This done, and the alteration made in the accommodation, which we have suggested, § 199, a parapet on the platform and pinnacles over the pendants, are all that are wanting to render this Design very much to our taste.

Design XXVI.—*A Cottage Dwelling in the German Swiss Style for a Man and his Family, with accommodation for two Horses and a Cow.*

203. *Accommodation.* This description of dwelling is common in the northern parts of the continent of Europe, and also in Switzerland. To economize heat, no less than to save expense in the first erection, the apartments for the domestic animals, and the places for carts, ploughs, and other country machines and implements, are all contained under the same roof. The occupier of such a dwelling is commonly a very small farmer, who joins to this occupation some description of trade or commerce; such as a carrier, coach-driver, jobber in cattle, fisherman, hunter, &c. There is a great objection to having cattle and horses under the same roof with living rooms for human beings, on account of the smells and insects generated by the former; but it must be recollected that in the warm season, the cattle are seldom in the house, and that during winter in the North of Europe, the great difficulty in human dwellings is to maintain heat. We have lodged in various dwellings of this description, from Stockholm to Naples, both in summer and winter, and cannot recollect that we ever felt much inconvenience from smells, but certainly some from insects. We do not, however, recommend this Design, where the expense of erecting the offices apart from the dwellings is not an object.—In the ground plan of this building, we have a place for a cart, waggon, or other carriage, and for ploughs and other implements of agriculture or trade, *a*; a three-stalled stable for two horses and a cow, *b*; a back kitchen, *c*; a privy, *d*; and a pigsty, *e*. On the principal floor, we have an entrance under a porch, ascended to by an exterior stair, *f*; a sitting-room, *g*; pantry, *h*; light closet, *i*; kitchen, *k*; closet under the stairs, *l*; bed-room stairs, *m*; and three balconies, *n, n, n*. The chamber floor consists of two bed-rooms, and two bed-closets.

204. *Construction.* The foundations, and the first story, as high as the floor of the living-rooms, are supposed to be built of stone, or brick with rusticated stone corners; the upper part of the building is entirely of timber. The roof is shown as covered with thatch, and without gutters. In Switzerland, where timber is abundant, and labour not high, the railing for the stairs and balconies of such a building is commonly massive, and very curiously carved. We have given a specimen, fig. 184, on a scale of half an inch to a foot, of a suitable railing to such a balcony.

205. *Situation.* Were such a building to be erected in England, it could only be for the sake of its character, and therefore the proper situation for it would be in a romantic, woody vale, glen, or dingle, like those of the South of Germany, and especially the valley of Kinzigthal, from a cottage in which, engraved and published, the idea of the present Design is taken. There are many situations in Wales, and in the West of England, and some in Scotland, where the appearance of such a cottage would raise up interesting associations in the mind of a continental traveller, and would fill the stationary inhabitants with surprise, and by exciting inquiry, might lead to the improvement of their taste. We are naturally indifferent

about what we do not understand; but the moment we begin to have a knowledge of any subject, we take an interest in it, which incites us to further inquiry, and ultimately brings us to an acquaintance with what is right or wrong, beautiful or deformed. To teach men to think is the grand object of every effort for promoting human improvement.

206. *General Estimate.* Cubic contents, 16,980 feet, at 6*d.* per foot, £424 : 10*s.*; at 4*d.*, £283; and at 3*d.*, £212 : 5*s.*

207. *Criticism.* The effect of the walls of the ground story being of stone is good, by giving the idea of great solidity in itself, and of stability and security in the superstructure. The three balconies are calculated to be very useful, and are not liable to the same objection as those exhibited in Design IX.; because they are not connected with any of the bed-room windows (see § 106). The outside stair, by artificially increasing the distance between the living-rooms and the stable, must in some measure diminish the quantity of effluvia from the cattle, conveyed thither by the clothes of those who attend on them. The eaves ought to have the addition of an ample gutter; and for our own taste, we should have preferred having two windows in each gable end, and none in the roof; dividing the garrets lengthways. We should not have truncated the gable, and we should have made a better preparation for the chimney stack, raising it higher, and in a bolder style.

XXVI.

Pl. 10 0 20 Ft

Design XXVII.—*A Dwelling for a Man and his Wife, with Children, or a Servant, with the usual Conveniences in a detached Building.*

208. *Accommodation.* This plan exhibits a porch, *a*; kitchen, *b*; back kitchen, *c*; parlour, or family bed-room, *d*; and children, or servants' bed-room, *e*. The privy, pigsty, cow-house, and similar appendages are supposed to be placed in a small yard, opposite the entrance to the garden, *f*. If this were the case, a wash-house might also be erected there; the apartment, *c*, being used as a kitchen, and *b*, as a parlour. This cottage might then be suitable for a small farmer, or jobber.

209. *Construction.* The walls may be of rubble stone, small land stones, or flints, set in good mortar. They may be finished at the gable ends with summer stones (stones placed on a wall, or on piers, for the support of beams, or

186

on the lower angle of gable ends, fig. 185, *g*, as an abutment of the barge stones, *h*), having worked cornices, fig. 186, and stone pinnacles. The roof may be of plain tiles or slates; the windows are shown as common sashes with large panes, hung in the usual manner. The door is ledged, with ornamental outside hinges, fig. 187, to a scale of three-quarters of an inch to a foot. The chimney tops may be of Austin's cement, or of soft stone.

210. *The Garden* contains two roods and a half; it is surrounded by a hedge of fruit trees, within which is a border, and walk; and the interior is in four main compartments, *i, k, l, m*, for the usual rotation; with two small plots, *n, o*, for fruit shrubs; two still smaller, *p, q*, for flowers; and three, *r, s, t*, for strawberries, tart rhubarb, and perennial pot and sweet herbs.

211. *General Estimate.*  
Cubic contents, 9,024 feet, at 6d. per foot, £225 : 12s.; at 4d., £150 : 8s.; and at 3d., £112 : 16s.

212. *Situation.* The designer of this building states, that it will have a good effect as a gardener's house, placed in the garden, in cases where the gardener is a single man. The apartment, *d*, may be the gardener's library and office; and *e*, his bed-room. He also thinks that it might answer well for a small proprietor in North

America; the farm lands surrounding the garden; or the garden placed near a public road. The house having windows on all sides, it ought evidently to be placed in an open, airy situation.

213. *Expression.* Something Gothic; and, from the cross over the entrance front, bordering on the ecclesiastical style. This expression is counteracted in a small degree by the modern windows; but more is gained to the inhabitant in comfort by those windows, than is lost to the man of reasoning taste, by this deviation from the details of correct style. However, as the comfort of a single man, for example, a gardener in his garden, is of much less consequence than that of a family, we see no objection to completing the effect of such a building by introducing mullions in the windows with lattice-work, and labels over them (a label, or hood moulding, is an outer moulding, crowning a door or window head, either plain or carved, and always returned at the ends, when straight, fig. 188); or, pointed topped windows may be employed; and, instead of lattice-work, with those very small panes, called by glaziers quarries (perhaps from *carré*, French, square), large panes may be used. It would also be an im-

188

provement to carry the chimney tops higher, and to have a panelled entrance door, studded with cast-iron nails, substituted for the ledged one; which, with a neat architectural parapet, fig. 189, would form a finish to the platform. The effect of the whole would thus be enriched, and rendered more characteristic of the style so obviously indicated; and it may be tried by such of our readers as can use a pencil, for themselves. We may remark incidentally, that the mere circumstance of deviating from the straight line in a very small degree in the window opening, as in fig. 188, at *u*, adds materially to the effect of that window, as a Gothic one. The more obvious forms of Gothic architecture are so universally known in this country, that the slightest line in a building which has an allusion to them, operates upon the imagination and at once gives the idea of style.

189

Design XXVIII.—*A Cottage in the Old English manner, containing a Kitchen, Living Room, and two Bed Rooms.*

214. *Accommodation.* The ground floor contains an entrance-lobby, *a*; back kitchen with oven, *b*; best kitchen or living-room, *c*; closet under the stair, *d*; stair to the bed-rooms, *e*; privy, *f*; and place for wood, pigs, or poultry, *g*. In the chamber floor, there are two bed-rooms; the largest, *h*, which is entered from the staircase, *i*, has a small closet, *k*; the other bed-room, *l*, has a press near the fireplace; and chests, and other articles, may stand in the passage, *m*.

215. *Construction.* The walls, as high as the bed-room floor, are of brick; and from the bed-room floor to the roof, of stud-work, or brick nogging plastered. The chimneys, fig. 190, are of brick, covered with composition; or they may be formed entirely of artificial stone. The roof is supposed to be thatched; the windows of lattice-work, and the doors ledged. The large projecting window in the centre of the gable end, is called an oriel, or bay, or compass window, and is constructed in the following manner, viz. heart of oak bearers, fig. 191, *n, n*, are projected from the walls at the given height in a horizontal position, and generally so as to form an angle with the wall of 45°. The ends of these beams are inserted in the walls, and the brick-work is carried up over them, so that they are retained in their places by the whole weight of the superincumbent structure. By these means the diagonal beams afford a sufficient support to a parallel beam, *o*, which is dovetailed into the

190

191

diagonal ones, as shown at *p, p*. The opening below the beams is covered in by the moulded boarding, *q*, in fig. 192, to a scale of three-eighths of an inch to a foot, and the section of the front, or parallel beam, *o*, is covered by the weather-boarding, *r*. The beams, *n, n*, ought to be of strong sound timber, and not less than fourteen inches by twelve inches. Oriel windows are generally constructed of wood-work, as being lighter than any other material; but beams of the above dimensions are sufficient to support a wall of brick or stone. The manner in which oriel windows of stone are carried up, is founded on the same principle, and will be described hereafter. Round the inside of these windows, are generally formed seats, which commonly open in front, at *s*; or at the top, like a ship's locker; so as to serve at the same time as a chest and a seat. Formerly these seats were called binks, bins, or bunkers, possibly a corruption of the French word, *banc*. The barge

XXVIII.

XXIX.

boards, and pendants, both for the gable ends and windows, may be varied at pleasure; and they form very fit subjects of composition for exercising the ingenuity of our female readers. The enclosure to the pigsty is of oak pales.

216. *General Estimate.* Cubic contents, 10,544 feet, at 6*d.* per foot, £263:12*s.*; at 4*d.*, £175:14*s.*:8*d.*; and at 3*d.*, £131:16*s.*

217. *Remarks.* This cottage is disfigured, rather than otherwise, by the two appendages, *f*, and *g*, at the end; not but what these appendages are essentially requisite, but that they are given in a mean and common-place manner. The door of *f*, is also in too conspicuous a situation, and

193 is too nearly resembling the door of the main entrance. In other respects the building is picturesque; expressive of what it pretends to be, an old English cottage; and not uncomfortable within. The mean character of the lean-to at the end, and the nakedness of the door of *f*, may very easily be remedied; as a glance at the ground plan, in Design XXVIII., and another afterwards at the plan, fig. 193, and at the view of the end of the cottage, as so altered, fig. 194, will sufficiently prove.

Design XXIX.—A Cottage Dwelling of Three Rooms, with various Conveniences

218. *Accommodation.* There is a good deal of convenience and comfort about this cottage, and it must be allowed to be, externally, rather an elegant object. It contains an entrance under a handsome recess to a lobby, *a*, which opens, on the

left hand, into a sitting-room, *b*, with a bed-closet, *i*, and, on the right, into the family bed-room, *d*. Directly in front is the kitchen, *c*; the back kitchen, *e*; dairy, *f*; place for fuel, *g*; privy, *h*; and place for poultry, or a cow, *k*. Where there is a small yard for a cow, poultry, fuel, &c., the apartment, *k*, may be enlarged, and turned into a green-house, heated by hot water from the back of the fireplace in the kitchen, *c*; and *d*, being changed into a sitting-room, may be connected, by double glass doors, with the green-house.

219. *Construction.* This building is well designed for having the walls executed in compressed earth, because these walls are thick, have few openings, and the dwelling is only one story high. The roof is of a low pitch, and should therefore be covered with some description of slate, tile, or metal, and not by any kind of thatch. Beneath the floors may be flues heated from a fire under the boiler in the back kitchen. The windows are shown in the French style, shutting by an air-tight joint, as exhibited in § 196, fig. 177. The panelled pilasters on each side of the door, and at the angles, a cross section of which is given in fig. 195, to a scale of half an inch to a foot, may be finished in plaster or cement. Fig. 196 shows the plan and elevation of one end of the chimney stack, which may be executed in brick-work, and covered with cement.

220. *General Estimate.* Cubic contents, 14,212 feet, at 6*d.* per foot, £355:6*s.*; at 4*d.*, £236:17*s.*:4*d.*; and at 3*d.*, £177:13*s.*

221. *Remarks.* The entrance front of this cottage is satisfactory, but the outline of the

ground plan is by no means so. For what purpose are so many breaks and angles made, when a plain square, as in fig. 197, would have given the same accommodation, with increased dimensions, and at less expense? The answer from the designer will probably be that the breaks are made to produce shade and variety in the elevation, as well as to mark the subordinate parts of the building, in order that an excuse may appear for their being executed in a cheaper manner than the rest. With respect to the first reason, we allow that some perpendicular shadows are by these means obtained; but no shadows whatever will, in our eyes, justify so direct a deviation from the principle of utility. Here are no fewer than five apartments or appendages diminished in size for the sake of getting four breaks and four perpendicular shadows. Surely this will not bear the test of reason. But it may be said by the author of this Design, that the breaks are made to show that what is included in them are appendages or offices, and that they afford a reason why these appendages or offices are placed under lean-to roofs, and have smaller windows, and thinner and lower walls, than those of the main body of the house. Here we admit the architect has reason on his side; for economy in building a cottage must ever be an important object, and indeed seems implied in the very name. The question, therefore, between the designer and us is, whether the superior simplicity and dignity of the exterior elevation that will be produced by avoiding the breaks, and having the walls and roof of the offices of the same height and character as the main body of the building, will not compensate for the additional expense incurred? We think it will; for nothing, in our eyes, adds more to the dignity of a house, than a general simplicity of form, communicating grandeur to it as a whole, and giving an elevated character to its appendages. By comparing the ground plan in Design XXIX. with fig. 197, the superior degree of simplicity of the latter figure, one would think alone sufficient to give it the preference over the other.

222. *Improvement.* A very suitable parapet for the terrace of this cottage might be formed by placing mignonette troughs of Austin's artificial stone, or of Peake's Staffordshire ware, such as fig. 198, on the top of a four-inch brick wall, formed of open or pigeon-hole brick-work, and carried to the height of eighteen or twenty inches. At the corner of this wall, solid square piers might be built, covered with plaster, and panelled like the pilasters at the end of the house, and these might be terminated by square mignonette boxes, fig.

197

199. This done, and corresponding terminations given to the chimneys, the design may then

198

be considered as tolerably complete. The mignonette boxes for mere admirers of flowers and lovers of sweet smells, may be filled with earth, and sown or planted with mignonette; but for botanical amateurs, they may be filled with alpinas, or herbaceous plants in small pots. To a botanist, even if he had no other resource than the native plants of Britain, this would afford a perpetual source of enjoyment; because the length of the four sides of the parapet being one hundred and sixty feet, the oblong and square troughs would contain six hundred and eighty pots of three inches in diameter, and of course as many species. These might be changed, arranged, and re-arranged, at pleasure.

199

Design XXX.—*A Cottage Dwelling with Five Rooms and various Conveniences.*

223. *Accommodation.* This may be considered a commodious cottage; and it might even be turned into two dwellings, by shutting up the door by which *c* communicates with *e*. The details of the ground floor are two open porches, *a, a*; a shop, or business room, *b*; a principal kitchen or living-room, *c*; two bed-rooms on the ground floor, *d* and *e*; dusthole, *f*; place for fuel, *g*; privy, *h*; back kitchen, *i*; pantry, *k*; and staircase, with closet under, *l*. The chamber floor contains two good bed-rooms, *m* and *n*, each with two small closets. We may observe here, that closets in the outer walls of bed-rooms are very apt to become damp; and that, in general, it is much better to keep clean clothes in wooden presses, commodes, or chests, and dirty clothes in bags. By these modes of keeping, also, less danger is incurred from the moth.

224. *Construction.* The walls may be of earth, of flints, or of bricks built hollow. All the floors may be heated by a flue from the back kitchen, *i*. Two plain mouldings are introduced in the principal body of the front, which will be easily understood from the cross section, fig. 200, to a scale of three-eighths of an inch to a foot. The projection over this ornament contains a sunk panel, the effect of which, as an architrave to the perpendicular mouldings, is satisfactory. The eaves of the roof ought to have gutters, as shown in the section, fig. 36, § 69; and the water may be conducted to a filtering tank under the pantry, from which it may be drawn up for use by one of Siebe's pumps. The roof may be of thatch.

225. *General Estimate.* Cubic contents, 20,762 feet, at 6*d.* per foot, £511: 1*s.*; at 4*d.*, £340: 15*s.*; and at 3*d.*, £255: 10*s.*: 6*d.*

226. *Remarks.* The simplicity of this Design must, we should think, be generally pleasing. The ample sized windows, with their large panes, give the idea of abundance of light and of cheerfulness within; and the circumstance of their being brought down to the floor, shows that elegance has not been lost sight of. Such a building would answer well for a bachelor who had a man and his wife as servants. The former might live in *b* and *e*, removing the bed from the latter room, and sleeping in *m* or *n*. The servant and his wife could sleep in *d*. The apartment, *e*, being made the dining-room, it would be requisite to have double doors between it and the kitchen, in order to exclude noise and smells; and the proximity of these two apartments would be found highly favourable for economising labour, and for what constitutes the essence of all good eating, having things brought to table hot. One little alteration in the plan would be requisite to answer the comfort of all parties, supposing the house turned to this use; and that is, that the staircase, *l*, should enter from *e*, instead of from *d*. This would require no additional expense at the first erection of the house, but merely forethought. Supposing that the master were desirous of having a bed-room on the ground floor, it would only be requisite to join *f*, *g*, and *h*, to *i*, in a new form, and to open a door from *e* to *o*, as in fig. 201. The house would

be greatly improved by this arrangement, and it might be rendered still more commodious, by having two steps down to *i*, so as to get a floor over *i*, *f*, *g*, and *h*, in which to form a bed-room for the married servants, to be entered by a stair from *i*. This would allow of *d* being used as a drawing-room. In this way a very simple cottage might, at a very moderate expense, and what is of more consequence, without injury to its beauty or character, be changed into a cottage villa, fit for the residence of any gentleman whatever. It would then deserve some ornament; and what we should prefer would be to surround the whole by a glass veranda, placing a light iron fence on the outer margin of the stone parapet, and ornamental chimney pots, fig. 202, on the stacks of chimneys; or a somewhat different style may be adopted, as in fig. 203.

Design XXXI.—*A Dwelling with Five Rooms, with Conveniences, in the Old English Style, where the building material is chiefly Stone.*

227. *Accommodation.* There is more show than space in this building, from the circumstance of there being only one room in width in the bed-room story. It is by no means recommended as a cheap Design, but as one ornamental and characteristic; and suited for producing a great effect, at comparatively little cost, in a country where free-stone, soft and easily worked, is abundant, and the price of labour low. The ground floor consists of an entrance and staircase, *a*; a kitchen, *b*; a wash-house, or back kitchen, *c*; a bed-closet, *d*; a milk-room, *e*; a closet under the stair, *f*; a bed-room, *g*; parlour, *h*; store cellar, *i*; place for coals, *k*; and privy, *l*. The chamber story contains two bed-rooms, *m* and *o*; a dressing closet, *p*; and a staircase and landing, *n*.

228. *Construction.* The walls should be of stone, in regular courses, or of brick; and the jambs (sides) of the doors and windows, with their sills, and lintels (covering stones) of hewn stone. These may, or may not, be bevelled at the angles. The mode of executing the summer stones and pinnacles, will be understood from figures already given, § 209, figs. 185 and 186. Great care should be taken in constructing the guttering over the bay windows, so as completely to carry off the water. These windows may have mullions, and iron casements made to open. The roof should be slated, and the chimneys may be of stone, and polygonal, or what are commonly called cannon chimneys. The chimney head cornice may be executed as in fig. 204. Some use may be made of the roof, to which light and air may be admitted by the small openings shown in the upper part of the gables.

229. *General Estimate.* Cubic contents, 23,024 feet, at 6*d.* per foot, £575:12*s.*; at 4*d.*, £383:14*s.*:8*d.*; and at 3*d.*, £287:16*s.*

230. *Remarks.* In England, this would be considered a very suitable house for a gardener or bailiff, where effect was an object; and it might be adapted to a small family, in easy circumstances, by rendering *g* a sitting-room; and by raising a floor over *c*, *d*, and *e*, for servant's sleeping-rooms; and another over *i*, *k*, and *l*, for a family bed-room; the dwelling would then be tolerably complete. A light stone parapet may be placed on the outer margin of the platform with ornaments at the corners somewhat analogous to those which terminate the gable ends. These, with the other variations and improvements of which this dwelling is susceptible, we leave to be designed by our readers.

XXX.

10 20 30 Ft.

Design XXXII.—*A Cottage Dwelling with Two Sitting Rooms, in a mixed style, where Timber, Brick, and Slate are the materials used for the Walls and Roof.*

231. *Accommodation.* This is a very commodious, convenient, and handsome dwelling; exhibiting every thing requisite for a cottager, whether a gardener, a bailiff, or a small farmer. It contains three floors,—for cellars, for living-rooms, and for bed-rooms. The cellar, or basement story, (see the plate forming page 117), contains a store-cellar, *a*; beer-cellar, *b*; coal-cellar, *c*; salting-room, *d*; and staircase, *e*. These are lighted by windows having sunk areas, *f*. The ground plan of the living-room floor (also in page 117) shews the principal entrance and staircase, *g*; a sitting-room, *h*; another sitting-room, *i*; a staircase, with a closet under it, *k*; a kitchen, *l*; a wash-house, *m*; a pantry, *n*; and a store room, *o*. This floor is surrounded by a terrace, part of which is covered by an extension of the roof of the kitchen and wash-house, as may be seen by inspecting the plates in pages 113 and 114. The chamber floor contains a bed-room, *p*; staircase and landing, *q*; closet, *r*; bed-room, *s*; closet, *t*; closet from the passage, *u*; passage, *v*; family bed-room, *w*; and nursery, or infant children's bed-room, *x*.

232. *Construction.* The walls are to be of brick; the roof covered with slates; the chimney shafts of cement, or artificial stone; and the balconies, brackets, posts, and gallery railings, of oak timber. The details of construction are given in the plate, forming page 118, in which fig. 1 is the open truncated pediment in front of the house; and shows the ends of the ceiling joists, *a*; the purlins, *b*; the covering of the pediments, *c*, *c*; the wall plate, *d*; and the bracket, *e*. Fig. 2 is a section at the eaves of the roof over the kitchen; in which is seen the rafter, *f*; the wall plate, *g*; the brackets, *h*, *h*; and the cross section of the post, *i*. Fig. 3 is the chimney top, in which is seen the chimney shaft, *k*. Fig. 4 is a cross section, or plan, of the chimney, in which one half, *l*, represents the plan of the base; and the other half, *m*, the plan of the top. Fig. 5 represents the balcony, in which is shewn the corbel, *n*, which supports the bracket, *e*; also the bracket, *o*, which supports the balcony; and the wall of the house, *p*. Fig. 6 shows the gable brackets to support the roof, in which is seen the gable wall of the house, *q*; and the section of the rafters, *r*, *r*. Fig. 7 shows the elevation of the lower part of the post; in which is seen a balluster, *s*, with a section of the upper and under rails. Fig. 8 shows the end elevation of the flower balcony; in which is seen the bracket, *t*, and the section of the wall, *u*. Fig. 9 shows the front elevation of the flower balcony. Fig. 10 is the section at the eaves of the front wall of the house; in which is seen the rafter, *v*; the section of the wall, *w*; and the bracket, *x*. Fig. 11 is the section of the plaster cornice of the sitting rooms, &c. Fig. 12 shows the section of the grounds (ground work, or foundation plan) for forming the architraves round the doors, windows, &c.; in which is seen the ground, *y*; and the jamb lining, *z*.

233. *Particulars, or Specification and Estimate.* The contributor of this very elegant and judicious Design, has sent with it a no less copious and complete specification and estimate. We consider the former, together with its accompanying explanations of technical terms, of the greatest value to the young architect, and the amateur. To the general reader, they will show the manner in which business is done among architects and builders, and their employers in England. A Design being once agreed on, details similar to those in the following specification, are first made out by the architect; and then the builder, who contracts for the work (either at the estimate made by the architect, or at one made by himself, after having had the plans and specification some days in his possession for that purpose), signs this particular, or specification; and also an agreement made out, according to certain legal forms. This agreement binds him to execute the work, under a certain penalty, according to the specification, and to the satisfaction of the architect, or of a surveyor (for a surveyor, as clerk of the works, is often employed in addition to the architect). Security for the execution of the work is also sometimes required of the builder; in which case, the guarantee also signs the agreement, or a bond for the amount of the penalty. The particular, or specification sent by our contributor, Mr. Richard Varden, as a fair specimen of the usual style, bears the following title:—"PARTICULARS of the several works to be done in building a cottage residence, according to the annexed plans, elevations, sections, and details, and the conditions subjoined." The work is classed according to the trades employed to execute it; and we shall give the specification, for each trade, in a separate paragraph. We may observe here, that the specifications and estimates of architects, surveyors, and builders, are frequently composed in a sort of professional, or abbreviated style, which, independently of its technical terms, is unintelligible to general readers from want of care in its grammatical construction. The terms are unavoidable; but the employers of professional men should insist on at least readable language. Another point which we

should always require would be perspective views, undisguised by trees, or gaudy colouring, of the edifice to be erected, independently of the necessary geometrical plans, sections, and elevations; and in works of importance, a model in unpainted wood should always be constructed, and maturely considered before a Design is determined upon.

234. *Specification of Excavator's, Well-Digger's, and Bricklayer's Work.* To dig out the earth for the basement story, together with the cesspools and drains, and the several trenches for the foundations of the whole of the building, of the respective depths and widths required; and to fill in and well ram the earth round the work. The surplus earth arising from these excavations, and from the well, together with the rubbish made in the progress of the work, to be spread round the house so as to form the terrace, shewn in the Designs (if more earth is required for this purpose, it must be brought to the spot at the expense of the employer); and the whole to be well rammed and consolidated.—To dig a well four feet clear in diameter, and forty-five deep, and to steen the same in four-inch brick-work, with the top properly domed over in nine-inch brick-work; leaving a manhole, twenty inches square, covered with a Yorkshire stone, having a strong iron ring on the top. If a greater depth than forty-five feet should be required, the additions must be paid for by the employer as an extra; and, if a less depth is sufficient, a proportionate deduction must be made. To dig a cesspool four feet clear in diameter, and nine feet deep, and steen it with four-inch brick-work; leaving a manhole, which is to be closed with a Yorkshire stone, the same as that used to close the well. All the bricks to be used in the building, or brought upon the premises, to be sound and good well burnt grey stocks (bricks made of marley clay; that is, clay having a certain proportion of marl naturally, or chalk artificially, mixed with it); those to be used in the external parts of the building to be carefully picked of an uniform colour; and the whole laid, and flushed solid (the joints filled up) in mortar, of the several heights and thicknesses, with the apertures specified in the drawings: none of the bricks to be brought upon the premises to be slack burnt (imperfectly burned), or overburnt. The mortar to be composed of the best well burnt grey lime (grey lime-stone, not chalk lime-stone), and clean, sharp, pit,

or river sand, well tempered together; and to be sifted through a screen, whose wires shall be at equal distances, and not less than thirty in every foot in breadth.—The walls of the foundations and cellars, up to the level of the platform, to be worked in brick-work, and grouted (fluid mortar poured into the middle joints) with hot lime and sand; the rest of the walls above ground to be of brick-work, and the external face to be worked with a neat flat ruled joint (a ruled joint is a joint struck flat with the trowel, with a line drawn in the centre by means of a small iron instrument, fig. 207, called a jointer, and an iron straight edge, or flat ruler). The terrace wall to be built battering (sloping inwards), from two feet three inches at bottom, to nine inches thick at top, with a nine-inch upright parapet, coped with bevelled bricks, and fourteen-inch brick piers, as shewn by the drawings; fourteen common garden pots and pans, twenty inches high, to be provided and fixed thereon. Four-inch brick discharging arches (arches built over lintels to relieve them from part of the super-

incumbent weight, fig. 208, in which is shown the discharging arch, *a*, and the lintel which it is intended to relieve, *b*), to be turned over all the openings in the interior of the walls; twelve-inch gauged arches (bricks reduced by rubbing on free-stone laid on a table, called a banker, to the shape of truncated wedges, so as to form arch stones, fitting exactly with each other, according to the curve of the arch; the faces of these bricks are also rubbed quite smooth), with eight-inch skewbacks (the space between *c* and *d*, in the gauged arch, fig. 209, is the skewback of that arch), and four-inch soffits (the under side of the arches) corresponding in width with the reveals (the outside jambs, or rabbets; see *q*, in fig. 180), to be put over all the external openings, made of the best grey cutting bricks.

207

XXXII.

XXXII.

Front Elevation.

Side Elevation.

Back Elevation.

Nine-inch brick inverted arches, fig. 210 (*fg* being the level of the ground, and *h* the window or opening over the arch), are to be turned, the whole thickness of the walls, under all the external openings and chimney jambs. Inverted arches are intended to equalise the pressure of the foundations on the earth, and thus to prevent the sinking of one part more than another, or what are called settlements: it is evident that whatever carries down *ii*, fig. 210 must also carry down the point *k*. The chimney hearths, jambs (see § 79. fig. 47.), backs, breasts, and shafts, to be of brickwork. All the flues to be fourteen inches square in the clear, properly gathered (drawn in above the fireplace, till they are reduced to the proper size), and pargeted (plastered with mortar, mixed with cowdung); and each flue, to have a Roman cement chimney shaft (as shown by figs. 3 and 4, in the plate of details, page 118,) flanching up (sloped in a way to throw off wet: in fig. 211, *l* is a section of the chimney shaft; *m*, a section of the flue; and *n n*, sections of the flanchings) with plain tiles set and rendered (plastered) in cement.

A strong iron chimney bar (fig. 212, *o o*. in this figure, *p* is the breast; *q q* are the jambs; *r*, the inverted arch under them; and *s*, the footing, or first course of the foundations), to be put to each of the fireplaces; and four-inch brick trimmer arches to be turned where required. (Trimmer arches are made to support the hearthstones, abutting at one extremity on the wall of the chimney, and at the other on trimming pieces. Trimmers are pieces of timber framed at right angles to the joists, against the ways (openings) for chimneys, and round the well-holes (openings left in floors for admitting the stair) of stairs, &c. Fig. 213 is a plan in which are seen the joists, *t t*;

the trimming piece, *u*; and the fireplace, *v*. Fig. 214 is a section of the same plan, in

which the trimmer arch, *w*, is shown abutting against the trimming piece, *u*, and the back of the chimney, *v*.) To build brick foundations for the sink, and for the stone steps; and nine-inch brickwork to surround the areas in front of the basement windows, coped with brick on edge set in Roman cement, and paved with bricks, having sink holes and drains, to deliver the water into the main drain. To put 100 feet of hollow tile drain, twelve inches clear in the bore, where directed; and to lay the whole of the drains with a proper fall, and at a sufficient depth to deliver the water away from the lowest part of the building. To provide nine cast-iron stink-traps eight inches square, and fix one at each external aperture of the drain. (The construction and action of a stink-trap will be easily understood from the section, fig. 215. Water falling into this trap, through the cover, *x*, escapes by the funnel, *y*, the inverted semicircle over which prevents all air from ascending. See figs. 222, 223, and 224. The terrace to be paved with pebbles laid in sand, properly currented, and well rammed. To build foundations and enclosure walls, and an oven three feet six inches by three feet in the clear, properly domed, plastered, and paved; and to find and fix the requisite ironwork for the same, such as an iron door and frame, hinges, latches, &c., complete. To fill in the nogging partitions with brick nogging flat (brick on bed).

To pave the wash-house, pantry, and store room, with dressed paving bricks (smoothed on one side by passing a cylindrical rule, wetted, over the soft brick when moulded); the kitchen to be paved with ten-inch tiles, bedded and jointed in mortar; and the rest of the basement story, throughout, with common stock bricks laid flat in sand: the whole to be properly levelled and currented to the several drains. The openings of the fireplaces, in the sitting-rooms and in the chambers, to be three feet high by their respective widths; and that of the kitchen to be four feet high. All the window and door frames to be properly bedded and pointed in good lime and hair mortar, and the sills underpinned. (When stone sills are built into any wall, they are generally made to bear on solid work only in those parts directly above which the wall is carried up. The reason is, that, in buildings of any height, the solid parts are apt to sink a slight degree more than those parts in which there are several openings one above another. Thus, in the sill, fig. 216, *a* and *b* represent those parts of the sill

on which the jambs of the doors or windows are carried up. Now, if the sill were bedded on solid walling throughout, from *a* to *b*, and especially towards *c*, it is evident that, if the walling sunk only half an inch at either *a* or *b*, not having the same superincumbent pressure, it would not sink to the same degree at *c*, and the consequence would be a rent in the stone at *d*. For this reason sills are left hollow between the two

points of bearing, until the walling is completed; and the filling up of the hollows after is called the underpinning. In brick buildings, the sills, whether of stone or oak, are not generally put in until the walls are carried up to their destined height, and they are then let in by cutting away part of the brickwork from the jambs.) The bricklayer is to find scaffolding for the use of the carpenter, slater, plasterer, and other trades requiring the use thereof for the outside work; and to allow the same to remain until the external part of the building shall be completed. The walls are to be carried up in an upright, substantial, workmanlike manner; and, in the progress of the building, no part is to be raised more than four feet above the other (in order that the whole may settle, or sink equally, and at the same time), except in gables and chimney-shafts; and the whole is to be built in a regular and equal manner. To fix the wooden bricks, and to bed all the plates, bond timbers, lintels, &c., in loam. To cut all the rakes and splays, and all the chasings required for the lead flashings (strips of lead to cover joints or joinings), and to make good and stop the same with Roman cement. To do all the wind-pinnings (filling in the angle between the wall-plate and the roof) and beam-filling (filling up with brickwork the interstices in the wall, between the ends of the beams) required. The bricklayer is to find all the materials, ropes, ladders, boards, tackle, tools, workmanship, and ironwork, for the completion of his work, and for the carriage thereof; and to do the

216

XXXII.

Ins. 12 6 0 3 5 9 Ft.

whole in the best and most workmanlike manner, subject to the general particulars at the end of this specification.

235. *Specification of Plasterer's Work.* The cement chimney shafts to be coloured twice over, of a good warm stone tint. To lath, lay, float, set, and white the strings of the principal stairs, and the ceilings of the sitting-rooms, of the passage, and of the chamber floor throughout. The ceilings of the kitchen, wash-house, pantry, store-room, and the whole of the basement story, as well as the pediment in front of the house, to be lath-laid, set, and whited. (To lath, plaster, float, and set, is to give what is called three-coat work; the first coat, given after nailing on the lath, is called pricking up; the second, floating; and the third, setting or giving a coat of fine stuff. The second coat is called floating, from the tool used in the operation, which is denominated a float. There are three sorts of these tools; viz., the hand float, the quirk float, and the Derby or two-handed float. The floated coat is brushed with a birch broom, to roughen the surface before the setting coat is applied. The first coat of two-coat work is called laying, when on lath, and rendering on brick. In three-coat work, the first coat on lath is called pricking up, and upon brick roughing in.) To lime white, twice over, the walls of wash-house, and the basement throughout. To lath, plaster, float, and set, for paper or colouring, the whole of the battening (pieces of wood fixed to the bond timber on the walls at regular distances, on which the lath is to be nailed) of the inside of the external walls, and partitions for lath of the principal and chamber floors (except the wash-house); and render-float (roughing in would be the more correct term here, but rendering is generally used, and is understood by the trade), and set, for paper or colouring, all the internal walls, and nogging partitions of both floors. All the external walls, with the exception of the wash-house, will be battened by the carpenter. All the timbers in the partitions, and the bond (the timber built into the walls), to be diagonally lathed. (Lathing diagonally lessens the risk of cracks in the plaster, in case the timber should shrink). The two sitting-rooms and passage to have plaster cornices, as shown in fig. 11, in the plate of details, page 118. The plasterer is to find all materials, tools, tressels (a sort of stool, sometimes five or six feet high, fig. 217, used for supporting scaffolding boards), boards, moulds, rules, carriage, and workmanship required for the completion of his work; and to run (a term used by plasterers, meaning to form) such beads, quirks, arrises (projecting angles), &c., as may be necessary for the perfect execution of the same; and to do the whole in the best and most workmanlike manner, subject to the general particular at the end of this specification.

217

236. *Specification of Slater's Work.* To cover the whole of the roofing with the best countess slates, nailed with stout wrought-copper nails; the eaves to be laid double, and the whole of the slates to have a sufficient overlap, and to be carefully sorted in courses consisting of slates of equal thickness, so as to exclude the weather effectually. The slater is to find all materials, tools, carriage, and workmanship required for the completion of the above; and to do the same in the best and most workmanlike manner, subject to the general particular at the end of this specification.

237. *Specification of Stone-Mason's Work.* All the windows to have York quarry stone sills, eight inches wide, beveled, throated (in the section of the stone sills, fig. 218, the throat is represented at *e*; *f* is the bevel of the sill, and *g* the oak sill of the window frame, resting on the stone sill; and also throated at *h*), and tooled (see § 82). The entrance door to have a landing (a piece of pavement of larger dimensions than ordinary) over the area, of Yorkshire stone, four inches thick, rounded at the edges; the terrace to have Yorkshire pavement laid the width of the stairs at the entrances; the steps and the coping of the spandril (the space between an arch and the member over it), together with the coping of the piers (the solid parts between any arches or openings) of the stairs, and those on the terrace wall, to be of York quarry stone. The coping of the spandrils to be twelve inches wide, and that of the piers seventeen and a half inches square, properly cramped and run with lead. Each parlour to have vein marble profile chimney-pieces, not exceeding seven pounds in value, exclusive of hearths and slabs. (Profile chimney-pieces are such as have projecting jambs, with their sides covered by slips,

218

fig. 219, *i i*, of marble, stone, or whatever material the chimney-piece may consist of. When there are two side slips, *i i*, and a slip in front, *k*, the chimney-piece is said to be in profile; when there is only one piece in front, it is said to be not in profile, and the front slip, *l*, is called a jamb.

Such chimneys have generally an inside slip, *m*; but this rests against the brick jamb of the fireplace, *n*, instead of the stone jamb, *o*, to which the slips of the chimney-piece are fixed. Fig. 220 is an elevation of a chamber fireplace chimney, in which *p* is the shelf; *q*, the mantel; *r r*, the jambs; and *s s*, the inside slips.) All the fireplaces to have Yorkshire stone hearths, and Portland stone slabs. The fireplaces of the front chambers to have plain Portland stone mantels, jambs, slips, and shelves with rounded corners. The kitchen to have one inch and three quarters thick Portland stone mantel and jambs. The kitchen, pantry, and store-room to have milled slate (milled slate is sawed

out of blocks by machinery; roofing slate is cleft into laminae by wedges) skirting (a bordering to the wall) seven inches high, and one inch and a quarter thick, properly cramped (by an iron or copper hook, fig. 221, driven into the wall at one end, and let

221

into the slate at the other), backed up, and set in Roman cement. The wash-house to have a Yorkshire stone sink, five feet long and two feet three inches wide, with a proper hole for the bell-trap (a kind of stink-trap usually made of bell metal, about three inches across and round, figs. 222, 223, and 224). The mason is to find all cramps, lead, and

222

223

224

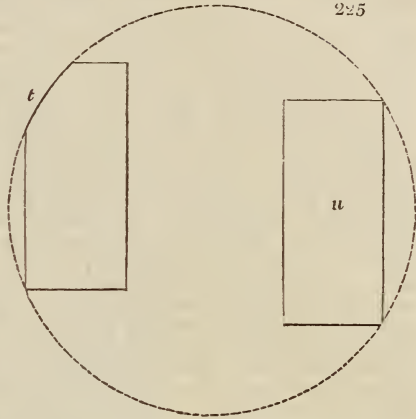

all the materials, as well as the carriage and workmanship required for the completion of the above; and to do the same in the best, most substantial and workmanlike manner, subject to the conditions of the general particulars.

238. *Specification of Carpenter's Work.* The whole of the bearing timbers to be sound, well seasoned, yellow Dantzic or Memel fir timber, except where otherwise specified. The whole of the carpentry to be framed in a workmanlike manner; and all the timber to be sawed square, and to be free from sap (outside wood, not properly matured), wanes

(deficiencies, as at *t*, in fig. 225, owing to marking the dimension too near the circumference, instead of making allowance for the sap wood, as at *u*), shakes (fissures in the wood), large knots, or other defects, and of the several dimensions, scantlings, and descriptions, which follow; and all the carpenter's as well as the joiner's work, to hold the several scantlings (the term scantling is generally applied by carpenters to the depth and width of a piece of timber) and thicknesses when finished, such which are named in the particulars: this must be particularly attended to. The principal and chamber stories to have two tiers of oak bond, three inches by two inches and a half, to pass through the openings, and not to be cut out until the work has become settled; and an oak wall-plate under each floor, four and a half inches by three inches,

dovetailed at the angles, and halved and spiked at the laps. To put double oak lintels four inches thick, and of the width of the respective walls, except the reveals (properly reveals, from *revelo*, to reveal or discover; the two vertical sides of the aperture between the outside front of the wall and the window), and to rest nine inches on the walls at each end. Wooden bricks of oak (see § 83), to be furnished to the bricklayer to be inserted in the jambs, not exceeding two feet apart, for fixing the linings to, where necessary. The entrance passage and the two sitting-rooms to have heart of oak joists six inches by four inches. The chamber floors to have fir joists nine inches by two inches and a half, not more than twelve inches apart; and trimmed (see § 234, and fig. 213), to the stairs and fireplaces, with trimmers and trimming joists nine inches by three inches and a half, with one inch and a quarter yellow deal keys (pieces of timber driven fast between each pair of joists, with their ends butting against the groin of the joists; they are commonly called strutting pieces, and their use is to stiffen the floor), in each chamber. The back chambers and passage to have ceiling joists four inches by two inches, and thirteen inches apart, firmly spiked to the common rafters, as shown by the drawings. The front rooms to have ceiling joists four inches by two inches, not more than twelve inches apart, and framed into the tie beams. The penthouse (a roof projected from a wall, and not supported by pillars) in front, to have ceiling joists three inches and a half by two inches, spiked to the rafters above the purlin. — Roof. Tie beams (see fig. 54) to be seven inches by four inches; framed principal rafters six inches by two inches and a half at bottom, and four inches by two inches and a half at top; purlins, five inches by three inches, to be framed to the principals; wall-plates, five inches by two inches and a half; pole-plates, four inches by two inches, supported by wrought curved brackets four inches and a half by four inches, as shown by the drawings; common rafters to be four inches by two inches, not more than thirteen inches apart, and properly trimmed to the shafts. The feet of the rafters which project beyond the brickwork are to be five inches by three inches and a half, wrought, notched, and spiked to the wall-plate and pole-plates. The roofing of the back part will be without principals or tie beams. The roof throughout to have one inch and a half yellow deal hips, nine inches wide; and ridge pieces of the same width and thickness, rounded off for the lead; the valleys to have one inch thick feather-edged flanch boards nine inches wide. (Hips and valleys are formed wherever

roofing meets at a right or other angle; the external angles, fig. 226, *aaa*, form the hips; the internal angle, *b*, the valley; *c c*, the ridge; *d*, the gable; *eee*, the eaves; *f*, the span; and *g*, in fig. 227, which shows a double

roof, the gutter between the roofs.) The chimney shafts to have one inch gutter boards and bearers, with feather-edged flanch boards nine inches wide; the eaves to have one inch and a quarter thick feather-edged eave boards, with wrought and rounded edge, and a wrought fillet between the pole-plate and eave boards, nailed to the feet of the rafters: three-inch thick cut brackets to be put under the projection of the roof over the gables (as shown by fig. 6, in the plate of details, page 118). The rafters of the roof to be covered with three quarters of an inch thick deal slips two inches and a half wide, for countess slating, with such tilting fillets (see fig. 55), &c., as may be required. The penthouse in front to have wrought and curved chamfered (the angles planed off, as in fig. 228, in which *h* is the chamfer) brackets six inches by ten inches, to support the plate, as shown by the drawings, firmly fixed at the lower end into the wall. Partitions for brick nogging flat (see fig. 58) to have heads and sills four inches by two inches; puncheons (quarters) and braces, four inches by two inches and a quarter, and eighteen inches apart; door-posts and principal quarters, four inches by three inches; nogging pieces, four inches by two inches. Partitions for lath to have heads and sills, four inches and a quarter by three inches; common quarters, three inches by two inches and a quarter, and twelve inches apart; braces, three inches by two inches and a quarter; door-posts and principal quarters, four inches by three inches. The whole of the external walls of the principal and chamber floors, except those of the wash-house, to be battened inside with one-inch thick yellow deal battens, two inches and a quarter wide, and twelve inches apart. The well to have a proper barrel curb, four feet high, boarded with one-inch thick boards, and oak stages to be placed in the well for fixing the suction pipe of the pump. A barrel curb is formed of circular ribs, generally of elm, on the outside of which slips of deal, four feet long, are nailed so as to form a cylinder, fig. 229, on which the brick steening is placed; the rest of the steening is built above it, as at *i*, in fig. 230; and, as the well is sunk, the curb

229

230

and superincumbent steening descend. When the well is in progress, the body of the earth, *k*, is dug out to the depth of two or three feet at a time, according as the soil may be more or less tenacious, and drawn to the surface in buckets; a band or rim, *l l*, being left under the curb; this band is afterwards dug out, when the curb descends, and several courses of steening are added above. The use of the curb is to keep the well perpendicular, and truly cylindrical during the work; it is left in the well, the interstices between the slips being filled in with brickwork. Oak stages are pieces of timber, with their ends fixed in the steening, which cross the centre of the well, at the distance of eight or ten feet from the bottom, and from each other; to these the pipe of the pump is fixed, in order that they may support its weight, and keep it steady.) The carpenter to make, fix, and refix, when required, such centring (frames of timber by which the brick or stone work

of arched vaulting is supported during its erection) as may be necessary for the brick-layer's or well-digger's use, in forming arches, trimmers, &c.

239. *Specification of Joiner's Work.* All the timber used by the joiner to be the best well-seasoned yellow deal listed (listing is cutting off a strip of such boards as are blue and sappy at the edges, so as to leave only the true wood), free from sap, shakes, and large or loose knots. The whole to be neatly wrought, framed, and finished off (rubbed after being planed) with firestone (a kind of soft stone, which serves to smooth the surface), in the most substantial and workmanlike manner. — Floors. To lay good one-inch thick yellow deal straight-jointed floors in the sitting-rooms and passage; and one-inch thick yellow deal folding floors throughout the chamber story. (The term folding is applied to a peculiar manner of laying floors. The first and fourth boards are bradded down (tacked, or slightly nailed; from brad, a small nail made without a head, so that the nail may be sunk into the wood), with an intervening space, *n*, fig. 231, something less than the breadth of the two boards, *o o*, that are to go between; so that when these two last are placed with their edges coinciding with the edges of those fixed, as shown by the section, *m o o m*, they rest, as it were, *folded* together in the middle, forming a ridge; on which ridge two or more workmen jump, till they force the boards down flat between the other two, they are then secured with brads. The object of this process is to procure very close joints.) The whole of the rooms to have proper oorders (narrow slips forming a margin) to the hearth slabs, &c. — Doors of Chamber Floor. To put one inch and a quarter thick four-paneled doors throughout this story, framed square on both sides, and hung with two inch and a quarter butt hinges (see fig. 65); and to have good iron rim locks, with plain brass knob furniture, one inch and a quarter single-rebated jambs (in fig. 232, *p* is the jamb, *q* the door, and *r* the rebate), with one-inch framed wrought and sunk grounds, five inches wide, and with quirk ovolo and fillets laid on to form the architraves. — Doors of Ground Floor. The doors opening into the entrance passage to be one inch and a half thick, six-paneled, and hung with three inch and a half butt hinges; having good mortised locks (locks which are inserted in a mortise, cut edgewise into the style of the door), with plain brass knob furniture; one inch and a quarter deal single-rebated jamb linings, with grounds (see fig. 12, in page 118) and mouldings the same as those of the doors of the chamber floor. The doors that open into the sitting-rooms to be moulded inside. The door at the top of the cellar stair, together with all the other internal doors on the ground story, that have not been specified, to be finished in the same manner as those of the chamber floor. The front entrance to have a two-inch deal sash door; one inch and a quarter astragal and hollow sash bar, fig. 233 (fig. 234 is an ovolo sash bar), circular-headed, with double-

231

232

233

234

margined and diminished styles, hung with three inch and a half butt hinges, and provided with two six-inch bright rod-boits (see fig. 68), and a ten-inch iron rim drawback lock (having a bolt which draws back from the inside by means of a knob), with brass knobs; the bottom of the door to be framed with three reeds, flush on one side, and square on the back, one-inch thick clamped lifting shutters, with studs and plates and screw fastenings, and one inch and a half rebated jamb linings and grounds, with mouldings to match the others. (Double-margined and diminished styles will be understood from fig. 235; in which, *s* is the style of its full breadth; *t* the style diminished; *u* the inner margin, for the purpose of receiving the shutter; *v* the sash; and *w* the panel. The section of the diminished style is shown at *x*, and the shutter by the dotted lines, *y*.) The back entrance door to be one inch and three quarters thick, six-pa-

neled, square on both sides; and to be hung and fitted as the front entrance door, with jambs, lining, &c., to correspond: both of the entrance doors to have oak-framed door cases and sills, five inches by three inches and a half. — Basement. The basement story to have one-inch thick deal proper-ledged doors (a ledged door is called proper, when it is wrought, ploughed (grooved), tongued (slips which go into the grooves, so as to make perfect joints), and bedded), and good oak proper door-cases, five inches by three inches and a half, (a door-case is called proper, when it is wrought, framed, rebated, and beaded), hung with eighteen-inch cross garnet linings, with stock locks (see fig. 69), and Norfolk latches (see fig. 67). The basement story to have solid oak proper two-light window frames, four inches by two inches and a half, with one-inch iron stanchion bars (properly, supporting bars, but here placed for protection), four inches apart, wrought-iron casements, and strong hinges, latches, stay irons (fig. 236), saddle-bars (cross-bars to which the leadwork of the glazing

is fixed), &c., complete. The other windows to have deal-cased frames, oak sunk sills, one inch and a half astragal and hollow sashes, double hung with iron weights, and best white lines, brass pulleys, and patent spring sash-fastenings. The sash windows, except the sitting-rooms, to have one-inch wrought hinges, and one inch and a quarter wrought and rounded window-boards. All the windows, except those of the basement, to have grounds and mouldings to match the doors. The kitchen, wash-house, store-room, and pantry to have one-inch thick square framed folding inside shutters, with rule joints, proper hinges, and iron bar fastenings. The sitting-rooms to have one inch and a quarter proper boxings (the frames which receive the architraves and the outer edges of the shutters are called proper boxings, when they are wrought, framed, rebated, splayed, and beaded), and architraves to match the doors; one inch and a quarter ovolo flat backs and splayed elbows (in fig. 237, *a* are the elbows; *b* is the capping, or, as it is called when of some width, the window-board), and soffits (the part of the architrave which projects over the columns, but the term is used generally for the under side of any horizontal projection), with proper capping (the coping or covering to the elbows and backs of the windows; viz., to *a* *a*, as shown at *b* *b* *b*, in fig. 237), one-inch bead and butt back linings; one inch and a quarter ovolo flat shutters, with one inch bead and butt back flaps (framed in panels, with a bead struck on the panel sides only), with proper hinges, strong wrought-iron spring shutter bars, and brass spring fastenings. (Fig. 238 is a section of part of a bead, butt, and square back door; in which, *c* is the style, *d* the panel, *e* the bead on the front side of the panel, and *f* the square back of the panel. Fig. 239 is a section of part of

Fig. 238 is a section of part of a bead, butt, and square back door; in which, *c* is the style, *d* the panel, *e* the bead on the front side of the panel, and *f* the square back of the panel. Fig. 239 is a section of part of

a bead flush door, in which the bead, *g*, is struck upon the styles, and returned on the rails, so as to surround the panel.) — Skirting. Chamber floor to have three quarters of an inch square skirting throughout, four inches and a half high. The sitting-rooms and entrance passage to have one-inch torus skirting, eight inches high; all the skirting to have narrow beveled grounds. (In fig. 240, *c* is a torus moulding on the skirting, *d*, which is nailed to the beveled ground, *e*; *f* is the wall; *g*, the plaster; and *h*, the floor of the room. The grounds are beveled, in order that they may retain the plastering better than by a horizontal joint.) Principal staircase to have one-inch yellow deal steps, risers, and carriage (pieces which bear the brackets till the steps are fixed), with moulded nosings to the steps to be housed (let in) into the close stringing, which is to be one and a quarter inch thick, sunk, and moulded with a moulded planceer (a moulded capping to the stringing into which the balusters are fixed) with one inch and a quarter raking (following a slope) torus wall string-housed to the steps and risers. To put deal turned newels (posts firmly framed to which the handrail is fixed) and moulded handrail, and three quarters of an inch square deal bar balusters, and one inch and a quarter square framed spandril to enclose the cellar stairs. (In fig. 241, *i* is the spandril of the stairs; *k*, the string; *l*, the planceer; *m*, the balusters; *n*, the newel; and *o*, the handrail. Fig. 242 represents the string board, in which the dotted lines show the housings.) The cellar stairs to have one-inch deal risers, one inch and a quarter oak treads with rounded nosings and proper carriage, a deal handrail, newel (turning) post, and one and a quarter inch string boards with steps housed in. The pump to have one inch and a half oak cheeks (sides) and sills, cased with one-inch deal, with proper cap, &c.; which is to be fixed in the wash-house. The angles of the chimney breasts to have proper staff beads (upright corner beads put at the external angles of chimney jambs, and in similar situations. In fig. 243, *p* is the section of the staff bead; *q q*, the plaster; *r r*, what are called the quirks in the plastering; and *s*, the wall.) Two hundred feet (lineal) of one-inch thick wrought and rounded shelf board, twelve inches broad, to be prepared and fixed with brackets and iron hold-fasts in the pantry, store-room, and closets, or elsewhere, as may be directed by the employer. Yellow deal balconies to be put up to one of the front and two of the side windows, as shown by the drawings; with moulded handrail, and turned balusters; the floor wrought on both sides, moulded on the edge, and two inches and a quarter thick; having four cut brackets three inches thick to support each: the whole to be firmly and securely fixed. Flower-stands of good yellow deal to be put up to the two front windows as shown by the drawings, and finished according to figs. 8 and 9, in plate of details, page 118. An oak moulded sill and a deal moulded handrail to be put round the back part of the building: these are to be framed into the posts, and the

242

turned balusters housed into the same. The posts are to be wrought, framed, and chamfered, seven inches square, with iron tenons (square pieces of iron fitted into mortises, that is, into holes cut to receive them) at bottom; and circular wrought framed braces at top, to support the eaves of the projecting roof of the kitchen, wash-house, &c. The carpenter and joiner are to find all tools, labour, glue, nails, and every description of ironmongery, locks, bolts, bars, hinges, fastenings, and the fixing of the same, and every thing required for the completion of their works; which must be done in the best and in the most substantial and workmanlike manner; and to prepare and fix all kind of beads, stops (a term variously applied, but chiefly to slips nailed on for doors or shutters to shut against, or for fixing work), fillets, grounds, linings, and backings (back linings, required for the perfect execution of the above, whether the same may or may not be minutely specified in this particular; the whole to be done, subject to the provisions in the general particular at the end hereof.

243

240. *Specification of Plumber's Work.* Flashings of milled lead ten inches wide, weighing five pounds a superficial foot, to be chased into the brickwork (see § 85), and fixed with wall-hooks (fig. 244.), where the roof abuts against the brick walls, as well as to each of the chimney shafts, which must have aprons (strips of lead, to throw the wet from the joint between the roof and the chimney shaft) where they are required. The gutters against the chimney shafts to be covered with lead weighing seven pounds to the superficial foot. The hips, ridges, and valleys to be covered with milled lead, fifteen inches broad, weighing five pounds the superficial foot; the whole to be properly lapped, dressed (smoothed), and nailed with lead-headed nails. The sink to have a six-inch brass grate and bell-trap (see figs. 222, 223, and 224), and a two and a half inch lead pipe. A good stout four-inch lead pump barrel, weighing 2 qrs. 14 lbs., with bucket, sucker, and wrought-iron handle, complete, and forty feet of two and a half inch lead suction pipe, to be put up in the wash-house.

244

241. *Specification of Glazier's Work.* The basement story windows to have lead lights, and Newcastle crown-glass (crown-glass is white or colourless, and is so called to distinguish it from green glass), in quarries. All the sashes, including that of the front door, to be glazed with good second Newcastle crown-glass; the best squares to be selected for the sitting-rooms.

242. *Specification of Painter's Work.* To knot (cover the knots with paint, before the general painting), prime (give the first coat), and paint the whole of the external wood and iron work four times in oil, with good white lead, and to finish the same in a light stone colour; with the exception of the doors, which are to be finished olive green. The whole of the joiner's work, internally, with the exception of the floors, shelves, and the risers and treads of the stairs, to be knotted, primed, and painted three times in good white lead and oil; and the sitting-rooms to be flatted (the glossy appearance of the

paint to be taken off by using turpentine in the last coat, instead of oil). The plumber, the painter, and the glazier to find all materials, workmanship, and carriage, and every thing requisite for the performance of their works; and to do the same in a perfect and workmanlike manner; subject to the conditions in the general particular at the end hereof.

243. *General Particular.* The whole of the foregoing works to be entirely finished and completed on or before the day of ; and the several portions to be performed in such order of succession as to insure the final completion of the whole by that time. Each contractor to be answerable for any damages that may be done to his respective work during its progress (fire excepted), whether by the inclemency of the weather, or otherwise; and to make all good, and to leave the same perfect at the final completion of the work. The whole of the works are to be paid for within

after the completion of the contract. If the contractor or contractors shall omit to complete the work by the time specified, a deduction of 1 per cent shall be made from the amount of his or their contracts, for every week the time shall be exceeded. The whole of the materials are to be of a sound and good description, and fit for their several purposes. The works are all to be done in a substantial and workmanlike manner; and every thing is to be performed that is necessary for completing the whole of the work in the usual and customary manner, notwithstanding any omissions that may have occurred in the foregoing particulars: and if any alteration shall be made, by the direction of the employer, it shall not vitiate or annul the contract; but the value of such alterations shall be ascertained at the customary prices of the neighbourhood, by of ; whose decision between the parties shall be final. And further, if any or all of the works should be performed in any way inferior to the description and intention of the particulars and drawings, or shall be deteriorated below a fair standard of good quality or sound workmanship; the same shall also be valued by as aforesaid, and the sum deducted from the amount of the contract by the employer: the decision in this case also shall be final. And further, if, in the course of two years from the completion of the said work, there should become manifest any latent defects, resulting from imperfect or careless workmanship, or from badly burnt bricks, unseasoned timber, or other materials, the contractor shall be held to make the same good, upon receiving notice from

to do so; and in case the said contractor shall neglect or refuse to make good such defects within one calendar month from the date of such notice, to the satisfaction of the proprietor, he shall be at liberty to employ such other persons to do the same as he may think proper; the expense of which shall be borne by the said contractor or contractors. The contractor or contractors to sign an agreement to perform the work according to the foregoing particulars and conditions therein; which agreement shall contain such additional clauses as the solicitor to the employer shall deem requisite to secure and enforce the fulfilment of the same. Satisfactory security for the performance of the work to be given by the contractor, if required.

244. *Estimate in Detail* of the expense of building a cottage residence according to the annexed plans and particulars of Design XXXII.

245. *Estimate of Excavator's, Well-Digger's, and Bricklayer's Work.* £ s. d.

One hundred and sixty-eight cubic yards of digging, filling, and ramming, for the foundations, cellar story, and drains..... ..	
One cesspool, dug and steened in four-inch brickwork, nine feet deep, and four feet clear in diameter .....	
One well, dug and steened in four-inch brickwork, forty-five feet deep, and four feet clear in diameter .....	
Five rods two hundred and fourteen feet of reduced brickwork in foundations below the level of the plinth (grouted) .....	
Ten rods two hundred and eleven feet of brickwork above ground, flushed solid, with flat ruled joints.....	
Two thousand and twenty-seven feet six inches, superficial measure, of extra-labour in picking stocks of equal colour for the facing .....	
One hundred and ninety feet seven inches of gauged arches .....	
Seventy-five yards and a half of nogging flat.....	
Fifty yards of stock brick paving, laid flat in sand .....	
Fourteen yards of paving bricks, bedded and jointed in mortar .....	
Twenty-four yards of ten-inch tile paving, bedded and jointed in mortar .....	
Seventy-six yards of pebble paving, laid in sand .....	
Thirty-four feet lineal of cuttings to rakes, &c. ....	
Thirty-four feet lineal of chasings cut for lead flashings, and making them good with Roman cement .....	

Fifty feet extra, to the setting of brick on edge coping in cement (labour and cement).....

Ninety-six feet of beveled brick coping, and fixing the same .....

One hundred feet of hollow tile drain, twelve inches clear in the bore (tube or tunnel), and setting the same .....

Eight feet superficial of Yorkshire stone paving, to cover the well and the cesspool .....

*Sundries.* — Two iron rings to the cover stones of the well and the cesspool, and letting in and fixing the same.....

Fourteen garden pots and pans for the piers of the parapet, twenty inches high .....

Twenty-two window-frames bedded and pointed in lime and hair mortar .....

Seven door-frames bedded and pointed in lime and hair mortar .....

Eight Roman cement chimney shafts seven feet high (as shown by the details), and fixing and flanching up the same with cement and plain tiles .....

Eight chimney bars .....

A cast-iron door with wrought-iron hinges, latch, &c., to the oven, and fixing the same.....

Five sink stones in the areas, with five holes cut in each .....

Nine cast-iron eight-inch stink-traps, and setting them.....

Bedding bond plates and lintels in loam (loam is used in bedding, because a bedding of lime is supposed to destroy the timber) .....

---

£362 : 6 : 4

246. *Estimate of Plasterer's Work.*

One hundred and fifty-eight yards of lime-whiting twice over.....

Two hundred and nineteen yards of whiting to new work .....

Forty-four yards of stone-colouring on cement .....

One hundred and fifty-five yards of floated render set .....

Eighty-seven yards of lath-layed and set.....

Three hundred and eighty-five yards of lath plaster, floated and set

One hundred and fifty feet lineal of plaster cornices, as per drawing

Four extra mitres in the cornices.....

---

£64 : 9 : 10

247. *Estimate of Slater's Work.*

Twenty-three squares and a quarter of countess slating, with wrought-copper nails .....

---

£41 : 17 : 0

248. *Estimate of Stonemason's Work.*

Seven feet superficial of plain work to the Portland stone shelf.....

Twenty-eight feet of Portland stone chimney-pieces.....

Eight feet ten inches of Portland stone, one and three fourths of an inch thick.....

Thirty-six feet seven inches of Portland stone slabs.....

Twenty-five feet six inches of Yorkshire stone hearths.....

Fifty-nine feet six inches of Yorkshire stone paving, and pier caps...

Eight feet nine inches of four-inch Yorkshire stone landing.....

Eleven feet three inches of Yorkshire stone sink, six inches thick....

Forty-six feet five inches of one and a quarter inch milled slate skirting, fixed with cramps, and set in cement.....

Ten feet two inches of lineal rounded edge to the Portland stone shelf .....

Five feet lineal of rounded edge to the Yorkshire stone landing, four inches thick .....

Seventy-three feet four inches of York quarry stone sills, eight inches wide, beveled, throated, and tooled (quarry stone is a term applied to stones prepared at the quarry, for any particular purpose, such as sills, copings, steps, &c.; without being very carefully tooled, or rubbed) .....

Ten feet of York quarry stone coping, twelve inches wide .....

Forty-five feet of Yorkshire stone steps.....

Two veined marble chimney-pieces in the parlours, at £7 each ...

- Twelve chimney cramps .....
- One hole cut in the sink for a bell-trap .....

£ 53 : 6 : 8

249. *Estimate of Carpenter's and Joiner's Work.*

- Four hundred and twelve feet eight inches cubic of Memel, or Dantzic fir, framed in the roof, the floors, and the partitions.....
- Twenty feet three inches of wrought and framed timber, in brackets, cut circular .....
- Six feet eight inches of wrought and framed timber, in brackets with chamfered edges.....
- One hundred and six feet ten inches of oak in the bond-plates and lintels.....
- Fifty-four feet eight inches of oak, framed in single flooring .....
- Sixty-six feet superficial of feather-edged valley-boards .....
- Sixty-seven feet eight inches of three-quarter inch wrought eaves fillet .....
- Nineteen squares sixty-eight feet of three-quarter inch slips, two and a half inches wide, for countess slating .....
- Twenty squares thirty-four feet of inch yellow deal battening, two and a quarter inches wide, and twelve inches apart .....
- Twenty-four feet superficial of inch gutters and bearers .....
- Ninety-four feet one inch superficial of one and a quarter inch keys .....
- Ninety feet nine inches of hips and ridges rounded .....
- One hundred and thirty-five feet four inches of feather-edged eave-boards, with wrought and rounded edges .....
- Fifty-three feet one inch of three-inch cut brackets, wrought and notched to the rafters .....
- Sixty feet of barrel curb to the well .....
- Sundries.* — Oak wood bricks.....
- Twenty-three slip centres to the arches (a slip of deal cut to the intended line of the soffit of the arch, and supported by an upright piece against each jamb. In fig. 245, *t* is the slip centre; *u u*,

the upright pieces which support it; *v v*, the jambs; and *w*, the arch .....

£ 810 : 17 : 1

250. *Estimate of Joiner's Work.*

- Eighty-five feet cubic of fir, wrought, framed, and chamfered .....
- Two cubic inches of oak-framed pump sill. (This may seem a small quantity; but the fact is, that surveyors and builders divide the cubic foot, which contains 1728 cubic inches, into twelve parts, which they call inches; so that the two cubic inches in this estimate are  $\frac{2}{12}$  of 1728, or 288 cubic inches. This custom is adopted by surveyors, to save them the trouble in calculating the money value of fractional parts of cubic feet.).....

Thirteen feet eleven inches of oak proper door-cases.....	.....
Six feet six inches of oak proper two-light window-frames .....	.....
Eighty-six feet superficial of three-quarter inch square skirting .....	.....
Ten feet four inches of laticing.....	.....
Two hundred feet of inch wrought shelves .....	.....
Thirty-five feet one inch of ditto bead and butt back linings.....	.....
Twenty-one feet eight inches of ditto pump casing.....	.....
Seventeen feet of ditto wrought lining tongued.....	.....
Five feet of ditto apron lining .....	.....
Fifty-eight feet six inches of ditto torus skirting .....	.....
Sixty-six feet of ditto proper ledged doors.....	.....
One hundred and twenty feet eight inches of ditto square framed folding shutters, with rule joints .....	.....
Eleven feet of ditto clamped lifting shutters, circular headed .....	.....
Two hundred and ninety-four feet six inches of ditto wrought, framed, and sunk grounds .....	.....
Fourteen feet seven inches of ditto deal risers and carriage.....	.....
Seventy feet one inch of ditto yellow deal steps, risers, and carriage (the piece which carries the steps), with moulded nosings (the edges of the steps which are exposed to view).....	.....
Seven squares thirty-four feet of ditto yellow deal folding floors....	.....
Three squares ninety-three feet of ditto yellow deal straight-jointed floor	.....
One foot of one and a quarter inch cap to the pump.....	.....
Fourteen feet eight inches of ditto square framed piers.....	.....
Nineteen feet six inches of ditto wrought and rounded window board	.....
One hundred and ninety-six feet four inches superficial of ditto four- paneled doors, both sides square.....	.....
One hundred and ten feet eight inches of ditto single-rebated jamb linings.....	.....
Twenty-four feet of ditto square framed spandril.....	.....
Thirty-four feet two inches of ditto proper boxings.....	.....
Twenty feet of ditto sunk and moulded close strings.....	.....
Fifty-two feet of ditto raking torus wall strings.....	.....
Twenty-five feet of ditto treads of oak, and rounded nosings .....	.....
Ninety-six feet six inches of ditto ovolo flat shutters, with inch bead and butt back flaps .....	.....
Forty-four feet nine inches of ditto ovolo flat backs, elbows, and soffits splayed.....	.....
Twenty-eight feet nine inches of one and a half inch single-rebated jambs, with circular heads .....	.....
Seventeen feet ten inches of ditto six-paneled doors, both sides square	.....
Thirty-five feet eight inches of ditto six-paneled doors, moulded on one side, and square on the backs.....	.....
Three hundred and eighty-six feet of ditto deal cased frames, oak sunk sills, one and a half inch astragal, and hollow sashes; double- hung with iron weights, best white lines, and brass pulleys .....	.....
Nine feet four inches of ditto oak pump cheeks.....	.....
Twenty-two feet nine inches of one and three quarter inch six-pa- neled doors, square on both sides, and circular-headed.....	.....
Twenty feet of two-inch deal floor to the flower balconies.....	.....
Twenty-two feet nine inches of deal sash doors, one and a quarter inch astragals, and hollow sashes, circular headed, double-mar- gined and diminished styles, three reeds, flush fronts and square back at bottom.....	.....
Ninety feet of two and a quarter inch deal wrought floor to the bal- conies.....	.....
One hundred and thirty-two feet nine inches of three-inch cut brackets, wrought.....	.....
Five hundred and nine feet superficial of mouldings.....	.....
Ninety-six feet superficial of oak mouldings.....	.....
Three hundred and seventeen feet three inches lineal of inch narrow beveled skirting and grounds .....	.....
One hundred and five feet of staff beads.....	.....
Five hundred feet of quirked ovolo, and fillets .....	.....
Fifteen feet of moulded planceer .....	.....
Six feet of moulded nosings (on the staircase landing to form the edge)	.....

- One hundred and eighty feet of three-quarter-inch square bar balusters.....
- Twenty-one feet of deal moulded handrails .....
- Six feet of plain deal handrails .....

251. *Estimate of Ironmongery and Fixing with Screws and Nails.*

£

- Four pair of eighteen-inch cross-garnet hinges.....
- Ten pair of rule-jointed hinges.....
- Twenty-four pair of shutter hinges.....
- Twenty-one pair of two and a half inch butt hinges.....
- Nine pair of three and a half inch butt hinges.....
- Four bright rod bolts six inches long.....
- Four stock locks eight inches long.....
- Two iron rim ten-inch drawback locks .....
- Seventeen patent spring sash fasteners.....
- Three mortise locks, with plain brass knob furniture.....
- Seven iron rim six-inch locks, with brass knobs.....
- Nine iron bar shutter fastenings.....
- Eight brass spring shutter fastenings.....
- Two studs and plates .....
- Two shutter lifts .....
- One plate and screw fastening.....
- Four Norfolk latches .....
- Five wrought-iron casements .....
- Five stay irons to the casements.....
- Twenty saddle bars of iron.....
- Twenty iron tenons.....
- Thirty square wrought-iron inch stanchion bars, three feet six inches long.....
- Forty holdfasts (fig. 246) to the shelves.....

- Twelve iron tie fastenings, to fix the brackets to the balconies.....
- Sundries.* — Four elbow caps.....
- Thirty steps housed into the strings at both ends.....
- Four deal turned newels .....
- Four turned knobs and bases, one foot high, and four inches in diameter.....
- Fifty-four turned balusters, three feet three inches high, and three inches in diameter .....
- One hundred and ninety-four housings to the balusters.....
- Forty wrought brackets to the shelves.....
- Forty-three turned balusters, three feet seven inches long.....

£260 : 11 : 7

252. *Estimate of Plumber's, Painter's, and Glazier's Works.*

- Thirteen cwt. 8 lbs. of milled lead.....
- Forty-one superficial feet of lead lights and quarry glass.....
- Two hundred and forty feet seven inches of Newcastle second crown-glass in sashes .....
- Four feet lineal of two and a half inch lead pipe to sink .....
- Forty feet of two and a half inch lead suction pipe .....
- One six-inch brass grate and bell-trap.....
- One stout four-inch lead pump barrel, and fixing the same.....
- One iron handle, bucket, and sucker, for the pump .....
- One hundred and ninety-two yards, three times painted in oil.....
- Forty-eight yards, three times painted in oil and flatted .....
- Three hundred and twenty-three yards, four times painted in oil.....
- Five yards, four times painted in oil of an olive-green colour.....

One hundred and five feet lineal of staff beads, three times painted in oil.....	
Twenty-seven feet of handrail, three times painted in oil.....	
Two hundred and twenty-nine feet six inches of skirting, four inches high, three times painted in oil.....	
Sixty-seven feet nine inches of torus skirting eight inches high, three times painted in oil and flatted.....	
Twenty feet of torus skirting, three times painted in oil.....	
Ten lights, five casements, three times painted in oil.....	
Twenty saddle-bars, three times painted in oil.....	
Nine shutter-bars, three times painted in oil.....	
Three newels, three times painted in oil.....	
Sixty balusters, three feet long, three times painted in oil.....	
Twelve dozen and a half of squares and frames three times, painted in oil.....	
Four dozen squares and frames, three times painted in oil, and flatted	
Sixteen dozen and a half of squares and frames four times, painted in oil.....	
Ten lights, five casements, and five stay irons, four times painted in oil.....

254. *Architect's Fee.* The above sum is exclusive of the Architect's fee, which, for small buildings, is generally 5 per cent on the amount, independently of a sum charged for the drawings; say, in the case of a cottage, £10, or upwards. In the case of larger buildings, say such as amount to £1000, or upwards, the Architect is content with his commission and travelling expenses; for which he supplies all the working drawings as the work is going on, and visits it from time to time. When plans are made for any building, and the work is not executed, a charge is made according to the value of the drawings. In many, perhaps in most, cases of very large buildings, a clerk of the works, resident on the spot, furnishes most or all of the working drawings, under the occasional direction of the architect, who in this case receives a smaller commission, or a certain sum per annum while the work is going forward.

255. *An Estimate* for this design, formed on the cubic contents, will serve in some measure as a guide for the price per cubic foot, at which dwellings so carefully finished and ornamented as the present, should be calculated. The number of cubic feet in Design XXXII. is about 32,000; which, at 7 $\frac{3}{4}$ d. per foot, amounts to £1060. If we add a farthing per foot for the Architect, we shall have about £1130 as the cost of this cottage, and 8d. as the rate per cubic foot, at which such cottages should be calculated, in a general or guess estimate.

256. *Remarks.* This Design conveys the expression of a comfortable, and even elegant dwelling. There is much of style in its external details, and yet we cannot point to any particular manner as its type. Its contributor, says, "I do not know what style it can be said to be in; it is of so complicated a nature in its details, that I know of no term which expresses their general result. Were I requested to analyse its component parts I should give it as my opinion that the gables resembled those of the Italian style; the balustrading and galleries, the Flemish or German manner; and that the large projecting eaves partake of the Swiss character. I say this with due deference to Architects who have visited foreign countries, for my ideas are derived from books alone. The hood over the entrance door is somewhat similar to those made use of in the Berkshire farm buildings. Whatever may be said of the kind of style exhibited in Mr. Varden's Design, all our readers, we think, will agree in the praise which we have already (§ 231 and 233) bestowed on it. The effect of the whole is highly picturesque, and nothing seems wanting to render the dwelling complete. Considering the number of rooms, the decorations, &c., it certainly cannot be considered an expensive structure, for the neighbourhood of London. A very good situation for it would be the north side of a public road, with a lawn in front, fig. 247 (on a scale of about forty feet to an

XXXIII.

XXXIV.

XXXV.

XXXVI.

inch), varied by groups of flowers, *a a*, and by scattered shrubs, and ornamental trees, *b b*; with two small flower compartments, *c c*; a narrow border at the base of the terrace, *d d*; an orchard of gooseberries, currants, and raspberries, *e*; a compartment for asparagus, sea-kale, tart rhubarb, strawberries, and other perennial crops, *f*; and another compartment for common culinary crops, surrounded on three sides by dwarf fruit trees, *g*. The boundary borders may be occupied with small and very early crops; and the walls should be planted with fruit trees. The walks may have box edgings, and be gravelled; or, should the dwelling be in a neighbourhood where flag-stones are abundant, they may be paved, the pavement resting on stone piers, by which a great annual expense in keeping the walks and their edgings clean and in repair will be saved, and the ground underneath them rendered available for the roots of the fruit trees in the borders.

Design XXXIII.—*Two Cottage Dwellings, under the same Roof; each having Two Rooms and other Conveniences.*

257. *Accommodation.* Each of these dwellings contains a porch, *a*; kitchen, *b*; and bed-room, *c*, which may be made a sitting-room, by placing the bed in the closet, *e*. There is also to each a back kitchen, *f*; a pantry, *g*; and a privy, *h*. One of these dwellings has an extra bed-room, *d*; and a very little change in the arrangement, as will be shown afterwards, would give a light bed-room to the other also. Some use may be made of the roof, by having trap-doors and ladders, as recommended in § 179. fig. 158.

258. *Construction.* This building having only one story, the walls may be made of earth, smoothed, and lime-whited externally; and lathed and plastered inside. The columns of the porch may be portions of the trunks of fir or pine trees, with the bark removed, and the knots and other irregularities reduced. The roof may be of slate; and, as it is of considerable span, it may be constructed as in fig. 248, with principal and secondary rafters.

259. *General Estimate.* Cubic contents of the two houses, 15,868 at 6d. per foot, £396: 14s.; at 4d., £264: 9s.: 4d.; and at 3d., £198: 7s.

260. *Remarks.* Looking at the elevation, we should say that this is a simple and somewhat elegant Design; and at the plan, that it appears convenient. When we examine it critically, however, we perceive that the windows are not sufficiently high for the purposes of ventilation; and that their proportions are not such as are commonly received as elegant. On examining the section, it will be found, that the heads of these windows are not near so high as the ceiling, and that the window sill is more than the usual height from the floor. We must, therefore conclude that the designer of this cottage intended it for a warm climate, where it would be desirable to exclude the light; but even if that were the object, it might have been effected better, by having windows of the same form close under the eaves. The interior of such a cottage, in Britain, would be gloomy, and the ventilation bad; but its appearance, as well as comfort, would be improved by changing the proportions of the windows. There is one great fault in delineating the elevation of this Design, which must not be passed over. It consists in representing the two false windows in the principal front exactly in the same manner as the real ones. Let the reader make a sketch without these false windows, or cut out a bit of white paper, and place it over them in our elevation, and he will see how different an effect will be produced. Whenever the effect of any design depends mainly on any thing not essential to its use, the critic may always be certain that there is something wrong. In general, also, when imitations of the effect of time on buildings are introduced in architectural designs, they are to be looked on with suspicion; as well as all accompaniments of trees, clouds, and figures. A design for a building should always have a distinct and independent beauty in itself; a beauty which can be conveyed by lines in correct perspective, without any reference to either shading, colouring, or accompaniments. Examined by these tests, some of the most showy works on Cottage Architecture, of the present day, will be found to be little better than pictures for the eye; or, as some would express it, to gratify the sense of the picturesque. The Design before us is capable of very great improvement; and, by altering the ground plan, as in fig. 249, two most comfortable

248

249

dwelling, of two rooms and two bed closets, with a back kitchen, pantry, and privy, to each, might be obtained under a very handsome exterior. Fig. 250 shows the perspective elevation of the principal front, in which a close porch, with square columns, is shown instead of an open one, with round columns. It is intended that the door shall be placed on whichever side of this portico may best suit the prevailing winds of the given situation. If the building were to stand east and west, the door of the porch ought to be on

250

one side, and that, of course, the south; if it stood north and south, then the door of the south porch ought to be on the south side; and that of the north, on either the east or west, which ever may be considered the mildest aspect. Fig. 251 shows the back elevation of these cottages, which will be found as handsome as that of the principal front, though differently composed. This also is a test of excellence in architecture. When-

251

ever any one side of a building is not as good in architectural design as another side, it may infallibly be considered as a proof of either poverty of invention or negligence in the Architect; or of want of means or of spirit in the employer. On the whole, for cheap and yet elegant cottages of the lowest degree of accommodation, we can recommend this improved version of Design XXXIII. as equal to any thing which has been yet given in this work. In a recent number of the *Gardener's Magazine* (vol. viii. p. 263), we have animadverted on the miserable hovels of one room, recently built on the Duke of Buccleugh's estate in Dumfriesshire; and on some still more wretched habitations, built along the coast in Wigtonshire. We would recommend to the amiable Duchess of Buccleugh to advocate the substitution of dwellings like those before us, for the cottages to which we have referred, on her husband's estate.

Design XXXIV. — *A Cottage Dwelling of Two Rooms, intended as a Gate Lodge.*

261. *Accommodation.* In the ground plan of this Design, fig. 252, there is a kitchen, *a*; with a bed-room, *b*; a light closet to the bed-room, *c*; a bed closet from the kitchen, *d*; and a pantry, *e*.

252

262. *Construction.* The exterior walls may be of earth or stone; and the interior of brick nogging flat, with the exception of the chimney stacks. The pitch of the roof being low, it must be covered with slates, or with Grecian or Tuscan tiles.

263. *General Estimate.* Cubic contents, 7770 feet, at 6*d.* per foot, £194*l.* : 5*s.*; at 4*d.*, £129 : 10*s.*; and at 3*d.*, £97 : 2*s.* : 6*d.*

264. *Remarks.* The expression is simple and appro-

private; and it is heightened by the bench under the recess, which may be supposed to be placed opposite the gate which the occupant is expected to open, and gives an air of ease and attendance on his part, as a porter's chair does in the hall of a mansion.

Design XXXV. — *A Cottage Dwelling of Three Rooms, with Back Kitchen, Cow-house, and other Conveniences.*

265. *Accommodation.* This is a commodious cottage, and all the accommodations being got within one roof, with the exception of two small lean-tos, it must be considered as promising to be economical in its erection. By the ground plan, fig. 253, it appears

to contain an entrance, *a*, from under a projecting porch; a kitchen, *b*, with a bed-closet from it, *c*, for a child; principal bed-room, *d*; parlour, *e*; back kitchen, *f*; shed for fuel, *g*; cow-house, *h*; dairy, *i*; water-closet, *k*, with a cistern of water over it, supplied from the roof; and pantry, *l*. If the cow-house and dairy can be dispensed with, or removed to the yard, then *g* and *k* may be got out of *h*, and the whole building included under one roof; always a most desirable object. This alteration effected, the back elevation may be rendered symmetrical, and altogether as handsome as the front or the ends, as exemplified in the improved plan, fig. 254.

254

XXXVII.

XXXVIII.

XXXIX.

XL.

266. *Construction.* The walls are for the most part shown thick, as if built of earth or stone; and the roof is covered with Peake's Grecian terro-metallic tiles. These being heavy, require considerable strength of timber in the rafters; but their durability we believe to be greater than even that of cast-iron.

267. *General Estimate.* Cubic contents 13,904 feet, at 6d. per foot, £347 : 12s. ; at 4d., £231 : 14s. : 8d. ; and at 3d., £173 : 16s.

268. *The expression* is somewhat analogous to that of the Scotch stone cottage, Design VII. ; but the low pitch of the roof, the Grecian tiles, and the porch in front, are great improvements.

Design XXXVI. — *A Dwelling, with Four Rooms, a Back Kitchen, and other Conveniences.*

269. *Accommodation.* This is calculated to form a very comfortable habitation, and all the rooms being on the ground floor, the walls may be built of earth, and the apartments heated by flues in the floor from the back kitchen. The ground plan, fig. 255,

255

shows a porch, *a*, a kitchen, *b*; parlour, *c*; two bed-rooms, *d* and *e*; a lobby, *f* (lighted from the dairy); a root-house, *g*; wood or coal house, *h*; pantry, *i*; privy, *k*; dairy, *l*; and back kitchen, *m*.

270. *Construction.* The walls may be of stone, finished with blocking courses, after the manner of Design VII. ; the roof of slate, and the windows of sashes hung with weights and pulleys. The floors may either be of boards, or paved, and heated by flues from the back kitchen.

271. *General Estimate.* Cubic contents, 19,468 feet, at 6d. per foot, £486 : 14s. ; at 4d., £324 : 9s. ; 4d. ; and at 3d., £243 : 7s.

272. *Remarks.* The expression is that of an humble but very comfortable dwelling ; though little care has been taken to create allusions to any particular style. The door in the porch, and also the entrance to the back kitchen, ought to be varied relatively to the position of the sun, and the prevailing winds.

Design XXXVII. — *A Dwelling of Four Rooms, with other Conveniences, intended as a Lodge, or a House for a Bailiff, or Head-Gardener.*

273. *Accommodation.* The ground plan, fig. 256, contains a kitchen, *a*, entered from under a veranda; a parlour, *b*; a small bed-room, *c*; back kitchen, *d*, from which the whole may be heated; pantry, *e*; dusthole, *f*; place for potatoes and other roots, and for fuel, *g*; and privy, *h*. There is a closet under the staircase; and in the chamber floor two small bed-rooms, and a garret over the kitchen.

274. *Construction.* The walls of the main building are shown of extra-thickness, with a view to situations where the cheapest building material is compressed earth, or rubble

stone. In brick countries, hollow brick walls will be found both the cheapest and the best, both for the main building and the lean-to, containing *d*, *e*, *f*, *g*, and *h*. The roof may be of slate; the windows latticed; and the pillars of the porch of squared wood; or, in some countries, they would be cheaper and better of slate, or slate stone. It is not the custom to form such columns of earthenware tubes, such as are made for flues in hot-houses, both in Britain and on the continent of Europe; but we have no doubt that such a mode would answer well, the weight being carried by a

256

prop of wood, iron, or brick, in the centre of the tubes. The ferro-metallic earth of Staffordshire would form admirable columns, lintels, summer stones, copings, ornamental chimney tops, and other component parts of buildings. Indeed, much might be done with common brick earth; but, unfortunately for Britain, all articles formed of this material are heavily taxed, and, to save trouble to the exciseman, the brickmaker is only allowed to make his bricks of certain forms and dimensions; viz. for building bricks, nine inches by four inches and a half, and two inches and a half. If he deviates from these, and makes a brick either longer or broader than usual, or impresses a moulding on one end, or on one side, he renders himself liable to such an increase of duty as amounts to a prohibition of the article. Two or three centuries ago, bricks were made in every form, ornamental and useful, which the Architect could desire; for a proof of which, we have only to look to the Elizabethan mansions which still exist in different parts of the country. Even so early as the time of Henry VIII., the art of making bricks to serve all the purposes of stone in the jambs and lintels of doors and windows, appears to have been carried to a great degree of perfection. At Sutton Place, near Ripley, in Surrey, built by this monarch's brewer, the piers, lintels, mullions, chimney tops, tracery in the windows of the chapel, and other parts, some highly ornamented, are formed of artificial stone or brick; and are still in excellent repair. Fig. 257, in isome-

257

trical perspective, on a scale of a quarter of an inch to a foot, shows the manner in which the shelf is supported over the window in the gable end.

275. *General Estimate.* Cubic contents, 10,818 feet, at 6*d.* per foot, £270 : 9*s.*, at 4*d.*, £180 : 6*s.*; and at 3*d.*, £135 : 4*s.* : 6*d.*

276. *Remarks.* What has the mental architect to say to this building? What is the kind of mind discoverable in the elevation? Certainly it does not exhibit a single feature of vulgarity. The pillars and cornice, and the brackets to one of the windows, have, on

the contrary, a simple and rather elegant appearance. The shapes of the three windows are different, and yet not opposed, and they are in three different positions relatively to the walls and the roof, forming an agreeable variety, or perhaps rather harmony. On the whole, we are satisfied with this elevation, and the plan is convenient.

Design XXXVIII.—*A Dwelling of Three Rooms, with a Back Kitchen, and other Conveniences, intended as a Porter's Lodge, or Gardener's House.*

277. *Accommodation.* The ground plan, fig. 258, shows an entrance lobby, *a*; kitchen, *b*; back kitchen, *c*; parlour, *d*; bed-room, *e*; closet, *f*; cellar, *g*; pantry, *h*; dusthole, *i*; privy, *k*; a place for fuel, roots, &c., *l*; and another for bees, exterior to *e*.

258

278. *Construction.* The walls are shown of a thickness proper for earth or rubble stone. The roof is in two parts, fig. 259; one part, *mn*, covering the main body of the house; and the other part, *opq*, being a lean-to at the back. From this construction of the roof, the whole of the water might be easily, and with little expense, collected, and conveyed to a cistern over *k*, or to a tank under *h* or *l*.

279. *General Estimate.* 13,334 cubic feet, at 6*d.* per foot, £333 : 7*s.*; at 4*d.*, £222 : 4*s.* : 8*d.*; and at 3*d.*, £161 : 13*s.* : 6*d.*

280. *Remarks.* The effect of the front elevation is dignified, and the expression, with reference to use, is that of substantial comfort. There does not appear to be much attempt at style. A side or back view would not give so favourable an expression,

because a great breadth of lean-to roof has always a mean effect. To counteract this, care must be taken in planting the garden, fig. 260, (drawn to a scale of a quarter of an inch to ten feet,) that trees be so placed as to break the horizontal lines from every point of view whence the lean-to part of the roof can be seen. The simplest mode of effecting this would be by planting a row of trees in the border below the terrace, commencing at *r*, and continued round *s* to *t*; but this would shade the windows, and stagnate the air about the house; and, therefore, a better mode is, to place only a few trees in that situation, and scatter others throughout the garden (but always so as not to impede its

regular cultivation), between the dotted lines  $u r$ , and  $v t$ , and the back part of the garden  $w$ . The reason for the range, precisely within which the trees must be planted, will be sufficiently obvious to all who have the slightest idea of perspective. Trees scattered along the boundary of the garden, from  $u$  to  $w$ , and from  $w$  to  $v$ , would never disguise any part of the house from a spectator walking along the outside of the boundary, because they would be too near the eye; and trees scattered any where between the dotted lines  $u r$  and  $x$ , and  $t v$  and  $x$ , would be of no use in disguising the lines of a roof, or indeed any other object, situated between  $r$  and  $s$ , or between  $s$  and  $t$ . When the view is unconfined, the horizontal range of vision taken by the eye is ninety degrees; and, consequently, a fixed position for the eye being given, the number of trees required to plant out any distant object, filling the whole of this angle, will chiefly depend on the distance of the trees from the eye: on the contrary, when an object, filling a small part only of the angle of vision, is to be concealed from a variety of points, through all of which the eye may range, the number of trees required will increase in proportion to their distance from the object. Thus, it will appear by fig. 260, that sixty-four trees would be required in the boundary hedgerow to hide that part of the house marked  $r s t$ , from an eye which could range from  $u$ , by  $w$ , to  $v$ ; whereas sixteen trees would effect the same object, if placed near the platform on which the house stands. In the case of this garden, we neither recommend the hedgerow,  $u w v$ , of sixty-four trees, nor the semicircular row,  $r t$ , of sixteen trees; but, as before observed, we would effect our object by scattering them in the garden at different distances from those parts of the house which are to be concealed.

Design XXXIX. — *Two Dwellings for Country Labourers, under One Roof, with Two Rooms in each, and other Conveniences.*

281. *Accommodation.* The ground plan, fig. 261, shows the following accommodation for each cottage: — a projecting open porch,  $a$ ; entrance lobby,  $b$ ; kitchen or living-room,  $c$ , with a closet under the stair; back kitchen,  $d$ , from which the whole might be heated; place for fuel or roots,  $e$ ; privy,  $f$ ; and cow-house,  $g$ . On the chamber floor there are one good bed-room and a closet to each dwelling. There is a small yard to each cow-house, with a pigsty,  $h$ ; dung-pit,  $i$ ; and a liquid manure tank,  $k$ . There is a grass-plot to each cottage; and a garden in front, and along one side; behind may be a grass field or lawn.

282. *Construction.* “The walls,” observes our contributor, “may be of stone, or mud; the roofs may be thatched with straw or reeds, and wattled down at the ridge with hazel rods, as shown in the elevation. The windows may be latticed, having the lintels, sills, and rabbet-heads, &c. plastered (the rabbet-head of a window is a Scotch

term for what in England is called the reveal of a window, viz. *p*, in fig. 262; and what in Scotland is called the back-filled rabbet, or the back-filled rabbet-head, is in England called the facing, or architrave, viz., *q*, in fig. 262, projecting an inch all round. This term is, however, only applied to plain facings round doors and windows externally; for, when the facings round both the exterior and interior openings are moulded, they are called, as in England, "architraves." Fig. 263 is a section across the chamber floor, to show, that a part of the height of the bed-rooms is obtained from the roof.

283. *General Estimate.* The two houses contain 12,986 cubic feet, which, at 6*d.* per foot, is £324: 13*s.*; at 4*d.*, £216: 8*s.*: 8*d.*; and at 3*d.*, £162: 6*s.*: 6*d.*

284. *Remarks.* There is an appearance of comfort about these cottages, and yet there is something mean in the roof slouching down over the two bed-room windows. The manner of roofing the lean-tos is altogether bad; a gutter against a gable-end wall

is almost certain to leak, or to become choked up, more especially when the roof is thatched. The building, however, is so far expressive of its purposes, that it can never be mistaken for any thing else than a cottage; and, on the whole, is rather picturesque than otherwise.

Design XL. — *Two Cottages of Three Rooms each, under the same Roof, with Cow-house, Pigsty, and other Conveniences to each.*

285. *Accommodation.* Each dwelling contains a porch, *a*; kitchen, *b*; back-kitchen, *c*; dairy, *d*; store closet, *e*; two bed-rooms, *f* and *g*; privy, *h* place for fuel, *i*; pigsty, *k*; and cow-house, *l*. Where neither cows nor pigs are kept, the cow-house may, with propriety, be used as a root-cellar and place for fuel, and the pigsty as a dusthole; or, *k* and *i* may be got out of the space occupied by *l*; and thus the whole of the conveniences required may be obtained under one simple parallelogram roof.

264

in the section, fig. 264, or in fig. 265, both to a scale of half an inch to a foot, as double or single rafters may be required.

287. *General Estimate.* Cubic contents, 26,304 feet, at 6*d.* per foot, £657 : 12*s.*; at 4*d.*, £438 : 8*s.*; and at 3*d.*, £328 : 16*s.*

265

288. *Remarks.* Considered as the lowest description of cottages, for country labourers these dwellings are commodious, and are calculated for being executed at a moderate charge. The walls in the ground plan are shown of more than the usual thickness, because they are supposed to be built of earth, with the exception of the chimney stacks. The partitions between the closets may be formed of brick nogging on edge, fig. 266. The floors may be paved with bricks, tiles, or flag stone; or formed of gravel or mortar mixed together, and laid down immediately, then beat smooth, and covered with a thin coat of cement. Of whatever earthy materials the floors are made, they must be heated by a flue from the back kitchen; because, otherwise, the dwelling would be cold and uncomfortable in winter. This flue will not require the fire to be lighted more than two or three times a week; because, if the floor be constructed as directed in describing Design I., it will retain the heat communicated to it by the flue for several days. If the floors be made of boards, the flue may be dispensed with; because, in that case, there will be a vacuity between the boards and the soil of, at least, two feet. The bottom of this vacuity should be,

266

at least, one foot above the surrounding surface, in order that no water may ever drain into, or rest upon it. Each cottage should have a yard behind it, surrounded by a wall of earth, with a projecting coping of slate, tile, or boards, and the entrance to this yard may either be at one side, or behind, according to the arrangement of the walks of the garden. It is almost needless to observe that there ought to be a dung-pit and liquid manure tank in each yard, communicating with the privy by a pipe-drain; and, where superior cleanliness is an object, this drain should communicate with the cow-house and pigsty in the same manner.

289. *Ornament.* These dwellings may be ornamented with handsome chimney pots; by covering the roof with a trellis for vines; by adding another pillar to each porch; and by a handsome architectural parapet. Supposing the slope of the parapet not to be less than forty-five degrees, and covered with turf, and the upper part gravelled, with a margin of turf of about a foot in width, the effect from the surrounding garden would be exceedingly good, without any other addition than the chimney-pots.

Design XLI. — *Six Cottages grouped together, with a view to Economy in building them.*

290. *General Arrangement.* The object of this Design is, to show the manner in which dwellings may be erected with the greatest degree of economy. We have before observed (§ 23), that, where this is the case, the external form will always approach more or less to that of a cube, and the internal apartments will also approximate to this figure. In the Design submitted, figs. 267 and 268, six dwellings are ranged round an

open yard, *a*, which contains a privy, *b*, and well, *c*, common to the whole; beside this is a wash-house and bake-house, *d*, also common to the whole. The building is two stories high, each story being eight feet high in the clear.

291. *The situation of this group may be supposed to be near a public road, c,*

268

separated from it by a small area, *f*, which may either be left open for a play-ground for children, or laid out as a drying ground, or flower-garden. The six kitchen-gardens are indicated as ranged on three sides of the building, and the whole space occupied by the dwellings and gardens need not, in ordinary cases, exceed one acre. The accommodations of the separate dwellings vary from two to four rooms each. The place for a wash-house and bake-house is intended to be used in rotation by each family, so that it will be employed as a wash-house and bakehouse six days in the week, and as a bake-house only on the Sunday morning. One of the cottagers may have the general management of the wash-house and of the oven; and this management may either be taken by all in turn, or a small payment be made for it monthly by all to one, &c.

292. *Accommodation of each Cottage.* The four dwellings, marked *g g g g*, contain each a principal room ten feet by twelve feet, and a small room of ten feet by eight feet, on both floors, with a closet under the staircase. The two dwellings, marked *h h*, contain each a room ten feet by twelve feet, on both floors, with a closet under the staircase.

293. *Construction.* The walls are supposed to be built of brick, and the roof slated. If, instead of brick, timber were used, there would, at the present price of British timber about London (£3: 10s. per load of fifty cubic feet), be a saving of from £50 to £60 on the six dwellings. In this case, all the exterior and foundation timber ought to be oak, but the rest may be of any description of wood of British growth. The floors of both stories are to be of deal boarded; the windows of latticework in iron frames, and the covers to the entrance porches of slate slabs.

294. *Specification and Estimate.* These are here combined; the building being of so simple a description, that a separate specification is not considered necessary.

295. *Bricklayer, Plasterer, and Slater's Work.* The bricklayer is to build the walls externally, and the division walls between each cottage, of one brick in thickness, with three courses of footings, one foot and a half thick. The openings of the chimneys on the ground floor to be two feet six inches wide, with jambs of one brick in thickness; and the chimneys of the chamber floor to be one foot six inches wide, with half-brick trimming arches. The space under each staircase to be paved, and enclosed with brickwork one foot six inches high, and half a brick in thickness.

£ s. d.

Fifty-three thousand bricks, per thousand 38s. ....	139	2	6
Six and a half bushels of lime for every thousand of bricks, at 8d. per bushel, is, per thousand of bricks, 4s. : 4d. ....			
Road drift (the scrapings of roads, being stone or gravel, ground to powder by the traffic on the road, and therefore become a sort of sand,) or pit or river sand, for every thousand of bricks say 2s. : 2d. Labour for every thousand of bricks, 8s. ....			
In all, per thousand of bricks, £2 : 12s. : 6d. which for 53 thousand is	139	2	6

Total (£98 : 10s. : 10½d. per dwelling, or)	£ 591	5	2

301. *The aforesaid prices* are prime cost; but if a builder be employed, a profit must be added, according to the mode of payment.

302. *Remarks.* For the foregoing very economical and convenient design, specification, and estimate, we are indebted to Mr. W. Laxton, Surveyor, Holborn Bars, London; well known among professional men as the author of *Laxton's Builder's Price Book*. We have given it exactly as received, in order that the specification and estimate might apply to the engravings; and we shall now show how we think it might be improved; though, of course, by adding to the expense. The first thing which we shall suggest is, the building of the walls with brick on edge, in the manner of Dearn or Silverlock, both to be hereafter described. According to Dearn's mode, a saving of one third in the number of bricks would be obtained, at once deducting £46 : 7s. : 6d. from the estimate, besides producing walls which would keep the apartments within warmer in winter, and cooler in summer. By raising the general floor of these dwellings two feet or three feet above the level of the surrounding surface, according to the nature of the soil and subsoil, and by having the oven in a sunk area three feet deep, a flue might be conducted from it under the ground floor of every apartment, as explained under Design I., § 34. Over the oven might be placed a box boiler, from which a flat tube, six inches by three inches, might be conducted horizontally under the floors of all the rooms on the ground floor; by which they would be sufficiently heated. If an underground smoke flue were employed, it would be necessary to have the floor paved, at least in part, with tiles or flag stones; but if a hot water pipe were conducted round the building, in the direction of the dotted line *i i i*, in fig. 267, a boarded floor might be used.

303. *Privy.* In the yard there ought unquestionably to be two privies, one for each sex; and these might, at a very little expense, be rendered water-closets; not by a cistern over them, the water in which would be liable to be frozen in winter; but by a cistern in the wash-house, which would, at the same time, supply water for washing and other purposes. Basins should be placed in the privies, as shown in fig. 13, § 38, and, in order to prevent the waste of water, an arrangement may be made only to admit a little to the basin, every time the door is opened and shut. For this purpose, in addition to the simple and efficient plans described under § 39, we shall here exhibit a less perfect one employed in the British Museum. In this example, which will be understood from fig. 269, as soon as the door of the water-closet is opened beyond a right angle, the

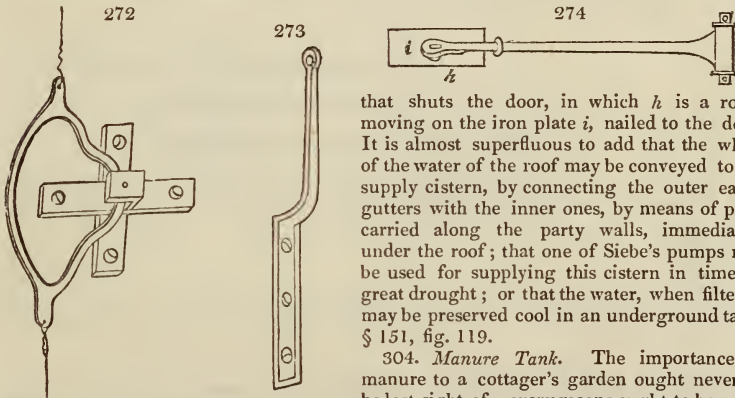

wrought-iron rod fixed on it at *a* pulls the brass chain through the pulley *b*, that communicates with the crank *c*; to which a wire is attached, that runs along as shown in the figure, between *c* and *d*. The crank *d* pulls down the lever *e*, which lifts the valve *f*, and consequently admits the water from the cistern through the small pipe *g*, to the basin. Fig. 270 shows the brass pulley, *b*, on a large scale. Fig. 271 represents

271

the crank *c*, also on a large scale. Fig. 272 is an enlarged view of the crank *d*. The cross pieces of the cranks for the reception of the screw nails are of iron japanned, and the other parts of the cranks are of brass. Fig. 273 represents the wrought-iron rod *a*, which is fixed on the door, and to which the chain is attached. Fig. 274 shows the spring

that shuts the door, in which *h* is a roller moving on the iron plate *i*, nailed to the door. It is almost superfluous to add that the whole of the water of the roof may be conveyed to the supply cistern, by connecting the outer eaves' gutters with the inner ones, by means of pipes carried along the party walls, immediately under the roof; that one of Siebe's pumps may be used for supplying this cistern in times of great drought; or that the water, when filtered, may be preserved cool in an underground tank. § 151, fig. 119.

304. *Manure Tank.* The importance of manure to a cottager's garden ought never to be lost sight of; every means ought to be made use of to collect it; and for this purpose not a drop of soap-suds or of foul water ought to be lost; but the cess-pool, provided in this design, is much too small, and very inconveniently situated for being emptied; not to speak of its proximity to the well of pure water. We would recommend a larger cess-pool in one of the gardens, connected with the one in the yard by a barrel drain, and conveniently situated for distributing its contents among the different gardens. We recommend attention to what we have before observed on this subject, when describing Design I.

305. *The Cistern* in the wash-house should be raised at least eight feet from the floor; and, besides supplying the water-closets, it may communicate with a filter of a simple construction, from which water may be drawn at pleasure for the purposes of cookery or washing. This filter may be thus constructed:—Fig. 275, *k*, represents the cistern; *l*, a cask; containing the filtering material at *m*, a space for the deposition of impurities from the water to be filtered, at *n*, and for the filtered water at *o*. This cask is connected with the supply cistern by the pipe

*g*, which, having a stopcock at *p*, water may be admitted to *n* at pleasure; and this water, by the pressure from that in the cistern, will speedily rise through the filter, *m*, to the space, *o*; from which it may be drawn off by the cock, *r*. There is also a cock, *s*, for drawing off the water from *n*, when it is desired to clean the filter, which may be done by allowing the water from *o* to descend. It may be observed, that if at any time, there should be a deficiency of water in the cistern, *k*, water from any other source may be filtered from the barrel, *l*, by the following means:—First, the filter, *m*, may be cleaned by pouring in water at the top of the cask through the funnel, *t*; and afterwards water from the well, or any other source, may be poured into *o*, and drawn off by *s* for use, till the cistern, *k*, is again supplied from the roof. A wooden or copper bath may be placed in the wash-house; which may be supplied with cold water from the filtering cask, or with hot water from the cistern over the oven, or from the washing and brewing boiler. The brewing utensils may also be deposited in this part of the building, and may be used in common.

306. A *Drying-Closet*, by another slight arrangement, might be formed over the oven; all that is necessary for this purpose, being to have the cast-iron box containing the water, fig. 276, made rather larger than the bottom of the closet; that part of the cover of

the boiler which forms the bottom of the closet being made perfectly watertight, and the boiler having an exterior opening at *a*, for the purpose of supplying it with water, and to admit of the escape of steam when the water boils. The portion of the cover of the boiler which forms the bottom of the closet may have grooves, *b b b b*, cast in it, or riveted to it, or to a false bottom, at six inches' distance from each other; in which grooves may slide clothes-horses, to hold the clothes to be dried. There should be a large cock for drawing off the water at *c*; and, from the side which will be placed next the wall, a conducting or outgoing tube, *d*, and a returning one, *e*, for the circulation of the hot water round the building. The upper surface of the outgoing pipe will be on a level with the floors of the rooms, and form part of them; and the projections of three inches on each side of this pipe are pierced with holes, to permit the heat from the sides of the tubes to rise into the rooms. Over the grooved surface of the boiler a closet may be formed, five or six feet or more in height, three feet wide, and four or five feet long. This would admit of four clothes-horses standing side by side, at six inches apart; and by a small opening in the bottom of the door (say half an inch in depth, and the whole of its width), with a corresponding opening in the ceiling of the closet at the opposite end, a current of air will be produced, which will rapidly convey away the moisture from the clothes. This arrangement would not in the least interfere either with baking in the oven, heating all the dwellings with hot water, or supplying hot water for ordinary uses, as the following figures will show:— Fig. 277 is the foundation plan of the wash-house, in which the oven, *f*, is retained in the same position as in fig. 267, but varied in size, and sunk lower; *g* shows the steps down to it; and *h* is the area for fuel. Fig. 278 is a surface plan, showing the drying-chamber, *i*, over the oven, and the boiler for washing and brewing, *k*. Fig. 279 is a section on the line A B, of the plans figs. 277 and 278, in which are shown the steps down to the oven, *l*; the hot-water box, *m*, and hot-air closet over it, *n*. Fig. 280 is a section of fig. 278 on the line C D, in which are shown the oven, *o*; the hot-water box over it, *p*; the hot-air closet, *q*; the opening under the door, *r*; and the other opening near the ceiling, *s*. Fig. 281 is a section on the line E F of fig. 278, showing the front of the hot-water plate, *t*, the cock for drawing

off the water, *u*, and the two pipes for circulating it, *v* and *w*. The hot-water box may be either of cast-iron in one piece, or of riveted plates of iron or copper. It may be

mentioned, that it would be an improvement to have what may be called a false bottom to the closet, made of iron, or even of wood, to which the grooves might be attached,

and placed about an inch above the top of the boiler, with an opening (of about half an inch in depth, and the whole width of the closet), at the door, for the admission of the air to be heated, and another at the opposite end, about twice the size, for the escape of the hot air into the closet. The effect of this arrangement would be, to carry off more heat from the cover of the boiler, and consequently to make the closet hotter. The principle has been illustrated in Perkins's steam-generator, as described in the *Mechanics' Magazine*, vol. xvii. This pipe for circulating the water should be of iron; and it would be an improvement to have the upper one square, or at least flat at top, about nine inches wide, with projecting flanches of grating, as in fig. 282, so that when the whole was laid down, painted of the colour of deal board, and completed, it might appear ornamental rather than otherwise. The grating on each side of the pipe, *x x*, in fig. 282, it is almost needless to observe, is to admit heat from the under pipe. By having the upper surface of the outgoing pipe no higher than the level of the floor of the apartments, no interruption is offered to the opening of the different doors which pass from the dwelling-rooms into the yard or to the wash-house. The low position of the pipes will also heat the air of the rooms more effectually than if they were higher; and,

so placed, they will be found convenient for warming the feet, and for keeping vessels of water or of food hot. Those who are acquainted with the mode of heating hot-houses by hot water will allow that there is not the slightest degree of difficulty either in erecting such an apparatus, in the first instance; or, when erected, in managing it, and keeping it in repair; and further, that, by it, it would be easy, in the most severe weather of even a Russian winter, to maintain a temperature of 60° and upwards in all the rooms on both floors of this group of cottages.

307. *Windows.* We do not like latticed windows, because they are generally cold and gloomy; but as they are much cheaper than sashes hung with cords and pulleys, where economy is a main object, recourse must either be had to them, or to iron windows. Windows of cast iron, very fit for cottages, are now made, of different forms, and very cheap. Fig. 283, which is one foot two inches and a half wide, and two feet four inches high, and weighs 8 lbs., costs in London, in 1832, by retail, only 3s. 6d. Fig. 284, in the Gothic form, which is one foot four inches wide, and three feet 7 inches high, weighs 23 lbs., and costs 6s. Fig. 285, two feet six inches square, weighs 19 lbs.,

and costs 6s. 6d. Fig. 286 is one foot seven inches wide, and three feet high, weighs 11 1/2 lbs., and costs 5s. 6d. Fig. 287 is one foot seven inches wide, three feet four inches high, weighs 20 lbs., and costs 6s. 6d. These windows have each, either ears in the centre, as at *a a*, figs. 285, 286, 287, by which they may be suspended, so as to open outwards at bottom, and inwards at top, or the contrary; or they have side-ears, to which hinges may be riveted, as at *b b*, in figs. 283 and 284. Fig. 288 is a superior description of

cottage window : it is two feet six inches broad, three feet high, weighs 34 lbs., and costs 15s. This sash is calculated for being fixed in the masonry, having in the centre a square of six panes, which opens for the admission of air. As it requires no window frame or hinges, it must be a very cheap substitute for the sash window. Mr. Laxton appears to have chosen the cheapest of these casements ; but, where ornament or style is thought worthy of attention, the Gothic or Grecian headed iron sashes, figs. 284 and 288, would still be found economical.

308. *Gardens.* We do not think it desirable that there should be a walk round this building close under the windows, because it would have a tendency to destroy privacy. We would rather give a small flower-garden or grass-plot, to each house, separated by low walls, and forming separate entrances through each plot, as shown in fig. 289. We

289

would by all means raise a terrace, two steps high, and four feet broad, round the whole, so as that the building might seem to stand elevated a little above the general surface ; and this would give the grass-plots or flower-gardens a slope outwards towards the walks

*c c*, &c. As the floors in the original plan, figs. 267 and 268, are already two steps above the surrounding surface, this terrace will occasion no other expense than the proper disposal of the earth which comes out of the foundations, the well, and the cess-pools. The kitchen-gardens, *d d*, would remain in the same positions as in fig. 267. We have shown a walk, four feet broad, round each garden, under the hedge, which may be of fruit trees, and we have placed the liquid manure tanks, *e*, in a situation which will be central to all the gardens. The emptying of these tanks should belong to each occupier in rotation. Nothing but useful plants and fruits will require to be grown in the large gardens, *d d*, &c., because the borders round the grass plots will be sufficient for flowers and ornamental plants. In order that this building may have a proper aspect, the diagonal of the parallelogram should form a north and south line, fig. 289, *s n*, (see § 24); however much the line of the front of the building may diverge from the line of the road. All that is necessary in this case is to include the building and its gardens in a parallelogram, one side of which coincides with the line of the road, as in fig. 290, in which *f* is the public road, and *g* is the building, in a parallelogram of exactly the same size as in fig. 289. Here it will be observed that the north and south line is at right angles with the public road.

309. *Ornament.* This building might be decorated, by surrounding it with a veranda, or a penthouse roof, which would give to each dwelling a covered walk during rain, or a hot mid-day sun, or under which clothes, herbs, or Indian corn, might be dried. The roof of this veranda or penthouse might be slated like that of the dwelling; and this would supersede the necessity of covering the entrance lobbies with slabs, as in fig. 267. Suppose the whole building surrounded by a penthouse roof; brackets placed under the eaves of the principal roof; Tuscan tiles used, and the common chimney pots supplanted by ornamental ones; the effect of the

291

whole would not be displeasing, fig. 291. Or if, instead of a veranda, Gothic porches were added to each entrance, as in the plan, fig. 292, and Gothic labels were placed over the lower windows, a Gothic character given to the doors, and to the cast-iron grating, and Gothic chimney pots added to the chimney tops, something ornamental in a different style would be produced, fig. 293.

Design XLII.—A Cottage of Three Rooms, in the Elizabethan Style.

310. *Accommodation.* From a porch, *a*, there are two entrances; one to a kitchen, *b*, with two light closets, *c*, *d*; and the other to a parlour, *e*, and a bed-room, *f*, with a closet, *g*. No out of door conveniences are shown; and they must therefore be supposed to be placed in a yard, at a short distance from the dwelling.

311. *Construction.* The walls are supposed to be of stone, and the roof covered with grey slates. The openings of the windows are shown with plain architraves or facings; and the sashes are modern, and hung with weights and pulleys. The porch is supported by a wooden column, which rests upon a square stone plinth, and has a plain capital. The chimney pots may be formed of cement, agreeably to fig. 294. The platform or terrace may either be finished with turf and gravel, or paved, as in Design XXXII., as may be most convenient in the given situation.

312. *General Estimate.* Cubic contents, 13,615 feet, at 6d. per foot, £340:7s.:6d.; at 4d., £226:18s.:4d.; at 3d., £170:3s.:9d.

313. *Remarks.* This is evidently an ornamental cottage, and certainly possesses some characteristics of the Elizabethan style. Were a cellar floor added, and the stair to it made in the closets *c* and *g*, the accommodation and convenience would be greatly increased; a small stair might be continued from the same situation to the roof, the space in which, as exhibited by the section, might be applied to various useful purposes. A garret, where there is a sufficient number of openings for ventilation

may always be made use of in the winter season for drying clothes, and in summer for drying green herbs, or seeds in the pod. In the larger houses in many parts of France, and in both large houses and cottages in most parts of Germany, clothes are always dried in the garrets. A decided improvement to this cottage would be an alteration in the position of the kitchen fireplace; by which means, by having a cast-iron back to it, it might be made to heat both the bed-room, *f*, and the parlour, *e*; either, or both, at pleasure. We do not think this mode so effectual as that by a flue under the floor, which, if a cellar story were added to this cottage, might be most conveniently adopted; but as it may be useful in the case of cottages with boarded floors, or with earthen or paved floors, so low, or otherwise so circumstanced, as that flues cannot be made in them, we shall show how the alteration may be made.

314. *Heating from the Back of the Kitchen Fire.* Suppose the fireplace of *b*, in Design XLII., to have a cast-iron back, three feet square, and that six inches of each end are built into the brickwork, as at *h h*, in fig. 295, then it is evident that whenever there was a good fire at *i*, a great portion of heat would be communicated to the space behind *o*; and that this heat might either be allowed to escape freely into both rooms, *k* and *l*, or confined by two doors, *m* and *n* (which may be wood), so as to admit the whole of the heat to either room at pleasure. By having a central door or movable partition in the situation of the dotted line marked *o*, the heat may either be equally divided between the two rooms, or half the heat may be admitted to one room, and none to the other, &c. By enlarging the size of the enclosure behind the cast-iron back, and by having an opening at the bottom of the doors, and another at the top, connected with an air flue in the wall, clothes may be dried in this closet with the greatest rapidity, and with very little labour. To increase the quantity of heat produced from these plates, when clothes are to be dried, or on other occasions when an extra-quantity of heat may be desirable, it is only necessary to place a plate of sheet iron, or a large slate, or even a well-seasoned board, at the back of the cast-iron plate, and separated from it about one inch; the plate being raised from the floor at the bottom, so as to leave a vacuity of half an inch, and another vacuity of the same dimensions should be left at the top, as represented in the section through both plates, fig. 296. The use of this additional plate is to confine the heating power or radiation of the cast-iron plate *p*, in fig. 296, and thus create a current in the vacuity *q*, on the same principle that water is boiled with greater rapidity in one of Perkins's double-bottomed boilers than in a common kettle. It must not be forgotten, however, that the additional quantity of heat procured by this means for the hot-air closet will increase the consumption of fuel in the kitchen fire; and also tend, by abstracting heat, to render the consumption of the fuel used there imperfect; but these are minor evils, compared with the saving of labour and the comfort which the judicious use of these cast-iron plates is calculated to afford. These plates, which are common in the north of France, have been introduced in the cottages on the estate of Closeburn, in Dumfriesshire, by its enlightened and benevolent proprietor, J. C. Stuart Menteach, Esq., who, having observed them in use on the Continent some years ago, immediately adopted them on his return home, with a degree of success altogether equal to his expectations and wishes.

Design XLIII. — *A Cottage of Three Rooms, with Back Kitchen, Cow-House, and other Conveniences.*

315. *Accommodation.* The plan exhibits an entrance porch, which serves also as a lobby, *a*; with one door opening to a kitchen, *b*; a back kitchen, *c*; and kitchen closet, *f*; another door opening to a bed-room, *e*, and bed-closet, *g*; and a third to a parlour, *d*. In a lean-to behind is an open shed, from which is an entrance to the dairy, *k*; and in the same lean-to there are a privy, *h*; pigsty or dust-hole, *i*; and cow-house, or root-cellar, *l*. There is a terrace shown round the building; but if the cow-house and pigsty are used as such, then the terrace may be limited to three sides, and the fourth enclosed as a yard. This is a very commodious and convenient dwelling, and would not

XLII.

Fl. 10 0 11 24 Fl.

XLIII.

be expensive or difficult to execute, either in earth or of rubble-stone. The parlour, *d*, might be very readily heated from the fireplace of the kitchen, *b*, by means of a cast-iron plate, as described § 314. The open shed behind will be found useful for various purposes, as well as being a passage of communication to the dairy, and having a place for fuel and lumber at the opposite end.

316. *An elegant improvement* would be, to remove the pigsty and the cow-house farther from the dwelling, and connect them by a covered way open at both sides, as in fig. 297, in which *m* is the dairy; *n*, the cow-house; *o*, the pantry; *p*, the water-closet

297

for females; *q*, that for males; and *r*, the passage which connects this wing with the house; *s*, a wicket gate, separating the yard from the passage, and from the platform on which the house stands; *t*, the yard; *u u*, tank for liquid manure and dung-pit; *v v*, pigsties; *w w*, inclined planes to the platform; and *x x*, grass-plots, which in some situations may be varied with flower-beds. It will be observed, at *y*, that we have altered the position of the steps to the terrace, and placed an open porch over the entrance. One advantage of this arrangement would be, that the terrace might be continued completely round the house; and, if it were thought desirable, as we undoubtedly think it would, the eaves might be made to project three feet, which would give a dry walk for infirm persons, or children, during rain.

317. *Construction.* The walls may be of earth; and, if it is found desirable, the whole of the floors may be heated from a flue from under the boiler, in the back kitchen, *c*; which, in this case, must have the space where the boiler is placed sunk three feet below the general level. The windows are shown with Gothic labels, and the door is ledged with ornamental hinges (fig. 298), on a scale of three fourths of an inch to a foot. The gable end is finished with a barge-board (fig. 299), to a scale of three eighths of an inch to a foot, but without a pendant or a pinnacle.

298

318. *General Estimate.* Cubic contents, 15,232 feet, at 6*d.* per foot, £380 : 16*s.*; at 4*d.*, £253 : 17*s.* : 4*d.*; and at 3*d.*, £190 : 18*s.*

319. *Expression.* Though we like the arrangement of this building in the interior, yet we by no means approve of the external expression. The projection of the roof at the eaves, which is here two feet, does not belong to the Gothic style; and to place labels over windows immediately under a far-projecting roof, is, in point of use, superfluous; since the original intention of labels was to throw off the rain from the windows, which is here already done by the eaves. The pitch of the roof is much too low for the Gothic or old English cottage, and is by no means suited for the ornamental barge-boards at the gable ends, which are never seen but against the ends of steep roofs. The windows ought to be of more lofty proportions, more especially as it appears by the section that they might be carried at least one foot higher; and, if they were lowered one foot, the window shelf would not be too low for use. The chimney tops rise

299

out of the roof without any preparation, which is always objectionable; and we do not think the position of the steps to the terrace particularly fortunate. If we were to alter

300

the ground plan, as in fig. 297, a very commodious and convenient cottage would be produced, and the elevation might then either be in the Italian, or modern style, as in fig. 300, or in the Gothic or old English manner, as in fig. 301.

301

Design XLIV. — *A Cottage of Three Rooms and a Back Küchen on the Ground Floor, with various Conveniences.*

320. *Accommodation.* In the ground plan may be seen an entrance lobby, *a*; kitchen, *b*; bed-room, *c*; parlour, *d*; closets, *e* and *f*; back kitchen, *g*; dairy or pantry, *h*; pigsty or dusthole, *i*; privy, *k*; and cow-house or root-cellar, *l*.

321. *Construction.* The walls may be of brick or stone; the copings and finishings to the walls, windows, and chimney tops, to be of the latter material, or of Roman cement. The chimney head cornice may be finished, as in fig. 302, to a scale of one inch and a half to a foot. The designer of this cottage recommends the roof to be covered with painted pantiles; the windows to be divided into three parts by two mullions, and each compartment to have one iron frame filled in with latticework. The surrounding terrace appears by the section to be formed of earth, and the floors seem to be paved.

322. *General Estimate.* Cubic contents, 12,330 feet, at 6d. per foot, £308 : 5s.; at 4d., £205 : 10s.; and at 3d., £154 : 2s. : 6d.

323. *Remarks.* The accommodations of this cottage are obtained at more than ordinary expense, on account of the numerous projections in the ground plan, and the consequent angles, hips, and valleys, in the roof. The style is somewhat Elizabethan; but it is hardly justifiable to raise the two pediments over the entrance door and right-hand window; when, according to the section, there can be no use whatever made of the roof. It will also be observed by the section, that the doors, even of the dairy and back kitchen, are six-paneled, which is not very consistent with the entrance door, that being only ledged. While there is this attention paid to the style of the doors in the interior, no cornices to the rooms are shown, nor any shelf to the kitchen chimney. In short, not to waste criticism on a design scarcely worthy of it, though there is something of style in the elevation, and of accommodation in the plan, yet the composition, taken as a whole, is not such as to be held up as an example for imitation, but rather as a beacon to be avoided.

Design XLV. — *A Dwelling of Four Rooms, with Back Kitchen, and other Conveniences.*

324. *Accommodation.* From the entrance passage, *a*, a door opens to the kitchen, *b*, which is connected with the back kitchen, *c*, on the one hand, and with the bed-room, *d*, on the other. There is a parlour, *e*, and another bed-room, *f*, with a closet, *g*; and, in a lean-to, we have a cow-house or root-cellar, *h*; pigsty, *i*; and privy, *k*. Should the cow-house and pigsty be occupied as such, then it would be necessary to have a yard joined to that side of the house, and to alter the slope of the platform within it, as in similar cases. Some use may be made of the roof by a trapdoor in the ceiling of the kitchen, and the whole may be heated from a fireplace in the back kitchen.

325. *Construction.* The walls may be of brick or stone; and the panels, shown in the elevation, either executed in the brickwork or formed in cement. The roof is low in pitch, and it is proposed to cover it with slates. The chimney stack is large, containing four vents or flues; it has a sunk panel in the lower part, which, with the cornice at its termination, will be understood by the vertical section fig. 303, on a scale of half an inch to a foot. The section fig. 304, to a scale of half an inch to a foot, shows the projecting frieze, under the eaves of the roof, which is supported by the paneled pilasters. The door is paneled, and the windows are in the modern style, with sashes hung by lines, weights, and pulleys, &c.

326. *General Estimate.* Cubic contents, 13,700 feet, at 6d. per foot, £342 : 10s.; at 4d. £228 : 6s. : 8d.; and at 3d., £171 : 5s.

327. *Remarks.* There is a simplicity and grandeur in the elevation of this cottage, which raises it above the character of a dwelling of the humblest class. The massive chimney stack corresponds well with the simplicity of the roof; the effect of which is supported by the smaller, but similarly formed, roofs of the projections at the ends. The paneled pillars or pilasters, with the cornice over them, have

a massive and architectural effect, forming a very complete system of vertical and horizontal bond or chain work, as the French term it; and they are supported and harmonised by the horizontal panels in the chimney stack. Where the perfection of architectural expression is aimed at, all walls should be built either on the principle of vertical and horizontal bond, by projecting piers and horizontal bands; or, on that of squared stones or bricks, with or without piers and bands. The pretensions of a wall to strength would thus, at all times, be obvious at a single glance. By altering the destination of some of the parts of the ground-plan, this building might be rendered fit for the habitation of what is called a genteel family. Thus, *h* and *i* might be joined in one, and form a small bed-room or book-room, to the parlour, *e*; and *h*, in like manner, might be made a bed-room, or a dressing-room, connected with *d*. The appendages, *h*, *i*, *k*, might be got in a separate building, connected by a lattice-roofed arcade, covered with ivy, from the door of *c*.

Design XLVI. — *A Cottage Dwelling, with Four Rooms, with a Back Kitchen, Cellar, and other Conveniences.*

328. *The accommodations* of this dwelling are, as usual, a kitchen, *a*, with closet under the stair, *h*; back kitchen, *b*; parlour, *c*; bed-room *d*; cellar, *e*; dusthole, or place for fuel, *f*; and privy, *g*: there is a bed-room over the kitchen; and two useful garrets, one over *c*, *e*, *f*, and the other over *b*, *d*, *g*, which may be lighted from the ends. The apartment *e* may, in this, as in most of the other Designs, be used either as a cellar or a cow-house, or a place for keeping fuel and lumber; or as a receptacle for potatoes and other roots, or whatever may be most desirable in the given locality. We are of opinion that in most parts of Britain it will not be found profitable for the labourer to keep a single cow; but we are aware that in most parts of Scotland and Ireland, as well as in the north of France, the cottager never thinks himself comfortable without one. We are aware, also, that there are objections to having a cow-house and pigsty too close to a dwelling; but it will be recollected that much depends on the manner in which these animals are kept; and that, by disposing of the liquid part of the manure in the manner we have directed, and having the door of the cow-house so far apart from the door of the house as we have always shown it, the practical inconvenience would not be felt. We think the apartment for a cow ought to be added to all cottages not having a cellar, because, if not used for the former purpose, it may be applied to the latter; and a cellar is almost every where a great source of comfort to the cottager.

329. *Construction.* The paneled piers may be built of stone in courses, or of brick; or they may be framed of wood, and filled in with brick, and covered with cement. The same may be observed as to the architrave which rests on these piers or pilasters, and supports the roof. The interspaces between the pilasters may be formed of pisé, of brick or clay nogging, of rubble stone, of pebbles, of flint, or, in short, of any material which will support its own weight, and be of sufficient thickness to keep out the weather, and maintain a steady temperature; for the weight of the roof in this Design, and in Design XLV., is supposed to be carried by the piers. As a good deal of the beauty of this, and indeed of most designs for cottages showing pilasters, depends on the materials with which the panels or cementitious part of the wall is filled up, we shall here introduce a few remarks on the materials for walls, with a view of directing the reader's attention to the subject.

330. *Materials for Walls.* The design, the style, the accompaniments, and all other circumstances, being the same, the effect of the walls of a cottage being of squared stone, of rubble stone, of red, yellow, or white bricks, of flints, of pebbles, of mud, or of boards, will be very different; and more so to the ordinary spectator than to the artist, or to the eye accustomed to study the effect of forms, shades, lines, and colours, in some measure, independently of materials. The nature of the material, therefore, of which the walls of a cottage are built, is a fertile source of variety, where several cottages are to be built on the same estate; or where a village is to be formed, in which variety of character in the

XLIV.

XLV.

buildings is an object. As a general principle, it may be affirmed that the materials of the walls of a cottage ought always to be such as are, or may be, furnished by the soil or vicinity where it is placed. In this point of view, mud, pisé, brick, and timber are the most universal materials for cottage walls; and, next to these, small land stones, so far broken or squared as to incorporate in a wall built either on the bond or on the cementitious principle of construction. Among the land stones of a country are included the shale, scales, or shivery stone, of some districts, and the pebbles and flints of others. We shall here confine ourselves to giving short directions for forming a flint wall; and we shall take them from the *Landscape Architecture of Italy*, by Gilbert Laing Meason. Before we give this quotation, however, we wish particularly to impress on the minds of our readers the necessity of having coignes and other supports of the roof, which shall act on the principle of independent strength, in all cases where the walls are to be formed of pisé, mud, pebbles, flint, or, in short, of any material, the strength of which depends upon the cementitious principle; that is, on the plasticity, when used, of a part of the materials. This Design and the preceding one are examples of this mode of construction, and these remarks are introduced here incidentally; but in the systematic part of our work the subject will be treated in detail, and it will then appear to be one of very great importance, though very little understood.

331. *Flint Walls.* "In the chalk countries of England, why may we not renew the flint-built walls of our ancestors, seeing that the Roman circus at Toulouse has endured so long? Build up the flints in frames, and pour cement into the interstices; the foundation should be on brick arches; and the cement employed may be composed of thoroughly burnt chalk, slacked with water, to reduce it to the finest dry powder; and then sifted, and added to two parts of rough sharp sand, with small sharp gravel stones. The whole should be mixed together dry, and then a sufficient quantity of water should be poured upon it to make it into a liquid paste, which should be used immediately. The slacking of the lime, the mixture, and the application to the walling, should follow one another without delay. A quantity of the sand and powdered lime ought to be at hand to throw into the moulds, in case the mortar should appear too thin. By such management this cement requires not age to harden it. On examination of the oldest parts of the ancient castle at Hastings, we are satisfied that the mortar employed was so formed, and thrown, in a very liquid state, into the centre of the thickest parts of the wall. Flint-built walls would produce an excellent effect in irregular buildings; for the roughness of the surface, in towers, gives the impression of strength and stability."

305

332. *General Estimate.* Cubic contents, 12,563 feet, at 6d. per foot, £314 : 1s. 6d. ; at 4d., £209 : 7s. : 8d. ; and at 3d., £157 : 0s. : 9d.

333. *Remarks.* The arrangement of the plan of this cottage is not favourable to economy in its execution, from the greater length than breadth of the body of the building, from the breaks and recesses in the walls, and from the raised part of the roof. All these deviations from the cube, which, it will be recollected, is the perfect form, increase the expense in proportion to the accommodation afforded. There can be no doubt, however, that this would be a comfortable building, because the heated air from the kitchen, *a*, would always keep the bed-room over it warm ; and the fire both of the kitchen and the back kitchen might, by very little contrivance, render a fire at all times unnecessary in the room *d*, which might, according to circumstances, be made a shop or a parlour. Were it desirable to enlarge this dwelling, it might be done with great effect, by opening the door from *a*, as in fig. 305, in which *i* is the additional room ; *k*, a small court-yard, containing the pigsty, *l*, and liquid manure tanks, *m* ; the apartment *e*, in Design XLVI., being considered in this ground plan as a cow-house. We have shown a walk, *n n*, surrounding this cottage, which leaves between it and the slope of the platform a border of an irregular width, *o o*, &c., which may either be covered with turf, or with shrubs, flowers, and two or three trees. Like Design XLV., this building, presenting a simple outline against the sky, is well adapted for a situation where it would be backed by a broken outline of wood. Having no windows in the ends, it is also better adapted for being viewed in front only, or chiefly, than for being seen on all sides.

Design XLVII. — *Two Cottages for Country Labourers, under One Roof, with Four Rooms in each, Back Kitchen, Pigsty, and other Conveniences.*

334. *Accommodation.* Each of these dwellings contains an entrance lobby, *a* ; kitchen, *b* ; back kitchen, *c* ; parlour or best bed-room, *d* ; staircase, *e* ; dairy, *f* ; place for fuel, *g* ; cow-house, *h* ; privy, *i* ; and pigsty, *k*. The chamber floor of each house contains a bed-room, *l*, with a landing, *m*, from the staircase, *n* ; and another bed-room, *o*. We have not shown the yard which would be necessary to the cow-house and pigsty, as we think it more probable that these appendages will be applied to other purposes.

335. *Construction.* The walls may be of stone ; but, as they exhibit few breaks or angles, they might be very advantageously built hollow, with bricks on edge, in Dearn's manner. In a country where fuel is abundant, we should recommend the floors of the kitchen and parlour to be of boards ; but where fuel is scarce and dear, or chiefly wood, we should prefer having the floors paved, in order that they may be heated by a flue from the back kitchen. Or, a flue may be made above the floor, so as to form a bench, in the Chinese manner (*Mech. Mag.*, vol. iv. p. 362.) ; in several returns one over another, so as to form a stove, in the German manner ; or in one of the partitions, as in the flued walls of gardens. Having recommended Dearn's mode of hollow walls as applicable to this building, we shall here proceed to describe it.

336. *Dearn's Method of building hollow Brick Walls.* The manner of bonding the work is shown in fig. 306, which is an elevation and section of part of a wall. "The three

306

lower courses, *q*, the upper one of which is proposed to be level with the floor, are intended as a footing to the superstructure, and are laid in what is called the old English manner, consisting of alternate courses of headers and stretchers. The next course above is a stretching course on edge, *p*, and the backing course is like it, leaving an interval between of the width of half a brick ; these are then covered with a heading course, *r*, laid flat ; and the same system is pursued until the whole height required be

XLVI.

XLVII.

attained. Fig. 307 is a plan taken on the upper course of the footing, showing the manner of bonding the angles. The dotted lines denote the course above, of heading bricks laid flat. The two bricks on edge marked *s s*, at the angle, will be reversed in each other course. Fig. 308 displays the manner of introducing a girder, *t*, into walls thus constructed. To support the stress of the girder, the intervals in the walls below it, *u u*, are filled in solid with brickbats from the footing to the course on which the girder, *t*, rests, by which means a solid pier is formed, nine inches wide. In the course on which the girder lies, it is proposed to introduce a piece of timber, *v*, for it to rest on, nine inches long, four inches wide, and two inches and a half thick. Mortises for the joists are shown in the girder at *w w*. Fig. 309 shows the elevation of part of a building of this kind, in which a doorcase and a window frame are introduced: these are proposed to be of the same scantling as usual; viz., window-frames, two inches and a half by two inches and a half, and door-cases four inches by three inches; but in order to conceal the hollows in the wall, it will be necessary to tack in a fillet in the front or back of each window and door-case. In order to secure the frames in the wall, a piece of inch stuff, four inches square, may be attached to them at *x x*, by screws; the heads of the screws to be on the outer side, that the frames may be taken out at any time, if found necessary, without injury to the brickwork. To take the weight from the heads of these frames, a lintel, four inches square, may be placed within the brick on edge course, marked *y y*, extending nine inches beyond the opening on each side.

337. *Economy and other Advantages of Dearn's hollow Walls.* First, a saving of one third will arise in the article of bricks; that is, if 4500 would have been required to complete a rod of reduced work in the common way, 3000 will be found sufficient according to Mr. Dearn's method: secondly, only one half of the mortar will be requisite: thirdly, the labour will not be greater than for common brickwork, though it will include rubbing the bricks in the heading course to one length, in order to supersede the necessity of rendering (plastering) within, and to leave the walls with a fair face ready for whitewashing or painting in oil: fourthly, the hollows in the walls will prove an antidote to damp: and, fifthly, all the expense of inside plastering will be saved.

338. *Dearn's proposed Variation in his Method of building.* Instead of the brick on edge course, half bricks may be used as stretchers, figs. 310, 311, and 312; the bricks being divided longitudinally, by drawing a knife or other sharp instrument about half through them, while in a state between wet and dry, and giving each a slight stroke of the trowel on the reverse side, to separate the halves, after it has been burned. This is done, partly because, if the halves were entirely separated before being

burned, the bricks would (in Britain) be subjected to a double duty; and partly because the half bricks, thus treated, cost less, and are less liable to warp in the kiln, than if moulded separately. A fair charge for removing bricks from the hack (the stock or pile on which they are placed to be burnt), with the cutting and replacing them, is 5s. per thousand. With respect to bonding the work, it may either be carried up in the old English manner (see § 336, and fig. 306); or in the Flemish manner: that is, having an alternate header and stretcher in each course; as the air may be made to circulate freely through the walls in both ways. The bond at the angles is shown in fig. 310; and fig. 311 shows the appearance of the work in elevation. Fig. 312 is a section in which at *a* is shown the footing, and three courses above it, carried up solid, with a drain brick, *b*, set in cement on a level with the supposed floor of the house. The use of this course of draining bricks is to carry off any water that might at any time find its way into the vacuity, when this mode of building is used in walls under the level of the ground.

339. *Dearn's Mode of building Fourteen-Inch hollow Walls.* When the thickness of the walls is proposed to be fourteen inches, the stretching course may be of whole bricks, instead of half ones, and the heading course may be bricks fourteen inches long, which are frequently made for the purpose of coping dwarf walls; but, should economy be the main object, Mr. Dearn proposes to use half bricks for the stretchers, which, he says, will produce a wall strong enough for all ordinary purposes; and which will only require some degree of management when used for underground walls, when it will be necessary to take care that the lateral pressure of the soil outside does not throw the wall off the

XLVIII.

XLIX.

perpendicular. Where there is any danger of this (which can only be when the foundations are made in very soft ground, or where the outside walls of a house are to be earthed up, in order to form a terrace), he directs the builder to extend the excavation, in those parts where the evil is anticipated, to a distance of not less than three feet six inches beyond the proposed face of the wall; and, as the brickwork is carried up, to fill in the earth not more than one foot thick at each time; to ram it well, and at each interval to introduce a thin layer of *green faggot*-wood, with the butt-ends to the wall: the ground thus made will unquestionably be found to settle; but there can be little or no stress on the wall, the lateral pressure being directed by the faggot-wood to the natural earth opposite."—*Hints on an improved Method of Building, &c.*, p. 36.)

340. *Dearn's hollow Walls, applied to the heating of Green-houses, as hot Walls for ripening Fruit, and for warming Barracks, Workhouses, &c.* Mr. Dearn thinks that conservatories, vineries, &c., attached to houses thus constructed, may be heated without much expense, if placed against or near the back of the kitchen fireplaces. For this purpose he proposes to form the back of the range of a plate of cast iron, not less than one inch thick, open on the reverse to the hollow in the wall. From this plate such a degree of heat would be diffused throughout the whole extent of the wall, as would probably be sufficient to preserve the tenderest plants in the most inclement seasons, and to forward vines as much as a common forcing-house. The heat might be regulated by an opening in the wall externally, either above the conservatory, &c., or on the side, as the case should require. Barracks, workhouses (commonly so called), houses of industry, and manufactories, built according to Dearn's method, may also, he conceives, be warmed, without any additional expense, and the heat so regulated as to answer the various purposes required. (*Ibid.* p. 37.) In our *Treatise on Country Residences*, 4to, 1816, we gave a plan of a house, with a large conservatory and vinery attached to it, both heated from the fires of the living-apartments, the kitchen, and the offices; and showed by the section, fig. 313, a very efficient mode of abstracting heat from cast-iron plates at the back of the different fireplaces. We have since put the plan in practice (in 1817); and it is but candid to state that we cannot recommend it either in point of comfort or economy. In point of comfort, it is objectionable, on account of the great quantity of heat which is drawn off, and the consequent necessity of attending constantly to the fire; and in regard to economy, the same abstraction of heat renders the consumption of the fuel, especially coal, very imperfect; and, consequently, more is required to produce any given temperature, than would be case were the back and sides of the fireplace either of fire-brick only, or of iron plates with solid masonry behind them.

341. *General Estimate.* Cubic contents, 27,760 feet, at 6d. per foot, £694; at 4d., £462: 13s. : 4d.; at 3d., £347.

342. *Remarks.* This Design is well calculated for being executed at a very moderate expence. The span of the roof not being more than 14 feet, timber of very slight scantling may be used both in the floors and in the roofing; and the walls, as we have seen, need not be wider than nine inches, and may be built hollow, either in the manner detailed, Chap. I. § 25; or according to some one of the modes just described. If it were desired to ornament such cottages, it might be readily done by placing chimney pots on the stacks, by porches, or by a veranda; in either case, adding a parapet to the terrace. The ends of both cottages, being without windows, may be covered by vines or fruit trees; and a few China roses may be planted along the front.

Design XLVIII. — *A Dwelling of Four Rooms, with a Back Kitchen, and other Conveniences.*

343. *Accommodation.* The ground-floor consists of a lobby and staircase, *a*; kitchen, *b*; back kitchen, *c*; dairy, *d*; parlour, *e*; bed-room, *f*; water-closet, *g*; and cellar, *h*. The chamber floor contains two good bed-rooms, *i* and *l*, with the staircase, *k*, between them.

344. *Construction.* Dwellings in this style are common in various parts of Gloucestershire, and other parts of England, where freestone is abundant, and easily worked.

They are generally covered with a grey slate, and the walls are in regular courses of tooled stone. As the inner part of these walls is generally built of rubble, they cannot be considered strong; unless, indeed, a mortar were used capable of becoming as hard as the stone itself, or at least as Roman cement. To add to the strength of such walls, what are called string courses are introduced in them; one of which may be observed in the elevation of this Design, as a horizontal band between the ground floor and bed-room windows. This band, horizontal chain, or string course, is supposed to be formed of stones of a sufficient width to cover the whole wall, and by that means to tie it together: and this, if the rubble part of the wall has been properly built, it will effectually do. If, on the other hand, the rubble stones have been small, and have not had true bearings, (that is, flat surfaces resting horizontally on each other), these string courses will add very little to the strength of the wall. When the reader comes to that part of our work which treats upon the principles of construction, he will find, what will probably surprise him, that the strongest, as well as the most durable, of all walls for dwelling-houses, are those of well burnt brick, covered with Roman cement without and plaster within. Even without these coverings, brick walls are stronger and more durable than stone walls, as the latter are generally built. There can be no doubt that stone walls might be, and sometimes are, so constructed for dwelling-houses, as to be stronger than common brick; but the expense, except under very peculiar circumstances, is too great for general use.

345. *General Estimate.* Cubic contents, 24,548 feet, at 6*d.* per foot, £613 : 14*s.*; at 4*d.*, £409 : 2*s.* : 8*d.*; and at 3*d.*, £306 : 17*s.*

346. *Remarks.* The rooms in this Design are of a convenient size, and the dwelling may be considered as suitable for a gardener or other upper servant. For effect, we should have preferred three lights in each of the bays of the kitchen and parlour, and no windows on the other side of these rooms. We say, that, for effect, we should have done this; but, for convenience and use, it is better that the light should enter on two sides, because two parties may then work at two different windows. Respecting the situation of this building, its contributor observes that it "should be placed on rather an elevated spot, thickly covered with wood. When the outline of a building is so constructed that the various projections throw a mass of shade upon the receding parts, then the object itself forms an independent picture; but in buildings of a plain unbroken outline, such as this cottage, some assistance is wanted to produce the picturesque; and trees will be found efficient auxiliaries in accomplishing this effect."

Design XLIX. — *A Dwelling suitable for a Lodge or Toll-house, having Three Rooms, and other Conveniences.*

347. *Accommodation.* The ground floor consists of an outer kitchen, which serves also as an entrance-lobby, *a*; large kitchen, or living-room, *b*; light bed-closet heated from the back of the kitchen fire, *c*; pantry, *d*; closet for fuel, *e*; cellar for roots, *f*; privy, *g*; dusthole, *h*; stair to the bed-room floor, *i*; and open shed, *k*. The chamber story contains two bed-rooms, *l m*, and the landing of the staircase, *n*.

348. *Construction.* The walls be may of brick, and the roof covered with tiles or slate. The cornice of the principal part of the building may contain a gutter cut in the stone, similar to that shown in the section fig. 40, § 74, if that material should be abundant; otherwise, the cornice and gutter may be of wood, as shown in the section fig. 63, § 84.

349. *General Estimate.* Cubic contents, 11,315 feet, at 6*d.* per foot, £282 : 17*s.*; at 4*d.*, £188 : 11*s.* : 10*d.*; and at 3*d.*, £141 : 8*s.* : 9*d.*

350. *Remarks.* The expression of this dwelling seems to aim at something more than a simple humble cottage, because it may be said to have a centre and two wings, like a cottage villa, or like what in Scotland is called a minister's house; yet there is no attempt at architectural style, either in the general forms or the ornaments. We leave our readers to contrive different modes of altering or adding to it, so as to make it more attractive without, and more convenient within.

Design L. — *A Cottage Dwelling of Four Rooms, with other Conveniences.*

351. *Accommodation.* On the ground-floor there is an entrance and staircase, *a*; parlour, *b*; bed-room, *c*; closet under the stairs, *d*; pantry, *e*; light bed-closet, *f*; and kitchen, *g*. The wash-house, privy, and other conveniences, are supposed to be in a separate building. The chamber floor contains a bed-room, *h*, and two closets, *i* and *k*.

352. *Construction.* All cottages having no cellar floor may have the walls built of rammed earth, on a brick or stone foundation; though we would never recommend earth where brick or stone can be afforded. The roof is shown with a considerable projection at the eaves, and it is covered with Grecian tiles.

L.

Ft. 10 0 20 Ft.

LI.

10 0 20 Ft.

353. *General Estimate.* Cubic contents, 15,704 feet, at 6*d.* per foot, £392 : 12*s.* ; at 4*d.*, £261 : 14*s.* : 8*d.* ; and at 3*d.*, £196 : 6*s.*

354. *Remarks.* The expression of this dwelling is agreeable, and the tiles give it somewhat the air of an Italian cottage. The windows, however, are modern, and the chimney tops are such as are used in various manners. As picturesque effect appears to have been studied in forming the Design of this cottage, we rather wonder that no porch was placed over the door, which would have added much to its beauty. It is true, the far-projecting roof will, in some measure, compensate for the want of this part of an edifice ; but we do not think it ought ever to supersede it. It is curious to observe, in the ground plan of this Design, the preference which the designer gives to irregular beauty over that which is regular. Had his object been to produce a regular symmetrical building, he might have done so out of the same extent of walling, by adopting the ground plan fig. 314. By this arrangement, *f* and *g* are greatly enlarged ; and a commodious back kitchen, *h*, linen closet, *i*, and a porch, *k*, are added. The apartment, *c*, will then become the kitchen (instead of *g*), and the pantry, *e*, and the back kitchen, *h*, will open into it. The space over *e*, *f*, *g*, and *i*, when equally divided, will afford two good bed-rooms in the chamber floor. The superficial surface of the ground occupied by this improved plan (fig. 314) is 1292 feet, while that of the original ground plan is only 875 feet. This difference will,

of course, occasion an additional surface of roofing ; but, as it is the angles and breaks of a roof which are the most expensive parts, the cost will be very nearly the same ; the improved plan approximating much nearer to the form of a cube, and requiring only a plain roof. The lineal length of external walling, or the girth of the building, is 135 feet in both plans, and the internal walling is but little increased in the improved one. Thus, the second plan, though containing so much more accommodation, would cost very little more than the first ; for though the cubic contents of the building, according to the improved plan, will be 17,664 feet, while those of the original Design were only 15,704 feet ; it must always be

remembered, by those who wish to make an estimate of the expense of, or to fix a value upon, buildings measured in this manner, that the contents of the original Design would require to be calculated at 5*d.* or 5½*d.* per foot, while those of the Design fig. 314 from its nearer approximation to a cube, and the simplicity of its roof, need not be estimated at more than 4*d.* or 4½*d.* per foot. The elevation of a building constructed according to the improved plan, would not be so picturesque as that of the original Design, but we do not think that it would be less beautiful. And why would it be less picturesque ? Because it would have less irregularity of form, of outline, and of light and shade ; and, consequently, of that kind of beauty which is more particularly adapted for transferring to paper, or to canvass : it would, therefore, not form so marked a character for the painter ; in the same way as a plain honest man would not afford so good a study for a novelist, or so interesting a subject for a biographer, as a man of irregular features, both of mind and character. Let it be observed, however, that we do not object to the irregular style of beauty, for those who can afford it : all that we mean to say is, that it is neither so economical to erect, nor so easy to keep in repair, as the symmetrical style ; and that, as we have frequently before stated, symmetry is the soul of Architecture.

Design LI. — *A Cottage Dwelling, with Six Rooms and other Conveniences.*

355. *Accommodation.* There is a good entrance porch, *a*, with two doors, the one to be kept shut when the other is open, to protect the interior from the weather most likely to penetrate into it. From this porch there is a door to a room, *b*, which might be used as a workshop for a tailor or shoemaker, or other similar trades, in the country ; as an infant school on a small scale ; as a shop ; or let off as a bed-room. There is a kitchen, *c*, communicating with the bed-room, *d* ; a back-kitchen, *e* ; and an ante-room, *f*. This ante-room may be used as a small green-house, or as a china closet, if the cottage were occupied by what is called a genteel family ; or if it were used as a public house, it would make an excellent bar ; or, for a private family in humble life, it might be a

314

child's bed-room, or a pantry. The parlour, *g*, communicates with the bed-room, *h*. The privy and other conveniences are supposed to be contained in a separate building on the outside of the garden.

356. *Construction.* The walls are shown of a proper thickness, for being built of earth, or of rubble stone, or of any description of cementitious wall without chainwork; that is, without what in carpentry are called ties and struts. The roof may be covered with slate, and finished, as in fig. 68, § 84.

357. *General Estimate.* Cubic contents, 16,848 feet, at 6*d.* per foot, £421 : 4*s.*; at 4*d.*, £280 : 16*s.*; and at 3*d.*, £210 : 12*s.*

358. *Remarks.* This is an example of an irregular, and yet not picturesque building, and of a good deal of accommodation without convenient arrangement. The plan is irregular, from the projection of the two bays of the apartments *f* and *g*; and from the projection of *d* and *h* beyond the line of frontage of *e*; but the regular pentagonal sides of the bays, and their tame roofs, present nothing strikingly irregular in the elevation. There is nothing irregular or picturesque in the roof, nor in the porch, which occupies too large and important a portion of the main building for its use. Bay windows are great additions to the cheerfulness of rooms when they have lights on three sides, and this they always used to have in Britain, till the great increase of window-duty, during the war with Bonaparte, rendered bay windows with three lights too expensive for the middle classes, not to speak of the lower. Bays, with only one light, as in the Design before us, are neither handsome without, nor cheerful within; and, in a cottage, the gain in point of room is by no means commensurate with the expense. In point of expression, bay windows of three lights convey ideas of ancient times; because the forms of the windows, in that case, are different from what they are when only one window is placed in the centre of each bay. In the Design before us, the modern window in the bay seems misplaced and incomplete. However, we have here the materials for a good comfortable dwelling. Let us suppose the central bay, *f*, made a central porch; the bay of *g* placed in the centre of that side of the room; the porch, *a*, turned into a pantry; and the bed-room, *b*, made to open from the kitchen. We shall then have the leading features of a good plan, fig. 315: and by adding a place for fuel, *i*; a privy, *k*; and carrying out the front wall of *e*, we shall have a dwelling fit for any person to reside in, all other circumstances, such as situation, aspect, dryness of floors, &c., being favourable. The elevation, at very little expense, might be rendered handsome, fig. 316. No particular

description is given of the garden, as it may be laid out and cultivated in the same manner as any of the gardens already described; as, for example, that of Design XIX. § 170.

Design LII. — *Ideas for altering the Front of an old Cottage, at present in a dilapidated State.*

359. *Present State*, fig. 317. The contributor of this Design observes that fig. 317 is an unsightly cottage, standing at the extremity of a village, and close to the gates of a venerable mansion built in the reign of James I., and much admired both for its antiquity, and the elegant comfort of its interior. He says: — “As I have the pleasure of being occasionally useful to my friend in some of his plans for improvements, he consulted me as to the way in which he might give the cottage a more agreeable appearance; and I suggested the alteration shown in fig. 318, which may serve as an example in what manner a cottage, with the inside sufficiently comfortable, may be altered, so as to change an ugly outside, at little trouble and expense, to one that is picturesque and pleasing. The house is convenient enough within, and has some very comfortable rooms; but as there is nothing in all this very remarkable, I will not trouble you with the ground plan.”

360. *Improved State*, fig. 318. “The object in the above alteration is, to break the straight horizontal lines, and thus improve the appearance of a very ugly roof. This is done by introducing a pediment, or gable, with barge boards over the centre window, and by bringing the roof lower down at the eaves, so that the upper windows may be let into it. The carcass of the house being a wooden frame filled in with clay nogging and plaster, the wall of the additional gable is constructed in a similar manner. By way of giving consequence to this dwelling, the style of the entrance door is improved, and a common window changed into a bay one.”

361. *Remarks.* The alterations are, no doubt, improvements; but there does not appear a sufficient reason, on the principle of utility or accommodation, for the introduction of the pediment or gable. If the window under it had been carried up half way into it, this sufficient reason would have been given at once; and no one, we think, can deny, that even the appearance would have been improved. Architecture is a reasoning art; that is, it is an art in which nothing should be introduced for which there is not a reason either real or apparent. A real reason is best; but, when we have not that, we should at least have its substitute. There is no reason in fig. 318, for the pediment, except that given by the author of the Design, which we hold in this case to be insufficient.

Design LIII. — *A Cottage for a Village Tradesman.*

362. *Accommodation.* This Design was made for a shoemaker, who wanted only three rooms on a floor. It was intended to be a corner house; and to contain, on the ground floor, fig. 319, a kitchen, with oven and boiler, *a*; parlour, *b*; cellar, under the stairs, *c*; pantry, *d*; shop, *e*; and privy, *f*. If it were desirable, a lean-to back kitchen or wash-house might be built in the situation of *g*. The chamber floor contains three rooms. Fig. 320 is the elevation.

363. *Construction.* The walls are supposed to be built of "brick and flints, in alternate squares. This mode of building with a mixture of stone, brick, or even chalk, with flints, is common in

several counties in England, and has a very picturesque effect, either with the different kinds of materials in alternate layers, or in squares, as in this Design. When chalk-stone forms one of the materials used, the roof should always project a good way over

the walls, to protect them from the rain; in which case, even if the chalk should be so soft as to yield to the impression of the nail, it will last very many years. The roof is thatched; the gables have stone tablings (barge stones), and the summer stones are cut in the form shown by *h*, in fig. 321. Sometimes the tabling, *i*, is formed of brick, but the summer stones are always required to be of stone. Figs. 322 and 323 are sections of stone window mullions, such as are common in the neighbourhood of Salisbury, and which are there considered very ornamental. Where stone is too expensive, these mullions may be made of wood. Fig. 324 is a plan of the chimney tops."

364. *General Estimate.* Cubic contents, 12,336 feet, at 6*d.* per foot, £303 : 8*s.*; at 4*d.*, £205 : 12*s.*; and at 3*d.*, £157 : 14*s.*

365. *Remarks.* The shoemaker, we are informed, "preferred being his own Archi-

tect; and erected a cottage of three rooms on a floor, fig. 325; and these all in a row. His kitchen and common sitting-room, *k*, is thus rendered a perfect temple of the winds. There are a door and window to the north, and the same to the south; besides three other doors, making of doors and windows no less than seven in a room only fourteen feet square. He also contrived to have the stairs come down by the parlour fireplace, *l*; and two of the bed-rooms above necessarily became passage rooms to the third. I mention this, to show how little notion people of this class have of comfort in houses."

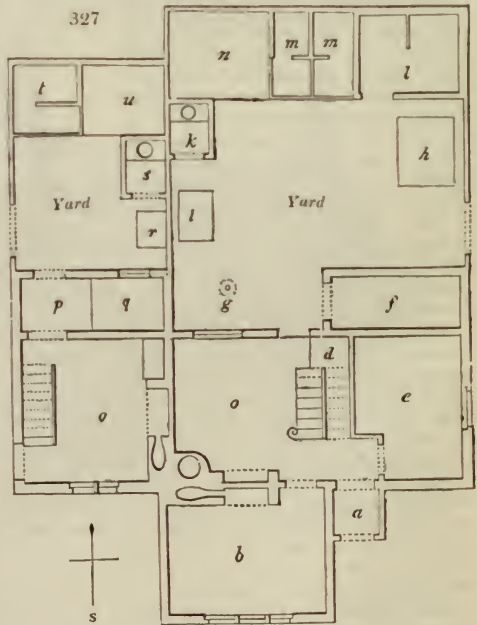

366. *Criticism.* When different kinds of materials are introduced into the walls of a cottage, some principle of fitness, independent altogether of picturesque beauty, ought to regulate the manner in which they are disposed. Where the specific gravity, hardness, and tenacity of the materials are equal, they may yet differ in their size, and in their form, or in the applicability of their surfaces. In this case, vertical bond in the form of piers, and horizontal bond, in the form of lintels or string courses, ought to be constructed of the large and flat-surfaced materials; while those of smaller size and less regular shapes should be used to fill up the blank compartments so formed. In the walls of a house composed of flints and chalks, greater strength will be produced by chalk over chalk, and flint over flint, than either by the mixture of these, or by their position in alternate layers, or squares. The picturesque beauty of such an arrangement will, we think, be at least equal to that of fig. 320; while it will have that most satisfactory beauty in addition, the beauty of fitness. In fig. 326 we have supposed the walls built of the same materials as those of fig. 320; but we have disposed them agreeably to what we consider the principles of architectural fitness, or, in other words, of sound architectural construction. There was no occasion for having the window of the bedroom over the parlour in the roof, when it might have been in the gable end; and that the fireplace is rather unfortunate in being placed in an outside wall. We should have placed it against the stair, for the sake of the heat to the staircase, and the rooms above; though we acknowledge that, in point of appearance in the interior of the sitting-room, it has a better effect where it has been put by our contributor. We believe that the greater number of our readers will prefer the fireplace where it is for another reason, and that is, having the chimney shaft as a termination to the gable end. This is good and reasonable, when we look no farther than commonplace ideas of external effect; but when we look at it with the eye of improved reason, and reflect that all fireplaces and flues in outside walls waste great part of their heat in the external atmosphere, and besides often do not draw well, we discover a reason why it would have been more beautiful, rising from some other part of the building, which might indicate that the flue was in an internal wall. Thus it is that taste, to be correct, requires to be founded on reason.

Design LIV. — Two Cottage Dwellings for Labourers, under One Roof.

367. *Accommodation.* The larger dwelling, fit for a man with a large family, will contain three rooms on a floor, with a cellar under the stairs, and a wood-house behind; besides a cow-house, pigsty, &c., in a small farm-yard. The smaller dwelling is intended for an old couple, and contains only two rooms. The details of the larger dwelling are as follow:— *a*, the porch; *b*, the kitchen; *c*, the back kitchen; *d*, the steps down to the cellar under the stairs; *e*, the dairy and pantry; *f*, the wood-house; *g*, the pump; *h*, the hay-stack; *i*, the wood-stack; *k*, the privy; *l*, the cow-house; *m m*, two pigsties; and *n*, the dung-pit. In the chamber floor there are three bed-rooms, over *b*, *c*, and *e*. The smaller dwelling contains a kitchen, *o*, with an oven on one side of the fireplace, a closet on the other, and a pantry under the stairs; a back kitchen, serving as a wash-house, *p*; a wood-house, *q*; a wood-stack in the yard, *r*; privy, *s*; pigsty, *t*; and dung-pit, *u*. There is one bed-room, and an apartment over *p* and *q*, in the chamber floor.

368. *Construction.* The walls of the ground floor are shown in the elevation, fig. 328, as built of stone, and the upper part of the building of framed work; the panels to be filled in with lath and mud plaster, or with wattled work; and, in whatever way done, plastered with lime mortar outside. The roof is of thatch, and the chimneys of stone.

369. *General Estimate.* Cubic contents, 15,360 feet, at 6*d.* per foot, £384.; at 4*d.*, £256.: and at 3*d.*, £192.

370. *Remarks.* The contributor of this Design offers the following observations upon it:—“ Double cottages have several advantages, especially in a scattered village. Two cottages are built cheaper, if united, than if separate; and the effect is often more

picturesque. Besides, it adds to the comfort of the poor, to have a neighbour close at hand, in case of sickness; and, in other respects, near neighbours may be mutually useful to each other. For example: suppose the mother of a family living in the larger cottage has occasion to go from home during the absence of her husband at his work, she may leave the key and her younger children with the old woman in the next house. It also facilitates attendance on divine worship, as the two families might alternately heat their ovens on Sundays, and one of the women might remain at home, to take care of the dinners for both houses, and have an eye to the gardens; a very necessary precaution in most English villages, particularly in the fruit season. Besides these obvious advantages, there is a feeling of security and cheerfulness in having a near neighbour, especially to an old couple, who must often stand in need of assistance. In closely built villages, three cottages may occasionally be united; but this number should never be exceeded; avoiding, above all things, that school of idleness, dirt, and wickedness, a continued row of cottages: —

‘That infected row, they call the street,’

as Crabbe happily expresses it; in which are commonly found the bad habits of a crowded city population; and where one dirty, quarrelsome, gossiping woman generally annoys or contaminates all her neighbours. Not that rows of houses are necessarily unpicturesque; for, though modern rows are usually frightful, streets of contiguous houses may be found in many old villages in England, which have an exceedingly pleasing effect. The principal objections to rows are, indeed, the demoralising effect they generally have upon the inhabitants, and the preference which almost all the well-disposed poor give to a detached house, or to only one or two neighbours.”

371. *Criticism.* We cordially approve of the reasons given for designing this double cottage. The evils of streets, in the present state of our working population, are no doubt great; because the labouring classes have as yet no idea of co-operating together either for enjoyment or advantage. If they had, as we shall hereafter show, the assemblage of houses in streets and squares to a certain extent, even in villages, would be attended with very great advantages. In a country where fuel is abundant, or the winter mild, as it generally is in Wiltshire (the county for which this cottage was designed), fires will seldom require to be made in the bed-rooms, and a flue under the kitchen floor will not be necessary. All the chimneys are well contrived to unite in one cluster of angular stacks; and this is judiciously placed in the interior, and not in the outside walls. The projection of the framework of the upper part of the walls, over the stonework of the lower, is both scientific and picturesque; because it will preserve the windows from the rain, and produce a striking horizontal line of shade across the elevation. Besides, when one object is placed upon another, we are pleased to see it either projecting outwards, like the capital of a column; or inclining inwards, at a regular slope, like the sides of an obelisk or pyramid. The source of the beauty lies in the evidence, which, in either case, is afforded, of the exercise of improved design. We do not altogether like the porch, which a stranger might mistake for some inferior appendage. A porch being, to a certain extent, a luxury, should, we think, be generally in a conspicuous style of art, compared with the rest of the building. Perhaps, also, the oriel window is rather too insignificant; but this might easily be remedied, by raising it at top, and lowering it at bottom. This done; the porch altered; and the whole placed on a platform, so as to keep the interior perfectly dry; the effect would be to us altogether satisfactory.

Design L.V. — *A Cottage of One Story, with Four Rooms, a Kitchen, a Back Kitchen, and other Conveniences.*

372. *Accommodation.* There are a large lobby, *a*, and kitchen, *b*, with a closet between; bed-room, *c*; parlour from the lobby, *d*; three bed-rooms, *e*, *f*, and *g*; cow-house, cellar, or place for wood, *h*; dairy, *i*; pantry, *k*; and privy, *l*.

373. *Construction.* The walls, in such a building as the present, may be all formed of mud; because they have nothing more to carry than their own weight, and that of the roof. The weight on them of the latter, which is thatched, is diminished on three sides by the columns of the veranda, or, as the Romans would have called it, the portico. Such a design is also particularly suitable for brick on edge walls; and having already (§ 336) explained Dearn's method of building such walls, we shall now describe a similar kind, invented by Mr. Silverlock of Chichester, and practised by him in the erection of garden walls, hot-houses, and cottages.

374. *Silverlock's hollow walls* are constructed of bricks set on edge, each course or layer consisting of an alternate series of two bricks placed edgewise, and one laid across; forming a thickness of nine inches, and a series of cells, each cell nine inches in the length way of the wall, four inches broad, and four inches and a half deep. The second course being laid in the same way, but the position of the bricks alternating, or breaking joint with the first, the result will evidently be a hollow wall, with communicating vacuities of the above-stated dimensions, equally distributed from the bottom to the top of the wall.

Fig. 329 shows the plan and elevation of such a wall, which differs only from the hollow wall of Dearn (fig. 306.) in being carried up in Flemish instead of English bond. At *m* is shown the manner in which piers may be built in such walls, so as to project equally on both sides of the wall, with a view to the north and south walls of gardens, both sides of which are equally valuable for training fruit trees. Fig. 330 shows how a pier may be built on one side of the wall only, with a view to the east and west walls of

gardens, the south sides of which are chiefly valuable for fruit trees, and to the walls of cottages, which should be made smooth in the inside; while, on the outside, the piers, independently of the strength which they

add to the walls, will form sources of architectural beauty. These walls have been built by Mr. Silverlock in a number of places, as garden walls, to the height of ten or twelve feet, and with very few piers. The saving is one brick in three; but the bricks and the mortar must be of the best quality. One great advantage of

LV.

LVI.

Fl. 10 1 0 1 20 Ft.

these walls is, that they admit of being equally heated throughout, by a tube of hot water or steam conducted along the interior, just above the surface of the ground. Several cottages have been built with walls of this description, on the estate of Robert Donald, Esq., near Woking, Surrey. It is evident that brick walls on the same plan might be built of eighteen inches or two feet in width, or, indeed, of any width, by joining two nine-inch hollow walls together, as in fig. 331, which, if a garden wall, might be heated

331

on one side, without being heated on the other; by carrying up the heading courses solid from the bottom, as in fig. 332; or, better, with a brick on edge wall in the centre, as in

332

fig. 333. A wall of this construction, with the bricks flat, would form one of the very cheapest and best descriptions of walls for a fruit-garden. For a fourteen-inch wall

333

bricks might be made of that length, as proposed by Dearn; and, for a wall two feet or more in thickness, the interior might be entirely hollow, with cross walls every four or five feet, as shown in *Gard. Mag.*, vol. iv. p. 228. To save bricks in the cross walls, and also to admit of the free transmission of heat from one division to another, they might be built in what is called the pigeon hole manner, viz. each stretching course having alternate vacancies, by leaving out every other brick, as in fig. 334.

334

u

375. *General Estimate.* Cubic contents, 29,348 feet, at 6*d.* per foot, £733 : 14*s.* ; at 4*d.*, £489 : 2*s.* : 8*d.* ; and at 3*d.*, £366 : 17*s.*

376. *Remarks.* The veranda in this Design being an object of luxury, or at least of elegant enjoyment, the wooden columns ought to have had plinths and caps, and the steps to the platform an air of more consequence conferred on them. However, the general form of this building, being that of a cube, is good, and the idea of the veranda on three sides is highly commendable.

Design LVI. — *A Dwelling of Four Rooms, with other Conveniences, and a large Rustic Portico.*

377. *Accommodation.* The entrance is direct into the kitchen, *a*, from which there is a passage, *b*, to the back kitchen, and to the cellar stairs ; staircase to the bed-room, *c* ; *d* is the back kitchen, from which there is a pantry, *l* ; *e* is the parlour ; *f*, a bed-room, or second parlour, in case this building should be made a public house, for which the large space under the portico is well adapted ; *g* may be a place for fuel ; *h*, a dusthole ; *i*, a place for ducks or other poultry ; and *k*, a privy. On the chamber floor there are a good bed-room, *m*, and a closet, *n*.

378. *Construction.* The walls are shown of sufficient thickness to admit of their being built of rammed earth ; but we are informed, by the contributor of this Design, that it is erected as a small public house by the roadside in South Wales ; and that the walls are actually formed of the land-stones of the country, thickly coated over with plaster within, and covered with rough-cast without. The columns which support the portico are of native larch fir, with the bark on, joined to the roof in the manner shown in the section, fig. 335, to a scale of half an inch to a foot. The roof is first thatched with straw, and then finished with a coating of heath over it. The ground floor of the house is raised about eighteen inches above the surface, and the floor of the portico about one foot above the surface. We have shown the ground on which the portico stands, higher in the Design, thinking one foot insufficient, either for the purpose of dryness, or of dignity of effect.

379. *General Estimate.* Cubic contents, 14,798 feet, at 6*d.* per foot, £369 : 19*s.* ; at 4*d.*, £246 : 12*s.* : 8*d.* ; and at 3*d.*, £184 : 19*s.* : 6*d.*

380. *Remarks.* There is comfort in this building, and also economy. The three cellars under *a*, *e*, and *f*, (which have no light, or means of ventilation, in order to lessen the risk of variations of temperature,) are well adapted for a public house, as is the pantry or store-room from the back kitchen. The presses shown in each of the rooms are also very suitable for a public house, being well adapted for holding glasses and china or earthenware. The apartment *g*, though used for keeping fuel, may be very properly substituted for a stable ; though this public house does not belong to the class of occupiers who receive travellers on horseback, for the night. It is needless to add that the great width of the portico affords an excellent protection to guests enjoying themselves in the open air. Having said thus much of the fitness of this building, with reference to its use, we shall next consider its fitness, as expressive of architectural design. It is an acknowledged principle, that whatever idea obviously pervades a building, taken as a whole, ought also to pervade all its separate parts. If the idea of the whole were that of an irregular mass, the parts ought to be irregular also ; if the whole were regular, or symmetrical, so ought to be the parts, and not only the parts, but their details. We do not say that these principles ought to be enforced in every building, whether or not they be consistent with comfort or convenience ; but we do assert that it is the main business of the Architect to accomplish this object, whenever it can be done without sacrificing the higher principle of purpose ; and that it is his duty to aim at this in the very smallest and most humble buildings, as well as in the larger and more important ones. Now, on looking at the ground plan of the Design before us, we shall find that the entrance front and the back front are regular and symmetrical in their general masses, and yet irregular in the details of these masses ; that is, in the disposition of the doors and windows. In the apartment *a*, for example, the entrance door is on one side, and a window on the other ; whereas, to preserve the principle of symmetry, the door ought to have been in the centre, with a window on each side : and this arrange-

ment would have been more suitable for a room, the windows of which must necessarily be darkened by having so wide a portico over them. Again, the doors from this room into *e* and *f* ought to have been opposite to each other, in order to maintain the same principle. There ought to have been another press, both in *e* and *f*; and the fireplaces ought to have been exactly opposite the windows in both of them. In the back kitchen, the press door ought to have been exactly opposite the door of the pantry; the outer door to have been in the centre; and the window, now there, in the position of the door. These alterations would render every thing regular, but the two small lean-tos containing *g*, *h*, *i*, and *k*. The doors of *g* and *k*, at present, answer to each other. Remove the partition between *i* and *h*; reverse the positions of the window and door of *g*; let the door of *k* be in one end; turn its present door into a window, to correspond with that of *g*; build up the door of *i*, and take down the partition between it and *h*, thus forming a dusthole and place for poultry in one apartment; and the thing is done, with a door less, and only one additional window, and without the slightest interference with the use of any one apartment. As minor faults in this Design, we object to the columns (even though they are nothing more than the trunks of trees with the bark on), for not having stone plinths and wooden caps. The former are of real use, in preventing the ends of the wooden columns from rotting, and of apparent use, by seeming to take a larger bearing on the surface of the soil; though this is rendered unnecessary, in reality, by sunk stones, or masonry, brought up as high as the surface. The wooden caps always give, or seem to give, a more secure bearing for the wall-plate or architrave, which is placed over them, besides protecting the end of the wooden column from the weather. Both the caps and the plinths have also the great advantage of calling forth the associations which belong to them, as parts of the orders of Grecian Architecture. It ought to be the maxim of all architectural improvers, never to neglect an established association, when it can be made use of without interfering with the principles of fitness and expression of purpose.

Design LVII. — *Two Dwellings under One Roof, Two Stories high, with Four Rooms in each, and other Conveniences.*

381. *Accommodation.* Each dwelling contains an entrance, and stair to the bed-room floor, *a*; kitchen, *b*, with closet under the stairs; small bed-room, or parlour, *c*; pantry, *d*; back kitchen, *e*; place for fuel, *f*; dusthole, *g*; privy, *h*; and root-cellar, *i*. The chamber floor contains two bed-rooms, *k* and *l*, with a closet to each, *m* and *n*; and a staircase, *o*.

382. *Construction.* The most suitable material for a building having so many internal walls is brick. The outside walls may be eleven-inch work, with a vacuity between, as shown in fig. 7, § 25; and all the others may be brick nogging on edge, with the exception of the party walls, which may be brick nogging flat, and of the chimney stacks, which should be solid brickwork. The roof is shown covered with semi-cylindrical tiles, which, though they are much used in Italy, and commonly called Italian, are, in reality, Moorish, and, as we are informed, the oldest description of tiles in the world. In Barbary, they are bedded in clay, laid on reeds.

383. *General Estimate.* Cubic contents of both houses, 22,050 feet, at 6*d.* per foot, £551 : 5*s.*; at 4*d.*, £367 : 10*s.*; and at 3*d.*, £275 : 12*s.* : 6*d.*

384. *Remarks.* We have engraved this Design as it was sent to us; because, though it is full of faults, it contains the germs of great beauty and interest; and because it affords a very good example of the kind of impracticable Designs which are frequently made by picturesque architects or amateurs. The plan is so far commendable, that all the apartments and appendages are obtained under one roof, and that the general form is symmetrical; but, in the ground plan, it is bad to have a place like *f*, without the means of either light or ventilation. It would be much better to divide the contents of that apartment between *g* and *c*, which could easily be done, by making the division *h* narrower, and that of *i* shorter. The division *g* would then serve its own purpose, and that of *f* also. The two false windows shown in the plan of the ground floor, and the two in the plan of the bed-room floor, which are seen in the elevations of both, are uncalled for, and add to the expense, without being requisite to carry on any idea of symmetry. The small windows shown in the ground plan, close to the staircase, are, or ought to be, intended for lighting the closets under them; but in the elevation they are placed much too high for that purpose, being even higher than the windows of the apartments *b* and *c*. Placed where they are, they could only light the staircase, which is superfluous, as this is already done in an ample manner by the broad mullioned windows over them. The boilers in the back kitchen are also badly placed, because they are against an outside wall, instead of an inner one; in which last case their heat would have served to increase the temperature of the interior, instead of being in a great

measure lost in the atmosphere. The divisions *g* and *h* should obviously be transposed; because the one would be improved by heat, and the other injured by it. In the chamber floor, a division wall is shown, so as to give to each house its portion of the balcony; but this division wall appears by the shading to be entirely omitted in the elevation. A protecting railing is also wanting to this balcony, and the windows in the elevation should

336

come down to the floor. Finally, the chimney stacks are too low, and the shafts too short, for grandeur and elegance of effect. We would change the plan as in fig. 336, and the elevation as in fig. 337.

337

Design LVIII. — *A Labourer's Cottage of Two Rooms, with other Conveniences.*

385. *Accommodation.* The plan, fig. 338, shows a porch, *a*; kitchen, *b*; with pantry *c*; bed-room, *d*; and light bed-closet, *e*. The privy and other conveniences, such as pigsty, cow-house, &c., are supposed to be placed in a small yard at a short distance.

338

386. *Construction.* The walls may be built of compressed earth. The floors should be formed by loose stones, and finished with a mixture of quick-lime and sharp sand; on the supposition that this construction in the given situation would not be too cold for the inhabitants. In a country where bricks are to be obtained at a moderate cost, the piers of the doors and windows, and the inner sides of the walls, might be built of them; and the main body of the

LVII.

L.VIII.

L.IX.

L.X.

wall afterwards filled in with mud, or turf, or rustic work, rough stones of any kind, or straw, heath, or reeds, to keep out the heat in summer, and to keep it in during winter. One fireplace might, by means of a cast-iron back, be made to serve both apartments, and an oven and boiler might be added. It is evident, that, by this mode of proceeding, a very comfortable interior might be included in a very simple, picturesque, or grotesque exterior. The brickwork of the interior, and of the doors and windows, being arranged, as in the ground plan (fig. 339, to a scale of  $1\frac{1}{8}$  of an inch to ten feet), no interior

339

plastering would be required, provided rubbed bricks were used. This adds greatly to the durability of the surface of rooms, and prevents them from being injured by children, and idle people, in countries where the labouring classes are not yet accustomed to comfortable dwellings. In this ground plan, fig. 339, *f f f f f* are the outside spaces, to be filled up with turf, rammed earth, rubble work, or whatever may be most economical in the given situation; *g g g*, inside spaces, to be fitted up as closet cupboards; *h*, bed; *i*, bed, with the foot projecting into a cupboard or small dresser in the kitchen or living-room, in the manner represented in fig. 143, § 171; *k*, dresser; *l*, pantry shelves; and *m m m*, piers of the porch built hollow. All the doors must necessarily have door-frames, with projecting heads or lintels, and sills, in order that they may build into the four-inch work. There should also be wooden bricks built in the door-jamb, to which the door-frames are to be nailed; and there must be a strong wall-plate to rest on the four-inch work, for the sake of equalising the pressure of the roof. Much may be done, in point of economy, by adopting this mode of building the walls of a house; and by using corrugated iron roofs, corrugated iron panels for the doors, and flues for heating, either under the floors, or as benches over them, in the Chinese manner, to be afterwards described.

387. *General Estimate.* Cubic contents, 8696 feet, at 6d. per foot, £217 : 8s.; at 4d., £144 : 18s. : 8d.; and at 3d., £108 : 14s.

388. *Remarks.* This cottage is not without comfort; and it would be improved, in point of architectural effect, and executed at less expense, if the porch were included under the same roof. We say, it would be improved in architectural effect, because the roof and ground plan would be more symmetrical, and symmetry is the soul of Architecture; but it would not be so picturesque as it now is, because the soul of that beauty is irregularity.

Design LIX.—*Two Cottages, of One Room and a Back Kitchen each, under the same Roof.*

389. *Accommodation.* Each dwelling contains an entrance lobby, which serves also as a place for fuel and tools, fig. 340, *a*; a kitchen, *b*; back kitchen, *c*; a place for keeping potatoes, or for poultry or a pig, *d*; and a privy, *e*.

340

390. *Construction.* The walls may be of stone; but brick walls, built hollow, would be greatly preferable. The roof may be slated. If desirable, the kitchen floor may be heated by a flue from under the oven in the back kitchen.

391. *General Estimate.* Cubic contents of both dwellings, 9110 feet, at 6*d.* per foot, £ 227 : 15*s.*; at 4*d.*, £ 151 : 16*s.* : 8*d.*; and at 3*d.*, £ 113 : 17*s.* : 6*d.*

392. *Remarks.* It is sufficiently obvious that the expression of this design is that of the subject. Each dwelling can only be fit for a single person; and the building must be favourably situated, in regard to a dry soil and free air, to admit of sleeping on the ground floor. As it is desirable, in cases where the sitting-room is also a bed-room, to have the bed in a recess, or of such a form as not to offend the eye of those who are not accustomed to live in bed-rooms, a press-bed may be employed.

Design LX. — *Two Dwellings, under One Roof; each containing Four Rooms, with Back Kitchen, and other Conveniences.*

393. *Accommodation.* Each house contains a kitchen, fig. 341, *a*; back kitchen, *b*; parlour or bed-room, *c*; bed-room, *d*; large bed-room, *e*; closet, *f*; pantry, *g*; privy, *h*; dusthole, *i*; and place for fuel, *k*; or the smaller apartments may be differently

341

arranged; thus, *l* may be a cowhouse, formed out of *f* and *k*; *m*, a privy; *n*, a dairy; and *o*, a pantry. With this arrangement, the platform will require the alteration indicated at *p*.

394. *Construction.* The walls may be of brick or stone, and the roof thatched. One roof covers the whole of the apartments belonging to both cottages, without any gutting, and with only two hips, or pavilion ends. Roofs so simple are particularly eligible for being covered with zinc, or sheet iron, instead of tiles or slates.

395. *General Estimate.* Cubic contents of both houses, 24,660 feet, at 6*d.* per foot, £616 : 10*s.* ; at 4*d.*, £411 ; and at 3*d.*, £308 : 5*s.*

396. *Remarks.* These are comfortable, unobtrusive dwellings, expressive of nothing more than what they are. All that we should wish to alter in this Design, would be the projections of the roof in front, which we would form into one general veranda, and return it also at the ends.

Design LXI. — *A Dwelling of Three Rooms on the Ground Floor, with a Back Kitchen, and other Conveniences.*

397. *Accommodation.* principal kitchen, or living-room, *b*; a best bed-room, *c*; another bed-room, *d*; with a closet, *e*; a pantry, *f*; a dairy, *g*; a place for fuel, *h*; privy, *i*; and cow-house, *k*.

The ground plan, fig. 342, contains a back kitchen, *a*; a

342

398. *Construction.*

The walls are supposed to be of stone; the roof thatched, and the chimney stacks in square divisions, as in fig. 343, on a scale of half an inch to a foot; the principal window, Gothic, with labels and mullions, as in fig. 344; on a scale of three eighths of an inch to a foot. The chimney stacks as represented in fig. 343., will, as building is now carried on in Britain, require to be executed in natural stone, artificial

stone, or in brick covered with cement; but, if the practice of employing ornamental chimney tops of this kind were general, they might be formed at every pottery of common tile ware, at half their cost in cement. Indeed a great deal is to be done in the commonest earthenware, not only in the way of chimney tops, but in cornices, labels to windows, string courses, mouldings, ornamental roof and weather tiling, and even in the internal finishing of kitchens, wash-houses, porches, &c.

399. *General Estimate.* Cubic contents, 9415 feet, at 6*d.*, £235 : 7*s.* : 6*d.* ; at 4*d.*, £156 : 18*s.* : 4*d.* ; and at 3*d.*, £117 : 13*s.* : 9*d.*

400. *Remarks.* There is something mean and depressed in the elevation of this building; though, to some tastes, this would be a recommendation to it, as a cottage. It is evident, that the main study of the Architect has been picturesque effect, else why so much irregularity, both in the masses of the ground plan, and in the roof? We do not like the truncated gables; but there can be no doubt that precedents are to be found for them. We have before observed that some Architects consider their art as one of imitation, even in its higher departments; and it is certain that the department of Cottage Architecture has been hitherto much more one of imitation than of improved design. "The general character of a cottage, as distinguished from that of dwellings of a higher class, is considered by Architects to consist in low walls, and of course low ceilings, in small windows rather broad than high, and in conspicuous high-pitched roofs, often with dormer windows in them. We admit, that, taking cottages as they are usually constructed, these features may be said to establish their character; and hence they are

generally employed by painters, and by poets, or other descriptive writers, who wish to portray a cottage of the present day. In the like manner, a certain degree of coarseness or homeliness of dress and manner may be said to have hitherto characterised the British labourer, as contradistinguished from the British gentleman. A romantic writer would, therefore, make use of these characteristics; and a poet or a sentimentalist might probably regret their disappearance, and the gradual assimilation of dress and manners between the labourer and the gentleman. The fault of the Architect is, that he has too closely followed the painter and the man of literature; forgetting that his art, being founded upon and guided by utility, ought to embrace all improvements, not only in Ar-

chitecture, but in the uses of buildings, as they are brought into notice. It is surely the duty of landed proprietors who build cottages, to encourage and elevate the character of the people who live on their lands; and that of the Architect, in conformity with this object, to consider, not what a cottage has hitherto been, but what it is capable of being made. Putting a servant into a handsome Gothic cottage, is like putting him into a handsome suit of livery; but there is, unfortunately for the servant, this difference, that the faults of the dwelling, if it does not fit, cannot be so readily perceived as those of the coat; and nobody may know, but the occupant and his family, how little comfort sometimes exists under a gay exterior. For our own part, we have seen so many ornamental cottages and lodges on gentlemen's estates, both in England and Scotland, small, damp, and badly contrived within, that we are compelled to consider them as much badges of slavery as a suit of livery. Let us hope that another generation will effectually simplify and improve the former, and entirely abolish the latter. We are aware that

there is a great prejudice in favour of Gothic buildings of every description, from the cottage to the palace; arising from the associations of reverence, antiquity, and chivalry, which are connected with them. Maturely considered, however, we cannot help sometimes doubting whether the existing prejudice in favour of Gothic Architecture does not reflect more discredit than honour on human nature: at all events, it is a prejudice unworthy of an age of rapid improvement like the present. We freely acknowledge that we do not expect many converts to our views in this respect; because simplicity is one of the last refinements men arrive at, not only in the progress of the arts, but in the progress of opinion. Believing, as we do, that this principle is undeniable, we have little doubt but that much of what is now considered beauty, both in art and in literature, will, by the next generation, be neglected; and, as the French characteristically express it, "réduit au mérite historique." (*Gard. Mag.*, vol. viii. p. 260.)

343

LXI.

LXII.

LXIII.

LXIV.

344

Design LXII. — A Dwelling of Four Rooms on Two Floors, with various Conveniences.

401. *Accommodation.* In the ground plan, fig. 345, there are a porch, *a*; kitchen, *b*; back kitchen, *c*; parlour, *d*; light bed-closet, *e*; root-cellar and lumber room, *f*; privy, *g*; pantry, *h*; and place for fuel, *i*. The stairs, *k*, lead down to a small cellar under *e*, and up to two good bed-rooms over *d* and *b*.

402. *Construction.* This dwelling, as an edifice, consists of three parts: one of these is two stories high, and contains the kitchen, the parlour, and the bed-rooms; another is a lean-to, containing the smaller apartments on the ground floor; and the third is the porch. The walls of the first part may be of brick or stone; but those of the other two parts, being much narrower, ought to be built of brick, or of nogging; or, if necessarily of stone, they should be double the thickness shown in the plan. The roof is covered with Grecian tiles, and all the flues are brought into one chimney stack. The door of the porch should be varied in position, according to the aspect of the entrance front, and to the prevailing winds of the country, as before directed.

403. *General Estimate.* Cubic contents, 11,692 feet, at 6*d.* per foot, £292: 6*s.*; at 4*d.*, £194: 17*s.*: 4*d.*; and at 3*d.*, £146: 3*s.*

345

404. *Remarks.* On the supposition that this house is to be seen principally in front, we consider it handsome; though, if it were to be seen alike on every side, it would be the reverse. The front part of this dwelling consisting of two stories, and all the windows, both of the ground floor and of the bed-room floor, being in front, the lean-to containing the inferior apartments may be well considered as the subordinate part of the building; whereas, in perfect designs, whatever meets the eye, whether in the back or front, ought to be noble. Placed on the outskirts of a wood, or half surrounded by an orchard, in the manner shown in fig. 260, § 280, it would be unexceptionable.

Design LXIII.—*Two Dwellings, of Two Rooms each, under One Roof.*

405. *Accommodation.* In the ground plan, fig. 346, there are shown, for each of these dwellings, a porch, *a*; kitchen, *b*; bed-room, *c*; back kitchen, *d*; pantry, *e*; place for fuel, *f*; and privy, *g*.

346

406. *Construction.* Nothing appears to require notice under this head, which may not be gathered from preceding designs; we may remark, however, that porches of the kind here shown, in many parts of the country, might be covered with lead, cheaper than they can be with slate, because in each of these porches there is not only a gutter between the roof of the porch and the roof of the main body of the house, but four ridge pieces on the hips, which must be covered with lead. The cheapest way, however, would be to make the porches lean-tos, when no lead would be required, but only boards at the sides. Chimney pots, such as fig. 347, on a scale of three quarters of an inch to a foot, may be used.

407. *General Estimate.* Cubic contents of both houses, 15,606 feet, at 6d. per foot, £390 : 3s. ; at 4d., £260 : 2s. ; and at 3d., £195 : 1s. : 6d.

408. *Remarks.* This Design, like the preceding one, is chiefly calculated for being seen in front, and, on the whole, though it has no pretensions in regard to style, we think it satisfactory.

Design LXIV.—*Two Dwellings under One Roof, each Three Stories high, and having Three Rooms, and other Conveniences.*

409. *Accommodation.* The ground plan exhibits an entrance porch, *a*; with a place for fuel or tools, *b*; kitchen or living-room, *c*; back kitchen, *d*; staircase, *e*; cow-house or root-cellar, *f*; dairy or pantry, *g*; pigsty or dusthole, *h*; and privy, *i*. Each of the chamber floors contains one good bed-room, *k*; and a landing from the stair, *l*.

410. *Construction.* The walls must necessarily be of brick, or of tooled stone; and the roof, being at a low pitch, should be slated. Should red harsh-coloured bricks be employed, they may be changed to a mellow tint, by a wash of quicklime, yellow ochre, and black; or the effects of time may be anticipated by a grey moss-coloured tint, composed of lime and black only. There is also a mode of imitating weather stains,

LXV.

Ft.  $\frac{10}{11}$  0 1 2 Ft.

technically called splashing, which will be described hereafter, as being more applicable to cottages in the Gothic style, than to the present town-looking edifice.

411. *General Estimate.* Cubic contents of both houses, 21,906 feet, at 6*d.* per foot, £540 : 3*s.* ; at 4*d.*, £360 : 2*s.* ; and at 3*d.*, £270 : 1*s.* : 6*d.*

412. *Remarks.* This Design, we are informed, is actually executed, with the exception of the platform. The situation is on the side of a road which passes through a high wood, on the steep slope of a hill in Devonshire. The object of the third story is said to be to show a part of the cottage above the trees, from the windows of the mansion of the proprietor of the estate, who resides in the vale below. This circumstance shows how much of the beauty of cottages must always be relative ; because, by itself, no one, we will venture to assert, would consider this a handsome building. The two wings or lean-tos are too small to become even secondary parts of so large a centre ; and yet they are sufficiently obtrusive to excite a wish that they were either removed or made larger. In a word, they do not co-operate with the main body in forming a whole ; and, though important in a useful point of view, they are worse than useless in point of either architectural or picturesque effect.

Design LXV. — *A Dwelling, with Three Rooms, and other Conveniences.*

413. *Accommodation.* The ground plan shows an entrance lobby, *a* ; kitchen and living-room, *b* ; bed-room, *c* ; back kitchen, *d* ; privy, *e* ; root-cellar or cow-house, *f* ; pigsty, poultry-house, or place for fuel, *g* ; dairy, *h* ; pantry, *i* ; and dusthole, *k*. The chamber floor contains one good room.

414. *Construction.* The walls of the main body of the building are shown of stone, the lower part of the centre has rusticated corners ; and the corners of the wings are plain. Some consequence is given to the entrance door by two projecting pieces on each side, which may be covered with one flat stone, that will thus serve both as a cap to the piers, and as a roof to the entrance.

415. *General Estimate.* Cubic contents, 13,056 feet, at 6*d.* per foot, £326 : 8*s.* ; at 4*d.*, £217 : 12*s.* ; and at 3*d.*, £163 : 4*s.*

416. *Remarks.* This dwelling is neat, and has an air of comfort. There are some faults in the ground plan, one of which is, the want of a cupboard closet in the kitchen ; but this is probably intended to be supplied by a corner cupboard and dresser. The wall enclosing the stair, considering that it is to be carried up two stories, is not of proportionate thickness, and a door should have been shown to the closet under the stairs. The terrace requires a plain parapet, which might consist of a pigeon-hole wall, terminating in a row of flower troughs of the kind delineated in fig. 198, § 222 ; and there might be piers at the corners, finished with vases, or with the square flower troughs, fig. 199, § 222.

Design LXVI. — *A Cottage Dwelling of Two Rooms, with a Smithy, Shoeing-Shed, and Three-stalled Stable.*

417. *Accommodation.* This is evidently a building for display, and therefore it may be called an ornamental smithy. It depends for beauty principally on its arcade, and its far-projecting Italian roof. The ground plan shows the walk under the arcade, *a* ; the entrance passage, *b* ; kitchen and living-room, *c* ; pantry, *d* ; bed-room, *e* ; child's bed-closet, *f* ; shoeing-shed, *g* ; forge and smith's shop, *h* ; three-stalled stable, *i* ; women's privy, *k* ; and common privy, *l*.

418. *Construction.* As this building has a great extent of walling in proportion to the number of openings, all the walls, with the exception of the piers and arches, might be built of earth, or of some other cheap adhesive material. The roof may be covered with Grecian tiles. The stable should be fitted up in the usual manner, with hay-rack, manger, &c. ; and the shoeing-shed ought to have rings in the walls for the bridles or halters of the horses being shod, to be fastened to ; but it will not require either racks or mangers, as horses should never be allowed to eat during that operation. Such a building as the present is very well calculated for being covered with an iron roof ; because the span is considerable, and the form simple. There are three kinds of iron roofs, any of which might be adopted for this building. The first is the cast-iron roof ; one kind of which, the invention of Carter of Exeter, has been already described, § 153 ; the second is the Russian roof, of wrought-iron rafters and sheet-iron plates ; and the third is the newly invented corrugated iron roof, without rafters of any kind. We shall here shortly describe the last two.

419. *Iron Roofs, as constructed in Russia.* The rafters, in the better description of houses, are for the most part of wrought iron, and of very small dimensions ; they are constructed on the same general principles of trussing as wooden rafters. In smaller houses, the rafters are of timber ; and in these houses, whether iron or wooden rafters

are used, the laths to which the plates are nailed are almost always of wood. We have, indeed, in Moscow, in 1814, seen iron rods substituted for wooden laths, and the sheets fastened to them by strong copper wire; but we do not think the practice general. The common mode of covering iron roofs in Russia is thus given in a late number of the *Repository of Patent Inventions*, &c. :—“ Sheet-iron coverings are now universally made use of on all new buildings in Petersburg, Moscow, &c. In the case of a fire, no harm can come to a house from sparks falling on a roof of this description. The sheets of this iron covering, measure two feet four inches wide, by four feet eight inches long, and weigh twelve pounds and a half avoirdupois per sheet, or one pound five ounces each superficial square foot. When the sheets are on the roof, they measure only two feet wide by four feet in length: this is owing to the overlapping. They are first painted on both sides once; and, when fixed on the roof, a second coat is given. The common colour is red; but green paint, it is said, will stand twice the time. Small bits, or ears, are introduced into the laps, for nailing the plates to the two-inch square laths on which they are secured. It takes twelve sheets and a half to cover 100 feet, the weight of which is only 150 lbs.; the cost only £1: 15s., or about 3d. per foot.” (*Sup. to Rep. of Pat. Inven.*, 1832, vol. xiii. p. 409.)

420. *Corrugated Iron Roofs* are composed of sheet iron, impressed so as to present a surface of semicircular ridges, with intervening furrows, lengthwise of the sheet. By this means, the sheet, from a plain flat surface having no strength but from its tenacity, becomes a series of continued arches, abutting against each other, fig. 348; and the metal, by this new position, acquires strength also from its hardness. To give an idea of the strength acquired, it is observed by Walker, the inventor of this mode of preparing sheet iron, that “ a single sheet of iron, so thin that it will not continue in a perpendicular position, will, after undergoing the process of corrugation, bear upwards of 700 lbs. weight, without bending in the least degree.” Iron so furrowed will be preferable to common sheet iron for covering a flat roof; because the furrows will collect the water, and convey it more rapidly to the eaves: but this is a trifling advantage, scarcely worth mentioning, in comparison with others which follow. Suppose, that, in addition to furrowing a sheet lengthways, so as to give it the appearance of fig. 349, it is also bent in one general curve in the direction of its length, so as to give it the appearance of fig. 350, we have then an arch of great strength, capable

*a a*, Tie rods. *b b*, &c., Corrugated arches, each forty feet span. *c c*, Segment rafter of wrought iron, supporting the tie rod and the roof of corrugated arches under it, and kept steady and strong by the trussing, *a a*, &c.

roofs of this span, or even one of more than double the extent, might be covered without a single rafter appearing inside. In short, no material hitherto brought into notice at all approaches this, in its capacities for forming light and economical roofs of the greatest extent of span, and with the least loss of interior room. Its durability will depend on the application of oil or tar paints: for barns, sheep-houses, and various other country buildings, and for all manner of sheds, both in town and country, it is particularly suitable. As the invention has only been known four or five years, much has not hitherto been done with it; but there are several roofs of corrugated iron in the London Docks, and fig. 353 represents a portion of one of them. "Its length is 225

353

feet, its width 40 feet, and the height of the columns on which the roof is supported 12 feet. The columns are of cast iron, a gutter of which metal is continued from column to column, the whole length of the roof; and in the gutter rests the edge of the roof. The arch is formed of several sheets of iron, curved in a reverse direction to the corrugated arches, as shown fig. 353, and riveted together longitudinally. Similar arches, connected to each other by rivets, compose the roof: every corrugated arch forms a watercourse, ending in the gutters at the side, and thereby rendering it quite waterproof. To give stability to the whole, a tie rod, fig. 354, is carried across the shed

from each column to the one opposite. Between this shed and the brick wall is a lean-to corrugated roof, forming a half arch, springing from the gutter, and resting against the wall, as shown in fig. 353." The walls of buildings may be constructed of this iron set on edge, either in single plates, or of double plates with a vacuity between, to lessen the effect of changes in the exterior temperature on the space enclosed. As the corrugation, or fluting, of the iron may be made either large or small, it may be adapted to the panels of doors, as in figs. 355, 356, and 357; or an

355

356

357

358

entire door, with the frame of rod iron, may be filled in, so as to serve as a substitute for a ledged door, fig. 358. The sliding gate, fig. 359, has been erected as an entrance to one of the docks. The frame is of the usual construction, of timber, and inserted in a

359

brick wall. The gate is composed of sheets of corrugated iron riveted together, so as to form one large panel, the size of the opening; the foot of this gate rests in a groove, as shown in the section, fig. 360, *b*, made of timber or stone, and embedded in the earth, so as to be level with the roadway. On the upper edge are two grooved wheels, which work on an iron ledge groove, *a*. Shutters to shops may be made of this description of sheet iron, as well as chests, and a variety of other objects which will easily occur to a practical man. The following are the prices at London in 1832:—Roofs, per square of 100 feet, £5: 10s.; verandas, per square, £7; and doors of the ordinary size, in six panels, as in fig. 357, £2: 10s. each. This description of roof is not particularly applicable for small-sized cottages, but may be used for large ones; and, for smithies, carpenters' shops, and all manner of sheds, it seems particularly appropriate. Portable houses might be very readily made of it for exportation; but, wherever such houses were erected, they should be covered with ivy, or some other evergreen creeper, to moderate the effect of changes in the exterior temperature.

421. *General Estimate.* Cubic contents, 28,636 feet, at 6d. per foot, £715: 18s., at 4d., £477: 5s.: 4d.; and at 3d., £357: 19s.

422. *Remarks.* There is a simplicity and grandeur in the elevation of this Design, which by no means belongs to a common dwelling; and, were the chimney tops omitted, we should be at a loss to know its purpose. The extent of the arcade, and its width, with the small windows under it, would seem to indicate that this Design has been intended for a hot climate; but,

LXVIII.

for such a climate, the chimney tops are too conspicuous. They are very well calculated for Britain or North America; but, for either of these climates, there ought to have been at least one additional window to each room. In the engraving, we have shown the tiles of the roof much more distinctly than they were seen in the drawing sent by our contributor. When the covering of a roof is (like thatch, plain tiles, or slate) neither ribbed nor definitely marked, except by its great outlines, indistinctness is no defect; but a roof marked, in consequence of its construction, by distinct lines and strong shadows, should have the parts as definitely made out in the picture as in the reality. Whoever will examine the published works of the Italian Architects, or the views of Italian buildings taken by British Architects or artists, will find that much of their beauty depends on the minute details of the roof, and especially of the projections of the eaves; and of the ridge pieces, as well of the hips as of the main roof.

Design LXVII. — *A Cottage Dwelling of Five Rooms, in Two Floors.*

423. *Accommodation.* The ground plan contains an entrance lobby and staircase, *a*; parlour, *b*; another parlour, or best bed-room, *c*; kitchen, *d*; back kitchen, *e*; closet, *f*; root-cellar, *g*; dusthole, *h*; privy, *i*; and pantry, *k*. The chamber floor contains two good bed-rooms, *l* and *n*; with a dressing-closet, *o*: the well-hole of the stair is shown at *m*.

424. *Construction.* The walls are shown of such a thickness as to admit of their being built of rubble-work. The roof is covered with slates, and the guttering, which is of cast iron, is calculated to serve as a cornice to the eaves.

425. *General Estimate.* Cubic contents, 29,044 feet; at 6*d.* per foot, £726 : 1*s.*; at 4*d.*, £484 : 1*s.* : 4*d.*; and at 3*d.*, £363 : 0*s.* : 6*d.*

426. *Remarks.* The chief merit of this building is, that it contains five good-sized rooms; for size is very desirable, both in a cold climate and a warm one. Air in large bodies is much more slowly either heated or cooled by the mere contact of hot or cold air, and it is also less liable to be traversed by currents of air, than when in a smaller volume. No one could sit in a small room with doors and windows on all sides, without experiencing what is commonly called a draught; but, in a very large room, doors and windows on all sides will occasion no such inconvenience. We object to the position of the recesses for cupboard closets in *b* and *c*; because they occupy the proper places for a sofa in the one room, and for a bookcase in the other: they also seem to divide the side of the room into two parts, and thus take away from the idea of a whole. If these rooms were to be handsomely finished, the doors in question would be highly objectionable, on the latter account. The closets in question ought to have been placed, one in both *b* and *c* exactly opposite the entrance door; and another, in each room, between the fireplaces and the side walls in which they are now placed. So large a dwelling, we think, ought to have had a porch; but that may be matter of economy on the part of the proprietor. There is a poverty about the elevation, which requires to be removed by architraves to all the windows, by sills to those of the chamber story; and by other means, which are by this time become familiar to our readers. We need not say that we object to the truncated pediments, which give a tame lumpish character to this dwelling, hardly in accordance with the bold and handsome chimney tops.

Design LXVIII. — *A Dwelling of Four Rooms, with other Conveniences.*

427. *Accommodation.* The door is protected by a far-projecting roof, and enters at once into the kitchen and living-room, *a*, in which is a staircase to the bed-chamber, with a closet under it, *b*; from this we have a room with a bed in a recess, *c*; and another of the same description, *d*: there are a back kitchen, *e*; privy, *f*; root-cellar and fuel place, *g*; and dusthole, *h*. There is a good bed-closet in the chamber story; and on the ground floor there is another closet, *k*, which may serve as a pantry, and a third, *i*, which may be used as an office, or place for books, &c., according to the occupation of the inhabitant.

428. *Construction.* The walls may be of brick, hollow, and the roof slated; but the building would have the best effect, if the walls were covered with cement or plaster, and coloured of a mellow tint. We say they would have the best effect; because the beauty of this dwelling depends on the contrast between its perpendicular and horizontal lines; and between its bright lights and dark shadows: and both lines and shadows are more conspicuous in light-coloured walls than in any other.

429. *General Estimate.* Cubic contents, 11 890 feet, at 6*d.* per foot, £297 : 5*s.*; at 4*d.*, £198 : 3*s.* : 4*d.*; and 3*d.*, £143 : 12*s.* : 6*d.*

430. *Remarks.* There is something pleasing in the contrast of the lines, and of the lights and shadows, in this dwelling; but it has not much of the expression of a cottage.

It seems better calculated for a small public-house, or coffee-house, to be placed on an eminence, commanding a fine prospect, or close by a river. The room *a* might then be the kitchen, and public sitting-room for guests, and there might be a good cellar under it; *d* and *c* might also be for guests, the bed recesses being concealed by folding-doors; and the room up stairs might be considered the principal room, as it would have the best prospect. The expression of the Design is somewhat Italian, but it wants the characteristic tiles. It will never be erected where economy in the construction is an object.

Design LXIX. — *A Cottage Dwelling, in the Old English Style, with Kitchen, Parlour, Business Room, Three Bed-chambers, and other Conveniences.*

431. *Accommodation.* The ground plan, fig. 361, to a scale of 20 feet to an inch, contains a porch, *a*; a lobby and passage, with staircase, *b*; a kitchen, *c*; a wash-house, *d*, with boiler, washing-trough, and sink; a store-room, *e*; pantry, *f*; business room, *g*; closet, *h*; and parlour, *i*. The chamber floor, fig. 362, contains three bed-rooms, *k*, *l*, and *m*; and a closet, *n*. The other requisite conveniences are supposed to be placed in the garden.

432. *Construction.* The walls may be of brick, or of rubble-work, with corners of squared stone. The roof is supposed to be covered with plain tiles, having barge boards against the west gable, as shown in the elevation, fig. 363; and also against the east gable, as shown in the elevation, fig. 364; and with the two other gables truncated, as may be seen in the south elevation, figs. 365 and 366. There are Gothic labels over the kitchen and parlour windows; and the window of the business room projects in the manner of an oriel, as may be seen in figs. 363 and 365. Perhaps it may be thought by some of our readers, that the chimney tops in this Design, and in a number of others, are carried too high; that is, higher than can be of any use, either in creating a draught for the smoke, or in rendering the dwelling more ornamental. Now we are prepared to give our reasons for denying these suppositions. In the first place, it is known and acknowledged, both in theory and practice, that the simplest and most effectual mode of producing a draught in a flue, so as to cure a smoky chimney, is, to add to its top a long narrow funnel. This funnel is, in all ordinary cases, an earthenware cylinder of eight or ten inches in diameter, and between two and three feet long: but, in difficult cases, the length is increased to five feet, by employing a longer earthenware tube; or to a still greater length, by employing those tubes of copper or iron called about London "tall boys." The five feet long chimney pots are made by joining two pots of the ordinary length together before they are burnt: but, as these long pots are liable to be broken in the kiln, the cost of them about London, in 1832, is 9s. each by retail; therefore two or more draining tubes, such as are shown in fig. 411, which cost 2s. each, are preferable. In the second place, with respect to ornament, our object is, by clothing these tubes, whatever may be their length, with architectural forms, instead of leaving them bare as is almost universally done, to render them handsome component parts of the building, instead of deformed appendages to it.

363

433. *General Estimate.* Cubic contents, 21,660 feet, at 6*d.* per foot, £541 : 10*s.* ; at 4*d.*, £361 ; and at 3*d.*, £270 : 15*s.*

434. *Remarks.* No one can mistake the expression of this Design, who has ever seen an English cottage. It pretends to be nothing more than what it is, and might be

364

mistaken for a copy from nature. It seems to us to want dignity, which might be given by heightening the windows of the parlour-floor, and by a surrounding terrace. The ground plan is very convenient.

365

Design LXX. — *A Cottage Dwelling of Four Rooms, with other Conveniences.*

435. *Accommodation.* The ground plan, fig. 366, shows a kitchen, *a*; parlour, *b*; best bed-room, *c*; bed-room, *d*; closet, *e*; recess for books, *f*; two closets, *g g*; pantry, *h*; wash-house, *i*; potato cellar, and place for lumber, *k*; coal-house, *l*; and privy, *m*.

436. *Construction.* The walls, which have brick footings to the height of eighteen inches above the surface, are of stud-work, covered with weather-boarding without, and lath and plaster within; the floors of *a*, *b*, *c*, and *d*, are of boards, and those of the passage and offices of tiles and bricks. The roof is covered with pantiles; it is in two parts, the higher and wider part being over the living-rooms, and the low narrow division covering the passage and the offices. There is a rustic veranda along one front, constructed of barked oak branches, on which vines and flowering shrubs are twined.

437. *General Estimate.* Cubic contents, 11,040 feet, at 6*d.* per foot, £276; at 4*d.*, £184; and at 3*d.*, £133.

438. *Remarks.* This Design is executed at Chingford in Essex, and it has been sent us as being very economical in the erection, and very commodious and convenient in the occupation. We have improved the forms, and increased the height, of the chimneys, for the sake of effect, and also in order to make them draw better. Without high, bold, and carefully studied chimney tops, a cottage, to us, is without one of its chief beauties; and it is, besides, very liable to smoke. Beauty, in this case, as in most others, goes hand in hand with utility. We by no means approve of the plan of having the outside walls of a cottage of wood; but, in many cases, it cannot be avoided. When an old cottage, with walls of this description, is to be improved, the weather-boarding may be covered either with what is called weather-tiling, of which we shall give a variety of shapes in a succeeding page, or with tiling so marked as, when put up, to resemble bricks, and known as brick weather-tiling, of which we shall also hereafter give specimens. Much of the effect of such a cottage will depend on the disposition of the flowering shrubs and trees on its veranda and trellised porch.

Design LXXI. — *A Castellated Lodge, as a Dwelling for a Gardener, or other upper Servant, on a Gentleman's Estate.*

439. *Accommodation.* The ground plan, fig. 367, shows a porch, *a*; kitchen, *b*; living-room, *c*; two light closets, *d d*; staircase, with closet under, *e*; place for coals, *f*; for wood, *g*; and water-closet, *h*. The chamber floor, fig. 368, contains two good bed-rooms, *i, k*; and two bed-closets, *l, m*.

440. *Construction.* The contributors of this Design, Messrs. W. and H. Laxton, have sent the following details. Fig. 369 is a section across the window in the living-room, in which is shown the wall of brick, *a*; label moulding over the window, *b*; reveal, with splay, finished with cement, *c*; frame to the casements, four inches by two inches, with hollow worked on the edge, rebated, and beaded, *d*; inch and half Gothic bar casement, rebated on the lower edge, to shut against an iron tongue, let into an oak sill, *e*; lintel, four inches and a half by three inches and a half, *f*; plate, four inches and a half by five inches, *g*; joists, seven inches by two inches and a half, notched on to the plate, *h*; ceiling, *i*;

LXIX.

LXX.

LXXI.

LXXII.

Ft. 10 0 20 Ft.

368

cornice, with flowers or bosses, fifteen inches apart, *j*; floor boards out of two cut battens, *k*; skirting board, with hollow worked on the edge and a groove, *l*; narrow ground, splayed for plaster, *m*; small fillet nailed on the floor, for fastening the skirting, *n*; wooden brick, four inches by two inches and a half, *o*; plaster, *p*; oak sill, *q*; capping, or window board, *r*; and window back, *s*.

Fig. 370 is a section showing the construction of the embattlements, in which we have the wall of the ground floor a brick and a half thick, *t*; the wall of the bed-room floor one brick thick, *u*; the coping of the embattlements formed of Austin's artificial stone, *v v*; and the moulded string under the embattlements, *w*. Fig. 371 is a section, showing the gutter and the roof, in which the wall-plate is represented at *a*; the ceiling joist, four inches by one inch and a half, is nailed to the side of the rafter at *b*; the rafter, *c*, four inches by two inches, is notched on to the wall-plate; the battens for the slates, three inches by three quarters of an inch, are shown at *d*; three quarters of an inch feather-edged eaves-board at *e*; a cast-iron gutter at *f*, moulded to form a cornice, and fastened by copper nails to the ends of the rafters; and slates at *g*. Fig. 372 is an elevation of the south-east end of this building. Fig. 373 is an elevation, to a scale of three eighths of an inch to a foot, of the chimney tops, formed of Austin's artificial stone.

441. *Specification and Estimate.* As the building is small and simple, these are combined in what is technically called one particular. The prices are calculated at the prime cost of materials and labour, in London, in the year 1832.

442. *Digger and Bricklayer's Work.*

	£	s.	d.
Twenty cubic yards, digging, wheeling, or filling in to the foundations, and over the whole surface, six inches deep .....	1	0	0
Seven rods and three quarters reduced stock brickwork, at £12 per rod .....	93	0	3

The walls are to have two courses of one brick in thickness, and the plinth is to be half a brick thicker than the walls above, as shown in the ground plan, fig. 367. There are to be one-brick footings,

372

eighteen inches high, to the partitions forming the sides of the stairs and lobby; and one-brick sleeper walls, for the joists under the parlour. (A sleeper is a piece of scantling, laid on the top of a low wall, under the flooring, on which the joists are to rest.)

373

Thirty yards of brick nogging of stocks laid flat to the partitions on the ground floor, at 3s. a yard .....	4 : 10 : 0
Five yards of brick paving of stocks, laid flat in sand, to the closet for coals, under the stairs, at 2s. 3d. per yard .....	0 : 11 : 3
Forty-five feet superficial of cuttings to the rakes of the gables at 3d. per foot .....	0 : 11 : 3
Ten feet superficial of two courses of plain tiles, bedded in cement, and rendered on the top, to the flat roofs of the towers .....	0 : 7 : 6
Two hundred and two feet lineal of cuttings to the splays of the windows and doors, at 2d. a foot (c, in fig. 369) .....	1 : 13 : 3
Cutting four small Gothic heads, and one large ditto; and four loophole crosses to the towers .....	0 : 10 : 0
One hundred and sixteen feet lineal of brick on edge, cut and set in cement, for plinth, 2½d. per foot (fig. 374).....	1 : 4 : 2

374

375

a

One hundred and sixty feet lineal bird's-mouth splays to the quoins (corners) of the towers, at 2*d.* per foot. (A bird's-mouth splay is an oblique angle, as at *a*, fig. 375, instead of a right angle.)..... £ s. d.  
 To build a small cess-pool, two feet six inches square, and one foot six inches deep, of one brick wall all round, under the water-closet; and to provide thirty feet of eight-inch drain pipes, and digging, to convey the soil to the common sewer; also an earthen-ware pan and tray..... 1 : 6 : 8  
 ..... 2 : 18 : 0

£107 : 2 : 6

443. *Slater's Work.*

Eight square forty feet of countess slating, at 25*s.* per square..... 10 : 10 : 0  
 Thirty-six feet lineal of glazed ridge tiles, at 6*d.* per foot..... 0 : 18 : 0  
 Eighty-six feet lineal of cement filleting to the gable, at 2*d.* per foot 0 : 14 : 4

£12 : 2 : 4

444. *Carpenter's Work.*

Seven squares of three quarters of an inch battening, two inches and a half wide, for slating, at 10*s.* per square ..... 3 : 10 : 0  
 Sixty-three feet superficial of three quarters of an inch feather-edged eaves-board, at 5*d.* per foot ..... 1 : 6 : 3  
 Eighty-six feet lineal of tilting fillets to the gables, at 1½*d.* per foot 0 : 10 : 9  
 Two hundred and ninety-eight cubic feet of Memel, Riga, or Dantzic fir, in bonds, plates, rafters, joists, and quarters, as under, at 3*s.* 6*d.* per foot..... 52 : 3 : 0

Ridge-pieces, ten inches by one inch and a half; rafters, four inches by two inches and a half; purlins, four inches by four inches; two collar beams, nine inches by three inches; ceiling joists halved on to the rafter, four inches and a half by one inch and a half; (joists are said to be halved on, when they are joined by half being cut out of the joist and half out of the rafter); a girder under the floor of the large room, nine inches by nine inches; joists, seven inches by two inches and a half; plates, four inches by four inches and a half under the roof, and under each floor, all round, except where the flues intervene; also two tiers of bond, four inches by two inches and a half; oak sleeper under the ground floor, and oak sill, four inches by four inches, to the partition on the ground floor; heads to the partition, four inches by five inches, to form the sill of the partition above, or the cross-tie to the roof; centre and door-posts, and door-head, four inches by four inches; quartering, four inches by two inches; door-posts and head to the water-closet, and the closets on each side, four inches by four inches, to be wrought all round; beaded head to the partition over ditto, four inches by four inches; puncheons, four inches by two inches. Three centres to the fireplaces, and ten ditto to the apertures of the doors and windows; one centre to the Gothic head .....

1 : 0 : 0

£58 : 10 : 0

445. *Joiner's Work.*

Nine and a quarter square inch deal wrought folding floors, at 40*s.* per square..... 18 : 10 : 0  
 Two hundred and thirty feet, lineal plain skirting out of two cut battens, with a hollow and groove worked on the face, backings, and wooden bricks at 6*d.* per foot (see *l*, and *o*, in fig. 369)..... 5 : 15 : 0  
 Eight one and a half inch four-panel square framed doors, six feet six inches by two feet six inches, with a hollow worked on the framing round the panels, as in fig. 376, hung with three-inch butt hinges, and fastened with a six-inch iron-rimmed two-bolt lock, one and a half inch rebated linings and mouldings round both sides, at 30*s.* per door..... 12 : 0 : 0

Four doors as above, with fillets nailed on the door-posts to form stops, to the water-closet, to the closets on each side, and to the

closet under the stairs; each door hung with three-inch butt hinges, and having a four-inch lock to each, at 22s. per door.....	£ s. d. 4 : 8 : 0
Four one and a quarter inch framed and beaded closet fronts, eight feet by three feet three inches, with four-panel square doors, hung with three-inch butt hinges, and having a moulding round, and a closet lock to each, at 26s. per door.....	5 : 4 : 0
A two-inch two-panel bead butt and square framed door, seven feet by three feet, with one and a half inch sash and shutter; the lower panels to be filled in with a Gothic moulding, and Gothic head, hung with four-inch butt hinges, and fastened with a nine-inch drawback lock, and two eight-inch bolts. A proper door-case of fir, four inches by four inches, with a moulding round inside.....	3 : 3 : 0
One and a half inch sash door to the back lobby, six feet six inches by two feet six inches, framed bead butt and square; with a shutter, and a pair of three-inch butt hinges, a thumb-latch, two bolts, a thumb-screw, and two stubbs; a proper doorcase of fir, four inches by three inches, with a moulding round inside.....	2 : 0 : 0
Eighty feet superficial of one and a half inch square framed partition, to divide the small room, on the bed-chamber floor, from the stairs; also over the stairs, with a four-panel square framed door in ditto, at 9d. per foot; sixteen feet of moulding round ditto; one pair of three-inch butt hinges, and a six-inch two-bolt lock.....	3 : 7 : 0
Four windows with one and a half inch deal casements, Gothic heads and spandril, four feet six inches by five feet in the clear; hung folding (both casements to open and shut against each other as in fig. 177 § 196,) with three-inch butt hinges, and fastened with two five-inch brass flush bolts, and a brass fastening; two-inch deal rebated and beaded frame, four inches wide, with hollow worked on the outer edge ( <i>d</i> , in fig. 369), and with oak sills, at £2: 2s. each.....	8 : 8 : 0
Four windows, three feet six inches by five feet, at £1: 18s. per window.....	7 : 12 : 0
Two pair of one and a half inch deal shutters, framed as doors, to the parlour windows, hung as sashes, with pulleys and boxings complete, each twenty-eight feet superficial, and with four feet extra-length of boxing, two brass flush rings, a brass thumbscrew, and two four-inch brass flush bolts to each window.....	4 : 0 : 0
A three-quarter-inch ledged shutter to the kitchen window, seventeen feet six inches superficial, with a wooden bar, and two staples.....	0 : 15 : 0
Fourteen feet superficial one and a quarter inch deal seat, riser and bearer to the water-closet; five feet superficial one and a quarter inch deal clamped flap, and beaded frame; six feet lineal inch skirting, four and a half inches wide, one pair of two-inch brass butt hinges, and two holes cut; and a small bull's-eye light frame and linings.....	1 : 13 : 0
Sixty-five feet superficial of one and a quarter inch deal steps, with inch risers, bracketed and housed into one inch and a half wall string, twenty-five feet superficial, with thirty feet lineal of beaded capping; and a deal moulded rail, fifteen feet lineal, fastened with three iron brackets.....	6 : 5 : 0
Deal dresser, seven feet long by two feet wide, with three drawers under, pot board and bearers; three-inch deal shelves over, and two cut standards (the upright piece of deal to which the ends of the shelves are fixed).....	3 : 0 : 0
One hundred feet of inch deal, wrought on both sides, to be fixed with bearers for shelves, at 8d. per foot.....	3 : 6 : 8

---

£ 89 : 6 : 8

446. *Stonemason's Work.*

Two profile stone moulded chimney-pieces, with slabs and back hearths, to the parlour and the room over; opening three feet high, by two feet eight inches wide.....	3 : 10 : 0
A set of stone jambs and mantle, five inches wide, to the bed-room, with slab and hearth.....	0 : 15 : 0

A set of one and a half inch stone ditto, eight inches wide to the kitchen, with slab and back hearth.....	£ s. d.
A six-inch stone sink, ten feet superficial, with a trap in ditto pinned into the wall on two sides .....	1: 5: 0
Two stone steps, seven feet lineal, to the doorway .....	2: 5: 0
	1: 1: 0

Total prime cost of this dwelling..... £ 357: 15: 7

450. *General Estimate.* Cubic contents 17,688 feet, at 6*d.* per foot, £442: 4*s.*; at 4*d.*, £294: 16*s.*; and at 3*d.*, £221: 2*s.*; by which it appears that 4½*d.* per foot is about a fair price for estimating lodges of this description.

451. *Remarks.* For an ornamental cottage this must be considered a very economical plan: its accommodations are insufficient for a small farmer, or a retired tradesman; but it would not be difficult to enlarge it, and yet preserve the general character of the elevation. The contributors of this Design (Messrs. W. and H. Laxton) have sent us a plan for this purpose, fig. 377; in which *a* is the entrance lobby; *b*, the parlour, or

living-room, with a wine closet, *c*, and a store-room, *d*; *e*, the principal room, with a china closet, *f*, and book closet, *g*; *h*, the passage leading to a staircase, with a light pantry under it, *i*; *k*, the kitchen; *l*, the lobby to the back entrance; *m*, the water-closet; *n*, a coal and wood-house; and *o*, the yard. We object to this plan, and also to that of the original Design, fig. 367, on account of the chimneys being placed in the outside walls; but this evil may be mitigated by an increased thickness, and by forming a vacuity all round the chimney and flue, so as to lessen the conducting power of the wall. Whoever, in a climate where fires are necessary one half the year, employs an Architect to design a dwelling, whatever may be its rank, from the cottage to the palace, ought to make it an indispensable condition, to have no chimneys in the outside walls; and none that shall not draw well. Every person looking through this work, with a view to make choice of a design, ought to bear in mind the same principle. With respect to the elevation, as shown in Design LXXI., p. 215, we cannot approve of carrying through, between the lower and the upper windows, the forms of battlements, as shown in the section fig. 370, in the manner of a string course; because such an ornament has neither the appearance nor the reality of use. A string course, or horizontal band, has the architectural expression (to speak technically) of binding and tying together the work below it, as well as, to a certain extent, of protecting it from the rain. It is true that the battlement forms, carried through, as in fig. 370, will also protect what is below from the rain; but they have not that expression, for every one knows that their usual purpose, on a building, is to form the termination of a wall. The effect of these battlements on the outline elevation, fig. 372, can hardly fail to deceive the unpractised eye; and, by raising the idea that the basement story of the building projects outwards, considerably beyond the upper story, creates a beauty in the design, as seen in an outline elevation on paper, which it could never have in reality. The shaded perspective view, Design LXXI., p. 215, may be referred to in proof of this assertion, as showing the advantages of such views in conveying correct ideas of the effect of architectural designs. We may further observe that it would be an improvement, to raise the angular towers two or three feet higher, so as to detach their summits more distinctly from the gable ends. The effect of this, as of all distinctness and bold relief in buildings, is to make the parts appear more decidedly what they are; in short, to add to the strength of their expression.

Design LXXII.— *A Dwelling of Six Rooms, with various Conveniences.*

452. *Accommodation.* From the entrance and staircase, *a*, there is a kitchen, *b*; with back kitchen, *c*; and pantry, *d*: there are two good parlours, *e* and *f*; a cellar, *g*; which, if thought necessary, might be connected with the kitchen; a place for fuel, *h*; dusthole, *i*; and privy, *k*. The chamber floor contains three good bed-rooms, *l*, *m*, and *o*; and a light closet, *p*.

453. *Construction.* The walls are supposed to be rubble-stone; the roof covered with slate; and the chimney tops, coping of the side walls, and tabling of the gable ends of tooled stone. The doors and windows have plain stone facings. The guttering is formed as in fig. 120.

454. *General Estimate.* Cubic contents, 22,839 feet, at 6*d.* per foot, £520 : 9*s.* : 9*d.*; at 4*d.*, £380 : 6*s.* : 6*d.*; and at 3*d.*, £265 : 4*s.* : 10½*d.*

455. *Remarks.* This building will be known at once to be in the Scotch style. This style, which is also common in the north of France and in Flanders, prevails in all those parts of Scotland where freestone is abundant; varying sometimes with plain tabling; with the tabling stones raised one above another like the steps of a stair, as in Design XI.; or in various other forms, as in figs. 378 to 385. As the chief characteristic beauty of this manner of building depends on the gables, we have given these different forms, which the reader may vary at pleasure. The next characteristic is the storm-head windows, fig. 386; and these admit of as great a variety as the gable ends. A third distinction of this style is the facings to the doors and windows, which may also be considerably varied. The chimney tops are generally very simple. Loopholes

and very small gable windows are frequently introduced, partly to give character, but chiefly for ventilation; and these also may be considerably varied. It is remarkable that houses in this style, which is evidently one attended with considerable expense in stone-cutting, are seldom found with a porch; though this appendage, in a climate like that of Scotland, would be of the most essential service in point of comfort: a porch in Scotland, however, is seldom seen to any building under the rank of a villa. The Design before us is given more as a specimen of the Scotch style, than as a model; though it is certainly commodious, and convenient in its arrangement. It would be much improved by a string course under the chamber-floor windows, and by squared stones at the corners. A better effect would have been produced in the elevation, as well as more heat in the interior, by having the fireplaces of the two living-rooms, *e* and *f*, against the partitions which separate them from the stair. These alterations made, and a porch added, the result would be fig. 387, which may be described as a specimen of the improved Scotch style of

tradesmen's houses. In this figure, the vertical and horizontal bond, both in regularly hewn stone, and the panels filled up with rubble-work on the cementitious principle, will be distinctly observed. Expression is by these means given to a mere wall, as such, without reference to what it has to support or enclose. The young architectural reader ought constantly to bear in mind, not only that every building ought to have its appropriate expression obvious at first glance, but that every separate part of a building ought to have its separate expression. The student ought, therefore, to exercise himself in endeavouring to analyse every edifice that comes before him, so as to be able to feel the force of every effect, and to refer it to its cause. Two of the windows of the original Design, p. 216, are false; which, in buildings of this class, is to us an abomination.

Design LXXIII. — *A Dwelling, Three Stories high, with Four Rooms, and various Conveniences.*

456. *Accommodation.* From a porch, *a*, the door enters into a lobby, *b*; whence there is a closet, *c*, under the staircase; there are a kitchen, *d*; back kitchen, *e*; pantry, *f*; parlour, *g*; closet cupboard, *h*; root-cellar, *i*; place for fuel, *k*; dusthole, *l*; and privy, *m*. The chamber floor contains two good bed-rooms, *n* and *o*; with a closet, *p*; and a landing to the stairs, *q*. The garret, which is entered by a trapdoor from this landing, is in one large room, lighted by a dormer window.

457. *Construction and Remarks.* The walls may be of rammed earth, of mud, or of rubble-stone; with the exception of the partitions, and the walls to *i*, *h*, *l*, and *m*, which may be of clay nogging. Near London, and in other situations where labour is high, walls of brick on edge, hollow, in Dearn's manner, § 336, would be equally cheap, and preferable on account of their neatness and durability. The roof is shown thatched, and without guttering, which, however, may be added; in which case it should be of wood or of cast iron, with an exterior moulding, as in fig. 388. In

LXXIII.

LXXIV.

LXXV.

LXXVI.

general, however, thatched roofs should either project so far as to protect the wall and windows, and also a space of two feet broad, to serve as a passage, and thus render a gutter unnecessary; or, they should have two or three feet at the eaves tiled or slated, in which latter case a much cheaper and neater form of guttering may be adopted; say as in fig. 389. One reason why guttering is objectionable to all thatched roofs is, that, by the continual decay of the thatch, they are very apt to become choked up. A large clumsy gutter, like that shown in fig. 388, is, no doubt, less liable to this than a smaller gutter, such as is suitable for a thatched roof with slated eaves, like that in fig. 389; but both will be found to require continual attention, and, after every violent shower, to be apt to choke up the descending pipe. There is a porch of trelliswork to this Design, which is so far good, as any description of porch is better than none; but there are two trunks of trees, in the manner of columns, without plinths below, and without anything in the way of an entablature above, which, we must say, we think in superlatively bad taste. What can be worse than a column supporting nothing but thatch? There is a false window to the parlour, on one side of the porch, which we disapprove of; because there must be something deficient in the invention of the Architect, when such windows are found requisite in buildings of this description. A window in a thatched roof is always bad; because the number of angles which it presents to the wind and the weather, makes the thatch which covers them go rapidly into decay, and soon admit the rain. If such windows are ever admitted, they should be in the style of that shown in Design XX., or in fig. 157. We never can bring ourselves to consider thatch as a proper covering for a building of two stories; we would limit it to low buildings, with mud or rubble-stone walls, and where no guttering was required: but let taste be free. The compactness of the plan, however, is commendable; and this is, perhaps, all that we can say in its favour. The cubic contents of this Design are 19,632 feet, from which our readers may easily form a General Estimate.

389

Design LXXIV. — Design for a Cottage Dwelling, in the Old English Style, and of a Construction suitable for having Part of the Walls covered with Weather-Tiling.

458. Accommodation. The ground plan, fig. 390, contains an entrance-lobby, *a*; hall and staircase, *b*; parlour, *c*; kitchen, *d*; wash-house, with oven-boiler and sink, *e*; pantry, *f*; dairy, *g*; beer cellar, *h*; and coal cellar, *i*. The chamber floor, fig. 391, contains three good bed-rooms, *k*, *l*, and *m*; and a light bed-closet over the lobby, *n*.

N 390

391

459. Construction. The foundations and walls of the ground-floor story should be of brick, or of rough stone with brick dressings (bricks at all the angles, whether of doors, windows, or corners), and with brick arches to the windows. These walls, of whatever material constructed, should have what is called a Welsh cornice (two or three over sailing (protruding) courses of brickwork, one of which has dentils, formed by the ends.

392

393

394

400

401

of bricks projecting at equal and regular distances,) to finish with at top; in order that the lower part of the weather-tiling, which is to cover the bed-room walls, may incline outwards, for the purpose of throwing off the water, and preventing it from running down the walls of the ground floor. The external partitions of the chamber floor should be formed of timber framing, lathed horizontally, to receive the tiling, which may be of any pattern, according to fancy. Our contributor has sent sketches, figs. 392 to 402, of all the different kinds which he recollects having seen; but as two or three sorts are generally used together, arranged alternately, it would be fruitless, he says, "to attempt sending all their combinations. It is very common to have two, three, or more courses of ornamental tiles, separated by a row of plain ones, which has a good effect." For the present Design he recommends employing successive courses of figs. 393, 394, and 395, separated by a course of fig. 392, as shown in fig. 402, "which would produce an agreeable play of light and shade, showing off some of the most pleasing alternations of straight and waved lines that this species of material is capable of producing."

It will generally be found advisable to colour the whole of the weather-tiling a light stone or cream colour, and the brick or stone walls below may be left uncoloured, or not, according to whether the natural tint of the material employed is agreeable or otherwise. The roof is to be covered

with the common plain tiles, and its picturesque beauty will be much improved if they are old ones that have lost the glaring hue which all tiles have when they are fresh from the kiln." With respect to colouring the materials of a building, it may be observed that it is not liable to the same objections as either plastering them over, or roughcasting or whitewashing them; because colouring, being much thinner, does not, to the same extent, disguise the nature of the material, and thus either destroy the natural expression of, or give a false expression to, the wall. A wall may be said to have its true and natural expression, when, at the first glance, it shows the materials of which it has been constructed; the manner in which these materials have been put together; and the principles of construction on which it depends for its stability, strength, and duration. Now, a brick or stone wall, on the external face of which the distinct shapes of the bricks or stones are clearly discernible to the eye, is the same thing, in point of the useful qualities mentioned, whatever may be its colour; but if the joints of the stones or bricks, and their surfaces, are covered with plaster or roughcast, or with such a thick coat of whitewash as to obliterate their forms and lines, the wall has lost its natural expression: it may be of brick, or it may be of hewn stone; but as every body

knows that whitewashing is generally applied for the purpose of disguise or concealment, it is fair to conclude that, wherever it occurs on the external walls of buildings, they are made of lath and plaster, or mud. To return to our Design, the general effect of the weather-tiling will be seen in the elevation of the entrance, or north-west front, fig. 404; in the south-west side, fig. 405; in the south-east end, fig. 406; and in the north-east side, fig. 407. The use of weather-tiling in England is chiefly confined to the marine

districts, where it is employed for casing the walls of buildings, whether formed of wood, brick, or stone, to protect them from driving winds that carry with them the spray of the sea, which, from the salt it contains, would otherwise render the walls damp. Weather-tiling is also used in some parts of the interior of the country, on the south-west and west sides of buildings, to protect them from the rains, which, in England, are not only more frequent from that quarter than from any other, but which are almost always accompanied by high driving winds. The most suitable weather-tiling, for this purpose, is that commonly called mathematical tiling, which is made to imitate bricks; but we shall defer our description of this kind of tiling till some future occasion.

460. *General Estimate.* Cubic contents, 18,749 feet, at 6*d.* per foot, £468 : 14*s.* : 6*d.* ; at 4*d.*, £312 : 9*s.* : 8*d.* ; and at 3*d.*, £234 : 7*s.* : 3*d.*

461. *Remarks.* This Design has been sent us by our valuable contributor Mr. Varden, chiefly with a view of showing the application of weather-tiling, as practised in the neighbourhood of Guildford, in Surrey. Speaking of the Design before us, its author observes that "it is one of the largest erections for which this manner is suitable. The effect generally pleases, from its homely and comfortable appearance. The masses are usually very irregular, convenience being more studied than uniformity; nevertheless, sometimes combinations of form occur, that would be highly gratifying to a lover of the picturesque, and might even afford useful hints to the professional Architect. This manner of building requiring an economical plan, the Architect avoids all breaks that allows the roof to project more than is wanted

Ornament is never intentionally introduced; and there is nothing in this style incompatible with the humble character of a cottage dwelling." The ground plan is compact, and the two principal fire-places are against the interior walls. It would have been easy to have changed the position of the oven and boiler in *e*, so as to have carried up the flues from them along with the others, and thus had only one stack of chimneys instead of two; but our contributor, in all probability thought that the boiler would be more convenient adjoining the sink; and, perhaps, also, he considered that two chimneys in the elevation would be more picturesque than one. For our own part, we consider that a boiler and an oven, when placed in the interior of a house, add so much to its comfort by serving as reservoirs of heat, that we always regret to see them placed against outside walls. Many persons, we are persuaded, are not sufficiently aware of the great quantity of heat that is generated in an oven, by the consumption of the most worthless looking spray or brushwood, which no good housewife would ever think of burning in an open fire-place. It is only by having an oven, surrounded by a mass of brickwork, that this spray can be properly turned to account; burned in an open fire, its heat is dispersed in the atmosphere, and speedily lost to the apartment; but burned in an oven, and the more rapidly the better, its heat is absorbed by the brickwork, and continues to be given out slowly during many

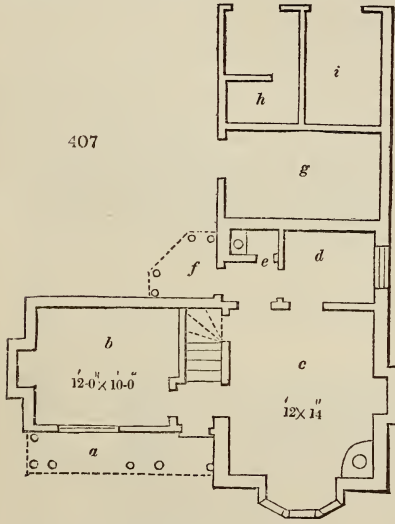

are not absolutely necessary, and never to throw off the water clear of the walls.

hours afterwards, to whatever surrounds it. If the oven has a horizontal flue proceeding from it, either under the floor as in our model cottages, or above it as a bench in the German or Chinese manner, both to be hereafter described, the heat given out will be so much the greater. The occupiers of cottages have much to learn in respect to the best mode of consuming fuel, and economising heat: but to be taught this they must become readers; or, we must have parochial discourses on economical subjects, as well as sermons on religious and moral duties.

Design LXXV.—*A Cottage in the Old English Manner, containing on the Ground Floor a Living-room, Kitchen, and other Conveniences, with Two Bed-rooms over.*

462. *Accommodation.* From the front porch, fig. 407, *a*, the entrance is to a passage and staircase, which leads on the left to a living-room, *b*; and on the right, to a kitchen, *c*; from which there is a closet, or coal cellar, under the stairs. From the kitchen there is a door to the dairy, *d*; and another to a lobby, which leads to the water-closet, *e*; and to the common entrance porch, *f*. There are a cow-house, *g*; a pigsty, *h*; and a place for hay and straw, *i*. The chamber floor, fig. 408, contains two

good bed-rooms, *k* and *l*; one of which has a fireplace.

463. *Construction.* The walls are of brick nine inches thick, and the partitions are of brick nogging flat. The roof is slated, and the chimney stacks are of brick set angularly. These angular chimneys are thus constructed: the shaft being finished square, as shown in fig. 409, an earthenware circular flue-pipe is placed over the opening of the chimney, and the square flue is made to unite smoothly with it, by being pargeted with mortar made of fresh lime and powdered brick. Bricks are then built round the upright pipe, leaving vacuities not filled up with mortar, in the four angles formed between the bricks and the pipe. As the work is raised in height, pipes are added; the length of each pipe being two feet, and each having an outside rebate at one end, and an inside rebate at the other, so as to admit of a perfect junction. We

may observe that the diameter of these pipes may be from nine to thirteen inches, according to the size of the fireplace below; and we shall show, in Book III. of this work, that by having tubes of this sort, of two feet, one foot, nine inches, and six inches, rebated as above, flues might be built in any direction, however crooked, which would require no climbing boy to sweep them, and would be attended, as we think, with all or most of the advantages of the circular flues of Hiort, Chadley, or Smith, at a comparatively trifling expense. Fig. 410 shows the plan of the projecting bricks set on edge, which form the dentils that support the capital of the shaft. Fig. 411 represents one of the chimney tops

complete, with its base, *m*; shaft, *n*; capital, *o*; and capping, *p*. Wherever a "tall boy" (see § 432.) is required to make a chimney draw, we would enclose it with brick or stone, in this, or in some similar manner, and thus get rid of those house-top deformities so cleverly ridiculed in the *Mechanic's Magazine*, vol. xvii. p. 316. "How generally," says this writer, "do we see fine terminations become pedestals for every foul thing in the shape of a cowl, a mitred, a caped, an uncaped, a vandyked, a perforated, a conical, a crooked, or a straight, "tall boy;" or to support a black pot, or a red pot, or some of the numerous devices which start up in such great profusion and variety, as soon as a new house is inhabited, or an old one changes its tenant: thus, as it were, proclaiming from the house-top, that the Architect and builder have been unsuccessful, and that some variety or other of the tinker's or potter's whims, to charm or coax out the smoke, has prevailed." What are called the genteel cottages about London, indeed, are, in this respect, a disgrace to their Architects and builders. The cow-house, hay-shed, and piggery are supposed to be of studwork,

weather-boarded, and roofed with pantiles. The ceiling of the living-room is curved, or coved at the sides (see the section fig. 412), by which means some addition is made to its height from the roof. Further details of construction will be found in the following specification and estimate; which, it may be observed, does not include the cow-house, hay-shed, and pigsty; the ingenious contributors of this Design, Messrs. W. and H. Laxton, considering that the occupant might be able, with a little assistance from a carpenter, to erect these additions at his leisure hours. The prices stated in the estimate, we should observe, are calculated for the neighbourhood of London, in the year 1832.

464. *Bricklayer and Digger's Work.* To build the walls, as shown in the plan, one brick thick, with one brick and a half footing, one foot high: —

	£	s.	d.
Five rods of reduced stock brickwork, at £12 per rod .....	60	0	0
Twenty-four yards and a half superficial of brick nogging flat, to the partitions on the ground-floor, at 3s. : 3d. per yard.....	3	19	8
Two yards superficial of stock brick paving laid flat, for the closet or coal cellar under the stairs, at 2s. : 3d. per yard.....	0	4	6
Two hundred and fifty-two feet superficial of foot tile paving to the kitchen, dairy, and fire-places, at 6d. per foot.....	6	6	0
Twenty-five feet lineal of eight-inch draining pipes, and digging for laying them, from the water-closet and sinkhole, to a tank in the yard, or some other part of the grounds, at 1s. per foot.....	1	5	0
A cast-iron basin and trap to the water-closet, figs. 413, 414, and 415. ....	0	10	0

(Fig. 413 is the surface plan of the basin; and fig. 414 is a view of it before it is built in. Fig. 415 is a section of the

basin, as built in; in which *q* is the trap; *r*, the riser of the seat; *s*, the seat; *t* *t*, the brickwork of the drain; and *u*, the drain. It is evident, from this figure, that no smell can penetrate from *u* upwards, it being intercepted by the trap, *q*; and the water into which it dips.)

Digging out foundation, levelling, &c., say .....	1 : 0 : 0
Ten squares of countess slating, laid on three quarters of an inch batten, with eaves, boards, and tilting fillets to the rakes, complete.....	17 : 10 : 0
Forty feet six inches lineal of ridge tiles.....	0 : 13 : 6
Three chimney pots formed in brickwork, set angularly.....	1 : 10 : 0

£92 : 18 : 8

465. *Carpenter's Work.*

Rafter and ceiling joists, four inches by two inches; ridge pieces, nine inches by two inches; wall plates, four inches by four inches; purlins, four inches by four inches; joists, seven inches by two inches and a half; bond, four inches by two inches and a half; and lintels, four inches by four inches: one hundred and forty-eight cubic feet of Memel fir timber, including labour and nails...	25 : 18 : 0
Three squares and a half of four-inch quartering in partitions, framed complete .....	5 : 5 : 0
Three squares and a half of one-inch deal wrought folding floors...	7 : 0 : 0
One hundred and seventeen feet lineal of skirting worked out of two-cut battens, including wooden bricks and backings.....	2 : 8 : 9
Seventy-four feet superficial of one inch and a half square framed partition, between the stairs and the small bed-room. ....	2 : 15 : 6
Eight one inch and a half four-paneled square doors, six feet six inches high, by two feet six inches wide, with one inch and a quarter single rebated linings, and a moulding round both sides; hung with three-inch butt hinges, and having a six-inch iron-rim two-bolt lock to each .....	11 : 4 : 0
Two outside bead butt and square doors, with fir frames, four inches by three inches, rebated and beaded, with a moulding round inside. The doors hung with three-inch butt hinges; and having two bolts, and a seven-inch three-bolt iron-rim lock to each.....	3 : 12 : 0
Four window frames and mullions, containing seventy-six feet lineal, of one and a half inch deal, wrought, rebated, and beaded, four and a half inches wide, with forty-eight feet lineal of moulding round the frames inside .....	2 : 0 : 0
One bay or bow window in three divisions, containing thirty-eight feet six inches lineal frame and mullions, four inches by four inches, wrought, framed, rebated, and beaded. Twenty-four feet lineal of moulding inside, and fourteen feet lineal of moulded cornice and base, to the top and bottom of the frame outside .....	1 : 10 : 0
Six three-quarter-inch proper ledged lifting shutters to the lower windows, four feet by one foot six inches, with fastenings.....	2 : 5 : 0
A flight of stairs, containing fifty-three feet superficial of one and a quarter inch deal steps, and inch risers, bracketed and housed into	

strings, fifteen feet superficial, one inch and a half deal wall string, and seven feet superficial of ramped ditto; twenty-five feet lineal of beaded capping, and three feet of framed newel .....	£ s. d. 3 : 17 · 0
One small skylight, frame and lining, to the upper part of the stairs, in the roof.....	0 : 7 : 0
One and a quarter inch deal seat, riser, and bearer, to the water-closet, with hole cut and cover lined, and skirting round.....	0 : 12 : 0

472. *General Estimate.* The cubic contents of this dwelling are 11,686 feet, which, at 6*d.* per foot, make £292 : 3*s.* ; at 4*d.*, £194 : 15*s.* 4*d.* ; and at 3*d.*, £146 : 1*s.* : 6*d.* As Mr. Laxton's estimate amounts to £229 : 19*s.*, it thus appears that about 4 $\frac{3}{4}$ *d.* per foot is a fair price for buildings of this description, in the neighbourhood of London, in the year 1832.

473. *Remarks.* The general effect of this building is good; but, for comfort, and especially warmth, the chimneys ought not to have been in the outside walls. In countries where fuel is abundant, or in those where fire is wanted chiefly for cooking and washing, this will be no great objection; but, in Britain, no exterior beauty or character can, in our opinion, compensate for having the fireplaces in the outside walls. When the chimneys are in the interior walls, they not only keep the whole house warm, but they invariably draw better. Knowing, and being deeply impressed with, these two facts, chimney shafts, when rising from the centre of a roof, always appear to us more beautiful than in any other position; and in this sentiment we think we are correct, because the origin of all beauty must necessarily be utility. The difference between us and those who prefer the chimney shafts on the gable ends, consists in their judging with reference to a different standard. If we ask what that standard is, we shall generally be told that it is picturesque effect; sometimes, perhaps, the imitation of particular styles of cottage building, which have resulted from accident; and occasionally, though rarely, symmetry and regularity. In our opinion, the grand and fundamental principle of exterior beauty in dwellings is to be found in their internal accommodation and comfort. Whatever is required by or consonant with this, must be beautiful in the eye of reason; and all exterior beauty inconsistent with this, must depend on associations, which, not having their origin in reason, may be called arbitrary or accidental, and ought therefore not to be relied upon. All Architecture being founded on necessity and reason, and not on the imitation of any objects whatever, either of nature or art, it follows that the external beauty of any edifice as a whole can never be truly judged of, without a knowledge of the uses for which it is designed. So also the beauty or propriety of the various parts and details of a building, such as walls, supports, openings, &c., cannot be properly appreciated, unless we know the nature of the materials employed. We cannot, for example, decide as to the width of a doorway or a window, unless we know the materials of the wall in which the opening is made; as well as the mode, whether by an arch or a lintel, in which that opening is covered. Neither can we estimate the weight which any prop or column will bear, unless we know the material of which it is composed. The proportions of a column, in timber, which may be very suitable for what it has to support, and therefore beautiful, would be more than sufficient, and therefore cumbersome and inelegant, in stone, and still more so in iron. It is true, that, in judging of doors, windows, and columns, a very small portion of man-

kind do so with reference to this standard; but it is not, on that account, the less founded on reason. The common standards of Architects, whatever may be the material employed, are the models handed down to us by the ancients; and the common standards of the rest of mankind are the works erected by the Architects for the time being. Thus precedent takes the place of principle; and in Architecture, as in every thing else, fashion ultimately usurps the part of reason. But it is the province of criticism to test the fashions of the day, by a recurrence to first principles, and to endeavour to recall mankind to the consideration of fundamental laws. In no art is this more requisite than in Architecture; the pretended knowledge of which has hitherto, in all ages and countries, been in the hands of a few; but which, to be improved and brought to perfection, ought to have its principles universally studied and understood, so as that its works may be examined and criticised on these principles by the many. In the infancy of all art, the many are necessarily led by the artists, and their arbitrary rules become law; but, with the progress of things, the many become enlightened, and, judging for themselves, force the professors of art to recur to fundamental principles; and it is self-evident, that, in a useful art, these principles must be based on utility. These remarks are not more applicable to this Design than they are to several others; but we consider it necessary to make them, with a view of impressing on our readers the necessity of mainly depending upon their reason, in judging of all architectural works whatever.

Design LXXVI. — *A Cottage Dwelling, One Story high, containing Six Rooms, a Wash-house, and other Conveniences.*

474. *Accommodation and Construction.* The ground plan, fig. 419, contains an entrance-porch, *a*; breakfast-room, *b*; dining-parlour, *c*; two good bed-rooms, *d* and *e*; with two closets in *d*; a servant's bed-room, *f*; kitchen, *g*; wash-house, *h*; and privy,

419

*k.* There is a cellar under *c*, which is descended to by the stairs, *l*. A well may be dug, and a pump fixed either in the wash-house, or in the yard, *m*. The wall *n* may be continued at convenience, the south-east side of it enclosing a yard, in which may be placed a chicken-coop, pigsty, coal-house, dirt-bin, wood-house, and other conveniences; and the north-west side may form one wall of the garden, against which, of course, fruit trees may be trained. It is proposed to have a cistern for rain water, over a part of the wash-house, to be formed of wood, and lined with zinc, as being much cheaper than lead. To this the water is to be conveyed by large wooden gutters, lined with zinc, to the thatched roof. The waste water from this cistern, and from the wash-house and from the pump, is to be led through the drain of the privy, to the liquid manure tank. The walls are proposed to be of chalk-stone with brick corners; and with brick facings

and labels to the doors and windows, which are intended to have stone sills; the roof is to be thatched with reeds, and the chimney tops are to be formed of Roman cement. The whole is to be embraced by a platform on three sides.

475. *General Estimate.* Cubic contents, 13,308 feet, at 6*d.* per foot, £332 : 14*s.*; at 4*d.*, £221 : 16*s.*; and at 3*d.*, £166 : 7*s.*

476. *Remarks.* This Design, which has been sent to us by our much-valued contributor, Samuel Taylor, Esq., of Stoke Ferry, Norfolk, is calculated for being built of chalk-stone, which forms the cheapest material of that country, and for being covered with reeds, the produce of the adjoining fens. It forms a comfortable and commodious dwelling, expressive of what it is; and, from the height of the walls and the proportions of the windows, is rather elegant than otherwise. We cannot justify the Gothic labels over the doors and windows, immediately under a far-projecting roof; because no other part of the building is in the Gothic style, and because labels of any kind, in such a situation, cease to have any character of use. "From truth and use all beauties flow." (*Epistle to Lord Lowther on Building and Planting.*)

Design LXXVII. — *The Model Cottages of the Labourer's Friend Society, as erected at Shooter's Hill, Kent.*

477. *Accommodation.* These cottages are built in pairs, in such a manner as to have the fireplaces in the party walls; the ground plan, fig. 420, shows, for each cottage, an entrance-porch, *a*; kitchen, *b*; pantry, *c*; and closet under the stairs, *d*.

The chamber floor, fig. 421, shows two good bed-chambers to each cottage, without fireplaces. The privy, pigsty, and other conveniences, are built apart. To each double

cottage are annexed two acres and a half of land.

478. *Construction.* The walls are raised on grouted foundations (grout is composed of fresh lime and gravel, mixed, and immediately thrown in, beaten down, and left some days to consolidate), two feet broad and two feet deep; over which are two courses of twenty-two inches in width, and two of eighteen inches, as a footing, and four courses of fourteen inches as a plinth. The walls above are nine inches,

and hollow, and one course of slates is laid before the floors commence. The bricks are all hard stocks; the timber Swedish or Baltic; the window sills and landings of York stone; the chamber flooring of inch and quarter deal, ploughed and tongued (a groove made along the edge of one board, and a tongue or projection worked along the edge of the other, to fit into it, fig. 422); the window casements are of iron, and the roof slated. The course of slates is laid along the walls, just beneath the ground floor, in order to prevent the damp from rising through the vacancies, which are two inches wide, being formed in the manner shown in fig. 7, § 25. The brickwork is worked to a smooth face inside, and not plastered, but only whitewashed. The outside of the walls is thus left rough, and it is brought to an even surface by rough-casting it with a mixture of lime and fine gravel, which, when completed, has the colour and texture of Bath stone. The floors of these cottages are fifteen inches above the general level of the surrounding ground: twelve inches of this space is filled with gravel, and the top

three inches with grouting, which forms a hard bottom, upon which is laid a flooring of foot square paving tiles. The roof, as shown in fig. 423, projects, in order to keep the walls dry.

479. *Estimate.* Twelve of these cottages have been erected on Shooter's Hill, at £115 per pair, under the direction of our contributor, W. Bardwell, Esq., for the Labourer's Friend Society. The cubic contents of the building are 9620 feet; which shows that  $2\frac{3}{4}d.$  per cubic foot is the proper rate for making a general estimate for this description of dwelling.

480. *Remarks.* This Design, which has been published in *Facts and Illustrations demonstrating the Benefits derived by Labourers from possessing small Portions of Land, &c.*, vol. i. p. 31, was recommended to us, for our work, by its author, Mr. Bardwell. Considering the size of the rooms, these dwellings are certainly remarkably cheap; and we are informed that, in consequence of the grouted floors and hollow walls, they are the driest cottages in the neighbourhood where they are built. We agree with the writer, who describes them in the work referred to, that, as all the materials are of the best quality, these cottages will be as durable as they are cheap; and that they may justly be considered elegant, from the proportions of the openings, the pediment ends, the low pitch of the roof, and "the Doric simplicity of their general form."

422

The quantity of land annexed

423

to them seems large; but the reason may be that the occupiers are supposed not to have regular employment, and to find a ready market for garden produce.

Design LXXVIII. — Six Cottage Dwellings, built at Abersychan, near Pontypool, in South Wales, with One common Wash-house and Bakehouse.

481. The object of building these dwellings, of which fig. 424 is the elevation, and 425

424

the ground plan, both to a scale of five sixteenths of an inch to ten feet, was to afford lodgings for the workmen of Messrs. Jones and Wilcox, builders, of Bristol, during the

time they were employed in erecting the extensive furnaces of the British Iron Company at Abersychan.

482. *Accommodation.* The ground plan of each dwelling shows a passage, with a wooden dresser along the side, fig. 425, *a*; living-room, *b*; and back-kitchen, *c*; over

425

which are two good bed-rooms. There are a wash-house, *d*, with two boilers and two ovens, common to the whole; and four privies, *eeee*. The front room, over the bake-house, belongs to the dwelling, *f*, which was occupied by the foreman of the masons; and the back room, over the privies, belongs to the dwelling, *g*, which was occupied by the foreman of the smiths. Each dwelling has a strip of garden-ground behind, and they are all supplied with water by a mountain stream, which afterwards passes through the drains of the privies.

483. *Construction.* The walls are of stone, quarried on the spot; the outside and party walls are eighteen inches in thickness, and the inside ones one foot. The floors are paved with stone, and the roofs covered with grey slate. The elevation, fig. 424, is wholly without ornament.

484. *Estimate.* These dwellings cost, including the wash-house, privies, enclosing the garden ground, &c., £800, which gives £133 : 6s. : 8d. for each cottage. As the whole line of building contains 61,005 cubic feet, it appears that 3d. per foot is the proper sum for employing in its general estimate.

485. *Remarks.* This Design was sent us by our esteemed friend, Samuel Taylor, Esq., as a specimen of a very cheap and simple mode of building dwellings of the lowest degree of accommodation in a stone country. The elevation has nothing to recommend it in point of effect: but, by advancing the wash-house in front; by putting a screen wall before the privies behind; by reversing the position of the doors of the three dwellings on the right-hand side of the centre, in order to get the fireplace of the end one against a party-wall, as well as to maintain uniformity in the position of the doors and windows; by projecting the roof at the eaves, and forming pediment ends; by introducing a string

426

course under the bed-room windows; and by raising and ornamenting the chimney tops, a very superior description both of elevation and plan, figs. 426 and 427 will be produced.

427

If such a line of cottages were erected in a country where fuel was dearer than it is at Abersychan, it might be worth while to keep the floor of the wash-house three feet lower than that of the dwellings, and to conduct the flues from the boilers and ovens under the floors of the living-rooms, in the manner indicated in § 19. Perhaps some might think that it would be an improvement in our elevation, fig. 426, to bring the windows of the living-rooms more into the middle of the space between the door and the party-wall; and also to bring the door to the back-kitchen into the middle of the space between the passage door and that party-wall, as in figs. 428 and 429; and we grant it

would, looking no farther than mere symmetry; but in figs. 425 and 427 there are spaces in the living-rooms at *h*, and also at *i*, in which a person may be seated at work without being in the draught between any opening and the fireplace; and also in which tables or dressers might be placed: but supposing the door of the back-kitchen and the front window placed in the middle of their respective walls, as in fig. 429, there will be no place for either table or dresser, and the whole room will become, as observed by one of our correspondents § 365, a complete "Temple of the Winds." Thus, though there cannot be a doubt that, in point of architectural symmetry, the elevation, fig. 428, is much more beautiful than fig. 426; yet, in point of fitness, that is, with reference to the interior plan, the latter is decidedly more beautiful than the former. Can there be a doubt, then, which kind of beauty ought to be preferred, in cases of this sort? We say there cannot. The most useful is unquestionably the most beautiful. When the question is between a beauty belonging to the expression of art, and a beauty connected with fitness for enjoyment, it is clear to us that the decision ought to be in favour of the latter. The great object of the Architect ought to be, to combine the two species of beauty; but as this cannot be done in every case, it is clear, that in judging of a building merely by its exterior, unless we are intimately acquainted with its use, we can only decide as to its symmetry, or other architectural expression. To form a just taste in architecture therefore, it is as necessary to study all the various purposes to which the different parts of the interiors of buildings are applied; and the different modes of lighting, warming, and ventilating, of supplying water and draining, of avoiding bad smells, damp, dry rot &c., as it is to study the original or conventional beauty of lines and forms. It may be useful to observe that the chimney tops in figs. 426 and 428 are formed by setting up four slate stones, such as fig. 430, two about a foot, and two about eighteen inches broad, and all from three to four

feet high; firmly flanching them to the top of the chimney shaft with cement, and sometimes cramping them with iron into each other. Over these slates is placed a two-foot square slab,

fig. 431; and on that a truncated pyramidal stone, fourteen or sixteen inches square at the base, fig. 432. The handsomest cottage chimneys on the banks of the lakes of Cumberland and Westmoreland are formed in this manner; and we shall give specimens of some of them in the historical part of this work.

Design LXXIX. — *Twelve or more Cottages in a Row, with a Kitchen, Wash-house, and other Conveniences, in common; the whole heated by the Fires in the public Kitchen.*

486. *The object of this Design* is to show how the modes of heating under the ground floor, and of having a common kitchen and wash-house, may be applied to a number of houses together, so as to produce very comfortable dwellings at a very moderate expense. By rendering fireplaces and chimneys unnecessary, not only is the expense of building them avoided, but also that of employing any other material than mud or earth in any part of the walls, or of having them, in any part, more than nine or ten feet high. It will be evident, after considering this Design in detail, that the domestic labours of a family living in one of these dwellings will be considerably diminished, and their comforts, at the same time, greatly increased.

487. *Ground Plan of the public Offices.* The dwellings and offices may be either erected in a straight line, or in a curved line; or they may form two or more sides of a quadrangle. For so small a number as twelve, we prefer a straight line. At one end of this line we place the common kitchen, fig. 433, *a*; in which there are two ovens for baking and roasting, *b*; an open fireplace, *c*; and three boilers for cooking and washing, *d*. The floor of this kitchen is four feet below the level of the floors of the dwellings, in order that flues from the ovens, and also from the boilers and the open fireplace in the centre, may be conducted under the floors of the drying-room and sitting-rooms, for heating them. Two ovens are shown, because, in the most severe weather in winter, the heat from one oven may not be sufficient for the floors. There are three boilers, in case of accident to one, and also because one boiler may be required for washing or brewing, while the others are being used, the one for boiling potatoes, and the other for making soup. The open fireplace is for the cooking of small articles by individuals. The roasting and baking is supposed to be carried on in the ovens, and the boiling meat chiefly in one of the boilers, in which also vegetables may be introduced to form soup; while another boiler may be devoted exclusively to potatoes; and the third to hot water. There may be a large table, with benches along its sides, in the centre of this kitchen, at which those who choose may dine. There are a cellar, *e*, and a store-room, *f*, adjoining, in which potatoes and other roots, flour, meal, barley, table-beer, &c., may be kept for sale to the occupiers. The common wash-house, *g*, is fitted up with washing-troughs, from *h* to *i*; and there is a pipe of hot water from the boiler in the kitchen, and another of cold water from a cistern over the wash-house; both which communicate by cocks with each trough. There is also a hole in the bottom of each trough, with a stopper, for emptying its contents into a common drain, connected with the cess-pool of the water-closets. There may be one of Siebe's pumps in the wash-house, where it would be completely protected from the frost; and by this, the water might be raised from a well, either in the floor of the wash-house, or at any convenient distance from it, to the cistern. This cistern would also be completely protected from the frost; and from it a pipe might be conducted along the upper part of the middle wall, which separates the sitting-rooms from the bed-rooms of the dwellings, so as to supply each house. Another pipe, with a ball cock, will give a perpetual supply to the hot-water boiler; from which the water may be drawn for the use of the kitchen by one cock, as it is in the wash-house by several. This boiler, intended for the purpose of affording a perpetual supply of hot water, should be raised considerably higher than the cooking boilers, in order to supply the water at a sufficient height for the washing-troughs; the floor of the washing-house being on a level with the floors of the dwellings, while that of the kitchen, as already observed, is four feet below them. Adjoining the wash-house is a drying-room, *k*, heated by the hottest part of the flues which proceed from the ovens, the open fireplace, and the boilers; and, to increase this heat, a part of the flues may be covered with cast-iron plates, over which may be a false floor, one inch distant from them, so contrived as to create a draught, on the

principle before mentioned, § 306. There are two divisions of privies; one for the females and young children, *l*; and the other for males, *m*. The drain, common to both, is connected with three covered cess-pools, *n*, *n*, and *o*; by which, with the aid of two sluices or plugs, as described in § 16, *s*, the liquid manure in one tank may be allowed to ferment, while one of the others is being filled, and the third being emptied. Over these cess-pools are two dung-pits, *n n*, and one pit for rubbish not convertible into manure, *o*.

488. *Accommodations of each Dwelling.* The entrance is by a lobby, *p*, in which there is a sink with a water-cock at one corner, and the other corner may do for the tools, brooms, &c. A door from this lobby opens into the living-room, *q*, which is of a commodious size, nineteen feet six inches by thirteen feet six inches. In this there is a place, *r*, with a raised hearth for keeping food or water hot over a lamp, a little charcoal, or a fire pail, there being a small flue formed of earthenware pipes, for carrying off the smoke. This cooking place, however, is only intended to be made use of in case of family sickness. Adjoining, there is a closet cupboard, *s*; and at the opposite end of the room there may be corner cupboards, a' dresser, or any piece of furniture or kind of fitting up the occupier may prefer or find necessary. There are three bed-rooms, *t*, *u*, *v*, the largest for the master and mistress; and the centre one, *u*, having the window down to the floor, paneled below, and to open as a door. This door is to be considered as exclusively for the use of the females.

489. *The flues under the floors* will be six in number, going from the three boilers and the two ovens. We propose that the whole of these flues should be placed under the floors of the living-rooms, and that all of them should go from the drying-room in direct lines to the extreme end of the dwellings, each outgoing flue having a return flue alongside of it. There will thus be six outgoing and six return flues; which, covered with one-foot tiles, will serve as flooring to the whole of the living-rooms. In order to prevent the smoke from rising between the joints, narrow slips of slate must be laid under each; or, what would make a warmer floor, the whole should be covered with cement, or artificial stone composition. As heat will not be required under any of the floors during the summer season, except that of the drying-room, it is proposed to have all the upright flues in the party wall between the drying-room and the first dwelling, and to have two communications with each of these upright flues, one from the outgoing flue immediately under it, and the other from the return flue of the same outgoing flue. By having a damper in the first, the smoke might be either sent round the horizontal flues, for the purpose of heating the dwellings; or, when heat was not wanted, allowed to escape through the upright flues. These dampers will thus serve to regulate the heat supplied to the floors of the dwellings; and, in the end of spring and the beginning of autumn, when only a little heat is wanting, some of the dampers can be drawn out; while in winter, when a maximum of heat is required, they can all be pushed in. The dampers will also be useful when first lighting the fires in the mornings; because withdrawing them will create a draught. The number of dwellings, which it is supposed these flues might heat, with no other fuel than what was required for the cooking and washing of the occupants, is here estimated at twelve; but, if the houses were placed on a slope, the fires at the lower end, and the upright flues at the upper end; the outgoing horizontal flues having no returns, the number would no doubt be greater. Much will depend on the kind of fuel used, and on care being taken to let no air pass into the flues from the furnaces or ovens, that has not entered by the ash-pit doors, and ascended through the fires; and also, that, when no fires require to be made, the furnaces, ovens, and ash-pit doors are kept closely shut. The best fuel for heating flues is that which burns the quickest, such as faggot wood, spray, shavings, &c.; and when once heated they ought to be closely shut up, to prevent a draught of air from cooling them.

490. *Construction.* We have shown all the outside and party walls as eighteen inches thick, and the partition walls as one foot thick, on the supposition that it would be cheapest to build them in mud or rammed earth: there will thus be no brickwork required, but for the ovens, fireplaces, and flues. The walls may be finished inside according to the taste or means of the party. The roof may be of thatch, or whatever material is cheapest in the given locality; it ought to project at least three feet on every side, as well for protection of the walls, as to form a covering to the terrace path, which will form the common passage from all the dwellings to the offices; and also to save the expense of gutters. In the roof of each dwelling there should be an opening of two or three inches square over the raised hearth, corresponding with a similar one in the ceiling under it, to admit the escape of smoke, when a lamp, embers, or charcoal,

434

happened to be used in the heating place. The opening in the roof may be simply a pan-tile with a covered hole, fig. 434, such as are common in the neighbourhood of London. If thought necessary, a small flue to each cooking place could easily be made by earthenware tubes, ten inches or a foot in diameter, such as fig. 435, with a cap to keep off the rain, fig. 436. These tubes are common in all potteries, and are sold in the neighbourhood of London at only from ninepence to tenpence per foot. The same description of tubes, twelve or thirteen inches in diameter, may be used in forming the six upright flues to the six fires, which will thus render brickwork unnecessary for them, except at the dampers, and for the chimney shafts. All the window casements may be of iron, and all the doors ledged; and no window shutters can be required where there is perfect security, and abundance of heat. Warm curtains of some cheap worsted stuff in winter, and calico blinds in summer, will be found preferable. The privies are not proposed to be made water-closets; but to prevent the rising of smell, a description of cheap basin and trap may be used, such as fig. 437,

manufactured at the common tile potteries about London, and sold by retail at 2s 6d. each; or fig. 438, which has a hole for a water-pipe at *w*, and forms altogether a very complete trap; these are also made at the tile works, and are sold at 5s. each. It will be understood that the upper part, *x*, of fig. 438, is a separate vessel, of a funnel shape, and that the lower part, *y*, is a basin with a soil pipe, *z*; and that when the funnel is placed in this basin, it must be so adjusted as to have its truncated extremity reach to within two or three inches of the bottom. As this funnel, from its construction, must then necessarily remain immersed in water as high as the under part of the soil pipe or discharge tube, *z*, it is evident that no smell can rise through the funnel. When *x* has been properly adjusted to *y*, it must be made air-tight with cement.

491. *General Estimate.* The cost of these dwellings will evidently depend much on the price of common country labour; for the work of the carpenter and joiner is very limited, and still more so that of the bricklayer. From a rough calculation made for us by an experienced surveyor, it appears that the whole of the twelve dwellings, with the requisite offices complete, as shown in the plan, might be executed, where common labourers' wages are 10s. a week, for about £500; which averages less than £50 a dwelling.

492. *Remarks.* Wherever this plan is proposed to be carried into execution, choice should be made of a dry soil, because that will greatly lessen the expense of the footings to the mud walls, to the flues, and to the platform. It must not be forgotten, also, that a level spot is to be preferred, unless one of a uniform slope is obtained, and the number of dwellings increased so as not to require the flues to be returned. We have no doubt that in many situations, perhaps in most, it would be least expensive to form all the flues of thirteen-inch tubes, so close together as to touch each other, supported on brick or stone piers, filling up the interstices above them, and levelling the surface so as to form a comfortable floor over them with concrete (gravel and mortar), and the flooring composition before mentioned, § 386. These, and every other description of flue in this position, the direction being straight, may be easily cleaned, which they ought to be at least four

times a year, by first pushing a slight line through them, by means of a series of hazel rods, or rods of any kind, tied one to another as inserted, and afterwards with this line introducing a rope, to which a bunch of straw is attached. Not one tile of any of the floors would require to be disturbed, but merely the ends of the flues opened, by taking out foot tiles, built in so as to be convenient for that purpose. The farther ends of all these flues will necessarily be on the outside of the gable end of the last dwelling, and the other ends will either form the throats of the ovens and furnaces, or they may terminate in the drying-room, close under the dampers, where their covering tiles may be taken up. It would save some trouble, if, when each flue was built, a copper wire were laid in it, extended from one end to the other. This might always be employed, when they were being swept, to draw through a rope. It may be thought that a line of buildings of this description, fig. 439, with no chimneys but in one place, would be rather

mean than ornamental; but that difficulty would be easily overcome, and would speedily be so, if such dwellings were found as comfortable and economical as we consider they would be. By employing tiles of any of the Italian forms for the roof, by heightening the architectural expression of the walls, and by surrounding the whole with a light zinc-roofed veranda supported by iron columns, the whole might be rendered elegant, as well as comfortable; not to speak of the additional beauty which might be given by ornamental shrubs and flowers, and by the gardens. In countries where grapes ripen in the open air, the whole roof might be covered with vines; and in colder climates, even apples, pears, cherries, or plum trees, might be trained over it in the same manner.

Design LXXX. — *Eighty Dwellings of the humblest Class, placed together, with a View of being heated by One common Fire, and enjoying other Benefits, on the Cooperative System.*

493. *General Purpose.* Our able contributors, Mr. Laxton and Mr. Taylor, have shown, § 290 and § 481, how six labourers' families may live together under one roof, and use, in common, the same wash-house, oven, drying-closet, well, &c.; and we have, in both cases, suggested how the six dwellings may be heated from one fire. In our last Design, we have extended the idea of a common kitchen, wash-house, and other offices, to twelve dwellings, and shown how they might all be heated from the fires which must necessarily be kept in these offices, for cooking and washing. We now intend to show an extension of the principle, so as to include any number of dwellings, with common offices for cooking, washing, baking, brewing, bathing, &c.; and, instead of employing common smoke flues, as in our last Design, for heating the whole, to adopt, for that purpose, steam or hot water. Mankind are beginning to allow that society is in its infancy, and that "the grand secret of its improvement is in union and cooperation;" although, as the writer in the *New Monthly Magazine*, from whom these words are quoted, observes, Mr. Owen, the founder of the cooperative system, may be laughed at in the mean time by those who do not comprehend his doctrine. Our object, in giving this Design, is to show the application of the cooperative principle in what may be called a college of mud houses, for the humblest class of country labourers; by which it will appear, that, by such a plan, their comforts, compared to what they enjoy at present, even in the best districts of Britain, may be increased in an almost incredible degree. We shall not go very minutely into details; because we are aware that the labouring classes

themselves must be rendered alive to the benefits which would result to them from adopting plans of this kind, before they can be carried into execution with much prospect of success. Good, however, will result from making such plans known, because it will prepare the way for them in the minds of the rising generation.

494. *Locality.* The place where such an assemblage of buildings ought to be erected must depend on the kind of labour supplied by the occupants, and the demand for it. Such a Design as the present would answer best in the immediate neighbourhood of a large manufactory, or, in a mining district; or, in short, wherever mankind are employed in masses: but it would also answer for a central situation in an agricultural district, where the number of hands required was such, that none of the eighty men supposed to be here congregated together would require to walk more than a mile to and from their work morning and evening. In the neighbourhood of a large town like London, such a working man's college might be set down, though at a distance of several miles; because there is always abundance of public conveyances to carry the occupants to and from their work, and others might be started, either by individuals or by the college itself, to carry a greater number, and at a cheaper rate. In the best cultivated districts of Scotland, where the farms are large, it is the custom, during harvest, and we believe also during the turnip-hoeing season, to carry the labourers to the field and back again in carts; the same thing is also done with the colliers in the coal districts of Staffordshire, and has been lately adopted with the letter-carriers in London. Why, then, might not even an agricultural college, and much more a manufacturing or a mining one, support a public carriage for the accommodation of those of its inmates who had to go the greatest distance to their work? Such a college must always have a certain portion of land for the growth of culinary vegetables, &c., the culture of which would fill up all the spare time of the horses and their driver.

495. *Situation.* Whatever may be the locality of such working-man's college, the situation ought to be dry and elevated; and the summit of a regular knoll, or a level spot, will always be found preferable to an irregular surface, on account of the greater

440

facilities which it affords for heating and supplying water to every separate dwelling. The aspect of this and of all similar buildings ought to be such as that the sun may shine on every front nearly every day in the year.

496. *General Form.* In all cases where economy is a leading object, the quadrangular form presents itself as the best. When the number of dwellings is few, as in Mr. Laxton's plan, fig. 267, or that of Mr. Taylor, fig. 424, or in a plan which we made in 1818, for a London college for working men (see *Mech. Mag.*, vol. xvi. p. 321), the whole of the buildings may be under one roof, and several floors may be formed one over another, and ascended to by stairs, or, as we proposed in the plan alluded to, by an inclined plane. In Design LXXX., however, we intend to have all the buildings only one story high, as cheapest, and as admitting of their being built of mud, or of compressed earth, chiefly by the occupants themselves.

497. *General Arrangement.* In the quadrangular plan, fig. 440, we have shown in the centre the public offices of the college, which include one fireplace, from which all the artificial heat required proceeds, and the public kitchen, store-rooms, dining-rooms, schools, &c. In the circumference we have placed eight lines of dwellings; every line containing ten dwellings marked 1 to 10, of four apartments in each, similarly arranged to the dwellings in the preceding Design. At the angles, *a a a a*, are water-closets; those entered from the inner side for the women and female children and infants, and those from the outer side for the men and boys. There is one carriage road, *c d*, which passes through the centre of the quadrangle, and two walks, *e* and *f*, which connect the centre with the circumference, at right angles with the carriage road. Both the central buildings and the outer quadrangle are raised on platforms; and the roof of the outer quadrangle is supposed to project at least three feet outwards from the walls, in order to give a dry path, at all times, along both sides of the dwellings. The four enclosed areas, *g, h, i, k*, may be devoted to public gardens and play-grounds. Exterior to the quadrangle, each dwelling is proposed to have a small grass plot or flower-garden, *l*, the width of its front, and about fifty feet in depth; beyond which there may be a circumferential walk, *m*; and, beyond that, gardens for fruit, flowers, and amusement, to each house, *n*. Last of all may come the vegetable ground, and dairy and poultry farm, belonging to the college, with its cow-house, stable, piggery, poultry-house, &c.

498. *Arrangement of the public Offices.* The most important of these is the fire and fuel room, fig. 441, *o*, in which all the artificial heat required either for cooking, washing, drying, &c., in the public offices, or for heating or cookery in the private dwellings, is generated; and from which it is distributed in the manner hereafter described. Adjoining this is the public kitchen and bakehouse, *p*, in which the roasting is supposed to be done in an oven, heated, of course, by the common fire in *o*; and in which there is also a baking oven, which may be either heated in a similar manner, or by Perkins's hot-water apparatus, which is connected with the common fire, and by which all the heat requisite for boiling, stewing, and similar culinary operations, is supposed to be supplied to the kitchen in small iron tubes of hot water and steam under compression, and raised to a temperature of from 300° to 400°. The same mode is proposed to be adopted for conveying heat to every public office and private dwelling. Adjoining the kitchen are, a scullery, *q*; dairy, *r*; larder and pantry, *s*; store-room, *t*; potato and root cellar, *u u*; brewhouse, with beer-cellar under, *v*; drying-room, *w*; wash-house, *x*; dining-rooms, *y y*; office for keeping the college accounts, and public library, *z*; infant school, *a*; boy's school, *b*; girl's school, *c*; bath for boys, *d*; and for girls, *e*. The mash tub may be in the upper part of the brewhouse, and the water may be boiled in it, by a pipe from Perkins's heating apparatus; from this the liquor may be let down into successive coolers, and working vats, till it is at last delivered by a funnel and pipe

441

to the different barrels in the cellar, as is done in the brewhouse of the Bush Inn, at Dudley. Adjoining the brewhouse is an apartment, *u*, with a cellar under it, for keeping potatoes and other roots; the upper part being devoted to fruits, herbs, and seeds. At this extremity of the building are the baths, &c. The two dining-rooms are each forty feet by twenty-five feet, which will afford space for two tables in each room four feet broad by twenty feet long; and these, with side-tables along the sides of the rooms, will dine 160 persons at once, in the two rooms. The entrance to these rooms is direct from the kitchen, and they are supposed to be surrounded by a sideboard shelf, one foot broad, above the dining-board, which may be two feet in breadth. The four detached tables are also supposed to have narrow elevated shelves, running along their centres, on which may be placed plates, and various articles, to which the party at table may help themselves, and thus lessen the labour of waiting. The tables may have a strip of iron along their margins immediately under the line of plates, and this iron may be easily kept hot during dinner by a very small pipe of hot water passing under it; thus preserving the food of each individual quite hot while being eaten. The office and public library, infant school, and the two Lancasterian schools for the older boys and girls, which, when not occupied by the children, may serve as lecture-rooms, places of public discussion, &c., may be heated by hot-water pipes from the common fire; as will the water in the baths, which it is supposed will be in use every day for washing the children. These bath rooms may, if requisite, be easily filled with steam, medicated or otherwise, for the benefit of rheumatic patients, and along their sides there may be long troughs, with forms beside them, for the larger children to sit on while washing their feet; and into these troughs hot or cold water may be admitted by cocks, and drawn off in the same manner by a waste pipe, which will convey it to the manure tanks. A similar process to this, for washing children's feet, is practised at Christ's Hospital, London. The chimney of the grand central fire may serve at the same time as a tower for a turret clock, which should have four faces, and be placed so high as to be seen from the inner windows of all the dwellings. It should be made to play chimes at certain hours, such as the time of rising, of taking meals, of going to school, &c. &c.; and at night the dials should be illuminated. In this tower there might also be a bell, for ringing on extraordinary occasions. In the fire house there may be a small two-horse power steam engine, which, by very simple machinery, may communicate with the kitchen, to work a kneading machine, a machine for chopping meat, breaking sugar, mashing potatoes, &c.; with the wash-house, to work the washing and wringing machine; with the scullery, for washing potatoes and other roots; with the knife and shoe house, for setting in motion a knife-cleaner (see *Mech. Mag.*, vol. ii. p. 409.), shoe-brusher (as at the Angel Inn, Oxford), a coat beater and brusher, &c.; with the drying-room, for working a mangle; with the dairy, for churning and breaking the curd of cheese, &c.; and, when employed in none of these offices, in turning a small bone-crusher, to prepare bones for making soup, and in raising water to a cistern over the scullery, placed on exactly the same level as the four cisterns placed over the four angular water-closets, and communicating with them in such a manner that there should always be the same depth of water in all the five cisterns. From the central cistern there should be pipes for conveying it to all the different offices, including even the dining-rooms and the schools; and to each cock there ought to be a small sink, communicating with a common drain leading to one of the four angular cess-pools. Many other modes of applying the power of the steam engine to domestic purposes will doubtless suggest themselves in practice. We have omitted to introduce a gasometer; because, though we believe that in towns gas might be advantageously employed for the purposes of cooking and heating, as well as lighting, yet, for a college of so humble a description, it might involve more expense and trouble than it would be desirable to incur. Neither do we consider the steam engine, nor the various machines which it is intended to set in motion, as at all essential to the plan; but we have suggested them, because, in many parts of the country, in the mining districts for example, the rate of wages is sufficiently high to allow of their introduction, and every one, in such districts, understands their management. The only feature in the way of apparatus, that is essentially necessary, is that of Perkins, for heating by hot water; and the reason why we consider this essential is, that it will convey to each of the eighty dwellings a higher degree of heat than can possibly be done by steam, and this at a cheaper rate, than by any other mode at present known. But if the idea of individuals ever cooking any thing for themselves in their own dwellings, or preserving any thing there at a higher temperature than 180°, is given up, which we think it very well might be, as the public kitchen is at a convenient distance for supplying hot water, &c., to all; then, instead of Perkins's apparatus for circulating hot water at a temperature of 300°, steam might be circulated at the ordinary temperature of 180° and upwards. The apparatus for this purpose would not be so cheap as that of Perkins, but it would be more easily put up, and kept in repair, in remote districts. In putting up a steam

apparatus, it must be kept in view, for the sake of economy, that all the mains may be of small half-inch pipe, which does not cost above 3*d.* or 4*d.* a foot, while the heating pipes under the floor of each dwelling, in order to give them abundant power, may be of six or eight inches in diameter. In the management of steam, with a view to economy, it should always be remembered, that it differs from water in this, that the mains may always be exceedingly small, however large may be the service pipes. Where steam is to be conveyed to a distance, this is a very great advantage.

499. *Arrangement of the Dwellings.* These, as before stated, are in eight divisions; by referring to the plan, fig. 440, it will be seen that the limits of each row of ten dwellings is determined by the carriage or foot entrance to the offices, at 10, at one end; and by the public water-closets, at *a*, at the other. We shall show, in succession, the mode of heating, and of supplying one of these divisions with water, the construction of the water-closets and manure tanks, and the drainage.

500. *For heating each line of Dwellings,* a steam or hot-water main proceeds direct from the central fire, to the end of the line, at 10. If steam be used, the main is there connected with two cast-iron pipes, the one under the floors of the living-rooms, six inches in diameter; and the other, under the floors of the bed-rooms, three inches in diameter. The main, and these pipes, must be laid with a gradual inclination from the boiler to the further extremity of the water-closets, which it also heats; and there each pipe must have a small return tube, gradually descending from that point to the boiler, to admit of the condensed water running back of itself. The mains, between the boiler and the dwellings, will be placed isolated within earthenware pipes; and these, and the return pipes of condensed water, will be included in a dry drain, filled with charcoal or coke. All the difference of level requisite to return the condensed water need not be more than one foot; so that, if this drain be two feet deep, the pipes will be sufficiently protected from the influence of frost. Under the floors of the dwellings, the drain need not be above ten inches broad and one foot deep, and it may be covered with one-foot tiles; or, the tubes may be made square, and their upper surface may serve as part of the floor, as suggested in fig. 282, for Laxton's small college, § 290; and also in § 489, for our college of twelve families. Should Perkins's hot-water apparatus be preferred to steam, common gas pipe may be used throughout, both for the mains and service pipes. A description of this mode of heating will be found in the *Repertory for Patent Inventions*, for March, 1832, and a more particular account in the *Gardener's Magazine*, vol. viii. p. 292, by Mr. Perkins himself. Should Mr. Perkins's apparatus be adopted, there

may, in the living-room of each dwelling, be what may be called a hot plate, connected with it; that is, a branch pipe may rise from the pipe in the floor, and terminate at top in a piece of cast iron, say of a foot or eighteen inches in diameter, like a small table, or like the raised hearths common in the kitchens abroad. The temperature of the upper surface of this table, when the apparatus was at work, would be between  $250^{\circ}$  and  $300^{\circ}$ ; and, consequently, it would boil water, broil meat or fish, toast bread, and perform every office of cookery, with the exception of roasting. This table would be most conveniently placed in a closet or cupboard, which might correspond in situation with the ordinary fireplace of a kitchen, so that it could be shut up at pleasure, and especially during summer, when the heat escaping from it might render the room too warm. In the roof of this closet there should be an opening in the ceiling, communicating with the open air through the roof, by means of a tile or slate with a hole, as shown fig. 434, § 490, to permit the escape of steam and smell.

501. *Supply of Water.* From a cistern thirty feet long, and five or six feet broad, over the water-closets, a lead pipe should be conducted along the bottom of the same channel which contains the steam or hot-water pipe; and from this, in each house, a branch pipe may rise, and terminate in a cock over a sink, either in the cooking closet, or in the entrance lobby adjoining, as at *p*, in fig. 433. In order that this cold-water pipe may not receive any heat from the hot-water or steam pipe above it, it should be laid at least a foot deeper, and covered with soil.

502. *Water-closets, Manure Tanks, and Drainage.* The situation of these is at the four angles of the quadrangle; and each is arranged, as shown in fig. 442; in which *f* is the range of closets for women and infants, and *g* the range for men and boys; *h h* indicate the situations of two tanks communicating with the cesspool, common to both ranges of closets. By means of a hole, with a stopper, at one side of the roof of each tank, it may be emptied by one of Shalders's pumps. There are drains directly under all the channels containing the steam or hot-water service pipes and mains, which convey the waste water from the public offices, and from all the sinks of the private dwellings, as well as all the water which falls on the surface, in equal parts, to the four cesspools of the water-closets. Thus an immense quantity of liquid manure will be formed. Wherever the surface water is allowed to enter one of these drains, a stink-trap must be used, to prevent the rising of smell. Of these there are many sorts very cheap; one of terro-metallic earth, made by Peake before mentioned, is of great strength and durability, and costs only 9*d.*; another, fig. 443, made in the tile-works about London, and very suitable for the sides of gravel walks, as the top lifts off, to admit of cleaning out the sand or rubbish which may have lodged in the bottom of the trap, costs only 6*d.* Over and adjoining each manure tank there is a place, *i*, for rubbish convertible into manure; and another smaller space, *k*, for broken crockery, &c., and such other kinds of rubbish as can be only useful in repairing roads, filling up pits, or making drains.

443

503. *The Plan of each Dwelling* we propose to be the same as that already detailed in fig. 433, § 487, for our smaller working-man's college, Design LXXIX.

504. *Construction of the Dwellings.* The walls and partitions of the whole of the private dwellings may be of earth, plastered over internally and lined, and coloured in imitation of stone externally. For this purpose the outside and party walls are shown eighteen inches in thickness, and the partition walls a foot. As no chimneys are required, and no second story, nothing can be more simple and economical than the construction of these walls. The floor may be formed of loose stones, gravel, or whatever material of the kind may be most conveniently had; and its upper surface may either be paved, or covered with a mixture of lime and gravel, mixed while the lime is yet hot, and spread out over the rough materials, and immediately beaten perfectly smooth. This mixture is called by London builders concrete, and, when covered with a thin coating of cement, forms an excellent flooring for either bed-rooms or sitting-rooms. The roof, as there is a central wall, need not be expensive; strong tie-beams may be dispensed with, by having the ceiling joists of somewhat larger dimensions than usual, so as to project three feet at the eaves; and by carrying up the central walls so as to serve as king-posts. The covering may be thatch, or whatever is cheapest; and unless the rain water be an object, there need be no gutters to the roof, as without them the water will drop on the slope of the terrace, which may be paved with pebbles, below which there may be a gutter, and under it a drain communicating with the main drains. The windows may be iron casements of the simplest kind, and without either inside or outside shutters; curtains, as before observed, § 490, where there is perfect security and an abundant supply of heat, forming a very good substitute.

505. *Construction of the public Offices.* All the walling, with the exception of that of the central chimney and clock turret, may be of earth. The chimney and tower must be built of stone or bricks. All the flooring may be formed in the same manner as that of the private dwellings. The baths may be simply square tanks, lined with Roman cement. The roof should project as in the private dwellings, as well for the protection of the walls, as to give a dry path completely round the whole, for the purpose of communicating from one door to another. Other details need not be entered into: the oven may be Hicks's patent one, described in the *Mech. Mag.*, vol. xiv. p. 417; the kneading machine, one of several also described in the same work; and the turret-clock may be of wood, a clock of that material being little more than half the price of one of metal (see *Mech. Mag.*, vol. iv. p. 142); the washing and wringing machine may be one manufactured by Weir, to be hereafter figured and described.

506. *General Estimate.* The expense of each dwelling, steam or hot-water pipe and cold-water pipe included, would, in most parts of the country, not exceed £50; and the expense of furniture to the occupier would evidently be less than in the case of single cottages; because vessels for cooking, baking, brewing, washing, &c., would be unnecessary. The expense of the greater number of the apartments, constituting the public offices, would be about the same, per cubic foot, as that of the private dwellings. The most expensive would be the fire-house and the kitchen. The different apparatus and machines would form a considerable item, because no part of the work connected with them could be done by the occupants themselves. Exclusive of the heating apparatus, and of the machines, and furniture of the public offices, the whole quadrangle might, in all probability, be completed for between £3000 and £4000; and £1000 more would supply all the machines, furniture, and fittings-up for the public offices.

507. *The general appearance* of such a working man's college as that we have just described will be simple, but not inelegant, as will be seen by the isometrical elevation, fig. 444. Much of the beauty and interest of the whole will depend on the keeping of

the gardens, and the cultivation of the farm; and much of the enjoyment of the occupants, on the building being placed on an elevated situation, commanding extensive prospects on all sides.

508. *Remarks.* Though we have recommended a quadrangle as the preferable form for a large working college in the country; yet there is no form which may not be adapted to this purpose, with advantages approaching more or less to those possessed by the quadrangle. One continued line along a road or river, up a steep hill, or across a slope, provided always that the floors of all the dwellings were in one plane, whether level or inclined, would answer perfectly. In such cases the general fire must always be placed at the lower end, and the general cistern for supplying cold water at the higher end, for obvious reasons. Even in a scattered village, if the floors of the houses were either nearly on one plane, or nearly on a level, they might all be heated from one fire; and their inhabitants might all have their cookery and washing performed in the same kitchen and laundry. Indeed, if Busby's mode of circulating hot water below the level of the boiler, by mechanical means, were adopted, the floors of all the houses might be heated, however different might be their levels. It would be easy to bring together double the

number of families in a quadrangle of the same dimensions as fig. 444, by diminishing the ground area of each dwelling one half, and raising a story over it, for completing the requisite accommodation. A second range of dwellings forty or fifty feet beyond the first, so as to form a double quadrangle, would give 120 additional dwellings of the same size and arrangement as those in fig. 440, making in all 200; and 400 might be obtained by having two stories. The situation of the dwellings of such an outer quadrangle is indicated by the dotted lines, marked one to fifteen, in fig. 440. The mode of having a double quadrangle would in general be much more economical than raising the buildings three or four stories high, and thus rendering a heating-pipe necessary for the living-rooms on the third story. In buildings of two stories, there would be no occasion for any other heating-pipe than that on the ground-floor; because the heat would readily ascend from that to the bed-rooms. If the occupants were to agree to dine at three separate hours, and to breakfast and sup in their own houses, no additional dining-rooms would be required; and the only alteration in the public offices would be an enlargement of the schools. Much more might be said on the subject of this Design, and on the immense advantages which would result from working men's colleges, to the labouring classes of every description; but the rising generation must be prepared for such a result by education. The first step towards living together in communities is being educated together in Infant and Lancasterian schools. In the mean time, those who have entered into the subject will be aware, that, by enlarging the separate dwellings, and using a superior description of materials and finishing in their construction, this plan might be rendered suitable for persons of any income; even so large as to require a set of stables and coach-houses, assembly rooms, a theatre, walled gardens, conservatories, hot-houses, pleasure grounds, and a park. The principle is the same in all,—that of producing in masses, by machinery, and by a division of labour, what has hitherto been effected in scattered fragments, by manual labour, and by every individual family for itself; and the advantages are, that by the cooperative system each member of the community obtains a much greater portion of comfort and enjoyment for a given sum or quantity of labour, than he could possibly have done singly. It would be foreign from this work to enter more fully into the subject, and we refer our readers to its enthusiastic advocate, Mr. Owen, and to an able exposition of the cooperative principle, as applicable to persons possessing from £500 to £1000 a year, given in the paper before referred to, in the *New Monthly Magazine* for August, 1832.

Design LXXXI. — *A Portable Cottage for the Use of Emigrants and others.*

509. *The principal object of this portable cottage is, to supply emigrants with comfortable and secure lodgings immediately on their arrival at a foreign settlement. It is well known that in all new countries the rent of houses or lodgings is extremely high: it follows, therefore, that when an emigrant arrives with his family at the sea-port town of the country where he is to be put in possession of a grant of land, he must take a lodging for his family and goods; probably for some weeks, or even months, till he has visited the interior of the country, examined it, and fixed upon the situation of his future residence. A single room at Hobart Town, in 1830, was often let at £1 a week; hence it may be easily conceived that a portable cottage, like that given in this Design, which costs in London £50, will afford, though only containing two rooms, a considerable saving to a family of three or four persons of different sexes. Security from thieves, and protection from vermin, are also other recommendations.*

510. *As secondary uses of a portable cottage, we may mention, that it may be carried in ships making long voyages, for the purpose of being set up on shore wherever any stay is made, either for the benefit of invalids, or the use of scientific persons; that it may be employed as a shooting-box, wherever there are tolerable roads, as it weighs little more than a ton, and might therefore be easily drawn by one horse. (It weighs about three tons ship's measurement, which is forty cubic feet to a ton; but as a cubic foot of Baltic fir timber weighs only thirty-four pounds, even if the 140 feet forming the three ship's tons were solid, the weight would be little more than one hundred weight and a half. Not being solid, it is found not to weigh so much by half a hundred weight.) Where public works are going on in any remote district, one of these cottages would form a very convenient dwelling for the overseer; and, being put on six wheels, might be moved forward as the work proceeded. When that stupendous undertaking, Napoleon's road over the Simplon, was being executed, the chief engineer, a general of high rank, lived in a portable cottage, about ten feet square, which was carried forward by men, from one position to another, as required; and the remains of which we saw in 1819, at a village near to where the road commences in the Valais, on the Swiss side of the mountain. A party exploring a river in any country, and wishing to study the natural history of the country on each side, or even to shoot and fish, would, if they had such a*

cottage in their boat with them, find it a source of great comfort, as it could be put up by a man and a boy in two hours, and taken down again in even less time.

511. *The Accommodation* of such a dwelling is limited to two rooms, as in fig. 445 (to

445

a scale of three inches and one eighth to twenty feet), each twelve feet by twelve feet, and eight feet high in the clear. One of the rooms may have an iron stove, *c*, at one corner; the pipe from which may be carried up within a square iron or wooden tube, with a vacuity of two or three inches between, in order to prevent the risk of setting fire to the tarpawling, which serves as the temporary roof. If necessary on account of cold, the stove might be placed in the partition between the two rooms, so as to heat both; or a tube from it might be carried round or along one side of either or both apartments. In general, however, horizontal pipes will be unnecessary, and one upright tube for carrying off the smoke will be found quite sufficient. The whole of the stove should be of wrought iron, for lightness.

512. *Construction.* The foundation of this structure consists of four sleepers, fig. 446,

446

*d d d d*, each thirteen feet long, and five inches deep by three inches wide. On these are placed grooved bottom plates, *e e e e*, forming the foundations of the flooring, of the outside walls, and of the partition. These plates are formed of pieces, five inches broad, and three inches deep, laid flatwise, grooved along the upper side, to receive the bottom rails of the paneled frames which form the walls of the cottage. These plates are let into the sleepers in the manner shown by fig. 447 (to a scale of three eighths of an inch to an inch). In this figure, *f* is the sleeper; *g*, the bottom plate; *h*, the corner post let into it, in which is fixed a screw-nut, for being taken hold of by a screw-bolt that passes through the bottom plate so that by means of a bed-wrench applied at *i* it can be screwed perfectly tight. The corner posts are eight feet six inches long, and three inches by

three inches on the sides. There are seven intermediate posts, and three posts in the partition, each of which is three inches and a half on one side, and two inches and a quarter on the other. There are five joists, each five inches by two inches, which are joggled on to the sleepers and to the bottom plate, as shown in fig. 448 (to a scale of

an inch and a quarter to a foot), in which *k* is the sleeper; *l*, the bottom plate; and *m*, the joist. The posts are grooved on the sides, and so are the top and bottom plates, for the purpose of receiving in the grooves the ends of the paneled frames. When the cottage is putting together, the paneled frames, fig. 449 (to a scale of an inch and five eighths to three feet), are put in between the grooved posts. Two of these panels are in part glazed, and hinged to a hanging style, which fits into the upright groove; thus forming at once all the doors and windows required. The panels being all fixed, a set of top plates is put on, similar in dimension to the bottom plates, and similarly grooved to receive the top rails of the paneled frames; and these are held together by iron screw-bolts at the corners, made fast by a bed-wrench applied on the upper side of the plates. On these top plates (which, in a common building, would be called the wall plates) are placed the rafters, seven feet six inches long, and four inches by one inch and a half

449

thick, which are let into a ridge piece at the top, as shown in fig. 450, and into the wall plates at the foot, as shown in fig. 451. A purlin is placed across the rafters on each

450

451

side, halved into them, and flush at top, as seen in the skeleton elevation, fig. 454. The flooring is formed of inch-deal boards, laid side by side, and let into the bottom plates, as shown in fig. 452 (to a scale of one eighth of an inch to a foot), in which *n* is the floor board; *o*, the bottom plate; *p*, the bottom rail of one of the paneled frames; and *q*, the joist. The construction of these frames will be understood by fig. 453 (to a scale of five eighths of an inch to a foot), in which *r r* are the styles; *s s*, the muntins, or muntings (from the French, *montant*, meaning the upright pieces between the side styles, into which the rails of doors, or other paneled compartments, are framed); *t t t*, the panels; and *u u*, the posts. The outside posts, to which the partition is joined, are

452

453

formed as in fig. 455 (one fourth of the full size), which requires no explanation. The roofing is generally completed by a tarpawling, which is thrown over the rafters, and,

having strings on the under side, is made tight by them to the rafters, while it is kept close down at the eaves by lines which are sewed along the margin of the canvass, and tied tight at the angles. All that is now wanting to complete the cottage are eight short posts, on which to place the sleepers, so as to raise the floor above the surface, in order

to keep it dry. These, however, may be generally dispensed with; for on very dry soils, or where the ground falls from the site on every side, the sleepers may be laid on the ground; and even in situations flat, and not very dry, a ditch may be dug round the

cottage, at the distance of about a foot from it, so as to produce the effect of placing it on a platform, as shown in the skeleton, fig. 454, and in the miniature elevation of the finished cottage, in isometrical perspective, *v*, in the same figure. Exterior appendages may be easily constructed of materials found on the spot. The tarpawling ought to be oiled, and all the wood-work should have at least two coats of paint. If instead of being painted with common oil paint, these cottages were coated over with any of the anticomcombustible paints or washes, the risk of accidents from fire might be diminished. The most effective wash of this description is said to be a saturated solution of silex in alkali. This is obtained by dissolving to saturation, in a lie of caustic alkali, siliceous earth properly prepared. Whatever material is washed with this mixture is said to become covered with a vitreous coat, and this has been proved at Munich and other places effectually to resist ignition. (*Rep. of Arts*, 2d series, vol. iii. p. 249.)

513. *Remarks.* We consider this cottage as one of the most perfect things of the kind that we have seen. Every part of it being made exactly of the same dimensions; that is, all the panels, posts, and plates, being respectively of exactly the same length, breadth, and thickness, no mistake or loss of time can occur in putting them together. Another great beauty in the construction is, that there is not a single nail used either in the carpentry of the separate parts, or in putting those parts together so as to form the cottage. All the framework composing the sides of the cottage being grooved and tongued, the weather is most effectually kept out; and at the same time this construction allows the work to shrink or swell, according to the changes of the atmosphere or the season, without deranging any of the parts. The inventor of this cottage, Mr. Manning, carpenter and builder, High Holborn, London, has made a great number of them for the Australian colonies, and particularly for the Swan River. Mr. Manning, who has a son settled at the latter colony, says, "These cottages were found to be of the greatest service to settlers, both in protecting their families from the weather, and their property from theft. Many persons who took out only tents, suffered severely in both respects; their tents being frequently blown down in the middle of a stormy night, and their goods being thus not only exposed to the weather, but to pilfering. Provided with a cottage of this description, an emigrant might land from a ship in a new country in the morning, and sleep in his own house on shore at night. Whoever can use a common bed-wrench can put this cottage up; and as none of the pieces are heavier than a man or a boy could easily carry for several miles, it might be taken even to a distance, without the aid of any beast of burthen. When a permanent situation is fixed upon, the cottage may be covered with shingles, or thatched with spray of trees, long grass, or such other suitable material as may be most readily obtained; and at any future period, when the emigrant is prepared to build a stone, brick, or earthen-walled house, all the posts, panels, &c., of the portable cottage may be brought into use as doors or partitions; or cut up for window-framing, shelves, chests, or a variety of other purposes; and the tarpawling, when no longer wanted for the roof, will always be a useful article for the agriculturist."

514. *A Portable Cottage may be used as a Substitute for a Country Residence.* Mr. Man-

456

ning has furnished us with an elevation and ground-plan, figs. 456 and 457, of one, which he constructed for Captain J. G. Hall, and which has been erected by that gentlemen as a residence, at Wargrave, near Henley upon Thames. It is placed on a rising ground, within sixty feet of the river, and forms a handsome and conspicuous object to persons sailing from Henley towards Reading. The accommodations of this cottage are, an entrance hall, *a*; servant's sleeping-room, *b*; kitchen, *c*; store-room, *d*; sitting-room twelve feet square, *e*; and bed-room, *f*. A lumber-room which is formed in the roof

457

has a floor of ploughed and tongued boards laid on ceiling joists, so as to form a ceiling to the room below, and a floor to that above. The roof is thatched; and the walls are painted, and dusted over with powdered freestone. The interior is painted in imitation of wainscot. The fireplace of the sitting-room is a ship's cabin stove, and that of the kitchen a ship's galley stove; both having iron piping for flues. By having horizontal piping from the kitchen through the servant's room, sitting-room, and bed-room, with a return pipe, one fire might suffice to heat the whole house. In this case, by a very simple contrivance, the smoke, during warm weather, instead of circulating through the horizontal flues, might be made to escape direct from the fire through the upright pipe (see § 489.). The cost of this cottage in London, exclusive of the stoves and the thatch, was only £120. For this sum, which would do little more than pay for a year's lodging of two rooms and a kitchen, in a fashionable street in London or New York, we have here a handsome and comfortable dwelling, abundantly commodious for a single person, or a man and his wife without children, and which, with moderate attention to painting, would last a lifetime. It must not be forgotten that a great saving is produced by the paneled walls, which render unnecessary all expense of plastering and papering, and which, when painted in imitation of wainscot, look remarkably well, and remain many years without requiring any repair.

515. *Ambulatory Cottage.* With such a portable cottage as this on wheels, a man with £200 or £300 a year might enjoy in Britain as much rural beauty and variety, as would cost another with a fixed town and country residence as many thousands.

516. *Cooperative Ambulatory Cottages.* If a family or a party intended to live in portable cottages, renting a small field wherever they found it desirable to set them down; and to change their place of residence frequently, say to the north of England or Scotland during summer, and to the south during winter, the most convenient plan would be to have not more than two rooms in one cottage, or, perhaps, even one room might be found enough, as the wheels should be low, and under the floor. At every place of encampment, the cottages, or rooms, any number of which might belong to one family, might be placed in a line, with the kitchen at one end; from which a steam pipe might proceed to heat all the others, and also a pipe of cold water from a cistern over the ceiling of the kitchen, filled by one of Siebe's pumps, and a long leathern hose, from any neighbouring well or brook. The roof and the floor of one side of every cottage might project three feet beyond the wall; and, when all the cottages were placed close together with the projections alongside of each other, a covered passage or veranda would be formed the whole length of the line of cottages. There would be no difficulty in heating all the rooms by steam from one fire, or in supplying all the bed-rooms with water from one cistern. Every cottage should have its own pipes for these purposes; and those of one cottage could be connected with those of another by right and left-handed screws and coupling pieces, as in Perkins's tubes for circulating hot water under compression. In short, by some contrivance, many of the comforts of a fixed residence might be obtained in these portable and ambulatory cottages; and many of the enjoyments and advantages of society and of cooperation, by a number of them encamping together. We do not say that the same comforts and advantages would be obtained so economically as in a fixed locality; but for those who have no occupation, and derive a great part of their enjoyment from visiting different parts of the country; who like to live by turns among mountains, by the sea-shore, in a fertile valley, or in the suburbs of a large town; among the lakes of Cumberland and Westmoreland in summer, and in Devonshire or Cornwall during winter, we do say that an arrangement of this kind would procure those enjoyments for one tithe of what they now cost.

## CHAP. III.

*Designs and Directions for Exterior and Interior Finishing, as connected with Furnishing, and for the Fittings-up, Fixtures, and Furniture of Cottage Dwellings.*

517. *Exterior Finishing* is the term applied to stuccoing, roughcasting, and plastering; and to whitewashing, colouring, painting, and similar processes, for exterior walls, and timber-work. It also includes troughs, gutters for projecting roofs, rain-water pipes, exterior window shutters and window blinds; and the application of exterior ornaments, such as barge-boards, canopies, ornamental chimney-pots, balconies, verandas, vases, trelliswork, and a variety of similar appendages.

518. *By Interior Finishing* is here to be understood the covering of the walls with various materials, partly with a view to use, and partly to ornament; such as affixing cornices, whitewashing, colouring, painting, stenciling, papering, &c. Architects include under the term finishing, all such portions of the joiner's work as are fixed, after the ceilings, walls, &c., are plastered; also locks, bolts, bars, and springs, to shutters and doors; and water-closets, baths, chimney-pieces, &c.: but, in this portion of our work, we have thought it best to confine ourselves chiefly to such parts of finishing as have not before come under our review.

519. *By Fittings-up* are commonly implied the putting up of wooden closets; the fixing of shelves; of seats and basins in water-closets; of cisterns; and of pipes and cocks to supply the different parts of the house with water; the hanging of bells; and the putting up of such other articles in a house, as cannot be taken down without deranging in some way or other the finishing of the apartments.

520. *By Fixtures* are meant stoves, grates, boilers, coppers, dressers, and sometimes bookcases and corner cupboards; all of which are more or less fixed to the walls, and, like the fittings-up, cannot be taken down without, in some degree, injuring or disfiguring the apartment.

521. *Furniture* includes all the portable articles introduced into apartments, for the purpose of rendering them habitable, comfortable, and agreeable: such as seats of different kinds, tables, beds, carpets, and curtains; wardrobes, and other portable receptacles for clothes, books, &c.; musical instruments; and also ornaments, such as pictures, sculptures, curiosities, &c.

522. *These different departments of the art of completing a house* are not alike susceptible of being illustrated by designs, which cannot, for example, be made to include painting, colouring, papering, &c. For this reason we intend to blend some general directions with our graphical illustrations, deferring the details of the processes of the painter, plasterer, paperhanger, &c., till we treat of these arts in a subsequent part of the work.

523. *In all that relates to finishing and furnishing*, the artist must be directed by the same general principles as those which were his guide in designing the building. These principles are as much founded on reason in the one case as in the other. The first impression which we ought to receive from seeing a human dwelling at a distance is that it is such; and that it is suited for some particular class or description of family, mode of living, or state of civilisation. On a nearer view, the parts and finishing of the exterior, as they develop themselves, ought to convey to us some ideas of the taste of the occupant. As we enter the porch, these ideas ought to be confirmed by the continuation of the same general style of taste, enhanced in degree, because nearer to the eye and under the protection of a roof; and, as we proceed to the principal apartment, the train of ideas awakened ought to be maintained, and increased, till it arrives at its ultimatum in the room where the mistress of the house receives visits from her friends. This is the general result to which all finishing and furnishing is, or ought to be, directed; and it may be reduced to two principles, unity of style, and gradation of excellence. Unity of style should pervade both the exterior and the interior; and there ought to be a regular gradation in the labour and care employed, from the outside walls and exterior finishing and ornaments, to the most highly enriched apartment within. Another principle, subordinate to these two, is, that as every apartment in a house has, or ought to have, its particular use, so it should be characterised by some particular piece of furniture essential to that use; and that all the subordinate articles and ornaments in such apartments should have a reference, or be appropriate, to the principal one. Thus a kitchen is characterised by the grate or kitchen range; the dining-room, by the sideboard; the library, by the bookcase; the drawing-room, by the sofa; and so on: the subordinate furniture must always accord with the principal article. Thus, the kitchen range should be supported in character by the dresser and plate-rack; the sideboard, by the cellaret and massive dining-table; the bookcase, by reading and writing tables and desks; and the sofa, by chimney and pier glasses, and by various descriptions of seats,

some with cushions. Every apartment, therefore, on being entered, ought to display a marked character of use; as well as a particular character of style, with reference to its finishing and furnishing. Whenever any doubt is left in the mind of the spectator, as to the use of an apartment into which he is conducted, something in that apartment must as certainly be wrong, as when the exterior of a building conveys a false idea of its use, and a human dwelling is mistaken for a stable or a chapel. This principle must also be extended to the exterior of a dwelling, and the windows and walling of a drawing-room, or library, or other superior living-room, ought never to be liable to be mistaken for those of a bed-room or closet. At the same time that the nobler parts of a dwelling are to be rendered prominent features in its general aspect, the meaner parts are not to be rendered more mean, but should rather be raised in character, so as to harmonise with the rest, and to support the general expression of the whole. These principles are as applicable to the humblest cottage as to the most elegant villa; and we shall proceed to exemplify their application in the order of exterior finishing, interior finishing, fittings-up, fixtures, and furniture. We should premise, however, that some parts of the present chapter must necessarily seem to belong as much to ornamental as to plain cottages; because the two subjects are so intimately connected, that it is almost impossible to separate them; nor, indeed, with a view to the improvement of the cottager, is it desirable that this should be done.

524. *Previously to finishing either exteriors or interiors*, a sufficient time ought to be allowed for what is called the carcass, or general framework, of a building to be thoroughly dried and settled in every part. The time requisite for this purpose will depend on various circumstances; but chiefly on the thickness of the walls, and on the doors and windows being left unclosed. The maintenance of this ventilation, when the house is finished, will depend upon the judicious introduction of openings in the side walls under all the floors, and under the eaves of the roof, for the admission of a free current of air. As a general principle, it may be laid down, that provision ought to be made for a constant circulation of air in all the voids of a building; or, in other words, wherever air is admitted, it ought to maintain a circulation with the external air. A circulation between the roof of a house and the ceiling of the uppermost room is maintained by small openings directly under the eaves; or by very small windows, loopholes, or slits, in the gable ends. A circulation is promoted under the floors of the different stories of a house by the introduction of small iron gratings in the walls, communicating with the vacuities between the floors and the ceilings. When precautions of this kind are neglected, premature decay is too frequently the consequence. What is called the dry rot in timber, every builder knows, is brought on by the use of timber imperfectly seasoned in parts of buildings excluded by position, or by neglect of the means, from proper ventilation. Even in cottages of the humblest class, therefore, the walls ought to stand some months before being roughcast, or coloured outside, or plastered inside; and the timbers of the floors should remain still longer before they are covered with the flooring-boards above, and closed up by the ceilings below: when all the timber-work is put up, it ought to remain another period before it is painted; and in some parts of Britain, and in most parts of the Continent, this period extends to a year and upwards, even in cottages. Common plaster, on brick or stone walls, ought not to be whitewashed or coloured in less than a year; or, if on lath and plaster, six spring or summer months. Where oil colours are used, the stuccoed plaster requires, in ordinary cases, to dry for one or two years. When this is neglected, the water enclosed in the walls cannot escape by evaporation; and is therefore, by the swelling of the mortar, forced through the paint; entirely discolouring it in some places, and occasioning it to peel off in others.

525. *Provisions for all the exterior and interior finishing and all the fittings-up and fixtures* of a dwelling, however humble, ought to be made in building it. Among these provisions, the principal ones are, proper openings for pipes for bringing in or carrying off water; tubes for conducting bell wire; recesses, flues, and other openings, for such of the new modes of heating or ventilating as it may be proposed to adopt; and places for cupboard-closets, water-closets, cisterns, &c. &c. There is not much to be provided for in this way in cottages of the class now under consideration, but still enough to warrant our noticing the subject in this place.

#### SECT. I. *Designs and Directions for the Exterior Finishing of Cottage Dwellings.*

526. *Outside Plastering* includes stuccoing with the different kinds of cement; rough-casting, Scotch and English; and common lime and hair plastering, ornamental or otherwise. The principal purpose for which any of these processes is adopted on the outside walls of a cottage is, to keep them dry; and a secondary purpose is, to render them ornamental, either by imitating stone, or by producing a surface more curious or agreeable to the eye, than the rude materials concealed by it.

527. *The Cements for Stuccoing* are chiefly the Roman cement, of which there are two

kinds common in Britain, Parker's and Mulgrave's; the Puzzolano; the tarras; the gypsum; the mastic; Frost's cement; the metallic cement; and Bailey's composition. The first two, and the gypsum, possess in an eminent degree the power of setting almost instantaneously, either with or without an admixture of sand. Puzzolano earth, tarras, and Frost's cement are better calculated than the Roman cements to indurate with lime; because they do not set so quickly. A very hard and durable cement may be formed of stone lime recently burned, and, immediately after being slacked, mixed with clean, sharp sand. This about London is called Bailey's composition, and is packed dry in casks, and sent to any distance. The usual proportions are, three of sand to one of lime. Mastic is a calcareous cement, which consists of earth, and other substances almost insoluble in water, to which, when pulverised, are added any of the oxides of lead, and also a quantity of glass, or flint stones; the whole reduced to a fine powder, and intimately incorporated with any cheap vegetable oil. This is rather too expensive a cement for cottages; but it forms a better imitation of stone, especially of freestone, than any other, and has this great advantage over all the others, that, when put up into casks, it will keep without injury for any length of time. In general, wherever good fresh lime and clean sharp sand can be had, an excellent cement may be formed. Mr. Frost has proved that lime, even chalk-lime, burned in a close kiln, and cooled without coming in the slightest degree in contact with the atmosphere, will, when afterwards slacked, and mixed with sharp sand, set as rapidly as Roman cement, and this even under water. (*See the Specification of the Patent in the Repertory of Arts.*) In England, the scrapings of the public roads, where limestone or sandstone is the material employed, are found to serve as a substitute for sharp sand, provided care be taken to wash from them their finer earthy particles. But on the subject of cements we shall enter more at length in a future part of this work.

528. *The object of covering the outside of the walls of cottages with cement is generally to imitate stone.* In this imitation, care must be taken that the lines drawn do not represent stones of too large a size; that the shapes of the stones at the corners, and for the lintels and sills of doors and windows, be suited to their situations and uses; and that, in the regular courses, the joints alternate and show bond properly, as in regularly built stone buildings. A dwelling with the walls of brick will often be much improved in appearance by forming the string courses, the facings or architraves to the doors and windows, the corner stones, the cornices, the tablings, and especially the chimney-tops, of cement in imitation of stone. Where the cement used for either of these purposes is lime and sand, it will resemble stone with little or no colouring matter added; but where Roman cement, or Puzzolano, or tarras, is used, the colour, after being laid on, will be dark, and the cement must therefore be brought to a stone colour by washing it over with washes, composed in proportions of five ounces of copperas to every gallon of water, and as much fresh lime and cement (to which some add tallow), as will produce the colour required. The copperas, or sulphate of iron, oxidises with the atmosphere, and produces a reddish tinge. The forms of the stones, defined by the lines, should, some days afterwards, be touched with umber, ochres of different shades, and occasionally with vitriol; which colours, if laid on by a painter who knows how to imitate the tints of nature, will produce a harmonious effect. Oil colours should not be used on cement laid on walls in the open air for a year or more, till the water mixed up with it is either solidified or evaporated. When cement is once thoroughly dry, its hardness and durability is greatly increased by washing it over with any oily or greasy matter, with or without a mixture of colour incorporated. There are various lithic paints for covering cement, all of which are composed of oxide of lead, powdered glass or other vitrified matter, and the colour of the stone to be imitated, intimately mixed together, and beaten up with oil.

529. *Roughcasting, or Harling as it is called in Scotland, is a mode of outside finishing well calculated to protect walls from the weather.* It is not capable of such a high degree of beauty as a covering of cement, because a roughcast wall is only a plastered wall with a rough surface, instead of a smooth one; but then it is considerably cheaper than any description of stucco. It is much used for covering rubble stone walls and houses, in Scotland and Ireland. The following is the process:—Plaster the wall over with lime and hair-mortar; when this is dry, add another coat of the same material, laid on as smoothly and evenly as possible. As fast as this coat is finished, a second workman follows the other, with a pail of roughcast, which he throws on the new plastering. The materials for roughcasting are composed of fine gravel, reduced to a uniform size by sifting or screening, and with the earth washed cleanly out of it; this gravel is then mixed with pure newly slacked lime and water, till the whole is of the consistence of a semi-fluid: it is then forcibly thrown, or rather splashed, upon the wall with a large trowel, which the plasterer holds in his right hand, while in his left he has a common whitewash brush. With the former he dashes on the roughcast, and with the latter,

which he dips into the roughcast, he brushes and colours the mortar and roughcast that he has laid on, so as to make them, when finished and dry, appear of the same colour throughout.

530. *Another description of roughcast*, which may be called English, as the other may be called Scotch, consists in dashing the surface of the plaster, after being newly laid on, with clean gravel, pebbles, broken stones of any kind, broken earthenware, scoria, spars, burnt clay, or other materials of the like description, sifted or screened, so as to be of a uniform size. The effect of surfaces of this kind is good, and the process admits of producing very great variety in the external appearance of cottages. The sea-side pebbles are frequently used in this way on the sea-coast of Norfolk: by being forcibly thrown against the moist plaster, they penetrate into it, and render it very firm and durable. Sometimes, instead of the stones, or other matters, being broken to a small and uniform-sized gravel, they are pounded into a coarse sand, and this is dashed against the moist mortar. The effect is pleasing, but the strength and durability are not so great as in the other mode. In using small stones or gravel, it is desirable, for the sake of effect, previously to render the moist plaster as nearly as possible of the same colour as that of the materials to be thrown against it. It is also desirable that all corners, sills, lintels, and, in short, all vertical and horizontal bond, should be tinted of the same colour as the roughcasting.

531. *Common Lime and Hair Plastering ornamented* is to be seen on the outside of cottages in several parts of England. When the plaster is in a moist state, impressions are made on it in various ways, and by various articles. Lines are drawn with the trowel, straight, wavy, angular, intersecting, or irregular. Stripes, chequers, squares, circles, or trelliswork, are also imitated. Wickerwork is a very general subject of imitation; and this is produced by pressing a panel, generally a foot square, of neatly wrought wickerwork, against the plaster, while moist. It is evident that this description of ornament might be greatly extended and varied; and that, instead of the panel of wickerwork, wooden plates of patterns, such as those used by room paper-printers, might cover the cottage walls with hieroglyphics, with sculptures of various kinds, with imitations of natural objects, or with memorable or instructive sayings, or chronological facts.

532. *Cementing, Roughcasting, and Plastering*, as means of ornamenting the outsides of buildings, are dangerous processes in the hands of a builder who is without a cultivated architectural taste. Let our readers never forget that the outside of a house, or a wall of any kind, covered in every part with roughcast, or with plaster ornamented in any way, except being lined and coloured in imitation of stone, is a mere blank or negation in Architecture. Such a wall has no beauty, because it has no expression. It may not even be a wall, but a panoply of plastered lath, imposed upon us as a substitute. No wall is worthy of the name that does not bear on its face the nature and kind of its materials, and the manner of its construction; or, in other words, that does not display in its physiognomy the character of its anatomy. A house, the walls of which are covered with roughcast, or with plaster whitewashed or otherwise coloured, whatever may be the beauty or magnitude of its doors and windows, is no piece of Architecture; it is not even an imitation of Architecture; because the elements of all architectural productions are the stones or bricks of which edifices are composed. A wall or a house, therefore, that does not show, either in reality or in imitation, the materials of which its walls are composed, can have no pretensions to architectural expression. This expression can no more be produced with its full effect, without the indication of the constituent materials of the edifice, than a sentence can be printed without employing the letters of the alphabet. There is not a more important principle than this for the young Architect to bear constantly in mind, in the whole range of the science of Architecture. The rule to be derived from it, in the practice of the art, is, whenever cement is to be employed on the outside of a building, and not to be lined and coloured in imitation of stone, there must be the requisite vertical and horizontal bond, for the strength, stability, and durability of the structure, of brick or of stone; or, in minor buildings, of timber, or of projections or piers of cement, lined and coloured in imitation of stone. The same rule applies to roughcasting and ornamental plastering. We shall illustrate this rule by the case of a plastered and whitewashed house, taken at random from a number seen from the window of the room in which we now write. Fig. 458 will, by general observers, be considered a very neat elevation; but those who have understood the principles we have laid down will see at once that it is totally without expression, having no appearance whatever of either vertical or horizontal bond. The facings to the windows convey the idea that these openings are surrounded by stone; but there is no evidence that these stone framings rest on any thing but plaster; the mind, therefore, does not follow up the impression made by the eye, and the imitation stone facings, for want of imitation support below them to carry on the illusion, sink into mere plaster ornaments. Let the plaster in front of this building be disposed either as in figs. 459 or 460, and how dif-

458

459

460

ferent would be the effect! In the first case, fig. 459, the vertical bond is produced, or, in other words, the roof is supported, by the squared stones at the angles, and the hewn stones forming the piers containing the windows; and in the latter case, fig. 460, the roof is supported by the pilasters, and the architrave over them; while the windows are supported by the string courses, or horizontal bond.

533. *Whitewashing* the outside walls of buildings is of very universal use, and it seems to please the eyes of persons of ordinary minds, by the contrast which it produces with the surrounding scenery. Bright whitewashing, however, has at all times been objected to by men of taste; particularly by artists, who, having cultivated the art of seeing objects with reference to their picturesque beauty, ought to be judges of its effect in scenery. Gilpin, speaking of the cottages in Wales, says, the Welsh generally "seem fond of whitening their houses, which gives them a disagreeable glare. A speck of white is often beautiful; but white in profusion is, of all tints, the most inharmonious. A white seat at the corner of a wood, or a few white cattle grazing in a meadow, enliven a scene, perhaps, more than if the seat or the cattle had been of any other colour: they have meaning and effect. But a front and two staring wings; an extent of rails; a huge Chinese bridge; the tower of a church; and a variety of other large objects, which we often see daubed over with white, make a disagreeable appearance, and unite ill with the general simplicity of nature's colouring. In animadverting, however, on white objects, I would only censure the mere raw tint. It may be easily corrected, and turned into stone colours of various hues; which, though light, if not too light, may often have a good effect." (*Gilpin's Wye*, p. 94.) Bartell directs, that, in colouring cottage walls, "every material of a strong harsh colour should be rejected. The fierce red of some kinds of bricks, and the perfect white of a wash of lime, are equally disgusting." (*Hints for Picturesque Improvement for Ornamental Cottages*, p. 10.)

534. *The Compositions for Exterior Colouring* are various. The following is said to be a very superior one:—Take 26 pounds of quicklime, slacked to a powder, and well sifted, and 28 pounds of tarras, sifted well. Mix these with a small quantity of water as quickly as possible. Beat them together with a wooden beater, upon a banker (a stone or wooden bench). Continue to beat them three or four times a day, for four days; and, at the end of that period, take three gallons of bullock's blood (which should be well stirred in the catching, to prevent it clotting), and add to it, when cold, three gallons of water. Put the lime and tarras into a tub, together with the blood and water, stirring them well to make the wash thin; when it will be fit for use. Keep stirring while using it, to prevent the tarras from settling at the bottom. Let the wall be first cleaned from moss and dirt, washing it twice with a watering-pot; and, before it is dry, begin to lay on the composition, observing not to work it too thick. In the second washing, add two quarts more blood, properly stirred while cooling, as before, to make the wash more sily and glutinous. If a yellow tinge be desired, put in a pound or more of stone or Roman ochre, according to fancy. Stale milk may be substituted for blood, though it is said by some not to make the wash resist the weather equally well.

535. *The common colouring* in use about London is composed of whitening made from chalk or other lime, charcoal, or yellow ochre, and copperas, in proportions according to the colours which it is desired should prevail. A preponderance of lampblack, or powdered charcoal produces a greyish white, which is a cold, and not in general a desirable, colour; lime and stone ochre produce a cream or freestone colour. Lime and copperas produce a bright white at first, which, in the course of a few weeks, changes to a white, with more or less of a reddish tinge, according to the proportion of copperas introduced.

536. *A whitewash which will adhere to woodwork*, and preserve it from the weather, is thus composed:—To three parts of unslacked lime add two of wood ashes, and one of fine sand, or of coal ashes sifted through a fine sieve. Let these be mixed with as much linseed oil as will bring the mixture to a consistence for working with a painter's brush. If the mixture be ground together, it will be an improvement. Two coats will be required; the first thin, and the second thick. The hardness of this wash increases by time. (*Smith's Art of House-Painting*, p. 36.)

537. *The colouring of outside walls* is most commonly effected by water colours, when the surface of the wall is new; or by colours incorporated with glutinous substances or oils, after the walls have been thoroughly dried. As a general rule in colouring walls, it may be laid down, that colours unmixed with glutinous bodies, and held in solution by water alone, may be laid on the wall at any time when the temperature is ten or twelve degrees above the freezing point, and in no immediate danger of falling lower, whether the walls are wet or dry, new or old. Colours mixed with glutinous matters or oils, on the other hand, should not be laid on new walls till they are thoroughly dried; or on old walls at a season of the year when their surface may be saturated with moisture. The reason for these rules is, that water colours do not impede the evaporation of moisture from the wall, and the absorption by the mortar of carbonic acid gas, by which it is hardened and rendered durable; while glutinous colours, by closing up the pores of the surface, do both.

538. *Water colours for outside walls* are generally formed on a basis of quicklime, Roman cement, tarrao, or Puzzolano. With one or other of these the colours are mixed as wanted, and are immediately laid on with a whitewashing brush. By far the most favourable time to do this is when the wall is newly built, or the plaster is recently laid on. In the case of old walls, they must first be thoroughly scraped, washed, and stopped; and afterwards brushed over with the colouring mixture, either as a flat shade, or clouded, as the expression is, to imitate the effects of time. This last purpose will be materially aided by taking any strong acid that combines with lime, or any metallic oxide, that will, of course, absorb oxygen from the atmosphere, and mixing these with water, in two separate pails, occasionally dipping the brush in one or the other. A very convenient acid is the sulphuric, in the proportion of one to ten of water; and a suitable oxide is the sulphate of iron, dissolved in water, in about the same proportion. The blotches moistened with the sulphuric acid will in time assume a rich cream colour, and those touched by the copperas will have a reddish tinge.

539. *Glutinous colours for outside walls* also take for their basis quicklime or some cement; and the glutinous matter is either blood, kept stirring till cold, to prevent it from becoming clotted, stale milk, or vegetable oils. Size and paste are sometimes used as glutinous media; and, in such cases, alum is mixed with them, to prevent them from fermenting, and becoming mouldy on the walls; but they are not durable, and, if exposed to driving rains, soon wash off. The desired colours are added to the glutinous matter, which is laid on of such a consistence as to part easily from a common whitewasher's brush.

540. *Painting the outsides of walls in oil colours* is too expensive for cottages, and, on the whole, is unsuitable for any structure not formed of timber. As a medium of giving colour, it is more expensive, and not much more efficient, than glutinous colours formed with blood; and, as a protection from the weather, three coats of oil paint are nearly as expensive, and far less effective, than one coat of quicklime and sharp sand, which will last as long as the atmosphere contains oxygen, and will grow harder as it grows older. In the United States of America, however, the exteriors of brick houses are said to be frequently "painted in oil, the colours being most commonly red or brown." It is also said that "the Dutch very generally cover their buildings with a composition of mortar, or plaster, mixed with oil and colour: blue, red or light pink, and grey, are the most common tints. These walls, when dry, have a kind of gloss like varnish, and of course resist wet." (*Mech. Mag.*, vol. iv. p. 98.) It appears to us that the protection afforded by this oil-colouring is not sufficient to atone for the bad taste which it displays.

541. *The kinds of colours most suitable for exterior walls* should generally be such as belong to the stones or bricks of the country in which the dwelling stands. These are chiefly whites, browns, yellows, reds, and greys. Yellow, red, and brown ochres are among the cheapest of colours; and from these, with whiting, charcoal, and bistre (or soot, from which bistre is made), all the colouring desirable for the outsides of cottages may be produced.

542. *Splashing* is a mode of colouring walls, which may be performed with equal success, as far as immediate effect is concerned, in water, in glutinous, or in oil, colours; and, in regard to the state of the walls, the same rules will apply in this case that have been already laid down in § 537. The object of splashing is either to imitate the lichens and weather stains of an old wall, or some particular kind of stone. It is seldom attempted in water colours, from their transient duration in the open air, but answers perfectly well with colours mixed with either blood, milk, or oil. The surface of the wall to be splashed must be well seasoned, and perfectly dry; and should resemble, as much as possible, the form of the stone or wall to be imitated; and the prevailing or groundwork colour of that wall should be given to it, by one coat over the whole. Then, several pots of different colours being mixed up, and a long painter's brush, called a duster, being put in each, the artist, holding a short stick in one hand, takes in the

other the brush, with the colour which he thinks it desirable to put on first, and strikes the head of the brush against the stick, so as to bespatter the wall with the colour. The taste of the artist must be his guide, as to the quantity of each colour which he throws on, and also as to the number of colours to be employed; but in neither case will he be at any loss, if he keeps the object to be imitated steadily in view. The first brushful of colour falls on the wall in circular patches, from  $\frac{1}{8}$  to  $\frac{1}{4}$  of an inch in diameter; the second brushful adds to the number of these round patches, and enlarges many of them, either by falling thickly among several, and joining them into one irregular blotch; or by falling on two or three, or on only one of the previous spots, and forming with it either an oval, or the figure 8. If we suppose the same process continued, on the same portion of surface, with different colours, it will be evident, that not only the shapes of the patches will be further altered by the addition of each splash of colour, but that their colours also will be varied. In this manner the process of splashing is carried on; and the result is obtained partly by chance, though chiefly by the skill of the artist. This kind of painting is less applicable to cottages than it is to imitations of rocks in garden scenery, and to Gothic buildings of a considerable size. In cottages, however, it may sometimes be usefully employed in colouring the imitations of stone or brick bond, where the rest of the walling is stuccoed, roughcast, or plastered; and, at all events, it is good to know every source of varied expression.

543. *In whitewashing, colouring, or painting the exterior walls of buildings*, the young Architect must constantly bear in mind that there are two objects in view; viz., the protection of the wall from the weather, and the production of a colour suitable to the object coloured, and agreeable to the eye. The protection of the wall is effected with glutinous or oil paints, by excluding it from all kinds of atmospherical influence, except that of change of temperature. The same object, but in a less degree, is produced by washes composed of lime or cement; which, while they do not prevent the atmosphere from evaporating the moisture of the wall in dry warm weather, yet exclude from its surface driving rains. The colouring matter in either of these cases is of very little consequence, so far as respects the protection of the wall. By having a clear idea of the purposes to be effected by colouring and painting, the Architect will know when to direct, or the cottager when to employ, colours or washes which will protect the wall from the drying influence of the atmosphere; and when such other colours and washes as will admit that influence ought to be preferred.

544. *On painting the woodwork of the outsides of cottages* little need here be said. If the wood be not thoroughly seasoned, it should not be painted with oil colours till it become so. It may be washed over in the mean time with water colours, or stained with nitrous acid, and dyed with logwood for immediate effect. We allude chiefly to the doors and windows. The larger outside timbers in cottages, especially those built of studwork and nogging, in countries where labour is abundant and paint dear, may be charred by the application of fire before being put up. We have seen buildings, the timbers of which had been treated in this manner, in France and Germany; and in Switzerland we have seen cottages in which the timbers had been charred, after having been put up, by the application of red-hot iron. The practice is not uncommon in some parts of Russia, not with a view to preservation, but for the purpose of ornamenting the very curious barge boards and gable ends which are sometimes seen on the cottages of enfranchised serfs in that country. The cheapest paint for the outside timber-work of common cottages in Britain is coal tar or gas liquor, which should be laid on hot during summer, when the timber is not only dry, but warm, and of which two or more coats, at intervals of two or three weeks, should be given, according to the nature of the timber, so as completely to saturate its pores. The colour cannot be called beautiful at first, but in the course of a year or two it assumes a subdued greyish tone, from the surface fibres of the wood becoming bleached by the atmosphere. Coal tar will, however, be sufficiently softened by the heat of the sun, to stick to clothes, or any thing that touches it, for three years; but is an excellent preserver where it can be used without inconvenience.

545. *The tiles, slates, and other roofing materials of cottages*, may be painted exactly in the same manner as the walls; but this can only be desirable with certain materials of a perishable nature, such as timber; or with others of a harsh glaring colour, such as red tiles. The latter will be greatly improved, both in durability and appearance, by being rubbed over or soaked in any greasy or oily matter, or by being painted with tar or gas liquor, before being put on the roof. But the best mode of colouring tiles and bricks is by mixing chalk, or ochres, or other oxides, with the clay, while it is being prepared for the mould. The tiled roofs of cottage lodges are sometimes splashed with oil colour, and the effect of age very successfully produced.

546. *The best description of paint, for all kinds of outside work*, is such as is formed by ground glass bottles, scoria from lead-works, burnt oyster-shells, and the required

colouring matter, powdered, and intimately mixed with raw linseed oil. Paint of this kind is prepared in London, and sold in a state of powder, under the name of anti-corrosion, lithic paint, &c. : but, as it requires to be mixed a day or more before it is used, as it is much more laborious than to put on than common paint, as it wears out the brushes in a very short time, and, above all, as it lasts so long when applied to iron, or well-seasoned timber, or masonry, as seldom to require renewal during a man's lifetime, painters very seldom recommend it. The appearance of a surface painted with anti-corrosion is rough, resembling that of unrubbed cast iron or freestone; and, when timber which has been once painted with it has to be cut up by a carpenter, it takes the edge off his tools (even his axe and saw), so that he also is against it. It is used, however, in some government works; particularly for cast-iron bridges.

547. *The Walls of Cottages may be protected and ornamented by Mathematical Tiling.* The object of this is to make the walls appear as if they were built of brick. The tiles, fig. 461, have their surfaces in two planes; each plane of the depth and length of a common brick; so that when tiles of this kind are placed against a wall, the one overlaps the other, as shown in the section, fig. 462; and the general appearance of the elevation is that of regular brickwork, as in fig. 463. There are bats or headers to imitate half bricks, fig. 464; and closers or quarter bricks, fig. 465, for the purpose of breaking

joint at the angles, and rendering the imitation more complete. When these tiles are of cream colour, their effect is very neat, clean, and handsome; but buildings in which they are used, to be in good architectural expression, ought always to have vertical bond in the form of projecting piers or angle stones.

548. *Mathematical and common weather tiles may be rendered ornamental,* either by varying their outline, or by impressing on them, in the mould, lines or figures. This has been done in a few places in England with bricks, and we think also with tiles. Fig. 466 shows some forms of weather-tiling, in addition to those before given, § 459.

By taking leaves of plants as the source for originating ideas for varying the outline, the variety of ornamental weather-tiling might be carried to a great extent; and we are informed by travellers that it would be a most valuable protection to the wooden walls of houses in America, as we are certain it would be to the earthen walls of the farm buildings which are put up in some parts of Ireland. Weather tiles might also be applied instead of barge boards, the tiles in that case being formed longer; and, when put on at right angles to the slope of the gable, finished by a projecting line of plain tiles over them. The colour of common weather-tiling might be varied, as well as the form, by the mixture of chalk, ochres, &c., with the clay while working it. Mathematical tiling might be ornamented on the surface by geometrical lines and figures; by

representations of natural objects, such as the sun, moon, and stars, as is sometimes done on the window-facings and barge-boards of the cottages in Russia; of animals; of the flowers of plants; of their leaves, &c. In fig. 467 *a*, *b*, *c*, *d*, and *e* show a few of the simpler patterns.

549. Various other articles might be employed to cover and ornament the walls of cottages, according to the effect intended to be produced. Trellis-work of various kinds gives a gay and dressed appearance, suitable for the immediate neighbourhood of a large town. A marine character may be given by shells; a rustic one by bark of trees; and a grotesque one by roots of trees; that of a Dutch cottage by glazed quarries (square tiles); and that of a Russian log-house by the outside slabs of trees (the first pieces sawn off, to reduce the trunk to a square, and of course flat on one side, and round on the other); the expression of warmth may be produced by clothing the walls with reeds; and of coolness by blue slates, &c.

550. The use of barge-boards, ornamental chimney tops, vases, verandas, terrace parapets, balconies, flower-stands, mignonette boxes, &c., may be considered as having been sufficiently illustrated in the preceding chapter. We have not hitherto, however, mentioned one very simple but neat cottage ornament, the sparrow pot, fig. 468, which is made of common potter's ware, and projected from under the eaves of cottage roofs at regular distances, by simply placing the pots, which have holes in the side of their bottoms, on nails or wooden pegs. The use of these sparrow pots is, to prevent the birds from dirtying the walls or windows with what falls from their nests, by keeping them farther from the wall; they also supply an easy means of taking either the birds or their eggs. We have seen a swallow pot for the same purpose, made by Adams, Gray's Inn Lane; but we are not certain that it succeeds. High and ornamental chimney tops will, however, generally be found to afford suitable angles and recesses for that bird (so useful to the cultivator in destroying winged insects) to build in.

551. The Doors of Cottages may be ornamented by adding strips of deal, in the form of muntins, styles, rails, beads, &c.; by ornamental hinges and latches; or by studding them over with imitation door nails. The plain door, fig. 469, may be rendered architectural, in the Gothic style, at a very trifling expense, by fillets nailed on so as to produce the effect of figs. 470, 471, or 472, or that of fig. 473; or by nails, as in figs. 474, 475, and 476. The woodwork should be painted in imitation of oak, and the heads of

the nails should be black. These nails are to be procured complete, of different shapes, in cast iron; but they are equally fit for producing effect when the heads are made of wood, and fastened on by a brad. When properly painted, it is impossible to distinguish the wooden nails from the iron ones. The shapes of the heads of these nails may be round, square, triangular, or polygonal; and with either flat or raised surfaces. A few of the different forms are shown in fig. 477. Ornamental hinges, or plates of iron as

in figs. 474 and 475, into which ornamental nails are driven, may also be imitated in wood, and completely disguised by paint; as may be certain parts of common latches, the

escutcheons of keyholes, &c. All knobs to cottage doors should be of real oak, laburnum (false ebony, as it is called by the French, from its hardness and blackness), yew, box, or other hard and tough wood, or of iron blackened or bronzed, but never of brass, which is too fine, and is besides liable to tarnish. The knobs, and other iron work of doors, may be blackened, by heating them nearly red hot, and immediately plunging them in oil; after being taken out and dried, they are polished with a coarse woollen cloth. Knobs, nail heads, and other parts of doors, whether of iron or wood, may be made to imitate bronze, by first painting them of a deep yellow colour, and then green: before the green is quite dry, it should be rubbed off the projecting parts, so as to allow the yellow to be seen through it. The greatest ornaments to cottage doors are, the porch, the penthouse roof, and the projecting canopy or shelf supported by brackets; but these may be considered as already disposed of.

552. *Windows* may be ornamented in a great variety of way. A plain sash or lattice window, figs. 478 and 479, may be disguised by a Gothic framework being put before it, as in figs. 480 and 481. In these cases it is supposed that the window to be disguised

shows outside reveals of at least six inches in depth, and that the thickness of the framework is not more than an inch, which will still leave five inches of reveal; a deep reveal being always desirable, as expressive of the thickness and strength of the walls. To disguise windows placed in nogging, studwork, weather-boarding, or other kinds of thin walls, which prevent any reveal from being shown on the outside, an artificial reveal must first be formed round the window by a projecting facing, in the manner of an architrave; and to be truly architectural, and to convey the expression of strength, this facing ought to be continued to the ground below, and to the roof above. Fig. 482 shows a portion of the front of a common weather-boarded cottage, in which it is desired to improve the appearance of the windows. Fig. 483 shows the windows improved in the manner described. On the supposition that these windows gave light to a stable and hayloft, to a tool-house with a seed-room over, or to any apartment not occupied as a dwelling, the windows might be further ornamented by placing a framework before the glass, as in fig. 484; or Gothic labels might be added, as in fig. 485. It will readily be conceived

that, by the application of facings round windows, and by placing framework, judiciously painted and shaded to imitate mullions and their mouldings, before them, an inexhaustible source is opened for the improvement of commonplace windows. Where the window to be improved is flush with the outside wall, even its proportions might occasionally be changed; its height might be added to by using framework in which there was much tracery in the upper part, painting the wall immediately behind it black; and the width might be increased in the same manner, by having narrow side-lights, and broad mullions and transoms. Thus, fig. 486 might be placed before fig. 487, and fig. 488 before fig. 489; the spaces marked *a* in both figures being painted black. In a country like

Britain, where the cottage windows are generally low and broad, nothing adds more dignity of character to a dwelling than heightening the windows; because high windows are expressive of lofty rooms. Where height cannot be given, and the obvious tendency of the openings is to width, the effect of the elevation is improved by increasing that tendency, because the idea of a larger room is thus given. From what we have said on the subject of disguising and ornamenting windows, we hope no reader will for a moment suppose that we intend any of the frames to be placed before the windows of the dwelling-rooms of cottages, in such a manner as to diminish the quantity of light and air admitted by them, or to injure the prospect seen from them. Nothing can be truly an ornament, or an improvement, to a house, which in the slightest degree diminishes the comforts or enjoyments of the occupier. There are few things to which we have a greater dislike than the practice of some great owners of parks, of putting labourers to live in lodges, and other ornamental buildings, which, with a great display externally, are scarcely habitable within.

553. *Outside Shutters* to windows or doors certainly cannot be considered as ornamental. To see on the outside of a building what we are accustomed to see on the inside, seems an offence against propriety; while it gives, at the same time, the idea of meanness and insecurity. Nevertheless, it is certainly more economical, in building a cottage, to have outside shutters than inside ones; and this circumstance, together with the influence that it is likely to have on the comfort of the cottager, being duly taken into consideration, we ought to moderate our dislike to them. What, perhaps, increases this dislike is the practice of holding forth these shutters as ornaments, by painting them green, and other gaudy colours; instead of keeping them subordinate, by making them the colour of the walls, or of oak; or by avowing them, and giving them the character of great strength, by fillets of wood, and nail heads, painted in imitation of iron; or by adding some description of architectural expression. When we consider the economy produced in interior finishing by having outside shutters, we think that, treated in this manner, they might be admitted even in ornamental cottages. Figs. 490, 491, 492, and 493, are examples of what may be called architectural shutters: those which

are meant to be completely subordinate should be painted, and marked with lines, in exact imitation of the forms and materials of the walls against which they are to be turned back. We have seen houses in the suburbs of Königsberg with the outside shutters painted so exactly like the walls on both sides, that, when shut, the house appeared to be without windows; and we were informed in 1813, by M. Koch, that several

houses escaped in this way from being plundered by the retreating French army, during the preceding winter. In the Duke of Northumberland's house, in the Strand, London, there is a gateway painted so exactly like the wall, as to deceive every body. Hinged shutters, when folded back, should be made fast in that position by the same bolt as that which fastens them when closed; and the strongest bolt for this purpose is one in which the end is turned up so as to form the handle, and render riveting on the knob unnecessary, fig. 494. The hinges used should be what are called set-back hinges, when it is wished to make the shutters fit close to the windows when shut, and to throw them back close to the wall when open, as shown in fig. 495. Outside shutters might also be made to slide in grooves, in the manner which we shall notice when speaking of outside blinds. Thus, outside shutters, which at first sight appear a deformity, may be converted into a source of beauty; for taste, like necessity, must bend to circumstances. The truth is, that the foundation of all taste, beyond that which is merely physical, lies in the mind; and, as a writer in the *New Monthly Magazine* observes, "every man manufactures for himself his own sublimity and beauty."

494

554. *Outside Blinds* form both elegant and useful ornaments to windows. The mind is at once reconciled to them, from the idea which they convey of shading and protecting something delicate and refined within. Their expression is the very opposite of that of commonplace window shutters, noble rather than mean; and the reason is, because, in Britain at least, they are almost exclusively used in superior houses. They have not only the effect of shading the curtains, carpets, and other furniture in a room, from the direct rays of the sun, and so preserving their colours; but, by reflecting back the sun's rays, they keep the rooms cooler during summer, and also darker; which last circumstance lessens the inducement for flies and other winged insects to intrude themselves. These outside blinds being only necessary during sunshine, various contrivances have been invented for putting them up in a compact form, during the night, or in cloudy weather; and this circumstance has given rise to boxes with cornices, which are fitted to the upper parts of windows, and joined to narrow wooden facings, or architraves, which extend along the reveals down each side. These boxes and facings are always more or less ornamental; and hence, even without blinds in them, they confer, when added to windows, a certain degree of dignity and beauty. All the different kinds of outside window blinds may be included in three divisions; viz., shutter blinds, Venetian blinds, and cloth or curtain blinds.

495

555. *Shutter Blinds* of the commonest kind, sometimes called folding Venetian blinds, are nothing more than outside shutters, opening in the middle, each shutter framed so as to form one panel, which is filled in with what are technically called luffer boards (inclined boards placed one above another in an aperture, so as to admit air, without permitting the rain to penetrate). These luffer boards are either fixed, or turn on pivots in the styles of their frames; their action, in the latter case, being like that of the common Venetian blinds. In shutter blinds, where the luffer boards move (which is always the preferable plan, as by it the admission of light and air can be better regulated), the movement is effected by a lever handle fixed on one of the luffer boards. These boards might be placed vertically, instead of horizontally; but the greater length required would render them liable to warp, and of course the shading would be imperfect. Outside shutter blinds are generally hinged like outside window shutters, and fastened back against the wall like them, by bolts, or button fastenings; but in very windy situations they are sometimes made to slide in grooves, which, as they are commonly made, are by no means ornamental; but by disguising them as string-courses, or labels, and painting them of the same colour as the walls, they may be rendered architectural as well as useful. These blinds, when the luffer boarding is shut close, serve, during night, as a secure window-shutter. In situations much exposed to the sun and wind, we consider this description of blinds, either running in grooves with fixed luffer boarding, or hinged and furnished with bolts or other fastenings, superior to any of the kinds of hanging outside blinds about to be described. From

the manner in which shutter blinds are generally constructed and hung, their outer surface, when shut, is even with that of the wall. This is objected to by some, in a picturesque point of view, as depriving the window of the effect of the lines of shade that would otherwise be thrown upon it by the depth of the reveals. To overcome this objection, it is only necessary to form the luffer boarding narrower, say two inches in width, and to hang the blinds with set-back hinges, so as to shut them close against the sash frame, like the outside shutter in fig. 495. Thus, if the depth of the reveal be seven inches without the shutter blind, it will only be reduced to five inches with it.

556. *Venetian outside Blinds*, of the common kind, only differ from inside Venetian blinds in having cornice boxes at top into which the blinds are drawn up, and frames at the sides which confine the ends of the laths forming the blinds, and prevent them from being blown about by the wind. In these blinds, instead of the laths being hung on tape, as is customary with inside Venetian blinds, slight brass chains are sometimes used. Outside blinds are generally painted of a stone or cream colour in the country; and green in towns. In Gothic cottages, showing oak framework externally, they may be painted in imitation of that wood.

557. *The Venetian Fan Blind*, an improvement on the common Venetian blind, is made by Messrs. Barron and Mills of London, and its object is, to admit a greater quantity of light and air than is done by either the common Venetian blind or the shutter blind. For this purpose the front of the blind is projected from the wall, at an angle which may be varied at pleasure from  $1^{\circ}$  to  $45^{\circ}$ ; and to prevent the sun from shining into the windows on the sides, admitting at the same time free circulation of air, fan blinds are there introduced. Both the front blind and fans are worked by means of one line connected with cords and pulleys, which is made fast to the frame in the same manner as in the common outside Venetian blinds. The front blind may be pulled up, and completely concealed under the cornice box at top, while the fan blind folds into a narrow box provided for it in the side frame. Hence, when this description of blind is not in use, the cornice box and side frame of the window have exactly the same appearance as those of any other hanging blind. A detailed account of the very intricate construction of this blind will be found in the *Repertory of Arts*, vol. viii. p. 449.; and we shall recur to it when entering more at length into the subject of blinds, under the head of Exterior Finishing to Villas. There is another description of outside Venetian blinds, in which the laths are formed of iron, and copper chains supply the place of tape. These blinds are fixed at top to a box which projects from the window, and are attached at the other end to a roller having a pulley at one end, by which, and by a cord which passes over a pulley in the reveal of the window at top, the blind is let down and rolled up. These bullet-proof blinds, as they are called, are manufactured by Bramah of Pimlico, and have been employed by the Duke of Wellington, at Apsley House, to protect his windows from the mob. They are most unsightly objects, and are only mentioned here as connected with the subject of Venetian blinds.

558. *Outside Curtain or Cloth Blinds* are of various kinds. The simplest form is where a curtain of the size of the opening of the window is furnished with rings on the margin of each side, which run upon two upright rods, concealed or not, according to the taste or means of the party, by side-framing. The lower edge of the curtain is attached to an irod rod, or a fillet of wood, to keep it down by its weight; and to this there is a cord attached, which, passing over a pulley in the middle of the soffit of the window, admits of pulling up the curtain, and fastening it in the usual manner. By another plan, the curtain is made to spread out in front like the Venetian fan blind. This variety is called a bonnet blind, and on it Messrs. Barron and Mills have made an improvement, which we shall hereafter describe. When these blinds are drawn up, they are as completely concealed, and protected from the weather by the box and frame, as any other description of blinds. The cloth generally used is strong linen, of the kind called gingham, and is generally striped with blue and white colours, which harmonise remarkably well with the sky and clouds. The cornice and frames are generally painted of a stone colour. A patent was taken out in 1826 for an improved mode of stretching by a contracting and collapsing apparatus, but it does not appear to have come into use. (See *Rep. of Arts*, vol. iv. p. 195.)

559. *Various other outside blinds of the curtain kind* have been used, and might be occasionally introduced in cottages. Projecting canopies, of different kinds, from the top of the window, might have corresponding balconies for flowers at the bottom; and, common curtain rods being concealed in the top of each canopy and in the bottom of each balcony, curtains, with rings affixed in the usual manner, might run on them, and be opened by hand, in the middle or at the sides, at pleasure. This would be a very cheap exterior blind, and one which, judiciously placed over the principal window of a cottage, would produce a very striking effect. Another description of blind is formed

by straining canvass, gauze, or fine wire cloth, on three or more light wooden frames; and, by hanging these horizontally to a frame of the size of the window, the small frames being connected on the opposite side to that on which they are hinged, by two slips of wood or by iron rods, they may be moved sympathetically to any angle, so as to keep out the sun. The slips of wood or iron rods must be screwed on so as to allow them to have free action at the head, otherwise they will not fall down. Blinds of this sort are kept in their position by a line fixed to the outer edge of the upper frame, which passes through a pulley at the upper end of the large frame, and being brought down, either on the inside of the window, or on the outside, is fastened as usual by a hook. It is evident that blinds of this description may also be hinged vertically; and if only two are used for each window, and these are hinged back to back to a style in the centre, one half of the window might always be uncovered, because before twelve o'clock it would be only requisite to keep that blind shut which was next the east, and after twelve o'clock that one which was next the west. Such blinds, however, would be chiefly applicable to windows facing the south. If, instead of being hinged back to back in the middle of the window, they were hinged to the side styles, and furnished with set-off hinges, they would form shutter blinds of a simple and cheap description. Roller outside blinds, such as are used to shade shop windows, are capable of a variety of useful and ornamental applications on the exterior of cottages.

560. *Wire outside Blinds* have not hitherto been used; but the very fine wire cloth now applied as inside blinds, might, we think, in some cases be advantageously placed outside, either as leaf or sympathetic frame blinds, § 559, or as shutter blinds. The great advantage of this wire cloth is, that it admits a view of what is without from within, while it completely excludes a view of what is within from without. Where a cottage is placed by the roadside, such blinds are very desirable, not only on these accounts, but also because they keep out the dust; and they are not less so where the windows on the south side of a house command a fine prospect. Much of the enjoyment of some rooms, in country houses, is lost during the finest weather of summer, from the necessity of keeping down the blinds; but, with wire blinds, the heat and great part of the light might be excluded, and yet the prospect be not only enjoyed, but even improved in effect, by the darkness of the room acting on the eye like the tube of a telescope. They should be painted to preserve them from the weather; and they may, in addition, be ornamented with landscapes, figures, or other objects; or, in the case of a country tradesman, in a roadside cottage, they may exhibit the owner's name, or the implements or products of his trade.

561. *Projecting fixed Canopies* are sometimes used for giving consequence to windows; and they might be occasionally employed in cottages. They are framed in wood, with paneled soffits, moulded cornices, and sometimes ornamented friezes, and they are supported by brackets. Figs. 496, 497, 498, 499, and 500, are canopies of this

sort. They may very properly be put over doors, and when they cannot be formed in solid timber, a plain kind of trellis-work may in some cases be introduced, for the purpose of supporting an ornamental climber.

562. *Other architectural modes of ornamenting the exteriors of either old or new Cottages* might be mentioned but we have said enough to lead the reader into a train of thought on the subject, and to point out to him to what parts of a plain cottage he ought chiefly to direct his attention, when his object is to ornament it.

563. *Ornamenting the exterior of Cottages by the productions of Horticulture, and by Landscape-Gardening*, is a subject which has occasionally occupied our attention in the course of the preceding chapter; and that of laying out the grounds round ornamental cottages and villas will be treated of in a future division of the work. We may here repeat, what we have before stated incidentally, that we by no means advise much to be attempted in the way of ornamenting cottages in the country by means of vegetation,

on account of the damp produced, and the insects harboured, by leaves ; and because, in proportion as any building depends for its effect on a covering of vegetation, in the same proportion does it lose its beauty as a piece of Architecture. We are more particularly anxious to impress on the minds of our readers the impropriety of planting trees, or creepers of any kind, against walls of cottages, which are shaded by opaque-roofed verandas, penthouses, or far-projecting eaves ; because in such situations they can never thrive, and not only have a sickly and disagreeable appearance, but actually, to a certain extent, contaminate the air by their decaying foliage. Life without health is without beauty.

SECT. II. *Designs and Directions for the Interior Finishing of Cottage Dwellings.*

564. *The Walls of a Cottage*, viewed externally, ought, by the appearance of the nature of the materials, and the mode in which they are put together, to give at the first glance unquestionable evidence of their sufficiency to support the roof. This being the case, on entering the dwelling we dispense with a repetition of this evidence, as far as the roof is concerned ; but if the apartments are large, and one is placed over another, as in houses of two or more stories, we require the appearance of strength in the ceilings to support the floor above them. Hence, the ceilings, in all very large rooms, should be thrown into compartments, by the reality, or by the appearance, of beams crossing the ceiling in the direction of its breadth, or shortest diameter. On the same principle it is desirable that these beams should be, or appear to be, supported at the extremities by piers or pilasters projecting from the walls, and sometimes even by detached columns. The finishing of these piers or columns is generally in imitation of some description of stone or marble, as belonging to the wall ; and that of the horizontal beams, of oak, or some other timber, as belonging to the superincumbent floor, or the roof.

565. *The Interior of the Walls of a Cottage* of the humblest class may, in some cases, require no other finishing than the rubbing or dressing of the material of the wall. This may be the case when the walls are built of brick, and the inner courses are rubbed and worked to a fair smooth surface. Rubbed sandstone may be applied in the same manner. For the plainest description of cottage the walls may be completely finished with one coating of plaster ; either by mixing the lime with a portion of Roman cement, or by using fresh-burnt stone lime and sharp sand, in the proportions of five of the latter to two of the former. The basement stories of many of the commoner street houses about London are finished in this manner ; by which not only the labour of putting on two coats of plaster is saved, but a more durable surface to the wall is produced. In general, however, the internal surfaces of cottage walls, of whatever materials they are composed, require to be plastered as indicated in the specifications already given ; for example, in § 80, and in § 235.

566. *Without a Cornice no Room can have a finished Appearance*, therefore we recommend cornices to be introduced into the living-rooms and principal bed-rooms of even the humblest cottages. The simplest cornice is formed by filling up the angle by a straight hypotenuse line, fig. 501 ; the next step is to curve this line convexly, fig. 502, or concavely, fig. 503 ; a square fillet, fig. 504, may be introduced ; or a round bead, fig. 505. In cottage dwellings, this bead is frequently formed of wood, as being

easier executed in that material than in plaster. The effect, when the bead is about an inch in diameter, is satisfactory ; and we think, instead of wood, it might, in some cases, be made of iron, fastened to the walls with staples ; and with one or two hooks to each length of rod between the staples, for the purpose of hanging pictures or other articles, agreeably to the practice in what are called gentlemen's houses. It is easy to conceive how a variety of cornices may be deduced from this simple form : by flattening the circle, by narrowing it ; by causing it to present the broad end of an oval, or the narrow end ; and by its being made, sometimes, to seem chiefly projecting from the wall, and, sometimes, chiefly from the ceiling. From these elementary forms a great variety of cornices may be produced. For example, in figs. 506 and 507 we

506

have ten different variations of the concave line, the lightest and most agreeable feature of all cornices, particularly when viewed from below, and the characteristic of the Gothic

507

cornice. Fig. 508 shows five sections of cornices having a convex curve for a leading

508

member. Fig. 509 shows modifications of the square, a leading feature in Grecian and Roman cornices. The square form, it thus appears, may be varied by approaches

509

to the parallelogram and to the rhomboid, and by altering its relative proportions with respect to the ceiling over it, and the surface of the wall beneath it. Composite cornices, fig. 510, may be formed by employing two or more of these five leading forms as

510

main features; and cornices in particular styles of architecture are obviously of easy composition, from the lines and forms which belong to those styles.

567. *The magnitude of a cornice* ought always to be regulated by the size of the room in which it is introduced; since the origin of the cornice of a column or wall was the edge of a plate of stone or timber, bedded on that column or wall, to receive with greater security, and give a better bearing to, what was to be placed upon it. A long narrow room does not require such a massive cornice as a square one covering the same surface, because there is less occasion for studying the security of the cross-beams or joists.

568. *Plaster Ornaments on Ceilings* have not hitherto been much introduced in cottages, on account of the expense. We scarcely think cornices with foliage or other cast ornaments desirable in plain cottages; but a rose or other flower, in plaster or composition, might often be introduced, at very little expense, in the centre of the ceiling of a cottage parlour. There is scarcely any part of a house in which a single ornamental form produces so much effect as in the centre of a ceiling. Fortunately for the builders

of even plain cottages, ornaments suitable for this purpose, and for various others in the finishings and fittings-up of rooms, have recently been manufactured by Messrs. Bielefelds and Haselden, at a very low price, of a description of papier maché. They are perfectly light and strong; and may be sent to any part of the world. They are fixed on by tacks or brads; and, being painted, will last as long as any other part of a house. Fig. 511, p. 275, is one foot in diameter, and costs 7s.; fig. 512 is two feet across, and costs £1; and fig. 513 is two feet and a half across, and costs £1: 15s. For the ceiling of the principal room of a well-finished cottage, it could not be thought extravagant to lay out 7s. on such an ornament as fig. 511. In all cases of introducing such ornaments, due preparation should be made for them, by raised borders, or mouldings, which should enclose them in a sort of framework.

569. *The Paneling of the Walls or the Ceilings of the Rooms of plain Cottages* is seldom attempted, otherwise than by lines painted on the wall, or by coloured papers; but there is no other reason than the expense, why it should not be adopted in the humblest cottage, as well as in the highly enriched villa. The occupant of the one may have a mind as susceptible of deriving enjoyment from the contemplation of elegant forms as that of the other, and he is therefore entitled to procure them whenever it is in his power to do so without interfering with any moral duty. Panels of this sort are generally formed by raised mouldings in plaster or stucco; but they may sometimes be more cheaply produced by mouldings of papier maché, some of which, such as figs. 514, 515, 516, and 517, p. 276, may be bought at from 2d. to 3d. per foot.

570. *Whitewashing and Colouring the inside Walls and the Ceilings of Cottages* should not be attempted till they have dried at least a year. If the plaster be of the commonest kind, without a finishing coat of stucco, it is only adapted for water colours, or colours rendered tenacious by glue, paste, or other mucilaginous matter, instead of oil; because of its porosity, which would wholly absorb the oil. The most common colouring for cottage walls is what is technically called lime whiting, which is nothing more than the finest particles of lime or chalk mixed with water, with the addition of a small quantity of size. The colour of this is varied by the addition of the black of charcoal (commonly called blue black, as distinguished from the soot of lamps, which is called lamp-black), or by yellow ochre, by verdigrise, or any cheap pigment.

571. *A superior description of whitening for interior walls* is thus formed:—Procure a quantity of the very best lime, and pass it through fine linen; pour it into a large tub, furnished with a spigot at the height equal to that which the lime occupies: fill the tub with clear spring water; beat the mixture with instruments made of wood, and then allow it to settle for twenty-four hours. When this period has elapsed, open the spigot, and allow the water to run off; then supply the tub with fresh water, and continue this operation for several days, until the lime attains the greatest degree of whiteness. When you allow the water finally to run off, the lime will be found in the consistency of paste; but when used it is necessary to mix a little Prussian blue, or indigo, to relieve the brightness of the white, and a small quantity of turpentine, to give it brilliancy. The size proper for it is made of glove leather, with the addition of some alum; and the whole is applied with a strong brush, in five or six layers, to new plaster. The wall is rubbed strongly over with a brush of hogs' bristles after the painting is dry, which gives it its lustre and value, and makes it appear like marble or stucco. (*Partington's Builder's Guide*, p. 550.)

572. *To whiten the Ceilings of Cottages.* Take the best white chalk, and add a little of the black of charcoal, “to prevent the white from growing reddish; infuse them separately in water; mix the whole with half water and half size of glove leather.” The size requires to be diluted, otherwise the whiting would come off in rolls when dry. Give two layers of this tint while it is lukewarm. (*Ibid.*) Instead of black, a small portion of any other colour may be mixed with the white, and Dutch pink is not unfrequently used for that purpose. The cornice, where there is one, forms a member of separation between the wall and the ceiling, and, being always an architectural object, should, for that reason, generally exhibit some colour belonging to stone, such as white, or some shade of yellow, grey, or brownish red.

573. *The colouring of the walls of rooms with water colours, or in what is called distemper*, only differs from whitewashing them, in the application being coloured. White, that is, lime or chalk, forms the groundwork or body of the composition, and the colouring is added by some concentrated vegetable extract, or metallic oxide. All the different colours are used for the walls of rooms; but the most common, after white, are some shades of yellow, red, green, or grey. As a general rule, the ceiling should be of a lighter colour than the walls; because it is found that, when it is darker, it is apparently brought nearer to the eye, and has consequently the effect of making the room appear low. Rooms which are too low may on the same principle be made to appear somewhat higher than they are, by having the walls a shade darker than is usual, and the

ceilings a shade lighter, and this effect may be heightened by a slight gradation in the shade of the wall from the base to the cornice. The manner in which the cornice is painted may also be made to cooperate in conveying the idea of height or the contrary. Small lines and mouldings, and faint shadows, convey the idea of distance from the eye, and the contrary that of being near it. Cornices of small dimensions, in plaster, may be apparently increased by lines of colour, and members not sufficiently distinct may be rendered so by shades. When the walls of rooms are paneled, the shade of colour of the panel, and of the styles, rails, and munnions, should be the same: but the shades of the mouldings between them should be lighter on the side on which the light is supposed to come; and darker on the opposite side, as in fig. 518, p. 276. Sometimes panels are formed by lines in imitation of raised mouldings as in fig. 519, which, with the preceding figure, may serve to show the method of paneling in plaster as well as in colours.

574. *As a cheap inside paint*, which a cottager may prepare, and lay on himself, we shall give a receipt for milk paint: we could add a number of others; but we have made choice of this, from having been assured of its superiority.

575. *Milk Paint.* Take of skimmed milk nearly two quarts; of fresh slacked lime, about six ounces and a half; of linseed oil four ounces, and of whiting three pounds: put the lime into a stone vessel, and pour upon it a sufficient quantity of milk to form a mixture, resembling thin cream; then add the oil a little at a time, stirring it with a small spatula; the remaining milk is then to be added, and lastly the whiting. The milk must on no account be sour. Slake the lime by dipping the pieces in water, out of which it is to be immediately taken, and left to slack in the air. For fine white paint, the oil of caraways is best, because colourless; but with ochres the commonest oils may be used. The oil, when mixed with the milk and lime, entirely disappears, and is totally dissolved by the lime, forming a calcareous soap. The whiting, or ochre, is to be gently crumbled on the surface of the fluid, which it gradually imbibes, and at last sinks: at this period it must be well stirred in. This paint may be coloured like distemper or size-colour, with levigated charcoal, yellow ochre, &c., and used in the same manner. The quantity here prescribed is sufficient to cover twenty-seven square yards with the first coat, and it will cost about three-halfpence a yard. The same paint will do for out-door work by the addition of two ounces of slaked lime; two ounces of linseed oil, and two ounces of white Burgundy pitch; the pitch to be melted in a gentle heat with the oil, and then added to the smooth mixture of the milk and lime. In cold weather it must be mixed warm, to facilitate its incorporation with the milk. (*Smith's Art of House-Painting*, 1825, p. 26.)

576. *The painting of the walls of rooms in oil* is seldom attempted, unless the walls have been finished with a coat of stucco; but, wherever both can be afforded, the result, in point of durability and beauty, is far preferable to what can be produced by water colours. The great advantage of oil colours is, that they will bear washing with soap and water, so that a room once finished with them will not require repainting for many years.

577. *Painting the internal woodwork of cottages* ought never to be neglected, both on account of its preservative quality and its ornamental effect. All woodwork, avowed as such, should, if possible, be grained in imitation of some natural wood; not with a view of having the imitation mistaken for the original, but rather to create allusion to it, and, by a diversity of lines and shades, to produce a kind of variety and intricacy, which affords more pleasure to the eye than a flat shade of colour. The most suitable colour for the woodwork of cottages is undoubtedly that of the prevailing timber of the district or country in which the cottage is built; at the same time, where this timber is but slightly veined or marked, it is allowable and advisable to imitate a better description of wood. Thus, in England, the prevailing timber in several districts is fir and poplar; but, as the wood of these trees is much inferior in beauty to that of the oak, the elm, or the chestnut, which respectively prevail in different districts in Britain, it would be allowable, and what would be considered in good taste, for the painter to imitate them. In this, as in every thing else, the Architect must be guided by the object in view. If a cottage be in the Swiss style, the larch and silver fir, being the two woods chiefly used in cottages in Switzerland, should be either procured by the builder, or imitated by the painter. In an Indian or Chinese cottage, the bamboo and other tropical woods, or their imitations, should predominate; and the same principle may be applied to other countries; always, however, bearing in mind, that the business of an Architect of reason and taste is not to produce fac-similes, or repetitions of objects, but imitations of their style and manner. For the method of imitating woods in painting, or what is technically called graining, as well as for the practical details of the painter's art, we refer to that part of this work where painting is treated of systematically, and also to *Smith's Art of House-Painting*, improved by Butcher, 12mo, London, 1825, price 1s. 6d.

578. *The Process of Stenciling Walls or Ceilings.* Stenciling, said to be a corruption

of stained ceiling, is of two kinds. The first, most ancient, and most universal mode, which is still generally practised in Italy, both on the outsides and insides of buildings, is that of pricking through, with a large-sized needle, the exact outline of a figure, previously drawn on paper or oilcloth; and then placing it against the wall, and striking the surface with a small gauze bag containing red or white chalk in powder, or powdered charcoal. The powder goes through the holes in the paper, and, lodging in the plaster, forms an outline, which is afterwards filled up by the painter. Sometimes, instead of pricking through the drawing, it is placed against the plaster before the latter has dried, and the outline is impressed on it by passing a blunt point over the outlines on the paper. This is generally done in the Italian practice of *al fresco*, a term applied in that country to the process of painting in water-colours on plaster, when newly laid on, and before it has set. The second mode of stenciling is the most common in Britain; by it, the patterns are all cut out in pasteboard or oilcloth, and as many pieces of board or cloth are employed for each figure, or compartment, as there are colours or shades to be laid on. This mode of ornamenting the walls of rooms is not unsuitable for cottages of the humblest description, on account of its cheapness; and because, in remote places, or in new countries, it might be done by the cottager himself, or by the local plasterer or house-painter. The beauty of the effect produced will depend on the suitability of the forms and colours of the figures to the style of the Architecture of the cottage; and on their disposition on the walls. Where the cottage displays externally any kind of architectural style, it is reasonable to conclude that some of the same style should prevail in the ornaments within, as well as in the furniture. A Gothic cottage should display lines, forms, and ornaments belonging to that style of Architecture, in all its interior, as well as exterior detail; and the same of other styles, or sub-styles. More judgment is required in the disposition than in the choice of ornament. There ought always to be an obvious reason why an ornament is placed in one position rather than in another; and wherever there is ornament or enrichment, there must be plain or flat surfaces to contrast with it. The side-walls of a room equally ornamented in every part by elaborate stenciling, or by a rich paper, would be intolerable, were it not for the contrast produced by the plain ceiling, and by the border with which the paper, or stenciling is finished under the cornice at top, and above the base or surbase below. If the same border, however, were carried across the middle of the paper, it would be as intolerable as the paper without a border, because the spectator would see no sufficient reason for its being placed there. In stenciling, and in every other mode of putting ornaments on walls, no figure, however appropriate and beautiful in itself, should be put down at random; nor should any wall be covered with figures for the sake of their individual beauty, but because they cooperate in forming a whole, or a particular object. That object may be the enrichment of the entire surface of the wall, by covering it, as it were, with a rich cloth or printed paper; or, instead of a cloth, by covering it, with a picture in perspective. The cloth, as a production of the loom, and the paper, as produced by printing, ought to exhibit a succession of the same figures at regular distances, and to be accompanied by all that uniformity and regularity which is characteristic of works effected by machinery. The perspective view, on the other hand, as an imitation of something existing, or supposed to exist, in nature, forms a whole with reference to itself, and not to the art by which it is produced, and consequently admits of almost endless variety.

579. *In the choice of patterns for stenciling*, not only the architectural style of the cottage, but its situation, whether in a town, the country, or in a village; and the occupation, native country, and taste or wishes, of the occupant, will naturally influence the artist. As contrast is one great source of beauty, both, as respects objects when placed so as to be seen together, and when placed so as to create allusion to other objects of the same order, but of a different class; so figures of flowers and plants in gay colours are more suitable for the town than the country, and figures of human beings, buildings, and streets, are more suitable for the country than for the town. The taste of a cottager living in a country far distant from that in which he was born may lead him to wish to create allusions to that country, by depicting some of its scenery; and, in like manner, another may desire to create allusions to scenery which he has heard of, but never seen. We state these things chiefly to show that, even in ornamenting walls, there should be a reason for every thing, and that this reason is, in every case, nothing more than a refinement on, or a correction, by a recurrence to original principles, of, the common practice of mankind. (See *Whitlock's Decorative Painter's Guide*.)

580. *A simple and elegant mode of stenciling the walls of plain cottages* consists in throwing them into panels, with lines of dark brown or grey; the general colour of the wall being white, a pale yellow, or fawn colour; and in forming ornaments at the angles. These panels should be coloured of a shade darker than the spaces between them, which are left in imitation of styles, muntins, and cross rails; for there can be no doubt that all paneling has had its origin in wainscoting. The panel may be ornamented,

and the styles and rails left plain, or the contrary. It is easy to conceive that there may be a great variety of stencil paneling adapted to plain cottages, which any cottager or emigrant, who could mix milk with ochres or any cheap universal colour, and use a blacking brush, might do for himself.

581. *Papering the Walls of Rooms* is a very general practice in Britain; and is applicable, to a certain extent, even to the humblest cottages. It is not adapted for kitchens or other apartments in which the coarser domestic labours are constantly going forward; but it gives a clothed, warm, and comfortable air to bed-rooms, and an enriched finish to the better description of living-rooms. The variety of papers for rooms is almost endless; beginning with a flat shade of colour, and rising through patterns of one, two, or three, or more, to twenty or thirty different colours, or shades of colours, as in the printed landscapes, some years since introduced into this manufacture by the French. All this variety may either be printed on the paper in water colours, or in colours in which oil is introduced, so as to admit of their being washed with soap and water. The figures on papers may be classed as architectural, either in the Gothic, Grecian, or other styles; as imitations of nature, either plants or animals, or combinations of these in landscape scenery; or as historical or biographical, and, consequently, either groups of figures or portraits. As the fashions of most of these papers change as frequently as those of printed cottons, it would serve little purpose to offer designs of them, either for the choice of the builder or the direction of the manufacturer.

582. *The designs which are printed on papers*, like those which are printed on different cloths, may be divided into two kinds: those which are intended to be correct imitations of natural or artificial objects, such as of particular species of plants or animals; and those which are fanciful compositions of artificial forms and lines, or of plants and animals imagined in imitation of nature's general manner, but not copied from any of her specific objects. All ornaments truly architectural or sculptural are of this latter class, and they are in no style more beautifully exemplified than in the Grecian; and, perhaps, in no ornament of that style more elegantly than in the sculptured honeysuckle which decorates many of the friezes of the ancient temples. As this style of design brings into exercise the imagination and invention of the artist, while the other (that of copying specific objects) only calls forth his powers of imitation, the former must necessarily be considered higher in the scale; and hence we find that the ornaments of the most cultivated nations of antiquity are of this class, while those of nations who have never excelled in the arts of design, as the Chinese for example, are of the other. Thus, while Grecian or Roman ornaments have only in their forms a certain allusion to particular plants or animals, almost all the plants and animals on Chinese papers and cottons may be referred to particular species or varieties. The imaginative style of design, carried to a high degree of perfection, is addressed to the cultivated mind, and excites admiration on the same principle, though in an inferior degree, as a painting or a piece of sculpture; and the imitative style, carried to an equal degree of perfection, is addressed to the memory and the judgment, and gives pleasure to the mind, by its imitation of well known objects, and by the associations which their images recall. As a proof that the imaginative designs, if we may so term them, are more permanently satisfactory than the merely imitative or natural history ones, it may be stated that all those patterns of papers and cloths which have withstood the changes of fashion are of the former description; while all those patterns which have soonest palled on the public taste have been attempts at close imitations of nature. At a large manufactory of tea trays, and other articles in papier maché, at Wolverhampton, a trial was made, a few years ago, to substitute portraits of plants botanically correct, for the imaginary compositions of flowers and leaves generally used; but the change was found unsatisfactory, as the articles would not sell. The drawing-room walls of the celebrated stock-broker Goldschmidt, at Morden, were covered with silk, painted with flowers and other objects, which were all drawn and coloured with scientific accuracy. We recollect the principal flower was the *Narcissus tazetta*, with its bulb and roots accurately portrayed; but, though we admired the figure in a botanical point of view, it gave us no pleasure as an ornament among other ornaments; because it had no connection with any of them, and did not combine with them in forming a whole. A showy geranium paper, and a red rose and green trellis paper, are seldom chosen but by those who cannot derive pleasure from a higher style of composition.

583. *In the choice of papers for a common cottage*, the same general principles may be observed respecting patterns and borders, as were mentioned under the head of stenciling. One of the best plain papers for the entrance lobby and the staircases of cottages, is one simply marked with lines in imitation of hewn stone; because, when any part of this paper is damaged, a piece, of the size of one of the stones, can be renewed, without having the appearance of a patch. There are very appropriate Gothic papers, with borders at the top, to imitate cornices, which are very suitable for Gothic cottages.

There are also papers covered with green trellis-work, with roses and other flowers entwined; and it is sometimes the custom to cover the ceilings, as well as the walls, with such papers. This practice may be allowable in towns, as creating an allusion to the country; but, in a country cottage, we consider it in bad taste, as not contrasting with local circumstances.

584. *An instructive natural history paper* for cottages, and the walls of nurseries and school-rooms, a contributor suggests, might be formed by printing figures of all the commoner and more important plants and animals with the scientific and popular names beneath them; each plant or animal being surrounded by lines, so as to appear either in frames, or as if painted on the ends of stones or bricks. The advantage of the framed lines would be to give unity to the paper as a whole, and also to admit of repairs by taking out any single frame or stone, and replacing it by another. There is no reason, but the expense, why a geographical paper should not be formed; or one exhibiting all the principal rivers, mountains, and cities in the world; or the portraits of eminent men, with their names; or perpetual almanacks; or lists of weights and measures; or chronological or arithmetical tables; or, in short, any useful and instructive subject, which it would be beneficial to the cottager to have frequently before his eyes. We all know how easily, and yet how deeply, the mind is impressed with objects that we are continually in the habit of seeing; and that what is learned through that medium in childhood is rarely, if ever, forgotten in after-life. Children, brought up in nurseries or cottages decorated in the manner we have mentioned, would thus have their minds stored with useful ideas, instead of fanciful images.

585. *The Floors of Cottages of the common kind* do not admit of much ornament. Entrance porches and lobbies may be paved with a description of tiles called quarries, which are formed in small squares of six inches on a side; coloured blue, red, drab, and black; and sold at Newcastle under Line, at from 2s. 2d. to 2s. 8d. per square yard. A superior sort is sold at 10s.; and a sort known as Wright's quarries, which have dark brown figures in pigment on their surface, let into a pale yellow ground, and are very ornamental, are sold for 25s. per superficial yard. In countries where tiles are not taxed as in Britain (where the duty, in 1832, is £1 : 4s. : 2d. per thousand), the price would of course be much cheaper. Quarries of different colours are set in mortar or cement, so as to appear like tessellated pavement; and Wright's figured quarries are used to form bordering and centres to his plain ones, or to floors of rubbed stone: in either case, they make a very ornamental and substantial flooring. When all the rooms of a cottage are on the ground floor, and when they are not flued under, a substitute for boards, at once ornamental, cheap, and comfortable, may be formed by paving them with one or different kinds of wood, obtained from the branches of trees, which have been cut into lengths of four or six inches, and set endways on gravel or in mortar; or, pieces of board, of various woods, resembling tile quarries in size, or stained of different colours by acids, might be embedded in cement, either in imitation of tessellated pavement, or of the Continental practice of parquetted floors. A very good composition for laying under such floors is made of one part of quicklime, two of sharp sand, and as much oil of any kind as will bring the other ingredients to the consistence of mortar. A sound, warm, and durable floor is formed in the following manner: the ground being well drained, and covered to the depth of a foot with loose stones, lay on these a stratum of a mixture of gravel and newly slacked lime, to the depth of six inches; let this be well beaten, and brought to a perfect level, and after it has dried a week or a fortnight, according to the weather, cover it, to the depth of two inches, with a composition of equal parts of quicklime and powdered smithy ashes, brought to the consistency of mortar by the addition of bullock's blood, stale milk, oil, or any other description of greasy matter. As soon as this is laid on, it must be well beaten with the back of a spade, or rolled with a cast-iron roller; after which, if immediately well and long rubbed with coarse woollen cloths, it may be brought to a high polish. The colour, when bullock's blood is used, is at first brown, but after some weeks it changes to a light grey. When yellow ochre is added to the mixture, a Bath stone colour is produced. One of the simplest modes of procuring a composition floor, in countries where Roman cement can be easily obtained, is to bed plain tiles in this material; then coat them over with a mixture composed of one part of cement, and two of sharp sand; and, a month afterwards, to give the floor a second coating of the same mixture, with the addition of as much lime and yellow ochre as will communicate a cream-coloured tinge to the surface. Or, the second coat may be composed of powdered Portland, Bath, or other freestone, and oxide of lead mixed up with oil, as in Hamlin's mastic (see § 527). A great object, in all ground-floors of cottages, is to lay such a foundation as to insure their dryness; we have mentioned several modes of attaining this end, and we add the following (which is said to be practised in Bengal), as suitable for districts in Britain, or other temperate climates, where pottery is cheap. "The area of the house or room to be floored is first made perfectly level; unglazed

earthen pots, each about a foot in height and large-bellied, are then placed with their mouths downwards, close together, over the whole surface. The vacant parts round the necks and tops of these pots are afterwards filled up with charcoal pounded fine (this substance being well known to resist damp); and, over the whole, a floor is formed of brick-dust and lime, well worked together, and made as hard as possible. (*Mech. Mag.*, vol. xi. p. 21.) We shall describe different modes of forming composition floors for the upper stories of buildings, when giving designs for fire-proof houses, in our succeeding Book.

### SECT. III. *Designs and Directions for internal Fittings-up for Cottage Dwellings.*

586. *Shelves* to pantries, closets, and closet cupboards should be formed of boards of some description of wood not liable to communicate its flavour to the articles laid on them; or, if such a wood cannot be got, the shelves ought to be painted in oil. The least expensive mode of fixing these shelves is by inserting their ends in the wall, or rather in the first coat of plaster; a better one is by fixing them to wooden bricks, but the best is by lining the walls with thin boards to which the shelves are attached. When shelves are put in by tenants, or temporary occupiers of houses, this last practice is sometimes adopted, for the sake of allowing the temporary occupier, at the expiration of the period of his occupation, to carry away with him his shelves, which in this case are no longer considered as landlord's fixtures.

587. *Of Seats and Basins to Water-closets, and of Cisterns for Water*, we have already said enough for this division of our work; and shall, therefore, not again recur to them, till we come to give designs for those of ornamental cottages and villas.

588. *Chimney-pieces* for the kitchens of cottages should generally be finished with stone facings and stone shelves; but, where the stone is sandy and brittle, it is much better to substitute stout shelves of deal or oak. The cottage parlour should, if possible, have a marble chimney-piece; and those of the bed-rooms may be of stone or composition. Designs will be found in our succeeding section, where we treat of fire-places which may be executed either in marble, or stone, or composition; in the latter case, and even where freestone or slate-stone is used, they may be painted in imitation of some variety of marble. In countries abounding with slate of the kind which rises in large laminae like that of North Wales, handsome chimney-pieces may be formed at very little expense, and painted so as to resemble either stone or marble. There are also chimney-pieces of cast iron, which are generally highly ornamented; and which are strong and durable when properly painted. The height of the shelf of the chimney from the floor is generally varied according to the width of the fireplace; but, in a cottage where the shelf is always turned to some use, its upper surface should generally be about four feet and a half from the floor; the projection of the shelf from the fascia, or face of the lintel, may vary from four to six inches, and its thickness should not be less than an inch. Where cast iron is used, and bronzed, so as to avoid the material, the thickness of the shelf need not exceed half an inch, and the general design may be much more varied and enriched. Were the plan adopted of enclosing fireplaces in glazed doors, so as to prevent the heated air of the room from escaping by the chimney, and yet to show the fire, for which a patent was taken out by a gentleman of Edinburgh some years ago (see *Rep. of Arts*), and which has been recently recommended by Dr. Arnott, cast-iron chimney-pieces would be found very suitable.

589. *A valuable substitute for Portland stone chimney-pieces* is thus formed:—"Take two bushels of sharp drift sand, and one bushel of sifted slacked quicklime; mix them up with as little water as possible, and beat them well together for half an hour every morning for three or four successive days, but never wet them again after their first mixture. To two gallons of water, contained in a proper vessel, add one pint of single size made warm; a quarter of a pound of alum in powder is then to be dissolved in warm water, and mixed with the above liquor. Take about a shovelful of the first composition, make a hole in the middle of it, and put therein three quarters of a pint of the mixture of alum and size, to which add three or four pounds of coarse plaster of Paris; the whole is then to be well beaten and mixed together rather stiff. Put this mixture immediately into the wooden moulds of the intended chimney-piece, the sides, ends, and tops of which moulds are made of movable pieces, previously oiled with the following mixture:—Take one pint of the droppings of sweet oil, and add thereto one pint of clear lime water, made from pouring boiling water on lumps of chalk lime in a close vessel till fully saturated: when the lime water becomes clear, it is in a proper state to be added to the oil, as above mentioned, and on their being stirred together they will form a thick oily mixture or emulsion, proper to apply to the moulds. In forming the side or jamb of a chimney-piece, the mould is to be first half filled with the sand, lime, and plaster composition; then two wires, nearly the length of the piece to be moulded, are to be wrapped round with a thin layer of hemp, and to be placed in parallel lines,

lengthwise, in the mixture or composition in the mould: the mould is afterwards filled up with more of the composition; and if there is any superfluous quantity, it is to be struck off with a piece of flat board. The lid, or top of the mould is then to be placed upon it, and the whole subjected to a strong pressure from powerful levers, or a screw press. The composition should remain under this pressure for twenty or thirty minutes; the precise time necessary being guessed from examining the state of a small specimen of the composition, reserved purposely to determine the time it requires to harden and set firm. The sides of the mould must be held together by iron clamps and wedges. The wires above mentioned answer a double purpose, by giving strength to the jambs, and retaining the whole mass together, in case it should at any time be cracked by accident. These chimney-pieces may be made either plain or fluted, according to the mould; and when moulded, they are finished off by rubbing them over with alum water, and smoothing them with a trowel, and a little wet plaster of Paris. A common plain chimney-piece of this composition was sold at only 7s., and a reeded one at 28s., in London, in 1832, completely fitted up." (*Trans. Soc. Arts.*)

590. *Bell-hanging* may be described as the art of conducting lines of wire, intended to ring a bell at one end, when pulled with a little force at the other, in all directions round the apartments and through the walls of a building, in such a manner as not to obtrude on the view. This is effected with ease in straight lines; and angles are got over by what are called cranks, of which there is a variety of sorts for external and internal angles. As few bells can be required for common cottages, we shall defer what else we have to say on the subject till we come to treat of public-houses and inns; merely observing here, that a modern improvement consists in having the wires entirely concealed; and, in having a small wooden or ivory knob, protruding either from the plain face of the wall, or from the centre of a rose, a cup, or other ornament, instead of riband or string bell-ropes suspended from the ceiling. Fig. 520 shows a bell handle of this

description, with its different parts: *a* is a cup, containing in the centre an ivory knob, by which is pulled the brass chain *b*; this chain passes over a pulley, *c*, and consequently may pull a bell in the direction of right or left, upwards or downwards, according to the side to which the pulley is turned; and when it is desired to pull the wire in a direction perpendicular to the face of the wall, the pulley is omitted, and the chain works solely in the groove *d*; *e* shows the outer rim of the cup unscrewed, in order to be cleaned if in wood, or new lacquered if in brass; *f* shows the ivory knob also unscrewed; *g* is the hollow of the cup, with the ears containing the holes for the screw-nails which fix it to the wall. The knob *f* is of ivory, and all the rest is of brass; but the cup might be made of ebony; or both cup and knob might be of bronze, or of iron painted to imitate bronze. The grooved bolt, *d*, in which the chain works, is generally made square, but it is here shown round, an improvement made by Mr. Nettlefold of London, which is found to make it work more truly and easily. The use of the grooved iron is to guide the chain or wire, in pulling it out, and in letting it spring back again.

#### SECT. IV. *Designs and Directions for Fixtures for Cottage Dwellings.*

591. *The fixtures* for cottages we shall take in the order of kitchen ranges, cooking stoves, warming stoves, ovens, boilers, grates, sinks, fixed basins, fixed washing troughs, fixed ironing boards, and other flaps and slabs, towel rollers, dressers, and corner cupboards.

592. *Kitchen Ranges* are manufactured in Birmingham, and sent to all parts of the world, and their variety is almost endless. All of them, however, may be included in two classes; those that have neither boilers nor ovens, either at the sides or behind; and those which have either or both. It is of great importance to the cottager to know, that when he is obliged to choose a kitchen fire-place that has neither boiler nor oven in the hob or jamb, he ought to choose a front and bottom grate only, and have the sides and back of his fire-place one solid mass of masonry, and if possible of fire stone or fire brick.

In every country there are clay stones to be found, so free from sand or lime as not readily to fuse; or clay so free from other substances as in like manner to resist the action of intense heat; and of one or other of these the backs and sides of all open fireplaces ought to be formed, where the object is to get the greatest quantity of heat from the smallest quantity of fuel, with the least quantity of labour. When the cottager can afford to purchase a range having an oven on one side and a boiler on the other, the kind which we consider the most suitable is that first made by Mr. Eckstein of London, fig. 521, in which the boiler occupies one side and the back, from *a* to *b*; and the oven is

on the other side, *c*; the fire comes in close contact with both oven and boiler, and heats them sufficiently without the aid of a flue under the former. This range, on a small scale, may be purchased in London, by retail, for five guineas; the size here shown costs eight guineas. The oven, in this and other iron kitchen ranges, would be much improved by being lined with fire stone or fire brick; the heat would be thereby moderated, rendered more uniform, and retained longer. For roasting meat, there might be a grated false bottom, with a valve in the lower part of the door of the oven, and another in the back part of its cover, by which a current of air might be admitted at pleasure to brown the meat. There is a very small cast-iron range made occasionally, in which a stove for heating irons, and for other purposes, is substituted for a boiler, and which costs only three guineas.

593. *A Design for a Cottage Kitchen Grate, of great ingenuity, and capable of supplying all the heat required, not only for cooking, but for washing, warming, and every other domestic purpose, has been sent us by our scientific and gifted correspondent, Mr. Mallet, jun., of Dublin, who informs us that he has tried it, and found it to answer in every particular.* Fig. 522 is a vertical section of this grate in the plane of the

breast of the chimney; and fig. 523 is a plan, or horizontal section, of the same, taken a little above the bottom grate. The sides and back of the fireplace are formed by the

hollow vessel *b*, of boiler plate iron, into which two pipes are inserted to produce circulation between the water in it and that in the apparatus shown in figs. 524, 525, and 526. The vessel *b* receives constantly that portion of the heat which would otherwise be dissipated in the brickwork of the back and sides of the fireplace, and transmits it to a hollow vessel, fig. 524, enclosed in a cast-iron casing with

at one time an oven or hot closet, and at another a water or steam bath: the temperature of either of these, however, can never be higher than 212°, unless oil be used. The upper surface of this case will be useful for culinary purposes, most operations of which require but a moderate heat. Fig. 526 shows the top of the water-bath, with holes at one end for inserting saucers, &c.; and with a hot plate at the other. This double-cased vessel is easily and cheaply made of boiler plates. Over the fireplace is another vessel, also formed of boiler plates, fig. 522, *a*, the water in which is heated by that heat which generally escapes up the chimney, to the amount of half that evolved by the fuel. The flue passes in a circuitous route, *c c*, and the ordinary flue receives the smoke at *d*; but if the smoke passed off by the dotted lines *e e*, more heat would be given out, though in that case soot doors would be necessary in the chimney breast, opposite the angles of the flues, to admit of cleaning them. This boiler or vessel will heat part, or the whole, of the cottage, according to its size; it will supply hot water for culinary or other purposes; and when the vessel *b* is not in use, the heat of *a* may be greatly increased by opening the cock *m*, which will permit circulation to take place between the upper and lower vessels. The vessel *a* is supplied with water by a small

cistern and ball cock, *f*, connected by the

pipe *g*, bent to prevent circulation, and sunk into the wall of the chimney; a simple smoke-jack may be placed over the opening of the flue, *c*, as shown at *h* in fig. 527; and a door of iron should be fixed in the breast of the chimney, a little higher up, as shown in the same figure at *i*, in order to get at the boiler at any time, and to sweep the chimney. Fig. 527 shows the elevation of the grate, which has a common crane, *k*, for hanging pots on; and two hinged cast-iron doors, *l l*, to turn back against the wall; by closing which the fire may be at any time intensely urged, and thus the water made to boil in both vessels in a few minutes (the cock *m* being open). By these means a bath may be procured in a very short time in any part of the house or cottage. Of course many modifications and applications of this Design are practicable; such as heating a conservatory or a poultry-house, hatching eggs, steaming fodder for cattle, &c.; all of which may be readily conceived and executed by any practical engineer accustomed to direct works in iron.

594. *Cottage Cooking-Stoves* are not common in Britain, but they are much used in those truly economical countries, Holland and the Netherlands; and might, in many districts, prove of great advantage to the British cottager. We shall give a description of the stove in use in the cottages about Bruges, as furnished us by Mr. G. H. Cottam, who adds that these stoves will be manufactured, in future, at the establishment of Messrs. Cottam and Hallen, Winsley Street, London. Fig. 528 is a vertical section, showing the furnace or fireplace, *a*; the flue, *e*; and oven, *o*. Fig. 529 is another vertical section, taken at right angles with the former; and fig. 530 is a perspective view, show-

ing the external appearance of the whole. Near the top of the furnace there is a square opening, fig. 528, *h*, to admit the hot air and smoke produced by the consumption of the fuel, to enter into the flue, *f*, in which it circulates round the stove, between the plates *p* and *q*, before it escapes up the chimney, *e*. The oven, *o*, is heated from the furnace, *a*; which furnace, being closed at top, becomes red-hot, or nearly so, and produces sufficient heat for roasting, or any other culinary purpose. The size of the fireplace can be increased at pleasure by taking off the grate, *g*, and putting in a smaller grate to rest on the projections, *i*; or a still smaller one on the shoulders, at the bottom of the opening at *k*. The cinders and dust from the fuel fall into the box, *b*; which pulls out, in order to remove them, without producing the slightest degree of dust or dirt. Thus, while bread is baking in one oven, and meat roasting in the other, boiling or stewing may be carried on by saucepans set upon the cover, or in holes cut in it, having lids with handles, *r*, which lift off. One of these lids, *n*, is directly over the fireplace, and the two others, *l* and *m*, open into the smoke-flue. Irons may also be heated on this plate. These stoves will consume the most inferior description of fuel, and will produce an intense heat, from what would scarcely burn at all in a common open fireplace, where the fire is, as it were, drowned with air on all sides, instead of being, as it is in the Bruges stove, surrounded on all sides by heat, and the air supplied in one stream from below, through a valve in the front of the drawer for receiving the ashes. Most of our readers will agree with us in thinking that this stove, when it becomes generally known, will form a treasure to the British cottager, as it will not only serve to cook his meat, &c., but will throw out more heat for the purpose of warming his room, than any open fireplace whatever. The construction of this stove, in a scientific point of view, is admirable; and all that is necessary, in putting it up, is to set it on the floor, a few feet from the chimney (if one should be already built), and to conduct the smoke funnel of the former into the flue of the latter, immediately under the ceiling of the apartment, or, if the cottage contains two floors, it might be carried through to the roof, in order to heat the bed-rooms. When this stove is used as a substitute for a kitchen range, the open fireplace, or the throat of the flue over it, should be closed up, in order to prevent the escape of the heated air of the room. The fireplace, indeed, might be turned into a cupboard. We hope to hear of orders being given for hundreds of Cottam's Bruges stove; because they would not only serve instead of all other kitchen fires for common cottages, but would prove a useful auxiliary to the kitchen in most houses. It would be easy to make an improvement on this stove, so as to circulate hot water from it all over a house, for the purpose of heating it; thus rendering open fireplaces totally unnecessary, and doing away, in ordinary-sized dwellings, with all the chimney-flues and chimney tops, except one.

595. *Warming-Stoves* are of endless variety. Those manufactured in Britain are generally of iron; and for the consumption of pit coal they are erroneous in one important particular, viz. that of not being surrounded by fire brick or fire stone, to serve as

a reservoir of heat. Were this done, or were even a double vacuity of air formed around, above, and below the furnace of a stove, by plates of iron, a great deal more heat might be procured from the fuel; because nearly the whole of the smoke might be consumed: all the difference would be, that the heat, instead of being radiated directly from the stove into the air of the apartment, would be radiated from the flue; and this flue, being of iron, might be conducted so as to heat several apartments, or the whole house. A good and cheap construction for this purpose is still wanting. A stove invented by Witty effectually consumes the smoke; but it is bulky, the fuel is supplied in an awkward manner, and the stove itself is rather too expensive for our present purpose.

596. *Cottage Ovens* are formed of either iron, fire stone, or fire brick. The two latter kinds are by far the best; because they do not, like iron, acquire suddenly so much heat as to burn what is to be baked or roasted in them; and because they retain the heat they do acquire for a long time. An excellent oven is formed by cramping together five square fire stones or fire bricks, of a foot or more in breadth each, and having a sixth stone or brick as a cover. The fire may be made within, and taken out when the stones are thoroughly heated. This oven may be fixed by the side of a kitchen fire, or set on a weak fire, as practised with a description of stone oven in use among the cottagers in Gloucestershire, and with clay ovens at Dunstable, in Bedfordshire. Excellent ovens of this sort might be made of Stourbridge fire clay; and Mr. Peake of Tunstall informs us, that not only ovens for baking bread, but entire fireplaces, with their flues, might be made of the same material, at a very moderate expense, if it were not for the present enormous duty. A fire clay fireplace, with an oven on each side, and requiring no ironwork, except a small grating in front and another at the bottom, would be a most desirable fixture for the cottage kitchen.

597. *Portable Iron Cottage Ovens* are common among the ironmongers, but they are not very desirable. Occasionally, however, they may be useful where nothing better can be got, and we shall therefore briefly notice two kinds. Fig. 531 is a front view of a portable wrought-iron cottage oven, which costs in London, by retail, 30s. It is intended to be placed over a fire, so that the smoke and hot air may enter at *a*, circulate round the oven, and escape by the funnel, *b*. There is a valve, *c*, to permit the escape of steam when meat is roasting. Fig. 532 shows a view of the oven with the door open, and with a false bottom, *d*, of fire stone, raised half an inch from the iron bottom, to moderate the heat. The dimensions of the chamber are, depth and height, thirteen inches and a quarter, and width fifteen inches. Another portable oven is nothing more than a common cast-iron flat-bottomed pot or stewpan, with a false bottom inside supported on pivots, under which sand is put, to diminish the intensity of the heat. When this oven is to be used, it is put on a moderate fire, and covered with a lid, which may be taken off occasionally to admit air. The cost in London, by retail, is only 3s. 6d. It will bake a small loaf, or roast a fowl.

598. *Boilers for Wash-houses* are commonly made of copper, and require little art in either making or managing, except, in setting them up, to provide for getting as much heat as possible out of the fuel burned beneath them; and to get ready access to the flues, to free them from soot. In all open boilers, as usually constructed, there must necessarily be a great waste of heat; and therefore, in cottages, we always desire to contrive the flues proceeding from them so as they may heat the air of the apartments.

599. *Parlour and Bed-room Grates* are manufactured in iron in the greatest variety; but it may truly be said that there is not one in a hundred of their forms worthy of being recommended, as being scientifically constructed, with a view to the complete consumption of the fuel used, and the radiation of heat into the room. The grand error of almost all of them

consists in their being exclusively constructed of iron. We hope the day is not very far distant when open fireplaces will be considered as relics of barbarism, and will be altogether banished from every room in British houses, except the kitchen: in the mean time, we recommend the cottager who persists in indulging his prejudice for the sight of an open fire, to form the sides and back of his fireplace with fire brick or fire stone; and to use no iron whatever in its construction, but four bars for a front to the fuel chamber and a bottom grate, which, together, in cast iron, will not cost more than 3s. or 4s. The most convenient fire bricks are what are called Welsh or Stourbridge lumps, from the names of the places where they are made; that is, masses of burnt clay, eighteen inches or two feet long, nine inches or a foot broad, and six or eight inches thick. One of these may form the back of the fireplace, and two others the two sides, as in fig. 533; in which a

533

represents the front bars; *b*, the bottom grate; *c*, the plan of the fireplace, the bars, grate, and Welsh lumps being shown in their proper places; *d*, the elevation; *e*, the section of the front bars, and the bottom grate, showing the inclination of the latter, *f*, towards the back of the fire chamber, in the proportion of about one inch in six, with a view of giving the ashes a tendency to the back; and *g*, a section of one of the front bars, of nearly its full size, showing the upper surface inclining towards the back of the grate, in the proportion of half an inch to an inch, *h* being the front of the bar. The nearer the fuel-chamber is placed to the hearth, the more heat will be radiated into the room from the increase produced in the space, *i*, between the grate and the chimney breast; and, on the contrary, the nearer the fuel chamber is to the chimney breast, the less will be the heat radiated into the room, though the chimney will draw better. The Welsh or Stourbridge lumps at the sides should form with those of the back an angle of forty-five degrees or upwards. In a fireplace of this sort a fire is much more easily lighted, and much less liable to go out when neglected, than in one having the back or sides of iron. It also consumes the fuel much more effectually; and, by not radiating the heat so rapidly from its surface as iron, it creates less draught up the chimney, and consequently carries less heat out of the room. When the mass of fire brick is once thoroughly heated, it retains heat for many hours after the fire has been extinguished; so that, if the fire is at any time suffered to go out from neglect, the room is not so soon cooled as it would be, under similar circumstances, by the radiating and conducting powers of cast iron. Where the grate is raised somewhat higher than is shown in fig. 533, a drawer may be added to the front bars, and bottom grate under the latter, for receiving the ashes, so as to prevent them from raising a dust, by falling from the bottom grate to the hearth, and at the same time to retain more heat about the fire. The ashes may also be carried away in the drawer, in furtherance of the same object; and by drawing it out more or less, or keeping it closely shut, the burning of the fire may be accelerated or retarded. As a further means of preventing the ashes from falling from the front bars on the hearth, the upper

surface of the former should always be made to slope inwards, as before stated, and the breadth of the bars should be somewhat greater than is usually employed. This is shown in fig. 533, *g*, and also in the section, fig. 534, to a scale of a quarter of an inch to a foot, in which *k k k* are the sections of the bars; *l*, the bottom grate; and *m*, the ash-drawer. The front bars should always be straight, because the consumption of the fuel depends on its being as little exposed as possible to cold air on the sides, and because the heat given out to the room depends on the breadth of surface of the ignited fuel, and not on the depth of the fuel chamber. Curved fronts, therefore, for fireplaces of this sort, are never to be recommended; not only because they increase the depth of the fuel-chamber, but because they expose a greater portion of the fuel to the action of the cool air, by which perfect combustion is rendered more difficult. With the fireplaces near the hearth, with front bars beveled inwards, and with an ash-drawer, the fender may be made very low; and thus the heat may be allowed to radiate freely to that part of the floor from which it is excluded by a high fender. It is necessary to observe that the bottom or ash-drawer is not recommended as a means of increasing the heat, because its front and bottom will prevent a portion of that from being radiated to the hearth, but chiefly as a means of regulating the draught of air through the fire, and consequently of accelerating or diminishing the consumption of the fuel; and partly for the sake of cleanliness, in preventing the small ashes from falling on the hearth, and avoiding the dust which in that case arises when they are swept up and carried away.

600. *A simple and economical Fireplace* for a cottage parlour the chimney of which is liable to smoke, is in use in some parts of Fifeshire and Mid-Lothian, and is worthy of imitation in countries where fire stone or fire clay can be readily procured. In the cottages alluded to, the sides or jambs, figs. 535, 536, *n n* (between which are fixed the front bars and the grate), are formed of

a kind of fire stone, found in the island of Cramond: the fire-chamber is wide in front, but not deep; in consequence of which it consumes but few coals in proportion to the heat it throws out. The upper part of the fireplace, behind, and at the sides, is formed of the same stone; and in front there is fixed a cast-iron plate, with an opening in it; which, though generally semicircular, might be made square, or Gothic, according to the character of the architecture of the house. These fireplaces are valuable for low-roofed cottages placed among high trees, as the chimneys of dwellings so situated are very apt to smoke. Fireplaces thus constructed draw well; but it must be obvious that, in proportion as this is the case, a greater amount of heat must be carried up the chimney. A thin plate (generally of sheet iron) is

sometimes hooked on in front of the opening, on first lighting the fire, in order to increase the draught, by preventing the cold air of the room from mixing with the heated air that has passed through the fire. In Ireland, we are informed by Mr. Buchanan, in his *Economy of Fuel*, p. 315, that, instead of using a cast-iron plate, the back of the upper part of the fireplace is formed into an oval niche, by fire stone or fire brick; the breast of the chimney being rounded off, and the throat very much contracted. A view of such a chimney is given in an excellent work, entitled *The Theory and Practice of Warming and Ventilating, &c.*, p. 183. We can only recommend such fireplaces, however, as a minor evil to that of a smoky chimney. The grate, fig. 535, and the preceding one, fig. 533, have one disadvantage for the cottager, common to both, viz., that of having no hobs; but this want may be supplied in the present grate, by omitting the cast-iron plate, when the tops of the jambs would become hobs, as is actually the case in the parlour fireplaces of cottagers about Edinburgh;

and hobs might be supplied to the grate, fig. 537, having the sides of the fire at right angles to the front, as indicated in fig. 538, in which *o o* are the hobs, formed of Welsh lumps, or fire stone; *ppp*, Welsh lumps forming the sides and back; and *qq*, angles filled up with mortar, or fragments of fire brick. In such fireplaces as fig. 533, a substitute for a hob may always be found in the movable bracket called a trivet, for hanging on the bars; or by a similar stand with three feet, for setting before the fire.

601. *An economical union of cast iron and fire stone or fire brick is sometimes attempted by ironmongers, by lining iron cases with stone or brick, as in fig. 539; in which the front plates of the jambs, r r, and the plates which form the hob, s s, are of cast iron; and the back and sides are also of iron, but lined with three fire stones, t t t.* The iron back and sides are of no other use than to retain the stones in their proper places, and thus render this fireplace portable, and, in consequence, an article of trade for ironmongers; since a much more effective and less expensive fireplace would be produced by having only the covers of the hobs, the front plates of the jambs, and the bottom grate, of iron, and building up from the hearth, the jambs, and the back, of solid masonry, and on that placing the firestone. A grate built in this way is both economical and handsome, more especially if it has broad beveled front bars and an ash-drawer, as shown in figs. 534 and 537; but, as Mr. Tredgold observes, "ironmongers, in general, seem to think it more desirable to use iron, than to economise fuel, or to work on sound principles."

In the neighbourhood of Birmingham, and in the coal districts of the midland counties, where coal is abundant, and the inhabitants are fond of large bright fires, the bottom grates are made so wide that cinders of considerable size are allowed to pass through them. To prevent these cinders from being lost, and also to prevent dust from being raised, by sweeping up and carrying away the ashes, what is called an ash-pan is often placed on the hearth between these fire jambs, immediately beneath the grate. This ash-pan, fig. 540, is a frame or box, with a grated top and a drawer underneath. The open spaces in the grating are about a quarter or three sixteenths of an inch apart, which is the width between the bottom bars of grates about London, and in most parts of the country where fuel is scarce and dear. In some places, the drawer or box is let into the hearth, and the grating over it is formed of brass wire, which gives a remarkably clean and warm appearance to the hearth, as no ashes can lie on the wires, which, from the reflection of the fire over them, present a glowing hue to the eye. Where provision has not been made for this recess in the hearth, the same effect may be produced by a box over it, the outer rim of which should form the fender, which will look better, and be more effective, than the ash-pan, fig. 540, which only receives the ashes that fall directly under the grate; leaving those which fall from the front bars to be swept up. By having the whole of the hearth within the fender formed of one shallow box, of which the fender is the outer rim; by having this box covered with brass-wire grating, and the front bars sloping inwards, no ashes could ever be

seen. In kitchens on the ground floor, it is a common practice, in many places, to leave an ash-pit under the kitchen range, three or four feet deep, covered with a wrought-iron grating, into which the ashes fall, and are only taken out when it is full, generally when the chimneys are swept. This practice is highly commendable, as saving the labour of daily carrying out and sifting the ashes, and bringing back the cinders.

602. *The rounding of the chimney breast, and the contraction of the throat of the flue,* whatever may be the kind of grate adopted, are points which contribute materially to the free draught of every chimney. The chimney breast requires to be rounded, in order to direct the current of cool air drawn from that of the room gradually upwards, so that it may mix in by degrees with the current of hot air ascending from the fuel chamber, instead of striking against it at right angles, which it must necessarily do when the chimney breast is not rounded. The object of contracting the throat of the chimney is to diminish the quantity of heat drawn from the room, by the current of air which is continually passing up the chimney; but the same contraction, it is justly observed by Mr. Tredgold, often augments the draught to such a degree, as greatly to increase the consumption of fuel. The grand point to be attained is, such a draught as will do nothing more than carry off the smoke, and keep the fire clear; because then there is the greatest radiation from the fire and fireplace, with the least waste of hot air from the room. The rounding of the chimney breast may either be effected by having a stone lintel or a cast-iron one. In countries where stone is so abundant that lintels of that material are thrown across the openings of the fireplaces, the under side may be rounded off as at *a*, in fig. 541, and the throat of the flue gradually contracted (as shown in the section from *c* to *d*, p. 113.), till, at the height of two or three feet from the chimney breast, the superficial area, in ordinary cases, is not more than 90 or 100 square inches; this being found by experience to be a suitably sized flue for an ordinary coal fire. When this contraction has been neglected in building the chimney, or done improperly; or when it is found necessary to contract the throat still farther, to create a draught; this may be done, in stone countries, by the piece of flag-stone, *b*, set on the surface, *c*, which may be moved backward or forward to adjust the draughts to the degree required. When fires are no longer wanted, this stone may be brought forward so as to lean against the breast of the chimney, as at *d*, to close up the flue; or thrown back, as at *e*, when the chimney is to be swept. That this may be done with ease, and without dirtying the hands, the stone may be removed by inserting the points of the tongs in two holes cut in its face for that purpose. In countries where brick is the principal building material, the chimney breast, as we have seen, § 79, is built on an iron bar: this bar is generally flat, and about three inches broad; consequently its inner edge presents a sharp angle, instead of the rounded surface represented in fig. 541: to remedy this, a bar has been invented by Mr. Chadley, fig. 542, the cross section of which, taken at the centre of the opening, is shown at *f*; and another cross section, taken nearer the end, is shown at *g*. This is obviously an excellent bar, and its cost, for an opening three feet wide, is not more than the usual expense of a common wrought-iron bar, suitable for the same opening.

The contrivance for contracting or closing the throats of chimneys, in brick-built buildings, is either by a plate of cast iron, formed with a base so as to stand like the stone,

*b*, in fig. 541; or by what is called a register plate, fig. 543. In the latter case the plate is furnished with a turn latch, which may be worked by the tongs, so as to regulate the distance between its upper edge and the breast of the flue. It may

be taken out to admit of sweeping the chimney; or the flue may be completely closed by it. "When the chimney top is properly contracted," Mr. Tredgold observes, "a register at the throat is not wanted, and it is always desirable to do with as little machinery about a fire as possible." He says that he makes the contraction at the top in order to reduce the opposition which the wind, and even the resistance of the air, make to the ascending smoke; also to prevent the chimney from being cooled by double currents of air (which is often the case in wide chimneys), and to diminish the loss of heat which would be required to sustain a current of smoke in a large flue. If the contraction were made only at the throat, the force of ascent would be diminished at the first effort; it would be like contracting the aperture of a pipe which supplies a jet; besides, if a larger opening were left at the top than what is absolutely necessary, the rain, cold air, &c., would descend, and interrupt the smoke. The degree of contraction at the throat of the flue Mr. Tredgold makes the same as that at the top of the chimney. He avoids all abrupt changes in either the form or direction of the flues; he prefers the circular form for them; and in 1816 proposed, in the *New Monthly Magazine*, to build them of earthen pipes.

603. *The American Stove* is adapted for a cottage in a country where wood is the fuel, where it is abundant, and where no great nicety of construction has yet entered into cottage dwellings; but it can never be recommended as so economical in the first cost, or so neat and cleanly in use, as a fireplace with the back and sides of non-conducting earthy material. It is formed entirely of cast iron, and has a large projecting cast-iron hearth, with a rim to it, serving as a fender; it has also sides serving as jambs, and a hood or shelf of cast iron. The fuel is burned on three or four iron bars, resting on dog-irons.

604. *Many other Stoves suitable for Cottages* might be described and figured; but we have deemed it more likely to be useful, to confine ourselves to two or three which we are perfectly certain are excellent, and which are fit for first-rate houses no less than for cottages. The fire-brick stove, fig. 533, is to be found in the libraries and business rooms of some of the largest mansions in London; for example, in Portland Place and St. James's Square.

605. *The Consumption of the Smoke in open Fireplaces* has long been a desideratum; and though it never can be accomplished effectually, it may in a great degree, by the use of a stove invented by Cutler, in which, instead of throwing coals on the top of the fire, in the usual way, they are supplied from beneath, by hoisting up a grated box, into which as many coals are put in the morning as it is supposed will be burned during the day. The invention is rather too complicated for common cottages; but, if a little trouble were not objected to, at least the grosser portion might be consumed by the following arrangement:—Supposing the bottom grate of the fuel chamber, as in fig. 533, to be within six inches of the hearth, all that is necessary is to char the coal by keeping it a day directly under the grate (with a good fire burning above), before it is used. The space below might be divided vertically into two chambers, and each sunk so deep into the hearth as to contain as many coals as would be used in a day. The bottoms of these chambers should have an ash-box fitted into them, into which the ashes and dross would fall when the coals were being lifted with a shovel to be put on the fire. Every morning one chamber would be found empty, or nearly so; and the ash-grate, being taken out, and its contents thrown in the dusthole, might be replaced, and the chamber again filled with coals. The coals might also be charred by having the jambs hollow, and the hobs to lift up; or by leaving a hollow in the back directly behind the fuel chamber, with a cast-iron door: but though these two modes would be much more cleanly than the other, they would not, like it, have the advantage of burning whatever was evaporated from the coals. It would be impossible for a quantity of raw coal to remain a whole day directly under a good fire, without being in a great measure deprived of the watery particles and grosser carbonaceous matters which are the principal ingredients in smoke; and equally impossible for this vapour to escape without passing through the ignited mass of fuel over it. We do not present this as either a perfect or an elegant mode of burning smoke in open fireplaces, but as one which may be universally adopted; and which, whether it succeeds in effectually consuming the smoke or not, is sure to do good, since the drier and hotter fuel is, before it is put on the fire, the better it will burn.

606. *Designs for more elegant Grates and Stoves* will be found among our fixtures for ornamental cottages and villas; and we shall treat more at length on the principles of warming and ventilating, in the Third Part of this work.

607. *Sinks*, or fixed shallow troughs, are usually placed in back-kitchens, sculleries, and wash-houses, for setting dishes and other articles upon which are to be washed; and for receiving and conveying away dirty water. They are generally formed of stone, fig. 544, but are sometimes also made of cast iron; and Mr. Mallet of Dublin, who

has made a great number, has sent us several Designs, of which fig. 545 is a corner sink, suitable for cottages. Sinks are also frequently made of wood, lined with lead or zinc. A sink, of whatever materials it may be constructed, should always either be raised on masonry, or placed on an iron or wooden stand, so as to have the upper edge about two feet and a half from the ground; and it should be fixed near a window, on account of the light. Where practicable, there should be a cock with a supply of water immediately over it; and, at all events, there should be a waste-pipe from it, leading to a drain, the orifice being protected by a bell stink-trap, as already described, § 237.

608. *Fixed Wash-hand Basins, Washing-Troughs, and Slabs* are little required in plain cottages; we shall therefore defer what we have to say of them, till we come to treat of fixtures for villas. Fig. 545, given as a corner sink, would make a very good fixed wash-hand basin.

609. *A Towel Roller* ought to be placed on the back of the kitchen-door of every cottage; or, if not on the back of the door, it should be near the sink or fixed wash-hand basin. It is formed of deal, or any common wood, fig. 546, to a scale of one inch

to a foot, and consists of a roller with a gudgeon, or small pin, at each end, which pins work in sockets cut out of brackets fixed to a door, or to any other perpendicular surface. One of these brackets, *a*, has its socket cut through, to admit of taking out and putting in the roller, when the towel requires to be changed; the other, *b*, has merely a circular hole cut into one side.

610. *A Rail for Towels*, fig. 547, to a scale of an inch to a foot, is a fixture suitable for

either bed-rooms or kitchens: it requires no description beyond the inspection of the figure; and may be nailed to a wall, to a door, or to the side of a wardrobe or chest of drawers. This rail should be made of strong wood, and painted of the same colour as

the walls or door of the room, or the wardrobe against which it is fixed. The use of the paint is not only to harmonise it with the rest of the apartment, but to preserve the wood from being first discoloured, and afterwards rotted, by the wet and damp of the towel. If it should be fixed against a papered wall, and near a wash-hand stand, a row of wooden pins or buttons, *e*, may be placed in the under side of the rail, on which may be hung a curtain of brown holland linen, or of any other material, to prevent the wall from being splashed.

611. *Hat and Cloak Pins* are sometimes formed of wood, turned or plain, and let into a rail of the same material; this rail being fixed to the wall, in the entrance lobby or passage, or sometimes in cottage bed-rooms. The more common pins for this purpose are made of cast iron; and figs. 548 and 549 show two of the most useful shapes: the latter answers two purposes, as a cloak may be hung on *d*, and a hat on *e*.

612. *An Iron Hand-mill*, for grinding coffee, rice, barley, and groats, and another smaller one for pepper, &c., are most valuable articles in the better description of cottages; because the cottager may not only roast and grind his own coffee, or any of the substitutes

for it, but he may, at pleasure, form rice flour from whole rice, for puddings, &c., for invalids or children; barley flour from pearl barley, for fever drink; or oatmeal from groats, for porridge or gruel. These mills are always easies to work, and most effective, when fixed; and for this purpose, if there be no stile of a door or quarter of a partition sufficiently strong, they must be bolted to the wall, unless provision was made in building it, by inserting a piece of strong timber, or a stone to which the mill could be cramped with lead.

613. *Fixed Ironing-Boards and Flaps* are useful both in kitchens and, on a smaller scale, in lobbies and passages, and even sometimes as brackets in sitting-rooms. Fig.

550

550 is an ironing-board, or flap table, which, in a cottage, may serve for various useful purposes, and, where the living rooms are small, will be found a most valuable substitute

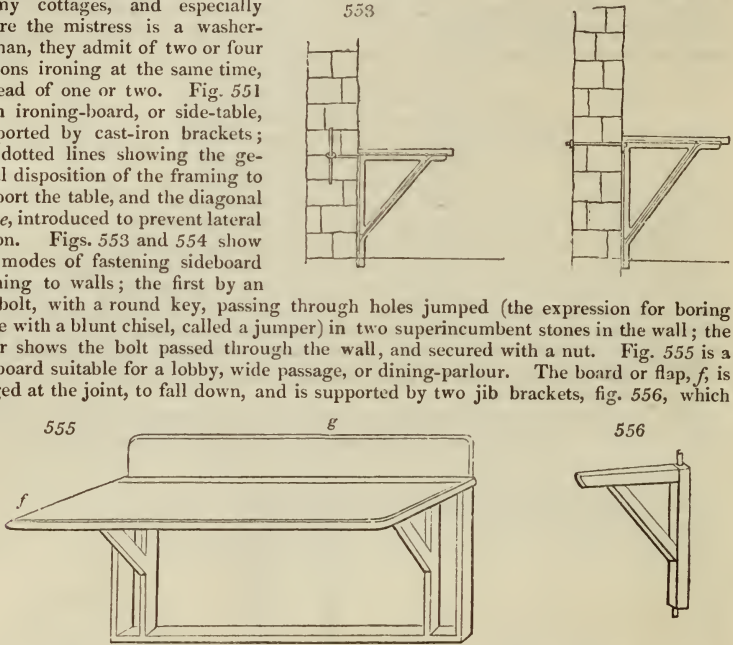

551

552

for a portable table. The piece of board, *a*, is made fast to the wall, either by holdfasts, or by being nailed or screwed to wooden bricks. The flap, *b d*, is hinged to it, and, when raised up, is supported in its place by the hinged folding legs, of which *c c*, fig. 550, is a plan, and *d* an elevation. Fig. 552 is an insulated fixed table, or ironing-board, supported by cast-iron framing, which is fixed by screw nails to the floor, and also to the under side of the top. Mr. Mallet, junior, of Dublin, who has sent us this Design, observes that all manner of kitchen tables may be supported in this manner, most securely and firmly, and at very little expense. Fixed insulated tables occupy more room than wall flaps; but in roomy cottages, and especially where the mistress is a washer-woman, they admit of two or four persons ironing at the same time, instead of one or two. Fig. 551 is an ironing-board, or side-table, supported by cast-iron brackets; the dotted lines showing the general disposition of the framing to support the table, and the diagonal rib, *e*, introduced to prevent lateral action. Figs. 553 and 554 show two modes of fastening sideboard framing to walls; the first by an

eye-bolt, with a round key, passing through holes jumped (the expression for boring stone with a blunt chisel, called a jumper) in two superincumbent stones in the wall; the latter shows the bolt passed through the wall, and secured with a nut. Fig. 555 is a sideboard suitable for a lobby, wide passage, or dining-parlour. The board or flap, *f*, is hinged at the joint, to fall down, and is supported by two jib brackets, fig. 556, which

shut into the frame when the flap is let down, and are concealed by it. There is a slip of board, *g*, above the flap, to keep things from rubbing against the wall. In the construction, the brackets are fixed to the frame, by having round pins worked in both ends of their upright piece, which turn in corresponding holes of the top and bottom rails of the frame.

614. *Dressers* are fixtures essential to every kitchen, but more especially to that of the cottager, to whom they serve both as dressers and sideboards. They are generally made of deal by joiners, and seldom painted, it being the pride of good housewives, in most parts of England, to keep the boards of which they are composed as white as snow, by frequently scouring them with fine white sand. The dishes, plates, &c., which they contain are also kept perfectly clean and free from dust, by being wiped every day, whether used or not. In old farm-houses, the dressers are generally of oak rubbed bright, and the shelves are filled with rows of pewter plates, &c., polished by frequent cleaning, till they shine like silver. The dresser may be called the cottager's sideboard, and in the dining-rooms of the first nobleman's houses in Britain, the splendid mahogany sideboards, set out with gold and silver plate, differ only in the costliness of the materials employed from the cottage dresser: nor do the essentials of human food differ more in the palace and in the cottage than the furniture; for, in Britain and America at least, good meat, good bread, and good potatoes are the main dishes on all tables, and may be obtained by the workman who has good wages and full employment, as well as by the wealthy merchant or hereditary aristocrat. When there is a pot-board affixed to the dresser, it is usually painted black or chocolate colour; and when the shelves and fronts are painted, it is generally white, or, what is in better taste, the same colour as the walls or doors of the apartment. Gothic dressers would be more appropriate if made of oak, or painted to resemble that wood. The price of a deal dresser, in London, is from £2 to £5.

559

560

561

562

563

564

565

566

615. *Dressers in the Grecian Style.* Fig. 557, on a scale of three eighths of an inch to a foot, represents a dresser in a plain Grecian style, the characteristic features being the square columns which support the drawers, and the board or table which covers them: under the drawers is seen the potboard, or place for setting pots, saucepans, &c., when not in use. There are three shelves, and two large drawers. Rails are fixed a few inches under each shelf, on which to rest the edges of the plates and dishes, in order that they may lean forward, so as to protect their faces from the dust, which, when they are in this position, can only fall on their backs. There are hooks fixed in the edges of the shelves, on which jugs and any small articles having handles may be hung. Fig. 558 is

a cross section of this Design, on a somewhat larger scale, on which are shown the ends of the shelves, *e*; of the plate rails, *f*; of the hooks, *g*; and of the potboard, *h*. Fig. 559, p. 295, is another dresser in the Grecian style, but differing from the other, in having beads fixed along the upper surface of the shelves, near the edge, to support the plates and dishes in a reclining position against the back. In this position they are liable to receive the dust on the face; but it is nevertheless preferred by some housewives, as showing better whether or not the plates are clean. Instead of an open potboard, there are two side-closets, and, in the middle, shelves. There are three drawers above: the centre one for tablecloths, towels, &c.; and the two side ones, one for knives, forks, and spoons, and the other for dusters, brushes, &c. In one of the cupboards below may be kept what wines or spirits are in daily use, glasses, &c.; and, in the other, bread, biscuits, groceries, or any other articles of food. The tea-tray and teacups may be put on the upper middle shelf, and the smaller saucepans, &c., on the bottom one. Fig. 560 is an end view of this dresser, on a somewhat larger scale, in which the ends of the beads, *i*, the hooks, *k*, and supporting brackets, *l*, are more distinctly delineated. The top of this dresser, being somewhat heavy, should be fixed to the wall by two holdfasts driven in above so as to be concealed by the cornice, or by screw nails to wooden bricks. Fig. 561, also to a scale of three eighths of an inch to a foot, is a very convenient dresser, used in the better description of cottage dwellings in Cambridgeshire. The middle drawer, which is shown drawn out, has a lift-out box or tray, which is divided in the centre for the knives and forks, and spoons, in daily use; and underneath, in the bottom of the drawer, is a space in which are kept those not generally in use. There are two other drawers, one on each side, for clean tablecloths and towels, and for dusters, &c. The cupboard in front is made, in order to look uniform, with three panels like doors, but the centre one is fixed, and behind it, in the middle, is a division forming the whole into only two cupboards, in one of which may be kept glasses, teacups, &c.; and in the other, the liquors, fruits, sweetmeats, &c., in daily use. Fig. 562 shows a section of this

dresser, in which is seen the middle drawer, *m*, with its lift-out tray, *n*, and the space below, for knives and forks not in use, *o*. This dresser being intended to have the plates leaning forward, as in fig. 557, sections of the plate rail for that purpose are seen at *p*.

616. *Dressers in the Gothic Style.* Fig. 563, p. 296, to a scale of three eighths of an inch to a foot, is considered in the Gothic style, from the character of its mouldings at *g g*, and of the upper part of its supporting columns, *r r*. It has an open potboard and two large drawers over it. The plates, &c., are intended to lean forward, as shown in this figure, and also in the section, fig. 564. Fig. 565 is a dresser more decidedly in the Gothic style, as is obvious from its openings with pointed-arched tops in the ends which support the shelves, and from its pointed-topped panels in the two cupboard doors. There are three shallow drawers under the board or table, two shelves in the middle, and a lock-up cupboard on each side. The plates are intended to lean back, as shown in the section, fig. 566.

617. *Fixed Corner Cupboards.* Where the dresser is without cupboards, as in figs. 557 and 563, a corner cupboard becomes requisite for cups and saucers, glasses, the tea-caddy, liquors in daily use, &c.; and these cupboards are cheapest when put up as fixtures; because the shelves, instead of being fitted into wooden sides or linings, are then let into the plaster, or fixed on slips nailed to the wall. In small rooms these cupboards are very convenient, as they occupy very little space, and, for a moderate sum, supply a handsome article of furniture.

618. *Fixed Corner Cupboards in the Grecian Style.* Fig. 567, p. 299, to a scale of three eighths of an inch to a foot, is the external view of a corner cupboard in a plain Grecian style. The side styles are finished with pilasters, and there is a handsome cornice at top. There are an upper cupboard with two glazed sashes, and a lower one with two paneled doors. Fig. 568 represents another cupboard, in the Grecian style, with the doors open to show the interior, and standing on turned legs, to give it the character of a portable piece of furniture. The shelves, which are supposed to be of deal, are let into the plaster; and the whole, outside and inside, including the plaster between the shelves, is painted of a wainscot colour. Fig. 569 is a Grecian corner cupboard in a more elevated style of design; the panels below and the round heads of the sashes give it an elegant and rather uncommon air.

619. *Fixed Corner Cupboards in the Gothic Style.* Fig. 570 is an open corner cupboard without doors. The shelves are nailed to slips of wood; and these, with the wall between them, should be painted of the same colour as the side styles or pilasters, and the whole will look well, if grained to imitate wainscot. Fig. 571, p. 300, shows a plain Design, with glazed doors above, and paneled doors below. Fig. 572 is a Design somewhat more elaborate; the pilasters having sunk panels; and the sash-heads and cornice having more work in them. The expense of fixed corner cupboards of the kind here shown, with glazed doors above and paneled doors below, varies from £2 to £5. The cost will be considerably diminished by having the upper doors in single wooden panels, instead of being glazed.

#### SECT. IV. *Designs and Directions for Cottage Furniture and Furnishing.*

620. *The Furniture and Furnishing of Cottages* have been hitherto neglected in every country where the comfort of the cottager has depended on those above him, and this never can be fully remedied till the inmate of the cottage is sufficiently enlightened to be able to take care of himself. We have shown, in our Chapter on Model Cottages, p. 8, that all that is essential, in point of the general arrangement of a house, may be obtained in a cottage with mud walls, as well as in a palace built of marble; and we intend now to point out in what manner all that is comfortable, convenient, agreeable, and much of even what is elegant, in modern furniture and furnishing, may be formed of the indigenous woods and other common articles of every country, as well as of the most beautiful exotic timbers, and other costly materials obtained from abroad. If it should be asked, whether we expect that such Designs as those which follow can be executed or procured by the cottagers of this country, we answer that we trust they soon will be; and we believe that the first step towards this desirable end is, to teach them what to wish for. As the spread of knowledge becomes general, it will be accompanied by the spread of taste; and correct habits of thinking will go hand in hand with comfortable dwellings, and convenient, neat, and elegant forms of furniture. An approximation to equalisation in knowledge will lead to an approximation in every thing else; for knowledge is power, and the first use which every man makes of it is, to endeavour to better his own condition. Our grand object, therefore, in this as in every other department of our work, is, to cooperate with the causes at present in operation for bettering the condition, and elevating the character, of the great mass of society in all countries. Though most of the Designs submitted are of a superior description to what are common in cottages, they are not on that account more expensive than various cumbrous articles of furniture now possessed or desired by

567

568

569

570

571

573

574

572

575

every cottager in tolerable circumstances. The difference will be found to consist chiefly in the kind of labour employed in making them, and in the style of design which they exhibit. To speak in familiar language, we have given more work for the joiner than for the carpenter; and our Designs pretend to nothing more than what could be invented by any joiner who could read and draw, and derive ideas from books. Mr. Dalziel, under whose direction most of them have been prepared, has shown superior taste in preserving the character of simplicity, and preferring what was really good in itself to what had only novel or showy appearance to recommend it. For the Designs for iron furniture we are chiefly indebted to Mr. Mallet, jun., of Dublin; but partly to Messrs. Cottam and Hallen, and Mr. Eckstein, of London. We shall present the following Designs in the order of sideboards, dumb waiters, bookcases, book-shelves, wardrobes, chests of drawers, tables, chairs, stools, benches, sofas, beds, cribs, window-curtains, inside blinds, looking-glasses, fenders, carpets, oilcloths, matting, umbrella stands and hat and cloak holders, mats, scrapers, clocks and musical instruments, pictures, sculptures, and other ornamental furnishing: the various utensils employed in cookery, brewing, baking, washing, the dairy, &c., or for the table and bed-rooms, including earthenware, China and glass of every description, with linen, the minor articles of ironmongery, cutlery, &c., do not come within our plan, because they cannot be considered as architectural in their Design.

621. *Sideboards for a cottage parlour* generally include cupboards, unless there should be a corner cupboard in the room, either as a fixture, or as a movable piece of furniture. Fig. 573, p. 300, shows a small cupboard side-board for a neatly furnished cottage parlour, in which there is not much room. In point of style it may be considered Grecian; because the panels do not indicate any thing of pointed architecture at their angles, and because the mouldings under the top belong to the former style. Fig. 574 is a Design in the Gothic style; and fig. 575 shows the interior of the Design. A partition is fixed in the centre, which divides the cupboard into two parts. One side has a drawer at the top, which drawer is partitioned, and lined with baize, for holding plate. There are four tray shelves below, which draw out, the space between them being of sufficient height to hold wine glasses, tumblers, &c. In the other side is one fixed shelf, leaving height enough for bottles and decanters both above and below. The lower part may be lined with lead, to keep wine and liquors cool; or it may contain earthenware wine coolers for that purpose, the bottom being lined with lead, and having a ledge in front about an inch high, to retain any water that may exude from the coolers. The top of this sideboard lifts up, and leaves a well for holding tablecloths, napkins, doyleys, tablemats, &c. This article may be made in deal and painted; or of any native broad-leaved wood, as oak, elm, walnut, &c., or of mahogany. Made of the last material, in London, the price would be from £7 to £12, according to the style of finishing.

622. *Corner Cupboards* are best put up as fixtures (see § 617), and Designs for them may be made after the style already given, figs. 562 to 574; all the difference in con-

struction between a movable and a fixed corner cupboard, being, that the former have linings or sides of boards, to which the shelves and side styles are fixed. In some old

cottages and farm-houses there is a sort of pyramidal corner cupboard, fig. 575 *a*, to a scale of half an inch to a foot, sometimes in use for holding glasses, the punch bowl, &c. ; and another sort of corner cupboard, fig. 575 *b*, to the same scale as the preceding Design, has this advantage, that, when not in use, its two open sides may be turned against the two walls of the room, and, its two close sides only being seen, it may pass with a stranger as a book or music stand, for which, indeed, a similar design is frequently used. There is a drawer below, for holding plate, and on the top may stand the tea-urn; or, in the event of its being used as a music-stand or book-stand, the drawer may contain manuscripts, and the top a globe or bust. This piece of furniture should stand on castors.

623. *Dumb Waiters*, or portable sideboards, are useful in small families, with few or no servants or children. The most common form is that of a candelabrum, with tiers of circular shelves fixed to an upright axis, the shelves diminishing from the bottom upwards, and the whole on castors. The two figures last described will also make very good dumb waiters.

624. *Bookcases and Escrutoires, Secretaries, or Bureaus*, are extremely useful for holding books, keeping papers, or writing on; and, therefore, no cottage parlour ought to be without one. Figs. 576 and 577 are bureaus in the Grecian style; the middle part of fig. 576 draws out, and the front lets down and forms a writing-desk. The lower part, enclosed by doors, may be either fitted up with shelves or drawers; the upper part is for books. Fig. 577 has a falling board or flap, which, when let down, as shown in fig. 578, forms a writing-desk. Figs. 578 and 579 are bureau bookcases in the Gothic style. In the first of these figures, the writing-table is formed by pulling out a drawer, and letting down its front, as in fig. 578; in the second (fig. 579), the sloping flap falls down, and rests on two sliding pieces, *a*, technically called lopers. This last description of secretaries is often made without the addition of the bookcase over it; and, instead of paneled doors, it is more common to have drawers exposed to view. The knobs to the drawer desks, figs. 576 and 578, are supposed to be made of wood, mahogany, ebony, or laburnum, as being more in harmony with the articles, and as less liable to tarnish than brass, the usual material of which similar handles are formed. The astragal moulding which covers the joint formed by the two doors of each Design is also commonly formed of brass; but wood, generally of the same sort as the rest of the fabric, is now substituted by the best manufacturers. Even the linings to keyholes, fig. 580, and the shields or escutcheons of locks, are now made of ebony, or some other hard wood, in all the better articles of cabinet furniture. Fig. 581 shows a section of the door style and astragal of the Grecian Designs; in which *b* is the astragal, and *c* the door style. Fig. 582 is a similar section, showing the Gothic astragal and door style. It will be observed that the astragal is not worked on the door style, but on a distinct piece of wood, *d*; which is afterwards glued, and rabbeted on to the edge of the side style. The situation in a room for pieces of furniture combining bookcases and secretaries should never be on the side opposite to the window; for nothing can be more awkward than the idea of a person sitting down to write with his back to the light, or, should the room be small, to an open fireplace. Recesses in those sides of a room, which form right angles with the window sides afford the most desirable positions; and, of these, the preference is always to be given to the side containing the fireplace. In rooms

583

625. *Book-shelves* will shortly become as necessary as chairs or tables, for the cottage of even the humblest labourer. We shall give two Designs, figs. 583 and 584; the first may be considered as suitable for a Gothic cottage, and the other for a plain one. Either of these Designs may be fixed against a wall, with the lower shelves about six inches higher than what is called chair-back height from the floor. Or they may be set on a chest of drawers, or secretary, provided these are in suitable styles of Designs. The balusters which support the shelves, in fig. 584, are called

by cabinet-makers shaped columns; and they may either be made plain; fluted or reeded, as at *g*; or with carved foliage, as at *h*, in the same figure.

626. *Wardrobes* are as essential in a bed-room, as a dresser is in a cottager's kitchen, or a cupboard, or sideboard of some sort, in his parlour. Figs. 585 and 586, p. 304, on a scale of three eighths of an inch to a foot, exhibit a Design for a wardrobe in the Grecian

576

578

580

577

581

582

579

585

586

587

591

588

589

590

style. Fig. 586 is a view of fig. 585 with the doors removed, showing four inside sliding tray shelves, with a deep drawer underneath for bonnets, &c. In this drawer are commonly fixed bonnet-holders, fig. 587, and against its sides cap pins, fig. 588. Fig. 589 is a Design for a wardrobe in the Gothic style, and also differently arranged in the interior. Fig. 590 shows a view of it with the doors removed. There is an upright division in the centre, with four fixed shelves on one side, and on the other an open space, with cloak pins fixed round it for hanging gowns, coats, caps, &c., upon. It is to be remarked, that the row of pegs is continued round the inside of the door. In the bottom of this division may be a fixed or portable bonnet-holder, such as fig. 587. These wardrobes may be made of deal, and painted wainscot colour, or of any other suitable to the other furniture of the room. The price in London is from £3 to £5 each.

627. *Chests of Drawers* are the common substitute for wardrobes, but they are very far inferior to them for keeping clothes, and create a great deal of useless labour in pulling out and pushing in drawers, and perhaps in locking and unlocking them; whereas one lock secures the whole of the wardrobe; and, by the opening of one door, the whole of the contents are exposed to view, and the article wanted can be had with the least possible trouble. For those who prefer the old mode, we have given the Design 591, to a scale of half an inch to a foot, which represents a chest of drawers in the Gothic style. It may be constructed of common deal, painted wainscot colour, with real oak knobs. The cost in London is from £3 to £4. A common chest of drawers may be made more

useful in a small room, by having a slider to pull out in front, from under the top above the first drawer, as in fig. 592, *a*; the two bottom drawers may, if required, be made into one deep drawer, to hold bonnets, &c., like the drawer in the wardrobe, fig. 586, p. 304. Knobs of the same wood as the furniture, fig. 592, *b*, are now generally substituted, as in most other pieces of furniture, for brass. They harmonise better, and

do not tarnish; besides, the fashion is, at present, comparatively new in London, and this confers on them a certain degree of factitious elegance, viz, that of novelty and fashion.

628. *Tables* are of numerous kinds and various forms. We shall take them in the order of kitchen tables, parlour tables, and bed-room tables.

629. *Kitchen Tables* ought to be strong, on account of their continual use; and, if possible, they should be contrived to fold up, or otherwise go into little space, when not in immediate use, in order to afford more room for carrying on the business of the kitchen. One of the most economical of kitchen tables is that formed by the kneading-trough, represented by fig. 593, to a scale of half an inch to a foot, of which *a* is an end view. Such tables are a good deal in use in the cottages and small farm-houses in many parts of England. The cover, which, when on the trough, serves as a table or ironing-board, either lifts off, or, being hinged, is placed so as when opened it may lean against a wall, when the trough is wanted to be used. Frequently a division is made in the centre of the trough, so that the dry flour can be kept in one compartment, and the dough made in the other. Sometimes there are three compartments, in order to keep separate two different kinds of flour or meal. The board forming the cover ought to be an inch and a half thick, and always in one piece, in order that neither dirt nor dust may drop through

593

the joints. There ought to be four fillets, *bb*, nailed along the under side of each edge of the cover, so as to keep it exactly in its place when on. Deal, beech, sycamore, and ash are good woods for the trough and cover of this table, because they are light in colour, and have a clean appearance. No part of them should be painted, because both the trough and cover, when used for making bread, will require frequent scouring to keep them clean; and, if the board should be used for an ironing-board, the heat of the irons would blister the paint, and make it stick to the cloth or blanket used to cover it. Fig. 594, p. 313, to a scale of half an inch to a foot, is a kitchen table on four fixed legs, which, by means of two portable legs in addition, can be extended at each end, so as to make a table of double its original length. Thus, suppose the table, fig. 594, when folded up, to be three feet long, and two feet six inches wide, it may, in two minutes, by screwing in the two portable legs, be made six feet long; and, instead of being only large enough for two persons, it may dine several, or be used as an ironing-board, which, in narrow rooms, must obviously be a great convenience. There is a drawer under the centre of this table, in which the portable legs may be kept; or they may be set elsewhere, and the drawer used for other purposes. This Design might be varied by having lopers to support the end leaves, instead of portable legs; or the leaves might hang down, like those of a common dining-table, and be supported by draw-out feet. In the construction, care must be taken to have the wood of the hinged leaves very dry and well-seasoned, otherwise they will warp; and the ends of these leaves should be clamped at each end, by a piece of wood the reverse way to the grain of the leaf or flap. The term clamping is applied by cabinet-makers, when a piece of wood is grooved, and another tongued into it, as in fig. 595. This table will cost in London from £3 to £4. Fig. 596, to a scale of half an inch to a foot is a fold-up kitchen table, chiefly valuable because it will take up little room when not in use, as in fig. 597.

595

596

597

The top consists of two leaves hinged together at the ends; and, when the table is opened, it is prevented from falling down in the middle by the wooden button, *c*, being locked into the notched piece, *d*, figs. 598 and 599. The former figure represents the under side of the table. The tops and feet of the standards, *e e*, and the rails, *f f*, must be beveled, to admit of their free action. The legs may be fastened together, when shut, by a hook and eye at each end, as shown at *g*, otherwise it would be apt to warp. This table will be found very convenient for carrying out to a cottage lawn or arbour, or for using under a veranda. Where, however, the veranda is narrow,

the preceding Design, forming a long narrow table, will, perhaps, be found more commodious. Fig. 601 shows a table with a semicircular top, double-hinged at the ends, and supported by three legs and a triangular frame, as shown in fig. 600. The two

legs, *h h*, fold out, to support one half of the top, when it is opened and turned over on them. As this table, when shut up, will stand against a wall, it will take up but little room, and is, therefore, very suitable to a cottage kitchen. A common kitchen dining-table, square, round, or oval, with a fixed centre, and two hinged folding-down leaves, supported, when up, by hinged folding feet, is so familiar a form, that we have not thought it necessary to give a Design for it. Its construction will be easily understood from that of the fixed flap table with folding legs, § 613, fig. 550.

630. *Parlour Tables.* Where the parlour is square, a round table will be found the handsomest and most appropriate. Fig. 602, designed by Mr. Mallet, shows a round table with a wooden top, supported on a cast-iron pillar, with iron castors. Each of these castors consists of a ball one inch in diameter, having free motion in every direction within a wrought-iron cup, which is pressed into its form in a fly press, from a piece of flat iron; and, the ball being put into it, it is then closed sufficiently at the mouth, to prevent the ball from falling out. The construction of this kind of castor (which Mr. Mallet informs us he invented some time ago, and which has been since used extensively) will be better understood by fig. 603, in which *a* is the ball of a single castor; *b b* are the sides of the wrought-iron cup; and *c* is the leg of the table, bed, sofa, or other piece of furniture, to which the

603

cup is riveted: *d* shows the plan of three castors, such as are used for the table, fig. 602; and *e* is a view of these castors appended to the round foot of any piece of furniture, the junction being concealed by the moulding *f*. Mr. Mallet states that three castors placed in this manner form an exceedingly firm and effective locomotive support for any heavy article of furniture. The pillar of this table is cast hollow and thin, so as to come far cheaper than the same Design could be made in the

604

commonest description of wood. Fig. 604, to a scale of half an inch to a foot, is a table on four legs, and which, when covered with green baize, is commonly called a

605

card table. The top is made double, and hinged at the back, so as to fold over, and there is a drawer in the frame. The two legs *g g* are fixed, but the other two, *h h*, are hinged, and fold out to support the folding flap. The joints, which are made in the rails of the folding legs, are of wood, as shown at *i* and *k*; and, being put together, a piece of strong iron wire is driven down the centre of the rounded ends, and forms the axis on which they turn. This joint is technically called a knuckle joint; and rails of tables hinged in this manner are called fly rails. Fig. 605 is a table, which, when folded up like fig. 604, has exactly the same appearance. The top is double, like the top of a card table, and turns round on a pivot *l*, having a fixed well, *n*, to answer the purpose of a drawer; when the flap is opened it makes a square table with rounded corners like the other. There is a rail, *m*, fixed to the upper side of the frame, to receive the pivot on which the top of the table works, as shown in the cross section, *n*, and longitudinal section, *o*. Fig. 606, to a scale of half an inch to a foot, is a table on four legs, with two drawers in

606

the frame. The end flaps, *p p*, are made to put on or to take off as required, by means of what are called strap-hinges, which are fastened to the flaps. These hinges are shown in fig. 606, in which *q* is the part screwed to the under side of the flap; and *r* the strap or part which is inserted under the top of the table, into an iron plate, *s*, screwed to the under side of the top, as shown at *t*. The hinge of the strap is of the knuckle-joint kind, as exhibited at *u*. After the flap is put in, it is supported by small fly-brackets, fig. 606, *v v*. This is certainly a very convenient table, and very simple in its construction: it might be made still more economically, by substituting fixed bracket-shaped iron straps to the flaps, in lieu of the strap hinges; which would render both the latter and the brackets, *v*, unnecessary. The only inconvenience of this plan would be, that the flaps, when not in use, would require to be taken out and put aside. Fig. 607, p. 313, is a table on four turned legs with castors, and with the ends of the frame made to draw out to support two flaps, which may be loose, and fastened at the joints by sockets, *w*, and pins, *x*; or the flaps may be hinged to the ends of the top, and lift up and let down, being supported, when raised, by the end frames. A shelf might be added to this table, about fifteen inches from the floor, which would be found useful for holding workboxes, books, &c. Fig. 608, p. 313, to a scale of half an inch to a foot, is a plain parlour work-table, with two drawers; and with flaps having ruled joints to fall down, and fly brackets to support them when up. Fig. 609, p. 313, to a scale of three fourths of an inch to a foot, is a work and writing table for a cottager's wife; for we trust that the time will soon come, when not only every cottager's wife will be able to write as well as read, but will have leisure to do so. This table may be made much plainer than is here shown, and consequently cheaper. For example, if the legs were not turned, and the whole were made of common deal, it would cost little more than an ordinary table with two drawers. The bag frame, which, when economy was the object, might be made of glazed coloured calico instead of silk, is made to draw out in front, and the writing-drawer over it pulls out at the end. In this drawer there is a flap to write on, hinged to a sliding piece,

which may be pushed back from the front of the drawer, so as to raise the desk upon the edge of the table to the angle required. Underneath this writing-board is a space for papers; and, to the right, another for the inkstand, pens, and wafers. The writing-board, or flap, might be made to rise with a rack and horse, (fig. 610, in which *a* is the rack, and *b* the horse); but the first plan is far simpler, and answers the same end. Indeed, even the sliding piece might be dispensed with, and the writing-flap adjusted to the proper angle by pulling out or pushing in the drawer. At the opposite end of this table a flap is shown, which may be put up or let down accordingly as it may be desired to make the table longer or shorter. This is evidently a very convenient table; because a cottager's wife may have a book to read in lying at one end, writing materials at the other, and her work in

the middle. Fig. 611 is a small tea or work table. The top is hinged on a triangular box, which may be useful to hold work in. When not in use, the top is set up on edge, and when brought down, it fastens itself by a common catch fastening. Fig. 612 is a neat work-table, which may be made by any joiner, out of the common woods of the country, at a very trifling expense, and placed on three of Mallet's iron castors, or even on turned knobs in imitation of castors; either of which, by raising it from the ground, would add much to the lightness and elegance of its appearance. Figs. 613, 614, 615 represent

a very useful article, called a camp table, from its going into little bulk, being light, and being used by officers in camps. Fig. 613 shows it opened out to its full extent; the top being hinged to the two legs, and supported by a portable leg which is fastened into it by a screw and socket, *c*, in fig. 613, and can be removed at pleasure. When not in use, this leg is fixed to one of the legs of the stand by two pieces of girth webbing, *d d* in fig. 615, which are fastened to the leg of the stand. When the stand is opened to its full extent, it stretches out, as a top, three pieces of webbing, which serve as a tray-stand; and a tray is generally made of a proper size to go along with the table. Fig. 615 shows how this camp table may be used as a common table; the hinges projecting above the rail of the stand in such a manner as to let the top turn round either way. Fig. 614 shows this table shut up; there are two turn buckles, *e*, on the legs at *f*, to keep the top fastened, and to prevent it from swinging about when the table is moved. In families, accustomed to give large dinner parties, these tables are found useful, as forming additions to the sideboard: they are also brought in requisition when parties are given in the open air, or when a meal is taken in any room deficient in tables.

614

615

631. *Bed-room Tables* are of three kinds: those for holding washing utensils; dressing-tables; and tables for sick persons. Fig. 616 is a small wash-hand stand, or table, in

617

the Gothic style, with a shelf below, and a drawer under it. The hole in the top is cut

round to receive the basin, and on the back-board is fixed a small shelf to hold a glass, trays for brushes, &c. This table may be made of oak, or of deal painted and grained in imitation of that wood. Fig. 617 is a small enclosed wash-hand stand with two cupboards; one of which will hold the ewer, and the other a night-vase. There are two hinged shelves, one on each side, supported by fly brackets, in order that they may be let down to save room, when not in use. Fig. 618 is a Design for a lady's wash-hand stand, which has been sent us by its inventress. When not in use, the basin is concealed by two box covers, which are hinged; and which open and turn over when the stand is used, affording space for soap-holders, brush-trays, &c. There is a drawer below, with partitions for keeping these and various other articles belonging to the toilette; one partition having a flat board raised two inches from the bottom of the

618

one partition having a flat board raised two inches from the bottom of the

drawer, and being pierced with holes for scent bottles, &c. Below this drawer there is a deep cupboard with double doors. This wash-hand stand, which has a neat and rather massive or architectural appearance, is said to be a great favourite with all the ladies who have seen it. Fig. 619, to a scale of half an inch to a foot, is a small dressing-table, with a drawer in front to hold combs, brushes, &c. Common dressing-tables, consisting of a top without flaps, supported by four legs, and with one or two drawers, are so simple in their construction as not to require any particular exemplification. Fig. 620,

619

620

to a scale of half an inch to a foot, is a table for invalids, commonly called a bed table; which is a very great convenience to a person bedridden. The top of this table is made to rise and fall at pleasure, by raising or lowering the upper part of the pillar, *a*, which is perforated with holes at given distances, and which works in a square groove, in the centre of the lower part. This lower part is formed of four pieces glued together, as shown in the plan, *b*, in fig. 621. It is firmly fixed in the bottom block by a mortise

621

and tenon, and at top the four pieces are confined by an iron ferule, to keep the joints from opening: the mortise at bottom sufficiently confines the lower part of the pillar. The height of the top is regulated by moving the pin at *c*; the block or foot, of which *d* represents a plan, is elongated on one side to about the same extent as the top is elongated on that side; and, when the table is in use, the block is turned under the bed, and the top over it; the latter being adjusted to the height most convenient for the patient. This table is very frequently used for reading in bed; and in that case it is generally made with a horse and rack, *e*, and a shifting ledge, *f*, to support a book, at one end. This ledge is fixed by two wire pins, fastened in its under side, which drop into two holes bored in the lower side of the flap of the table. On the edge of this ledge are affixed two book-holders, *g*, commonly made of brass, but which are much better if made of ivory, or of ebony, box, or any other hard wood. This table, in mahogany, costs in London

from £5 to £7; but, made of any common wood by a joiner in the country, it would not come to half the amount. Fig. 622 is a cheap invalid's bed table, which we had made at Bayswater some years ago, for our own use. It is simply a piece of mahogany board, about three feet long, and one foot nine inches wide, supported by a wrought-iron pillar, with a brace, *h*, and two feet, *i i*; the latter extending nearly the length of the top from the pillar, and spreading out at their extremities to about its width; thus producing in effect a table with three feet. It is placed on castors, and is light and strong. The height of the pillar must be regulated by the height of the bed. The mahogany board cost 5s., and the iron work and castors £1.

632. Seats may be arranged as stools, forms, benches, chairs, and sofas.

633. *Stools.* Common kitchen stools for children admit of little variety of design, without incurring more expense than would be justifiable by the use and place of the object. Fig. 623 shows the construction of a plain round stool, with three legs framed together at the top, and with rails about six inches from the ground; *a* shows the proportion which the triangular frame bears to the circular top. Fig. 624 is a round stool, which may be called in the Gothic style, and would be suitable in a Gothic cottage, where every thing was in character with that style. Fig. 625 is a

623

624

625

box stool; the lid slides in a groove, as shown by the section, *b*; but there is a stop, to prevent it from being taken off entirely. The box may be useful for a child to put its playthings in, and to teach it betimes those habits of order and neatness which are so highly essential to its success in life. Figs. 626, 627, and 628 are stools with cast-iron

626

627

628

legs or pillars, invented by Mr. Mallet. The tops may be of any common wood, with or without cushions, according to the use for which they may be intended. Fig. 629 is a long stool, in the Gothic style, for a child; and fig. 630, one, also for a child, suitable for a plain cottage.

634. A *Footstool*, either plain or covered with carpeting, is an article of essential utility in every cottage where there is a mother; and it also forms a seat for a child. In England, they are very

629

630

commonly formed by covering a bundle of bulrushes with rush matting, and they are then called hassocks. Fig. 631 is a design for a box footstool, which has been sent us by a lady. The top is formed of an outside frame, on which is stretched strong webbing, for the purpose of supporting the stuffing above, which is covered with carpeting of the same kind as that of the floor of the room in which it is to be used. The sides are of wood, painted of the same colour as the other furniture.

635. *Forms* may be described as long stools, for the use of several persons; and, as such, are useful in cottage kitchens, and in lobbies and passages. In the scullery they also often serve as stands for tubs, and for various

631

632

articles to be washed or cleaned, to prevent stooping more than is necessary. Two or more of them are, therefore, always requisite about a house. Figs. 632 and 633 are

633

Designs for forms in the Grecian style, the construction of which will be understood by

634

every carpenter. Figs. 634 and 635 are forms in the Gothic style, equally simple with the others. All these Designs are to a scale of half an inch to a foot.

635

636. *Benches* are broad forms with backs to them, and sometimes with arms. Fig. 636 is a kind of bench with solid back and arms, for a cottage kitchen, commonly

called a settle, and frequently to be met with in public houses. The back forms an excellent screen or protection from the current of air which is continually passing from the door to the chimney. The drawers below are deep, and will be found very useful for a variety of purposes. On the back there might be a towel roller; or, in a superior kind of cottage, the back of the settle might be ornamented with prints or maps, in the manner of a screen. Placed in the open floor, where it would seldom require to be moved, there might even be book shelves fixed to this back, and a flap might be hung to it, with a jib bracket, to serve as a reading or writing table, or for other purposes. Fig. 637 is a handsome Grecian bench with turned legs and open back, but without arms at the ends, or drawers under the seat. Fig. 638 is a Gothic bench also without arms or drawers, but with a paneled back and square legs. Fig. 639 is a Design for a handsomer Gothic bench

636

637

the back of which may either be paneled or open, according to the position, in the kitchen, where it is intended to stand. It has arms and two drawers, and has below the latter a broad shelf about three inches from the ground, on which shoes, &c., may

638

stand, or a dog may have a mat for sleeping upon. All these benches are to the same scale of half an inch to a foot.

637. *Chairs* may be classed as suitable for the lobby, kitchen, parlour, and bed-room.

638. *Lobby Chairs*, being seldom moved, may be made of heavy massive forms in timber, or of cast iron, so as to have a decidedly architectural character.

Fig. 640 is a lobby chair of cast iron, suitable for a porch. The Design is Etruscan; and Mr. Mallet, to whom we are indebted for it, says that it may be cast in two pieces. It would, therefore, come cheap, and would look exceedingly well in the porch of a cottage in the Italian style. Mr. Mallet observes, that "where carved work, or much ornament, is to be executed in furniture, cast iron will always be found cheaper than wood, even though a small number only of the article were wanting." We hope that this hint will not be lost on Architects, who might thus introduce a style of highly improved design in all the principal articles of furniture, at a moderate cost. Chairs of this description, whether made of iron or wood, may be painted in imitation of oak in the following manner:— Give two coats of white lead in the usual mode; add a third coat of a pale yellow, as near as possible to the lightest part of the oak board to be imitated. Yellow ochre is rather too deep for most varieties of oak board; but stone ochre and white may be mixed together, till the exact shade be produced. When this coat is dry, the graining colour is to be laid on. This colour is not fluid like common oil paints, but is a mixture about the consistence of thick treacle, composed of various ingredients, and technically called meglip. The recipes given for making meglip are various; but the following are the articles principally used: sugar of lead, rotten stone, linseed oil, white wax, and spirits of turpentine. These are all ground up together, and immediately after the colour they produce is laid on, the graining is made by passing horn combs over it before it is dry. These combs have their teeth of different widths and lengths, and may be had of every combmaker. Fig. 642 is a lobby chair of wood in the Grecian style, which may be made of deal, with the exception of the legs, which, being turned, should be of beech or some fine-grained wood suitable for that operation. This chair may be painted of the colour of the wall against which it is to stand. Fig. 641 is a lobby chair in the Gothic style, which may be made entirely of deal, or of any other common wood, and painted and grained in imitation of oak.

640. *Lobby chair of cast iron, suitable for a porch.*

639. *Küchen Chairs.* Fig. 643 is a Windsor chair, one of the best kitchen chairs in general use in the midland counties of England. The seat, fig. 644, is of elm,

somewhat hollowed out; the outer rail of the back is of ash, in one piece, bent to the sort of horseshoe form shown in the figure, by being previously heated or steamed; its ends are then inserted in two holes bored through the seat, and are wedged firmly in from the under side. An additional support is given to the back, by two round rails, fig. 644, *b*, which are also made fast in two holes, formed in a projecting part of the seat, *c*. These chairs are sometimes painted, but more frequently stained with diluted sulphuric acid and logwood; or by repeatedly washing them over with alum water, which has some tartar in it: they should afterwards be washed over several times with an extract of Brasil wood. The colour given will be a sort of red, not unlike that of mahogany; and, by afterwards oiling the chair and rubbing it well, and for a long time, with woollen cloths, the veins and shading of the elm will be rendered con-

spicuous. Quicklime slacked in urine, and laid on the wood while hot, will also stain it of a red colour; and this is said to be the general practice with the Windsor chair manufacturers in the neighbourhood of London. Fig. 645 is a chair with a seat like the Windsor pattern, but with a different back, the two side styles of which are mortised into the seat, as shown at *d*. The legs are put together by dowels (wedges put in tenons after they are inserted in the mortise, to prevent them from being drawn back), like the Windsor chairs before mentioned, fig. 643. This forms a very comfortable and cheap chair. Fig. 646 is a very strong chair, being put together with mortise and tenon: it forms the common kitchen chair about London. It is generally made of deal, but sometimes of birch or beech, and is usually painted. Figs. 647 and 648 are two Gothic arm-chairs for kitchens; and fig. 649 is a kitchen workbox and table chair. The

workbox is formed beneath the seat, and is got at by a fall-down flap, *e*, supported by small chains or strong tape. The table, *f*, is simply a board which draws out from under the seat three fourths of its length, the remaining fourth remaining in to steady it; by which means lopers or fly-brackets are rendered unnecessary. Such a chair will be found very useful, and it may be made of deal, at a very trifling expense, by a common carpenter. The bottom of the box below may be loose, so that by turning the chair upside down, it may be taken out, and the box cleaned. Fig. 650 is a Design for an iron elbow kitchen chair, by Mr. Mallet. The back and elbows are cast in one piece; the supports for the elbows and also the legs are of gas tubing, screwed into a cross frame of iron, which proceeds from the back of the chair under the wooden seat. This is a strong, durable, and cheap chair, and only wants good cushions, for the back, elbows, and seat, to render it a most comfortable article for a cottager. Fig. 651 is a Design by Mr. Mallet for a cast and wrought iron chair, with a wooden seat. It is cast in one piece, the legs being tubular, with wire stays; the whole forming an exceedingly light and yet stable chair, weighing less than most oak ones. This chair might have a cushion seat, and also a cushion for the back, which the cottager might make himself of bulrushes, or of any other monocotyledonous water plant (the pith of these being filled with air, and therefore bulky, soft, and elastic), or of the chaff of Indian corn; covering them with cloth, and tying them on the chair with tape.

640. *Parlour Chairs.* These are of various patterns; and, as the characteristic of the kitchen chair was strength and durability, so that of the parlour chair is lightness and elegance. Figs. 652 to 657, p. 314, are plain Grecian chairs, sold in London at from 7s. to 12s. each. They are usually made of beech, and may be stained to imitate mahogany, by the following process: — Wash the wood, after the chair is completed,

with red ochre mixed with thin glue and water, quite hot ; when dry, rub the chair well with woollen cloths, till it assumes a good colour, and afterwards varnish and polish it. Chairs of this sort are made in great numbers in Buckinghamshire, where there are extensive beech woods. The commoner sort are generally nailed together, but the best are screwed or mortised, as in figs. 654 and 657. The bottoms are made of cane, with the exception of fig. 654, which is covered with leather. These chairs are generally painted and varnished ; but they are sometimes stained either black mahogany colour, or a rosewood pink. We shall give the processes from *Partington's Builder's Guide*.

641. *For a deep Black*, the wood is brushed over four or five times with a warm decoction of logwood, made by boiling one pound of logwood for an hour or more, and afterwards as often with decoction of galls, allowing it to dry thoroughly between the several applications of the liquor : thus prepared, it receives a fine deep colour, from being washed over with a solution of vitriol, in the proportion of two ounces to a quart : in the room of which some use a solution of iron in vinegar, keeping the vinegar for this purpose upon a quantity of the filings of the metal, and pouring off a little as it is wanted. A pretty good black is also obtained, more expeditiously, by brushing over the wood, first with the logwood liquor, and afterwards with common ink.

642. *A very fine Black* may be produced by brushing the wood over several times with a solution of copper in aquafortis, and afterwards with the decoction of logwood (*Hæmatoxylo-n campechiense*), repeated till the colour be of sufficient force, and the greenness produced by the copper overcome. The blacks may be varnished as the other colours.

643. *A light red-brown Mahogany colour* may be given to wood by means of a decoction of madder and fustic wood (the wood of *Maclura tinctoria*), ground in water, in the proportion of half a pound of madder and a quarter of a pound of fustic wood, to a gallon ; or, instead of the fustic wood, an ounce of yellow berries (the berries of *Rhâmnus tinctorius*) may be used. Brush over the wood with this solution, while boiling hot, till the due colour be obtained. Nearly the same effect may be produced by a tincture made by dissolving an ounce of dragon's blood in a pint of spirits of wine ; and a similar tincture of turmeric root (*Curcûma longa*), made by putting an ounce of the powdered root to a pint of spirits of wine, and after it has stood some days straining off the mixture.

644. *For a dark Mahogany*, take the infusion of madder as above, and substitute for the fustic wood two ounces of logwood : and when the wood has been brushed over several times, and is dry, wash it over with water in which pearl ashes have been dissolved, in the proportion of a quarter of an ounce to a quart. The wood, in the better kind of work, should be afterwards varnished with three or four coats of seed-lac varnish ; but, for coarse work, resin and seed-lac varnish may be used, or the articles may be well rubbed over with drying oil.

645. *Wood may be stained Yellow* by the above tincture of turmeric root, or by a tincture of yellow berries applied boiling hot ; the wood, when dry, being brushed over with weak alum water, used cold.

646. *For Rosewood Pink*, make an infusion of a pound of Brasil wood (*Cæsalpîna brasiliensis*) in a gallon of water impregnated with pearl ashes, in the proportion of an ounce to a gallon of water. The infusion should be frequently stirred, and should stand two or three days. When wanted for use, two ounces more pearl ashes should be added, and the mixture strained, and made boiling hot. It should then be applied to the wood, which should be afterwards brushed over with alum water, made in the proportion of two ounces of alum to a quart of water.

647. *Elbow Parlour Chairs in the Grecian Style.* Figs. 658, 659, and 660, p. 314, are Grecian elbow chairs with stuffed seats. Fig. 660, has a workbag under the seat, which draws out on one side; and on the other a slide, which serves as a table. These chairs may also be made of beech or birch, and stained or painted like the other. The silk or glazed cotton, for the workbag and the covers for the cushions, should be of the same colour as the window curtains and the cover of the sofa, if there be one in the room.

648. *Gothic Parlour Chairs.* Fig. 661 to 666, p. 323, are Designs for chairs made of beech; the first with a rush bottom; the second, third, and last with cane bottoms, and the two others with stuffed bottoms. Figs. 667 and 668, p. 323, are Gothic elbow chairs with stuffed bottoms. Fig. 669 is a Gothic chair, with a workbag and sliding board for table. All these chairs may be made of any strong fine-grained wood, mortised together, and afterwards painted and grained in imitation of oak. In the construction of chairs, care should be taken that the feet of the back legs should always spread out an inch at least more than the top rail of the back, in order to keep the latter from touching the wall, or paper, or window, when set against it.

649. *Bed-room Chairs.* These are of two kinds; a light sort for common use, and strong elbow or easy chairs for times of sickness. The light chairs may be any of those frames figured in p. 314, but with rush instead of cane bottoms. Figs. 670 and 671 are two strong elbow chairs for the use of a labouring man, when confined to his bed-room. Pillows may be put in them as cushions, both for the seat and back. Fig. 672 is a bedside chair of the same description, with a cupboard beneath for containing a night convenience of the simplest description. Such a chair ought to be in the bed-

room of every cottage. Fig. 673 is a very comfortable easy chair, stuffed in the back and sides, with a movable cushion as a seat; beneath which is a night convenience.

650. *A Sofa* is a piece of furniture which affords a great source of comfort to its possessor; and therefore the cottager ought to have one as well as the rich man. Let him strive to obtain it, for no parlour is completely furnished without one; and he will certainly succeed. We shall give some Designs for sofas, and also for sofa-bedsteads, which we hope will come within the reach of many cottagers; and shall commence with figs. 674 and 675, p. 324, which are Designs for sofas of a superior description. Fig. 674 is in the Gothic style, with castors sunk in its legs, a great improvement with regard to appearance. We may here observe, generally, that good castors are essential to the convenient use of every piece of furniture to which they are applied. Many persons, by saving a few shillings in castors, deprive themselves of the full enjoyment of what, if easily moved, would be a most useful piece of furniture; besides which, bad castors destroy the carpets of sitting-rooms, and scratch the boards of bed-rooms. Purchasers of furniture, who are no judges in this respect, are often deceived; for of two articles of furniture, exactly the same in size and appearance, one may

661

662

663

664

665

666

667

668

669

674

675

676

677

678

be sold by a manufacturer for a pound sterling less than the other, merely from his having employed in it the most common, instead of the best, description of castors. We are informed by Mr. Dalziel, who is extremely particular to use only the very best materials in all the articles which he manufactures, that the best castor at present in use is that of Cope of Birmingham. This is a ball working in a cup, something in the manner of Mr. Mallet's iron castor; and the more pressure there is on it, the easier it works. The cushions and mattresses of sofas are commonly stuffed with hair or wool; and sometimes, for cheapness, with chaff, chopped hay, or straw, or bran; but an article has been lately introduced into this manufacture, which is found to answer as well as baked hair, and not to cost above a third of the expense. This is the *Zostera marina*, or sea wrack grass, found on the coast of Norfolk; abundantly in the Orkneys and Hebrides; and on the northern shores of the German Ocean. When gathered, it is repeatedly washed in fresh water, to deprive it of all its saline particles; and, being afterwards dried in the sun, it is twisted into thick ropes, and in that state sent to the manufacturer, who has it untwisted, and cut into short lengths for use. Whatever material is used for stuffing, it is first enclosed in strong canvass, and afterwards covered with black horse-hair, moreen, or damask, nailed on with brass-headed nails, or with a loose cover of printed cottons or other stuffs. A very cheap and yet tasteful loose sofa cover may be made of glazed self-coloured calico, with a narrow piece of different coloured calico, or shawl bordering, laid on about a couple of inches from the edge. This kind of cover lasts clean much longer than one of common printed cotton; and, when the bordering is carried round the covers of the cushions, bolsters, &c., it has a pretty and even elegant effect. In all cases where the covers of sofas are made of a material which admits of a choice of colours, those should be preferred which prevail in the carpet and window curtains of the room; the principal reason in this, and all similar cases, being, that such a choice indicates unity of design.

651. *Sofa Beds.* Sofas which may be converted into beds are most convenient articles of furniture for cottages and other small dwellings. Fig. 676, p. 324, shows a bed formed out of a sofa of this description. The back of the sofa is hinged, as shown in fig. 677, at *a*; and it falls down, and is supported by two portable legs, fig. 678, *b, c*: these legs are tapped and screwed into the top rail of the back (that is, a screw is formed on the upper end of the leg, and, a hole being bored in the rail, nearly of the same diameter as this screw, an instrument called a tap is introduced into the hole, and being turned round, grooves out a path for the screw; this path, or screw groove, is called the female screw, and that which goes into it, the male screw). The end, *d*, is made to shift; it is fastened to the side rail of the seat of the sofa by the two wooden dowels, *e e*, which go into the rail, and is secured to the back and bottom by two thumb screws, at *f f*. When the bed is used, this end is shifted to that opposite, in order to form the head of the bed; the end style of the back of the sofa having holes to receive the same dowels and thumb-screws, so as to retain it in its place. Underneath the sofa there is a well for the legs, fig. 676, *g*, which may either open to the front or the back, and may be either concealed by the valance of the sofa cover, or by a movable panel of wood. There is a cupboard which opens at one end, as seen at *h*, in fig. 678. Fig. 679, p. 327, is a view of a sofa which may be turned into a bed with posts and curtains. Fig. 680 shows

680

the first process, that of removing the sofa cover, mattress, and cushions of the seat, and the mattress of the back. Here is seen a third mattress, *i*, which is kept in a well underneath the seat, and sufficiently long to hold it in a curved though not in a straight position. The remaining part of the space underneath the seat is occupied by

a cupboard, *k*. Under the cushions which form the seat of the sofa, and above the well, may be seen the folding frame, *l*, which forms the bottom of the bed. Fig. 681 shows

this folding frame opened out, and supported by four portable legs, tapped and screwed into its sides. The bedposts are, in like manner, tapped and screwed into the top rails of what formed the sofa ends; and the tester laths, and their side pieces, forming the top, drop on to iron pins inserted in the upper ends of the bedposts. The legs, the posts, the tester laths, and side pieces, all go into the same well as the mattress, when not in use; and when the sofa cover is on, it completely conceals the holes which receive the bedposts, and also the well and the cupboard. Fig. 682, p. 327, shows the bed with the mattresses and bolsters laid in their places, and the curtains put up. This is a very desirable description of sofa bed to have in a cottage parlour, or, indeed, in any small dwelling either in town or country. The cost, complete, in London, is from £10 to £15. There are also chair beds, which are formed by drawing out a frame from under the chair, so as to triple the length of the seat; on which frame are arranged the cushions which were previously placed against the back and sides of the easy chair. The bottom of the chair may be formed into a cupboard to open at the side.

652. *Beds* of other descriptions may be classed under the following heads: folding or camp beds; stump, press, and half-tester bedsteads; couch, box, and French beds; tent and four-post bedsteads, and children's cribs. In our opinion, those cottagers who can afford to have good furniture are often disproportionately extravagant in the article of beds and bedding. In Scotland and France, where the cottager's parlour has frequently a bed in it, luxury in this article may perhaps be excusable; but in England, where the bed-room of a cottager is seldom entered by a stranger, we think it would be a wiser economy to have the bed plain, though, in all respects, comfortable, and to expend any surplus money, which might have been spared from it, on the furniture of the parlour. However, we make the remark with great deference to the opinion of the cottager's wife, who must be allowed to be the best judge on the subject.

682

679

694

695

653. *Folding Camp Bed.* This is one of the cheapest of all beds; and when the sides and feet are made of iron rods, with no wood but the head board, it goes in very little bulk, and costs complete, with sacking, not more than 15s. Fig. 683, to a scale

of half an inch to a foot, is a view of a folding bed, with the sides and feet made of wood, which may be manufactured complete, in London, for £1. The head board has two iron pins in its lower edge, which drop into holes made in the side-rails of the bed. When a cottage is small, we recommend all boys to be made to sleep on beds of this kind, which they ought to be taught to fold up and put away in the morning, as soon as they get up; and to bring out and make up for themselves at night. The boy or lad who cannot sleep soundly on such a bed must have something either physically or morally wrong in his constitution; and is, in either case, not very likely to become a man capable of earning his bread by labour.

654. *Stump Bedsteads* are common in the humblest description of dwellings in England, both in town and country. They are commonly made of wood, with sacking bottoms; but as these materials are apt to harbour vermin, they have lately been manufactured entirely of wrought iron; the place of the sacking or canvass bottom being supplied by interwoven thin iron hooping, as shown in fig. 684, which is manufactured by

Messrs. Cottam and Hallen of London, and sold complete with castors, when two feet six inches wide, for one person, at 23s. each; and at a proportionate increase of price, according to the width, up to 33s., which is the price of an iron stump bedstead five feet wide.

655. *Press Bedsteads* are very common in kitchens, and, sometimes, in parlours where there is a deficiency of bed-rooms; but they are objectionable, as harbouring vermin, and being apt soon to get out of order when in daily use. They have, however, one advantage, which is, that persons sleeping in them are generally obliged to get up betimes in the morning: we, therefore, present one Design. Fig. 685 is a view of the press when the bed is put up. There is a cupboard shown at one end, and the remainder of the lower part is occupied by a drawer which is made to appear like two externally, in order to form to a regular front, with that of the cupboard. Fig. 686 shows the manner in which the bedstead folds up: *a* is one of the feet, which is

685

686

hinged on an iron pin, and is seen when down, as in fig. 687. The other two feet, *b b*, in fig. 687, are placed, when folded up, as shown in the section, fig. 686, at *b*; *c*

687

represents part of the front and top, lifted up and folded back. Press bedsteads are sometimes made to imitate a chest of drawers, or a secretary, in front; in order, if possible, to prevent the real use of the article from being discovered: a proof that beds of this kind are not held in much repute; because they indicate a deficiency of bed-rooms.

656. *Half-Tester Bedsteads* are used in small rooms, where it may be desirable to turn them up during the day, in order to allow the occupant to work in the room. They have this advantage over press beds, that they are turned up and let down with very little trouble; and that when turned up, and the curtain drawn round them, they are by no means unsightly objects in a room which is to be considered as a bed-room; but they are quite inadmissible in a kitchen or a parlour. Fig. 688 is a Design for a half-tester bedstead, with the posts, rails, and feet of wood, and the bottom of sacking. It is shown in this figure as turned down, and ready to receive the mattress and bedding. In fig. 689 the bed is shown turned up, by which it appears that the turned legs, *d d*, are hinged and fold down, so as to occupy less space. The manner in which the curtain rod is fixed is also here shown. It is fastened to the lath at the middle of the front, at *e*, and at both its extremities an eye is formed, which drops on a hook, as shown at *f*. The fixed feet are always placed in an inclined position, to give greater steadiness to

688

the bed, they are shown straight in fig. 688, and curved in fig. 689, to indicate that they may be made either way. Fig. 691 is an iron half-tester bedstead, which, however, does not fold up, but which has the great advantage of being remarkably cheap. It is manufactured by Messrs. Cottam and Hallen, of two feet six inches in width, for 46s. 6d.; and of five feet in width, for 68s. in both cases it is complete, with castors, head board, and curtain rods, and is thrice painted in oil. Fig. 692 is another wrought-iron half-tester bedstead, one half of which folds over the other: it is the invention of Mr. William Mallet of Dublin, who, we are informed, has made many thousands of them. In this bedstead both the head board and the foot board are of iron. Fig. 690

689

690

is a different modification of the same bedstead, intended for sick persons, which is made to rise with racks, *h h*, so as to place the patient, though still recumbent, at any angle that may be required. An important addition to this bed would be two upright rods, one on each side, about half way between the head and foot, securely joined together by a strong rod at top, so as to be perfectly firm; from this top rod a cord,

sash, towel, or piece of girth webbing, might be suspended, or even a hooked walking-stick put on, for the bedridden patient to take hold of, to assist him in turning, or otherwise changing his position. Every person who has been long confined to a bed knows that this simple contrivance is the most valuable part of a sick man's bedstead; and it is one reason why the beds of all elderly people should have bedposts and testers, because from the centre cross laths this simple contrivance, for the comfort of an invalid, may be suspended. Both figs. 690 and 692, we are informed, can be afforded for less than the price of the frame of a common wooden bedstead.

657. *Couch Beds* may be described as sofas used as beds; and, for our parts, we prefer them to either the press or the half-tester bedstead. They are very common in France and Germany. Fig. 693 is a Design, by Mr. William Mallet of Dublin, for an iron couch bed frame. The head is cast in one piece, the back in another, and the frame in a third. All the rest is of wrought iron; the four legs of gas pipe, the braces of quarter-inch wire, and the bottom of iron hooping. Castors might easily be added; and this Design would then form a suitable article for some descriptions of cottages.

658. *Box Beds* are common in the better description of cottages in Scotland, and also in Alsace, Lorraine, and other parts of the north of France, and in Holland and Flanders. This bed is of the usual length, and in general four feet wide within. There are four

square posts, at the four corners; and the back and ends are filled in with boarding grooved and tongued; while the front is formed into panels, one of which at top and another at bottom are fixed, and two between them slide in grooves, and form the door of the bed. The roof is of boards, and the bottom of laths, three inches wide, and about two or three inches apart. There is generally a shelf, and sometimes two, fixed to the inside of the bottom of the bed, just above the bedclothes; and sometimes there is one at top, close under the roof. There are also sometimes one or two shelves against the back of the bed; so that this piece of furniture not only serves as a bed, but as a wardrobe and linen chest. In some parts of the country the bed doors fix within by bolts, or have a lock to fasten them on the outside; so that a person going to bed, with all his treasure round him on the surrounding shelves, may secure it while he is asleep at night, or going out to work in the daytime, by bolting or locking the doors. These box beds can be easily taken to pieces, and put together again; the ends, backs, and roofs being in separate pieces, and fitting into grooves in the posts, and in the top and bottom rails, in the manner of Manning's portable cottages, § 512. Besides serving as a wardrobe, &c., a box bed may be made to supply the place of a partition, two of them being often placed, in Scotland, as well as in Alsace, across any apartment of fourteen or fifteen feet in width, which they thus divide into two rooms (a *but* and a *ben*), leaving a passage between them. In roomy cottages, four are sometimes so placed back to back; thus giving two beds to be entered from the kitchen, and two from the parlour. A bed of this sort, well made, was formerly considered the principal article in a Scottish cottager's furnishing; and this is still the case in Alsace and Lorraine, as we learned when we visited those countries in 1829. Something might be made of these beds in any country where the cottager's house is his own, and where he is likely to be a permanent resident; but they are too costly, and too cumbersome, for a tenant at will, or on a short lease.

659. *French beds* are generally formed like couch beds, especially those in use by French cottagers. Fig. 694, p. 328, shows a French bedstead of an improved description, with the furniture complete. There are two drawers underneath, and a small cupboard, all of which open from the front; because the furniture would be in the way if they opened at the ends. There is a turned rail above the headboard, to keep the furniture from the face; and another over the footboard, to be uniform with it. The pole which supports the curtain is screwed into an upright piece, which is securely fixed by a mortise and tenon to the back rail of the bottom of the bedstead, as shown in fig. 695, so that the bedstead and furniture can be removed from the wall. Castors may be introduced into the four pillars, so as not to be seen. It will be observed that the Design of fig. 695 is different from that of fig. 694: both may be considered elegant, and well adapted for a superior description of cottage. These bedsteads may be made of deal, and painted, with the exception of the upright piece, which should be of beech or some other stiff wood. Fig. 696 is a French bedstead of wrought iron, which costs

when two feet six inches wide, 46s., and when five feet wide, 84s. The curtains, in this case, are supposed to be thrown over a pole, projecting from the wall, and supported by a bracket.

660. *Tent Beds* are in universal use, and scarcely require description. Fig. 697, to a scale of three eighths of an inch to a foot, shows the framing or woodwork of the bed :

*a, b, c,* is the bed frame, *a* and *b* being the side rails, and *c* the bottom rail; *d* is the head-board which fixes into a groove in the head posts. These posts, being intended to be covered with that part of the bed hangings called the head piece, are made plain; while the bottom posts, which are intended to be exposed, are generally turned or covered. Fig. 698 is a tent bedstead with the curtains complete. Fig. 699 is an iron

tent bedstead, manufactured by Messrs. Cottam and Hallen, which costs, when two feet six inches wide, 56s. 6d., and when five feet wide, 77s.

661. *Four-Post Bedsteads* are more suitable for villas than for cottages, except perhaps the cheap and excellent ones made of wrought iron, which do not cost much more than a tent bed of the same materials. Four-post bedsteads, however, of every description, are objectionable for cottagers, both on account of the room they take up, and the quantity of bed furniture which they require.

662. *Cribs* are bedsteads for children so young as to render it unsafe to trust them by themselves in beds with unguarded sides. They are generally intended to be placed, during the night, by the bedside of the mother; and, for that purpose, the height of the crib should correspond with that of the large bed, and one of its sides be made to lift out. This is effected by grooves in the upright posts, with tongues on the end styles of the side. Fig. 700 is a Design for a crib in the Grecian style, and fig.

703. for one in the Gothic style, both by Mr. Dalziel, who recommends that the heads of the bed-screws, with which fig. 700. is screwed together, should be concealed by a wooden cap, fig. 701, instead of by a brass one, as is commonly done. In the leg of the Gothic crib, fig. 703, the screw is concealed by means of a small wooden panel made to take out. The turned rails of the sides, in fig. 700, and the plain rails in the Gothic Design, are considered better than the open canework usually employed for crib sides, through which children are apt to put their fingers and hurt themselves. Cribs are sometimes made with only one side, the rail on that opposite being held close to the rail of the large bed by hooks and eyes. Any joiner might make these cribs of deal, or any other cheap wood; and they may be painted or stained to harmonise with the bedstead and chairs of the room in which they are to be placed. Fig. 702 is a view of a cheap crib, the frame and bottom of which are formed of wrought iron,

701

702

and the sides and ends of deal. It may be made for 15s. Swinging cribs and cradles are now justly exploded.

663. *Bedding* includes palliasses, or straw mattresses; hair, wool, or other mattresses; hay, chaff, or feather beds; bolsters, pillows, sheets, blankets, and counterpanes. The palliass is an inflexible mattress, stuffed with drawn wheat straw; placed as the lower layer of the bedding, for the purpose of raising it, and giving a more agreeable basis to the feather-bed. The common mattress is formed by stuffing a

703

canvass case with flocks, wool, baked horse-hair, sea grass, technically called *U'va marina*, or any other articles which when put together form an elastic body, and afterwards quilting it down, and covering it with a description of cloth called ticken. The feather bed and the pillows are stuffed with feathers. In Scotland, mattresses and bolsters, exceedingly agreeable to sleep upon, are stuffed with the outer chaff of the oat, carefully sifted from the smaller chaff, and from all dust, and renewed once a year. In Italy, and in countries where the maize is in common culture, excellent mattresses are formed by stuffing them with the chaff of that grain. A few flowers of the hop mixed with the chaff of the bolster gives that article an agreeable fragrance, which is at the same time soporific. George III. at one time slept on a pillow entirely stuffed with hops; and some years ago, when in Worcestershire, we think in 1815, we slept at a farm house, on a bed, bolster, and pillows, all stuffed with hops, and found that they formed a species of bedding soft and powerfully fragrant, though said to be unwholesome.

664. *Substitutes for Stuffing* to beds, bolsters, and pillows have been proposed by upholsterers at different times, and some of them have lately been a good deal used: of these we shall mention three; viz., wire springs, air, and water.

665. *Wire Springs* for stuffing are nothing more than spiral coils of wire, fig. 704, generally an eighth of an inch in diameter for mattresses, and smaller for cushions, carriage seats, &c. These springs are placed, side by side, on interlaced webbing, of a frame of the size of the intended bed, cushion, or seat; they are then all confined by cords to one height, and covered by a piece of ticken or strong canvass, strained tightly over them. On this is spread a layer of curled horse-hair, and an upper cover of ticken is then put over the whole, and nailed down tight to the under side of the wooden frame with tacks. For our own part, we prefer beds made with these spiral springs to any other; not only from their greater elasticity, and the equal diffusion of the support which they afford to the body, but because, from the quantity of air among the springs, they can never become so warm as beds stuffed with any of the ordinary materials. The effect of spiral springs as stuffing has been long known to men of science; but so little to upholsterers, that a patent for using them in stuffing was taken out, some years ago, as a new invention. Beds and seats of this description are now, however, made by upholsterers generally, and the springs may be had from Birmingham by the hundred weight.

704

666. *Air Beds and Cushions* were invented by John Clark of Bridgewater, in 1813. He first renders the case of the bed, pillow, hammock, or cushion, impervious to air, by preparing it with caoutchouc; he next encloses it in another case not impervious to air, and afterwards forces the air into the inner case by means of an air-pump, preventing it from returning by an air-tight stopcock. He observes "that these beds afford the most renovating and easy repose; that they may be rendered soft to any required degree, and either cool or warm, by changing the air; that, on the general principle of fluids maintaining a uniform level, they are not subject to hard lumps or knots, like feathers, wool, or down; that they never can get damp; that they require no making up; that the largest bed weighs only a few ounces, and that, being exhausted, they may be folded or rolled up, so as to go in very little bulk, and hence their great advantage to travellers." For medical purposes, he says, "they may be filled with air at any required temperature; or with water, steam, or other fluids, either wet or dry, elastic or non-elastic, to which the case is impermeable. Seamen's hammocks, if filled with air, would be light, portable, and buoyant; and, in case of shipwreck, might be used as life preservers. Cushions, pads, and carriage linings thus, filled, will also be eligible and commodious, from their lightness and elasticity. (*Repertory of Arts*, vol. xxiv. p. 157.)

667. *The Hydrostatic Bed for Invalids* is a recent invention of that enlightened and benevolent physician Dr. Arnott, the author of the *Elements of Physics*, and is already coming into general use in the London hospitals. Its object is to mitigate all, and entirely to prevent some, of the evils attendant on remaining for a great length of time in a reclining posture. "The health, and even life, of every part of the animal body depends on the sufficient circulation through it of fresh blood, driven in by the force of the heart. Now, when a man is sitting or lying, the parts of his flesh compressed by the weight of his body do not receive the blood so readily as at other times; and if, from any cause, the action of his heart has become weak, the interruption of the circulation will both follow more quickly and be more complete. A peculiar uneasiness arises where the circulation is thus obstructed, impelling even a healthy person to involuntary changes of position: when the body is debilitated with sickness, however, these changes occasion much fatigue; and should the sensations after a time become indistinct, as in delirium, palsy, &c., or the patient have become too weak to obey them, the compressed parts are kept so long without their natural supply of blood, that they lose their vitality, and change to what are called sloughs, or mortified parts. These have afterwards to be thrown off, if the patient survive, by the process of ulceration; and they leave deep holes, which require to be filled up with new flesh during a tedious convalescence. Many a fever, after a favourable crisis, has terminated fatally from this cause; and the same termination is common in lingering consumptions, palsies, spine diseases, &c.; and, generally, in all diseases which confine patients long to their beds." (*Penny Mag.*, vol. i. p. 215.) Dr. Arnott, having tried various descriptions of beds contrived for invalids, including air pillows, down pillows, &c., thought at last of a hydrostatic bed. He "reflected that the support of water to a floating body is so uniformly diffused, that every thousandth part of an inch of it has, as it were, its own separate liquid pillar, and no one part bears the load of its neighbour; that a person resting in a bath is nearly thus supported; that a patient might be laid upon the surface of a bath over which a large sheet of waterproof India rubber cloth had been previously thrown, his body being rendered sufficiently buoyant by a soft mattress being placed beneath it; and that it might thus repose upon the surface of the water, without sensible pressure any where." (*Ibid.*) The hydrostatic bed is made of the usual dimensions; and is nothing more than a wooden trough, say four feet wide, six feet long, and one foot deep, lined with lead or zinc, to render it water-tight. Over this is thrown a sheet of India rubber cloth, as large as would be a complete lining to the box if it were empty. The edges of this sheet are secured by narrow slips of wood, or tinned iron hooping, firmly screwed down all round the top of the trough, shutting in the water as completely as if it were in a bottle, the only opening being at one end, which is filled by a cock. Upon this India rubber sheet a mattress, pillow, and bedclothes are laid, as in common beds. The box may be made by any carpenter, and lined by any plumber, and the India-rubber cloth is manufactured by Mackintosh and Co., Charing Cross.

668. *Bed Furniture*. The usual material for the hangings of cottage beds, especially for tent beds, is dimity, which has the advantage of being easily washed, and may thus be always contrived to have a clean appearance. Printed cottons, Manchester stripes, and chintzes are also very suitable, particularly the latter, for French beds; but moreens and other woollen stuffs should never be used in cottages, as they have not only too heavy an appearance for a small room, but are liable to harbour dust and vermin. The furniture of the bed, and the curtains of the windows of the room in which it is placed, should always be of the same material and colour.

669. *Window Curtains* give such an air of comfort to a room, whether it be to the

spectator from without, or to the occupant within, that we could wish no cottage, however humble, to be without them. For the same reason, we should wish cottage windows to be large, that the curtains may be displayed without too much obstructing the light. Window curtains give the mistress of the house an excellent opportunity for exercising her taste in their arrangement; and it is but doing justice to the French and Germans, to state that they are far in advance of the British, or, indeed, of any other people of Europe, in this particular. From Stockholm to Naples, the room of a Frenchman may always be known, before entering it, by the curtains of his window. It is not that they are formed of expensive materials, for these are seldom employed, except in a superior description of houses; but muslins, cottons, and lenos, of different colours, sometimes accompanied by shawl bordering, sewed upon the cottons, are put up with a degree of style and taste which indicates both talent and a love of home in the occupant. It would be easy to introduce the same taste in Britain, if it were once properly pointed out to young females, and exemplified by the comparatively enlightened cottager; for example, in the dwellings of the married upper servants of country gentlemen. The first step, however, is to have large windows. Fig. 705, p. 339, is a very plain style of hanging curtains. A round pole of wood is supported at each end by a bracket, fig. 706 a,

706

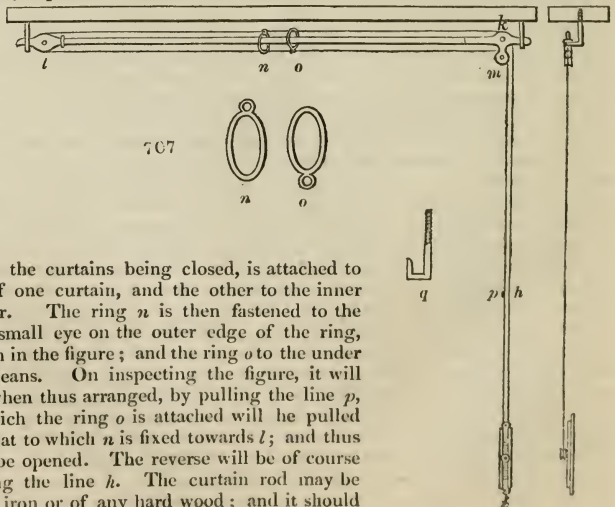

which is fixed by screw nails to the architrave of the window. The pole is kept securely in its place by the screw-pin, *b*, which passes through the bracket, and is screwed into the pole so as to keep it quite firm. On the pole are fourteen rings, generally of brass, but for a common cottage they might be made of iron bronzed; and in the lower part of each ring there is a small eye, *c*, in which is inserted the end of the wire hook, *d*, which is sewed along the inside of the upper margin of the curtain. By these means the curtain can be unhooked, and taken down to be cleaned at any time. The curtain, when not drawn, may be supported by a wooden pin, by a brass pin, by a brass band, *e*, which fits into a socket, *f*, and will stand either upright, or horizontal, at pleasure, accordingly as the square tenon of the band may be introduced. In fig. 705, this band is shown at *g g*, placed horizontally; in fig. 706 it is shown placed upright. Instead of a pin or band, a piece of riband or curtain line, with a ring on each end, might be hooked on two knobs, and thus loop up the curtain. The manner in which this curtain, which opens in the middle, is made to draw from the centre to each side of the window, is shown in fig. 707. A line, *h*, is passed round the small pulley which works in the pulley rack, *i*;

it is then carried over another pulley at *k*; then over a third at *l*; and a fourth at *m*, returning to the pulley rack, where it is joined to its other end.

There are two rings at *n* and *o*; one of which, the curtains being closed, is attached to the inner edge of one curtain, and the other to the inner edge of the other. The ring *n* is then fastened to the upper line, by a small eye on the outer edge of the ring, which may be seen in the figure; and the ring *o* to the under line, by similar means. On inspecting the figure, it will be evident that, when thus arranged, by pulling the line *p*, the curtain to which the ring *o* is attached will be pulled towards *m*, and that to which *n* is fixed towards *l*; and thus the curtains will be opened. The reverse will be of course effected by pulling the line *h*. The curtain rod may be formed either of iron or of any hard wood; and it should

707

705

708

710

711

be fixed to the under side, or soffit, of the window, by hooks of the form shown at *q*. This is the very simplest form of curtain made to draw apart, and it may be made by any country carpenter. The cheapest material for these curtains is calico, dyed crimson, blue, or any other ingrain colour that will wash. They may also be formed of dimity, with a strip of glazed calico about an inch and a half wide, of any colour suitable to the other furniture of the room, sewed on about two inches from the margin. This coloured calico is, of course, taken off when the dimity is washed, and, with care, will last clean and look well for years. Coloured calico cut in vandykes, or in any other pattern, and sewed on close to the edge, may be substituted for the plain strip, if preferred.

670. *Window Curtains in the Grecian style.* Fig. 708, p. 339, may be considered as suitable for a cottage finished in the Grecian style, including under that term the Italian manner. This curtain requires a different bracket from the other. A lath, four inches wide, fig. 709, *r*, is fixed on the architrave of the window, by an iron angle bracket, *s*. The bracket which supports the pole, *t*, is of brass, and it is fastened by screws on the top of the lath. The curtains are arranged as in the preceding Design, and the drapery or valance over them, at top, is hooked into the rings (shown in fig. 708), in a similar manner to the curtains, so that both drapery and curtains may be taken off to be washed. The pole to which the drapery is attached would look remarkably well if stained of a mahogany colour; or, in a Gothic cottage, to resemble oak. Fig. 710, p. 340, is another curtain in the Grecian style, in the construction of which the plaited drapery, or valance, is tacked to the cornice in a manner which we shall include in our description of the next figure.

671. *A Gothic Curtain and Cornice* are represented in the Design, fig. 711, p. 340. The cornice may be made of deal, and painted and grained to imitate oak. The drapery is nailed on to the lath with tacks, the heads of which are covered by the cornice, as shown in the sections, p. 340, *u*. The cornice takes off and puts on by means of what are called cornice slides, *v*, which go into a broad staple, *w*. The curtain runs behind the drapery, on a pulley rod, as shown in the section *x*, in fig. 708, p. 339. The pins to support the curtains may be made of oak, in order to harmonise with the cornice.

672. *Curtains for the humblest description of Cottages.* Where an apparatus of lines and pulleys would be too expensive, a simple curtain, opening in the centre, may be formed by nailing two pieces of dimity, coloured calico, or printed cotton, to a square cornice, either painted, or covered with a piece of paper bordering; these curtains may be looped back by a piece of sash line, or coloured cord, twisted round hooks fixed to the architrave, and will thus form a kind of Gothic drapery across the window. Another simple description of curtain is formed by nailing a piece of dimity, or other material, of the requisite length and width, to a flat piece of wood, in one end of which are inserted two pulleys; while two others are let into it, one in the middle, and the other at the opposite extremity. Three pieces of tape are sewed down the curtain, one on each side, and one in the middle, to which are affixed small rings, at regular distances: through these rings are passed three pieces of cord, which afterwards go over the pulleys, and, being fastened together on one side, are kept tight by means of a pulley rack. By this apparatus the curtain may be raised or lowered at pleasure. The board with the pulleys is concealed by a cornice, to which a valance, or any other description of drapery, may be attached.

673. *Inside Window Blinds* are of various kinds; but the chief are roller blinds, Venetian blinds, and wire blinds. The roller blind, being much the cheapest, may be considered the most suitable for common cottages. It is simply a piece of linen, of the height and breadth of the window, nailed to a roller, which has a pulley at one end, by means of a string over which the blind is pulled up; and it is drawn down by a cord and tassel fixed to the middle of its lower edge. The blind is kept extended to the width of the window by a lath, passed through a broad hem, at the opposite end to that which is fixed to the roller. The roller works in pivots at each end; and motion is usually communicated to it, for the purpose of drawing up the blind, by an endless cord, which passes over the wooden pulley on the end of the roller, and under the small brass pulley in the rack. (A rack is shown in fig. 707, at *i*.) As the pulley and rack often require adjusting, a more simple plan is to have the pulley affixed to the roller of the blind, with a cylinder or axis smaller in diameter than that of the roller on which the blind is wound up. To this is attached a line, the length of which should bear the same relation to that of the blind, as the diameter of the cylinder of the pulley does to that of the cylinder of the roller. The line must be affixed when the blind is wound up on the roller, so that the action of drawing down the blind may wind up the cord.

The smaller the diameter of the axis of the pulley is in comparison with that of the roller, the shorter will be the length of string required. A great improvement in this description of blinds has been made by forming the roller of a tin case that encloses a spring, which acts so as to turn the roller, and pull up the blind of itself. The best description of this spring roller blind is one improved by Messrs. Barron and Mills, which we shall describe when treating of blinds for villas. Sometimes, instead of linen blinds being plain, they are painted with transparent colours, so as to represent stained glass windows, landscapes, &c. These blinds, while they exclude the sun, admit abundance of light, and are very suitable for staircase windows, or the windows of cottages which have either no view, or one which it is desirable to exclude. A great improvement has lately been made in the manufacture of transparent blinds by Mr. Newbury of London, who paints them on a superior description of gauze, of his own invention. Long and short Venetian blinds, and short inside wire blinds, are not unsuitable for the better description of cottages; but we shall defer what we have to say of them till we come to speak of Villa Furniture.

674. *Commoner descriptions of Short Inside Blinds* are formed of muslin or leno, either flounced all round, and opening in the middle, or with flounces only at top. These blinds may be affixed to the windows either by a piece of tape drawn through a string case running across the blind near the top, and fastened by brass hooks to the side styles of the window; or by brass wires or rods passed through broad hems at the top and bottom of the blind, and having a loop at each end, to drop on the pin of a small brass bracket affixed to the side style or bead of the window frame. Other blinds may be netted by the cottager's wife, of white cotton, or green worsted, the size required, and hung on brass hooks fixed to the astragals and side styles of the window. Various other blinds may be formed of equally cheap materials, according to the taste and skill of the mistress of the cottage.

675. *Lines and Knobs for Curtains and Blinds, &c.* The description of line used should always be the plaited thread line, which, being of the same material throughout, is much stronger, and lasts four or five times as long as the common twined sash line,

which in many cases is made of one material on the outside and another in the interior. This patent thread line, as it is called, is manufactured of all sizes, from that fit for a carriage window blind, to one thick enough for a ship's cable; and it should be used, not only in curtains and blinds, but in hanging sashes, pictures, and, in short, in all cases requiring lines. Knobs of iron, brass, or wood, for the purpose of fastening lines round, are far preferable to the hooks of different kinds in common use; because they have a more solid and architectural look; are more removed from a common nail; and are not so apt to catch the corners of the laths of Venetian blinds, or to tear cloth blinds or curtains.

676. *Looking-glasses* for cottages may be divided into two classes; chimney or pier glasses, and dressing-glasses. Fig. 712 is a Design for a chimney glass in the Grecian style, and fig. 713 is another in the Gothic manner. The frames may be of deal, painted in imitation of oak, or they may be gilt, which is generally considered to look best. For a Gothic cottage, very handsome and cheap pier and chimney glasses may be formed by constructing a frame like a Gothic window, and glazing it with panes of plate glass, or of a superior descrip-

tion of common glass prepared as looking-glass. The same may be done in Grecian cottages by imitating a Grecian window. By placing mirrors of this kind so as to reflect the best exterior views, apparent extent, variety, and gaiety may sometimes be added to even small rooms. Where it is desired to have richly ornamented frames, they can be had in great variety, and at a very moderate price, made of the papier maché of Bielefield and Haselden (see § 568), or of a composition manufactured by Jackson of Rathbone Place.

677. *Dressing-glasses* may have their frames made either in the Grecian or Gothic style. Fig. 715 is the ordinary form, improved in the style of design, so as to harmonise with Grecian forms; and, if the supporters were of cast-iron bronzed, it might be recommended: but, made of wood, it is not heavy enough to resist the action of the wind against the back of the glass when the window is open; and, accordingly, bed-room glasses of this description are very frequently blown down and broken. Fig. 714 is

also a Design in the Grecian style, with a plinth or base of solid wood, on which it stands. Such glasses are called by cabinet-makers plateau glasses; and they are far preferable to the common sort, for obvious reasons. Figs. 716 and 717 are Designs for plateau glasses in the Gothic style, which are given principally to show that style should be attended to in minor as well as in major articles of furniture. Fig. 717 has a drawer for trinkets, &c.

678. *Fenders* should be low, and may be narrow, when the fuel chamber is placed low; and more especially when the beveled front bars and drawer, § 599, fig. 534, are used. The lower and narrower the fender, the more heat, other circumstances being the same, will be radiated into the room. The front of the fender, unless very low indeed, ought always to be of open work, in order to admit through it the radiation from the fire. The forms and lines and general style of the fender ought to be the same as those of the grate; and both ought to harmonise with the chimney-piece. We have seen a cottage fender with a well hole inside for containing coals; thus serving instead of a coal scuttle, and at the same time drying the fuel so as to diminish the quantity of smoke produced; in this case the fender and its well fitted into a sunk panel in the hearth, and as it was in the house of a toll bar keeper, who had to sit up all night, it proved convenient; because the coals were always at hand, and burned readily when put on the fire. Fenders should have stands for fire-irons, unless a substitute is provided by holders being screwed to the grate. The cheapest kind of cottage fenders are of painted wire, and these may do for parlours and bed-rooms; but there are very handsome and cheap fenders of cast iron, which are much more appropriate for kitchens.

679. *Fire-irons, stoves, and grates*, when of polished iron or steel, require a great deal

of severe and disagreeable labour from women, which we have long wished to see put an end to, by the substitution of a more rational mode of heating than that of open fire-places; but, in the mean time, as the cottager must have fire-irons of some sort, we recommend him to have plain patterns, and rather to indulge in some other description of furniture which requires less care in keeping. Where wood is the principal fuel, we recommend the kitchen poker to terminate at the lower extremity in two claws like a claw hammer, or a crowbar; and to be hollow, with one orifice between the claws, and another at the opposite end for applying the mouth to blow the fire, or rather to rouse the embers after they have been collected together from the ashes by the claws. We have seen the use of such pokers in the kitchens of inns in Germany; and think they may be safely recommended as very superior to those in common use, where wood is burnt on a hearth.

680. *Carpets* are sources of comfort in every room; and we should wish the cottager to have not only one in his parlour, but, if possible, also one in his bed-room. For neither the parlour nor the bed-room would we recommend the carpet to be fitted to the room; because such carpets can very seldom be either turned or changed in any way. In general, whatever may be the shape of the room, the carpet ought to be in the form of a square, a parallelogram, or a circle. A square carpet may be changed eight times, so as to be worn equally on every part of both sides; a circular one, indefinitely. A parallelogram may be changed four times, which will also admit of wearing it with tolerable regularity. A carpet, accurately fitted, or planned (the term among upholsterers), to every projection and recess of a room, cannot even be changed once, unless the projections and recesses should be of a particular description of symmetry, which is very seldom to be met with. It is evident, then, that a fitted carpet, which can neither be changed nor turned, will not last more than one eighth the time of a square one, or one fourth the time of a parallelogram. For a cottager's bed-room, we would chiefly recommend one piece of carpeting placed by the dressing-table, and pieces neatly fitted to each other to go round the foot and sides of the bed. In general, the parlour carpet will require to be made fast at the margins with a few tacks, but the bed-room carpets may be left loose. Stair carpets give an air of great comfort and finish to a house; and a cottage should never be without one. We shall describe the manner of laying these down, and shall enter into other particulars respecting carpets, when we come to speak of Villa Furniture. When a parlour carpet does not cover the whole of the floor, there are various ways of disposing of the margin between it and the wall. Some recommend oil-cloth, others baize, drugget, coarse broadcloth, or brown linen; for our part, we greatly prefer to any of these, painting that part of the boards of the floor which is not covered with the carpet, of the same colour as the woodwork of the room; taking care that the margin painted shall exceed in breadth by a few inches the space which it is intended to leave uncovered. This is by far the best mode in staircases and in bed-rooms, as well as in parlours; it also saves a great deal of the most disagreeable part of a woman's household labours. When the woodwork of the room is painted to imitate oak, this mode of treating the margins of the floor has a particularly good effect. The expense may be objected to; but we shall show, when we come to treat of the art of house-painting, how easily any cottager or his wife, though they never before saw a paint brush in their lives, may learn in an hour to grain the woodwork of their cottage, in imitation of oak, sufficiently well for every purpose they can require. Round carpets are not very common in England, but they are not unfrequent on the Continent, and look exceedingly well in a square room.

681. *The kinds of carpets most suitable for cottages* are chiefly the Scotch and the Kidderminster, on account of their cheapness; but we consider none too good for the cottager, provided he can afford to pay for them. In choosing a pattern, the smallest is generally to be preferred, not only as a matter of taste, as being more in accordance with small rooms, but in point of economy; because, in sewing the breadths together, it requires less cutting out to make it match, and because, when the carpet gets old, the patches put on in mending are less conspicuous. The parlour carpet, and the carpets of at least one bed-room, should be of the same pattern, in order that, when the former is partly worn out, the latter may be used to mend it; because it is always bad, both in point of effect and economy, to mend what is old with what is quite new. A very neat pattern for carpets has lately been introduced for libraries, but it would suit Gothic cottages equally well. It consists of an imitation of wainscot, has a quiet subdued tone of colour, and accords well with furniture made, or painted in imitation, of oak.

682. *Colours of Carpets.* Much of the opinion which we form of all objects depends on the effect of the first impressions which we receive from them. Our first ideas of any man or woman, on seeing them at a short distance from us, are taken from their height and clothing; and our first ideas of a room, from its size, and the covering or colour of its floor and walls. Taking the room as a whole, and considering its effect as

a picture, the colours of the carpet and of the walls will form the principal masses in the composition, and will necessarily influence every other component part. If the floor and the walls were of the same colour, there would be a deficiency of force and of effect, from want of contrast; if they were of different colours, equally attracting the eye, the effect produced would not be that of a whole; because a whole is the result of the cooperation of different subordinate parts with one principal part. The harmony of the colouring of a room, therefore, can only be produced by the same kind of knowledge which guides an artist in painting a picture. The principles of the art of painting supply the principles for the art of distributing colours in furnishing; but, as this art cannot all at once be communicated to the reader, all that we shall attempt, at present, is, to supply him with a few hints, drawn from the usual practice of upholsterers. These are, that neither the colours of the carpet should be so brilliant as to destroy the effect of those of the paper, nor the contrary; and that the curtains should always be of a colour suitable to both. It is not necessary that they should be of the same colour, but that they should be of colours that harmonise, or, in other words, look well together. A very brilliant colour, such as crimson, in the carpet, may have a drab or other subdued colour in the curtains and paper; but then there should be some of the brilliant colour introduced in both, as bordering or ornaments. Thus, a room with a bright blue or crimson carpet may have white, yellow, or drab, curtains and paper; but blue or crimson bordering or ornaments should be introduced in them, to harmonise the effect. It would not do, in the case of the blue carpet, to have green curtains or paper, or with the crimson to have scarlet; because these colours do not accord. A green carpet may have black, red, or white curtains, with green borders and ornaments. A yellow carpet may have black curtains, and a dark grey paper with yellow borders and ornaments. Whatever will apply to a self-coloured carpet, curtains, or paper, will apply equally well in all cases where those colours predominate. It should never be forgotten, that the whole effect of an elegantly furnished room may be destroyed by the selection of a carpet which, though handsome in itself, does not harmonise with the other furniture.

683. *Geographical Carpets.* The idea of a geographical carpet, that is, a carpet with the lines of a map substituted for a regular pattern, has been suggested (*Mech. Mag.*, vol. xii. p. 21.); and we agree with the author of the suggestion in thinking that "a carpet is so admirably adapted to geographical instruction, that it may be almost said to be a natural article for the purpose. A map is a picture of the surface of the earth, and on the ground is the place to view it. One on so large a scale as a paper would admit, is calculated to give a more correct idea of the relative position of places than could be effected by the largest map now extant. A family in the daily occupation of a room furnished with such a carpet, would acquire unavoidably a more permanent knowledge of a given portion of the earth than could be obtained by any other means; and, when the local position of the room would admit, the carpet might be placed agreeably to the bearings of the compass, and it would thereby give a correct idea of the real direction of places on the map." The principal objection to this plan seems to be, the great difficulty which would attend its execution. A map, such as above described, might, however, be printed on fine cloth, or brown holland linen, and might then serve as a cover to a carpet. This would be particularly suitable for a school-room or nursery.

684. *Substitutes for Carpets.* Green baize and drugget are often used as substitutes for carpets, and are not only cheap, but in many cases look remarkably well. When a drab drugget is used, a border of black or any dark-coloured cloth, laid on about two inches from the margin, has a very good effect. Cheap carpets may be made by industrious housewives of a kind of patchwork. Remnants of cloth bought from the woollen-drafter, or tailor, and cut into any kind of geometrical shapes, may be sewed together, so as to form circles, stars, or any other regular figures that may be desired; and, when arranged with taste, produce a very handsome and durable carpet, at a very trifling expense. The figures, of whatever nature they may be, should be always symmetrical; and a handsome border should invariably surround the whole, so as to preserve the idea of unity of design; care should also be taken that the colours employed harmonise, not only with each other, but, as before advised, with those of the other furniture of the room.

685. *Paper Carpets* are formed by cutting out and sewing together pieces of linen, cotton, Scotch gauze, canvass, or any similar material, &c., to the size and form required; then stretching the prepared cloth on the floor of a large room, and carefully pasting it round the margins so as to keep it strained tight. If cotton be the material, it will require to be previously wetted. When the cloth thus fixed is dry, lay on it two or more coats of strong paper, breaking joint, and finish with coloured or hanging paper, according to fancy. Centre or corner pieces, cut out of remnants of papers, which may be bought for a mere trifle, may be laid on a self-coloured ground, and the whole surrounded by a border; or any other method adopted which may suit the taste or circumstances of the

occupier, or accord with the other furniture of the room. When the carpet is thus prepared, and quite dry, it should receive two coats of glue, or size made from the shreds of skins, such as is used by carvers and gilders. This size should be put on as warm as possible, and care should be taken that no part of the carpet be left untouched by it; otherwise the varnish to be afterwards laid on will sink into the paper, and spoil it. When the size is perfectly dry, the carpet should have one or more coats of boiled oil; and when that is dry, a coat of copal or any other varnish. The varnish is not absolutely essential, as boiled oil has been found to answer very well without it; but where oil only is used, it requires several more coats to be applied, and takes a much longer time to dry. These carpets are portable, and will roll up with about the same ease as oilcloth. They are very durable, are easily cleaned; and, if made of well-chosen patterns, have a very handsome appearance. Where labour is cheap, the cost will be very trifling; the materials being of little value, and the expense consisting chiefly in the time requisite to put them together. Where cloth cannot be easily procured, the carpet may be made by pasting paper to painted boards; when, by repeated coats of paper, it is become strong and firm, it will separate from the paint, and will be as durable as if mounted on any kind of cloth. For earth, brick, or stone floors, in order to render them impervious to damp, these carpets may be made with two faces, by pasting paper to both sides of the cloth which forms their basis, and well oiling or varnishing them on the under as well as upper surface: they may also be bound with leather or any strong substance, to prevent moisture from penetrating to the paste. The paste used in the preparation of these carpets ought to be very strong, and is best when beer or sweet wort is substituted for common water. It must be kept free from lumps, and, when taken from the fire, stirred till cold. Papers used for carpets should have sufficient gum or size employed in the printing of them, to enable them to withstand the effects of the washing over with warm size. If printed in oil, a strong coat of size should be given to the back to prevent the oil from penetrating through the paper, otherwise it cannot be pasted to linen, cotton, or any thing else. Papers printed in oil will not require any size before they receive the finishing coats of boiled oil and varnish. When varnished on one side only, they ought to be rolled up with that side outwards, to prevent its cracking. (*London Jour. of Arts and Sciences.*) Paper carpets would perhaps be better for geographical subjects, than carpets formed of any material produced by the loom. We have before suggested the idea of geographical, natural history, and other scientific papers, for the walls of apartments; and, if these were once made, they might be transferred to paper carpets at pleasure.

686. *Hearth Rugs* are of various patterns and prices. Their use is obvious, in saving the carpets from becoming worn by the constant movement of persons near the fire. When economy is an object, a piece of carpeting the same as that of the room, and the width of the hearth, may be employed, and this may be either hemmed at the ends, or surrounded by a deep fringe of black or very dark brown worsted, which the mistress of the cottage may net herself, and sew on. A cheap rug may also be formed of a piece of drab drugget bound with black, or any other colour to suit the paper and curtains, and fringed; either with or without a strip of cloth, of the same colour as the binding, laid on about two inches from the margin. This kind of rug does very well without the fringe. Another kind of cheap hearth rug may be made by the cottager's wife, of remnants of cloth cut into narrow strips about half an inch broad, and three or four inches long; these strips are doubled, and sewed at the bend, in rows, to a strong piece of cloth, or knitted into a framework of packthread. In either case the colours are disposed so as to form some kind of pattern; and, the ends being left loose, and cut even when the work is finished, with a large pair of scissors or shears, the whole presents a remarkably rich, warm, and massive appearance.

687. *Painted Floorcloths* may sometimes be used in the lobbies and passages of cottages; but they are not economical articles, where there is much going out and coming in of persons generally employed in the open air, and of course wearing strong shoes, probably with nails in the soles. When they are used in cottages, the most appropriate patterns are imitations of some materials usually employed for floors, such as tessellated pavement, different-coloured stones, wainscot, &c.; but, for the better description of dwellings, where oilcloths are considered chiefly as ornamental coverings, there seems to be no reason why their patterns should not be as various as those of carpets.

688. *Matting of different sorts* may be extensively used in cottages. There are some kinds, which the cottager might make for himself in the winter's evening; and there are others that he may purchase cheap. Matting is manufactured, in many different manners, out of the straw of corn, rushes, or other long, narrow, grassy or sedgy leaves. Among the uses to which a cottager might apply mats of this sort, which he could make himself, are, seats for chairs, stools, and benches; foot mats for outside doors; and screens, than which there is not a more useful article for the cottage kitchen. In Monmouthshire,

easy chairs with hoods, like porter's chairs in gentlemen's halls, are constructed of straw matting on a frame of wooden rods, or of stout iron wire; and chairs like fig. 718 are made entirely of straw in different parts of England, in the same way as the common beehives. Matting of this sort might in some cases be employed as partitions, and is extensively used in the more miserable of the cottages both in France and Scotland. Russian matting, or bast, made from the inner bark of the lime tree, is very cheap, and might be useful to the cottager in many ways: the walls and partitions might be lined with it, and temporary ceilings formed of it in hovels where there were none. There are various other applications of Russian matting, which will readily occur. Indian matting, when bound with black or coloured ferreting, is a very neat article, and may be used either for walls or floors.

689. *Door Mats* may be made of basketwork, straw, rope, hair, wool, sheepskin, &c. A very good outside mat, or rather perhaps scraper, is formed by a piece of flat wickerwork, somewhat coarser than that of a common hamper; it takes the dirt effectually from the soles of the shoes, and as it falls down in the interstices between the rods, the wickerwork has only to be lifted up now and then, and the dirt swept away. A mat which operates like this wicker mat has been formed in Germany of flat tarred rope, in the following manner:—The breadth of the rope, fig. 719 *a*, full size, is about three quarters of an inch, and it is something more than a quarter of an inch thick. The outline of the mat is first formed by setting the rope on edge on the floor, or on a piece of board, in the manner of a frame, and attaching it in two or three places with nails or pegs; the rope is next returned on itself in zigzag lines within the frame, either by

continually going round it till it ends in the centre, or by going backwards and forwards from one end to the other, till it finishes on one side. This being done, all the parts which touch are sewed together, and the result is a mat like fig. 719, *b* (to the scale of half an inch to a foot). These mats are imported from Germany; and, when used as shop-door mats in London, they are found to be more durable than any other kind that has yet been tried. One of the commonest and most useful out-door mats is made of untwisted rope yarn, woven into very coarse canvass, and then cut, so as to present a brush-like surface, on which, not only the soles of the shoes may be cleaned, as in the wicker and rope mats, but also the sides. In-door mats are made of hair, tow, or wool, in various modes. One of the best for a cottager's bed-room door is a black or grey sheepskin, with all the wool on. A black or dark goatskin makes also a very handsome mat. Skins with white or other light-coloured hair or wool make very handsome mats, but are hardly advisable for a cottager, as they require frequent washing.

719

690. *Scrapers* for the feet may be let into the wall of the cottage, on each side of the door, a cavity being left over the scraper for the foot, and one under it for the dirt. There are various forms of scrapers for building into walls, which may be had of every ironmonger; and all that the cottager has to do is to choose one analogous to the style of his house. There are detached scrapers in endless variety; the most complete are those which have brushes fixed on edge, on each side of the scraper, which, with other forms, we shall describe and figure under *Villa Furniture*. Scrapers are so essential to cleanliness, that, where the cottager can get no better, he may drive two short stakes into the ground, about a foot apart and half a foot high, and let into them a piece of iron hooping edgewise; or he may sink the blade of an old spade, with its edge upwards. The last two scrapers are very suitable for gardens; and, unless the cottager keep his garden walks perfectly clean, or at least free from the clods of earth which will stick to his feet when working in the compartments, he cannot expect to have the gravel of his platform in nice order, or his entrance-porch clean. A dirty entrance is a sure sample of an untidy housewife; and little comfort can be expected in a cottage the floor of which is soiled with filth brought into it from without. Those cottagers who can afford it may purchase the portable scraper, fig. 720, which costs, in London, only 1s. 6d., or fig. 721, which costs 2s.; both of which will answer either for the entrance door or the garden walks: or they may take the dibber scraper, fig. 722, which costs only 2s. 6d., and may be stuck into the garden anywhere, and pulled out again to remove it, at pleasure.

An excellent scraper, partaking of the nature of a mat, may be formed by letting a number of pieces of iron hooping edge-wise into a wooden frame, say a foot or more wide, and eighteen inches long. The pieces of hooping may be from an inch to an inch and a half apart. Wooden hooping, or straight-edged laths, may be substituted for iron; but the latter is more effective, as well as more durable. Scrapers of this sort may be let into a stone, so as to be level with the adjoining path or pavement; but in this case there should be a pit, three or four inches deep, beneath the scraper, and the latter should admit of being taken out, to remove the dirt from the pit. In Holland a very good cottage-garden scraper, particularly for sandy soils, is formed by fixing small iron bars, or pieces of hooping, in the circumference of two segments of ovals, fig. 723; the chord of the segment is about nine inches in length, and the width of the scraper a foot. When it is used, the sand, or other dirt, drops from the soles of the shoes, between the bars; and, when the space is filled, the scraper is lifted up, and the dirt removed.

691. *Hat and Umbrella Stands.* Both these articles combined, as in fig. 724, may form a suitable piece of furniture for a Gothic porch or passage, where the walls are covered with pictures; or where there are other objections to having coat and cloak pins fixed against them. Besides, it is always better for hats to be hung on stands in the free air of the apartment, than to have them placed on a table, or against a wall, where they get the air only on one side. In the box at the bottom of this stand, there is a tray of tinned iron, painted black, which lifts out, in order that it may be emptied of the water which may run into it from wet umbrellas, &c., and be cleaned. Where there is sufficient space in the apartment, hat and cloak pins may be put on both sides of the tree; in which case there should be a second box. We have shown on the two upper branches or rails of the trunk, or upright piece, five hat pins, or surplice pins, as they are called by upholsterers, which may be made either of brass, or of iron bronzed. On the lower rail there are four wooden pins, which may be either made of oak, or painted in imitation of it. These pins are formed in two pieces; the stem, or shank, and the head; and the latter is screwed into the former, as indicated in fig. 725. Such

pins are made of mahogany, in Birmingham, in large quantities, and are sold to the trade all over the country. They are far superior to brass or iron knobs or pins; because they never tarnish or rust, and because they give decided evidence of improved design, in their far removal

from the common nail or hook. The umbrella stand, fig. 726, might very well be made of cast iron; and could not, in that material, cost more than a fourth of what it would

in any description of wood; but in this, and in similar cases, the objection is, the first expense of the pattern, which, being necessarily considerable, cannot be prudently incurred, unless the manufacturer be secure of an extensive sale. We could wish that our furnishing ironmongers would direct a portion of that power of invention which seems to be now almost exclusively occupied in contriving bad fireplaces, to the improving of the designs and lowering the price of cabinet furniture, by the judicious introduction of cast iron. Much, we are sure, will one day be done in this way. For a small cottage, a very useful corner umbrella stand, may be formed by bending a piece of stout brass, or iron wire, somewhat in the form of *c d* in fig. 727, and fixing it in the angle of the porch, immediately within the outside door; placing below a corner tray of tinned or cast iron, *e*, to receive the water from the wet umbrellas. The use of the wire is to prevent the wet umbrellas from touching the wall, and the use of the bends in it is to keep the umbrellas or walking-sticks apart.

692. A *Towel Horse* has generally one rail at top; but a double rail, as in fig. 728, is a great improvement; for, when a wet towel is thrown across both rails, the air has freer access to it, and it dries much sooner. It may be formed of deal, and should at all events be painted, for the reasons given when speaking of fixed towel rails, § 610.

693. *Clock-cases* for cottages may be harmonised both with the style of the building and that of the other furniture, by the lines of their mouldings and the forms of their panels. Figs. 729 and 730 are examples; the former in the Gothic, and the latter in the Grecian style.

694. A *Folding Screen*, for keeping off the wind, is required in most cottage kitchens, particularly such as have no porch or lobby. The most suitable, where there is room, is the settle, § 636, especially with the addition of Mallet's iron castors; but very light and efficient screens may be formed by two or more wooden frames, five feet high, and two feet wide, hinged with girth webbing or leather, so as to fold either way. The mode of hinging, so as to admit of this, is by nailing the pieces of girth which serve as hinges, alternately to one side of

the one hanging style, as at *a*, fig. 731, and to the opposite side of the other, as at *b*. Supposing two hinges done in this way, the two alternate ones should be nailed, as indicated by the dotted lines at *c* and *d*. A brass hinge, to answer the same purpose, has been lately invented by Mr. Vokins, architect and builder, of Wilton Road, London; several of whose ingenious inventions and contrivances we shall have to notice when speaking of Villas. The wooden frames for the screen may have canvass strained on them, in order that they may be covered with paper; or they may be covered with green baize, drugget, or any similar material, with a border of ferreting, attached by brass-headed nails, or bordered by the nails only. In case of the screen being covered with paper, maps, subjects of natural history, arithmetical or chronological tables, almanacks, or, in short, any kind of useful subjects, should be preferred, for the reasons given, § 584.

695. *Fire-screens* may be wanted in a cottage as well as in a palace. A lady has sent us a cottage fire-screen, made of straw, with a hook attached to it, by which it is hung on the back of a chair, fig. 732, which will answer very well when sitting with the back to the fire. To shield the face a standard fire-screen is required; but we shall leave the reader to contrive one for himself from the Designs, which he will find in another part of this work, under the head of Fire-screens for Villas.

696. *Clothes Horses and Stands for brushing Coats.* Clothes horses, for drying linen, &c., are open frames hinged in the same manner as folding-screens; and one or more of them should be found in every cottage, not connected with a public drying establishment. There are generally three horizontal rails to these clothes horses; one at top, one within two feet of the bottom, and one between. In a small cottage the clothes horse might be contrived to answer the purpose of a screen, by having a movable cover, either to slip on, or to be attached by hooks, or pieces of tape. Stands for brushing clothes are formed of a foot in the form of a Greek cross, with an upright piece firmly mortised into it at the point of intersection; into the top of which, about five feet from the ground, is mortised another piece, about two feet long, which serves as arms, on which is put the coat to be brushed. Where there is not room for a stand, the arms, with a post of six or eight inches in length, may be hinged to the back of a door, so as to fall down like a flap when not in use, and be supported by a bracket, or horse and rack, when a coat is to be brushed; or the form shown in fig. 733 may be adopted,

732

in which the jib bracket, *e*, works by two pins in *ff*, and the cross piece, *g*, also works on a pin in the upper part of the bracket; the holes, *h h*, are for slipping it on to nails fixed to any wall or door. Whatever kind of coat stand or horse may be used, there should always be a table at the command of the person brushing the coat, on which to fold it up, previously to putting it away.

697. *Children's Furniture.* To enable a mother who has no servants, to relieve herself at pleasure from carrying her child, there are various contrivances in use in England, which deserve to be mentioned; and there is one, for cleanliness and decency, which deserves imitation in every country, and more especially in our own. Fig. 734 is a swing chair, formed out of ten pieces of elder tree, *a*, six inches long, and an inch and

a half in diameter, with the pith burnt out with a redhot poker, or other iron; nine rails about a foot long, with a round hole at each extremity, *b*; a bottom board a foot square, with a round hole in each corner, *c*; and four sash lines or cords about a quarter of an inch in diameter, and of sufficient length to reach from the ceiling of the room in which the chair is to be hung. Knots being made on the ends of the lines, the tubes and rails are strung on as in the figure, and the other ends of the cords tied together and suspended from a hook in the ceiling. By omitting four of the cylinders and four of the rails, a chair may be made for an infant of the earliest age. A cushion may be put in the bottom, or the bottom may be stuffed. Fig. 735 is a go-gin for a child who can stand, to teach him to walk. It consists of a perpendicular shaft, long enough to reach from the floor to the ceiling, which turns in a hole in a brick or stone of the floor, and within a staple driven into the side of one of the ceiling joists, or by any similar means. The piece *d*, about eighteen inches long, is mortised into the upright shaft, about eighteen inches from the ground; and the wooden ring, *e*, about seven or eight inches in diameter, has a piece about six inches long, which is hinged at one end, and fastened with a hook and eye at the other. This opens, and the child being put in is enclosed at the height of the waist. The ring taking part of the child's weight, he cannot fall, and he soon learns to walk. Frequently this ring is made of twisted withy, fig. 736, with an eye at one extremity and a hook at the other: or each extremity is made to terminate in a loop, and when the child is put into the ring one of these is slipped over the other, and a hooked wooden pin serves to keep them together: in both cases the hinge is made like that of the handle of a basket. Both these pieces of furniture are made in England by every cottager for himself. Fig 737 is a hollow cylinder, nothing more than the section of the trunk of an old pollard tree, commonly to be met with in England; the inside and upper edge are smoothed, and a child just able to stand is put into it, while its mother is at work by its side, or going after the business of the house. Fig. 738 is a go-cart which is frequently made of willow rods without castors, but is here shown as a piece of carpentry, standing on castors. The ring, *f*, opens with a hinge, and shuts, and is made fast like *e* in fig. 735. Children readily learn to walk by these machines, without the danger of falling. Fig. 739 is a pierced chair, made entirely of wickerwork, which costs, complete, about London, only 4s. 6d., while there is a cheaper sort, with a rush bottom, at 2s. 6d. Every one who can make a basket can make a chair of this description. First form the skeleton frame, fig. 740; then commence round the circular hole in the centre, and work in either willow rods or rushes towards the extremities, according

to the kind of chair it may be wished to produce. The cover of the vase in the seat, *g*, is lifted off by two thumb holes, so as to be quite flat for the child to sit upon when the vase is not in use. There are two holes in the elbows of the chair, through which may be placed either simply a rod to keep the child from falling out, or a table flap, *h*, with two pins at the ends to fit into the holes; the table being also supported by a movable leg in front, and having a ledge round it for holding the child's playthings; its pins being kept in their holes by the elasticity of the sides of the chair. In England the cottager's child is placed on a chair of this sort after he is a week old; but in Scotland there is neither this chair, nor any substitute for it. In both countries there are small chairs with long feet, for elevating children to the height of an

ordinary table, so that they may sit and eat with their parents; and these, like the pierced chair, ought to be universally in use.

698. *Other articles of furniture* might be enumerated, and various hints given for the selection of household utensils and instruments, but we are doubtful whether in this work they would be seen by those who would feel most interest in them, or to whom they would be most useful. A washing and wringing machine, such as we shall figure in our next Book would be too dear for one cottager; but we would strongly recommend that half a dozen cottagers should join in purchasing one; as it would afford a great saving of labour, and that, too, of the most oppressive kind, to the cottager's wife; since wringing is, to a female, almost as great an exertion as mowing is to a man. Washing-tubs have hitherto been chiefly made round, and by the cooper, probably to accommodate the form to the ancient practice of washing by treading with the feet; but oblong troughs are much cheaper, and far more convenient. — Every house whatever ought to possess the means of filtering the water used in cookery. We have shown how this may be done on a large scale, § 31 and 305; on a small scale, the operation may be performed with a common garden flower-pot of a foot or more in height, according to the impurity of the water to be filtered. Over the hole in the bottom of this flower-pot should be placed a piece of sponge; around and over which should be put two or three pieces of smooth clean stones, to keep it in its place, and, at the same time, to prevent the pressure of the filtering materials (to be placed over them) from rendering the sponge so compact as not to allow of the escape of the water. Fill the pot, when thus prepared, to within two inches of the brim, with a mixture of one part of powdered charcoal, and two parts of clean sharp sand, and on the top of this lay a piece of flannel, letting it sink in the centre, but making it fast on the outside of the pot, by a string tied tightly under the rim. The upper surface of the pot will now form a shallow basin, lined with flannel, into which the water to be filtered is to be poured, and it will be found to come out rapidly at the bottom, quite clear. As the flannel will intercept the grosser impurities, it should be taken off frequently, and washed and replaced; and two or three times a year the sand and charcoal ought also to be taken out and washed. This will be found absolutely necessary; for the purification is effected simply by the filtering materials attracting the impurities in the water; the sand the earthy particles, and the charcoal those of organised matter. From this use of the charcoal the reader may learn to increase or lessen its proportion, according to the nature of the water to be purified. — When a cottager keeps a cow, he will require a churn, and one of the cheapest and best is the patent box churn which may now be had at Weir's manufactory, London, for £1. Butter may be made in this churn with a fourth of the labour requisite with the common plunge churn; it is, besides, much more easily used, and when not wanted as a churn, makes an excellent vessel for holding water. In the choice of utensils much depends upon knowing when to choose iron, and when wood, earthenware, or papier maché. Cast-iron pots, tea urns, tea and coffee pots, and parlour candlesticks, are excellent; but iron tea trays are bad, as compared with those of papier maché, because one of the latter will last out a dozen of the former. The same may be said of all vessels of copper or pewter, as compared with those of cast iron. It must never be forgotten that copper, pewter, and lead vessels sell for nearly as much by weight, when old and worn out, as when new, and that even cast iron will sell for something, but that vessels of wrought or turned iron, when worn out, are of no value at all. Spoons, forks, and other articles, made of a composition of nickel and other ingredients, and known under the name of German silver, or of Beauchamp's British plate, may be recommended as very good substitutes for real silver.

699. *Pictures, Sculptures, and other internal Ornaments.* There is no cottage or dwelling, however humble, in which there will not be found some object purely ornamental: we have observed this to be the case in the most wretched log-houses in Russia, where engravings of the rudest kinds, and sometimes fragments of glass or earthenware, such as no one would think worth picking up in the street in England, are placed in rooms which cannot boast of either chairs, tables, or beds. The occupants of these hovels sleep in their sheepskin clothes, on the stove in winter, and on the floor or out of doors in summer; and their seats and tables are wooden forms or turf benches. It seems, at first sight, difficult to account for a taste for ornament existing among people so circumstanced; but the truth is, that man, whether in a state of barbarism or refinement, is essentially the same animal, and ornaments his home, because he loves it, and wishes to render it agreeable. The trumpery of the Russian boor, and the pictures and statue of the English gentleman, are collected and displayed exactly on the same principle. It is clear, therefore, that every cottager must have ornaments in his house, as well as flowers in his garden; and, since whatever it is worth doing at all, it is worth doing well, we strongly recommend him to cover his walls with the best engravings he can get, and to ornament his chimney-pieces with handsome plaster or terra cotta casts. Such articles may now be had for a mere trifle; for example, alto relievo plaster portraits, on

tablets six inches or eight inches square, of eminent men, remarkably well cast, may be had in London by retail, at 6*d.* each; casts of Venus, Cupid, Adonis, and of various celebrated antique statues, eighteen inches or more high, may be had at 5*s.* each; busts of a large size may be had at the same price, and Swiss figures in terra cotta at 2*s.* 6*d.* each. By sizing over plaster casts when they are first bought, and quite clean; and afterwards, when the size is perfectly dry, washing them over with copal varnish, they may be made to look almost as beautiful as marble sculpture. (*Mech. Mag.*, vol. xiv. p. 96.) Excellent engravings of subjects of every description may now be had for a few halfpence each: the commoner sorts the cottager may paste on the back of his settle, fig. 636, § 636, or kitchen screen, and varnish them; and the better kinds he may frame with common deal, painted to imitate maple, and either glaze or varnish them according to his means. When there is a good broad chimney shelf, there will be room for other ornaments of a smaller description than busts or sculptures, such as curious stones, spars, ores, or other minerals, or coins, and objects of art and antiquity; and these the cottager will collect as he can. The public taste for articles of this description has improved in an astonishing degree within the last twenty years; and, as knowledge spreads, and the working classes acquire that leisure which, in consequence of this spread of knowledge, will become a necessary of life to even the most hard-working country labourer, this improvement will increase. But the objects with which, above all others, we should wish to see the cottage ornamented are books; and every room, even the kitchen and bed-room, ought to have its book shelf. If we were asked what sort of books we should recommend generally to the cottager, meaning in this term to include the very humblest class of society, as well as the more elevated, we should reply that, as our aim is to render him free and independent alike mentally as physically, to fit him in short for taking care of himself, we recommend, first and principally, works on morals and politics: the former, that he may know the principle on which the social duties of all individuals are founded; and the latter, that he may learn the use and duty of public government. Next, we recommend books on his own art, trade, and manner of living; and, for the rest, we leave him to his own taste. Every cottager ought to possess a general encyclopædia, and to take in a newspaper. The penny magazines, and other cheap literature of the present day, though more calculated to amuse the cottager, than to instruct him how to improve his condition, will end in creating a demand for something better.

700. *Remarks.* Some other articles of furniture and decorations suitable for cottages might be enumerated; but we have, we think, done enough, in Designs both for cottages and furniture, to prove the assertion with which we set out (§ 14), that all that is essentially requisite for "health, comfort, and convenience, to even the most luxurious of mankind," may be obtained in a cottage, the walls of which are of mud, as well as in a palace with walls of marble; in a working man's college of one story, as well as in the magnificent halls of Oxford and Cambridge, or in the elegant club-houses of London. A number of our readers will, no doubt, object to many of our Designs, both of cottages and furniture, as being beyond the reach of the great majority of British cottagers; but let such recollect that, in our Introduction to the Book of which this is the conclusion (see § 13), we included under the term cottager, not only labourers, mechanics, and country tradesmen, but small farmers and cultivators of their own land; and the gardeners, bailiffs, land stewards, and other upper servants, on gentlemen's estates. Let them consider, also, that our plans and views extend to both hemispheres (see § 1); and that the citizen of America, who thinks with his countryman, Dr. Dwight, that all private dwellings should be as much as possible alike in accommodation, and that architectural display should be confined, as in ancient Greece, chiefly to public buildings, may on his part not only find the Designs given not too good, but may even object to our making any distinction between Cottages and Villas. The British cottager or workman is, no doubt, at present in a widely different situation from the American; but we anticipate for him a new era, and a condition very different from that in which he now is, at no great distance of time. All the evils which have so long afflicted him have arisen from his own moral and political ignorance, and from his consequent incapacity for self-government, either individually or collectively; and they will be dispelled by the education of the rising generation, and the new order of things which will thenceforth be established. The working classes will then be able to take care of themselves; and never, till this shall be the case, will they obtain those comforts and enjoyments which ought to be in the possession of the industrious labourer, as well as of the wealthy capitalist. Every country is essentially the property of its inhabitants; and it is only in ages and in countries where education is partial or unequal, that wealth and the enjoyments of life can be very greatly different.

## BOOK II.

## DESIGNS FOR FARM HOUSES AND FARMERIES, COUNTRY INNS, AND PAROCHIAL SCHOOLS.

701. *The Designs which compose this Book* are calculated for three of the most important occupations of man in civilised society; viz., that of raising food on a large scale; that of furnishing all domestic comforts to travellers and others, who are absent from or have no home; and that of the education of youth. The last subject does not necessarily belong to an *Encyclopædia of Domestic Architecture*; but, as our main object in this work is the amelioration of the great mass of society in all countries, and as we consider education as the source of all amelioration, and, in fact, as the only means of preparing the most depressed part of society for appreciating and obtaining the comforts and conveniences which we are pointing out to them, we find that the parochial school, for the purpose of mutual instruction, is the most important feature for the accomplishment of our object; and, as such, ought not to be passed over unnoticed in a work like the present.

702. *The Arrangement of these Designs* will be in three chapters; viz., on Farms, on Inns, and on Schools. The first section in each chapter will consist of Fundamental Principles and Model Designs, on which the Miscellaneous Examples given in the second section of the same chapter are founded; and the third section of each chapter will be devoted to such Furniture as may be peculiar to the class of subjects of which that chapter treats.

---

 CHAP. I.

*Designs for Farm Houses and Farmeries, exhibiting various Degrees of Accommodation, from the Farm of Fifty to that of One Thousand Acres, suitable to different Kinds of Farming, and in different Styles of Architecture.*

703. *A Farm House* differs from other dwellings, more in the circumstance of its situation, being adjoining a farmery, than in its accommodation; but still there are some extra-arrangements, which require to be provided for in designing it, according to the kind of produce raised on the farm, the manner in which it is manufactured or disposed of, and the mode of lodging the labourers employed.

704. *A Farmery*, or set of buildings necessary for carrying on the business of a farm, consists of various structures and enclosures; some for lodging animals, and others for securing farm produce, for keeping farm implements, and for other purposes; with yards for enclosing cattle, and for preparing or keeping manure; others for containing ricks of corn, and stacks of hay, or other produce. The house in which the farmer resides is no essential part of a farmery, and is therefore left out of view in this enumeration of its leading features. These features are three: the buildings, the court-yard, and the rick-yard. The rick-yard does not form an essential part of the farmery; because but little inconvenience would result from having the ricks placed apart from the farm; and, indeed, in some parts of Britain the produce of every field is formed into a rick, or ricks, in one of its corners. The two essential parts of a farmery, then, are the buildings and the court-yard; and all the variations of which these are susceptible, in point of design, are founded on their relative position with regard to each other. Thus, all farmeries may be included under two classes; viz., those in which the buildings surround the court-yard, and those in which the court-yard surrounds the buildings; and a model of each mode must necessarily be the groundwork of every variation or combination of the component parts of a farmery.

705. *The Divisions of the Buildings of a Farmery* admit also, to a certain extent, of being founded on model plans; because the animals which, in temperate climates, are to be lodged in them, are every where of the same species, and require the same extent and kind of accommodation and food; because the manner of threshing out grain is, or may be, the same throughout the world; and because the implements to be worked by the same animals cannot differ greatly in bulk in different countries. Previously, therefore, to giving Model Plans for Farm Houses and Farmeries, as a whole, we shall submit General Principles, and give Model Designs and Directions, for the construction of their component parts.

706. *Every particular situation and kind of Field Culture* requires an appropriate arrangement in its Farmery; therefore our object, in giving Model Designs, is chiefly to embody principles in a tangible shape, to which practical men may recur for general rules for application to peculiar localities. The manner of applying these rules we shall

exemplify in a series of Miscellaneous Designs for Farm Houses and Farmeries, most of which have been executed in different parts of Britain, and some in France.

707. *The Arrangement of the first two Sections of this Chapter*, therefore, will be in the order of General Principles with Model Designs, and Miscellaneous Designs with Details and Remarks.

SECT. I. *General Principles and Model Designs for Farm Houses and Farmeries.*

708. *The object of this section* is to show what parts of a farm house are peculiar to it as such, and the best mode of constructing and arranging these; what are the details of a farmery, with the relative position for each object there; and what is the best arrangement for a Farm House and Farmery, as a whole.

SUBJECT. I. *General Principles and Model Designs for the Arrangement of a Farm House.*

709. *The Interior of a Farm House* may be arranged in three divisions: viz., the apartments of the family, including such of the servants as live in the house; the rooms for farm-house stores; and the places where the in-door business of the farm house is carried on. In farm houses of the smallest size, all these may be obtained under one roof; but in the case of large farms, where fifteen or twenty persons live on the premises, all those offices, or places, in which the in-door business of the farm house is carried on, such as the dairy and its appendages, the cider-house, the brewhouse, the bakehouse, the wash-house, and the cleaning place, ought to be in a building or buildings separate from the house, but not far distant from it. Cellars of most kinds, however, such as those for potatoes, and other roots or vegetables to be used by the family; for fruits; and for beer, ale, wines, &c.; and the larder, pantry, and coal-house, may be in the same building as the farm house.

710. *Of the Apartments for the Family* we need enter here into few details in addition to those which have been given in the preceding Book. The number of living-rooms in a farm house will depend on the extent of the farm, and on the style in which the farmer chooses or can afford to live. The smallest farm-house should have at least one good parlour; and for a farm of 300 acres or upwards, of good productive soil, there ought to be in the dwelling-house, at least two good sitting-rooms, and a small library or office for business; besides three or four bed-rooms, and a nursery. In farm houses where it is the custom to board and lodge the out-door labourers, a larger kitchen will be required for them to dine in, and a larger kitchen range to cook their food. More bed-chambers will also be necessary, and these should always have a separate staircase from that leading to the better rooms. In some parts of Britain where the farmer and his out-door labourers are nearly on a par in point of intelligence and manners, they continue to dine at the same table in the kitchen. This is by no means the practice in districts where the farmers are highly intelligent, and superior in their manners to their servants, as, for example, in East Lothian; but when the latter are raised nearer to the level of the former by the universality of education, this excellent patriarchal practice will in all probability be restored.

711. *The Sleeping-Rooms for unmarried Farm Servants*, in most parts of Britain, are generally such as merit extreme reprobation. Those of the men are frequently in lofts over stables or cow-houses, without light, or sufficient space for air; subject to the deleterious exhalations arising from horse or cow dung; sometimes badly ventilated, and at other times under a roof insufficient to exclude the wind and the rain. Female servants are lodged in-doors, but often in damp back-kitchens, store-rooms for the coarser articles, harness-rooms, dark closets, or low, ill-ventilated garrets. "I am sorry," says the excellent and benevolent Mr. Waistell, when speaking on this subject, "that the health of servants is often less attended to than the health of cattle. Too often," he adds, "there is neither chimney nor window by which to ventilate servants' bed-rooms, and when there is no window they are not likely to be properly cleaned. What renders them still worse is, their being partly occupied as store-rooms for green fruit or bacon, or for drying new-made cheese: the effluvia from all these articles contaminates the air, and renders it greatly injurious to the health of those who breathe it; indeed, all strong-scented bodies, placed in bed-rooms, are more or less pernicious. I shall, therefore, enumerate," he continues, "a few more of those things from which farmers and their families not unfrequently suffer in their healths, without being, perhaps, at all aware of their pernicious effects. The air of rooms is rendered unwholesome by keeping in them oil, oil colours, impure wool, sweaty saddles, soap, tallow, fat, fresh meat whether raw or dressed, wet clothes and other wet articles; by foul linen, washing, drying, and ironing; by the fumes from charcoal fires, which are extremely pernicious, and frequently fatal; by green plants, and flowers however fragrant; and by saffron and hops, which last articles, Dr. Willich says (*Encyc. of Dom. Econ.*), have also sometimes proved fatal." (*Waistell on Agricultural Buildings*, p. 22.) There is no department of farm architecture

in which reform is more necessary than in the rooms appropriated to unmarried servants; unless, indeed, it be in the cottages of the married ones. The state of both in Britain is disgraceful to the farmers and their landlords.

712. *The Places in which the ordinary Farm-House Stores are kept* are, the potato or other root-cellar, the cabbage-cellar, the liquor-cellar, the fruit-room, the cheese-room, the larder, the pantry, and the coal and wood cellar. In general, all articles that are not frequently wanted are better kept in a dry cellar than any where else, because they are there less subject to atmospherical changes. If cellars, however, are damp, they are unfit for storing up any thing except liquors in glass or in earthen vessels.

713. *In the Construction of Cellars* the first thing is, to provide such a drainage as will draw off the water at least one foot lower than the surface of the cellar floor. If the soil be naturally wet, this floor, which should be of flag-stones or tiles, should be laid hollow; the walls should also be built hollow, and, if convenient, with a powerful cement, rather than with common mortar; or, at least, they ought to be coated over with cement in the inside. In all very cold or very hot countries, provision should be made for double doors and double windows, even though the inner window should be nothing more than a boarded shutter; and the windows, in all such cases, ought to fit tightly. The space between the double windows need not be more than from six inches to a foot; but the space between the double doors ought to be at least three feet, so that the one door may always be shut before the other is opened. In cellars so constructed, even ice, enveloped in abundance of straw, might be kept without danger of melting; and it is so kept in most of the confectioners' cellars in London. As cellars are not places to live in, they need not necessarily be made higher than seven feet. In general they are better underground, and arched over with masonry; but the same results may be obtained above ground by double walls, very small and double windows, double or thickly thatched roofs, and double doors.

714. *The Potato and Root Cellar* may be under the floor of some part of the house, when the soil is dry naturally, or capable of being rendered so by drainage. The opening by which the potatoes or other roots are introduced should be on the outside of the house, and not higher than the level of the ground, in order that a cart may be set back against it, and the potatoes or other roots shot out and shoveled down the opening. This opening should have double shutters, in each of which should be at least one pane of glass, to admit sufficient light, and yet effectually to exclude the cold in winter and the heat in summer. The panes of glass should be in the upper part of the shutters, so as to be protected, by the lintels of the windows, from the direct rays of the sun; but, if the opening be to the north, this precaution is unnecessary. The size of a root cellar, where the roots are merely for the consumption of the family, need not be large: ten or twelve feet square, and seven or eight feet high, will be sufficient dimensions in a house calculated for from twelve to twenty persons. When there are different roots to be stored in the same cellar, they may be separated by temporary partitions of boards.

715. *A Cabbage-Cellar* is a common appendage to a farm house in Germany, and might well be introduced in Britain and North America. It may be formed either above or under ground, provided it can be rendered quite dry, and lighted by one or more windows, with double sashes, about six inches apart, to guard against extremes of temperature. This cellar ought to be twice as large as the other, because the manner in which the cabbages and other articles are disposed in it requires a good deal of room. The common method is, to cover the floor with soil to the depth of a foot, and to plant in it, at the commencement of winter, full-grown cabbages, broccoli, lettuce, endive, &c., as close together as they can be placed without touching each other. Water is given occasionally in the course of the winter, and the greatest care is taken to remove every leaf as soon as it shows symptoms of decay. The improved method which is adopted in the better description of cabbage cellars is, to surround the cellar with shelves about eighteen inches in width and three feet apart, which, if convenient, may be formed of flag-stone or slate, or, if these materials are not to be had, of strong wood. On these shelves are placed layers of earth, with alternate layers of cabbages or other vegetables; with their tops projecting beyond the shelf, and their roots and stalks bedded in the soil. Where the soil is of a sandy nature, bricks, moss, straw, or some other suitable material, should be introduced in the front part of the soil, to keep it up. Not only the cabbage family, but the lettuce, endive, celery, beet, sweet herbs, and a variety of other culinary vegetables, are kept in this manner from October till May, in Bavaria, Wirtemberg, Baden, and other states. In very severe weather, or when the air is more than usually humid, hot embers are placed on the floor to raise the temperature, or dry the air; or, when the cellar has a chimney-flue, which is the preferable mode, provided it be kept shut when not used, a fire may be made in a small iron stove.

716. *A Cellar for forcing some kinds of Culinary Vegetables* might be formed in every house, merely by placing an iron stove in any cellar sufficiently protected by external

walls. Light is not necessary. In boxes or pots, or in beds of earth on the floor, or on shelves, may be placed roots of tart rhubarb for its footstalks; succory for its leaves; hops for their tops, as a substitute for asparagus; asparagus roots, sea-kale, &c. Potatoes might also be placed in such a cellar, to make them throw out fresh tubers; but, as the young ones so produced would be merely a transfer of nutriment from what we consider a better to a worse state, we cannot recommend the practice as one of utility. Were light admitted into a cellar of this description, mustard, cress, and other small salading might be grown; and roots of parsley, mint, and other herbs, and of beet, sorrel, and other spinaceous plants, for their leaves, might be planted. In short, a good dry cellar with double doors and windows, might, with very little trouble, be made to produce a great many articles of convenience and luxury for the table, which are now grown in glass frames, or hot-houses, at very considerable expense. Every body knows that mushrooms can be grown in a cellar better than any where else. We do not, however, recommend the practice of forcing for general adoption; thinking it, with a few exceptions, in better taste to take the vegetable productions of nature or art in the open air, by turns, in their proper seasons. Our exceptions are, tart rhubarb, sea-kale, asparagus, mushrooms, succory, and small salading; all of which are as good, when forced, as when grown in their natural climate.

717. *A Fruit-Room, or Fruit-Cellar*, is essential to every farm which has an orchard; and no farm ought to be without one where fruit will grow. The great art in preserving fruit is, to keep it dry, and, at the same time, so as to prevent evaporation from its surface; for this last purpose, all change of temperature and moisture in the air must be guarded against. The simplest mode of effecting these objects is, to place the fruit on a thick bed of dry straw, and to mix and surround it with an ample mass of the same material in any situation dry and protected from the weather; but a better method is, to place the fruit in a dry cellar, on a layer of dry sand, and to cover it with the same material, or with fern, finishing with an upper layer of straw. The superiority of the sand consists in its coolness, and comparative freedom from air, by which the fruit is less liable to wither. Where there are several kinds of fruit to be kept in one cellar, shelves may be employed; and if the cellar be not often entered, so as to admit air of a different temperature or degree of humidity, the fruit need not be covered at all, or may only have fern strewed over it. Where the situation does not admit of an under-ground fruit-cellar, a fruit-room may be formed above the surface, with thick or hollow walls, and double doors, windows, and roofs. The size for a fruit-cellar, on a farm of even considerable extent, need seldom be more than an area of ten feet on a side, and seven feet high.

718. *Cellars for Liquors*, including ale, beer, cider, wine, and spirits, are essential to every farm house. In even the smallest there ought to be one cellar for beer, empty casks, brewing utensils, &c.; and another, opening out of it, for ale, wines, and spirits. The area of the former, in the smallest farm house, should not be less than twelve feet by twelve feet; nor that of the latter less than six feet by eight feet. The beer-cellar, and that part of the wine-cellar which is to contain ale, should have brick or stone benches or shelves built solid, or on arches or piers about two feet high, on which to place casks, for the greater convenience of drawing off their contents. That part of the inner cellar which is to contain wine should be fitted up with cells, or bins, one above another, of about two feet broad, and the same height, and of any convenient depth, provided it be a multiple of the height of a common wine bottle. A part of the wine-cellar should be fitted up with stone shelves, for spirits or other liquors, and for various articles which are best preserved in the temperature of a cellar.

719. *The Larder and Pantry* are conveniently placed near each other, and close to the kitchen. Both ought to face the north; and the former more especially ought to be thoroughly ventilated, by openings near the floor on one side, generally in the lower part of the door, and near the ceiling, generally in the outer wall, on the other. Both larder and pantry should be fitted up with shelves and hooks; and the larder may have a wooden grating or cradle, called a rack, three or four feet wide, about one foot deep, and of any convenient length, suspended from the roof, for the purpose of holding bacon. In old farm houses these racks are generally placed in the kitchen, but in very large establishments, or where bacon forms the principal animal food of the labourers, as it does in the midland counties of England, there is often a separate room fitted up with racks and shelves, set apart for keeping it.

720. *A Salting-Room* is necessary in every house where the farmer occasionally kills his own meat. The effluvia from this room being both disagreeable and deleterious, it should, when convenient, form one of a detached group of buildings. In small establishments, or where only a part of the meat used is killed at home, an airy cellar, facing the north, may be employed. The room should be fitted up with strong benches for cutting up the meat, and salting it on; and fixed long shallow troughs, generally lined with lead, for holding the sides of bacon, &c., while in pickle. These troughs should be provided

with cocks, or holes with plugs, at the bottom, for the purpose of drawing off the brine, and cleaning them; the brine, when boiled and skimmed, being fit for use several times. Smaller troughs, or round earthenware pans, are generally employed for holding tongues, pieces of beef, and other smaller articles; and the whole should be carefully provided with the means for being kept clean, by having pipes of water conducted into it, and the floor arranged so as to have a gradual inclination towards a corner, having a trap and drain.

721. *The Coal-house and the Wood-house* should always be adjoining the kitchen or back kitchen, and both should be perfectly dry; since whatever moisture is added to fuel, beyond what it contains in combination, must be driven off before combustion can take place; and this must always occasion a certain loss of heat. Both places ought to be of considerable size, because in well regulated farms there are only certain periods of the year when the farmer finds he has leisure to bring fuel from a distance, and to store it up: he will also by the same means be enabled to take advantage of a temporary depression in the fuel market.

722. *A Tank, or a Well for Water*, is essential to every farm house, independently of the provision of water for the farm-yard; but we have already sufficiently enlarged on this subject in § 30 and § 151; and the subject of supplying water to the farm-yard will occur hereafter.

723. *A Place for brushing Clothes, and cleaning Knives and Shoes, &c.*, should form part of the arrangement of every farm house; and as this is necessarily a place where much dust and dirt are generated, it should be kept apart from the house, and especially from the back kitchen, which is too generally made use of for these purposes. As a mere open shed, which every countryman may erect for himself, will suffice for a cleaning place, there can be no sufficient excuse for not having one adjoining every farm house; and, indeed, every labourer's cottage or human dwelling whatever. Conveniences of this sort, which are within the reach of every one, and which may be obtained rather by thought and contrivance than by expending any considerable sum of money, are indeed some of the distinguishing marks of a high state of civilisation and refinement. A savage is satisfied with mere food and shelter; and, if he pretends to more, takes delight in showy or gaudy ornaments; but the man whose mind has been enlightened by education prefers simplicity in decoration, and only employs his leisure time and money in contrivances to lessen human labour, and obtain the greatest possible proportion of comfort which his opportunities will permit. Ample apartments and sumptuous furniture can be obtained but by few, and, as they contribute little to happiness, are not worthy of becoming objects of ambition to any rational being; but a clean, comfortable, and well arranged home is an essential ingredient in human happiness, and, as such, ought to be sought after and obtained by every one. Cleanliness is also essential to health; and this blessing, so desirable in every condition of life, is particularly so to a labouring man, as without it he cannot perform his daily toil.

724. *The Wash-house, Bakehouse, and Brewhouse*, in small farms, are commonly all united in the back kitchen; but in extensive establishments they, together with the laundry, dairy, cheese-room, cider-house, salting-room, and smoking or curing room, should be in a building or buildings apart from the house, but connected with it by a covered way.

725. *The Wash-house* should be well lighted; and therefore, if united with other offices, it should, if practicable, be made a corner building, and have windows on two sides. Instead of portable round tubs, which, as noticed in the preceding Book, are the most inconvenient of all the forms that could be devised for washing by hand, oblong troughs, about three feet in length, eighteen inches wide at top, one foot wide at bottom, and eighteen inches deep, should be fixed round the two lighted sides of the room. Each trough should have a hole and stopper in the bottom; and close under these holes should be a gutter, common to all the troughs, which may convey away the waste water to the manure tank. In one corner or side of the room the boiler should be placed; and over it a supply pipe from a cold-water cistern. Pipes may be conducted from both the cold-water cistern and the boiler, so as to deliver, on turning cocks, cold or hot water, at pleasure, into each trough. The main part of the washing, however, we should propose in all cases to be done by a washing-machine, of which we shall hereafter give an improved Design; and this, with a pressing or wringing machine hereafter, may be worked by a horse or steam power, which may also be applied in churning and other operations, to be carried on in this department of the farm offices. The floor of every washing-house ought to be very carefully paved, with an inclination of an inch in a yard towards one corner, in which there ought to be a trap drain leading to the manure tank. This inclination, which will hardly be perceptible to the eye, or recognised in standing or walking, will yet be most useful, by directing all the water, which must be occasionally spilt on the floor, to the point where it will be carried off. Close under the ceiling there ought to be several openings communicating with the open air, to carry off the steam, and

in the bottom of the door there ought to be correspondent openings to admit fresh air : both openings ought to have shutters sliding in horizontal grooves, with hooks in them, so as to admit of their being easily drawn back, or pushed forward.

726. *The Laundry*, the business of which in small dwellings is generally performed in the kitchen, may be very conveniently placed over the wash-house ; and, like it, should have windows on two sides, and ventilators under the ceiling, and in the bottoms of the doors. Against the two lighted sides, tables or flaps for ironing on may be fixed ; and in the corner behind, directly over the boiler, may be placed a drying-closet ; which may be partly heated by the flue from the boiler, and partly by the requisite ironing-stoves, or by a steam-pipe. If the laundry should be placed on the same floor with the wash-house, it should adjoin it, so that the back of the boiler fire may heat the drying-closet. In this closet the clothes may be dried by the arrangement described § 306. Where a drying-closet is not used, the clothes may be dried, as is usually done, in the open ironing-room, either on common clothes horses, or on rails suspended from the ceiling by ropes and pulleys, so as to be raised or lowered at pleasure ; or by lines stretched across the room, which may also be raised or lowered by means of pulleys. The last mode may be very completely effected by having the pulleys to work in vertical grooves, or in hollow rods similar to that invented by Mr. Vokins for hanging pictures, to be hereafter described. The mangle may stand in the middle of the room, or on the dark side not occupied by the drying-closet.

727. *The Bakehouse* should be close to the wash-house, in order that their united flues, with those of the dairy, scullery, and the brewhouse, may form one stack. The bakehouse may have light on one side only. The oven should be lined with fire-bricks ; and immediately without its iron door there should be a grating over an ash-pit, for the reception of the ashes when it is cleared out. Height in an oven is of no use, but rather tends to bake the bread unequally : eighteen inches will generally be found sufficient for private ovens, and the length and width need not be more than three or four feet. Against the light side of the bakehouse should be placed a flap or table, for making up the loaves on, with a kneading-trough close to it ; and near the kneading-trough should be a flour chest or cask. If a kneading machine be employed, which for large families ought always to be the case, not only from the saving of labour, but from the greater certainty of cleanliness, and the more thorough working of the dough, it should take the place of the kneading-trough. In the largest private establishments it may also be found worth while to construct the oven on Hicks's plan, so as to be able to condense the spirituous vapour produced from the dough while baking. The plan will be found detailed at length in the *Repertory of Arts*, new series, and in *Mech. Mag.* vol. xiv. p. 417.

728. *The Brewhouse*, for the reasons before given, should adjoin the wash-house and the bakehouse. It should occupy two floors, in order that the malt may be placed in the upper floor, and be conveniently put through a shoot into the boiler, which should be near the ceiling of the lower room, to allow of the liquor or wort being conducted from its bottom by pipes or tubes to the coolers, which again should be sufficiently raised from the ground floor to allow of casks being placed under them, so as to be filled without trouble ; or, where it is practicable, a small pipe may be conducted at once from the coolers to the beer-cellar in the house. Where the cellar is under the brewhouse, which, however, is seldom desirable when the latter is detached from the farm house, the same arrangement may be adopted as that mentioned § 498.

729. *The Dairy* is one of the most important of farm-house offices, and yet it is seldom properly constructed. The desiderata are, equality of temperature during every season of the year ; and frequent renewal of the air, so as to have it perfectly fresh and sweet. Equality of temperature is easiest obtained when the dairy is under ground ; but in this case the ventilation is insufficient to supply the other desideratum. Where the dairy is in a detached building, a compromise between a cellar and a room above the level of the ground may be formed by sinking the dairy two or three feet, and covering the outside of the walls and the roof very thickly with thatch ; or by forming the walls hollow, and raising against them a bank of earth covered with turf. One of the most complete modes is, to form the walls hollow, and to throw over the room two or three arches of masonry, one above the other, covering the whole with a mound of earth, like that of an ice-house, but with proper windows for light and ventilation, protected from the covering mound by projecting side walls, with lintels or arches over them of corresponding depth. The windows, in this and in every case, should face the north, or north-north-east, or north-north-west, and should be double ; the outer window fixed and of wirecloth, and the inner one of glass and to open. There should also be double doors, and the space between them should not be less than three or four feet. In both doors there should be panels of wirecloth, to exclude the flies, and yet admit the air. In the most severe weather of winter, the wirecloth of both doors and windows may require to be protected by temporary shutters of either mats or boards.

730. *Where the dairy is connected with a group of other farm-house offices, including the dairy scullery, cheese-room, cheesepress-room, &c., it may occupy the north angle, or part of the north side of a square mass of building.* The walls should in this case also be double, and the windows should be treble; the outer one of wirecloth, and the two inner ones of glass. There should be double doors, and care should be taken that one should always be closed before the other was opened, and that neither should ever be left open for more than a few minutes at a time. To compensate for all inequalities of temperature, there should be a power of introducing a stream of water to run through the dairy, or spring water from a well, tank, or spring, so as to cover the whole of the floor, or to sprinkle it and the shelves, at pleasure, and thus reduce the temperature of the air in summer, or raise it in winter. To do this more rapidly, part of the floor may be perforated, and from each small hole a jet of water may be contrived to rise, on turning a cock; or perforated pipes may pass under the dairy shelves, and under the middle part of the ceiling; and from these there may be a power of producing an artificial shower to raise or lower the temperature at once. The process of introducing water in this way, either from the floor or from the ceiling, may seem at first intricate and expensive; but whoever has seen it done in Messrs. Loddiges's palm-house will allow that it is neither. We shall give some details hereafter, when speaking of fountains for villas. Common lead pipes, of half an inch in diameter, may be used; and the perforations may be made with a stout sewing needle. The only matter of expense is the tank, or cistern of water, which should be so placed as to maintain the same temperature throughout the year; and at the same time be above the level of the dairy ceiling, so as to give due force to the delivering pipes. If, however, the dairy be properly constructed, and a power contrived for flooding its floor with water (and, if no permanent jet can be made, this may be done by a common watering-pot), the two grand desiderata may in every case be certainly and economically obtained. The floor should be accurately paved, and should slope to a trap drain in the corner, as before directed for the washing-house. The shelves and benches should be formed of thin flag-stones, or slates, or of wood covered with lead; the walls and ceiling should be plastered with cement, or coated with a firm-setting mortar, or should be inlaid with glazed tiles. The milk-pans are better portable than fixed; because, if fixed, they must be scalded in the dairy; and hot water should never be introduced into it, in summer at least, on account of its raising the temperature. Even milk directly from the cow should be allowed to stand to cool in the dairy scullery, before it is taken into the dairy; because its temperature, when in large quantities, either in summer or winter, would soon raise that of the apartment. A thermometer should be kept in the dairy, and the temperature should be never allowed to fall below 50°, or rise above 55°; experience proving that most cream is thrown up by milk in a medium between these degrees. If at any time in winter the temperature of the dairy should fall too low, vessels of hot water may be carried in and set down on the floor, or the milk, in such a case, may be sent in direct from the cow. No articles of food, but milk, cream, and fresh butter, should ever be kept in a dairy; nor, as Waistell tells us, should any thing that has a strong scent, even though it may be sweet, be placed in or near it. "Bad scents," he says, "greatly lessen the product of butter dairies, by preventing the complete separation of the cream from the milk." It is also certain that raw meat, if kept in a dairy, has such an effect upon the cream as to prevent the butter produced from it from keeping. This, and the facts stated by Waistell, it is difficult to account for, but not more so than others equally well ascertained; such as the influence which the leaves of certain milky-juiced trees, such as the papaw tree and the fig for example, have in interenerating fresh meat.

731. *The Dairy Scullery* should be near the dairy, though not immediately adjoining it; it should have a boiler for heating water, and two underground pipes with traps; one for foul water, communicating with the liquid manure tank, and the other for waste milk, communicating with the pigs' food tank. From the latter pipe there may also be a communication with the dairy; because it may sometimes be advisable to empty out milk there, without bringing it into the dairy scullery. The churning may be carried on in the dairy scullery; for which purpose, on a large farm, provision ought to be made for the introduction of a shaft from a horse or a steam power for working the churn. There ought to be fixed benches and movable forms, for setting milk-pans and other dairy utensils on; and a portable rack with a wheel and two feet like a wheelbarrow, for draining the pans and pails, and wheeling them out to a shed to dry. Figs. 741 to 746 show a Design for a double dairy, which will keep the produce at a proper temperature, in whatever climate it may be built. It may also, with very little alteration, be partly or chiefly used as an ice-house, or as a wine or ale cellar. We shall first describe it as a dairy. Fig. 741 is the ground-plan, in which *a* is an outer room, for airing and drying the utensils, or for drying cheese; being warmed by an open fireplace at *b*, and lighted and ventilated by two windows, *c c*, beneath which are two elevated sinks, *d d*.

close to one of which is a Siebe's pump, from a well or tank common to the whole dairy. It will be observed, by the five steps at *e*, that the floor of this building is three feet below the common surface of the soil. The room marked *f* is the dairy scullery; in which may be observed a boiler, two windows, two sinks close to one of which is a Siebe's pump, and five steps at the entrance door. In this room the dairy utensils are to be washed; and churning may be performed, if it should be a butter dairy; or cheeses pressed, if the object should be cheese-making. In both these rooms there should be traps to a common drain; and from one of the sinks in each room a bell trap communicating with the pig's food tank, unless the piggery should be at such a distance as to render it more economical to convey the milk thither in wheelbarrow tubs. The two milk rooms, *g g*, are to the right and left of the lobby or drying-room; and these are surrounded by slate or thin stone shelves two feet broad, with smaller shelves beneath them eighteen inches broad, indicated in the section, fig. 742. Each range of shelves has two small

sinks, at the two corners next the lobby and scullery: one of these sinks is for waste milk for the pigs, and the other, which has a Siebe's pump close beside it, for waste water. It is to be observed that we mention Siebe's pump, because it goes into less bulk than any other; and, indeed, when the handle is taken off, and an escutcheon put over the keyhole, no appearance whatever of a pump is discernible. These pumps are also worked in much less space than any other. In the centre of the floor of each of these milk-rooms is a small circular basin, and under the shelves in each is a trap to a drain. There are skylights directly over the two circular basins, which are seen in the section fig. 742, at *h h*. These are covered with glass cases, which project and are open at the eaves; and under these are other glass cases, *i i*, which are lifted out during summer, but put in again during winter for the purpose of retaining heat: below these cases are wire-cloth frames, which remain on always, in order to exclude the flies. There are three windows, *k k k*, in the side walls of these milk-rooms, with three frames, shown both in the plan, fig. 741, and in the section, fig. 742. The outer frames of these windows are filled in with wirecloth, and fixed; the two inner frames with glass, each in two vertical divisions, hinged, so as to admit or exclude air at pleasure. There are double doors to each of the rooms, one of which is chiefly of wirecloth, and the other of wood, so that ventilation may be allowed to take place from or to the drying-room, *a*, as may be required to warm or cool the milk-room. It will be observed that the milk-room is surrounded by double walls; and by the section fig. 742 it will be seen that the whole is covered with a mound of earth, which necessarily produces the long tubular openings to the side-wall windows, *k k*, so favourable for producing currents of air during the warm season, and for tempering the frosty air during winter. Fig. 743 is a cross section,

in which *ll* represents the ground's surface, *m* the top of the upper milk shelves, and *n* the skylight. It may be observed that, instead of employing glass and wirecloth frames for these skylights, vessels of water with glass bottoms might be introduced; which, while they admitted light, would exclude heat in summer and cold in winter; and they might be rendered further useful, by having openings in their bottoms, to be regulated by cocks within the dairy, so as to allow water to drop down on the basin below, whenever it was desirable to increase the coolness of the temperature. The vessel might be covered above with a skylight, and supplied either by the Siebe's pump within the dairy, or by a pipe and ball-cock from some exterior source.

The water might contain gold and silver fish. The glass might be stained, as might that of the side windows; and, instead of a small circular basin in the centre, there might be a deep well for containing very cold water. — We shall now describe this building as two ice-houses with a dairy between. The shelves of the milk-rooms should be removed, and the windows closed up entirely; and, instead of a skylight at top, there should be three flag-stones substituted for the frames containing the upper skylight, the under skylight, and the haircloth, and resting on the same ledges on which they rest. There are three offsets or ledges, shown at *h i*, in the section fig. 742, for this purpose. The object of leaving these openings in the ceiling is to put in the ice; and this being done, and the flag-stones replaced, the space between them should be filled in with barley straw. The traps to the drains before mentioned will serve as conduits for such water as may be produced by the thawing of the ice; the well in the centre will also hold a part of this water, which will be valuable for its coolness even after the ice is gone. The spaces *o o*, between the doors, must be kept constantly filled with straw cushions. The room *a* may be fitted up with shelves as a dairy, the chimney being turned into a ventilator; and the room *f* may remain a dairy scullery, as at present. For a wine or beer cellar this building is admirably contrived, whether for a very warm or a very cold climate. The wine or ale may be kept bottled in bins, or in casks on benches, in the milk-rooms; and it may be supplied to customers in the room *a*, while the cleaning operations go on, and the attendants wait, in the room *f*. Wine and

ale cellars of this description are little known in Britain, though there used to be a wine-cellar for draught wine near old London Bridge; but in Germany they are frequently to be met with. There is a very large one at Munich, covered with an immense cone of

earth, in which ale is kept and drunk at the same temperature both in the hottest summers and the severest winters of that climate of the most opposite extremes. There is an excellent one at Silberberg, near Stuttgart, both for ale and wine; and there are nume-

There is an excellent one at Silberberg, near Stuttgart, both for ale and wine; and there are nume-

rous others in the neighbourhood of Vienna, which no doubt are familiar to many of our readers. By a third arrangement, one of the milk-rooms might be made a dairy; the other milk-room a wine and ale cellar, and the lobby a drinking-room. The appearance of such a construction, to whatever use it may be applied, when covered with green turf, need not be disagreeable; we have given the architectural parts something of an Egyptian character, as may be seen in the elevation of the end, fig. 744; of one side, fig. 745; and in the perspective view, fig. 746.

732. *The Cheese-press-room* may be very properly placed between the dairy and the dairy scullery. It should be surrounded by shelves, and the presses may stand in the middle of the floor. The shelves should be grooved across, with a small gutter suspended in front, to collect from the grooves the whey which runs from new cheeses, for a day or two after they are taken out of the press, and before they are carried up into the cheese-room. These gutters may deliver their contents into one upright pipe, communicating with the pig tank. As a good deal of whey will also run from the cheeses while in the presses, grooves may also be formed along the floor communicating with the same pipe.

733. *The Cheese-room* may be over the cheese-press-room, the dairy, and dairy scullery. There should be windows on opposite sides of this room, for thorough ventilation; and these windows should have outside wire shutters, to exclude flies and vermin, and yet admit a free circulation of air. The best position for the shelves is in the middle of the room, so that the cheese may have air on all sides. The shelves should be of the breadth of the cheese intended to be made, and should be perfectly smooth and level. They may be supported from the floor, or, if danger from mice be anticipated, suspended from the ceiling by iron rods.

734. *A Drying-shed* is a useful appendage to the back kitchen, dairy scullery, wash-house, and even brewery. It is useful not only for drying every description of wooden vessel, but even clothes, leaves, such as those of tobacco, ears of maize, garden seeds, &c. In old English farm-houses, the penthouse, or far-projecting eaves, supplied the place of this appendage; and in Switzerland the galleries answer the same purpose; but Waistell, by far the best British writer on farm buildings, as Morel-Vindé is by far the best of the French writers on the same subject, recommends that a drying-shed should be built on purpose. We are decidedly of the same opinion, unless verandas connecting the different parts of farm offices, and forming covered passages between them, can be made to serve the same end.

735. *The Cider-house*, on a small farm, where cider is not made for sale, may be dispensed with, and the apples ground in the churning-room, or in any room or shed where steam or horse power can be applied to turning the grinding rollers. On large cider farms, the cider-house requires to be of considerable size, for holding the fruit before and after it is ground, and for holding the rollers or mill for grinding it, and the press. In Worcestershire the dimensions of the best cider-sheds are twenty-four feet in length by twenty in breadth. The rollers are turned by horse power, communicated by a gin wheel operating on a pinion on the end of a horizontal shaft, in a similar manner to what takes place in a horse churning or washing machine. The cider-house is occasionally open on one or more sides, and the liquor, after being expressed from the pulp, is carried in pails to the cider-cellar, which is commonly under the dwelling-house; but a better mode would be, to have a cellar under the cider-house, and to let down the liquor into the casks by pipes, in the manner suggested for the brewery, § 728. The floor ought to have an inclination to a trap at one corner, in order that it may be easily washed; and this trap ought to communicate with the manure tank. A second trap and pipe should lead to the pig's food tank, to pour down it such liquor as may not be fit for putting in the casks.

736. *An Ice-house* for a farm house may be considered a superfluous appendage in Britain, but it is common on the farms in America, and therefore its construction deserves a place in this work. There are various descriptions of farms in Britain, particularly those belonging to public-houses and inns, to which an ice-house would be a most desirable appendage; not only as affording the means of preparing ices, cooling wine, &c., but as supplying a place for preserving fish, meat, fruit, and vegetables fresh, much longer than can be done by any other means. The simplest mode of keeping ice is by enveloping it in an immense body of loose straw above the surface. For this purpose, the first operation is to form the surface of the ground into a flattened cone, for the sake of drainage when the ice happens to melt; next, put on a layer of faggots, and straw a foot or more in thickness; then lay on the ice, in a conical mass, the larger the better, and cover it with straw to the thickness of one foot, and afterwards with faggot wood to the thickness of two feet, for the purpose of preserving a stratum of air above and around it; lastly, cover the whole with two or three feet of straw, arranged as thatch. The ice will now be surrounded on every side by such a powerful non-conducting medium, that scarcely any heat from the atmosphere will be able to penetrate to it; while whatever portion of

it may thaw will find its way off through the under stratum of faggots, without the admission of air. Ice has been kept in large quantities in this manner both in England and America, throughout the year. The best situation for such an ice stack is under the shade of trees, or under a shed roof, closed on the south side, and open on the north.

737. *An underground Ice-house* may either be a large cellar, with hollow walls, hollow floor, hollow roof, and double doors; or, it may be a separate structure, in the form of an inverted hollow cone, with a drain and trap at the bottom, and double doors on one side at the top. When a cellar is employed as an ice-house, a proper drain and trap should be provided in the lower floor, for carrying off such water as may be produced by the melting of the ice, without the risk of introducing air. When the ice is about to be put in, the floor and sides of the cellar are thickly coated over with strong wheat straw, or reeds, as a powerful non-conducting medium. Double, treble, or quadruple doors are always requisite to an ice-house of this description, according to the use which is to be made of the space between the doors. Where these spaces are to be used as pantries, four doors are requisite; and two should never be opened at once. The space between the outer door and the second door should always be kept filled with straw, and that of barley is found better than the stiffer straw of wheat, rye, or oats. The space between the second door and the third should, if possible, be kept filled with straw also; but the space between the third door and the fourth should be of sufficient width to admit of its being fitted up with shelves, on which the articles to be preserved fresh are to be placed. From time to time, the door of the ice-house may be opened, in order to reduce the temperature of this space, and to freshen the air. In some cases there is a movable shelf or table placed over the ice, immediately within the inner door, as a substitute for the shelves in the passage. When an ice-cellar cannot be formed under or adjoining a dwelling, it may be constructed above ground, even on wet soils, covered with a mound of earth, and that mound further protected by trees, evergreen shrubs, or, what is equal to any thing as a non-conductor, and at any rate far superior to deciduous trees, ivy. The common form of out-door ice-houses, is, as we have before observed, an inverted cone, and the supposed advantage of this form is, that, as part of the ice thaws, the remainder slides down the sides of the cone, and still keeps in one compact body. This is no doubt true; but the advantage by no means compensates for the difficulty of constructing an ice-house in the conical form. A plain square room, with double side-walls, say a foot apart, a double arch over, and a double floor under, which can be built with the same ease as any common cellar, will, all other circumstances being alike favourable, keep the ice as long as any conical form whatever. Where there is a doubt of being able to exclude the heat, treble walls, roof, and floor may be resorted to; and the entrance, which should always be three or four yards in length, instead of being straight, may be made crooked, with a door at each turn. The space between at least two of the doors should always be filled with straw; and, to render the removal of this straw easy, when passing from the outer door to the ice-house, it might be put into two or more canvass bags, like immense cushions, which might be hooked to the ceiling and the sides, so as to close up every interstice. The space between the second and third doors may always be widened, and fitted up, as before described, with shelves for holding articles which require to be kept cool, but not to the same degree as if they were placed in the ice-house. It ought always to be recollected that any perfectly dry cellar may be made an ice-house, by employing faggots as well as straw, in the manner we have described as proper for preserving a stack of ice above ground. The French preserve ice in frames of wood-work suspended in cellars or pits, in the form of inverted cones, surrounding the whole with a thick covering of straw. Both the French and Italians also form ice-houses in dry, chalky, or calcareous soils, deep under ground, where neither drains nor straw are necessary, with the exception of as much of the latter as will close up a long circuitous opening. In England, many persons are deterred from forming an ice-house, by the idea that the form of an inverted cone is essentially necessary to it; that it must be under ground; and that ice is only useful for making ice-creams and cooling wines: but an ice-house may be made any where; and, as a place for preserving meat, fish, fruit, and vegetables, there is not a more useful appendage to a country house. Fig. 747 is a section, and fig. 748 a ground plan, of an ice-house on the inverted cone principle, but of an improved construction. This form, as usually employed in English country seats, very frequently fails in keeping the ice, from not having double walls, and double or treble doors, or from imperfect drainage; but the plan now submitted is free from these defects, and will keep ice throughout the year, in any climate, if covered with a sufficient thickness of earth or straw. In this Design, *a* is the well or cellar for the ice; *b*, a drain from its bottom, for carrying off such water as may be produced by the gradual thawing of the ice; *c*, a trap in this drain, to

prevent the external air from communicating with that of the ice-house; and *d*, a lead pipe from this trap, connected with one of Siebe's rotatory pumps at *e*. The object of this pump is to allow of making use, during the heat of summer, of the very cold water produced by the thawing of the ice, either for cooling wines, or, after filtering it, for drinking. There are five doors to this ice-house, at *f*, *g*, *h*, *i*, and *k*; and a <sup>n</sup>vacuity, *l*, one foot wide, between the two walls, surrounding the cellar, and covering the inner division of the passage, *m*. This passage may be fitted up with shelves, as a place for keeping ve-

747

getables, and various other articles of food (raw or cooked), fresh during summer. The natural level of the ground is shown at *n n*; and the whole superstructure may be covered, in Britain, to the depth of two or three feet with earth, planted with ivy, and surrounded with trees. In warmer climates the depth of earth ought to be increased to eight or ten feet. The size of the well ought also to be enlarged, and it might be well to have even a third vacuity round it. The space between the doors *i* and *k* should be filled up by a barley-straw cushion, and it would be well to have similar cushions against the doors *g* and *h*, at least during summer. The two recesses, *o* and *p*, are here shown only two feet in depth; but, by making the walls behind them of brick, that depth may be increased at pleasure. It may also be observed, that, in situations where brick is cheaper than stone, all the walls in this Design may be built, in Dearn's manner, hollow; and that the side walls of the ice-well need not be more than the length of a brick in thickness, the one wall being tied into the other. It may be further observed, that, if it should be inconvenient to cover the building with earth, a covering of straw or reeds, or even planting ivy against the outside walls, and surrounding the whole with a few trees, will be equally efficient in keeping out the heat. If trees cannot be planted, on account of the soil, or of shutting out any view, a slight roof elevated on props of any sort will have the same effect. One of the most effective ice-houses which we have ever seen was covered in this manner, by a wire trellis and Ayrshire roses, mixed with honeysuckles, clematis, and Virginian creeper. Ice-houses, we are persuaded, would become much more general, were country gentlemen fully aware of the fact, that they might be built square just as well as round, and be equally effective at less expense, above the surface than under it. A square ice-house above ground, or sunk three feet into it, may have treble hollow floors formed of bricks on edge, covered with foot tiles or flag-stones; and its side walls may be treble also, of brick on edge, in Silverlock's manner. To form the roof, a nine-inch semicircular arch may be first thrown on these walls, and on this arch three vacuities built of bricks on edge and tiles: there may be five doors, as in fig. 748; and the whole may be covered with a cone of earth, or thatch, four feet thick, and clothed with giant ivy. In filling an ice-house, the ice, being collected and laid down outside of the exterior door, is there broken into small pieces, and reduced to a powder composed of particles not larger than those of sand or salt. It is then carried into the house and thrown down into the ice-well, in which a man is placed with a rammer to beat, and ram it closely; occasionally sprinkling it with a little water to consolidate the whole. An improved method consists in using water saturated with salt, by dissolving ten pounds of salt in ten gallons of cold water, and pouring it on the ice through a common garden watering pot every two feet of thickness, as the house is filling, and finishing with a double quantity of the salt water. "The ice, in houses filled in this manner, will be

found, when opened in summer, to be as firm as a rock, and to require, at all times, the force of a pickaxe to break it up. Thus prepared it will be found to keep three times as long as by the common method in the house, and it will also keep three times as long when exposed to the air, from salt water, and consequently salted ice, having a less capacity for heat than fresh water, or fresh ice." (*Gard. Mag.*, vol. iii. p. 139.)

738. *A very cool Place for the Preservation of Meat, Butter, Vegetables, &c.*, might be formed as follows:—Construct a frame of wooden or iron rods, in the form of a cone, or in any convenient form, and raise it from the ground on pillars between two and three feet high; form a door of wirecloth on one side, and one or two openings as windows, also filled in with wirecloth, on the other. Cover the whole, except the doors and windows, with a coating of cement, and form a double floor of boards. The result will now be a conical bottle of cement, with three wire openings in the sides. Place on the summit of the cone a vessel of water, or conduct a pipe of water there, and allow it to trickle down the sides of the cone, and the greater the heat of the weather, the cooler will the area be made within, by the heat carried off by evaporation. Perhaps it would be better to form the cone over a pit or well, and without any openings in its sides; entering under ground to the pit or well, in which the heavier articles might be put, while the lighter ones were placed on shelves suspended from the roof. In an airy situation, in the shade, it is presumed the temperature, through the continued evaporation of the water, would be kept sufficiently low for every purpose that could be required from an ice-house pantry. Perhaps the water might be conducted more regularly from the apex to the base of the cone, by forming round it a screw gutter, something like the rings of a straw beehive.

739. *A Room for smoking Hams and other dried Provisions* is, in some countries, particularly in Germany and Sweden, a general appendage to a country house or a large farm. It is usually built of stone or earth, and placed apart from other buildings. It may be a square room, ten feet on the sides, and ten feet high, open to the roof; and it may have iron ceiling joists, at about two feet apart, in both sides of which hooks are fixed for suspending the articles to be smoked. The smoke is generally allowed to escape through crevices in the roof, or through chimneys or apertures formed of slates, or thin stones, placed like luffer-boarding; but, in an improved construction, air-hole tiles, like that shown in fig. 434, or central luffer-boarded chimneys which admit of regulation, like those of stables, to be afterwards described, would be an admirable substitute; because, while they admitted the escape of smoke, they would exclude the entrance of rain. In Germany, not only bacon, beef, and mutton hams are smoked in houses of this kind, both as a means of preservation, and to communicate a flavour; but venison, geese, ducks, salmon, cod, haddock, eels, herrings, &c., are so cured. The preserving principle is the pyroligneous acid, which being purer in wood than in coal, the former is always employed. The flavour depends upon the kind of wood used: that most esteemed is communicated by the juniper, with which the Westphalian hams and the Embden geese are smoked. The wood most generally next in use is the beech; but in Sweden and in Pomerania the spruce fir is often used, either alone or in mixture with the birch. In Hampshire, and other counties, where much bacon is smoked, the kiln is egg-shaped, with a door in one side, and a covered chimney on the narrow end: the hams are suspended from hooks in the roof, and a smothered fire of sawdust is kept up on the floor, by throwing on successive handfuls of sawdust. The sawdust of hard wood, such as oak, ash, beech, &c., is preferred to that of resinous trees. In Cambridgeshire, and other parts of England, hams and bacon are frequently smoked by hanging them in a wide kitchen chimney, and making a fire of sawdust on the hearth; and, in the north of Scotland, gentlemen often send their bacon or mutton hams, wrapped in paper, or coated in sawdust, to their tenants, to be hung up in their wide kitchen chimneys where peat is burned below. In the neighbourhood of Aberdeen, and in various places in the north of Scotland, haddocks are strung up on rods called spits, and suspended in wide chimneys, under which peat and sea-weed are burned, and sometimes fir; though the flavour of the sea-weed and peat is greatly preferred. Red herrings are strung by the gills on wooden spits, and these spits are suspended in rows above each other, in a house which is kept filled with the smoke of birch for several weeks. As this process cannot require to be performed more than two or three times a year on a private farm, the same apartment might serve for distillation; or for smoking willows with sulphur, to bleach them, where basket-making was carried on; or straw, where hat-making was practised. In the same room, also, articles of carpentry intended for the open air might be either saturated with pyroligneous acid, or actually charred at the ends to be inserted in the ground. The value of the saturation process is evident from the great durability of the timber of the roofs of cottages which have imperfect outlets for the smoke; many in Scotland, and some in England, might be referred to as examples.

740. *As an Example of the essential Accommodations of a Farm House on a small scale,*

and on the most economical principle of construction, we may refer to fig. 749. The walls of this house may be built of rammed earth, or mud, or clay nogging, or in whatever manner is cheapest and best suited to the particular locality; and, as all the accommodation is on one floor, the highest of these walls need not be more than ten feet above the stone or brick foundation. The accommodations are, an entrance-porch, *a*, facing the south-west; a hall or lobby, *b*; kitchen, *c*; back-kitchen, *d*; place for fuel, *e*; larder, *f*; pantry, *g*; place for fuel for lighting fires, and women's water-closet, *h*; ale and beer cellar, *i*; dairy, *k*; room for potatoes and other roots, *l*; wine and spirit cellar, *m*, with a china closet over, opening from the dining-room; boys' bed-room, *n*; lobby to the three family bed-rooms, and to the private water-closet, *o*; master and mistress's bed-room, *p*; girls' bed-room, *q*; stranger's bed-room, *r*; parlour, *s*; single men's sleeping-room, *t* (the window of which is also a door, by which they can go out early in the morning without disturbing the family); maid-servant's room, *u*; dining-room, *v*; drying-closet, heated from the back of the kitchen fire, *w*; and projection over the oven, *x*. There is a flue from the oven across the dining-room, going round the parlour, and back again; which, with the heat from the drying-closet, will, it is calculated, render open fire-places wholly unnecessary, and therefore none are shown. By examining the section, fig. 750, the simplicity of the construction of this building will be obvious. The outside walls are only seven feet high, but the capacity of all the rooms is rendered sufficiently ample by raising

the ceiling, as shown in the section. To admit of raising the ceiling, a chain of purlins, fig. 750, *y*, is placed in the direction shown by the dotted line *c b d*, &c., in fig. 749, and is carried round the house. These purlins are supported by the cross walls; and on them, and on the wall surrounding the dining-room, the rafters, which are of short lengths, find a secure support. From the entrance-door to the door of the dining-room there is a rise of two feet, effected by an inclined plane; and there is also a declination from the door of the back-kitchen to that of the root-cellar, also of two feet, by which

750

the ceiling, as shown in the section. To admit of raising the ceiling, a chain of purlins, fig. 750, *y*, is placed in the direction shown by the dotted line *c b d*, &c., in fig. 749, and is carried round the house. These purlins are supported by the cross walls; and on them, and on the wall surrounding the dining-room, the rafters, which are of short lengths, find a secure support. From the entrance-door to the door of the dining-room there is a rise of two feet, effected by an inclined plane; and there is also a declination from the door of the back-kitchen to that of the root-cellar, also of two feet, by which

means the fireplace of the oven is sufficiently low to admit of the flue from it passing under the dining-room floor; or the same purpose may be effected by having a few steps down to the oven furnace. There may be an upright flue from the oven, for use during summer. The stairs down to the wine-cellar are shown with a line across the steps, indicating that it is to be constructed with double treads, in order to gain space, as shown § 164, fig. 137. The windows in the roof are double; the outer sashes being glazed with small panes, to resist hail; and without cross bars, like hot-house sashes. The inner ones are upright, and hung in the usual manner. A line passed diagonally

through this house, from the south to the north, should intersect the centre of the farm-yard, which would thus be completely overlooked from every part of the parlour, &c, which for that purpose has windows on both sides. Fig. 751 is the elevation of the entrance,

or south-west front; fig. 752 that of the south-east front; and fig. 753 is a perspective view. This building might be erected, in the neighbourhood of London, reckoning

labourers' wages at 18s. a week, and carpenters' at 25s. a week, for £250; and, were there no duty on glass, the sum would be much lower; because, the floors and walls being of earth or composition, and the roof of short pieces of timber and thatch, the chief expense is incurred in the doors and windows.

741. *A Farm House with an enlarged degree of Accommodation*, but still on the most economical plan, for a country where the cheapest material for the walls is earth, and for covering the roof, thatch, might be formed from the same ground plan, with a story over it. The change in the destination of the apartments shown in fig. 749 may be as follows: — *r* may be an office, the window serving also as an outside door, for the entrance

of persons on business belonging to the farm; *t*, a fruit-room and china-closet, or room for the use of the mistress; and *u*, a laundry. Fig. 754 may be the plan of the bed-room

or garret floor, in which *a* is the room for female servants, and *b* that for single men; *d*, *e*, *f*, and *g* are bed-rooms for members of the family, or for strangers; and *h* is a lumber-room. The entrance to the two servants' rooms is from the landing of the staircase, in consequence of which they can go down stairs without disturbing the rest of the family; and the entrance to all the other bed-rooms is from the gallery, which is projected from the side walls of the dining-room, as shown in the section fig. 755. The

755

gallery, the staircase, and also the dining-room below, may be amply lighted during the day from the four skylights, which lights have double sashes; viz., outside ones of the same slope as the roof, which slide the one over the other like those of a hot-house, with very small panes, as before described; and inside ones, which are perpendicular, and open like common sash windows. Both sashes may be worked from below by lines and pulleys. A lamp suspended in the centre of the dining-room will light it, the staircase, and the doors opening into all the other rooms, in the evening. For the sake of economy, the outer walls of the bed-rooms are kept low; but as they are larger in length and width,

there will be an ample volume of air in each for health. The whole of this house may be effectually heated by the oven and kitchen fires, without any others. An ironing stove may be placed in the laundry; for which purpose there may be a flue built in the stack which contains the kitchen flue. In this Design, and the preceding one, it will be observed that there are no passages; which is a great saving of room. The general appearance of this farm house may be as in fig. 756.

756

742. A Model Farm House for a small Farmer has been given by Morel-Vindé, which we consider perfect in its kind, for a country where the chief material of construction is timber of a small size. No piece of wood, in constructing this Design, is longer than ten or twelve feet, or thicker, when squared, than six inches on the side. It is not intended that this wood shall be cut out of large trees, but that it shall be squared from young trees or branches; to the end that, in countries abounding with wood, it shall not cost more than that which is used for fuel. The walls are framed of timber, and the panels filled in, and covered with weather-boarding or plaster, outside, and lath and plaster inside. The cellar floor of this Design, fig. 757, contains two divisions, a bake-

757

house, in which there is a stove, *c*, for heating the apartments above; an oven, *h*; and a supporting post for the parlour floor, *k*. The cellar has also a supporting post, *l*, and the entrance to both has six descending steps at *o*. The use of the two posts, *k* and *l*, is to admit of forming all the joists of the floor above of wood not longer than ten or twelve feet. Fig. 758 is the plan of the ground floor, in which may be seen the parlour, *a*, with a small office, *b*, and a bed for the master and mistress in a recess, *c*; the kitchen with its dresser, *i*, at one end of which there is a post, *h*, to support the floor above. In the centre of the building may be seen the stove funnel, *f*, with three small openings to the two bed-rooms, *h h*, and to the parlour, *a*; one of the bed-rooms containing two beds, *d d*, for children, and the other two for female servants, *e e*. In the mid wall may be seen at *g* the flue from the oven; and at one end the dairy, *m*, and the harness and small tool room, *n*: at the opposite end is a water-closet, *p*; and a house for wood and the larger farm implements, *q*. The entrance is by the ascending

steps, *r*. The plan of the ceiling joists over this floor is represented in fig. 759. Over these joists there is a garret, which may be entered either from a staircase, formed in a porch behind, placed at *o*, in fig. 758, and corresponding with that in front; or by an outside ladder. On the supposition that it is entered by a ladder in front, its door is represented in the elevation, fig. 760, in which may be seen the two small windows to the bake-house and cellar; the doors of the harness-room and water-closet in the two wings; the entrance door of glass, the window to the kitchen, that to the parlour, and that to the cabinet or office. Fig. 761 is a side view, in which the projection of the porch is conspicuous at *s*, the window of the harness-room is seen at *t*, and of the dairy at *u*. Fig. 762 is a longitudinal section, in which the oven is seen at *h*, with its ash-pit underneath; the kitchen fireplace over it at *z*, the parlour at *k*, the garret at *l*, the ventilator to the dairy at *m*, and to the water-closet at *n*; and the doors to the two bed-rooms at *o*. In fig. 763 we have given a perspective view of

760

this improved French farm house, varying the form of the chimney-tops; of the angle brackets of the porch; adding rails to the outside stair; giving a Gothic or old English character to the ventilators; and placing the whole on a platform. A further improvement

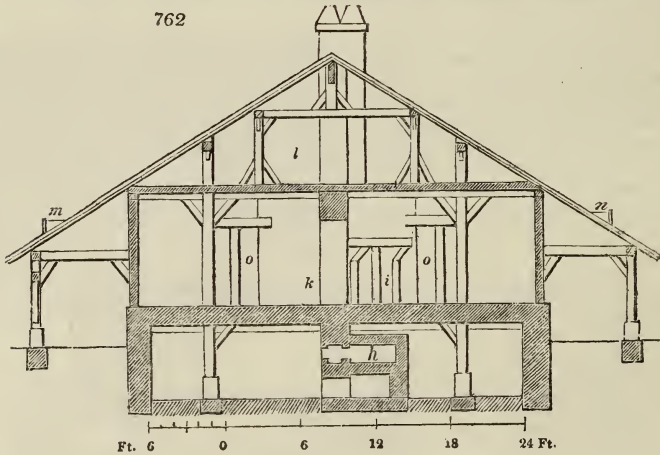

on the original Design is a glass window as a door to the garret, instead of the boarded one shown in fig. 760. This garret, instead of being entered by a ladder outside, might be got at by a trap-door in the ceiling of the kitchen, with a hanging ladder like that shown in fig. 158, § 179. The area covered by this building is 920 superficial feet; and it would cost, in the neighbourhood of Paris, £258 : 8s. : 4d. ; but in the departments of France the expense would not be above half that sum.

743. On the Construction and Arrangement of this Design, Morel-Vindé has the following remarks : —

The post which, in fig. 758, is shown at *k*, as proceeding from the kitchen dresser, may be thought to be inconvenient, but it is not found to be so in practice; on the contrary, it serves as a standard to drive hooks or nails into, on which to hang things: at all events, its position there is essential to the solution of the problem of using

762

no wood in the whole building that is longer than ten or twelve feet. However, where wood is abundant, it might be avoided by substituting over it one strong and long beam,

instead of two short joists. The privy or water-closet is thus constructed:—A tub, firmly held together by iron hoops, is sunk in the earth to the brim; and it has two strong hooks which project from each side. Over this tub is placed a portable seat, with a funnel, which descends into the tub, and there is a lid to the opening in the seat. All the soap suds, and other waste water of the house is poured through this funnel. Directly over the tub, in the rafters of the roof, a pulley is fixed; and, when the tub is full, which it will be once or twice every week, the portable seat is removed, and the tub is raised up and placed on a wheelbarrow, by means of a cord passed over the pulley. The tub is then wheeled away to two tanks, or small trenches; into one of which is poured the liquid matter, and into the other the more solid contents. The tub is then washed out, and returned to its place; and the liquid matter is immediately rendered thick by mixing with it powdered lime, chalk, or marl; or, in default of either of these, powdered lime rubbish. This manure is what is called in France *urate*. The thick matter the farmer allows to dry, and afterwards he reduces it to powder, when it forms that excellent and high-priced manure so well known throughout Europe, and especially in France, as *poudrette*. Finally, the *urate* and the *poudrette* are mixed together in a large tank, having the bottom and sides of masonry; and soap suds, or the liquor from stable dung, being added, the whole is worked till it becomes of the consistency of mud. After this, powdered plaster of Paris, or lime, or marl, is added, and thoroughly incorporated, till the whole is so thick that it can scarcely be stirred with a stick. Left to itself it soon sets, and in three weeks will have become so firm, that it will cut like cheese, and may be taken out and dried in lumps about twice the size of bricks. These bricks Morel-Vindé calls *stercorat*, and he says that they form as powerful a manure as pigeon dung. When used they are reduced to powder, and strewed over the soil by hand, as a top-dressing. In situations where neither plaster of Paris, lime, nor marl is to be had, the *urate* and *poudrette* may be mixed up with clay, when the *stercorat* is to be used on sandy soil, and with sand when it is to be used on clayey soil. This, Morel-Vindé says, is the best of all known manners of employing the contents of privies, and he speaks from long practice on his own estate, at Celle, near St. Cloud. (*Essai sur les Constructions Rurales Economiques, &c.*, p. 26.)

SUBJECT. 2. *Fundamental Principles, Directions, and Model Designs, for the Construction and Arrangement of the various Parts which compose a Farmery.*

744. *The Parts which compose a Farmery* may be arranged under two heads, buildings and yards. The buildings may be classed as houses for lodging and feeding live stock; storehouses for produce and food; houses for preparing food, or carrying on in-door farmery operations; houses for portable machinery and implements; lodgings for single men, and houses for married men. The yards are chiefly two; the cattle or dung yard, and the rick or stack yard: but in large establishments there are, besides these, the pig yard, the poultry yard, the carpenter and smith's yard, and some others, according to the kind of farm.

745. *The Principles on which the Lodging-places of all domestic Animals are designed* must necessarily be drawn from the size of the animal, the temperature of its native climate, its habits of life, and the state of domestication to which it has been brought. The domestic quadrupeds which form the inmates of farmeries are chiefly the horse, the cow, the sheep, and the swine; and these, in their artificial state, may be considered as requiring the same climate, or nearly so; and as not differing very materially, either in the kind of food which they eat, or in their manner of taking it. They may all feed from a rack or manger, of nearly the same height relatively to their own; and, taken in the plan, or vertical profile, they are all more or less wedge-shaped; the head being placed at the narrow end of the wedge. The chief difference, therefore, is in their magnitude as wedges; and it is to ascertain this difference that the Architect who wishes to draw his practice from fundamental principles ought in the first place to direct his attention. A horse of average size, he will find, forms a wedge eight feet long, six feet and a half high; two feet broad at one end, and one foot and a half broad at the other. A cow or bullock of average size forms a shorter and somewhat blunter wedge than the horse; being generally seven feet and a half long, five feet high, two feet and a half broad at one end, and, allowing for the horns, nearly two feet at the other. Taking the horse and ox together, we may consider them, on the average, as wedges eight feet and a half long; two feet and a half at the broad end, and two feet at the other; and six feet and a half high. The sheep we may consider as three feet and a half long, two feet high, eighteen inches broad at one end, and, allowing for the horns of the ram, one foot at the other; and the swine may be considered as a wedge of the same size and shape as the sheep. Assuming these averages to be sufficiently correct for practice, two important conclusions may be drawn from them: first, that the most economical mode of lodging the first two of these quadrupeds must be in houses the walls of which form concentric

circles, or segments of circles parallel to each other; and that the rack or manger being required for the small end of the wedge, should always be placed against the smallest circle or segment; and, secondly, that in all open yards where quadrupeds are allowed to run loose, and eat from racks or mangers, the length of the rack or manger required to allow the whole to eat at once may be obtained with certainty when the kind of animal is given; since, when the rack or manger is to be in a straight line, the breadth of the broad end of the wedge must be allowed for each animal, and when it is to be curved, the radius of the curve must be determined by the breadth of the smaller end of the wedge. From this theory it may also be deduced, that there must be one magnitude, as well as one form, more economical than any other, for lodging each of these animals; and that this magnitude must be that circumference of a circle which the narrow ends of the wedges completely fill up, and no more. Fig. 764 shows the number of horses, or horned

cattle, that will stand together in the circumference of a circle, with their heads towards the centre; and fig. 765 shows the parallelogram that would be required to contain the same number of the same-sized animals, supposing them to be placed in a straight line. Fig. 767 shows the number of average-sized sheep or swine that would stand in a circle; and fig. 768 the parallelogram that would be required to contain them in a straight line. The loss of space, in both instances, is about one fourth. It is true that, in practice, animals can never be placed so near together for any length of time; but the comparison which we have made sufficiently establishes the principle, that, in calculating the room required for lodging these animals, or feeding them from racks or mangers in open courts or yards, they must be considered as wedges. In applying this principle to practice,

the habits of each animal, and the kind of food to be given to it, will form subordinate principles, which must also be taken into consideration by the Architect. We shall endeavour to illustrate this in the case of the animals above mentioned.

746. *The Horse and Ox* are capable of lying down and rising up, when they have a vacant space of a foot round them on every side. This will give a wedge-shaped stall, eleven feet long, five feet broad at one end, and four feet broad at the other; in which they will have ample accommodation, and the saving of room on each animal, in a stall of this description, as compared with a parallelogram stall, will be five and a half

superficial feet, or above one eighth part of the whole. The circular building best suited for this accommodation would have the radius of the inner wall fifty-four feet six inches, as in fig. 766; and, therefore, if (other circumstances being the same) stables or cattle-houses in farmeries could be built in this form as easily as in the parallelogram shape, there would be an obvious saving of space to the above extent; and this, in a stable of twelve horses, or a cattle-shed of twelve cows, would amount to sixty-six feet; or, in other words, more room would be gained than would be sufficient for an additional stall. Wherever curvilinear stables, or cattle-houses, therefore, can be introduced into a farm-yard, the Architect may feel satisfied that the proper radius for the smaller circle, when the animals are of medium size, is fifty-four feet six inches.

747. *Sheep and Swine*, from the necessity of the former being kept in almost continual exercise, and being surrounded by, or at least having above them, a great abundance of fresh air, and from the restlessness of the latter, are never kept tied up in stalls; and therefore the curvilinear principle, as applied to them, refers only to the lineal direction of their mangers or troughs. Allowing a full-grown sheep or swine, when feeding at a rack, three inches on each side of his head, this will give fifteen feet nine inches as the best radius for the convex side of sheep racks, which are intended to be eaten from on one side only; and for the feeding-troughs of full-grown swine kept in a yard. This will be seen on inspecting fig. 769, in which the inner circle represents a trough or manger, out of which fifty-eight sheep or swine might eat on the outside, though not half that number within. As the difference is considerable between the width of a horned sheep and one without horns, this radius will require to be varied according to the proportion of horned to polled sheep in the flock.

748. *These Principles* for the curvilinear arrangement of stalls, racks, and troughs, we do not lay down as of very great importance, but rather with a view to induce the young Architect to enquire into the reasons of things; and to endeavour, in every thing, to take principles into consideration rather than precedents. We shall now proceed to give details of, accompanied by reasons for, the more ordinary modes of constructing stables, cattle-sheds, and other buildings for animals which belong to a farmery.

749. *The Buildings usually employed for lodging, feeding, or fattening Live Stock*, comprise the stable, cow-house, calf-house, cattle-stalls, hammels and sheds, sheep-house, piggery, poultry-house, rabbit-house, pigeon-house, and house for sick horses or cattle. These should either be connected together, and open into one yard, or they may be separated by the barn, and open into the same or different yards. On no account should they be intermixed with the implement and machine houses, or with the cart-sheds.

750. *Stables*. The horse is an animal in a highly artificial state, and requires to be treated with a degree of care beyond that bestowed on any other domesticated quadruped. The stable in which he is lodged should have its doors and windows to the south-east, as the mildest aspect, and, in general, have all its openings on one side, and in the roof, to prevent cross draughts of air. It ought to be on a dry soil, or, if on a wet one, it should be raised above it by a hollow floor; or by materials of a kind which will contain interstices of air between the natural surface and the artificial floor. All stables should be large, cool, and capable of being well ventilated. The proper temperature for a horse is 50° in winter and from 60° to 65° in summer. The best mode of ventilating a stable in winter is by trunks or tubes of boards, about a foot square, forming openings under the eaves, or carried up through the ceiling, where there is one, so as to pass through the roof; their tops being covered in such a manner as to exclude the rain, without impeding the ascent of the heated air. The inside openings of all these tubes

should have small sliding shutters to regulate the ventilation. In summer, this is best effected by having the windows filled in with hinged luffer-boards; or by having glass windows, with outside luffer-blinds. In the latter case, the quantity of air admitted, both in summer and winter, may be very accurately regulated by the degree to which the glass windows are opened. It was formerly supposed that darkness was favourable to good condition in horses; but this has been found to be a mistake, and light is now freely admitted, as well as fresh air. The floors of that part of stables in which the horses stand should be level; because, when raised towards the horse's head, they are found to put the back sinews on the stretch, and thus to fatigue the animal when he ought to be at rest. The urine may be carried off by a drain under each compartment, covered by a grating; and this grating where the horse stands loose, should extend from the centre of the compartment in four directions, like a right-angled cross. When the horse stands in a stall, in addition to the gutter behind, there ought to be a branch from it carried up the middle of each stall, a third part of its depth; and this, also, ought to be covered with a close grating of cast iron, or, as it generally is on the Continent, of oak pierced with holes. These cover gratings ought to fit into the tops of the gutters, so as to lie close and level with the adjoining floor, without requiring to be fixed, in order to admit of their being lifted out occasionally, for the purpose of cleaning out the gutter. This gutter should communicate with a covered liquid manure tank by a drain; or, if it communicates with an open tank, there ought to be a stink-trap in the drain immediately without the stable door, to prevent the entrance of a current of air through the grating, which air being necessarily saturated with the volatile alkali of the urine, would contaminate the atmosphere of the stable. The great advantage of this drain and grating is, that the evaporation of urine in the stable is in a great measure prevented by it; and not only its atmosphere rendered much more healthy, both for men and horses, but the whole of the ammonia of the urine is transferred safe to the manure tank, where it forms one of the most valuable portions of the manure. To get rid of this ammonia in the stable, all droppings from the horse should be removed immediately, if practicable; and, at all events, the litter which has been stained by the urine or the dung ought to be removed to the dung-pit, or to the outside of the stable, at least twice a day. It is the practice with some farmers to clean out their stables only once or twice a week; but the exhalations produced by such an accumulation of matter cause many diseases in the feet and legs; and the floor, by the unequal accumulation, being rendered uneven for the horse to stand on, he is strained and fatigued when in the stable, instead of being rested. The litter kept in a stable should be only such as is dry and sweet; and that taken out should be immediately put into the dung-pit, to prevent evaporation. The eminent veterinary surgeon Blaine observes, in an excellent article on the horse, in our *Encyclopædia of Agriculture* (2d edit. § 6706.), that horses should not stand on litter during the day; because, though it is thought to save their shoes, and even their feet, by preventing the uneven surface of the floor from hurting them, he affirms that it "holds the urine, injures the feet, and is very apt to encourage swelling at the heels." As stables are commonly constructed and managed, it is by no means desirable to have a hay-loft over them; unless this is floored in such a way as to prevent the dust and dirt from the hay from descending upon the horses, and the ammoniaical gas from ascending into the hay. Upright racks are preferred to racks which slope forwards, because the horse in drawing out the hay is less liable to get dust and hay-seeds in his eyes; but, if the best and most economical system of horse feeding were adopted, viz. cutting all the hay and fodder, and giving it to them well mixed with corn and pollard in their mangers; and if these mangers were watertight, and the hay and fodder, previously to cutting, sprinkled with a solution of salt and water, no racks whatever would be necessary. When the horse is tied up, the halter should be contrived to run in a groove in the manger post, or in a tube behind it, to prevent it from becoming entangled with his feet. Stalls should always be wide, and for single horses of full size not narrower than six feet, and at least eight feet deep. Stalls for two horses ought not to be less than ten feet wide and eight feet deep, unless the horses are under the middle size. These are the fundamental principles and rules on which all stables ought to be formed, when the health of the horse, and the prolongation of the working period of his existence, are the objects in view. We shall now show their application.

751. *The Stables* for farm buildings ought to be at least sixteen feet wide from wall to wall. The walls ought to be nine feet high; there ought to be no ceiling or floor over; and the width allowed for each horse should be at least five feet, whether they are separated by partitions or not. In stables without partitions, or with partitions of not more than three or four feet from the head wall, four feet six inches may suffice; but it has been observed that, when horses are crowded together, they do not lie down near so frequently as when they have ample space; and it has been further remarked that horses tied up in stalls do not lie down near so frequently as horses which are shut up

loose in separate compartments. When it is considered how much the health of almost all quadrupeds depends upon their reposing a portion of every twenty-four hours in a horizontal position, and more especially when we reflect that the horse is particularly liable to have swelled legs and heels, we cannot help being of opinion that all horses whatever ought to be lodged in separate cells or rooms, with divisions so high as to prevent them from seeing each other. We are informed by Waistell that some stables in the north of Yorkshire are divided in this manner, and that horses have been found to lie down in these stables, which would seldom do so when tied up with other horses, either with or without stalls. In several stables in Britain for hunters or riding horses, we have seen this practice adopted; and it is very general in the great breeding establishments known by the name of *des haras* (studs) in France. There is a very large stud of this kind in the neighbourhood of Nancy, which we visited in 1828; and where we found entire ranges of stabling partitioned off into separate cells for mares and foals, with a passage behind. The dimensions of these cells, as estimated by us on the spot, and marked down at the time, were about fifteen feet square; the partitions were of inch and a half boards, ten feet high, grooved and tongued into each other; and in the centre of the side next the passage was a doorway opening into it: this passage was at least six feet wide. These dimensions, being for mares with foals, are much more ample than would be required in farm stables: in these, eight or nine feet by twelve feet, the dimensions adopted in the north of Yorkshire, would be sufficient. It is well known that almost all hard-worked horses fail first in the legs and feet, and that the best way to alleviate this evil is to induce them to repose as much as possible in a reclining position. Now, since horses are found to lie down more readily in separate rooms than in stalls, there can be no doubt that, as a matter of economy, this mode of lodging them would repay a farmer for the extra-expense. This once proved by practical men in the best cultivated districts of Britain, such as East Lothian or Northumberland, for example, such stables would as soon be substituted there for those now in common use, as the threshing mill was fifty years ago for the flail, in the same districts. Whether the stable is laid out with stalls, or in separate compartments for single horses, there ought to be a broad passage behind, between the stalls or horse-rooms and the wall; which passage ought to be paved, and kept at all times dry, clean, and free from litter. In the wall

there ought to be one or more windows, according to the size of the stable, for light and ventilation. Each window may contain two glass sashes, sliding past each other in grooves, and should have on the outside fixed luffer-boarding, or shutters of that description, either hinged, or also sliding in grooves. Under each window there should be a recess for a corn bin; or these may be placed at the extreme ends of the passage, or in the foddering bay. There ought to be tubes under the eaves for ventilation, protected outside by luffer-boarding, and furnished with sliding shutters inside, for the purpose of regulation. There ought to be cupboards formed in recesses in the walls, one for each man who works a pair of horses, in which he may keep the currycombs, and other articles necessary for cleaning them. The harness of every horse that is in daily use ought to be hung against the wall behind it, in order to lose as little time as possible in taking it off and putting it on; and that which is only used occasionally should be kept

in the harness-room. There should be one or more lanterns, suspended by cords and pulleys from the roof over the passage, for putting lighted candles in, while feeding or cleaning the horses during winter. The racks, when placed on the floor, should occupy two thirds of the width of the stall or horse-room, and the manger ought to occupy the other third, its top being on a level with that of the rack; or the rack may occupy one angle, and the manger the other. The loft being condemned in farm stables, a place must be provided for holding food and litter: the most convenient is one or two divisions in every stable opposite its door, into which the food, whether green clover or tares in summer, or hay or roots in winter, can be readily carried from without, and easily distributed within. Being near the door, the food will be better ventilated than it could be in any other part of the stable, and it will occupy the least valuable part with reference to the horses; it being well known that in farm stables the horse which stands opposite to the door is more liable to take cold than any other. The corn bin or chest may also be kept in one of these divisions, and, in that case, should be so large as to have separate compartments for corn and beans, and for cut straw or hay, or bruised furze to mix with the corn or pulse. Stable doorways ought to be made four feet wide, and seven feet high; and the door ought to have no projecting latches or handles, because these are apt to hurt the horse, or become entangled with the harness. Racks and mangers are very frequently made of cast iron, and they are found much more durable and economical than wood, without any inconvenience being experienced from them. Fig. 770 is a cast-iron rack, two feet four inches long, one foot wide in the centre, and one foot four inches high. The bars are one inch and a half by five eighths of an inch in thickness, and two inches and a half apart; the whole weighs thirty pounds, and costs by retail 8s. 6d. Below it is seen a cast-iron manger, three feet long, one foot three inches wide, outside measure, at top, and eight inches deep. It weighs two quarters thirteen pounds, and costs 10s. 6d. Fig. 771 is a wrought-iron angle rack. The chord of the arc on each side is two feet eight inches; the surrounding frame is one inch and a half by a quarter of an inch;

the ribs are round iron rods five eighths of an inch in diameter; and the whole weighs twenty-four pounds and a quarter, and costs 6s. Below it is an angle manger of cast iron, which measures three feet in length in front, with a basin one foot seven inches long, one foot wide, and eight inches deep. It weighs two quarters twenty-three pounds, and costs 9s. Fig. 772 is a wrought-iron rack, three feet long, eighteen inches high, and eighteen inches wide. It weighs thirty pounds, and costs 6s. 6d. Fig. 773 is a cast-iron bull's-eye rack two feet and a half in diameter, which costs 7s. 6d. These iron racks are far more durable than wooden ones; and, about London at least, cost less.

752. As an Example of a Stable with high Racks, Mangers, and partitioned Stalls, constructed in the most approved manner, we refer to figs. 774 to 779. Fig. 774 is the

774

ground plan of a stable for eight horses, in which the racks are upright. In the centre there is a foddering bay, *a*; with a corn chest, *b*, placed on blocks of stone, to prevent its bottom from rotting; in the front walls there are recesses, *c c*, six inches or more deep, according to the kind of wall, for hanging harness in the upper part, and for pails and other articles used in the stable to stand in below. The recesses under the windows will allow of placing a small corn bin or cupboard there. The dotted lines from *d* to *d* represent the main gutter drain, and the short dotted lines from it, *e*, the branch drains into the different stalls; the dotted lines at *f* indicate a drain communicating with the liquid manure tank. The gratings placed over the main and stall gutters may be of stone or oak, pierced with holes; or of massive cast iron, like fig. 775, which, when twelve inches square, costs 4s.; when fifteen inches, 6s. 9d.; and when eighteen inches, 9s. 9d.

775

Fig. 776 is a cross section on the line A B; in which is shown a ventilator in the roof, formed by a tube, with a stopper, *g*, sliding horizontally, continued up immediately under the roof, and opening in the ridge, under a protecting cover composed of two large slates, *h*; *i* is a cast-iron harness peg; *k* is the corn chest; *l*, the rack; *m*, the manger; *n*, the grating at the termination of the stall gutter; and *o*, the main gutter; *p*, the space under the rack, into which dust, seeds, and other matters from the hay or fodder drop down through the grated bottom of the rack, and are taken out, from time to time, by removing the bottom board in front.

776

Fig. 777 is a front elevation of this stable, in a simple style, which may be called Grecian. Two of the windows are shown with outside blinds, and two glazed between upright bars, without horizontal ones, in the manner of hot-house sashes. The intention of this mode of glazing is to avoid collecting the moisture and dust which otherwise are always found on the cross bars of stable and out-house windows. All the windows are intended to have outside

The intention of this mode of glazing is to avoid collecting the moisture and dust which otherwise are always found on the cross bars of stable and out-house windows. All the windows are intended to have outside

luffer-board blinds, to be worked from the inside by a lever handle, in the manner which we shall describe hereafter. Fig. 778 is an elevation of the plan, fig. 774; supposing

it to be finished exteriorly in a style which may be called Gothic. Fig. 779 is a cross section, in which is seen the small corn bin or cupboard for currycombs, &c., under the window, *q*; the ventilator, with its protecting cover, *r r*; the gutter drains with their gratings, *s*; the cast-iron manger, *t*; the bull's-eye cast-iron rack, *u*; the bottom of the rack, *v*, beneath which is the space for dust and seeds; a cast-iron ramped cap, *w*, to the partition between the stalls; and a cast-iron sill, with a groove for receiving the ends of the boards from the partition, *x*. The stable-post, *y*, in this section, is also of cast iron, and it costs 20s.; the ramped iron copings cost 12s. each, and the sills 7s. each. These cast-iron copings and sills for stalls are manufactured by Messrs. Cottam and Hallen; and they afford a very cheap, easy, and durable mode of forming the partitions between stalls.

753. *The different Modes of arranging the racks and mangers of stables are shown in figs. 780 to 785.* Fig. 780 is a front view of the rack and manger, shown in the section fig. 776; and fig. 781 is a front view of the bull's-eye rack and cast-iron manger shown in fig. 779. Fig. 782, two corner cast-iron racks, and a cast-iron manger. Fig. 783 shows what is called a corner manger, with a standard corner cast-iron rack, which costs 10s. 6d., and of which fig. 786 is a perspective view. Fig. 784 is a standard rack, extending two thirds of the width of the stall, in which the horses or cattle are supposed to eat from the top when standing, and from the side when lying down. The length of the manger is one third of the stall, and the space under it is fitted in with spars, so as to form a continuation of the rack. The bottom of the rack is raised six inches from the floor, and is sparred somewhat closer than the sides; the top has cross spars, one foot apart, to prevent the animal from tossing the fodder out of the rack. Fig. 785 shows a cast-iron manger, and a projecting quarter circle rack; that is, the fourth part of a grated

780

781

782

783

784

785

globe, open at top, for putting in the hay or other fodder. When the upright rack shown in fig. 780 is formed of wood, the staves or upright spars are one inch and a quarter square, or round, let into top and bottom rails, three inches and a half by two inches and a half. If the staves are square, they are mortised into these rails; and, if they are round, holes are bored in the rails, to admit their ends. The common width of the openings between the staves is two inches and a quarter; but large horses require three inches. The bottom of the rack is filled in with spars of the same dimensions as the staves of the rack, and at rather less distance from each other. The partitions between the stalls, when made of wood, are thus formed:— A strong post, called the heel-post, or stable-post, six inches square, and seven or eight feet long, so as to stand six feet high when the lower end is inserted in the ground, is firmly fixed by ramming round its lower end with earth and stones. Into this post two rails are mortised, the other ends of which are nailed to the uprights which support the rack, and against these rails upright boards an inch thick are nailed, and terminated by a capping piece, straight or ramped, according to taste. Short partitions, three or four feet long, and seven feet high, are sometimes formed between stalls, to prevent horses adjoining each other from eating together. The width of stalls with these short partitions, Waistell observes, may be about four feet and a half. Long partitions to stalls, he says, should be about eight feet; and the width of each stall, from five feet and a half to six feet. In some parts of the country, it would be cheaper to form the partitions of slate or flag-stone, or even of common rubblework; or of rammed earth, or of cob.

754. *The Window most suitable for Stables and Cow-houses*, we think, should be composed of glass within, and of luffer-boarded blinds, to serve also as shutters, without. The construction is shown in figs. 787 to 793. Fig. 788, to a scale of a quarter of an inch to a foot, is a view of the glass window, as seen inside the stable or cow-house. It is composed of two sashes, *a, b*, one of which slides past the other, in two grooves, in the top and bottom of the frame, as shown in the section fig. 787. These two sashes are without horizontal bars, and are glazed in the manner of hot-house windows, for the reasons before mentioned, § 752. At *c* is a mortise cut in the side style of the window frame, for a handle to move up and down in, which is used to work the outside blinds, and this handle can be locked by an iron pin, when the blinds are used as shutters. Fig. 789 is an outside view of the same window, with the blinds placed before it; the laths or luffer-boards being in a horizontal position, to admit the greatest quantity of light. Fig. 791 is a cross section of the window complete, with the luffer-blinds, *d*, outside, and the two sashes, *e*, inside. In this figure is seen the lever handle, *f*, which works the luffer-boards. In the knob of this handle there is a small hole, which (when the

787

luffer-boards are shut close down, so as to admit the least quantity of light, and the handle is, in consequence, raised to *g*) necessarily coincides with the ring staple at *g*; when, by inserting an iron pin through the hole in the lever handle, and through this staple, the luffer-boarding is locked, and becomes a secure shutter.

Fig. 790 is a view of a single lath or luffer-board, in the ends of which are seen the two small iron pivots or studs which work into the holes shown in the two lever rods, fig. 792. Fig. 793 is a fragment of the section fig. 791, on a large scale; in which are shown the luffer-boards locked, the lever handle, *h*, being at its highest point. These figures will be understood by any carpenter, if not by all our readers; and though windows and blinds of this

description may be thought too good for stables and cow-houses of the commonest kind, yet, for amateurs, we have no hesitation in stating it to be our opinion, that they are far preferable to any others which have yet been invented. No other construction gives

such command of light and darkness during the day, and of air at all times. In common farm stables, windows might be formed of broad luffer-boards, so hinged as to shut close when it was desirable to exclude air, and to open to different degrees according to the quantity of light or air, or both, which might be wanted. In these broad luffer-boards, there might be inserted one or two small panes of glass, for the purpose of admitting light in severe weather when it was not desirable to admit much air. On the whole, whatever description of window is used in a stable, it ought to be such as will when it is desirable, as in very cold weather, for example, admit light without air, and in very warm weather, in the day time, admit abundance of air without much light.

755. As an Example of a Stable with Boxes as well as with Stalls, such as is usually erected for gentlemen keeping hunters, we shall give the plan and other details of a Design sent us by Mr. Perry, and executed under his superintendance, for a gentleman in the neighbourhood of Godalming. Fig. 794, to a scale of one sixteenth of an inch to a foot, is the ground plan, in which *a b* are two-stalled stables, each seventeen feet by

792

790

791

twelve feet six inches, and containing mangers, *c*, of the width of the stall, and quarter circle upright racks, *d*, in the angles of each stall. There is a common sash window to each stable, and near it an angle hay bin, *e*, formed of boards, with a lid, and capable of containing a truss of hay. The two-horse boxes, *f f*, are each twelve feet six inches by nine feet six inches, and have mangers, racks, and hay bins like the stables. There is an entrance lobby, *g*, with stairs to the rooms over, and this entrance has double doors, as appears by the elevation, fig. 795. Fig. 796 is a longitudinal section from A to B, in which are shown the partitions between the stalls, *h h*; the mangers, *i i*; the situation of the drains beneath, *k k*; and the openings in the exterior walls for ventilation, *l l*.

Above are two rooms for any convenient purpose, *m m*. Fig. 797 is a cross section on the line C D, in fig. 794, in which may be seen the mangers, *n n*; the racks, *o o*; and the

ventilators, *pp*. Fig. 798 is a plan of the flooring of the rooms over the stables, exhibiting the channels or grooves in the walls, for ventilation, *q q*; and the appearance of these openings exteriorly is indicated in the end elevation, fig. 799. Fig. 800, to a scale of two thirds of an inch to a foot, shows the manner of finishing the eaves of the roof; in which *r* is the principal rafter, eight inches by three inches at bottom, and six inches by three inches at top; *s*, the wall-plate; *t*, the pole-plate; *u*, the upper rafter; *v*, the eaves board; *w*, the slate boarding; *x*, the bracket; *y*, a bed-moulding; and *z*, the soffit boarding. The stalls in this stable have level floors and gratings similar to those in fig. 776, § 752; the floors of the boxes are also level, and paved with flag-stones, all of which, except about eighteen inches in width round the box, are perforated with holes about the fourth of an inch in diameter at top, and gradually widening to the under side of the stone, like the holes in the tiles of a malt kiln. The centre stone lifts up, for the purpose of cleaning out the drain below.

756. *Houses for Horned Cattle.* The anatomical structure and physiology of horned cattle are much less intricate than those of the horse; and the animals are consequently much hardier, and much less liable to disease. They will endure a greater degree of cold in winter, and of heat in summer; and they require less delicacy of management in their lodging, either in respect to space or ventilation, than horses. No horse could be kept in a stall for months, without exercise in the open air, and yet retain his health; but cattle have been so kept till they have been made sufficiently fat for the butcher; and milk cows have been kept in the neighbourhood of London, standing in the same stall, without having been once taken out, for two years. (*Encyc. of Agr.*, 2d edit. § 6898.) It does not follow from this, however, that great improvement might not be introduced into cow-houses and cattle-sheds; and that exercise in the open air would not add to the flavour and wholesomeness both of butcher's meat and dairy produce: on the contrary, the cow-houses in Holland, and the cattle hammels, or small feeding yards, of Northumberland, may be referred to as proofs that this is actually the case. The principal difference between a house in which cattle are tied up, and one in which horses are either kept in stalls or in separate rooms, is the open gutter behind, which has hitherto been considered indispensable in cattle-houses, on account of the more fluid nature of the dung of the animals. This gutter, or some substitute for it, is

certainly essential where cattle are tied up; and one of the principal points in the construction of the floor, in every house for horned cattle, is, to place the gutter at

797

798

a proper distance from their hind feet. This distance, in Holland, is never less than six inches, nor more than a foot. The gutter is generally made a foot broad, and three or four inches deep; it is usually perpendicular on the sides, but sometimes the cross section of the gutter is that of a semicircle or semioval; which last form is, however, objectionable, as it is apt to make the cattle slip when they cross it to their stalls. Whatever be the form of the section of the gutter, the hoe or scraper employed to clean it out must have its blade of a corresponding shape. In houses where cows or cattle are kept untied, two or three are generally placed together in an apartment ten or twelve feet square, opening into a small yard of twice that area. Such cattle-houses are called, in Northumberland and Berwickshire, hammels; and in them there is no regular gutter, but simply a very gentle inclination of the floor of the shed and of the surface of the yard to one angle, where there are, or should be, a trap and drain, communicating with the liquid manure tank.

757. Cow-houses, in which cows are kept for giving milk, require to be constructed with more care than other cattle-houses, with respect to ventilation, light, and cleanliness.

Cows on common farms are not generally kept in separate stalls, except in cases of sickness, or when they are near the period of calving. The width of a common farm cow-house, where the cows are to be ranged lengthwise of the building, should be at least sixteen feet, and the width allowed for each cow, of the largest and most improved breed of cattle, should not be less than five feet, or, when the cows are kept in-doors throughout the year, six feet; and the space from the manger to the gutter should be eight or nine

feet. The manger should be a boarded, stone, or iron trough, placed so that the upper edge may be from a foot to eighteen inches above the surface of the ground, or about the height of the cow's knees; and it may be eighteen inches broad, and a foot deep. It should be divided into three parts, to admit of putting dry food in one, moist food in another, and water in the middle. In default of this arrangement, there ought to be a division of the manger for water between every two cows. Where cows are not kept in separate stalls, there ought to be a partition between every two pair, to reach half-way or more to the gutter behind. Between the manger and the wall there should be a passage of at least three feet in width, for supplying food, and for cleaning out the mangers from time to time. The gutter behind the cattle should be at least a foot wide; and this will leave a passage, between the gutter and the wall, of three feet in width. There ought to be a door in one end of the foddering passage; and, another as an entrance for the cows, in the end of the broad passage. The food may either be kept in an empty stall next the door, or, what is preferable, in a foddering bay, into which the doors should open. In every cow-house there should be windows for light; and there ought to be tubes for ventilation in the side walls, or in the roof, similar to those recommended for stables, to use when the windows cannot be conveniently opened. The cows may be fastened to the front rail of the manger by a halter or chain passed through an iron ring, and loaded at its lower end. The floor of the standing-room ought to be perfectly level, because it is found that, when it is lower towards the gutter than at the manger, it is apt to occasion abortion, when the cows are in a gravid state; and, for the same reason, the top of the manger or rack, if there is one, should never be higher above the floor than eighteen inches. Morel-Vindé observes that the farmers of Normandy are so particular in this respect, that they not only have their mangers and racks very low, but, when the cows are turned out to grass, they always harness them with a bridle and brechin (*bricole Normande*), in such a manner as to prevent them from tossing up their heads, or reaching to the branches of trees.

758. *A cow-house in which the cows are to stand across the building* will afford the same accommodation as that in which they stand with their heads against one of the side walls, at less expense of walling; because the foddering bay, which need not be larger in this case than in the other, serves at the same time as a foddering passage. In these foddering bays Waistell recommends that a cistern should be constructed, in order that when the turnips are topped and tailed in the field, the cart which brings them home may be backed into the bay, and the turnips tilted into the cistern, where, by stirring them a little, the loose earth which adheres to them will readily drop off, and they may be taken out of the cistern, and supplied as wanted to the mangers. This operation is performed by means of a grated iron scoop with a long handle.

759. *In the cow-houses of landed proprietors of taste, or in those of large establishments near town, various improvements may be suggested on the above arrangements.* One of these is, to have a drain covered with oak planks pierced with holes or cast-iron grates along the bottom of the gutter, for the purpose of allowing the urine and thin dung to pass immediately through it, and be carried off, as was practised in the Harleian dairy, near Glasgow; thus diminishing smell and evaporation, and presenting at all times an appearance of cleanliness. The gutter, in this case, may be very shallow; and, indeed, if a broom be now and then passed over the grating, so as to press all the dung into it, it might be raised to a level with the floor, and the open gutter entirely dispensed with. Grated bottoms to gutters, with drains underneath, are common in the cow-houses of men of wealth in France and Germany; where there is sometimes, as in the king of Wirtemberg's dairy at Weill, a supply of water at one end of the gutter, always ready to be turned on by a cock, every time it is cleaned. This is the case also in the cow-houses of the Agricultural Institution at Schleissheim; and it is found there not only to keep the gutters sweet, but, by the obvious increase it affords of fluid matter in the manure tank, to supply the means of rotting a greater quantity of straw in the dunghill which is there kept over it, and moistened with the fluid beneath by means of a pump. Another improvement is, having all the divisions in the manger, intended for water, on the same level, by which means they may be simultaneously supplied by turning a cock; or the same thing may be accomplished, if they are on a uniform slope, by sinking them six or eight inches below the general surface of the bottom of the manger, and having a false bottom, or water channel, leading from one to another. In this case, after the first division was filled, the water would run along the false bottom or water channel and under that of the dry and moist food divisions of the manger, to the next water division, and so on to the end. It must be confessed, however, that supplying cattle with water in this way is a refinement that can only be worthy of adoption in very extensive establishments; for cattle, like all other animals, when regularly fed, and properly treated, will only drink at stated periods after they have had their due supply of solid food, and at these periods they could be let out to drink in the

open air. Water is supplied in the manner above mentioned at Rhodes's dairy, at Islington (see *Encyc. of Agric.*, 2d edit. § 6897.), where one division for water is formed in the manger between every two cows; and these divisions are furnished with covers, which are put on when the cattle are eating dry food, to prevent them dropping any of it into the water, and thus dirtying it. As abundance of light in every farm building is highly favourable to cleanliness by exposing the want of it, large glass windows might be formed in every description of house for cattle; but these should always be provided with outside shutters; or, what is preferable, luffer-boarded outside blinds, as recommended for stables, fig. 789, § 754, to keep off the intensity of the light, and also the heat of the sun. These shutters or blinds should be opened whenever the master or mistress may enter the building, or when it is to be cleaned out; but at other times they should generally be closed, as it must not be forgotten that light stimulates the animals, and prevents their repose, while it favours the introduction of flies and other insects, which are always very troublesome to cattle. In the royal cow-houses at Bagatelle and at Villeneuve d'Etang, near Paris, the windows reach from the floor to the ceiling, and open like those of a drawing-room. They have outside shutter blinds, and hinged panes of glass at top and bottom, for giving air in the winter season. The walls and ceilings are plastered, and finished as carefully as those of a common dwelling-house in London; and a person being constantly in attendance to remove any dung that drops, the place is as clean and sweet as can be desired. We speak of them as they appeared to us when we visited them in 1828. In Flanders the cow-houses are equally clean and sweet; and Radcliffe, in his *Husbandry of Flanders*, informs us that, in the winter season, the farmers generally breakfast in them: he adds that he did so himself, and found no inconvenience from either bad smells or want of cleanliness. In general, indeed, cow-houses and cattle-houses, as well as the animals themselves, are kept far cleaner and wholesomer on the Continent than in Britain. In the Harleian dairy establishment, which existed some years ago at Glasgow, some ingenious contrivances for cleanliness were introduced, which may deserve imitation. In front of each cow, between the manger and the foddering passage, a wire grating was suspended by cords and pulleys like a window-sash, which was lifted up when food was given, or the mangers cleaned out. The racks for hay were also suspended by cords, weights, and pulleys; so that they could be pushed up out of the reach of the cows, when moist food was put into the mangers. In the gutters there were round apertures, of about six inches in diameter, with cast-iron covers fitted to them at short distances, and through these the dung was swept into large drains below, whence it was carried away by its fluidity to a dung-pit. The tails of the cows were tied up to the ceiling at milking time, as in Holland, and they were regularly combed and brushed twice every day. A stream of water could be introduced into the mangers and gutters at pleasure, for the purpose of cleaning them, or for supplying water to the cattle to drink. No litter was used, but the floors of the stalls were formed of boards, and the gutters behind were furnished with grated bottoms, and openings with covers, at intervals, as before mentioned. The temperature of these cow-houses was regulated by a thermometer. We cannot approve of this plan of not littering the cows, which is still adopted in some of the large dairies near London; because it must be more comfortable to the cattle to lie down on straw than on bare boards or pavement, however smooth or clean either may be. Much less can we approve of the plan of not turning cows out of doors at least once or twice a day for exercise: this is always done on the Continent, even in the winter season, unless during a heavy fall of snow, or during continued heavy rain. Cows are universally cleaned like horses in Holland and the Netherlands, and in all the first dairies both in France and Germany; and the Continental custom of tying up their tails at milking time, already mentioned as practised by Harley, is beginning to meet with imitators in this country. Curry-combing and brushing have long been in use in gentlemen's dairies. We mention these things with a view of supplying the young Architect with ideas for the introduction of these and still further improvements in the design and construction of this kind of buildings; since no Architect can improve the arrangements of a building, of which he does not thoroughly understand the use; and the mere improvement of its Architecture, or external effect, without adding to its utility, is calculated to excite a feeling of contempt, rather than of approbation or respect.

760. *Calf-houses* ought to be placed near the cow-houses, to lessen the labour of carrying the milk to them; but they ought never to be so near as to permit the cow to see or even hear the calf; because either would disquiet her, and prevent her from feeding. The best mode is to have a separate house for the calves, and to tie them up to stakes like cows. The width of the space allotted for the calves need not be more than eight feet, and it should be arranged in every respect like a cow-house in miniature. Where calves are to be fed for the butcher, they are sometimes enclosed singly in

small pens, between six and seven feet square; but this is an unnecessary expense when the object is simply to rear the calf. In general, no arrangement is advisable by which two or more calves are kept loose in the same pen; because, so placed, they are apt to suck one another, and also because milk or food cannot be given to more than one calf at a time, and the others are liable to be injured while being driven off. As calves require the greatest attention to keep them clean, all the architectural arrangements connected with them ought to be especially directed to that end. The best constructed calf-pens in Middlesex have false bottoms of boards pierced with holes, through which all moisture escapes, by which means they are kept quite dry; and, by a little care on the part of the attendant, they may also be kept perfectly clean and sweet.

761. *Feeding-sheds for horned Cattle* may be constructed on the same plan as cow-houses, and the cattle placed in pairs between wooden, stone, or slate partitions. The cattle may either be ranged along the side walls, with a foddering passage at their heads, and a cleaning passage behind (the foddering bay being at one end, or at both ends); or they may be ranged across the building, with bays for holding fodder, or serving as passages for supplying it, alternating between every two rows of cattle. A house sixteen feet wide and twenty-eight feet long will contain eight head of average-sized cattle, in a row, with their heads to a foddering passage three feet wide, at one of the side walls; and with a cleaning passage four feet wide behind them. A house thirty-two feet long and fourteen feet wide will contain the same number of cattle, with their heads towards a foddering bay, and place for giving fodder in the middle of the house, eight feet wide. This last mode of placing the cattle is much more convenient than the other, and though it contains four feet more of circumferential walling, yet, if we make allowance, in the former case, for a building to contain the fodder, the latter will be much the more economical as well as the more convenient mode.

762. *Feeding-houses for loose Cattle*. It has been found that many descriptions of cattle, and particularly those bred up in mountainous districts, which are naturally small and active, do not fatten so well when tied up in stalls, as when left loose in a limited space, with a well-littered house or shed to take shelter in at pleasure. This is the general practice in Northumberland, and in most parts of Scotland. The sheds or houses may be fifteen or sixteen feet square, and fitted up with racks, either at the angles or against the partitions. The open yards may be of the same size as the covered sheds, with walls four feet high, and doors lifting out of grooves; or in two parts, with the upper half hinged, and the lower part fitted in a groove, so as to lift out. The reason why it is proposed to fit the doors in grooves, or to have them in two parts with the lower part grooved, is, that, in opening doors hinged in the common manner, they are apt to be obstructed by the litter which generally, though improperly, covers every farm-yard passage. In some Scotch farmeries, not only the doors of hammels and pigsties lift out of grooves, but even the gates lift out in a similar manner, or are suspended by weights with cords and pulleys, and are raised up and lowered like common sash windows. All this is owing to the practice of keeping yards covered with litter; but, when the management of cattle and manure is properly understood, the former will always be kept in houses or hammels, in order to moderate temperature; and dung and litter always under a roof, in order to lessen evaporation.

763. *Feeding-places for growing Cattle* are nothing more than open sheds fitted up with racks, each having a court or yard of proportionate size to the shed; that is, containing three or four times its area. In general it is desirable to divide these yards or sheds, so that not more than six or eight head of cattle may be together in the same yard. Besides the rack in the shed, there ought to be fixed or portable racks, with roofs to them, in the open yard. All cattle-racks ought to be placed on the ground: their height need not exceed two feet and a half, and their width eighteen inches. The top should have cross bars eighteen inches apart, to prevent the cattle from tossing out the fodder, and the bottom should be grated, to allow reeds, stones, dust, or other matter to drop through on the ground.

764. *Houses for working Oxen* may either be fitted up like the cow-houses, or, what is preferable, like the cattle hammels; a pair of oxen being allowed for each hammel. Whether oxen are kept loose in hammels or tied up in stalls, provision ought to be made under cover, and near them, for hanging up their harness; and for keeping the curry-combs and other instruments or utensils with which they are cleaned or fed. As it requires two pair of oxen to do the work of one pair of horses, on a farm where the ox is the principal beast of labour, a proportionate increase of building is required; and, in general, also an additional labourer for every three or four pair, for the purpose of cleaning them, and their stalls, harness, &c.

765. *Piggeries*. The swine is an inhabitant of all climates, and eats every kind of food; but he is nevertheless averse from extremes of either cold or heat. Nature has taught him, in a wild state, in the torrid as well as in the frigid zone, to seek the recesses

of the forest, both for food and shelter; where, while grubbing up the soil for roots, he is protected, by an impenetrable non-conducting mass of branches and foliage, from the heat of the one or the cold of the other. The domestic swine is in a highly artificial state, and requires to be kept warm by abundance of dry litter in the winter; and cool, by shady well ventilated houses or sties in summer. Seeking his food chiefly in the soil, he cannot be considered a delicate animal; and he has few diseases compared with either the cow or the horse. Uniformity of temperature, therefore, seems to be the chief thing to be studied in the construction of piggeries. As pigs are generally fed in great part with refuse from the kitchen and dairy, the piggeries should be so placed in a farmery as to be accessible from the offices of the dwelling-house, without passing through any of the straw yards, and at the same time not so near as to prove an annoyance in summer by their smell. The construction of piggeries is exceedingly simple, each pigsty consisting of a covered lodging, and a small open court; the latter for feeding and the former for sleeping in, in the case of store pigs; though, for fattening pigs, especially in winter, the feeding troughs are frequently placed in the covered or warmest part of the structure. In a complete piggery for fattening pigs, there should be, at one end, or in the middle, a bay or compartment for pig's food dry and moist; and on the two sides of a passage may be placed rows of separate sties; each with its feeding-trough in the side next the passage, and with a swing-door on the opposite side to a small yard. The use of the swing door, which is nothing more than a frame of boards suspended from a rail, the ends of which move in sockets freely either way between the jambs of the door, is to prevent the door from ever being left open in severe weather. When the pig wishes to go out, he soon learns to push it before him; and the same when he wishes to return. Fig. 801 is a section across a wall containing a pig's trough, in which *a* is a swinging flap or door; *b b*, stops to prevent it from being pushed too far either way; and *c c*, holes for a bolt to fix it in the position *d*, when the troughs are to be filled with food, or to be cleaned; or at *e*, when the pigs are to eat. The pigs, however, will keep the flap open themselves while eating. This arrangement is well calculated for fattening pigs, when there is not more than one in a sty; but for store pigs, or for a sow with a litter, it is desirable to have a longer trough, or to have two or more small troughs, as the strongest pig is apt to get into the trough while eating, to the exclusion of the others. The floors of all pigsties should have an inclination to carry the moisture to a trap or drain; and no animal requires a greater abundance of dry litter. If under a good roof, and well supplied with this material, the pig will keep himself warm and comfortable, almost any where, and in any season.

801

766. *Sheep-houses.* The sheep is a native of temperate climates, where the ground is not long covered with snow during winter; but it has become an artificial inhabitant of all countries from Iceland to the equator. It is only in those countries where it cannot pasture in the open air, from the snow covering the ground during some weeks at a time, or where the extreme heat of summer burns up the herbage, that sheep-houses ought to be required. There are, however, other cases, in which, from the imperfect state of agriculture, and the absence of fences to the fields, or from imperfect civilisation, or the want of rural police, and the consequent prevalence of thieves and wolves, sheep-houses become necessary for protecting the sheep during the night. Structures of this kind are common in Russia, to prevent the sheep from being famished during the long winters of that country; and in France they abound as nightly shelters to guard them from the wolves. In Britain, folds, or walled enclosures, are almost the only description of sheep-houses in use; because our sheep can pasture in the open air during every month in the year, and all our fields are enclosed by hedges, walls, or other barriers. In some of the mountainous districts it becomes necessary to protect and feed the sheep during severe storms; and this is done in Scotland by square or circular folds, called stells, into which the sheep are driven and fed. Sometimes these stells are roofed in, but in general they are left open. The sheep-houses of France and Germany are simply roofs supported by posts, and covering a space sometimes open on all sides, but generally closed to the height of six or seven feet. Across, or lengthwise, in this space, hay-racks are placed;

and, instead of side and end walls of masonry, there are generally wooden pales. The roofs are made very high and steep, in order to acquire strength to bear, and inclination sufficient for throwing off the snow, at the least possible expense of timber. As there is no objection to numerous posts within, provided they be in the line of the racks, sheep-houses of the largest dimensions may be constructed of pieces of timber not more than ten or twelve feet long, or thicker than six inches. Sheep-houses, or folds for feeding and housing sheep in bad weather, are, in England, Mr. Main observes, "square enclosures erected in sheltered places, formed of an outside wall built of turves or other materials, about six or seven feet high; and all round the interior are lean-to thatched sheds, supported on posts about four feet high. Against the back wall are racks for hay, and troughs for chaff, bran, oats, or peas, &c. The middle of the fold is kept well littered with straw; and on one side of the gate there is a lock-up shed for keeping the provender. These folds are usually about fifty feet square, and are no less serviceable to the flock in bad weather, than to the farm in making great quantities of excellent manure." In the north of Germany, and in Poland and Lithuania, there are immense sheep-houses of a very simple construction, which nevertheless are exceedingly effective. A skeleton roof, sometimes circular and sometimes oblong, is formed of long poles, chiefly young spruce fir trees, with their lower ends inserted in the ground, and their points meeting at top; across these, smaller poles are fastened, not by nails or wooden pins, but by withy ties. The whole is then covered, or thatched with branches of spruce fir. The doors and places for ventilation are merely gaps, stopped up or opened according to the discretion of the shepherd. These sheep-houses answer their purpose perfectly. They are sometimes also used for sheltering cattle.

767. *The Sheep-house at Celle, near St. Cloud*, may be given as one of the most complete in France. It was erected in 1809, by Morel-Vindé, on his own estate, and the plan published fourteen years afterwards, as of a construction which, during that period, had given entire satisfaction. Long experience has convinced Morel-Vindé that every sheep in lamb, or with a lamb, to be at its ease, ought to occupy a superficies of ten square feet; that every full-grown sheep without a lamb requires a space of six feet; that every ewe requires a length along the edge of the rack and manger of one foot, in order to eat at ease; and that every ram with horns requires fifteen inches along the rack; that the racks are best when portable, that is, when they are capable of being taken down from the posts on which they are hung, as shown in fig. 802; and, lastly, that in no case should

802

a sheep-house have a floor over it, the health of the sheep depending essentially on their having a great height of open space over them. On these fundamental principles the

sheep-house at Celle was designed. Fig 803 shows the ground plan, in which *a a a* are double racks and mangers, like that shown in fig. 802, placed lengthwise in the middle of the building; and *b b* a single rack and manger, continued round three sides. There are three doors at one end, *c c c*. These doors may be seen shut in the elevation, fig. 804; and the double and single racks may be seen in the cross section, fig. 805;

Ft. 6 3 0 6 12 18 24 Ft.

middle of the building; and *b b* a single rack and manger, continued round three sides. There are three doors at one end, *c c c*. These doors may be seen shut in the elevation, fig. 804; and the double and single racks may be seen in the cross section, fig. 805;

804

805

in this section, also, are seen two bull's-eye openings, *d d*, in the end, for ventilation, and which are kept open at all times. Fig. 806 is the side elevation, in which are shown the situation of small sliding shutters, immediately under the eaves, at *e e*, and that of small

806

openings close to the ground, at *f f*, which have also sliding shutters, and which are for the purpose of establishing a current of air on a level with the soil. Fig. 807 is a

807

longitudinal section, showing the framing of the roof. The dimensions of this sheep-house are thirty feet in width, and seventy feet in length; giving, exclusive of the space occupied by the racks, eight parallelograms, marked from 1 to 8, in fig. 803, each thirty feet by ten feet, and each containing sufficient room for thirty sheep in lamb, or fifty without lambs. The racks cover a space of 370 superficial feet, exclusive of the 24,000 feet devoted to the sheep. The great merit of this structure is its economy; it having cost only £117 : 10s., which was mainly owing to the circumstance of its construction requiring only short pieces of wood; none of these exceeding twelve feet, or measuring

more than six inches on the side, as before mentioned. In France, wood which does not exceed these dimensions sells at the same price as firewood.

768. *Goat-houses* are not in use in Britain; but in France the celebrated manufacturer, M. Ternaux, who introduced the Cachemire goat from Persia, keeps them in his grounds at St. Ouen, near Paris, in the same description of houses as he does his sheep. In similar houses deer might also be kept.

769. *Rabbits* may be kept in any dry house. Sometimes they are allowed to run at large on the floor, and a range of boxes, eighteen inches high, and two feet broad, is placed round it, at the foot of the walls, divided into compartments of two or three feet in length, with one small door, a foot high and six inches wide, to each. On other occasions, where there is a scarcity of room, or where rabbits are to be fed, they are kept in tiers of boxes, one above another, called hutches. Each box or hutch, in this case, has a grated front, and behind, or at one side, an inner box or division, for the animal to enter and repose. The size of this inner box may be a foot by eighteen inches, and eighteen inches high; and the size of the open part of the box may be a cube of eighteen inches. The bars or spokes in front may be an inch square, and two inches apart. Two of them ought to take out, for the purpose of putting in food, &c.

770. *Poultry-houses* require no particular form or magnitude; because, the animal being small in size, there is no necessity for accommodating the shape of the house to its particular figure. Both terrestrial and aquatic poultry agree in requiring a dry and rather warm lodging; and they differ, in that the web-footed birds all roost on a flat surface, while gallinaceous fowls roost best at some height from the ground, on roundish horizontal rods or rails, of a size suitable for being grasped by their claws, but neither perfectly round nor perfectly smooth. All fowls, when in a state of incubation, require repose, to which darkness is favourable as well as solitude; and places where they can have these requisites must be provided for them, as well as separate places for fattening them, to which also solitude and darkness are congenial. Poultry of every description, while growing, are exceedingly active, and, in an artificial state, require a considerable extent of yard to enable them to take sufficient exercise for health. The variety of their food is also considerable, including not only animal and vegetable matter, but even, as a help to digestion, salt, sand, or small pebbles. As land poultry require a dry yard, so aquatic poultry require ponds; and, while the common hen will roost at the height of a few feet from the ground, the turkey and peacock prefer the highest trees. It must be evident from this variety in the nature of these animals, that every kind will require a separate house or compartment of a building, and that this house or compartment should be in four divisions; one for rearing, another for keeping full-grown fowls, another for incubation, and a fourth for feeding. For the first two of these houses or divisions, a yard for the purpose of allowing the fowls to take exercise and pick up food is essential, and in this yard there ought always to be an open shed for shelter from the sun or rain, abundance of sand, and small pebbles; and, for aquatic fowls, a large pond. The healthiest poultry of every description are those which are well fed in their yards in the morning, and allowed free exercise out of them the greater part of the day; and the fittest poultry are those which are confined in the dark, and not allowed to take any exercise. In all cases where poultry have not the free use of a large yard, they should have troughs filled with sand and small pebbles, placed so as to allow them to pick them when they choose, to promote digestion. We have described, in the *Encyclopædia of Agriculture*, the mode of fattening geese and other poultry, as practised at Strasburg; but it is too disgusting to wish for its adoption in any other country. These being the general circumstances connected with domestic poultry for architectural purposes, they may be classed in the three following divisions: viz., the web-footed or aquatic, which must necessarily, for every kind of treatment, be lodged on the ground floor; the common cock and hen, which prefer the floor above; and the turkey, guinea fowl, and peacock, which roost in lofty open sheds, or on trees. In small farms, therefore, all the different kinds of poultry may be lodged in the same house. Ducks and geese, with the other kinds, while rearing, on the ground floor; common fowls, when full grown, and while in a state of incubation, on the middle floor; and the turkey, &c., above. One yard may answer for the whole, provided it be sufficiently large, and contain a large pond. As warmth is highly conducive to the prosperity of poultry, common fowls are frequently lodged above cow-houses or stables, or even pigsties; and in other cases, when it is very desirable to cause hens to lay early in the season, their houses are heated by flues. When, however, the house is of a construction well calculated to retain heat, and it is perfectly dry below, and has few openings above, and a roof sufficiently thick to exclude all frost, artificial heat can very seldom be necessary. When it is desired to rear chickens for sale very early in the season, the eggs may be hatched by hot water, or in a bed of tan, dung, leaves, or other fermenting matter; and, after being hatched, they may be reared under a roof of glass, which roof may be employed in the summer season as a covering for vines. At Bagshot Park,

Surrey, there is a very extensive poultry establishment; and early in the season the fowls are reared in a vinery; and a writer in the *Gardener's Magazine* (vol. viii.) not only rears, but hatches, in a house of the same description. In the centre of the large yard at Bagshot there is a tree partially denuded of its branches, in order that it may serve as a roosting-place for the turkeys. In every poultry-house the places for incubation are small stalls or boxes, eighteen inches or two feet square, and open in front, in which the fowls sit on their eggs; and, after these are hatched, they are taken out into the yard, and the mother is confined in what is called a coop, an inverted cup of wickerwork, with the interstices large enough to allow the young brood free egress and ingress, while the parent cannot escape. These coops are frequently boarded on all sides, with a grated door opening in front. Partridges, pheasants, quails, bustards, and other gallinaceous birds are sometimes bred and reared in artificial structures, with a view to their domestication or increase in any particular locality. When this is the case, it is necessary to enclose them above and on all sides by netting, to prevent their flying away; because these birds are not susceptible of perfect domestication.

771. *The Pigeon-house, or Dovecote*, has been an appendage of the country-house from the earliest ages; and nothing can be more simple or universally known than its structure. The only essential requisite is, that it must be at some distance from the ground; because the pigeon is a bird that flies much higher than any of the domesticated fowls before mentioned. The openings for the birds may be in the roof, or in the highest part of the side walls, with shelves before the holes for the birds to alight on; and the walls of the interior may be lined with boxes, divided into square holes, for the birds to make their nests in; in short, into pigeon-holes.

772. *The Farmery Infirmary* is simply a house, or one or more divisions of one, in a quiet part of the farmery, large enough to contain a horse or cow in each division, and to serve as lodgings for animals under a course of medicine. Dryness and a command of temperature and ventilation are essential.

773. *The Store-houses for the Produce of the Farmery* include the barn; the straw-house; the granary; the root-house; the hay-barn; the maize-barn; the place for keeping pigs' food; the wool, hair, and feather room; the hop-loft; and the loft for miscellaneous products.

774. *The Barn* combines a manufactory and a storehouse, and is to the farm-yard, in the former capacity, what the kitchen is to a human dwelling; that is, it manufactures a great part of the food consumed in the other apartments or divisions of the premises. Formerly the corn barn was much larger than it has become necessary to have it since the introduction of threshing-machines. It should still, however, be of considerable size, so as to contain a rick of unthreshed corn of the size that such ricks are generally made on the farm. The size of the ricks, and the size of that part of the barn which is to contain the unthreshed corn, should be accommodated to each other; and the size of that part of the barn which is to contain the straw after it has been threshed, if the straw-room is not a separate building, should be accommodated to both. The form of the barn should, in almost every case, be a parallelogram, and at least twenty feet wide, with walls twelve feet high. The length will depend chiefly on the size of the ricks, and it is always most economical to have these small; not only because a small barn costs much less than a large one, but because both grain and straw are sweeter, and more relished by cattle, when recently threshed from the rick, than when they have been long kept in a barn, granary, or straw-room. Where the expense is not an object, it is desirable to have a room, as a granary, over that part of the barn which contains the machinery for threshing, and the room for cleaning up and measuring the corn. Into this granary the corn, as measured and put into sacks, may be hoisted up through a trapdoor by a windlass, with a rope and pulley. The position of the barn relatively to the other buildings of the farm-yard, depends on the position of the stables, and cattle-houses; it should always adjoin or be central to them, and be close to the rick-yard. Where the threshing-machine is to be driven by horses or steam, the barn may be set down on whatever side of the farmery is thought best for it; but where it is to be driven by water, local circumstances must often determine its position. In general, as the buildings of a farmery form a shelter to the cattle-yard, and as the barn is the highest of these buildings, it should be placed on that side from which the coldest winds blow; and this is also favourable for its proximity to the rick-yard, which ought to be in the most windy situation, for drying the corn when it is newly stacked. There is another reason for placing the barn on the most airy side of the farm-yard, which is, that when the threshing-machine is driven by horses, they are less apt to be heated in the track-shed, which should always be as open as possible on all sides. Wind machinery is also sometimes employed for driving a threshing-machine; and, when that is the case, the north side of the farmery is, in Britain at least, still the best situation. The most desirable power for driving a threshing-machine is water; and the next, in a coal country, steam.

775. *A Corn Barn on Posts* was erected by Morel-Vindé, at Celle, St. Cloud, in 1812; and the plan and details of it are given in his excellent work. He observes, that though the construction of a barn on posts is necessarily more expensive than one the floor of which is the ground, yet that it does not cost more than one third of a barn of the same size built of masonry, while it is a great deal better, especially in countries where timber is at a low price. When Morel-Vindé's work was published, the barn at Celle had stood twelve years without undergoing any alteration, or requiring the slightest degree of repair, and without a single mouse or rat ever having been seen in it. The great advantage of this barn is that of preserving the straw always as fresh as if it had just come from the flail: he has preserved it one and even two years, without its undergoing the slightest damage. The saving from the ravages of rats and mice, produced by such a barn, is found by experience to be more than fifteen per cent; and, compared with barns built of masonry, there is also another saving, that of being able to fill it with corn the first year; whereas a barn with stone or brick walls requires a year to dry them. The wood of which this barn is composed was not felled on the 25th of March, 1812, and yet the barn was completed by the 25th of June in the same year; and in the harvest following 15,000 sheaves of wheat were put into it. The only kind of wood employed in this barn is that of the Lombardy poplar, with the exception of the posts, two feet high, which are of oak; it is covered with slates; and the whole cost was only £182 : 5s. : 10d. in the neighbourhood of Paris. In the departments of France, the cost is estimated at £109 : 7s. : 6d. Fig. 808 is the ground plan, on one half of which are shown three sleepers

the whole length of the structure, *a a a*, which support the joists, *b b*, on which is laid the planking, *c*. Fig. 809 is a cross section of fig 808 on the line A B, on which are shown the threshing-floor, *d*; a floor over it, *e*, and the suspended fold-up steps, *f*. Fig. 811 is a cross section of fig. 808, on the line C D,

showing that there is no second floor over any part of the barn, but the threshing-floor, as seen in the preceding figure. Fig. 810 is an elevation of one end, showing the cross braces, which are only placed in the ends and sides. Fig. 812 is a side view in which may be seen the threshing-floor, *g*; the end of the floor over it at *h*; and, in the roof, four small openings for the escape of the wind during stormy weather, to prevent its blowing off the roof

The side view of these openings is seen in fig. 811. Fig. 813 is a longitudinal section, showing the cross braces which strengthen the upright posts, and the construction of the roof.

812

776. In the Construction of the Corn Barn at Celle, the object was to enclose a space fifty-five feet long, twenty-two feet broad, and twenty-two feet high, without taking into calculation the space contained in the angle of the roof, which was eleven feet high in the centre, the angle of the side being at forty-five degrees, for the better throwing off of the rain. Numbers divisible by 11 were made choice of, because

experience has shown that eleven feet is the maximum of length which can be given to beams placed horizontally, without risking their bending. The fifty-five feet of length are therefore divided into five bays, which are contained between six frames of carpentry, placed eleven feet apart, and of which two form the gables at each extremity. Eighteen foundations of masonry are built in the angles of ten squares (see fig. 808), each eleven feet on the side, and carried up fifteen inches above the surface, in order to support eighteen stone plinths, on which are placed eighteen oak posts, two feet high and one foot square, fixed to the stone by oak pins one inch square and two inches long, which are let half way into the post and half way into the stone, with tenons at their upper extremities for being mortised into the sleepers. By these means the eighteen pillars are raised to the height of three feet from the surface of the ground; the two lower feet are covered with slates, as shown in fig. 814 from *i* to *h*, and the foot immediately under the joists is covered with twelve panes of window glass, each a foot square, retained in their places by two small fillets of wood at *k* and *l*, to which they are cemented at the upper and lower edges only, and without any finishing at the angles. The glass is to prevent the ascent of rats.

813

814

On the eighteen pillars, presenting on their upper extremities eighteen tenons, is placed, first a frame of carpentry composed of three sleepers the whole length of the structure, which may be easily cut out of trees of Italian poplar; and, secondly, six sleepers of twenty-four feet long each, crossing the three long sleepers, and let into them by notching out each to the depth of one third. The three long sleepers contain, on their under sides, mortises to receive the tenons of the oak pillars, and these are made fast by wooden pins. On this frame is placed the skeleton of the building, which is rendered plain by the sections and elevations represented in fig. 809 to 813. The skeleton of the superstructure consists of twelve upright posts, each twenty-two feet high, framed into two top plates extending the whole length of the barn, and into six cross plates. This framework completes the skeleton of the rectangular part of the building. The roof is composed of twelve principal rafters, on which are placed two purlins; and on these rest the secondary rafters, to which are nailed the laths for receiving the slates. The eaves of the roof project about four feet on each side, to protect the unthreshed corn or straw from the rain; it also projects about two feet at each end, for the same purpose. This is the more necessary as the sides are not covered with boards. All the joinings of the timbers in this building are by tenon and mortise, and all the pins used are of wood, with the exception of those employed for nailing on the laths for receiving the slates, and the nails used in fastening them. With these exceptions, there is not a single piece of iron in the whole of this structure; and there is no other metal used, except four pieces of lead for the four openings in the roof. In order to make certain of excluding the rats and mice, by rendering it impossible that the thresher should ever forget to turn up the folding stair when he leaves his work, two chains or ropes are attached to it, one on each side, counterbalanced by heavy weights, as shown at *m*, in fig. 815. In case of the roof requiring repairs, twenty-four hooks of iron may be placed at equal distances along the ridge, to which the slater's ladder may be hooked on. Instead of painting or tarring the timber work, it may be covered, on the exterior sides, with slates. We examined this barn and the other buildings at Celle, with M. Bailly de Merlieux, in 1828, and were highly gratified with it. We consider it a model for economy and usefulness, and would strongly recommend it to the American farmer.

777. *The Straw-house* is generally the end of the barn opposite to that in which the unthreshed corn is placed; but in large farms it forms a separate building, adjoining and connected with the barn, and opening into the different cattle-houses and cattle-yards.

778. *The Granary*, where the barn is not sufficiently high to admit of its being placed in the roof, is commonly placed over the cart-shed, or some other building. It is sometimes built apart; but this is a needless expense, and seldom incurred in wooden constructions. A detached granary should be built on pillars with projecting caps, to prevent the ascent of rats and mice; and it should have windows filled in with luffer-boarding on all sides, for thorough ventilation; it should generally be placed exterior to the cattle-yards, in any open situation not far from the barn. When the granary is placed over any other building, it is always convenient to have a windlass fixed in it; either immediately over a trap-door in the floor, or over a door in the outside wall; through the first of which, sacks of grain may be hoisted up from the corn-room of the barn, should the granary be placed over it; in the other case, be raised up from, or let down into, a cart.

779. A Granary with a Loft for Wool above, and a Cart or Implement Shed beneath it, is given by Morel-Vindé, which, where economy of room and money is an object, we consider a most excellent model. The material of construction is entirely timber of small dimensions, no piece in the whole structure exceeding ten feet in length; and only the story posts, or supporting pillars, are so much as nine inches square.

Fig. 816 is the ground plan of the cart-shed or ground floor, fifty feet by thirty feet. The height to the under side of the floor above is ten feet. The two longitudinal sides of this plan are carried up perpendicularly as gables, and the two ends are hipped in at an angle of forty-five degrees, as shown in figs. 818 and 819. The granary floor is of the same dimensions as the ground floor, and the wool floor, which is above the granary, is thirty

feet by thirty feet. The height to the under side of the floor above is ten feet. The two longitudinal sides of this plan are carried up perpendicularly as gables, and the two ends are hipped in at an angle of forty-five degrees, as shown in figs. 818 and 819. The granary floor is of the same dimensions as the ground floor, and the wool floor, which is above the granary, is thirty

817

feet by thirty feet. The granary and the wool-room are both seven feet high. The grain and wool are both taken up and let down through a trapdoor, by means of a windlass fixed over it, as shown at *a*, in the plan of the wool room. Fig. 818 shows the longitudinal elevation of the building, in which may be observed three doors to the corn granary, and one door to the loft over it. Fig. 819 is a longitudinal section through the centre of the building, showing the situation of the windlass, *b*; and the pulley over which the rope passes, *a*. Fig. 820 is an end elevation, and fig. 821 a cross section. The total expense of this structure, in the neighbourhood of Paris, in 1819, was £247, and the estimate for the departments of France was £150. Such a building is admirably calculated for a country where small timber is the cheapest building material; and we have introduced it with a particular view to America and Australia, as it might be put up by the very commonest description of country carpenter. The granary might even be used as a hay-loft, or a loft for maize or Indian corn in the ear, and the wool-room may be employed as a granary or seed-room, according to local circumstances. By means of

818

the trapdoors and windlass, any article might be hoisted up from or let down into carts with very little labour or loss of time. Should it be intended, before creating this

819

building, to use the granary as a hay-loft, or hay-barn, the floor need not be laid with boards.

780. *Storehouses for Roots*, such as potatoes, turnips, mangold-wurtzel; and temporary depositaries for clover, tares, or other green food, or for chaff, hay, or other dried food, should be placed next to the houses or yards of the animals which are intended to be fed by them. In form they should either be squares or parallelograms, as giving most space at least expense. They should have ample doors, generally of such a width as to admit of setting back a loaded cart into them, and shooting down the article to be stored up. Food which is to be consumed immediately in feeding cattle, such as green clover, tares, turnips, &c., may also be laid down at once in proper recesses or stores formed in the houses or sheds in which the cattle stand. Food which is to be steamed, or otherwise prepared, before it is given to cattle, should be stored next to the place of preparation.

781. *A Barn for Hay* is used on some farms, though the practice is given up by the best farmers as too expensive, and as being less favourable for keeping the hay than stacks or ricks in the open air.

782. *A Barn for keeping the Ears of Maize* is sometimes required in countries where that corn is grown upon a large scale. Barns of this description should be made quite narrow, and open on the sides, so as to admit a thorough current of air; and, to prevent the weight of the ears above from compressing those below, there should be horizontal

820

floors of open work on which the corn may be borne in separate layers. A small maize-barn on this construction, and supported on posts six feet from the ground, has been erected by M. Mathieu de Dombâsle, at Roville, near Nancy.

821

783. *A Store Place for Pigs' Food* is a most useful part of a large farmery, which never can be properly conducted without keeping pigs. It ought to be a dry well-aired room, near the piggeries, and should be of considerable size, so as to have two tubs or tanks for liquid food, the one being always filling while the other was emptying, after the contents had undergone proper fermentation; and three or four divisions, for different kinds of meal and other dry food. The situation should be close to the pigsty, so as to minimise the trouble of supplying their troughs.

784. *Storehouses for Hair, Wool, and Feathers* should generally be formed in dry airy lofts; and, as nothing is more offensive or unwholesome than the decomposition of these materials, no one, as before observed (§ 711), ought to be allowed to sleep, or to work for any length of time, in such places.

785. *The Storehouses for the Machinery and Implements of the Farmery* include the cart and roller shed, the plough and harrow house, the house for hand implements, the harness-room, the chaise-house, and the place for miscellaneous articles. Of several of these it is unnecessary to say any thing.

786. *Storehouses for portable Machinery and Implements* should be placed apart from the houses for live stock; and they should not, if it can be avoided, open into a yard in which cattle or swine are at large. The sheds for carts and waggons are generally left open in front; and, when this is the case, they should face the east, in preference to the west, from which driving rains are to be expected; and the north, rather than the south, because the intense heat of the sun is apt to warp the wood, and occasion a shrinking in the joints. Houses for smaller tools should have closed doors, and luffer-boarded windows for better ventilation, and their floors should always be perfectly dry and free from litter. In general small implements should be hung up, or supported at some distance from the floor, that they may be kept drier and more airy; and those of iron should be placed horizontally rather than vertically; because it is found that in the latter position they become in time magnetised, and more apt to rust and decay at their extremities.

787. *A Harness-room*, for harness not in use, should also be a dry airy loft, or otherwise a room on the ground floor, with a fireplace to admit of occasionally drying and ventilating it by artificial heat.

788. *The Working-houses of the Farmery*, besides the barn already mentioned, include the slaughter-house; the carpenter's shop; the smith's shop and shoeing-house; and a room for pickling wheat, cutting potatoes, carrying on various miscellaneous works, &c.

789. *A Slaughter-house* is necessary in a farmery of considerable extent, as it will always be found profitable for a farmer to kill as much of the meat used on his farm as possible. This part of the farmery should face the north: it should be well ventilated, but without admitting light, because darkness tends to exclude the flies. The floor should be paved, and have a sink and trap communicating with a manure tank.

790. *A Room for a Smithy, and another for a Carpenter's Shop*, are required in very extensive farmeries; and they should generally be placed so as to open into a small yard devoted to the different materials used by the carpenter and smith, and to machines and implements undergoing repair, &c.

791. *A Room of All-work* is necessary in every farmery, whether small or large, and it may generally adjoin the slaughter-house. In it there should be a boiler for preparing drinks for sick cattle, or for supplying hot water for other purposes. Wheat may be pickled or brined, and other seeds prepared, in this room; harness cleaned, tools sharpened on a grindstone, chaff or roots cut by machinery, malt ground, &c.

792. *Bee-houses* are seldom requisite, where bees are kept, unless for the purpose of preventing the hives from being stolen; and this Huish and other writers propose to do by chaining them to the bee-stand. A bee-house is very conveniently formed in the end or side of any building, or in a wall, facing the south-east, east, or south. There should be a recess, or a projection formed so as to give the effect of one; and in this recess there should be shelves of stone or boards, eighteen inches broad, and from eighteen inches to

two feet one above another. In front there may be either a grated iron door, or several horizontal iron bars, to lock, so as to permit the free ingress and egress of the bees to and from their hives, and yet prevent any person from taking them out.

793. *Dogkennel.* A watchdog is common to most farmeries, and the shepherd's dog is a valuable assistant where flocks of sheep are kept. The proper position for the watchdog is the middle of the open area between the farm house and the farm-yard, in order that the dog may have a complete view of the yard, and be seen both from the yard and house, as well as by all strangers who approach either. The lodging-place for the dog is commonly a roofed wooden box with an opening only on one side, the consequence of which is, that he may be passed by persons on the other sides without his seeing them. We would suggest the idea of raising the dogkennel eighteen inches or two feet, by placing it on a knoll sloping on every side, and of having two or three panes of glass on each side, that he may see every way around him. To enable the dog to lie in his kennel with comfort during hot weather, we would form two openings the whole length of the sides of the kennel, close under the eaves of the roof, by means of hinged flaps, which could be let down during summer, and put up and fastened with wooden buttons in severe weather. Kennels for dogs kept for field sports belong to the subject of villas.

794. *A Lodge for single Men* sometimes forms a part of farmeries, and should always consist of one large well lighted and comfortable room for cooking and eating; and another, also large, dry, and well ventilated, for sleeping in. These rooms ought to be placed near to the stables and cattle-sheds; and perhaps it might not be amiss, in some cases, to have speaking pipes from the stables and cattle-houses to the men's bed-room, in order that they might the more readily hear any noise made there in the night-time. Near London, where farms are liable to be robbed, we have known the farmer have a speaking or hearing pipe, communicating from his bed-room to his dogkennel, and also a wire connected with his dog's collar, by means of which he could loose the animal, without moving from his bed. Mr. Ackermann, the celebrated printseller, has a contrivance somewhat similar, in his villa near Fulham.

795. *Cottages and Gardens for married Servants* are built in the neighbourhood of the farmery, in all the large farms in the north of England and in the south of Scotland. Sometimes they form part of the farmery, but in general they are 200 or 300 yards apart from it. The convenience of proximity is, however, so great, that we think the distance should be diminished rather than increased. These cottages, in Scotland more particularly, are very wretched habitations, even on the most extensive and best cultivated farms. In 1831, we examined some farm labourers' houses of this description on a very large and admirably cultivated farm, on the Duke of Buccleugh's estate in Dumfriesshire. The dwelling-house on this farm (Cumroo) is more than usually large, with two rooms in its width; a part of its exterior wall is covered with well trained and wide-spreading fruit trees; and there is an excellent kitchen-garden, well stocked, and apparently in good order, in which, when we saw it, a professed gardener (judging from his blue apron) was at work; so that the whole, had it not been for the farm-yard behind, might very easily have been taken for a mansion residence. Passing this house, and advancing about half a furlong, we came to a row of fourteen cottages, occupied by yearly servants of the farmer who resided at the large house, and who, we were told, came from the best-cultivated district in Scotland, East Lothian. Observing that to every door in this row of cottages there was but one window, we entered one of them, and found a woman sitting at a table, writing a letter (which seemed in a very good hand for a person in her rank in life), while she rocked the cradle with her foot. The room, which comprised the whole cottage, was about fourteen feet square, without a ceiling, and open to the roof; the floor was of earth, and the walls were left rough, just as the stones were put together in building, but whitewashed: there was a fireplace, but only one fixed window of four small panes. In this room there were two box-beds, placed end to end, and, behind, a space of about two feet in width for fuel and lumber. The furniture and utensils, though scanty, were clean and neat; more especially when contrasted with the floor, which, underneath the box-beds, which have no valances, was of earth, quite loose, though near the fire were laid some flat stones, which the woman said her husband had picked up and put down himself. The cottage window, as already observed, was fixed, and incapable of opening to give air. There was no back door, and no opening either in the roof or walls for ventilation, except the entrance door and the chimney. There was no appendage, nor garden ground of any sort, behind these cottages; but across the road, in front of them was a narrow strip of ground, divided so as to allow one fall (thirty-six yards square) to each cottage. In these gardens was no structure of any kind. (*Gard. Mag.* vol. viii. p. 265.) There are few of the houses of married farm-servants in Scotland any better than those at Cumroo, where they are built by the tenants; but we hope that the time may not be far distant, when the landlords will

undertake this part of the farmery, as well as those buildings which are destined to lodge cattle, or protect produce or implements; which are now deemed of so much more importance than the cottages, that their erection is not intrusted to the farmer.

796. *By the Extra-Buildings of a Farmery* are to be understood those which do not belong strictly to agriculture; but which, nevertheless, are to be found on particular farms, and the businesses for which they are calculated carried on by the farmer, as well as the common culture of the farm. This practice is, no doubt, at variance with the principle of the division of labour; but as it does exist in many cases, and must necessarily long continue to do so in new countries, we cannot avoid shortly noticing such extra-buildings, in a work addressed to occupiers of land, and dwellers in the country generally. They may be included under corn mills, malt-houses, hop oasts or kilns, cider-houses, kilns for drying corn or other seeds, and for general purposes, limekilns, houses for manufacturing meal from potatoes, distilleries, beet root sugar manufactories, &c. We shall shortly describe the most common of these, and such as are most closely connected with general agriculture. The reader whose situation may render him particularly interested in any of those not noticed in this work will find every information he could wish, accompanied by plans, sections, and details, in the *Dictionnaire Technologique*, and in the *Agriculteur Manufacturier*; the latter one of the most scientific agricultural periodicals published in France.

797. *Corn Mills* are of various kinds; the principal of which are those for grinding or husking oats, barley mills, and flour mills. The first class is sometimes connected with the threshing-machine; more especially in Scotland, where it is driven by water, or impelled by steam. The farm in this case is always small, seldom exceeding 100 acres; and, as the occupier's attention is divided between his mill and his land, he rarely succeeds either as a miller or a farmer. Still we see no reason why an active intelligent man, with sufficient capital, might not excel in both, and thus secure to himself the profits of the grower, as well as those of the manufacturer, of corn. The same observation may be made with respect to barley and flour mills; and, no doubt, will apply to a variety of others which are used for manufacturing farm produce.

798. *Malt-houses.* The manufacture of malt being a much more simple process than that of grinding meal or dressing flour, a malt-house is a very common appendage to the farm-yard in the barley districts of England. A malt-house and kiln comprehend three divisions; a floor, or place for steeping the barley, and managing it, till it has germinated; a kiln for drying it, to check vegetation; and an airy loft for cooling it, and rendering it so dry as to admit of its being put up in sacks, without the risk of its undergoing fermentation in them. The floor for germinating the corn may be level with the surface of the ground; or, if the soil be dry, it may be three or more feet below it, as, the warmer and moister the atmosphere is, the better it will be for the vegetative process to be carried on. One end of this room should contain a cistern for steeping the barley; and near it should be a pump for supplying water. The barley, when the process is completed, is thrown out on the floor, and turned over till it has sufficiently germinated. It is now ready to be put on the kiln; and, after being properly dried there, it is spread out on the floor of the loft, which is generally over the malting-room, and of the same size; being thoroughly ventilated by having luffer-boarding on both sides. The building containing the kiln may be advantageously placed at that end of the malting-room which is opposite to the end containing the cistern; and the floor of the kiln, and that of the upper or drying room, ought to be on the same level, for the convenience of throwing out the malt to be cooled and dried. The common form of all kilns is that of an egg, with the broad end uppermost; or of two inverted cones, placed base to base, the floor for drying on being formed where the diameter of the shape so produced is broadest. The fire is made at the bottom of the kiln, and the smoke from the fuel, and the vapour from the articles drying, are allowed to rise directly through the floor above it, and to pass off by a chimney covered with a cap or cowl, mounted on an upright shaft, and furnished with a pivot, so as to turn freely with the wind, and present the opening for the emission of smoke and vapour always on the sheltered side. This form of kiln and mode of management are still continued in Aberdeenshire, and in other parts of the north of Scotland; and the malt made there takes a particular flavour according to the kind of fuel used. The malt most in repute is what has been dried with birch wood. In England the fuel used is most generally wood, coke, or Welsh coal; none of which produces a smoke injurious to the flavour of the malt, so that the heated air which arises from the fire is allowed to pass directly through it. The principal modern improvement in the construction of malt-kilns consists in the employment of a furnace and flues, in the lower part of the kiln, by which common coal, or any description of fuel, may be burned there; and heated air, being generated on the sides of the furnace and around the flues, ascends through the malt, instead of the combination of air and smoke which issues from an open fire. The sides of malt-kilns are of masonry, and the drying-floor is commonly formed of cast-

iron plates, sixteen inches square, and three eighths of an inch or half an inch thick, pierced with holes an inch apart, half an inch in diameter on the under side, and contracted to the eighth of an inch on the upper side. Sometimes tiles pierced in the same manner are used instead of iron plates; and a kiln tile, about a foot square, ought to contain 900 or 960 small holes. Whether tiles or plates are used, in either case they rest loose on wrought-iron rafters, with a narrow rib along the middle of the upper edge, which forms two rabbets for receiving the plates or tiles. Wirecloth, supported by iron rafters, is used occasionally, but it is found not to be sufficiently durable; or perforated sheet iron may be employed. This last material was formerly almost exclusively used for drying pale malt, but it is now found that with cast-iron plates or tiles, like those above described, the malt may be made pale or brown at pleasure. The space between the floor tiles and the top of the furnace or flues is commonly between five and six feet: this space is called, in Norfolk, the *dunge*, and into it fall the chives or cooms which, in the process of turning and drying, are rubbed off the malt; and these form an excellent manure, under the name of malt dust, as well as a good mash for sick cattle. The proportions of the openings on the top of the kiln, and for admitting air to be heated over the furnace, relatively to the area of the surface of the kiln, are points rather difficult to adjust. For a kiln twenty-seven feet square, a circular opening at top, of about five feet in diameter, will generally be found sufficient; and the area of the openings on each side of the furnace and flues, for the admission of cold air to be heated, must, when united, equal that of the opening at top. These openings for the admission of the external air should have regulators of sheet iron balanced by weights, so as to adjust the draught according to the heat, and the state of the malt. A great improvement has been lately effected in some of the Norfolk malt-kilns, by the dismissal of that unsightly and expensive appendage, the cowl, before-mentioned, as being placed over the orifice at top. This cowl, until of late years, was deemed an indispensable part of every malt-kiln; but to Mr. Salmon of Stoke-ferry is due the merit of the discovery that it may be wholly dispensed with. In lieu of them this gentleman substitutes a flat circular canopy of sheet iron, supported on iron rods. By this improvement, not only the exterior deformity is got rid of, but also two large interior beams; the one forming a guide, and the other a base and pivot for the upright axle of the cowl. In a country like Britain, where malt is heavily taxed, there are necessarily a variety of observances having reference to the duties of the excise officers, which occasion some peculiarities in the details of construction; such, for example, as the malt couch, dry cistern into which the malt is thrown from the steeping cistern, before it is spread on the floor, in order to be gauged; but these we leave unnoticed at present, as unconnected with general principles.

799. *Hop-Oasts, or Hop-Kilns*, are constructed much in the same manner as the malt-kilns; and the principal modern improvement which has been made in them, that of substituting hot air cockles for open fireplaces, is common to both. In the old plan of the hop-oast, the fire was made on a grating at the bottom of the kiln, with what is called a spark plate (a broad plate of cast iron, to reflect back the sparks, and prevent their reaching up to the hops) placed at the distance of a few feet over it. Instead of being laid on a perforated floor of iron or tiles, hops are almost always dried on haircloths. These are supported on a floor formed of wooden spars or laths, about two inches and a half square, and nailed, two inches apart, to wooden joists. The haircloth is laid upon this floor, and its edges round the sides of the kiln are hung up by loops, to prevent the hops from falling over into the fire-chamber below. The form and size of hop-kilns vary, but they are generally built square, as being most suitable for covering the drying-floor with a cloth; and the ordinary size of a drying-floor for a hop ground of two statute acres and a half, is eleven feet on the side. This size will dry three changes of hops in twenty-four hours. The floor of the kiln ought to open into a loft on the same level, into which the hops are thrown to cool. In one part of this loft is a circular hole, about two feet in diameter, with an iron rim round it, on which is placed the hoop to which the mouth of the bag or pocket in which the hops are to be packed is sewed. This bag hangs down through the floor into the place below, which may be a cow-shed, or, as it is very frequently in Worcestershire, a cider-house; and a man gets into it and treads down the hops as they are thrown in to him. The fuel which is used for drying hops, when the smoke is allowed to pass through them, is coke; and that made from very sulphureous coal is preferred, as tending best to preserve the colour of the hops. In the management of hops in Britain, there are a variety of arrangements connected with the kiln and hop-loft, rendered necessary by the mode of collecting the excise duty; but these we take no notice of here, as our object is merely to lay down the general principles of drying, from which every Architect can deduce the most advantageous forms.

800. *A Drying-Kiln for General Purposes* is a useful building for a corn farm in a wet climate, and it may be easily constructed, at very little expense, and scarcely any loss of room; since the drying-floor may be used as a granary or store-room, when not

required for drying on. In the north of Russia it is frequently found necessary to dry the corn, while in sheaf, in a particular description of kiln, the characteristic of which is, that the floor is of wooden rafters about a foot apart, and at least twenty feet above the hearth on which the fuel is burnt. There are various uses to which a farmer could apply such a kiln as might be used for drying either malt or hops; and since it is very desirable for every farmer who grows barley, to make his own malt, and brew his own ale, we think a drying-kiln ought to be considered as a part of the farmery on every large farm.

801. *A Cider-house* is only essential to an orchard farm. Where the fruit, as in Devonshire, is ground between rollers, the house for containing these need not be large; but where it is ground in a circular trough by a stone roller mill, as in Worcestershire, greater extent of space is requisite. It seems to be agreed on by the most competent judges, that the Worcestershire practice is by far the best; for, while the fruit is merely torn and crushed to pieces by being passed between two revolving cylinders, it, together with the rind and seeds, is reduced to a pulpy mass by the continued revolution of the stone wheel in the trough. The exposure of the pulp to the atmosphere, while this process is going forward, is also more favourable to its absorption of oxygen, than that given to it by the cylinder mill, from which it drops at once into a vat. Hence the great superiority, in flavour, of the Herefordshire and Worcestershire cider over that of Devonshire. It may be observed, also, that the malic acid corrodes the metal of the iron cylinders, and thereby injures the liquor; and further, that the machinery which impels these cylinders is much more liable to get out of order, than the extremely simple apparatus by which the roller mills are driven. In choosing a stone for a roller to grind fruit, all such as contain lime must be avoided, on account of the action which the acid of the fruit would necessarily have on it. Granite, quartzose rock, or millstone grit, is therefore necessary. The stones are mounted so as to turn in a circle of from ten to twelve feet in diameter, in the manner which we shall describe when we give an example in our succeeding section.

802. *A Limekiln* is a most valuable article on a farm containing limestone, or with limestone in its neighbourhood. We are even of opinion that, where fuel is abundant, a kiln for burning a portion of the soil of the farm, whether calcareous or clayey, would be a valuable source of manure; because all calcined earths, in consequence of their affinity for oxygen and carbonic acid gas, decompose air, water, and insoluble organic matter. Almost all clayey soils contain a certain proportion of lime; and it has been found that when such clays are calcined, and spread on any soil, even the same as that from which they were taken, they add to its friability and fertility. There are various rude modes of burning lime adopted in different parts of the country: in some districts it is mixed with the fuel, and burned in heaps; in others it is burned in kilns in the form of an inverted cone, or of an egg with the broad end uppermost; but the most improved form has been determined, by Mr. Menteth of Closeburn, after long experience, to be that of an inverted wedge rounded at the angles. The advantage of the wedge or oval form in the ground plan of a kiln is, that it admits of two or more openings at the bottom for emptying the kiln, by which that work can be more speedily performed than in the common round kilns, which admit of only one opening; and by which improvement, of course, more lime can be burned in a shorter time. The great object, in burning lime, is to burn it thoroughly, with the least possible expense of fuel, and in the shortest time; and for these purposes the kilns of the most improved construction, in addition to the wedge shape for the expeditious emptying of the kilns, have either non-conducting movable covers, or very small openings at top, into which the fuel and limestones are thrown. The first inventor of the cover for limekilns was Booker of Dublin; but they have since been greatly improved by Mr. Menteth, as we shall show hereafter, in giving designs. A most scientific combination of a limekiln with a coke oven has been made by Mr. Heathorn of Maidstone; in which the lime is burned by the gases which are driven off from the coal while it is being turned into coke, and which gases would otherwise be entirely lost. Of this kiln, also, we shall hereafter give a plan.

803. *Buildings for carrying on Agricultural Manufactures*, such as making potato flour, extracting sugar from the beet, maple, or cane; distilling spirits; crushing seeds for oil; preparing woad, or weld, or flax, or hemp, and similar operations, have nothing so peculiar in them as to demand the particular study of the Architect; the building being, in all these and similar cases, rendered subservient to the machinery.

804. *Water* is essential to every farmery, both for supplying the cattle with it to drink, for washing the feet of horses, &c., and for other purposes of cleanliness. The most convenient form of supplying this is from a well with a pump, in a central part of the yard. If the subsoil do not naturally afford water, the well, or in that case the tank, must be supplied artificially, either by pipes laid from some distant spring, pond, or brook; or from the rain which falls on the roofs of the buildings. We have already, § 151, given Mr. Waistell's design for a tank, and shall here submit a plan which has been sent us by our ingenious and most scientific contributor Mr. Mallet.

805. *Mallet's Tank*, fig. 822, is calculated to save expense; first, by using a figure of maximum capacity and minimum surface; and, next, by being able to dispense entirely with the centring, which, according to the present practice, is used for arching over tanks. Mr. Mallet proposes for very large tanks to adopt a spherical form; but for any of less than five or six feet in diameter, a short cylinder with hemispherical ends, as shown in fig. 822. The excavation being made, the building is commenced, either with a single brick at the bottom, *a*; or better with a circular piece of stone laid on a layer of tenacious clay, tempered as dry as possible, well beaten together, and previously mixed with some salt to prevent the worms from working through it. This layer of clay, *b*, completely surrounds the brickwork in every part, to make it retain the water. The bottom part is now built all with common mortar, in the form of an inverted dome, nine inches thick; then the perpendicular part, *c*; and, lastly, the upper dome. Now, any common arch may be built without centring as far up as where the courses lie at an angle of about thirty-two degrees, or what is called the angle of repose for masonry; that is, where the bricks will first begin to slip off; but a brick dome may be built of any size, entirely without centring, for the following reason. — Referring to fig. 823, *d d* are two bricks supposed to belong to part of the course of bricks next above that at the angle of repose. Each of these is to be considered, with the mortar in which it is embedded, as a quadrangular prismatic frustum, whose sides all incline towards the centre of the hemisphere at *e*: now, the upper surfaces of these two bricks form an internal or reentering angle with one another, from the position they lie in on the preceding courses; that is, they lean against each other, as if they lay on opposite inclined planes, as shown in fig. 824. If, then, these

bricks slip, they must do so in the line *e f*; but, in doing so, they must approach each other: but they are already in contact, therefore they cannot slip. This demonstration applies to any greater number of bricks, until the whole course is finished, when the bricks are sustained by their lateral thrust. There is a limit to the weight of the voussoir (the overhanging part of an arch, looking up from under it) which will support itself in this way, as must be obvious to every one from the common principles of gravitation. It is also obvious that a dome may thus be either left open, or closed at top. To make the tank perfectly watertight, it is finally coated over two or three times with coal tar inside. A manhole is shown at *g*, in fig. 822, for getting in to clean it out occasionally. This plan of building without centring is applicable to constructing large architectural domes, provided they be of brick, and that they be afterwards plastered outside with Roman cement, which would stand as well on a dome as on a wall; and, the great expense of heavy domical centring being got rid of, domes on our large public buildings might be more common than they are at present. The hollow bricks invented by Mr. Frost might be here advantageously used. The usefulness of this plan of building without centres, in constructing ice-houses, fruit-cellars, ovens, kilns, sewers, &c., is obvious. Mr. Mallet adds, "I have built one tank on this plan, which holds sixty hogsheads: it was built by one mason in four days, and never leaked a drop, although one side of it stood close to an area wall, where the least moisture would have been visible."

806. *Ponds* formerly were thought essential to farm yards, partly for supplying water for the cattle to drink; but chiefly for the horses to wade through, in order to wash their

feet. The first use is now, in all the best-planned farmeries, supplied by troughs or cisterns from pumps; while the horses' feet are either washed in the stable with water in pails; or the horses are made to walk repeatedly through a narrow trough with a paved bottom, and with oak or stone sides. This trough, which ought to be placed near a pump, and opposite the stables, in the side of the passage between the buildings and the dung-yard, may be three feet wide, six inches deep at the two ends, and gradually increasing in depth to the middle, where there may be three feet of water. It must be acknowledged, however, that in many, perhaps in most cases, the best mode is to wash the legs of horses while in the stable; because, when they are ridden into a pond or trough, while warm from the plough or the cart, they are very apt to catch a cold or rheumatism from the sudden chill produced by the cold water. This will chiefly depend on the distance which the horses have walked after they have left off work. Horses taken out of the gin wheel of a threshing-machine should never either be driven through a pond or through a trough, for similar reasons, as will be obvious to every farmer. In all cases, when the feet and legs of horses are washed, they should be immediately rubbed dry with straw and cloths.

807. *The Yards of Farmeries* are, the corn-yard, the hay or dried herbage yard, the cattle-yard, the sheep-yard, the poultry-yard, the dung-yard, the implement-yard, and, in large farmeries, the yard for the carpenter and smith.

808. *The Corn-Yard* is that which contains the stacks of corn, and should always be placed adjoining the barn, and on the most elevated and airy side of the farmery. The size ought to be regulated by the size of the arable part of the farm, and of the barn; because no rick ought to be made larger than what could be contained at one time by the corn bay, or end for unthreshed corn, of the barn; and, consequently, a small barn will require a larger rick-yard than a large one. The form, in this case, as in almost every other yard or building on a farm, ought to be rectangular, and as near as may be convenient to that of a square. Acute-angled or round forms are necessarily attended with loss of space, and great inconvenience both in building the ricks, and in removing them to the barn. The ricks ought to be placed in parallel rows, with a sufficient space between every two rows, for a cart to pass along, either to unload when building the ricks, or to load when taking them into the barn. Round the ricks, on the margin of the yard, there ought to be a space sufficiently wide for a loaded cart; and at the angles this space ought to be increased by the omission of a rick, in order to admit of the cart's turning round easily. All the ricks ought to be placed upon stands or saddles, so as to keep them dry and safe from rats and mice. These stands are of different kinds, some of which we shall notice.

809. *The Rick Stand* most common in countries where wood is the cheapest material is formed of oak pillars inserted in the ground, and standing two feet high above it, with a frame over them composed of joists of any cheap wood. The plan is round when the ricks are to be small and rectangular, and generally a parallelogram, when the ricks are to be large.

810. *The rick stand*, in wet climates, where the corn is frequently obliged to be carried before it is perfectly dry, has, in addition to the flooring of joists, a funnel, formed by a frame of wood, carried up from the flooring to the summit of the rick, passing, or at least which ought to pass, through it, and terminating in a light cap of sheet iron. The funnel is commonly not carried higher than two thirds of the height of the rick, but this often defeats the object in view, for, from the sluggish nature of air, it will not ascend freely unless it have a clear passage from the base of the stack to the summit; and therefore the funnels, to be efficacious, ought always to be carried through the thatch of the rick.

811. *The rick stand*, in countries where stone is more abundant than wood, and where central funnels are unnecessary, is frequently nothing more than a wall two feet high, of the size and shape of the intended rick, with a coping of stone or wood, projecting at least six inches over the wall outwards, to impede the ascent of vermin. The foundations of this wall should be a foot or more beneath the surface, to prevent vermin from burrowing under it. The interior space may be partially filled with earth or loose stones, according to the nature of the soil, keeping in view the importance of preventing the ascent of damp into the rick.

812. *The rick stand*, where cast and wrought iron are cheap materials, may be formed of cast-iron pillars set on stone plinths, with cast-iron copings and joists; and a cylindrical funnel of wrought-iron round rods held together at intervals by circular rods, and terminating in a cap above the thatch. Corn stands and funnels of this kind, but not carried through the thatch, and without the cap, are not uncommon in the iron districts of Scotland; having been first invented by Mitchell of Balquharn, near Alloa, in Stirlingshire.

813. *A square or parallelogram rick stand*, fig. 725, is manufactured by Messrs,

Cottam and Hallen. It consists of cast-iron pillars fig. 826, two feet six inches high, which cost 8s. 6d. each. Wrought-iron rods, *a*, six feet eight inches long, which cost 10s. each; secondary rods, *b*, six feet eight inches long, which cost 3s. 4d. each; and small rods, *c*, five feet six inches long, which cost 1s. 5d. each. The method of fixing the principal rods is shown in fig. 827; that of placing on them the secondary rods, *b*, in fig. 828; and that of fixing the small rods on these last in fig. 829. A square yard

of this description of rick stand costs in all 12s., which may be considered cheap for an article which, if heated, and afterwards rubbed over with oil or tar, previously to being put up, will last many years.

814. *Waistell's circular rick stand*, fig. 830, is formed entirely of stone, and consists of two concentric circular walls; the outer wall is twenty inches high, to the top of the projecting flags; at about half its height, four grates of cast iron, about six inches square, and half an inch thick, are placed in openings left through the external walls, at equal distances from each other, to admit air. The bars of the grates are a quarter of an inch broad, and a quarter of an inch distant from each other, which is sufficiently close to prevent the entrance of mice. Stands thus constructed are considered, by those who have tried them, to be less expensive, and more effective, than on any other plan that has been invented. The air that passes through these four grates, and through the openings in the internal walls, will circulate freely under the rick; and, if a chimney be carried up the middle of the rick to its top, the current of air that will pass up through it will carry off the heat and moisture which might otherwise injure, and even spoil, such corn as was rather too moist when carried." (*Waistell's Designs, &c.* p. 101.) These rick-stands seem to have been invented by Mr. Waistell's nephews, who built the outside wall twenty inches thick, the inside wall eighteen inches thick, and left a distance between the two walls of eighteen inches. Across this space hedge-stakes or faggots were laid, sufficiently long to support the sheaves. The funnel in the centre, when necessary, need have no

frame round it, but may be merely a circular opening, of two feet in diameter, left in building the rick.

815. *Morel-Vindé's rick stands* are of two kinds, one of which is circular and the other square, and both are calculated for containing 3000 sheaves. The circular rick stand, fig. 831, is twelve feet in diameter; and, to contain 3000 sheaves, the rick must be carried up to the height of twenty feet. It is surrounded by a ditch from two to three feet deep, the soil from which serves to elevate the stand or basis of the rick. On this is placed a bed of faggots, which is first covered with straw, and on which the sheaves are afterwards built in the usual manner. *Morel-Vindé's square rick stand* is called in France the *American rick stand*. It is formed of a square frame of carpentry, fig. 832, with a St. Andrew's cross in the middle, and is placed on five posts, each of which is furnished with a cone of tinned iron, in the form of an inverted basin, to prevent the ascent of vermin, as shown at *a a*, in fig. 833; on this frame are placed faggots and straw, and afterwards the

sheaves; and, when the sides are twelve feet high, this square rick, at that height, will contain 3000 sheaves.

816. *The Dutch rick stand* is made square in the plan, with a frame of wood, placed on five wooden posts, furnished with tinned iron cones, like the American rick stand; but it differs from it in having the corner posts, twenty-five feet high, tied together at top, so as to be there at exactly the same distance as at bottom, by horizontal rails, as shown in fig. 834; and further braced at top by two pieces in the form of a St. Andrew's cross, as shown in fig. 835. The sheaves are built in the usual manner within the four posts; and in the centre of the under side of the cross of St. Andrew, at top, is fixed a pulley, to which is suspended a light roof, formed of deal, and covered with matting of drawn wheat straw, placed quite thin, or of oiled or tarred canvass, as shown in figs. 836 and 837. This light roof is raised and lowered at pleasure by means of the windlass *b*, in figs. 834, and 835 and a cord, which passes over a pulley placed on the top of one of the corner posts, as shown at *c*, in figs. 834 and 836. The rest of the construction of this rick stand will be sufficiently obvious from the figures. We agree with M. Morel-

Vindé in thinking, that, as the great object of the farmer is to do the most at the cheapest rate, the common round or square rick stand, on posts, and without a roof, is the best. This is more especially the case where the barn is sufficiently large to contain a rick at a time. The Dutch, no doubt, contrived these ricks for very small farms, and small barns, where the sheaves were put on the rick by a few at a time, as they were harvested, and taken into the barn by degrees as they were to be threshed.

817. *The Hay-Yard* of a common country farm is generally much smaller than the corn-yard; because the horses and cattle eat straw of different kinds rather than hay. On grass farms, however, the hay-yard is often the largest. The same principles of form and arrangement are applicable to it as those laid down for the corn-yard, with this difference, that its position should be placed as near as possible to the stables, cow-houses, or such houses or yards in which it is to be chiefly consumed.

818. *The Dung-Yard* ought to be central to the stables and cattle-houses, for the reception of the dung produced in them as it is daily wheeled out. The common situation is the centre of the farmery, where it is enclosed by a wall, against which, in large farms, there are frequently open low sheds for cattle, and pigsties for swine. Both these animals, as well as poultry, are allowed the run of the yard over the dung, to which they do good rather than harm; the pigs and poultry by picking out grains and seeds, which would otherwise be lost, or spring up as weeds when the manure was spread on the land; and the cattle, by treading the straw into the moister part of the manure, and thus preparing it for being carted out and put into a dunghill for fermentation. The surface of the dung-yard ought to slope towards its centre, or towards one point which ought to be the lowest, and under which point there ought to be two capacious liquid manure tanks, with which all the drains of the stables, cattle-houses, piggeries, &c., ought to be connected. In this tank there ought either to be a pump constantly standing, or a hole for inserting one at pleasure, in order to admit of pumping up the liquid to moisten the straw of the manure, or into a barrel cart, for being carried off to form *urate*, or to apply at once to growing crops. In small farm-yards, where few or no cattle are kept loose in a central enclosure, instead of a dung-yard there is simply a dung-pit, into which all the dung produced in the surrounding houses is thrown, and into which all the gutters and drains (except those which are merely intended to collect rain or underground water) are to be directed. This pit ought either to be sufficiently deep to contain the liquid manure among the dung, or, what is far preferable, a liquid manure tank ought to be formed under it. All dunghills ought to be kept constantly covered with dry loose straw, to diminish evaporation by the sun and wind.

819. *The Poultry-Yard*, as we have already mentioned, § 770, should be in front of the poultry-houses, and should be divided into the breeding, rearing, and fattening yards. These ought always to face the warmest aspect, being well sheltered from cold winds; and the breeding-yard ought to contain a large pond for aquatic fowls. In most country farms the aquatic fowls are allowed to run at large over the farm, as being useful for picking up slugs, worms, tadpoles, &c., and even the common poultry are allowed the run of the dung-yard, rick-yards, and, in general, all that constitutes the farmery. The poultry-yards, therefore, are chiefly used for rearing, and, to a certain extent, for feeding in.

820. *The Carpenter's and Smith's Yard* is placed in front of the shops or work-places to which it belongs; and it ought always to be quite distinct from any of the other yards which have been already mentioned; particularly those containing straw, on account of the danger from fire. On the largest farms, in the most improved agricultural districts, a carpenter and a smith are kept constantly on the premises; and in those of a smaller size, these tradesmen attend one, two, or more days in a week, fortnight, or month, according to the size of the farm and kind of culture pursued. In either case, shops for these mechanics become requisite on the farmery; these shops and yards serve also as repositories for such articles as require repair, and for rough timber, hurdles, gates, bricks, lime, and other materials of construction.

821. *Passages* or roads are required, in large farmeries, between the yards and the houses, and these ought to be of such a width as to allow two carts to pass each other, and so rounded at the corners as to prevent any difficulty in turning. Their width, in general, should not be less than sixteen feet, and there should be as few gates across them as possible. As the surface water collected in the gutters of these passages is not intended to be conveyed to the dung-pit or manure tank, they should never be covered with litter, but kept as clean as any other gravelled, macadamised, or paved road.

822. *The System of Drainage* in a farmery is a matter of very great importance, and it ought to be determined on before any part is commenced of the yards, farm buildings, or farm house. There are three distinct systems of drainage which must necessarily exist in every well-constructed farmery: the first is the underground drainage of the natural soil, so as to render it perfectly dry beneath, and fit for serving as the immediate basis of the floors of the different buildings to be erected; the second is the surface drainage, for the removal of rain water from the roofs and passages; and the third the liquid manure drainage, for conveying the urine from the stables, cattle-houses, pigsties, &c., and the dung liquor from the hammels and yards, to the liquid manure tank. We shall offer a few words on each of these systems, for the guidance of the Architect.

823. *Underground Draining.* It seldom happens that the site for a farmery is so dry as not to require some underground drains around and through it, for carrying off the water that either sinks into the soil from the surface, and is retained there, or is found latent in the subsoil, or from some other cause. In making these drains, particular care ought to be taken that they be made so as to dry thoroughly the ground under the floors of all the houses; and, at the same time, neither in the houses nor in the yards to interfere with the underground gutters to the manure tank, so as to carry off any of the liquid manure. For this purpose, and also because their object is chiefly to carry off underground water, they ought to be deep, and they need not come within a foot or more of the surface. In general, one drain should surround the farmery, so as to intercept all exterior sources of water; and others should cross the farmery under the principal lines of buildings and roads or passages. The dung-courts will, by those lines, be rendered sufficiently dry for containing manure. As the drains under the passages, and in the rick and hay yards, will have to receive the surface water through traps, they ought to be barrel drains; but all the others may be formed of loose round stones of three inches in diameter at the bottom, four or five inches in the middle, and of the size of large gravel at top.

824. *Surface Drainage.* The water of the roofs should all be collected by gutters at the eaves; and, if not wanted for a well, tank, or pond, it should be conducted direct to the underground drains. The water which falls in the passages, roads, courts, or yards not covered with litter, and more especially in the rick-yard, ought to be collected in gutters, and also conveyed direct to the underground drains, through air traps. These traps ought to be of such a construction as to retain the sand and grosser particles, which might choke up the drain, and also to admit of being readily cleaned out. There are various forms very suitable for this purpose; but one of the cheapest and best at present in use is the iron one of Messrs. Cottam and Hallen, shown in the perspective view fig. 838, which weighs 4 cwt. 19lbs. and costs 50s. In this figure, and in the section, fig. 839, *a* is the level of the water, on both sides of the trap, *b*; *c* is the opening by which the water escapes; and *d* the place where the sediment is deposited. The grating at top, *e*, lifts off; when this sediment is to be removed. Gratings of this kind ought to be placed all along the gutters, at distances of thirty or forty yards; in order that no great accumulation of water may ever take place on the surface. The grating being hollow in the middle indicates that the direction of the bars ought to be across the line of gutter; their strength is sufficient to bear the pressure of the most heavily laden waggon. The contents of all the underground drains about a farmery should be conducted to a pond where they may be rendered available for the purpose of the surface irrigation of grass land; for, notwithstanding all ordinary care and attention that may be given, to prevent the water collected from the surface by these drains from being mixed with manure

838

839

liquor, some, if only from the droppings of horses and poultry on the passages, will find its way into it.

825. *Underground Gutters for Liquid Manure.* In general, there ought to be a cess-pool, or liquid manure tank, in the centre, or in the lowest part of every dung or cattle yard, or yard which is intended to be kept generally covered with litter; or where a number of small yards, such as those of hammels, are to be placed together, one tank centrally situated may have communications with the whole. The inclination of the surface of every part of every yard should be to the cess-pool, or to the trap of the drain communicating with it; and the underground drains from the cattle-houses, stables, piggeries, &c., should always be conducted to the nearest cess-pool. These underground drains or gutters need neither be large nor deep, and may in general be formed of brick earth draining-pipe of three or four inches in diameter. To prevent the possibility of a current of air passing through these pipe drains, the end which enters the cess-pool may either have a trap there, or be carried down the side walls to near the bottom of the tank, so as always to be filled with water at their orifice. This is easily done by carrying up the requisite number of funnels in the side walls of the tank, from the bottom of the tank to the bottom of the drain, as shown in the section, fig. 840, in which *a* is the bottom

and cattle-houses being added daily, the manure produced would be as good as if the straw had been trodden by cattle in a yard or in a cow-house; while the loss which that practice occasions, by evaporation and by what sinks into the soil, would be saved, and the cattle preserved clean, and better in health, as well as more agreeable in appearance. The mode of feeding cattle with straw is also in its infancy. We are persuaded that it

would pay a farmer to have his straw cut by a machine into lengths of three or four inches; and afterwards to have it boiled or steamed, and mixed with a portion of succulent food of some kind. For litter and thatch the larger and stronger the straw is kept the better; but both for eating and for manure it would be more easily managed if cut into short lengths. The science and the art of making manure are alike unknown to the great majority of even the best British farmers, and will be so till they learn something of chemistry. In every farmyard, at present, it may safely be affirmed that there is nearly as much manure lost as made. A liquid manure tank, connected by underground tubes with the back-kitchen, and kitchen-court, with all the privies, and with all the houses or yards in which cattle are kept, in short with every source of water impregnated with animal or vegetable matter or with any of the alkalies, would alone, on a large farm, supply manure for several acres yearly. Even supposing the manure tank not to be adopted, the mere circumstance of placing all the dung made on a farmery in one dunghill under a roof, where its more valuable parts would neither be washed away by the rain nor carried off by the sun and wind, would be an immense saving. We say nothing here of other sources of manure, such as stall-feeding, which ought to be universally substituted for grazing, &c. We strongly recommend the subject of employing manure tanks and dunghill roofs to the land stewards of country gentlemen, and to scientific agriculturists, and rural Architects generally.

826. *The Liquid Manure Tank*, to be generally adopted, ought to be of a very simple construction; for which purpose a square or a parallelogram plan, with perpendicular side and end walls, and a semicircular arch over, with a manhole in the centre for the pump, and for entering to clear out the interior, may be recommended as of easy erection by any country bricklayer or mason. The walls may be built with common mortar, provided they are well puddled behind with clay; but cement will make the strongest work, and will render a clay puddle unnecessary. In some parts of Germany, where timber is abundant, the liquid manure tank is made ten or twelve feet wide, about the same depth, and is covered with joists of wood, on which first coarse litter, and afterwards the stable and cattle dung, are put as made.

827. *Gates* for farmyards and fields are commonly treated of in works on Farm Architecture; and a very excellent wooden one is given by Waistell, which we have copied in our *Encyclopaedia of Agriculture*. We shall here, therefore, confine ourselves to two very strong and cheap iron gates, and to a mode of opening gates, which, though chiefly applicable to gates on public roads, may also be occasionally adopted with entrance gates to farms, or farmeries.

828. *Buchanan of Catrine's Field or Farm Gate*, fig. 841, on a scale of five sixteenths of an inch to a foot, is composed of a frame or rim of bar iron, seven feet long and four

feet high, one inch and three quarters broad, and three eighths of an inch thick, not riveted, but welded at the angles, and the rim presenting its edge to the face of the gate. The head style and the falling style are each projected about three inches above the rim, for the purpose of retaining a horizontal rail of wood, about three inches by two inches, placed on the top bar, in order to make it more conspicuous to cattle than the narrow edge of the top of the iron rim. The diagonal strutt or brace is of the same breadth and thickness as the surrounding rim, to which it is firmly riveted at both extremities. The vertical round rods are eleven; six of them are three quarters of an inch in diameter, and five are five eighths of an inch; they are riveted into the top and bottom rails, and firmly fixed into the brace, by being put through it cold while the brace is red-hot. The

hanging post is continued down nine inches at bottom, so as to form a pivot for working in a socket fixed in a stone; and up, so as to turn in a hook. The shutting post admits of the application of any description of fastening; one of the best for a cattle-yard, to which this gate is particularly adapted, is a spring latch, which shuts into a recess in the falling post, as seen in the figure. These gates are manufactured in the workshops of the inventor, at Catrine, and the prime cost, in 1831, was found to be about 30s.

829. *Cottam and Hallen's Iron Field Gate*, fig. 842, is made of wrought iron, the horizontal bars and braces being made of flat bar iron, riveted together at every intersection, in order to prevent the swagging or sinking of the head or falling style. The lower rails are placed sufficiently close together to prevent pigs and lambs from passing through between them. This gate can be supplied, singly, for 26s. each, and by the dozen 10 per cent lower. Mr. Cottam considers this gate stronger, more durable, and far more economical, than any gate which can be made of wood.

830. *The Closeburn Field Gate* is the invention of C. J. Stuart Menteath, Esq., and of which he has lately sent us a sketch, fig. 843. The material is timber; the construction is very light and strong, and so economical that it may be made in some parts of the country, where young fir trees are abundant, for 7s. When the head sinks, it is raised by the simple operation of adding another washer between the key, and that which retains the hook of the upper part of the hanging style at *a*. The fastening latch is protected from the rubbing of cattle, by being made to shut into a recess in the falling post at *b*. When gates of this sort are made of young timber, it is, after being seasoned and put together as a gate, it receives three coats of boiling hot tar.

831. *Gates to open by Machinery*. One of these, for a park or farm, made to open on the approach of a carriage, will be found in our *Encyc. of Agr.*, § 3107; and we shall here describe two others; one of which is used as a turnpike gate at Scotforth, in the neighbourhood of Lancaster, and the other is the invention of our correspondent, Mr. Saul, of that town. Mr. Saul has sent us the following account of the mode of opening the gate at Scotforth. In fig. 844, *a a* represent two fixtures; each consisting of two posts, with rollers between, for guiding the chains *b* and *c*. The chain *b*, fixed to the lower bar of the gate, is the opening chain; and the chain *c* is the shutting one. There is a continuation of these two chains in tunnels under the road, represented by the dotted lines *d d*; and both chains pass under a roller at *e*, after which they rise through a wooden tube to *f*, in the sleeping-room of the toll-house. They are there worked by a winch, which being turned one way opens the gate, and the other way shuts it. Mr. Saul was informed by the gatekeeper that this gate did not work freely; and he has suggested what is obviously a far more efficient plan, of which he has given us an explanation, accompanied by the sketch, fig. 845. In this figure, *g* represents a horizontal shaft placed in a tunnel made across the road directly under the gate; working at one end on the heel of the hanging post by a pinion at *h*, and at the other by a beveled pinion at *i*, on the upright shaft *k*. This shaft has another pinion at its upper end, which works into the pinion *l*, on the axle of the winch *m*, supposed to be at the bedside of the gatekeeper. It is evident that, by turning this winch, the gate may be opened or shut to any extent at pleasure. The whole of the machinery may be concealed under ground, and in the wall of the house; the winch alone protruding into the bed-room of the gatekeeper. Any millwright could easily make a working plan from the above description and sketch. It may sometimes be worth while to have the principal entrance gate to a farm-yard constructed so as to open in this manner, and the use of the contrivance for toll gates, and for the coach-yard gates of inns, is obvious. We hope also that the time is not far distant

842

843

when the occupiers of mansions, whose approach roads are guarded by entrance lodges and gates, will so far study the comforts of their gatekeepers as to introduce this piece of mechanism, or something better, to prevent the necessity of their getting out of bed to

open the gate in the night-time. In Germany the toll-bar or beam (schlagbaum) is balanced by a weight at one end, and the other is held down by a cord, which passes under one pulley and over another into the bed-room of the gatekeeper; who, without rising from his bed, pushes out through a small opening a long-handled iron ladle, in which he receives the toll, and, afterwards untying the cord, the weight raises the bar, and the traveller passes through.

832. *A Gate with a Puzzle Latch, to serve as a Substitute for a Lock, fig. 846, is in use on the estate of R. Bevan, Esq., Rougham, Suffolk, and the following description of it has been sent us by Mr. John Levett. The latch, a, is fastened by a brace, with a screw bolt and nut to the head of the gate, and it works on the joint b. When this latch is drawn back by pressure on the top of a, it raises the rod c, which is connected with the catch d at e. The catch d being now raised, the pin f, fixed in the head of the gate, is allowed to pass, and the gate is opened. The catch d, and plate for the rod, marked e, are fastened to the post with four screw nails and two screw bolts.*

SUBJECT. 3. *The Farmery considered as a whole.*

833. *The Farmery, as a whole*, may be considered with reference to its situation on the farm; its extent and character relatively to the size of the farm, and to the kind of culture pursued or of crops raised; its position relatively to that of the farm house; the style of its architectural design; and the materials of its construction.

834. *The Situation* of every farmery ought, as far as practicable, to be in the centre of the farm; because this will reduce the labour of carting home produce, and carting out manure, to a minimum. When the surface of a farm is very irregular, or where it consists of the sloping side of a hill, the site of the farmery should be chosen at that point of height in the slope where the extra-labour of carrying home the crop will always be balanced by the extra-facility of carting out the manure; and where, as much as possible, the labour of the two operations may be equalised. The most difficult case for choosing a proper site for the farmery is where the lands lie on the two sides of a valley: here there is no choice but that of placing the farmery in the valley, and laying out the fences, roads, and even ridges of the fields, in directions athwart the slopes, so as to diminish all the farm labours to the extent of one half of what they would be by ascending and descending in straight lines. All labours with ploughs, carts, or waggons, and even harrowing, and the manual labours of hoeing and reaping, may be diminished on this principle. In laying out farmeries in all old countries which have been long intersected by hedges and roads, and the boundary lines of all landed property in which is exceedingly irregular, numerous cases occur where true principles must give way to circumstances; and all that the Architect can aim at is, after weighing well the arguments for and against particular situations, to make choice of that which has a maximum of advantages. Our intelligent contributor, Mr. Main, has paid much attention to this subject, and has sent us the following observations: — “Proximity to a high road, to a natural pond, or to the summit of a dry knoll, in order to be free from floods, is an advan-

tage which is never disregarded by the British farmer; but, for the sake of these, we often see others of much greater importance wholly neglected. If the buildings are on the highest ground belonging to the farm, it follows that carting out manure from the yards must be facilitated; but that, on the other hand, all the produce will have to be carried up-hill; and if, for the sake of water, the homestead be placed in a valley, that these circumstances will be reversed. A gentle eminence, near the centre of the farm, is, on all accounts, the most eligible, provided only that water can conveniently be had near it; but, now that the practicability of obtaining water by boring, in almost any situation, has become so well known, no homestead need be wrongly placed merely on that score. Some old homesteads are badly arranged in other respects; such as placing them across public footpaths or bridleways; in which case gates are frequently left open by careless passengers, and much damage is often sustained by the straying out of cattle, &c. There are even instances of farm houses standing on one side of a turnpike road, and the barns and yards on the other; but surely accident, and not design, must have produced such absurdities."

835. *The Size of the Farmery, and the Kind of Buildings which compose it*, must necessarily be regulated by the extent of the farm, and by the kind of culture pursued on it. A farm wholly arable will obviously require different buildings from one chiefly in pasture; and an arable farm, on a strong alluvial soil, on which wheat, beans, and clover are chiefly cultivated, will require different buildings from a farm on a light soil, on which turnips form a principal article in the succession of crops; and, consequently, extensive cattle-sheds are required for lodging the cattle to consume them. On this subject Mr. Main observes: — "The size of a farm regulates the extent and number of the buildings belonging to it. The lowest grade of farmeries has only a dwelling-house of two or four rooms, with a small barn on one side, and a cow-house and stable on the other. A front fence (generally carried across from the outer end of the stable to that of the barn) forms the yard. The rick-yard is behind the barn, and the orchard and garden are behind the stable and dwelling-house. The carts or waggons, when not in use, are usually kept loaded with straw to preserve them from the weather; pigsties lean against the end of the house or stable; and the whole is on a very homely and limited scale. Such a homestead is only fitted for a farm of from forty to sixty acres. Large farms require buildings in proportion. Those belonging to a farm of 500 or 1000 acres appear like a little town. In arranging these buildings, it should always be contrived to have all the barn doors and cattle-yards in view from the dwelling-house. The superintending eye of the master, or of some of his family, assists the vigilance of servants, and accidents among the live stock are sooner observed and prevented, or remedied. Another point, in disposing the buildings, should be, to have the lowest on the south, and the highest on the north and east sides, for the purpose of shelter to the yard. Where the buildings are insufficient for the purpose of shelter, closely planted ranks of spruce firs are available. A horsepond is generally supposed to be a desirable appendage to a farm yard: but a pump and trough in the yard are far more suitable. Cart horses are liable to greasy heels; and the having their legs wetted in the pond causes irritation, which they generally indicate by constant stamping for an hour or two afterwards; and this is sometimes attended with dangerous wounds, loss of shoes, &c. The pantry and dairy are always placed on the north side of the house. The latter, on a dairy farm, is usually a large clean room, with a stone floor, four or five feet below the surface; and a ceiling lofty and plastered. At one end, on the ground surface, is the churning and scalding room; and on the outside of this, next the yard, are the hog-cisterns, for the reception of the whey, skim-milk, &c. It is an advantage to have barn room enough for every crop, especially in climates where the corn is quickly and thoroughly dried. But in cold humid districts of country, it is absolutely necessary either to have Dutch barns, or covered rick stands, § 816, or to set the corn abroad in small cocks, thatched, to receive the sun and wind for several months before housing. Agriculturists are generally of opinion that a well-proportioned farm should consist of one third of meadow and pasture ground, and two thirds of arable land; because all the advantages of the plough and the hoof will thus be so well balanced, and each will assist the other so beneficially, that there need be neither redundancy nor waste of any of the produce; but all may be turned to the best account in the shortest time. In grazing farms, the above proportions are reversed; one third of arable land being considered necessary to supply litter for the cattle, and straw for thatching ricks, &c. The buildings on such farms are also different; as, instead of barns, they have extensive feeding-houses." We might enlarge on this subject at great length, from the circumstance of having been early initiated in farming under our parental roof, and having since farmed extensively on our own account, as well as from having designed several farmeries, and executed some of them: but having already treated on the subject in detail, in our *Encyclopædia of Agriculture*, we purposely refer the reader to that work; being desirous of not repeating any part of it in the present one, and of saying no more on

the subject of agriculture than what is absolutely necessary to put the Architect in possession of the requisite data and desiderata of the buildings which he will be required to design.

836. *The most desirable Position of the Farm House, relatively to the Farmery*, has already more than once (see § 740 and 741) been incidentally mentioned; and it is only necessary to repeat, that it should always be such as to command as complete a view of the yards and the doors of the buildings as possible. For this purpose, when the living-rooms of the house have windows on two sides, as in fig. 749, § 740, the diagonal of the square of the house ought to be parallel to the square of the farmery; but when the parlour or living-room has windows only from one side, its front may be parallel with the front of the farmery. On whichever side of the farmery the house is placed, the buildings or walls on that side should always be so low as to be overlooked by the dog-house and the windows of the parlour.

837. *The Style of Architectural Design, in Farm Houses and Farmeries*, may be considered in two points of view: first, with reference to the nature of the buildings; that is, their magnitude, shape, materials, and uses; and, secondly, with reference to the other buildings of a superior character, when there are such on the estate to which they belong. Grecian architecture is best suited for low extended buildings, and for buildings constructed of timber, and abounding in piers and posts; and Gothic architecture is best calculated for lofty buildings of stone, without detached outside piers, posts, or pillars. The prevailing lines in Grecian architecture are horizontal, and lead the eye along the eaves of the roof; the prevailing lines in Gothic architecture are perpendicular, and lead the eye upwards, by long, narrow, upright openings, and high gables. A Gothic building of one story produces no effect, because there is no room for the extension of its characteristic lines; but a low Grecian building may have the full measure of its characteristic expression by extending its length. It is clear, therefore, that the Grecian style is better adapted for farm buildings than the Gothic style; and that, if expense were not an object, the piers and posts of a farm yard might be, with propriety, finished as Grecian columns and pilasters; and open cattle-sheds and cart-sheds might show the noblest colonnades, arcades, and piazzas. On the other hand, when the mansion, or château, or convent, or college, or school, to which the farm belongs, is in the Gothic style, there is a propriety in yielding to accidental circumstances, and conferring the same character of style on the farm buildings. As this cannot be done by general forms, since it would be useless to carry stables and cattle-sheds three or four stories high, it is to be attempted chiefly by the character of the openings, and by highly raised roofs. The barn may have something of the forms and proportions of a cathedral; the cart and cattle sheds, of cloisters; and the stables and cow-houses, of lodgings for monks, like those common in old monasteries. We throw out this idea respecting the Gothic style more in conformity with the taste of the times than with our own, which in every case of farm buildings is in favour of the greatest simplicity of design, and of the indication of the Grecian style rather than of any other.

838. *The Materials with which Farm Buildings are constructed* are commonly those which are most abundant in the given locality. As the improvements which are constantly taking place in agriculture necessarily occasion changes in the buildings for storing or consuming its produce, it does not seem essential that the constructions on a farm ought to be of the same degree of durability as those for a dwelling-house or for a public building. Indeed, as society advances, change will enter more and more into every thing, and almost the only buildings that will eventually require to be made of great durability will be those of a public nature; such as bridges, which ought to be the most durable of all architectural constructions, piers, quays, sewers, public offices, parochial schools, &c. As the walls of the greater part of farm buildings have no weight to support but the roof; as the retention of a high temperature within is seldom, if ever, an object; and as scarcely any fires are requisite, timber seems a very suitable material of construction; and in all countries where wood abounds it will be found the cheapest. The objection hitherto has been the want of durability, but this evil may be in a great degree remedied by raising proper footings of masonry, as basements for the framework of the walls; by thoroughly seasoning the timber before it is used; and by coating it over, after it is put together, with tar, or some description of paint or other adhesive material, which will effectually exclude the air and the weather. Walls of mud, or of compressed earth, are still more economical than those of timber; and if they were raised on brick or stone foundations, the height of a foot or eighteen inches above the ground, or above the highest point at which dung or moist straw was ever likely to be placed against them, their durability would be equal to that of marble, if properly constructed, and kept perfectly dry. The cob walls of Devonshire, which are formed of clay and straw trodden together by oxen, have been known to last above a century without requiring the slightest repair; and we think that there are many farmers, especially in America and Australia,

who, if they knew how easily walls of this description could be built, would often avail themselves of them for various agricultural purposes. We shall therefore here describe the Devonshire practice, as furnished us by the Rev. W. T. E——, who has himself built several houses of two stories with cob walls, in the manner which he details in the following paragraph; and who, moreover, informs us that he was born in a cob-wall parsonage, built in the reign of Elizabeth, if not a few years earlier, which was only taken down last year (1831) to be rebuilt.

839. *Cob Walls*, as they are called, are composed of earth and straw mixed up with water like mortar, and well beaten and trodden together. Chapple, in his *Survey of Devon*, 1785, derives *cob* from the British word *chuap* (*ictus*), or from the Greek *κοπτος* (*contusus*), because the earth and straw ought to be well beaten or pounded together. The earth nearest at hand is generally used, and the more loamy the more suitable it is considered for the purpose. These walls are made two feet thick, and are raised upon a foundation of stonework. The higher the stonework is carried the better, as it elevates the cobwork from the moisture of the ground. After a wall is raised to a certain height, it is allowed some weeks to settle, before more is laid on. The first rise, as it is called, is about four feet; the next not so high; and so every succeeding rise is diminished in height as the work advances. The solidity of cob walls depends much upon their not being hurried in the process of making them; for, if hurried, the walls will surely be crippled; that is, they will swag, or swerve from the perpendicular. It is usual to pare down the sides of each successive rise before another is added to it. The instrument used for this purpose is like a baker's peel (a kind of wooden shovel for taking the bread out of the oven), but the cob-parer is made of iron. The lintels of the doors and windows, and of the cupboards or other recesses, are put in as the work advances, (allowance being made for their settling), bedding them on cross pieces, and the walls being carried up solid. The respective openings are cut out after the work is well settled. In Devonshire, the builders of cob-wall houses like to begin their work when the birds begin to build their nests, in order that there may be time to cover in the shell of the building before winter. The outer walls are plastered the following spring. Should the work be overtaken by winter before the roof is on, it is usual to put a temporary covering of thatch upon the walls, to protect them from the frost.

840. *In forming cob walls*, one man stands on the work to receive the cob, which is pitched up to him by a man below; the man on the work arranging it and treading it down. Each workman generally uses a common pitchfork, though sometimes a three-pronged fork is employed. Cob houses are considered remarkably warm and healthy; and they are generally covered with thatch. The durability of cob is said to depend upon its having "a good hat and a good pair of shoes;" that is, a good roof and a good foundation. The Devonshire thatching is very superior to that in most other parts of England. It is done with combed wheat straw, called reed, consisting of the stiff, unbruised, and broken stalks, which have been carefully separated from the fodder straw by the thrasher, and bound up in large sheaves called nitehes. In this way the thatcher is enabled to finish his work much more neatly than in other counties where no reed is made. Instead of brick nogging for partitions, cob is used for filling in the framework, which is previously lathed with stout slit oak or hazel. This sort of work is called *rab* and *dab*.

841. *Cob walls thatched are very common for garden boundaries*. The trees are trained against them by being pinned with maple hooks; but such walls in the course of time become full of holes, and afford a hiding-place for insects; they, therefore, frequently require a fresh coating of plaster.

842. *In estimating the merits of cob walls*, it must not be forgotten, that, when pulled down, the materials are good for nothing but as manure; whereas the materials of brick, stone, and sometimes even of timber walls may be used in rebuilding. It also deserves to be remarked, that earth or mud walls are not in use in any district of Britain which is in an advanced state of improvement; they appear to be chiefly suitable to a rude state of society, where every man is his own builder, and where mechanical skill, and good tools for working in timber and stone, are scarce. However, though they cannot be recommended for general adoption where brick and stone walls are common, yet the very circumstance of their being neglected, or not known, in such places, renders it probable that a great economy would be produced by their occasional use; on the same principle that, in a country where the common labourers live on bread and butcher's meat, one of them who should determine to subsist merely on oatmeal or potatoes would save money.

843. *For covering the Roofs of Farm Buildings*, the cheapest material will generally be the straw raised on the farm, which, when laid on thick, and with a steep slope, lasts many years. The spray of trees previously well seasoned, hoop chips, and the chips from other articles made of coppice wood, form more durable materials for thatching with than

straw, and we think they might be more used than they are, with advantage. Nevertheless, thatched roofs have disappeared with the improvement of agriculture in all the more advanced districts of Britain, and have given place to tiles and slates. It would appear, therefore, that mud walls and thatched roofs, like the practice of using oxen in field labours, notwithstanding all that is said in favour of the former for excluding extremes of temperature, and of the latter as combining a working with a beef-producing animal, are fast falling into disuse. Our own opinion, with respect to thatched roofs, is, that in very many cases they are preferable, both for farm buildings and cottages, to roofs of tiles or slates, as these are commonly constructed, even where the latter two are cheaper, because they are less liable to admit through them the influence of every change of temperature.

844. *For Details of Construction* common to buildings in general, we refer to that part of this work which treats of the practice of building; or the Architect may consult Waistell's very excellent chapter (v.) on this subject.

## CHAP. II.

*A Miscellaneous Collection of Designs for Farm Houses and Farmeries, in different Styles of Architecture, and adapted to different Kinds of Farms; with Specifications, Estimates, and accompanying Remarks.*

845. *The following Designs* exhibit various combinations of the separate buildings, courts, and yards which compose a farmery; and exhibit also farm houses with different degrees of accommodation, from those of the gentleman's bailiff, and of the rent-paying occupier of a hundred acres, to that of the wealthy proprietor who cultivates his own estate. Though there is little room for a display of style in the necessarily simple form of farm buildings, yet we shall endeavour to show in what manner style may be introduced even in the humblest of them; because the farm house is as susceptible of architectural design as any other dwelling; and when it is in the same style as that of the farmery, it gives a first impression, which should be found to be echoed, as it were, through all the subordinate buildings. With respect to the arrangement of these Designs, it is enough to say, that, like those of the cottage dwellings in the preceding Book, it is miscellaneous.

Design I. — *A Bailiff's Cottage, in the Old English Style, intended for the Manager of a Farm in the Neighbourhood of London.*

846. *Situation.* This dwelling, which has been erected at Bury Hill, near Dorking, Surrey, the seat of Charles Barclay, Esq., was designed by John Perry, Esq., architect, Godalming, and executed by contract, in 1831, under his direction. It is situated on the south side of the farm yard, which will form the subject of our next Design, and of which the bailiff has the management. We were shown the house and the yard by Mr. Barclay, in October, 1831, and were so much gratified with both, that we requested his permission to publish Designs of them. This permission he kindly granted; and, by the liberality of our excellent friend, Mr. Perry, we are here enabled to give them, with the most ample details of construction, and with the original specifications and estimates signed by the contractors who executed the work.

847. *Accommodation.* The ground floor, fig. 847, p. 419, contains a porchway, *a*;

hall and staircase, *b*; parlour, *c*; pantry, *d*; store room, *e*; dairy, *f*; scalding-room, or dairy scullery, *g*, containing a pump, *h*; oven, *i*; drying-room, *k*; and terrace, *l*. The

I.

850

851

852

853

chamber floor, fig. 848, to a scale of twenty feet to an inch, contains four good bed-rooms, *m*, *n*, *o*, *p*; each with fireplaces, and all commodiously entered from the landing, *q*, of the stairs, *r*. The basement story, fig. 849, to the same scale, contains an outer cellar, *s*, and an inner cellar, *t*. There is an area, *u*, to the kitchen window, with a trap over a drain, *v*, which is conducted under the cellar floor; in one corner of which, another trap, *w*, is placed over it, for carrying off any moisture spilled in the cellar.

848. *Construction.* The walls are of local sandstone, in random courses, with brick arches and coins; and the window sills, lintels, labels, and chimney shafts are of Bath stone. The posts of the entrance and drying porches, are of oak and the superstructure of the drying-porch is of framed oak, filled in with brick nogging flat, as shown in the elevation of the south front, fig. 850, p. 419. The roof is covered with plain tiles. The different elevations are shown in p. 420; fig. 851 being the north front, fig. 852 the east front, and fig. 853 the west front. The ground floor is raised three feet six inches above the general surface, and the terrace three feet; as shown in the different elevations, by the line *x*, which represents the solid ground, as compared with the line *y*, which represents the surface of the terrace. The cellar is shown at *z*, in fig. 850, p. 419, in fig. 853, p. 420, and in fig. 854; the latter being a section across the cellar, *z*; the

854

parlour, *c*; the kitchen, *f*; and the bed-rooms, *o*, *p*. The foundations and their footings are distinctly seen in this section, and in the different elevations.

Fig. 855 is an end view of the drying-porch, and fig. 856 a side view of the same;

855

856

both to a scale of one eighth of an inch to a foot. The columns here, it will be observed, are twisted; a practice not unfrequent in old English cottages of the better kind, and which is in perfect accordance with the enriched barge boards and the turned balusters of the balustrade.

Fig. 857 shows the plan of the drying-porch.

Fig. 858, to a scale of one inch to a foot, is a section across the balustrade, in which *a* is the top rail, and *b* the bottom rail.

Fig. 859, to the same scale, is a section of the moulded face of the beam, *c*, in figs. 855 and 856.

Fig. 860 is a section of the top of the columns, on which the beam, *c*, is placed.

Fig. 861 is a section of the base of the same columns.

Fig. 862, to a scale of one fourth of an inch to a foot, shows one of the piers to the parapet of the terrace, supposed to be of stonework; in which *d* is the line of the solid ground; *e*, the surface of the new ground; *f*, the level of the terrace; *g*, rough stonework; and *h*, worked stone.

Fig. 863 shows the bottom part of the gable post, seen in fig. 865, and which also serves as a pattern for the pendants from the verge boards. The scale of this figure is two inches to a foot.

Fig. 864 is a section across the eaves of the roof, in which are seen the face of the wall, *i*; the bed moulding, *k*; the soffit, *l*; the situation of the bracket, *m*; the eaves moulding, *n*; the rafter, *o*; and the eaves board, *p*. The scale of this figure is two inches to a foot.

Fig. 865 is a view of part of the barge board, and the gable post; in which are shown the sunk panel, *q*, of the pinnacle; the gable post, *r*; the pierced openings in the verge board, *s s*; the raised ornaments on the same, *t t*; the cross section of the verge board, *u u*; and the cement verge of the tiling, *v v*. The scale of this figure is two inches to a foot.

Fig. 866 is the front view of the entrance porch, and  
 Fig. 867 is the side view of the same porch; both are drawn to a scale of six feet to  
 an inch.

Fig. 868 is a cross section of the oak coping of the wall of the porch.

Fig. 869 is a view and sections of the bracket part of the post, and part of the arch,  
 in the gable of the porch. In this figure, *a* is the commencement of the arch, which

corresponds with the same letter in fig. 866; *b b* show the section of the moulded face of the arch; *c c c* are the three ornaments shown at *c* in figs. 866 and 867; *d, e, f* are the ornaments shown as decorating the outer sides of the corner posts in figs. 866 and 867; and *g* is the side view of the brackets shown at *g* in the same figures; *h* is a section

of the face of the corner post, and of the impost over it; *i i*, the front view of the bracket; *k*, a front view of the impost over the bracket; *l*, the soffit of the arch; and *m*, the inside view of the corner post, shown without ornament.

Fig. 870 is a baluster in the side of the entrance-porch, in which *n* is a section of the top rail.

Fig. 871 shows the gate-post, *o*, and a cross section of the top rail of the gate, *p*.  
 Fig. 872, bottom rail of the gate, *q*; and lower part of a baluster, under the rail, *r*.  
 Fig. 873 shows a horizontal section of the gate-posts, *s*, and of the gate-head, *t*.  
 Fig. 874 is a baluster of the gate, different from that in the side rail, shown in fig. 870.  
 Fig. 875 is the elevation of the external door of the house, to a scale of four feet to an inch; below which are the plan, *a*, to the same scale; and the section of the muntings, *b*; the latter to the scale of a quarter of an inch to an inch.

Fig. 876 is a horizontal section of part of a window, showing the stone window jamb, *c*, stone munting, *d*, and the cast-iron frames of the windows let into them, *e e e*.  
 Fig. 877 is a section of the stone drip mouldings, or labels, put over the windows, to a scale of one inch to a foot.  
 Fig. 878 shows three sections of different parts of the chimney shafts, to a scale of one inch to a foot; *f* is a section of the head of the shafts; *g* is a section of the base; and *h* is a section of the drip moulding under the base, shown at *h* in figs. 879 to 882.  
 Figs. 879 to 882 are the elevations of the four different patterns of chimney shafts, below which are the plans, *i i i i*.

Fig. 883 is a section showing the footings of the walls, and their depth under the original surface line, *k k*, of the ground on which they are built.

Fig. 884 is a section showing the relative height of the ground floor, *l*, and the surface of the terrace, *m*. In this figure are also shown the joists of the ground floor, *n*; the wall plate on which they are placed, *o*; and the chain plate, *p*, which is continued round the whole building.

*Particulars of the several Works to be done in building a Bailiff's Cottage at Bury Hill, near Dorking, Surrey, for Charles Barclay, Esq., according to the Plans, Elevations, Sections, and Details, severally signed by the Parties undertaking the same.*

849. *Excavator's, Bricklayer's, and Well-digger's Work.* To dig out the earth for the basement story, and the several trenches for the foundations of the whole of the building, of the respective depths and widths required, and to fill in and well ram round the work. Surplus earth arising therefrom to be spread round the building, to form a terrace, as shown in the plan. To dig a well in the dairy scullery, 4 feet clear in diameter, 45 feet deep; to steen the same in 4-inch brickwork, and to dome it over in 9-inch brickwork. The soil and rubbish which may be made during the carrying on of the works to be taken out of the building, from time to time, as occasion may require. All the bricks to be used in the building, or brought upon the premises, to be sound and good well-burned stocks. The mortar to be composed of the best well-burned grey lime, and clean sharp sand, well tempered together. The footings and foundations to be built of sandstone, and below the ground line to be grouted with hot lime and sand. The remainder of the walls above ground to be built of sandstone laid in neat random courses, with a flat joint garreted on the external face; the stones to be properly headed and prepared, and flushed solid in mortar; the whole of the coins, arches, and inverted arches to be of brickwork, and all the walls to be built of the several heights and thicknesses shown in the drawings, leaving the several apertures therein described. The chimney breasts, jambs, and backs to be of brickwork, with inverted arches under the lowest fireplaces, the flues to be properly gathered and garreted (this operation is usually performed with loam and cow-dung; but quicklime and pounded brick are found far better, and are now generally used by the best London builders), 12 inches in diameter in the clear. A strong iron chimney bar (see § 602, fig. 542) to be put to each of the fireplaces, and 4-inch brick trimmers to be turned where required. To build stone foundations for the porchways, stone underpinning for the partitions, brick foundations for the sink and to the dairy steps, and an area of 9-inch brickwork to the cellar window, paved with bricks, with sinkhole and drain to deliver the water into the main drain. To pave the cellar and passage adjoining with building bricks laid flat in mortar; and the pantry, store room, and kitchen with dressed paving bricks, bedded and jointed in mortar; and to wheel in such sand as may be required for properly levelling and currenting the same. To put hollow tile drains, 7 inches clear in the bore, where shown by dotted lines in the plan; altogether a length of 200 feet; and to provide and fix 6 cast-iron stink-traps, 8 inches square, one at each of the external apertures thereof; the whole to be laid with a proper fall, and sufficient depth to deliver the water away from the lowest part of the building. To pave the drying-porch with pebbles; to build brick steps, and to bed the oak nosings (the nosing of a step is the front part of the tread, between the line formed by the meeting of the riser with the tread) to the cellar stairs. To build the foundations, the enclosure walls, and an oven 4 feet by 3 feet 9 inches in the clear, properly domed, plastered, and paved; and to find and fix the requisite iron-work and door for the same complete. To build brick benches, with 4-inch arches and piers, in the dairy, to receive a slate covering. To fill in the nogging partitions with brick nogging flat. The bricklayer to find scaffolding and ladders, and to fix and refix the same as occasion may require, as well for his own work as for the other trades requiring the use of them; and to allow the same to remain till the external part of the house and chimney shafts shall be completed. The walls to be carried up in an upright,

substantial, and workmanlike manner; and in the progress of the building no part of the work to be raised more than 4 feet above the other, except in the pediments, but the whole to be carried up in a regular and equal manner. To fix the wooden bricks, and to bed all the plates, bond timber, and lintels in loam. To cut all the rakes and splays, and all the chasings required for the lead flashings; to make good and stop the same with Roman cement; to bed and point the door frames in lime and hair, and to underpin the sills. To cover the whole of the roofing with old sound plain tiles (old are preferred for their picturesque effect) laid on straw to a  $7\frac{1}{2}$ -inch gauge, with heart of oak laths, the hips, ridges, and eaves in mortar: the straw to be of equal thickness throughout, and in sufficient quantity to exclude the light: no crooked, cracked, or cornerless tiles to be used; and the whole of the tiling to be done with particular care, so as perfectly to exclude the snow, rain, and wind. (The gauge of plain tiling is reckoned from the distance which the first and third laths are apart, measuring from centre to centre. For a  $7\frac{1}{2}$ -inch gauge, the workman nails on a lath, and, with a measure or gauge 7 inches and a half long, finds the place of the third lath; and, having fixed that, nails another lath between. This arrangement, when the tiles are hung on, causes them to overlap, so as to show uncovered 3 inches and a quarter of each course. By this means the third tile overlaps the first 2 inches and a half, which makes the work impervious to rain. This will be rendered clear by the section fig. 885; in which *a a* are the tiles; *b b*, the laths; and *c c*, the wooden pegs, by which the tiles are hung on the laths.) The fillets, listings, and verges to be of Roman cement. (The fillets are narrow strips of lime and hair, or cement, put to cover the horizontal joints, where tiling abuts against walls; the listings are the same upon an inclined plane. The verges are the external edge of the tiling in gables, which are covered with lime and hair, or Roman cement.) The bricklayer to find all the materials, ropes, boards, tackle, tools, workmanship, and ironwork, for the completion of his work, and the carriage thereof; to do the whole in the best and most workmanlike manner; and to colour twice over in good stone colour, to match the stone part of the chimney shafts, the whole of the brick coims and brick part of the chimney shafts. To do all the beam-filling, and wind-pinning required. The whole to be done subject to the provisions of the general particular at the end.

850. *Plasterer's Work.* To lath, lay, set, and colour stone colour, the gable of drying-porch. To lath, lay, set, and white the ceilings of basement story and scalding-room, and to lime-white the walls twice over. — Ground Floor and Chamber Story. To lath, lay, set, and white the whole of the ceilings, except the parlour, which is to be lath, lay, float, set, and whitened. To lath, lay, and set the whole of the battens and strings of the stairs; and to render set the walls and nogging partitions, so as to fit them for colouring, and in the parlour for papering. All the timbers of the partitions to be diagonal-lathed. The plasterer to find all materials, tools, tressels, boards, moulds, rules, carriage, and workmanship required for the completion of his work; and to do the same in the best and most workmanlike manner, subject to the provisions in the general particular at the end hereof. [The same person contracts for both the bricklayer's and the plasterer's work, and signs this particular in the following form: —]

I, the undersigned, hereby undertake to perform the foregoing bricklayer's and plasterer's work for the sum of four hundred and eighty-five pounds five shillings and eleven pence. S. B.

851. *Mason's Work.* To pave with Yorkshire stone paving, properly squared in courses, the porchway, the dairy, and the scalding-room; the dairy floor to be rubbed; with proper holes for stink-traps where required; with Yorkshire steps and risers where shown in the plan, and with a solid Yorkshire step at the entrance door of the house. To put Yorkshire curb stones to the drying-porch and area, 5 inches by 4 inches, properly cramped, and run with lead. To put plain Portland stone shelves, mantels, jambs, slips, and bases to the chambers; and the same, with profiles, and reeded shelf and turned pateras (the representation of a cup in bas relief, a common ornament in friezes), in parlours, with Yorkshire stone hearths, and Portland stone slabs to each. The kitchen to have inch-and-three-quarters Portland stone mantel jambs and shelf. To put a Yorkshire stone sink in the scalding-room, 5 feet long, and 2 feet 3 inches wide, with proper hole for washer. To put moulded window frames, labels, and chimney shafts of Bath stone, properly cramped and run with lead, according to the drawings, and properly to fix, and run with lead, the iron frames, lights, and stanchion bars. To put milled slate benches in the dairy, an inch and a quarter thick, with rounded edges, and milled slate skirting

7 inches high, backed up, and set in Roman cement, in the kitchen, dairy, pantry, and store room. The mason to find all materials, carriage, and workmanship required for the completion of his work in the best and most workmanlike manner; and to fix the whole complete, subject to the conditions in the general particular at the end hereof.

[The mason contracting for this, affixes his signature to the same form as before.]

The terrace shown in the drawings (see the figures in p. 419 and p. 420) is not described in this particular, nor included in the estimate; as the expense depends upon whether the free sandstone, of which it should be built, can be obtained with facility or not.

852. *Carpenter's and Joiner's Work.* The whole of the materials to be provided and sawed out square free from wane, of the several scantlings and thicknesses herein specified; to be carted to the spot by the contractor, and to consist of the best yellow Dantzic or Memel fir, or English oak, free from sap, shakes, or large and loose knots. The whole of the carpentry is to be framed in a workmanlike manner, according to the drawings; the carpenter finding labour, nails, and tools, and all kinds of ironwork required for the purpose; the whole to be done subject to the provisions of the general particular at the end hereof. The bond is to pass through the openings, and not to be cut out till the work has settled. To put a chain plate of oak, 6 inches by 4 inches and a half, round the whole of the building, and the middle wall in the centre of the same, at the height shown in the plan; the whole to be properly halved, and bolted at the laps, and dovetailed at the angles. To put three tiers of bond in the ground floor story, and three tiers in the chamber story, of oak, 3 inches by 2 inches and a half; and an oak wall plate under each floor, 4 inches and a half by 3 inches, dovetailed at the angles, and halved and spiked at the laps. To put double oak lintels, 4 inches thick, to all the openings, of the width of the respective walls or reveals, to lie 9 inches on the wall at each end. Oak wooden bricks to be provided in the jambs, for fixing the several linings where required, not exceeding 2 feet apart. — Parlour. To put oak joists, 6 inches by 3 inches, 12 inches apart; the trimmers and trimming joists to be 6 inches by 4 inches. — Chamber Floor. To put fir joists throughout, 9 inches by 2 inches and a half, 12 inches apart. The trimmers and trimming joists to be 9 inches by 3 inches and a half, with one row of 1 inch and a quarter, fir keys (or strutting pieces) in each of the large chambers. — Ceiling Floor throughout. The ceiling joists to be 4 inches and a half by 2 inches, 12 inches apart, with binding joists, 5 inches by 3 inches and a half, and angle beams fixed with iron screw pins to the tie beams, 5 inches by 3 inches and a half, trimmed to the chimneys, and for a trapdoor over the landing to the stairs. — Roofing. Gutter plate, 8 inches by 4 inches. Tie beams, each in one length, joggled to the plates, 7 inches by 4 inches; king posts, 9 inches by 3 inches, with three quarters of an inch iron screw pins 2 feet long, with nuts 3 inches long, mortised through the king posts. Struts, 4 inches by 3 inches; framed principal rafters, 6 inches by 3 inches at bottom, and 4 inches by 3 inches at top; purlins notched on the back of the principal rafters, 5 inches by 3 inches; oak wall plate, 5 inches by 3 inches; pole plate, 4 inches and a half by 2 inches and a half; 1 inch and a half sleepers, 5 inches wide, laid on the back of the rafters to form valleys, 1 inch and a half ridges and hips, 6 inches wide; common rafters, 4 inches by 3 inches, 13 inches apart; inch yellow deal gutter board and bearers, with feather-edged flanch board; and the same to the chimneys. The middle gutter is to be 12 inches wide at the narrowest end, and to rise 2 inches in every 10 feet, with one 2-inch splayed drop; proper valley boards are to be put for the lead valleys. The roof of the scalding-room, and of the porches and oven, are to have plates, rafters, ridges, valleys, and gutters, as before described, and the whole of the eaves are to have feather-edged oak eavesboard, 4 inches and a half wide, and 1 inch and a quarter, and three quarters of an inch thick, with inch brackets to receive the eaves moulding and soffit. — Partitions for Nogging Flat throughout. To put heads and sills, 4 inches and a quarter by 3 inches; and common quarters, 4 inches and a quarter by 2 inches and a half, 18 inches apart; door posts, principal quarters, and braces, 4 inches and a quarter by 3 inches; and nogging pieces, 4 inches and a quarter by 2 inches. All the heads of partitions to be dovetailed into the plates. All the external walls are to be battened inside with inch oak, 2 inches and a half wide and 12 inches apart. To make a proper barrel curb, for the well-diggers, and such centering as may be wanted for the archers and trimmers.

853. *Joiner's Work.* To be done according to the several drawings of details. All the stuff to be of the best well-seasoned (kept till so dry as to be in no danger of shrinking when used) yellow deal, listed, free from sap and shakes, and the whole to be neatly wrought and finished off in a workmanlike manner. — Floors. To lay inch straight joint floors, with proper borders to slabs in the parlour, passage, and bed-rooms. — Doors. To put inch and three quarters four-panel both sides square doors to all the rooms and closets, and to the head of the cellar stairs, hung with 3 inches and a half butt hinges, and 6 inches iron rim brass knob locks, with 1 inch and a half single-rebated

jamb, having framed grounds beaded on edge, with quirk ogee fillet and square, to form architraves. To put an inch wrought ledged and beaded trapdoor to go into the roof, with inch rebated linings. The external doors into the entrance-porch, and the drying-porch, to be of oak, with doorcase, hinges, and linings, &c., according to the drawing; and to have a 10-inch iron-rim drawback lock, and two 8-inch bright rod bolts to each. The cellar door to be inch proper ledged, with oak proper doorcase, 5 inches by 3 inches and a half, with lock and key, and hung with 18-inches cross garnet hinges. — Windows. To prepare a wood model, and provide cast-iron lights, casements, frames, hinges, fastenings, and stay bars to the several openings, according to the drawings. To provide stanchion bars four to each light, of an inch square wrought iron, in the dairy, the pantry, and the store room. The dairy, the pantry, and the store room to have fly wire (wirecloth to exclude flies) inside of the windows, and the casements to open from the outside, with two panels of fly wire in the door between the pantry and the passage. The several windows to have inch window boards with rounded edge, and also three quarters of an inch splayed jamb linings, and soffits with framed grounds, and moulding for architraves, to match the other doors, except those in the cellar, store room, pantry, dairy, and scalding-room. The kitchen and parlours to have 1 inch and a quarter square framed folding inside shutters, with back flaps, proper hinges, and iron bar fastenings. — Skirtings. To put inch torus skirting 7 inches high in the parlour, and three quarters of an inch square skirting throughout the chamber floor. All the skirtings to have narrow beveled grounds and backings. — Staircase. To put inch steps, risers, and carriage, housed into the string boards, and 1 inch and a half close string, with moulded planceer and raking skirting. Moulded handrail, and inch square bar balusters, with iron balusters, and turned newels. The spandril to be filled in with inch and quarter both sides square framing; and to put proper apron lining (the lining which cases the trimmer) and nosing to the landing. To put oak framed nosings to the brick steps of the cellar stairs, with oak wrought and rounded handrail and newel posts. To put inch and half oak pump cheeks and sills, and to case the same with inch deal, and proper cap, &c., and to fix the same in the scalding-room. To put proper staff beads to the angles of the chimney breasts. To prepare and fix with iron holdfasts, 150 feet run of inch and quarter shelf, 12 inches wide, and brackets in the pantry, store room, or elsewhere, as may be directed. To put 2 inches and a half oak carved verge boards with crown mouldings, and carved pendants, with three quarters of an inch wrought oak soffits to all the pediments, and eaves moulding, and three quarters of an inch soffit and bed mould, also of oak, to all the eaves. The entrance porch and drying porch also to be fitted up with oak, the whole according to the drawing of details. The carpenter and joiner to find all the materials, tools, labour, nails, glue, and every description of ironmongery, locks, bolts, bars, hinges, and fastenings, and the carriage and fixing thereof, and every thing required for the completion of his work in the best and most workmanlike manner; and to prepare and fix all manner of beads, stops, fillets, grounds, linings, and backings required for the perfect execution of the work, whether the same may or may not be minutely specified in this particular. The whole to be done, subject to the provisions in the general particular at the end hereof.

[Signed, as before, by the person undertaking the carpenter's and joiner's work.]

R. S.

854. *Plumber, Painter, and Glazier's Work.* Plumber. To put flashings of milled lead, 8 inches wide, 5 lbs. to the foot superficial, chased into the stonework, and fixed with wall hooks to each of the chimney shafts; and to put gutters, 18 inches wide, of 7 lbs. cast lead, and aprons to such as require it. To cover the middle gutter, and gutter at the drying-porch, with cast lead, 7 lbs. to the foot superficial, to turn up 8 inches under the tiles on each side, and to put 3 inches lead rain-water stack pipes, with cistern heads to bring the water to the ground in the angle of the north front, and at the drying porch. To cover the valleys with 7 lbs. cast lead, 15 inches wide. To put proper flashings of milled lead, 5 lbs. to the foot superficial, 12 inches wide, chased into the stonework where the roofs of the scalding-room and of the porchway abut against the same. To put a 5-inch brass grate, and bell trap, and 2 inches and a half lead pipe to the sink. To put a good stout 4-inch lead pump barrel, weighing 2 qrs. 14 lbs., in the scalding-room, with 50 feet of 2 inches and a half lead suction pipe, with bucket, sucker, and iron handle complete. — Glazier's Work. To glaze and back putty all the lights and casements, with good second Newcastle crown glass. — Painter's Work. The whole of the iron frames, lights, and casements, and fly wire to be painted inside and out, four times, in good oil colour. The whole of the internal joiner's work to be knotted, primed, and painted three times in oil stone colour. The oakwork is not to be painted. — The plumber, painter, and glazier to find all materials and workmanship; and the carriage thereof, and every thing requisite for the performance of his work; and to do the

same in a perfect and workmanlike manner, subject to the general particular at the end hereof.

[Signed, as before, by the plumber, painter, and glazier.]

W. B.

855. *General Particular.* The bricklayer's work to be completed by the day of . . . . . The naked floors and roofing to be fixed and finished by the day of . . . . . The whole to be covered in by the day of . . . . . The plastering to be begun as soon as the roofing is covered in, and finished, as well as the mason's work, by the day of . . . . . The whole of the joiner's work to be finished by the day of . . . . . ; and the painter's by the day of . . . . .

The glazing to be done as soon as the lights and casements are fitted in. Each contractor shall be answerable for all damage done to his respective work during the progress, either by the inclemency of the weather or otherwise; and shall make all good, and leave the same perfect at the final completion of the work. The work to be paid for within one month after the certification of the completion of the contracts. — The whole of the materials are to be found by the contractors, and are to be of the best of their several kinds, and fit for the purpose. The work is to be done in a substantial and workmanlike manner, under the direction and to the satisfaction of the Architect appointed for the purpose by the employer; and every thing is to be performed that is necessary for completing the whole work in the usual and customary manner, notwithstanding the same may not be mentioned in the specification. And, if any alteration shall be made by the direction of the employer, during the progress of the work, it shall not vitiate or annul the contract, but the value of such alteration shall be ascertained, at the customary prices of the neighbourhood, by the Architect, whose decision between the parties shall be final. The full amount of the contracts to be paid when the several works are certified by the surveyor to be complete and finished. And, if any material shall be brought upon the premises which is disapproved by the surveyor, or any workman employed whose skill is considered insufficient by him, the said materials or workman to be removed or discharged immediately, upon the contractor receiving notice from the surveyor so to do, either in writing or verbally. And further, if any or all of the said works should be performed in any way inferior to the description or intention of the particular and drawings, or shall be deteriorated below a fair standard of good quality or sound workmanship, the same shall also be valued by the said Architect as aforesaid, and deducted from the amount of the contract by the employer; and his decision in this case shall also be final. The several contractors to be responsible to make good all latent defects arising from bad work or bad materials, notwithstanding the certification as aforesaid. The contractor or contractors are to sign an agreement, when required so to do, to perform the work according to the foregoing particulars and conditions; which agreement shall contain such additional clauses as the solicitor to the employer shall deem requisite to secure and enforce the fulfilment of the same.

[This general particular is signed by all the different contracting tradesmen who have signed the separate particulars, in the manner before shown.]

Bricklayer .....	444	1	4
Plasterer .....	41	4	7
Mason .....	234	12	1
Carpenter and Joiner .....	485	7	11
Plumber, Painter, and Glazier .....	68	18	10

£ 1274 : 4 : 9

863. *General Estimate.* This cottage contains 22,842 cubic feet ; which, at the above sum, amounts to 1s. 1¼d. per foot, which thus appears to be the proper sum, per cubic foot, for estimating dwellings of this description in the neighbourhood of London.

864. *Remarks.* Our readers, we think, will agree with us in highly approving of this cottage, both for its internal accommodations and arrangements, and for its external effect. The parlour and kitchen are of good sizes, and are both well lighted ; and the cellarage, pantry, store room, and dairy are ample. The latter is large, because it is supposed to furnish supplies to the family residing in the mansion. It is very properly placed on the north side of the building, and both doors and windows are protected by wirecloth from the entrance of flies. The pump being in the dairy scullery is a great convenience. The drying-porch, judiciously placed on the south side of the building, is a most useful part of this house, and we could wish it appended to every dwelling in the country ; not only on account of the accommodation which it affords for drying things in wet weather, and for sitting or working under, but for its ornamental effect. It is a more social appendage than the veranda, because it allows of a party sitting round a table, either to work or to eat. In America such a porch would be a delightful place for husking Indian corn, as described by Cobbett ; or, in Savoy, for taking the skins off walnuts, to prepare them for being crushed for oil, as described in the interesting *Travels*

in the *Tarentaise*, by the eminent geologist Bakewell. All the chimneys are in the interior wall, which brings the shafts exteriorly to the highest part of the general mass, and completes what Hogarth, in his *Analysis of Beauty*, calls the painter's pyramid. It is always more satisfactory to see chimneys issuing from the highest part of the roof, than from the side walls, or from any lower part; because the rising sides of the roof seem to conspire in supporting what issues out of its apex, as the leaves of a plant seem to support the flower stem which proceeds from its centre, or the spreading lower branches of a fir tree do its spiry top. When it is known, also, how much this disposition of the chimneys contributes to their drawing well, and to the general warmth of the house, its satisfactory effect cannot but be greatly heightened in every well regulated mind.

Design II. — *A Farmery in the Old English Style, chiefly calculated for Dairy Husbandry, and conducted by a Bailiff, for the Proprietor of the Land.*

865. *Situation.* This farmery, of which fig. 886 is the isometrical elevation, and fig. 887, the ground plan, is built a few yards to the north of the bailiff's house, which

886

forms the subject of the preceding Design. Both, as before observed, were erected in 1831, at Bury Hill, near Dorking, for Charles Barclay, Esq., from the Design, and under the superintendence, of John Perry, Esq., Architect, of Godalming.

866. *Accommodation.* The ground plan, fig. 887, to a scale of forty feet to an inch, shows a cattle-shed, *a*; waggon and implement house, with granary over, *b*; hay-store, *c*; calf-pen, *d*; cow-house, *e*; another calf-pen, *f*; slaughter-house, *g*; swill-cisterns and tanks for holding liquid food, and bins for dry food, for pigs, *h*; piggeries, *iiii*; passage between the piggeries and the fowl-houses, *k*; fowl-houses, *llll*; and two places for fuel, *mm*. There is a pigeon-house over the granary, as may be seen in the elevation, fig. 888. These buildings are placed on three sides of a cattle-yard, which is open to

the south, and overlooked in that direction by the windows of the bailiff's house. There is no stable in this farmery, all the field labour being performed by four pair of oxen, which stand in the cattle-shed. The surface water may be supposed to be conveyed from the passage round the farm-yard by a gutter, forming a line of demarcation between that passage and the space for the dunghill in the centre, and having traps communicating with an underground drain. The water from the roofs may be collected by gutters at the eaves, and conveyed to the same underground drain as that which carries off the surface water. All the liquid matter of the cow-house, cattle-sheds, and pigsties should be collected by gratings into covered gutters, and by them conveyed to two liquid manure tanks in the centre of the yard, over which should be placed the dunghill; and, if the greatest economy of manure, and also a pattern to surrounding farmers, were, as we think they ought to be, leading objects, this dunghill ought to be covered with a roof.

867. *Construction.* The walls are built of local sandstone, with the exception of the south wall of the cow-house, and of the west wall of the granary; both of which are of studwork, weather-boarded. The roof, over the cattle-shed and hay-store is to be covered with pantiles, and all the other roofs with hoop chips. Hoop chips are the shavings made by the coppice cutters, when splitting and preparing large hoops from long hazel and other rods grown in coppice woods: they are generally upwards of an inch broad, a quarter of an inch or more thick, and from 18 inches to 3 feet in length. They are laid on, and sewed to the laths, like thatch; and, after a few years, are hardly to be known from a roof of that description. Their durability, when the roof is so steep as to throw off the water effectually, is equal to that of tiles, and they require less repair. Fig. 888 is the south elevation, in which may be seen the manner in which the oak gate-

posts are kept firm in their places, by the underground braces, to the subsills, *n n*. Fig. 889 is the back elevation of the cow-house, in which are seen, to the right, the

gable end of the granary, and its outside step-ladder. Fig. 890 is the front elevation of the cow-house and the slaughter-house; showing the manner in which the former is ventilated by luffer-boarding under the eaves. Fig. 891 is an elevation of the waggon-house, with the granary over, in which is seen a side view of the outside wooden stair or step-ladder; and, under the ground line, the inverted arches, on the abutments of which the stone bases of the story posts are placed. These stone bases are shown in fig. 892,

on a scale of half an inch to a foot. In this figure, *o* is the post; *p*, the stone base; and *q*, half of the plan of the same. Fig. 893 shows the elevation of the front of the fowl-houses, and the end of the slaughter-house; and fig. 894 the front of the pigsties. In the last figure are seen, at *r r*, the ends of the cast-iron troughs, which project about a foot from the

wall, for receiving the pigs' food. They are seen in the ground plan, fig. 887, at *s s s*. All these elevations are to a scale of forty feet to an inch. Fig. 895 shows the construction of the roof of the cow-house, and fig. 896 that of the roof of the granary; both to a scale of twelve feet to an inch. Fig. 897 shows a section, on a scale of twelve feet to an inch, through the piggeries and fowl-houses, in which *t* is the fowl-house; *u*, the passage between the fowl-houses and the piggeries; *v*, the pigsties; and *w*, the open yards in front of them. Other details of construction may be gathered from the following particulars of the work to be done:—

*Particulars of the several Works to be done in erecting certain Farm Buildings at Bury Hill, near Dorking, Surrey, for Charles Barclay, Esq., according to the Plans, Elevations, Sections, and Details severally signed by the Parties undertaking the same.*

868. *Bricklayer, Excavator, and Well-digger.* To dig out the several trenches for the foundations, of the respective depths and widths required, and fill in and well ram round the work. To level and form the ground for the farm-yard and paving, and to spread the surplus earth, if any, wherever required so to do, any where within 50 yards of the farm-yard: if an additional quantity be considered necessary, it is to be carted to the spot by the employer. To dig a well, 4 feet clear in diameter, 45 feet deep; to steen the same in 4-inch brickwork, and to dome it over in 9-inch brickwork. All the bricks to be used in the work, or brought upon the premises, to be sound and good well burnt stocks. The mortar to be composed of the best well burnt grey lime, and clean sharp sand, well tempered together. The foundations of the walls to be built of sandstone below the ground line, and to be grouted with hot lime and sand. The remainder of the walls above ground to be built of sandstone, laid in neat random courses, with a flat joint garreted on the external face; the stones to be properly headed and prepared, and flushed solid in mortar; the whole of the coins, and arches, and inverted arches, to be of brickwork. The whole to be built of the several heights and thicknesses shown in the drawing; leaving the several apertures therein described. The chimney breast, back, and shaft, for the copper in the slaughter-house, to be of brickwork, and the flue to

be properly pargeted, with a second-size chimney pot, well flanced up with plain tiles and Roman cement. The shaft and pot to be coloured stone colour. All the door and window frames to be properly bedded and pointed with good lime and hair mortar, and the sills to be underpinned. To build underpinning of stonework, with proper footings for the partitions where required, and foundations for the stone bases to the cattle-shed. To put a coping of semicircular bricks, 14 inches wide, to the fence wall, the back of the hay-store, and the front of the pigsties, set in Roman cement, with proper stay irons at all the coins. To fill in the nogging partitions with brick nogging flat. To pave the four fowl-houses with paving bricks, flat bedded and jointed in mortar. To pave the coal places, pigs' lodgings, and slaughter-house with brick stock paving on edge in sand. The passage, cow-house, calf-pens, cattle-shed, hay-house, and pigs' yards to be paved with pebbles laid in sand, properly currented and rammed. To build and pave proper swill cisterns of brick, set in Roman cement, and rendered inside with the same, so as to be perfectly watertight. To colour twice over in good stone colour the brickwork of all the coins, arches, and coping. To lime-white the inside of the slaughter-house and fowl-houses. To bed all the plates, bond, templets (short pieces of timber laid under girders and beams, to distribute the weight), and lintels, in mortar. To cover the roof of the cattle-shed and hay-store with pantiles jointed in mortar; to build foundations for the posts, and to cover all the other roofs with hoop chips from large hoops, finding straw, binders, rods, twine, &c., and laths. The bricklayer is to find all the materials, carriage, scaffolding, tools, workmanship, and ironwork for the completion of his work, in the best and most substantial manner. The whole to be done under the inspection and to the satisfaction of the Architect, subject to the several conditions contained in the general particular at the end hereof.

[Signed by the bricklayer, in the same form as before.]

S. B.

869. *Carpenter and Joiner.* The whole of the materials to be provided and sawed out square, free from wane, of the several scantlings herein specified; to be carted to the spot by the contractor, and to consist of the best yellow Dantzic or Memel fir, or English oak, free from sap, shakes, or large loose knots. To frame the whole of the carpentry in a workmanlike manner, according to the drawings; finding labour, nails, and all kind of ironwork for the purpose, subject to the provisions of the general particular at the end hereof.—Waggon-house with Granary over To put oak story posts (upright timbers supporting brestsummers or girders), 9 inches by 9 inches, and circular braces, 8 inches by 9 inches, wrought, framed, and chamfered; each post to have a square iron tenon let into the stone base. To put wall plates of oak under the floor and roof, 4 inches and a half by 2 inches and a half, with fir sills to the external partition, 12 inches by 6 inches. To put fir girders, 12 inches by 12 inches; each girder to be fixed with a three quarters of an inch iron screw pin and nut to the sill, and to have an iron tie, with an S iron through the wall, properly spiked to the girder. The joists to be framed into girders, 12 inches by 2 inches and a half, 12 inches apart. The external partition to have principal quarters, 6 inches by 6 inches, with common quarters and braces, 12 inches apart, 6 inches by 3 inches and a half; head, 6 inches by 6 inches, covered with oak or yellow deal weather-boarding and fillets, with flanch board and brackets at bottom. To lay the floor with inch and quarter yellow deal, wrought, ploughed, and tongued. To put 3 tiers of bond, 4 inches by 3 inches, in the walls of the granary. To put fir proper window frames, filled in with three quarters of an inch deal wrought luffer-boards housed into the frames; with oak wrought and beveled drip sills to the front and back windows. To put an oak proper doorcase, 5 inches by 3 inches and a half, to the granary, with oak drip sill, 9 inches by 3 inches and a half, with inch and quarter deal proper ledged door, hung with strong hook and eye hinges, and with a strong iron-rim lock. To put a step-ladder of 2-inch oak, with the steps housed into the sides with three iron screw braces and nuts. The steps to be fixed with strong iron hook and eye hinges to the sill.—Roof. To put fir tie beams, 9 inches by 4 inches; king posts, 9 inches by 3 inches, with three quarters of an inch iron screw pins 2 feet long, with nuts 3 inches long, mortised through the king posts; struts, 3 inches by 3 inches; framed principal rafters, 6 inches and a half by 3 inches at bottom, and 5 inches by 3 inches at top, fixed at each end with screw pins to the tie beams. Purlins, 5 inches by 3 inches, notched on the back of the principal rafters. Pole plate, 4 inches and a half by 3 inches; common rafters, 13 inches apart, 4 inches and a half by 3 inches; ridge pieces, 9 inches by 1 inch and a half, with oak eaves board. The joists, to receive the pigeon-house floor, laid on tie beams, are to be 6 inches by 2 inches and a half, trimmed for a trapdoor; the floor is to be of inch deal, rough, with edges shot, ploughed, and tongued, with trapdoor and hinges, and step-ladder, complete. To put 1 inch and a quarter oak shelves and penthouse to the pigeon-holes, with oak cantilevers to support them. A rough partition to be put across in the roof, covered with weather-

boarding, with a door, hinges, and lock, to go into the pigeon-house end. — Cattle-shed and Hay-house at the back of the Granary. To put fir posts, 7 inches by 7 inches, wrought, framed, and chamfered, with iron tenons and braces circular on plan, 6 inches by 3 inches; fir plates, 7 inches by 4 inches; pitching piece, 4 inches and a half by 3 inches; tie beams, 7 inches by 4 inches; principal rafters, 5 inches by 3 inches; struts, 3 inches by 3 inches; purlins, 5 inches by 2 inches and a half; common rafters, 13 inches apart, 4 inches and a half by 2 inches and a half, covered with pantile laths, with oak feather-edge eaves boards. To put oak proper door-case and sill to the hay-house, 5 inches by 3 inches, with 1 inch and a quarter yellow deal proper ledged door, hung with strong hook and eye hinges, strong Norfolk latch, and 8-inch stock lock. — Cow-house, Calf-pens, and Slaughter-house. To put oak sills to the external partition in front, 6 inches by 3 inches, with fir principal posts, 6 inches by 3 inches; common quarters and braces, 5 inches by 2 inches and a half; the head, 6 inches by 3 inches; oak wall plates, 4 inches and a half by 3 inches. The front to be covered with weather-boarding at bottom, and with open filleting (slips of deal nailed at one or two inches apart), at top; to put oak proper door-posts, 5 inches by 3 inches, with 1 inch and a quarter oak proper ledged doors, with strong hook and eye hinges and fastenings and the same to the slaughter-house. The calf-pens to be parted off with oak posts and arris rails (rails presenting two surfaces to the eye, which two surfaces unite in forming an edge or arris between them), filled in with oak slabs, with a small gate hung on hook and eye hinges, with a hasp and staple. To put proper cow-bows (a contrivance for fixing the cow's head over the manger) and mangers for twelve cows. To put an oak proper 2-light window frame, and oak drip sill with iron casement, to the slaughter-house. To put tie beams, 7 inches by 4 inches; struts, 3 inches by 4 inches; principal rafters, 5 inches by 3 inches; purlins, 5 inches by 2 inches and a half; common rafters, 4 inches and a half by 2 inches and a half; ridge pieces, 9 inches by 1 inch and a half, with oak eaves board. — Fowl-houses and Piggery. The roofing to be of the same scantlings with oak eaves board, as last described; and the window frame in the swill-house the same as that in the slaughter-house. The door and doorcases the same as those in the cow-house, with 8-inch stock locks. The partitions of the fowl-houses to be framed for brick nogging flat, with oak sills, and English fir puncheons (short pieces of timber used in framing partitions). The front of the pigsties to have oak sills with fir puncheons, 4 inches by 2 inches and a half, covered with weather-boarding. The division of the sties and of the back partition to be of oak posts, 5 inches by 5 inches, with arris rails, and filled in with oak slabs. The pigsty doors to have oak frames wrought and rebated, with inch oak wrought ledged doors, with strong hook and eye hinges, and hasp and staple fastenings. To find and fix five pig troughs of cast iron, 6 feet long each. To put a proper wrought framed and beveled oak curb to the swill cisterns, 6 inches by 2 inches and a half. — The three Gates. To put oak posts wrought and chamfered, 9 inches by 9 inches, with proper sills, subsills, and braces, to the wide gates. To put cast-iron moulded and beveled caps, as in fig. 898, to the posts. To put yellow deal, 2 inches and a half, wrought, framed, and braced gates, filled in with inch yellow deal, wrought, ploughed, tongued, and beaded, with proper strong wrought-iron hook and staple hinges; the staples to be fixed with nuts and screws, and bar fastenings; the large gate to be a folding one. All the gates to have wrought, beveled, and moulded capping, and strong Norfolk latches. To put 1 inch and a half oak pump cheeks and sill; to case the same with inch deal, with proper cap, and fix the same where required. To make a proper barrel curb for the well.

[Signed by the contractor, as before.]

898

R. S.

870. *Plumber, Glazier, and Painter.* To put lead lights and glass to the window frames in the slaughter-house and swill-house. To put a lead flashing, 5 pounds to the foot superficial, to the roof of the cattle-shed and hay-store, 12 inches wide, worked into the joint of the stone wall of the granary and coping, and also to the shaft of the chimney to the slaughter-house. To put a good stout 4-inch lead pump barrel, weighing 2 quarters 14 pounds, with 50 feet of 2 inches and a half lead suction pipe with bucket, sucker, and iron handle complete. To paint all the gates, doors, and window and door frames, inside and out, and all the weather-boarding outside four times in good oil colour. The work to be done, finding all materials, workmanship, and carriage, subject to the provision of the general particular at the end hereof.

[Signed, &c., as before.]

W. B.

871. *Stone-Mason.* To provide and fix Portland stone bases, properly tooled and beveled, for the story posts of the granary and the cattle-shed, and to fix iron tenons in

them run with lead. To be done subject to the provisions in the general particular at the end hereof.

[I, the undersigned, hereby, &c., as before.]

W. G.

872. *General Particular.* See that at the end of the particulars of the cottage, § 854.

873. *Measurement and Estimate.* Account of the quantities of the several works required in building the farm-yard at Bury Hill, with an estimate of the expense of performing the same.

874. *Bricklayer, Excavator, and Well-digger.* A. M.

176 cubic yards and a half, digging, filling, and ramming in again ; the surplus earth to be wheeled to any distance not exceeding 50 yards .....	
10 rods 248 feet reduced of stonework grouted. ....	
21 rods 73 feet, ditto, above ground, with garreted joint .....	
92 feet reduced of brickwork .....	
45 feet-ditto ditto, set in Roman cement .....	
205 feet ditto of brickwork, in dry steening, without labour.....	
8 squares 83 feet superficial pantiling pointed .....	
63 squares and a half superficial hoop chip thatch, with chips from large hoops, including laths and every thing .....	
178 yards lime-whiting .....	
8 yards stone-colouring .....	
27 yards brick nogging flat .....	
41 yards rendering in Roman cement .....	
29 yards paving bricks flat bedded and jointed in mortar.....	
7 yards paving bricks in cement; two courses of bricks, and one course of plain tiles (in swill-cisterns) .....	
63 yards stock paving on edge in sand .....	
226 yards pebble paving .....	
94 feet, run one half round, 14 inches brick coping set in cement ...	
30 feet verge in cement .....	
30 feet deep of well-digging, and labour to steening.....	
15 feet ditto ditto (extra-depth).....	
1 chimney-pot and flanching, with tiles in cement .....	
3 stay irons to coins of coping.....	
6 window frames bedded and pointed.....	
16 door frames ditto .....	
Forming cattle-yard, with dish and current.....	
Colouring the coins, arches, and coping stone colour .....

37 feet 1 inch cubic Dantzic fir in bond plates, &c. ....	
943 feet 8 inches cubic ditto, framed in roofs, floors, and partitions...	
5 feet cubic proper doorcase and window frames .....	
40 feet 6 inches cubic oak in plates, &c. ....	
20 feet 5 inches cubic ditto, framed .....	
80 feet 7 inches cubic, wrought, framed, and chamfered .....	
33 feet 6 inches cubic, ditto, ditto, cut circular .....	
3 feet 11 inches cubic drip sill, wrought, framed, and beveled .....	
3 feet 9 inches cubic wrought, framed, and beveled curb to pigsty ...	
33 feet 1 inch cubic oak proper doorcase ... ..	
25 feet superficial three quarters yellow deal lining .....	
93 feet 4 inches superficial three quarters luffer-boarding.....	
18 feet 5 inches superficial inch yellow deal wrought pump casing ...	
9 feet superficial inch ledged flap.....	
46 feet 10 inches superficial inch oak proper ledged door .....	
7 squares 82 feet superficial inch weather boarding .....	
7 squares 79 feet superficial inch yellow deal floor rough, edges shot, and ploughed, and tongued.....	
7 squares 79 feet superficial 1¼-inch yellow deal floor, wrought, ploughed, and tongued.....	
247 feet 9 inches superficial 1¼-inch proper ledged door .....	
20 feet 3 inches superficial 1¼-inch wrought oak shelves to the pigeon house.....	
9 feet 9 inches superficial 1½-inch oak pump cheeks .....	
23 feet 10 inches superficial 2-inch oak wrought sides to ladder .....	

37 feet 2 inches superficial 2-inch oak wrought and beveled.....	
32 feet 3 inches superficial 1½-inch yellow deal ridge.....	
76 feet superficial 2½-inch yellow deal wrought, framed, and braced folding gates, filled in with inch deal, wrought, ploughed, and tongued.....	
96 feet superficial slab filling in .....	
51 feet superficial rough partition and boarding with ledged door.....	
8 squares 62 feet superficial pantile lathing .....	
3 squares 22 feet superficial partition for nogging flat .....	
2 squares 47 feet superficial partition to the front of the pigsties.....	
4 squares 7 feet superficial enclosure of posts, arris rails, and slabs ...	
30 feet run throating in oak .....	
433 feet 6 inches run oak eaves board.....	
14 feet 6 inches run fir beveled and moulded capping .....	
80 housings to luffer-boarding.....	
34 ditto to steps .....	
2 oak cantilevers cut.....	
1 step-ladder, made complete, to go into the loft over the granary....	
6 posts, prepared and fixed.....	
4 arris rails, ditto .....	
5 cast-iron pig troughs, 6 feet long.....	
1 hole for the pump handle, in oak.....	
1 cap to pump case .....	
1 barrel curb for the well.....	

876. *Ironmongery and Fixing.* A. M.

10 square iron tenons.....	
3 ¾-inch iron screw pins and nuts to the girders. ....	
3 iron ties, and 3 irons to ditto .....	
6 iron screw pins to the principal rafters.....	
3 ditto to the king posts .....	
3 iron screw bars and nuts to the step-ladder.....	
1 iron casement .....	
6 cast-iron beveled and moulded caps to the gate-posts .....	
1 bar gate fastening .....	
1 pair of strong hook and eye hinges for the granary door .....	
1 strong lock for ditto .....	
1 pair strong hook and eye fastenings to the granary ladder.....	
1 pair 16-inch cross garnet hinges.....	
1 pair 18-inch ditto .....	
17 pairs of hook and eye hinges to hay-store, cow-house, fowl- houses, &c. ....	
4 strong Norfolk latches .....	
13 fine plate stock locks .....	
7 hasps and staples .....	
5 pairs hook and eye hinges to pigsty doors .....	
4 pairs strong hook and staple hinges, with nuts and screws.....

Total ..... £ 998 : 4 : 10

880. *General Estimate.* As the number of cubic feet in the buildings of this farmery is 73,383, it appears, from the actual cost, that 3¼*d.* per foot will give a near idea of the price of such buildings similarly circumstanced.

881. *Remarks.* There is no great room for ingenuity of contrivance in a farmery of this description, on a small scale; but the minutiae of the construction, as given in the particular, will be found very useful to those connected with this department of building. The appearance of the whole, as seen in the isometrical view, fig. 886, is neat, plain, and substantial; the true characteristics of an English farm-yard. The practice of roofing such buildings with hoop chips is little known in Scotland, but is well deserving of imitation in that country; and we should think it would be also found suitable for America and Australia. In some parts of the country the granary would have been supported by stone pillars, instead of oak posts; but it must be recollected that the necessarily increased diameter of the former, occasions a great loss of room in the cartshed, since no cart can be introduced that will not pass between the pillars.

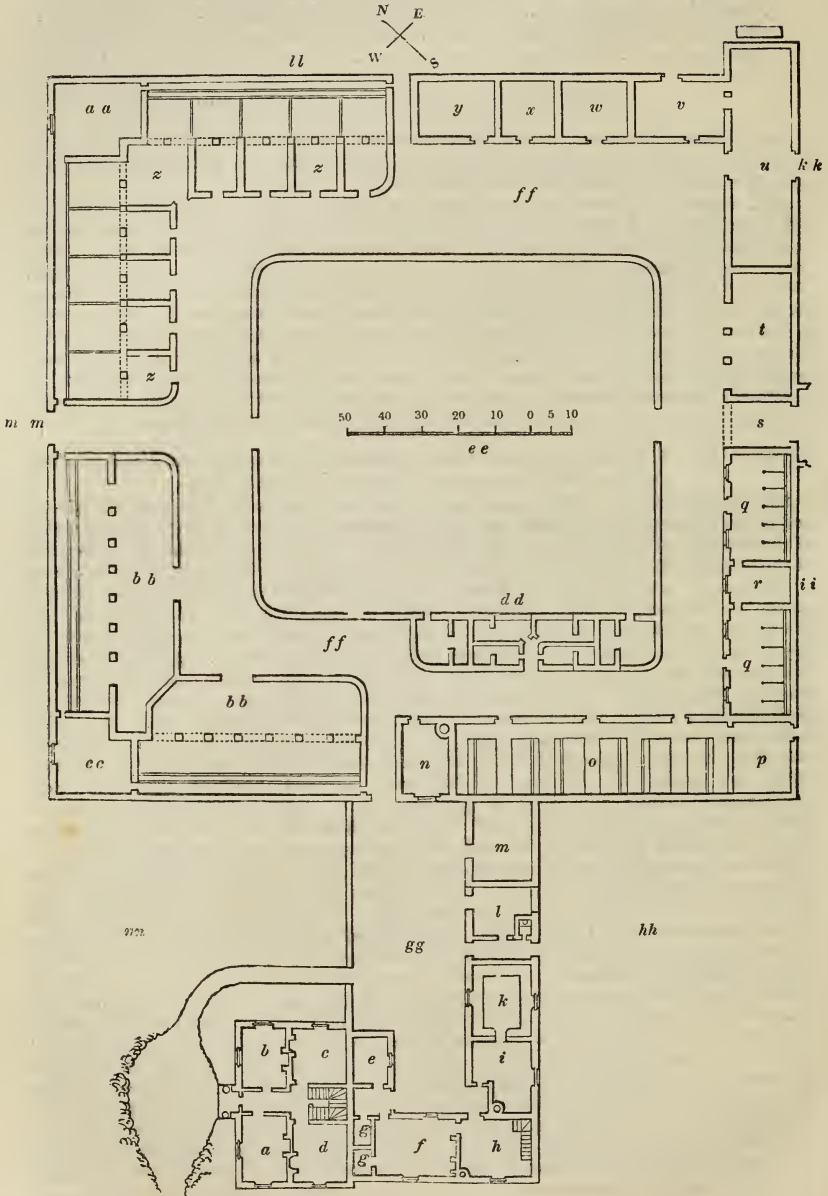

Design III. — *A Farm House and Farmery suitable for a Farm of Six Hundred Acres of Turnip Soil, executed at Halstone, in Dumfriesshire.*

882. *Accommodation.* The ground plan of the house, and its kitchen court and offices, and of the farmery, and its courts and yards, is given in fig. 899; and the general effect of the whole is seen in the isometrical view, p. 443. In fig. 899 are shown, in the plan of the house, a drawing-room, *a*; dining-room, *b*; parlour, *c*; bed-room, *d*; store-room, *e*; kitchen, *f*; two pantries, *g g*; kitchen scullery, with stair to servants' bed-rooms over it, and the kitchen, *h*; dairy scullery, *i*; dairy, *k*; ash-pit, *l*; and coal-house, *m*. In the farmery are shown a steaming and boiling house, *n*; cow-house for eighteen cows, *o*; hay-house, *p*; two stables for six horses each, *q q*; harness-room, *r*; gateway from the hay-yard and the rick-yard, *s*; cart-house, *t*; barn, with a threshing-machine driven by water, *u*; straw-house, *v*; calf-house, *w*; stable for a sick horse, or mare and foal, *x*; potato-house, *y*; eight cattle-hammels for feeding twenty head of cattle, *z z z*. A turnip-house, *aa*; two cattle sheds and courts, *bb*; hay and green wood house, *cc*; piggeries, *dd*; dung court, *ee*; passage between the dung court and the buildings, *ff*; kitchen court, *gg*; garden, *hh*; hay-yard, *ii*; barn-yard, *kk*; straw-yard, *ll*; grass field, *mm*; and lawn and shrubbery in front of the house, *nn*. The letters *ii* to *nn* will also be found in the isometrical view, p. 443. It will be observed that in this Design there are regular foddering passages to the cattle and cow sheds, and to the hammels; and that the hay and green food houses are judiciously placed adjoining them, for the convenience of having a supply of food at hand. In the stables the horses stand in separate stalls, and the cows are allowed a width of five feet each. Fig. 900 shows a plan of such parts of the buildings as have a second story, with the roofs of the other parts. In this plan, *a* and *b* are two best bed-rooms, with a dressing-closet, *c*, between them; *d* is the chamber lobby, and staircase; and *e* and *f* are two family bed-rooms; *g* is a nursery or lumber room; *h h* are two servant's bed-rooms; *i* is the open yard for ashes and rubbish, in which yard there is a privy; *k* is the hay-house, or house in which food is stored for the cows; *ll* are the hay-lofts over the stables; *m* is the corn-room, over the harness-room; *n* is the granary over the cart-house; *o*, the barn; *p p p*, the yards to the hammels; *q q*, the yards to the cattle-sheds; *r r r r*, the yards to the pigsties; *s*, lobby for supplying food to the four fattening pigsties; *t t* are two sties for breeding pigs, with doors which open to the dung-yard, *u*; *v* is the principal entrance to the farmery from the fields, and from the public road; *w* is the covered entrance from the rick-yard; *x* is an entrance from the straw-yard, in which straw is stacked to be given to cattle as wanted for food or litter; *y* is the entrance from the kitchen court; *z* is the kitchen-garden, and *g*, the lawn.

883. *Construction.* The walls are of freestone found on the premises, squared, and regularly hewn at all the angles and openings, with stone sills, jambs, and lintels. The roofs are covered with blue slates, and the whole of the court, passage, entrances, and kitchen court, is paved with granite.

884. *Remarks.* This Design was furnished us by Walter Newall, Esq., Architect, Dumfries, under whose superintendance it was erected on the extensive estate of the Duke of Buccleugh in that county. It is remarkably complete in point of accommoda-

899

tion; and, like all the buildings erected on the duke's property, is most substantially and durably executed. We observe that there is no poultry-house, and but a very small kitchen-garden; which is characteristic of the Scotch farmers, who care little about the minor comforts. We could suggest some additions to the house, one of which no Englishman, with a dining-room, drawing-room, and parlour, would be without, we mean a water-closet. We wonder, also, that to such a house and yard, there is neither a chaise-house, nor a stable for saddle horses. Why not a green house?

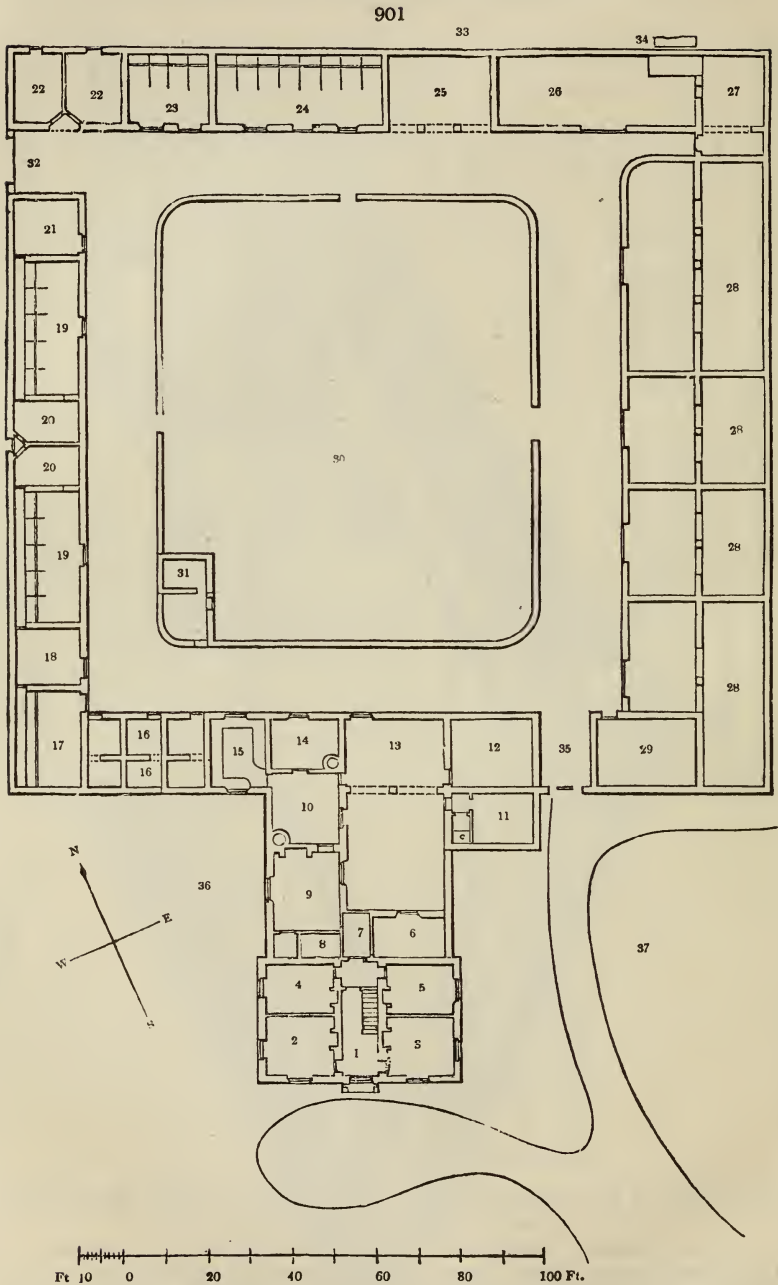

900

Design IV. — *A Farm House and Farmery, suitable for an extensive Turnip Farm, executed at Gatestack, in Dumfriesshire.*

885. *Accommodation.* In the ground plan of the house, fig. 901, there are a lobby, 1; two parlours, 2 and 3; two bed-rooms, 4 and 5; a store-room, 6; back lobby, 7; with a pantry, 8; kitchen, 9; with a small pantry adjoining; scullery, 10; ash pit, 11; wood and coal house, 12; open shed or cleaning room, 13; boiling-house, 14; dairy, 15; pig-houses, 16; feeding-house for cattle, 17; turnip or green food house, 18; cow-houses, 19 19; calf-houses, 20 20; hay-house, 21; potato-houses, 22 22; a stable for four horses, 23; a stable for eight horses, 24; cart-house, 25; barn, 26; straw-house, 27; cattle-sheds and courts, 28; and house for turnips, tares, or clover, 29. In one corner

of the dung-court, 30, is a pig-house, 31; the entrance from the rick-yard and the fields of the farm is at 32; the rick-yard is at 33; the water-wheel for the threshing-machine is at 34; and the main entrance at 35. There is a garden at 36; and a lawn, with shrubs and ornamental trees, at 37. The three references 33, 36, and 37 are also introduced in the isometrical view, p. 444. Fig. 902 is the plan of the chamber floor of the house,

902

and of the lofts and roofs of the farmery. 38 and 39 are two best bed-rooms, with a dressing-closet between; there are two other bed-rooms, 40 40, and a servants' bed-room, 41 : 42 and 43 are the yards to the pigsties; 44, the wool-loft; 45, two hay-lofts; 46, the granary; 47, the upper part of the walls of the barn; 48, the straw-house; and 49 49 49 49, the yards to the cattle-sheds. The dung-court is indicated by 50; the kitchen-court by 51; the kitchen-garden by 52; and the pleasure-ground by 53.

886. *Construction.* The walls are of stone, and the roofs slated, with ridge stones of the free red sandstone of the district. Fig. 903 is a cross section of the cow-house, marked 19 in fig. 901; in which may be seen the feeding-passage, two feet and a half wide, *a*; the partition of flag-stone, *b*, which separates this feeding-passage from the feeding-trough or manger, *c*; the partitions between the stalls, formed by single flag-stones, *d*; the level surface of the stall, *e*; the gutter behind, *f*; and the passage, *g*. At *h* a vertical line is shown which indicates a round iron rod, half an inch in diameter, on which a ring runs, and to which the cattle are fastened by halters or chains. Two stand together between each stall. Fig. 904 is a longitudinal section of a part of these

stalls, in which the fastening rods, *h*, are more distinctly seen: *i* is the elevation of the manger; *h*, the partition between the manger and the foddering-passage; and *l*, the top of the side wall. The stalls for every two Ayrshire cows are five feet long from the manger to the gutter, and five feet and a half wide from partition to partition. The manger is one foot and a half wide, and the gutter behind one foot two inches. Each separation partition is a flag-stone four feet and a half long, three feet and a half broad, and six inches thick, let into the ground, to the depth of a foot.

887. *Remarks.* This Design, by Mr. Newall, which was also executed under his superintendence, on the Duke of Buccleugh's estate, affords a very good specimen of a breeding and feeding farmery, where the produce is chiefly consumed in feeding cows for their milk to rear calves, but partly also in fattening cattle for the butcher. The wool-loft bears evidence that sheep form a part of the live stock; and, from the number of stalls for horses, it may be concluded that about 500 acres are annually under the plough.

Design V. — *A Farm House and Farmery for a Farm of 150 Acres of Arable and Pasture Land, in Buckinghamshire.*

888. *Accommodation.* Fig. 905 shows the general appearance of the whole; and in fig. 906 the ground plan is exhibited, containing a parlour, 1, with a cellar under it,

into which the beer is let from the back kitchen by a pipe, and which is lighted by a window on the garden side: this parlour has a bed-room and attics over it. The front door and stairs are shown at 2; the front kitchen at 3, having a glass door into the garden, and containing the door to the cellar and pantry, with dry cupboards for groceries, &c., and bed-rooms and attics over; 4 is a pantry under a lean-to, the floor of which is two feet under that of the kitchen; the back kitchen, 5, has two coppers, a large oven, a well and pump, and a sink, with men's bed-room over, and stairs to the same; the dairy, 6, is three feet below the floor of the back kitchen. The pantry, oven, and dairy are all under a lean-to roof. There is a wood and coal house, with a granary over, 7; the granary being entered by a swing step-ladder from the yard, as seen in the

isometrical view; 8 is a stable for six horses, with a hay-loft over; 9 is a chaff or fodder box at the end of the stable; 10 is a hen-house fitted up with roosting-poles and laying-boxes three feet from the floor; the poultry go out and in at a hatch-hole, three feet above the surface of the yard, by means of a short ladder fixed at *a*. The entrance to the potato-house, which is under 14, is at 11; 12 is a duck-house; and 13 a goose or turkey house: both these houses, together with the hen-house, are under a lean-to roof; and the potato-house is under the straw-house and barn, 14 and 27; 15 is a straw-house; 16, store pigsties, the ends of the feeding-troughs shown at *bb*; 17 are fattening pigsties; 18, a meal-house, with five bins, *c*, for meal and dry food of different kinds, with a large hog-tub, *d*, for liquid food, and showing the ends of three feeding-troughs at *eee*; 19 is a cow-house, with calf-pens at one end, *f*, and a hay-bin or cupboard in one corner, *g*; 20 is a cattle-shed, with a rack and manger; 21 is a waggon and cart lodge, the entrances to which are outside of the yard; 22 is the principal gate of entrance, made of oak, nine feet wide with five bars, and a strong diagonal brace; 23 is a circular open shed or hovel, for sheltering cattle while eating, with a rack under; 24 is the rick-yard; 25 is the gate from the fields; 26, small doors of the barns, with locks; the large doors bolting in the inside in a manner which will be mentioned hereafter; 27, wheat barn, consisting of a threshing-floor, *h*, and two bays, one at each side, *ii*; 28 is the barley-barn, consisting of two bays on one side, *h*, and one bay on the other, *l*, and a threshing-floor between, *m*; 29 is the oat-barn, with a threshing-floor, *n*, a double bay for unthreshed corn on one side, *o*, and a single one on the other, *p*; 30 is a water-trough for supplying the horses and cattle with drink, filled from the pump in the back kitchen by means of a spout through the wall; 31 is a light open fence or palisade; 32 is a fence of oak pales; 33, a hedge; 34, a lawn, with groups of shrubs and flowers; 35, a kitchen-garden; 36, a best privy; 37, a privy for the female servants; 38, wood-stack; (these last three being represented some yards nearer the house than they really are, in order to bring them within the compass of the plate); 39, orchard; 40, privy for the men-servants; and 41, hollow basin sloping on every side, to receive the waters of the yard and the dunghill.

889. *Construction.* The dwelling-house is built of brick, and is covered with plain tiles; all the other buildings are of timber in frames filled in with studwork, and covered outside with weather-boarding; their roofs are of plain tiles, with the exception

of that of the cow-house, cart-house, and central hovel, which may be thatched with straw, chips of wood, or spray. The walls of the cart-shed, 21, are frames filled in with studwork, into which branches of furze are thickly wattled, a species of covering which lasts several years, and is easily renewed. Where furze is not abundant, common spray may be used. Fig. 907 is a section across the round hovel in the yard, to show its construction.

907

Four posts are fixed in the ground, which at the height of ten feet support four horizontal pieces, each twelve feet long, and placed at right angles, as shown at 23, in fig. 906; on these, poles of any sort are laid so as to form a circular flooring, on which faggots are built in such a manner as to form a cone, and these are slightly covered with straw or chips so as to throw off the rain. A round fodder-rack is formed on the ground, by placing four short posts in such positions as that they will form a circle with the four long ones, as shown in the plan, fig. 908, in which *q* shows the long posts for supporting the roof; *r*, the short ones for the frame of the rack; *s*, the horizontal joists placed at right angles to one another; *t*, the rough poles, placed diagonally to the joists; and *u u*, the short poles, or branches, laid on the others, to form a flooring for the faggots. Fig. 909 is a section of the wheat-barn, to show the framing of the principal timbers, six of which frames form the two ends, and the five intervening spaces called bays. The central bay is the threshing-floor, which is laid with joists or sleepers, across the potato-pit, or cellar, *v*, which, as before mentioned, is entered from one end of the barn, at 11, in fig. 906. The sleepers are generally of oak or beech, and they are covered with oak planking, an inch and a half or two inches thick, halved into one another along the edges, or tongued and grooved. Along the sides of the threshing-floor are what are called mowsteads, *w*; which are generally frames of woodwork boarded, carried up to the height of two feet and a half or three feet, with a coping of wood, to separate the corn which is being threshed, from the unthreshed corn on one side, and the corn or straw on the other.

908

Fig. 909 is a section across the porch of the barn, showing the doors removed, and the position of the barn-door lift. In this section, *a* is the sill of the door, six inches square, sunk level with the threshing-floor, and supported by two stout posts or wheel-pieces, *b b*; *c c* are posts eight inches by six inches, framed to the sill at their lower end, and at the upper end to the top plate *d*, which is six inches square.

909

The inner angle of the front of the posts is rebated one inch for the shutting of the doors, *e e*. These doors are made of inch deal, nailed to stout ledges or back boards, which lock into each other by means of their beveled ends, as shown by the dotted lines in *e e*. The doors are hung with strap hinges, on stout hooks driven into the posts; and they shut against, and are fastened to, a movable bar, *f*, which fits into mortises, one of which is a trap mortise, in the posts. To this bar the barn-cloth, *g*, is hung by loops of tape: it is let down when threshing is going forward, to prevent the corn, which flies up in all directions from the flail, from falling over the lift, *h*. This lift is made of inch deal ledged, two feet four inches high, and fits into grooves chiseled out of the spur pieces, *i i*, spiked to the sill and posts. The barn doors swing two feet above the level of the floor of the barn, in order that they may not be obstructed by the litter in the yard. The back door of a barn of this description has no porch, neither is it usually made so large as the front door: if it allows an empty cart or waggon to pass out, for which an opening eight feet wide and ten feet high will be sufficient, that is all that is required; for these doors are only used for taking out a cart after it has been unloaded in the barn; it being dangerous to back a thill or tram horse on the threshing-floor, which, from its smoothness, is generally slippery. Such doors are also used for taking in corn by manual labour from the rick-yard. Fig. 911 is a view of the side of the barn-door porch, in which is shown the base of brick or stone work, *k*, with a coping of wood, *l*, forming a sill to the small lock-up door, *m*, which is shown at 26, in fig. 906. The thresher, on leaving his work at night, makes fast the large double doors by means of the movable bar *f*, and, passing out by the small door, locks it, and secures the whole. The wall or eaves plate of the barn, it is to be observed, is carried directly through the porch, for the greater

security of the structure. Fig. 912 is a section across the meal-house, *n*; covered part of the pigsties, *o*; and pigs' yard, *p*, in which is seen the bin, *q*; hog-tub, *r*; shoot, *s*;

hog-troughs, *t*; and in the background the end of the man's privy, *u*. The hog-troughs are formed of two long boards, and two short ones, in the very simple manner exhibited in fig. 913. Fig. 914 is a section across the cow-house; and fig. 915 is a longitudinal view of the cow-stall, in order to show the manner of fastening the cows to it. In these

figures, *a a a* are upright pieces of oak three inches square, sunk in the ground at the lower end, and kept steady by braces, *b*, at their upper ends. At a foot from the ground, and also near the top, these posts have double ledges, or horizontal pieces, *c c*, nailed on behind, and in front, for the movable check-pieces to traverse in; they being fixed with pivots at *e e*. These pieces lean back to admit the cow's head at *f*, and they are then moved to a perpendicular position, as shown at *i*, and kept in place by catch-pieces, *g g*, which have mortise holes which fall down on tenons on the ends of the check-pieces: these catch-pieces also move on pivots, which are fixed in the uprights. The calf-pens, *h*, at the further end of the cow-house, are enclosed by boards five feet high from the ground, with a door to each; but the floor of the pen is raised one foot above the floor of the cow-house, and is formed of stout oak boards pierced with holes to allow the escape of urine: each pen has a door two feet wide. The drainage of the yard is to a hollow space between the pigsties and the central hovel; this space being central to the piggeries, the stable, the cow-house, and the cattle-shed, which are the great sources of manure, and to the three barns, which are the great sources of litter. In this situation the dung-hill is at the farthest point from the house; and, therefore, least likely to be offensive by its smells. There is an open gutter surrounding the interior of the yard, so as to receive the water from the eaves of the roofs, and conduct it out by the back gate, there to irrigate a grass field.

890. *Remarks.* This Design was furnished us by Mr. Main, who informs us that it is very nearly a fac simile of the Warren Farm in the parish of Chalfont, Buckinghamshire. It does not exhibit the modern improvements of a threshing-machine, or a liquid manure tank; but, considering it as a farm house and farmery of the old school, it is, perhaps, as complete a thing of the kind as is any where to be met with. There is nothing superfluous or extravagant, and yet nothing wanting, either for the business of the farm or the comfort of the farmer. As compared with the two spacious Scotch farmeries before given, we cannot help remarking the difference between the essential requisites in the appendages to an English and a Scotch farm house. Here, in a house for a farmer occupying only 150 acres, and that of poor flinty clay, we have every convenience for baking, brewing, and keeping ale and beer; a large pantry, and a large dairy; poultry-houses for three kinds of poultry; and well contrived piggeries and calf-pens. Besides the lawn or flower-garden, and the kitchen-garden, there is an orchard; for apple puddings and damson pies are necessities of life to the English farmer, though they are hardly ever seen on the table of a Scotch one, whose indulgence in this way lies in marmalades, jellies, and other sweetmeats. There are no less than three privies to this comparatively small establishment, while there is but one to each of the magnificent Scotch quadrangles, p. 442 and p. 446, the dwelling-house to one of which has three sitting-rooms. The propriety of the situation of the privies, in Mr. Main's Design, is also worthy of notice: that of the workmen being placed in the most obscure corner of the yard, and that of the maid-servants being near the wood stack. In countries where the threshing-machine is in general use, the smallest of the barns would have sufficed; and, in others where the importance of liquid manure was fully understood, there would probably have been a liquid manure tank under the dung-hill, communicating by underground gutters with the stable, cow-house, and pigsties; and probably, also, the dunghill would have been covered with a roof: but these constitute the chief improvements which would probably be introduced, if this farmery were to be reconstructed at the present day. Looking at it as a piece of Architecture, it will give no pleasure to the Architect, as an artist, because it does not display externally any thing of architectural style; but that it has the beauty of fitness in an eminent degree, and that it is characteristic of an English farmery built of timber, we think no one will deny who has gone over the details.

Design VI.—*A Farm House and Farmery for a Farm of 600 Acres of Turnip Soil, in Ayrshire, under a Rotation of Five Years, and employed partly in breeding and partly in feeding Stock.*

891. *Accommodation.* The general appearance is shown in fig. 917; and the ground plan in fig. 918. The ground plan of the house shows a common parlour, 1; best parlour or dining-room, 2; kitchen, 3; scullery, 4; pantry, 5; and dairy, 6. The chamber floor, fig. 916, contains two good bed-rooms, *a, b*; two second-best bed-rooms, *c, d*; a lumber-room, *e*; a maid-servant's bed-room, *f*; and three closets, *g g g*. The farmery, fig. 918, exhibits a stable, 7, for eight horses in separate stalls, forty-eight feet by sixteen feet; a hay-house, 8, eighteen feet by sixteen feet; another stable, 9, for nine horses in separate stalls, fifty-four feet by sixteen feet; a cart-house, 10, for seven carts, fifty-four feet by sixteen feet; a tool-house, 11, eight feet by sixteen feet; a cart-way, or place for backing a cart loaded with

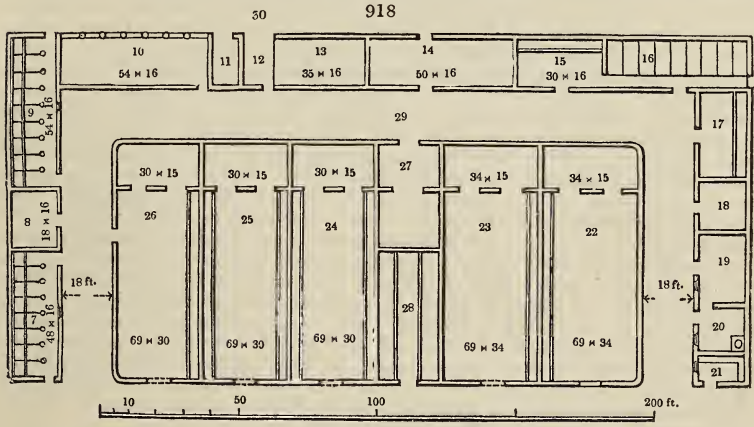

917

corn, 12, twelve feet by sixteen feet; a barn, 13, thirty-five feet by sixteen feet; a straw barn, 14, fifty feet by sixteen feet; a cow-house for eight cows, 15, thirty feet by

918

sixteen feet; a calf-house, 16, forty-nine feet by sixteen feet; another cow-house for eight cows, 17, thirty feet by sixteen feet; a house for a mare and foal, 18, seventeen feet by sixteen feet; a potato-house, 19, twenty-five feet by sixteen feet; a boiler-house, 20, sixteen feet by sixteen feet; a poultry-house, 21, sixteen feet by ten feet; five cattle hammels, 22 to 26, two of them thirty-four feet by fifteen feet, with sheds and yards sixty-nine feet by thirty-four feet, and three of them with sheds thirty feet by fifteen feet, and yards sixty-nine feet by thirty feet; these yards to the hammels have each a fodder rack along the whole width of one side; a shelter shed, and yard for

young horses, 27, the former twenty feet by fifteen feet, and the latter twenty feet by seventeen feet; and, finally, two ranges of pigsties, 28, each range containing three sties, six feet wide and twelve feet long, with a passage between, six feet wide. There is a paved way between the yards and the buildings, 29, which is eighteen feet wide. The rick-yard is placed to the north side of the farmery at 30, and the kitchen-garden to the south-west side at 31; the lawn is on the south front of the house, and the orchard, 32, is on the east side.

892. *Construction.* The walls are of rubblework, and the roofs are slated or tiled. The greatest width of any of the buildings, except the house, is sixteen feet within the walls; and, the walls being eighteen inches thick, this gives nineteen feet for the tie beams of the rafters, supposing them to be placed on the wall plates; but, as in buildings of this description, in the northern counties of the island, they are generally placed three feet higher, their length will be about fifteen feet.

893. *Remarks.* This Design has been sent us by Mr. Donaldson, land steward to the Marquess of Hastings, at Loudon Castle, Ayrshire, a scientific agriculturist, who studied the theory of his profession under the late Dr. Coventry, and its practice in Northumberland. The following remarks accompanied the plans and elevations:—"This plan may be altered to suit circumstances. If the stack-yard stand on the east or west side, the barn and cart-shed must be shifted to the wings; but they should, if possible, be central. The granary is over the cart-shed, and has a communication with the barn by an inside stair. The stables have lofts to hold hay and straw; and, having a communication by means of these lofts with the granary, corn, &c., may be discharged into the corn chests or bins in the stables, without any out-door carriage. The grain in bags for the market is intended to be let down into the carts in the shed through a trapdoor in the floor, by means of a cord and pulley. The feeding-yards may be divided by a cross wall, if thought too large; and shelter sheds may be erected on the sides, but not in front, as that would exclude the sun from the yard behind. Feeding cribs or racks may be erected in the shelter sheds, if thought necessary, to admit of the cattle eating under cover. In the calf-house each calf has its own apartment, with a slip or sliding board in the door, through which it receives the milk. The pigsties have a back door for discharging the dung made in them into the yards of the hammels; and the floors of these pigsties are raised considerably above the level of the yards. They are designed on the plan of keeping swine for eating the offal made on the farm; but, if they are kept on a larger scale, the plan must be more extensive; and perhaps the oval form, with a boiler in the centre, as recommended by the late Mr. Arthur Young, will be found the most convenient. The cattle yards and sheds, and the paved way, have an inclination to a point, where an iron grate receives the water, and conveys it to an arched conduit leading through the centre of the homestead or farmery; which conduit discharges the water at some convenient place for irrigating grass land. Each of the open yards ought to be supplied with water from a pump, for the placing of which no particular directions can be given, as much depends upon situation and circumstances. This dwelling-house and farmery are constructed in a plain substantial manner, and nothing is done for show; but decorations may be added according to the taste and ability of the proprietor." The above plan we consider a most excellent one; there is nothing that we should wish to add but a few conveniences and appendages to the house, which might be contrived in a small kitchen court between it and the farmery.

Design VII. — *A Farm House and Farmery for three Ploughs, erected at Ingleston in Dumfriesshire.*

894. *Accommodation.* The general appearance may be seen in the isometrical view, fig. 919, and the ground plan in fig. 920. The house contains a parlour, *a*; kitchen, *b*, with a closet under the stairs; bed-room, *c*; another bed-room, *d*; scullery or back kitchen, *e*; and dairy, *f*. The farmery contains a pigsty and yard, *g*, for store pigs; two sties, *h h*, for fattening pigs; a cattle shed and court, *i*; a house for stirks, *k*; stable for six horses, *l*; cart-house, *m*, for four one-horse carts; barn, with a threshing-machine driven by water, *n*; straw-house, *o*; byre or cow-house, *p*; calf-house, *q*; and dung yard, *r*.

895. *Remarks.* This Design, furnished us by our excellent contributor Mr. Newall, was erected under his superintendence, a few years ago, in Dumfriesshire, for what is considered in that agricultural county a small farm. The farmery is complete of its kind; but the house wants pantries and closets; and the pigsties are nearer to it than would be approved of in England. No poultry-house is shown; but hens are probably kept over the calf-house. It is remarkable that such an establishment should be considered complete with only two small bed-rooms. On the whole, the horses and cattle are much better provided for than the human beings. Extent without comfort is too frequently the characteristic of modern Scotch farmeries.

919

921

922

Ft. 10 5 0 10 30 50 70 90 100 Ft.

Design VIII. — *A Farm House and Farmery for three Ploughs, erected at Alton in Dumfriesshire.*

896. *Accommodation.* The general appearance is shown in fig. 921, and the ground plan in fig. 922. The ground plan of the house shows a parlour, *a*; kitchen, *b*; bed-room, *c*; smaller bed-room, *d*; lobby and stair to garrets, *e*; scullery, *f*; and dairy, *g*. The farmery contains a house for store pigs, *h*; two houses for fattening pigs, *i*; stable for seven horses, *k*; cart-house, *l*; straw-house, *m*; barn with threshing-machine, *n*; cattle-shed with court, *o*; another cattle-shed, also with court, *p*; calf-house, *q*; byre or cow-house for twenty cows, *r*; spare stable, *s*; dung-pit, *t*; potato-house, *u*; kitchen court, *v*; and cleaning-shed, *w*.

897. *Remarks.* There is something like comfort in this dwelling-house, though a pantry is wanting, as well as certain conveniences in the kitchen court. In the small farm-houses, in Scotland, the dairy is commonly used as a pantry, to the injury of the milk and butter, as well as of the meat and bread. In making these remarks on the want of comfort and accommodation in Scotch farm-houses and farmeries, we hope it will not be for a moment imagined that we consider the fault in any degree owing to the Architect: the evil is much deeper seated, and belongs essentially to the state of civilisation. The Scotch farmers are not yet sufficiently free and independent to assert their rights to those comforts and enjoyments which belong to men with equal capital, intelligence, and responsibility, in almost every other country.

Design IX. — *A Farm House and Farmery for a small Farm for breeding Sheep and Cattle, erected at Holecleugh in Dumfriesshire.*

898. *Accommodation.* The general appearance is seen in fig. 923, and the ground plan

923

in fig. 924. The latter shows, in the farm-house, a parlour, *a*; kitchen, *b*; bed-room, *c*; scullery, *d*; dairy, *e*; cleaning-shed, *f*; kitchen court, *g*; potato-house, *h*; green-meat house, *i*; stable for four horses, *k*; stable for two horses, *l*; three pigsties, *m*; cattle-shed, *n*; green-food house, *o*; cart-house, *p*; barn, with threshing-machine driven by water, *q*; cow-house for eight cows, *r*; calf-house, *s*; cow-house for eight cows, *t*; and dung-pit, *u*. Fig. 925 shows a plan of the roofing of the farmery, and the four garret bed-rooms of the house.

899. *Remarks.* This is a compact and yet commodious farmery, and the house is not altogether without comfort, considering that there are a kitchen-court and a shed. In the cart-house, *p*, of this Design, and in the cart-house of preceding Designs, by the same most intelligent and experienced Architect, it will be observed that there is a space at one side, which, considering that the carts must be set back in a direct line with the openings between the piers, must be left empty. This space is purposely provided for harrows, ploughs, and other implements. It will be observed in this plan, as in most others, that there is generally a granary over the cart-shed; and that the barn is two stories high. Some descriptions of implements, and also boards and other bulky articles, are generally kept under the roof of the cattle-sheds, being laid across the tie-beams. These beams, or the beams of the cow-house, also form the roosting-place of the hens, where there is no poultry-house; and the ducks or geese, when there are any, take shelter where they can. In Scotland, this description of stock is despised by the large farmer as an article of profit, and not prized as an article of table

comfort. For this Design, and all our others from Dumfriesshire, we are indebted to Mr. Newall: as they have been, for the most part, erected on the property of one of the most wealthy men, and extensive land-owners in Britain, the Duke of Buccleugh, they may fairly be considered as specimens of the best erections of the kind in Scotland. As we examined several of them, when in the west of Scotland in the summer of 1831, we can vouch for their substantialness, and we have no fault to find with their arrangement. The accommodation afforded, however, is, we think, less complete than it might be; there is no liquid manure tank, and no proper provision made for making the most of the waste waters, and other matters suitable for manure, produced in the dwelling-house. The dwelling-houses also want conveniences both for cleanliness and decency. That the absence of all these things, and of good gardens and orchards is entirely owing to the want of taste for them in the tenants, we had a decided proof in that part of the country; having stopped a day and night at the house of one of the Duke of Buccleugh's tenants, who, being engaged in commercial pursuits, and having consequently mixed much with society, knew what comfort was. At this gentleman's house we found not only a liquid manure tank, and a complete system of underground drainage to it, but every other rural comfort, and even luxury, both in the house, farmery, and gardens, that we could wish. The place we allude to is Woodhouselees, between Longtown and Langholme. That the Architect is not responsible for either the deficiencies in the farmeries, or in the dwelling-houses, is rendered certain by the villas which he has erected in various situations in the neighbourhood of Dumfries, containing every comfort, and modern refinement in convenience and arrangement, and at the same time displaying a high degree of architectural taste. Mr. Newall, indeed, has had and profited by every advantage that an architect can have, not only in Britain, but in France and Italy. This will be rendered obvious by some of his designs for villas, which will be given in the succeeding Book of this work.

Design X. — *A Farm House and Farmery for a Farm of two Ploughs, erected on the Grebten Estate in Dumfriesshire.*

900. *Accommodation.* The general appearance is shown in fig. 926, and the ground plan in fig. 927. In the latter the dwelling-house exhibits a parlour, *a*; three bed-

926

rooms, *b*; store-room, *c*; kitchen, *d*; scullery, *e*; dairy, *f*; coal-house, *g*; wood-house, *h*; potato-house, *i*, and kitchen court, *k*. The farmery shows a stable for a loose horse, or a mare and foal, *l*; a four-stalled stable, *m*; cart-house, *n*; barn, *o*; straw-house, *p*;

927

cow-house for five cows, *q*; calf-house, *r*; cattle-shed, *s*; cattle-court, *t*; hammel for a loose cow, *u*; pigsties for fattening pigs, *v*; sties for store pigs, *w*; dung-pit, *x*; garden, *y*; road to the farmery, *z*; and rick-yard, *g*. Fig. 928, is the front elevation,

928

by which it appears that the house is only one story high; and fig. 929 is the north-west elevation, in which, at *a*, may be seen the four vertical slits, two or three inches

929

wide on the outside, splayed to one foot within, in the barn walls, for the admission of air and light: these slits are never above three inches wide on the external surface of the wall, but on the inside are spread out as much as a foot or eighteen inches, to promote a free circulation.

901. *Remarks.* This is a compact Design, and the house, with its kitchen court, is more than usually commodious for one of the smallest size: as in most of the others, however, privies are wanting.

Design XI. — *A Farm House and Farmery, for four Ploughs, designed, and in part executed, in Dumfriesshire.*

902. *Accommodation.* The general appearance is shown in fig. 930; and the ground plan in fig. 931. In the latter, the house exhibits an entrance-hall, *a*; lobby and stair-

930

case, *b*; dining-room, *c*; drawing-room, *d*; library and office, *e*; store-room and pantry, *f*; kitchen, *g*; scullery, *h*; dairy, *i*, from which there is a veranda or covered way to the kitchen door; coal-house, *k*; kitchen court, *l*; servants' privy, *m*; best privy, *n*; ash-pit, *o*; steaming-house, *p*; feeding-house for cattle, *q*; loose stable, *r*; pigsties, *s*; stable for eight horses, *t*; cart-house, *u*; barn, *v*; straw-house, *w*; horse-walk for threshing-machine, *x*; cattle-sheds and courts *y*; cow-houses, *z*; potato-house, *aa*; open courts, *bb*; rick-yard, *cc*; dung-court, *dd*; pleasure-ground, *ee*; and kitchen-garden, *ff*. Fig. 932 is a plan of the second floor of the house, and of that part of the farmery which is carried up two stories high. In the house there appear four good bed-rooms, *a*; a closet, *b*; and three servants' rooms, *c*. The farmery exhibits a hay-loft over the stables, *d*; a continuation of the barn, *e*; a granary over the straw-house, *f*; and another granary over the cattle-shed, *g*. Fig. 933 is a front elevation of the house, with the south-east side of the farmery; and fig. 934 is an elevation of the north-east side of the farmery and of the farm house.

903. *Remarks.* The house is commodious, and the covered way from the kitchen to

931

932

933

the dairy, gives an idea that something is known about comfort, as the two privies do respecting cleanliness and decency. It is possible that one may walk about this farmery

934

without being shocked on turning every corner; but even in this respect it is not complete, as there should have been a third for the men-servants. It will be observed that the stable and cart-house, and the piggeries, and the three houses, *p*, *q*, *r*, are double buildings, use being made of both sides of the middle wall. This is always desirable when it is compatible with other arrangements, because not only a wall is saved, but guttering; and both buildings are kept warmer in winter and cooler in summer. On comparing this farmery with the most improved mode of arranging farmeries in Northumberland, the cattle-sheds and courts appear to us too large; it being found there that not only feeding-cattle, but even store beasts, always do better when three or four, or at most six, are together, than when a greater number are put into the same yard. Judging from the length of rack in the three cattle-sheds, *y*, one of them is calculated for two dozen, and the others for a dozen and a half each. There are no poultry-houses shown in the Design before us; and we are surprised that the kitchen-garden is not surrounded by a wall, which it always is in Northumberland.

Design XII.—*The Villa Residence and Farmery of Riddenwood, in the Parish of Kirkmahoe, Dumfriesshire, in the Occupation of the Proprietor, James Kerr, Esq.*

904. *Accommodation.* The general appearance is shown in fig. 935, and the ground

935

plan in fig. 936. In the latter, the house contains an entrance-hall, *a*; lobby, *b*; parlour, *c*; dining-room, *d*; drawing-room, *e*; closet, *f*; kitchen, *g*; store-room, *h*;

scullery, *i*; dairy, *k*; coal-house, *l*; gig-house, with poultry-house and dovecot over, *m*; kitchen court, *n*; ash-pit, *o*; servants' privy, *p*; best privy, *q*; pig-houses, *r*; steaming-house, *s*; dung-pit, *t*; cattle-shed and court, *u*; cattle-house, *v*; cow-house, *w*; green-food house, *x*; barn, *y*; cart-house, *z*; hay-house, *a'*; stable for five horses, *b'*; stack-yard, *c'*; kitchen-garden, *d'*; back entrance to the farm-yard, *e'*; plantation, *f'*; lawn varied with groups of shrubs and flowers, *g'*; and the approach-road to the house, *h*. Fig. 937 is a plan of the second floor of the house, and of such parts of the offices as are carried two stories high; in which *aaaa* are four good bed-rooms; *bbb*, three large closets; *c*, the servants' room; *d*, turkey-house; *e*, hen-house; and *f*, granary.

905. *Construction.* The walls, like those of almost all the buildings in Dumfriesshire, are of reddish sandstone, and the roofs of blue slate. Fig. 938 is an elevation of the south or entrance front; fig. 939, an elevation of the east front; fig. 940, an elevation of the north side of the house, and kitchen offices, from the farm-yard; fig. 941, a general elevation, from the west side. The racks and mangers of the stables in this Design are somewhat differently constructed from those in general use. Each stall is five feet wide, one corner of which to the extent of two feet is occupied by a manger two feet square, and one foot deep; and the remaining three feet by a deeper manger of the same width, which reaches to within one foot of the floor, and in which the clover,

tares, potatoes, and other succulent food given to horses, are placed. Above, at the usual height, and on the old plan, is placed a common hay-rack, projecting from the wall. Fig. 944 shows a plan of this corn and fodder manger, in which *a* is the corn-manger; *b*, the fodder-manger; and *c*, a rail across it, to prevent the horses from tossing out the fodder, chaff, &c. Fig. 943 is an elevation of the same manger, in which *d* is the corn-

manger; *e*, the fodder-manger; *f*, the partition rail; and *g*, the hay-rack. Fig. 942 is a section in which *h* is the corn-manger; *i*, the fodder-manger; *k*, the partition rail; and *l*, the rack.

906. *Remarks.* This Design, by Mr. Newall, presents a handsome and commodious country residence; and one, judging from appearances, very suitable to what is called a gentleman farmer. It is a favourable circumstance for the effect of the house, that the

ground on which it stands is somewhat above the level of that of the farmery. The piggeries are very conveniently placed, with reference to the scullery and dairy; but unless

they are kept very clean and sweet during summer, being so near the living-rooms, their smell will be offensive; we may say the same of the dunghill, which we should have

preferred in the situation of the cattle-shed, unless, indeed it be roofed over; a refinement, however, which we suppose is not yet introduced into Dumfriesshire. The foddering-

manger we consider a good idea, and worthy of imitation; indeed, we believe it is now frequently to be met with in the south of Scotland and the north of England. When the cheapest and best mode of feeding horses and cattle is better understood, all the hay and straw given to them will be cut, by machinery, into short lengths; then mixed with corn, or with roots, or other succulent food, and water, and flavoured with salt; and probably, in the case of fattening cattle and sheep for the butcher, with the addition of highly aromatic herbs, to give a flavour to the meat. *Melilotus officinalis* will one day be as important a plant to the British farmer as it now is to the farmer of Switzerland.

907. Specification for Dumfriesshire Farmeries. The following detailed particulars of

the mode of building farm houses and farmeries, such as we have given above, has been furnished us by Mr Newall: —

*Specification of the Materials and Works required to build a Dwelling-house, and a Steading of Farm Office Houses at agreeable to given Plans for*

908. *Digger and Leveller.* The whole of the surface mould is to be stripped from the site of the buildings, the dung and court yards, and to the extent of 2 feet beyond the respective outside walls of the buildings, and it is to be laid into the proposed garden. The site for the buildings is to be properly levelled, agreeably to the sections and plans; and these levels are to be taken from the level of the principal floor of the dwelling-house, which is marked by a post fixed into the ground at the south corner of its site. The cellars under the parlour are to be sunk to the depth of at least 9 feet 6 inches below the level of the principal floor of the house. If it be found, after these levellings and excavations are made, that there are any soft parts in the ground along the lines of the foundations, trenches are to be cut through these parts for the footings of the walls, to a sufficient depth to insure a proper foundation. All the earth, rubbish, &c., of these excavations and levellings, together with all the rubbish that will accumulate during the building and finishing of the houses, are to be removed to such place or places as shall be fixed upon before entering into contract.

909. *Dwelling-House.—Mason's Work. Foundations.* The foundations of the thick walls are to be laid with large suitable flat-bedded stones (stones level on the under surface), which are to be at least 6 inches thick, and so broad as to leave offsets on each side of the respective walls, as shown by the sections of the footings.

910. *External Walls.* The walls of the front and gables are to be built with coursed rubblework (courses of unequal height, but of hammer-dressed stones), neatly dressed, and closely jointed; all the other external walls are to be of good rubble building, neatly dressed; and the inside thick ones to be likewise of good rubble building. All these walls are to be properly built in the heart (in the centre or middle of the walls) with good lime mortar; and they are to have such a proportion of in-bonds (bond stones stretching across the wall) throughout the whole of them, that these shall not be more than 4 feet apart in any direction on either side of the walls: these in-bonds are not to be less than 18 inches in length, and 16 inches into the wall; but they are not to be more than 9 inches in height.

911. *Hewn Works.* The whole of the window rybets (reveals), sills, and lintels; the entablatures over the windows, and all the other dressings round the front and gables; the portico and doors, ingoings (jambs or sides), and stair of the front entrance-door; the wall head cornice and gutter, with a 6-inch course under the cornice, are to be of neatly polished freestonework; and all the entablatures, cornices, and other dressings, are to be cut to the respective drawings. All the other door and window rybets, sills, and lintels; the wall head tabling of the low buildings; the chimney tops (or stacks), and the external corners, and base course, are to be of droved (a particular mode of hewing with a broad chisel, called a drove by masons, which leaves its marks, not unlike the squares on a chess-board, but smaller) freestonework.

912. *Chimney-pieces, Hearth, &c.* The chimney jambs and hearth are to be of fine polished freestonework, and those of the two parlours are to be cut to imitate marble ones, as shown by the drawings. The chimney flues are to be built oval, and neatly plastered. The hearths of the first (ground) floor are to be laid in mortar over a mass of dry whinstones (granite, or any local stone, not freestone), enclosed with rubble building.

913. *Stairs.* The stairs are to be of polished freestonework; and the fronts of the steps, &c., to have torus and fillet mouldings; and the whole to be finished with polished stone skirting.

914. *Stone Floors.* The floors of the entrance-lobby and passages are to be laid with fine polished pavement, at least 2 inches and a half thick. Those of the kitchen and scullery are to be laid with the hardest pavement that can be procured in the quarry; and the flags are to be at least 3 inches and a quarter thick. Those of the dairy and cellars are to be laid with good droved pavement; the flags to be 2 inches and three quarters thick. They are all to be square-jointed at least 2 inches from the face, and set with lead and oil putty to a similar breadth. Preparatory to laying these floors, all the earth, rubbish, &c., is to be cleared from the respective apartments, to the depth of at least 18 inches below the level of the floors; and these spaces are to be filled with clean small whinstones to the depth of 12 inches, over the top of which a stratum of lime riddlings (or any such mixture) is to be put, so compact that the sand (or mortar) in which the flags are laid will not pass through it. All these stone floors are to be finished round with polished stone skirting, at least 5 inches high.

915. *Stone Tables.* The dairy is to have polished stone tables (or shelves) round it, as shown by the plans, and they are to have polished stone skirting along the top of them, at least 6 inches high.

916. *Catacombs, or Bins.* The spirit cellar is to have two tiers of catacombs (bins) along the side of it, with divisions over the second tier to form a third tier. These catacombs are all to be of plain droved work.

917. *Partitions.* The thin partition walls are to be constructed with hard-burnt bricks.

918. *Dwarf Walls.* Dwarf walls, 12 inches thick, are to be constructed to support the sleepers of the floors of the two parlours, bed-rooms, &c., on the ground (or first) floor. Stones of droved work, 8 inches thick, are to be built into the high walls, along the lines of the roofs of the low buildings that join the high ones, for the purpose of inserting lead aprons to cover the joinings of the slates, &c., with the high walls. All the rubble and brick buildings are to be built with strong well prepared lime mortar; and all the hewn works are to be set with lead and oil putty.

919. *Carpenter's Work. Inside Lintels.* The inside lintels of the door and window spaces are to be of British oak, free from sapwood: they are to be not less than 6 inches square, and to have at least 12 inches of bond (or wall-hold) on each end.

920. *Roofs.* The roofs are to be constructed as shown by the plans; and the scantlings of the timber are to be of the sizes figured thereon; the small couples (couples of the narrow houses) and half couples (hip and valley rafters) are to be placed at no greater distance from each other than 16 inches between their centres. The diagonal and alley beams are to be 9 inches by 2 inches. The slate laths are to be sawn ones, 1 inch and a half by five eighths of an inch.

921. *Joists.* The joists and sleepers of the principal part of the house are to be of Memel timber; those of the chamber floor are to be 10 inches deep, and 2 inches thick; and they are not to be more than 14 inches apart; they are to have two tiers of bracing (strutts, nailed diagonally between the joists, to keep them firm) to the floor of each room, which bracing is to be 9 inches deep by 1 inch and a quarter thick. The sleepers are to be 5 inches deep, and 2 inches thick; they are to be supported by the dwarf walls formerly specified, and they are not to be more than 14 inches apart. The joists over the kitchen, scullery, &c., are to be 9 inches by 2 inches, and placed 14 inches apart; they are to have two tiers of bracing, similar to those specified for the other floor.

922. *Flooring.* The flooring is to be at least 1 inch and an eighth thick when finished, and none of the boards are to exceed 6 inches in breadth; they are all to be feathered and grooved, and nailed through the feather edge, and the wood employed is to be perfectly sound and seasoned.

923. *Partitions.* Those partitions in the chamber floor that are to be constructed with timber, are to have the stiles 4 inches by 1 inch and a half, and placed at no greater distance from each other than 12 inches between their centres: they are to be properly braced.

924. *Doorcases.* The doorcases (or jambs) are to be constructed with timber 2 inches thick, but their breadth must be regulated by the thickness of the respective walls into which they are placed; and their size is shown by the plans.

925. *Stoothing (quartering).* The whole of the insides of the external walls are to be properly stoothed (battened); the wall-straps (battens, or pieces of quartering on which to nail the laths) are to be 1 inch and a quarter thick, by seven eighths of an inch, and placed at no greater distance from each other than 12 inches between their centres; the wall docks (plugs of wood) are not to be more than 16 inches apart. N.B. If whinstones are to be employed in building the inside walls, and the insides of the external ones, bond timber must be used; and large blocks of timber must be built into proper situations to receive the bell wires, &c.

926. *Doors.* The framings and mouldings, &c., of the doors are all to correspond in size with their respective sections; those of the first or ground floor are to be hung with 5-inch double-jointed hinges, and those of the chamber story are to be hung with  $4\frac{1}{2}$ -inch double-jointed hinges. The locks of the principal rooms are to be 7-inch mortise ones, value each 10s. 6d. The entrance-door to have one, value 15s. All the other doors are to have each a rim lock, value 6s. The spirit-cellar lock is to have a copper bolt, and its value is to be 8s. All the press doors are to have suitable press locks, value each 3s. 6d.

927. *Windows.* The windows, including the skylights, are to be good astragal (the bars with astragal mouldings) ones; the sash frames of those of the first floor are to be  $2\frac{3}{8}$  inches thick; the frames of all the others are to be 2 inches thick. They are all to be glazed with second crown glass, and to be finished with three coats of lead and oil paint. They are all to be double hung (each sash is to be hung) with axle pulleys, and best window line. The skylights to be hung on the upper parts, ends with pivot hinges, and each to have a hinged rack for holding them up or down.

928. *Window Shutters.* All the windows are to have framed shutters; the framings and mouldings to correspond with their respective sections. Those in the principal rooms of the first floor are to have framed back-laps (parts of the shutter that fold behind the part seen) to correspond with the shutters. The shutters are to be hung with 3-inch hinges, and the back-laps with  $1\frac{1}{8}$  inch back-lap hinges.

929. *Soffits, Ingoings, Scuncheon Linings, &c.* All the windows of the principal rooms of the first story, and those of the chamber story, are to have framed soffits and ingoings to correspond with the shutters. Those of the other parts of the house are to be plain. The scuncheons (the beveled parts, splays, or elbows, of the inside of a window opening, where the shutters are placed) of the two parlour windows are to have framed linings to correspond with the shutters; all the other windows are to have plain linings, and those of the low buildings are to have plain soffits and ingoings.

930. *Architraves, Facings, &c.* The doors and windows of the two parlours are to be finished with double-faced architraves, and all the other doors and windows are to be finished round with moulded facings; they and the architraves are to be made to correspond with their respective sections. The skylights are to be finished with suitable linings and facings.

931. *Bases.* The two parlours are to be finished with bases to correspond with their other finishing, the plinths of which are to be 6 inches and a half high. All the other apartments, passages, &c., that are floored with timber, are to have skirtings to correspond with the facings of the respective apartments, &c. Those of the first and chamber floors are to be 6 inches and half high; and those of the kitchen buildings are to be 5 inches and a half high. The parlours are each to have a surbase to correspond with the base; and the window architraves and facings, the bases and skirtings, and the surbases, are all to have suitable grounds. Those of the windows are to be dressed; and those of the thin walls are to be built into them.

932. *Jamb Moulding.* The chimney jambs, that are not made in imitation of marble ones, are to have jamb mouldings round them, and light entablatures over them.

933. *Stair of Kitchen Buildings.* The stair to the apartments over the kitchen, scullery, &c., is to be of timber; the steps are to be 1 inch and an eighth thick; it is to have a suitable plain rail. The stair to the chamber floor is to have a suitable hand-rail of wainscot, fixed upon plain iron balusters, three fourths of an inch square, which are to be battled (run with lead into holes chiseled out for their reception) into the steps, &c.

934. *Press Shelving.* All the presses are to have tiers of shelving; and the store closet is to be fitted round with three tiers of shelving; each tier to be 14 inches broad.

935. *Slating.* The roofs are to be covered with best second Lancashire ton slates (or others according to local situation), hung to the laths with Memel timber pins, and to be rendered (pointed inside) with good plaster. The slates are to have at least 3 inches of bond at the eaves; but the bond may gradually diminish to 2 inches at the ridges. The ridges and piens (angles of the hips) are to be slated watertight before they are covered with the lead. The ridge and pien batten rods (ridge and hip rods) are to be 2 inches' diameter, and they are to be covered with lead, 6 pounds to the square foot, which is to be at least 12 inches in breadth. The alleys are to be laid with lead, 7 pounds to the square foot, which is to be at least 14 inches in breadth. All round the chimney stalks (shafts), where they are intersected with the slates, coverings of lead, 12 inches broad, are to be inserted into the chimney heads, to cover the joinings, and these coverings are to be of lead, 6 pounds per square foot. All along the lines of the roofs that intersect the higher buildings, the joinings of the slates with the walls are to be covered with aprons (or flashings) of 6-pound lead at least 12 inches broad. The skylights are to be laid round with gutters of 6-pound lead, at least 12 inches broad. The aprons round the chimney stalks, and those that cover the joinings of the low roofs, are to be inserted into mortises or grooves, made in the stones as formerly specified; and they are to be puttied into these mortises with lead and oil putty, mixed with fine sand, or dry pounded sandstone, well burnt (or roasted). This roasting is to destroy all earthy matter, &c.

936. *Plasterers' Work.* The ceilings of all the apartments, passages, &c. of the first and chamber floors, and the walls of the entrance-lobby, passages, and staircase, are to be finished with good three-coat plaster. That of the ceilings to be on laths three sixteenths of an inch thick; and each apartment to have a suitable cornice, finished agreeably to the sections. All the ceilings of the kitchen buildings, and of all the other walls not specified above, are to be finished with fine two-coat plasterwork, to be properly straightened (made even or smooth with the edge of a board or float), &c. Behind all the ingoings, soffits, bases, and skirtings, &c., the wall is to have one coat of plaster, without finishing.

937. Though a variety of the materials and works are described in the foregoing specifications, yet it is not to be considered that the whole are specified, but it is to be distinctly understood that the whole are to be included in the estimate; so that the house may be built and finished with materials and works of the quality and relative scantlings with those specified and figured on the plans, without any other charge than that in the estimate; and the whole of the materials and works are to be done to the satisfaction of \_\_\_\_\_ by the \_\_\_\_\_ day of \_\_\_\_\_, under a penalty of £ .

938. *Office Houses. — Rubble Walls.* The foundations of the thick walls are to be laid with large flat-bedded rubble-stones, and the whole of the walls are to be good rubble-work, properly built in the heart with good lime mortar; and such a proportion of large bond stones to be used throughout the whole of them, that they shall not be more than four feet apart, in any direction, on either side of the walls.

939. *Hewn Work, &c.* The door and window rybets, sills, and lintels are to be of droved freestonework; they are all to have canted corners (the sharp angle of the corner cut off). The suncheons of the doors are to be splayed 4 inches wider inside than at the rybet cheeks (see § 282, and fig. 262), and their inner corners are all to be rounded. In-bond rybets with 12-inch heads are to be built at proper heights for fixing the crooks of the door hinges. The lintels are to be at least 12 inches square. The window sills are to be weathered (beveled so as to throw off the rain) at least 2 inches, exclusive of a sinking for the wood sills, as shown by the sections. All the external corners are to be of droved work. The wall-head tablings (copings beveled to throw off the rain) are to be of droved work 3 inches thick, and to project 5 inches beyond the line of the walls. The door suncheons and lintels of the cart-house and loose cattle sheds are to be neatly draughted and scappled (stones are said to scappled or scabbled, when they are dressed with the pick end of the hammer; they are called draughted and scappled when worked round the edges or joints with a chisel and hammer-dressed in the centre), and the corners canted with droved work. The pillars for the cattle are to be in one stone each, and to be finished in a similar manner with the suncheons. The door suncheons, sills, and lintels of the barn-ventilators, &c., are to be draughted and scappled.

940. *Barge Stones over the Slates.* Droved stones 4 inches thick, weathered on the upper side, are to be built into the walls of the high buildings, along the lines of the roofs of the low ones that intersect them; these stones are to project at least 4 inches in front of the walls, to cover the ends of the slates, and to lie close upon them, fig. 945; and ragalets (grooves), 2 inches deep into the walls, are to be made under these stones, to receive the ends of the slates. In fig. 945, *a* is the wall, *b* the situation of the groove, in which the slate, *c*, is shown inserted; *d* is the upper part of the wall; *e*, the weathered stone inserted into it; *f*, the rafter; and *g*, the wall-plate.

941. *Floors.* The barn is to be floored with the hardest freestone pavement that can be procured in any particular quarry in the neighbourhood. The flags are to be square-jointed, and set with oil putty; and they are to be laid on a preparation of whinstones, similar to that specified for the floors in the dwelling-house. There is to be a 6-inch skirting built into the walls at the level of the floor, so that the flooring may be jointed to it with putty. This is to prevent the operations of vermin. The floors of the pig-houses are to be laid with rough flags closely jointed; and these floors are to have a current of at least 9 inches from the back walls towards the doors. The stables, byres, and all the other houses not specified above, are to be paved (pitched) with small whinstones set in sand, and all the requisite sewers are to be made in the cattle-sheds, stables, &c. The byre is to have a freestone kerb along the sides of the grip (gutter), the stones of which are to be 16 inches deep and 4 inches and a half thick, and placed so that they will stand 6 inches above the bottom of the grip, all as shown by the plans.

942. *Partitions of Byre.* The byre is to have stall partitions of freestone, each to be in one stone 4 feet 6 inches by 5 feet, which are to be sunk into the ground 1 foot, and on each side of these partitions there is to be an iron rod, with a sliding shackle (fig. 946 is a section across a stone partition, in which the iron rods at *h h* are the shackles) upon it, upon which the collar is fixed for binding the cow. The feeding-crib is fitted up with rough droved work, and the partition between it and the fotherum (foddering-passage) is to be of freestone flags set on end, and to stand at least 2 feet 6 inches high above the crib. All these are shown by the detailed plans and sections.

943. *Cope of Court Walls, &c.* The court walls of the pig-houses are to have a cope (coping) 6 inches thick, of draughted and scappled work; but the joints are to be droved and jointed with oil putty. The cope is to be laid even with the walls on both sides. The walls of the kitchen-court, large court, dung-court, &c., are to be covered with a 3-inch cope of droved work jointed with putty. The cope is to be laid even with the walls, on the sides next the large court and cattle-sheds; but it is to project 3 inches on the side next the kitchen court, 2 inches on the side next the dung-court, and 6 inches on the side next the garden.

944. *Stable Windows.* The stable windows are to be made ingoing ones (recessed from the inside), in order that corn-chests may be fitted into them. The upper sashes are to be astragal ones, glazed with third crown glass, and the under ones are to be sliding wooden frames, for ventilation, &c. The back wall of the barn is to be sunk sufficiently deep for the wheel of the threshing-mill and the race (horse-course) from it. The hewn work is all to be jointed with oil putty, and all the rubble-work is to be built with good lime mortar.

945. *Inside Lintels.* The inside lintels of the door and window spaces are to be of British oak timber; they are to be proportioned in size to the width of the respective spaces; and they are all to have 12 inches of bearing on each end (or bond).

946. *Roofs.* All the roofs are to be constructed, as shown by the plans, with trussed principals; which are all to be of the dimensions figured on the respective sections. These principal couples (rafters) are to be placed at no greater distance from each other than 6 feet 6 inches between their centres. The purlins are to be 7 inches by 3 inches and a half, and placed no farther asunder than 3 feet 6 inches. The rafters are to be 2 inches and a quarter square, and placed no farther asunder than 16 inches between their centres. All the roofs are to have sawn laths 1 inch and a quarter by five eighths of an inch each.

947. *Slating.* The whole of the roofs of these office-houses are to be covered with second Lancashire slates (or as the case may be), hung with Memel timber pins; and they are to be rendered with good plaster. They are to have 3 inches of bond at the eaves; but the bond may gradually diminish to 2 inches at the ridges. The under eave-courses are to be laid full, and they are to be double-nailed at the shoulders with 12-lb. nails. The ridges and piens are to be slated water-proof, before the pien and ridge-stones are laid over them. The gables are to be slated over, and the skew-stones (the coping-stones of the gables, called barge-stones in England) are to be laid over the slates, but to project 3 inches over the line of the walls, and to be pointed along the ends of the slates under them with Roman cement. The eaves slates are to project 4 inches beyond the line of the tabling. The ridge and pien stones are to be of fine droved work; they are to be made correctly to the angles of the respective roofs; to be closely jointed with oil putty; and, when perfectly dry, to be painted with three coats of oil paint, the same colour with the slates.

948. *Joists.* The joists of the granary floors are to be 12 inches by 2 inches and a quarter, and placed no farther asunder than 16 inches between their centres: they are to have a tier of bracing along the centre of each floor, 11 inches by 11 inches. Those of the stable lofts are to be 8 inches by 2 inches, and placed no farther asunder than 18 inches between their centres. The flooring is all to be 1 inch thick when finished, and none of the boards are to exceed 7 inches in breadth; they are all to be feathered and grooved. The granaries and haylofts are to be finished all round with skirting, not less than 5 inches high; the walls of the haylofts are to be plastered at least 9 inches above the skirting; and the walls of the granary are to be plastered at least 2 feet above the skirting.

949. *Doors.* The whole of the doors of the office-houses are to be stout batten ones. The front boards are not to be less than seven eighths of an inch thick, and the battens are not to exceed 6 inches in breadth; the back battens are to be 1 inch thick, those of the small door to be not less than 7 inches broad, and those of the large ones not less than 9 inches broad. These doors are all to be hung with stout crooks and bands. The doors of the stables, barn, byres, granaries, calf-house, potato-house, and coal-house are each to have stock-locks, value 4s. each; and the doors of the granaries and stables are to have likewise thumb latches. All the other doors are to be secured with bolts, &c. All the hinges, &c., are to be proportioned in size to the size of the respective doors.

950. *Stables.* The stables are to be fitted up with stall partitions of 2-inch battens, fixed in oak posts 6 inches square, with canted corners; and they are to be fixed under beams 6 inches square, which are to extend the whole length of each stable, under the joists of the hayloft. The feeding (or hay) cribs of the stables are to be constructed like mangers; but they are to be about 18 inches deep and 18 inches wide at the top; and are to have two slanting iron bars rising from the front of them to the wall, at an angle of about 45°. The corn manger occupies about one third part of the width of the stall, and the feeding-crib the other two thirds (as shown by detailed drawings). The granary windows are to be sliding-framed ones, or they may be made with shades similar to Venetian ones, proper for ventilation, &c.

951. *Cattle-sheds.* The cattle-sheds to be fitted up with feeding-cribs, the bottoms of which are to be raised 9 inches above the level of the floors; they are to have 3 rails in front, fixed to the upright posts. The upper one is to be 4 inches by 3 inches, the middle one 3 inches by 1 inch and a half, and the under one 5 inches by 1 inch and a half. The bottom rails are to be 2 inches by 1 inch and a half, and placed no more than 1 inch and a half apart. The side next the fotherum is to be finished with 1-inch

battens to the height of 2 feet 6 inches. Fotherums are not always introduced in cattle-sheds (see the sections, &c.).

952. *Feeding-houses.* The feeding-houses are divided into stalls of 12 feet 6 inches each (either with stone or timber); and the hayracks are placed along the tops of these partitions, nearly in the form of two sides of an equilateral triangle, at the height of about 4 feet 6 inches from the floor. These racks extend from the feeding-cribs to the front of the covered part of the shed. The feeding-cribs are constructed similar to stable-mangers, but they are to be 18 inches wide and 10 inches deep, and are raised 9 to 12 inches above the level of the floor. The partition between the crib and the fotherum is to be of 1½-inch battens. These cribs may be of wood, or they may be constructed of similar materials to those of the byres. The byre partitions may be of timber, where stone cannot be procured.

953. *Gates.* The gates of the court-yards, &c., are all to be constructed as shown by the plans; and they are to be hung with stout crooks and bands (hooks and strap hinges). The gates, and all the outside doors, the stable and granary windows, are to be finished with three coats of oil paint.

Design XIII. — *A Farm House and Farmery for 100 Acres of Land to be cultivated on the Norfolk System, with a Flour Mill driven by Wind.*

954. *Accommodation.* The general appearance is shown in the isometrical view, p. 473. The ground plan, fig. 948, exhibits a dwelling-house, containing a parlour, 1; kitchen, 2; counting-house or keeping-room, 3; store-room, 4; pantry, 5; wash-house and brewhouse, 6; and dairy, 7. Over these are two large bed-rooms with fireplaces, and four other bed-rooms without fireplaces. The farmery contains a central building of two stories, in which, on the ground floor, are, a passage to the mill, which serves also as a foddering-passage, 8; a place for turnips, 9; for calves, 10; for four cows, 11, over which there are a granary, and a retail shop for flour, lighted by glazed tiles (fig. 947) of cast iron (weight four pounds and a quarter, price, unglazed, 8*d.*, glazed, 1*s.* 4*d.*) from the roof; a house for six oxen, 12; for chaff, 13; the mill, 14; the barn, 15; the cart-house stable, with hayloft over, 16; lean cattle lodge or shed, 17; the harness-room, 18; piggeries, 19; cart lodge, 20; drive-way to the mill, 21; hackney stable, with hayloft over, 22; customers' stable, 23; colt stable, 24; and gig-house, 25. There are two ample yards, 26 and 27, for the lean cattle and the colts; and two also, 28 and 29, for the piggeries.

947

955. *Remarks.* This plan has been furnished us by William Thorold, Esq., Architect and Engineer, of Norwich, accompanied by the following observations:—"The capital required to carry on a mill must necessarily limit the size of the farm. We will, therefore, take a farm of 100 acres of land, four fifths being arable, and the remainder in grass; and we will suppose the mill competent to grind thirty quarters of corn per week, twenty of which would be manufactured into flour and sold, and the remaining ten used as grist for the neighbourhood; the mill being supposed to be situated in a rural district. The mill should have a threshing-machine and hay-cutter attached to it; the threshing-machine to be made capable of drawing, that is, of husking, trefoil, clover, and other small seeds. Pumps can also be added in situations where water is at a great depth, which will often occur in places proper for a windmill. A number of pigs may be kept, to eat up the offal of the mill; and this will, of course, require buildings for their reception more extensive than the piggeries on a common farm, while the buildings for the other cattle are fewer in proportion. The mill is placed in the centre, for the sake of uniformity and economy. It is necessary to have one side of it accessible to waggons, and also in case of repairs being done to the sails. The piggeries I have placed on the north side; knowing, from experience, that they are intolerable in summer, if near the house. In constructing the mill, a horse walk should be added to it, in order that the machinery of the mill may be occasionally worked with that power. There is stabling for four farm horses, and for two hackney or trade horses, besides a loose stable for customers' horses: there is also a cow-house for four cows; stalls for six grazing bullocks; and a lodge for lean cattle. This will generally suffice for milling and farming as it is carried on in Norfolk. The house contains a parlour and kitchen, with a brewhouse and wash-house combined, on the ground floor; and it has six sleeping-rooms in the upper story. It is kept low, in order that it may offer as little obstruction as possible to the wind. The fireplaces for the kitchen and for the office or keeping-room are contrived so that the chimneys may be conducted under the stairs, and form one stack with the other chimneys. The parlour window is to have French casements, opening in the middle. The mill will cost from £800 to £1000, according to the quantity of machinery employed. The sails,

948

as shown in the Design, are upon the principle generally adopted in Norfolk, called Cubitt's Patent: they should never be horizontal, as such sails have only one fourth of the power of vertical ones. Norfolk is considered to be superior to any other county in England, as to windmills." We consider this a remarkably well arranged Design, which will not surprise those of our readers who are aware of the experience which Mr. Thorold has had as a farmer, as well as an Architect and Engineer. The entrance to the cattle-house, being near the dwelling-house, is convenient, on account of its supplying a covered passage to the mill-house and barn: and this passage is not merely a matter of convenience as such, but it is essential to the cattle-house for conveying fodder from the straw-house at one end, and turnips from the turnip-store at the other to the oxen. It is always gratifying when a really useful object or arrangement can be rendered at the same time ornamental or agreeable. The back cart or waggon entrance to the mill is exceedingly well contrived, while it serves at the same time as the waggon court, which could not have been dispensed with in a farmery of this extent when combined with a mill. The architecture of a building containing a windmill will be given in the next subsection.

XIII.

XIV.

XV.

Design XIV.—*A Farm House and Farmery for a Farm of two Ploughs, in the County of Northumberland.*

956. *Accommodation.* The general appearance is shown in the isometrical view, p. 474; and the ground plan in fig. 949. The latter shows, in the dwelling-house, the parlour, *a*; kitchen, *b*; back-kitchen, *c*; and dairy, *d*; with two bed-rooms in the chamber floor, one over the kitchen, and the other over the parlour. The farmery contains a stable for four horses, *e*; a hay-house, *f*; two cattle-hovels, *g*; a barn and straw-house, *h*; foal-house, *i*; calf-pens, *k*; cow-house for four cows, *l*; cow-house for eight cows, *m*; two fold-yards, *n*; and stock-yard, *o*.

957. *Construction.* Fig. 950 shows a section across the house, in which appears the manner of roofing, and also that the floors are paved. Fig. 951 shows a section across the stable, in which is seen the manner of constructing the partitions between the stalls, *p*; and that the partition post, *q*, is let into a stone at the lower end, and at the upper end fixed to the tie-beam. The flooring of the stable is also shown perfectly level, which is consistent with the most improved ideas on this subject.

958. *Estimate.* The total expense of erecting this farmhouse and farmery was £550;

950

a sum which will appear remarkably low to a London Architect: but it must be recollected, that, in Northumberland, freestone is generally found for the trouble of

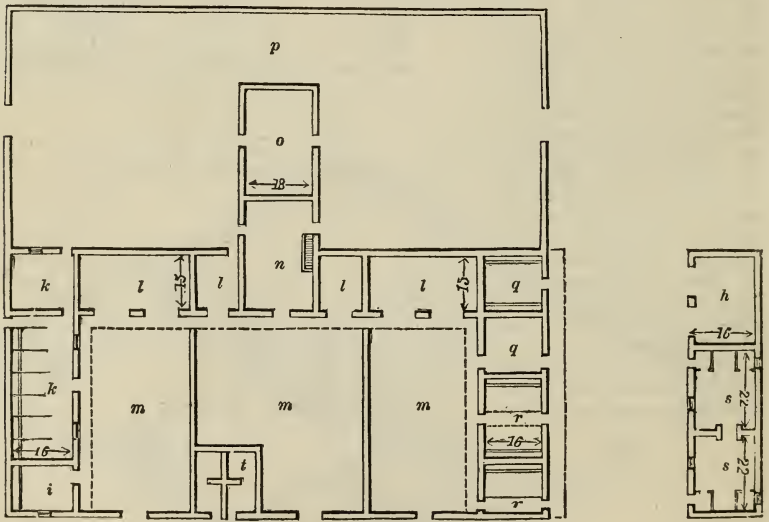

working it, on the farm; and that the carriage of all materials is performed by the tenant.

959. *Remarks.* The house has few conveniences, and there is no enclosed kitchen-garden shown: the stack-yard, however, is surrounded by a stone wall; a commendable practice, if it were only for the air of neatness and finish which it gives to the whole.

Design XV.—*The Farm House and Offices at Cochlaw East Farm, on the Beaufront Estate, Northumberland.*

960. *Accommodation.* The general appearance is shown in the isometrical view, p. 474, and the ground plan in fig. 952. In this plan the farm house contains a kitchen, *a*; a parlour, *b*; back-kitchen, *c*; dairy, *d*; coal-house, *e*; and place for ashes, *f*. There is a garden, *g*, enclosed with a wall. The farmery exhibits a cart-shed, *h*; foal-

952

house, *i*; stable and hay-house, *k*; four hovels, *l*; three folds, *m*; straw-house, with granary above, *n*; barn, *o*; stack-yard, *p*; calf-house and turnip-house, *q*; two byres (cow-houses), *r*; two cottages, *s*; and piggerly, *t*.

961. *Construction.* Northumberland being a county abounding in freestone, the walls are of that material, and the roofs of Baltic timber, covered with Westmoreland slates. Fig. 953 shows a cross section of the dwelling-house. A specification, applicable to Northumbrian farms generally, will be given with a succeeding Design.

953

962. *Estimate.* The contributor of this Design, John Green, Esq., Architect, Newcastle, having supplied us with the amount of the actual cost of the different buildings composing this Design, we have made out the following table, with a view of obtaining an approximation to the cost per cubic foot:—

	Cubic Feet.	Per Foot. d.	Estimated Cost. £	Actual Cost. £
Contents of the cart-shed, <i>h</i> .....	6,480	2	54	50
Contents of the foal-house, <i>i</i> , and stable and hay-house, <i>h h</i> .....	18,000	2	150	145
Contents of two hovels, <i>b d</i> .....	21,432	2	178	168
Contents of the barn, <i>o</i> , and straw-house, with a granary above, <i>n</i> .....	25,442	2	212	177
Contents of two cow-houses, <i>r r</i> , and calf-house, <i>q</i> .....	18,000	2	150	129
Contents of two pig-houses, <i>t</i> , with yards.....	4,804	2	20	27
Contents of the farm-house, and kitchen offices, <i>a, b, c, d</i> , &c. ....	31,570	3½	460	453
Contents of two cottages, <i>s s</i> .....	11,520	2¾	132	130

From the above it would appear that, in Northumberland, 2*d.* per cubic foot is a fair sum for estimating farm buildings; 3½*d.* for farm houses and their offices; and 2¾*d.* for cottages.

963. *Remarks.* The farm house in this Design is placed on one side of the farmery; but that circumstance, we presume, is owing to some local peculiarity in the surface; since it must, when no obstacle is in the way, generally be desirable to have the house so placed as to command the whole of the farm-yard. In this instance there is not a single window of the living-rooms which looks in that direction. We observe that the fireplaces are all made in the outside walls, which would be bad in a country where fuel is scarce and dear, but which is probably thought nothing of in Northumberland, where it is abundant and cheap.

Design XVI. — *A Farm House and Farmery for seven Ploughs, proposed to be executed in Northumberland.*

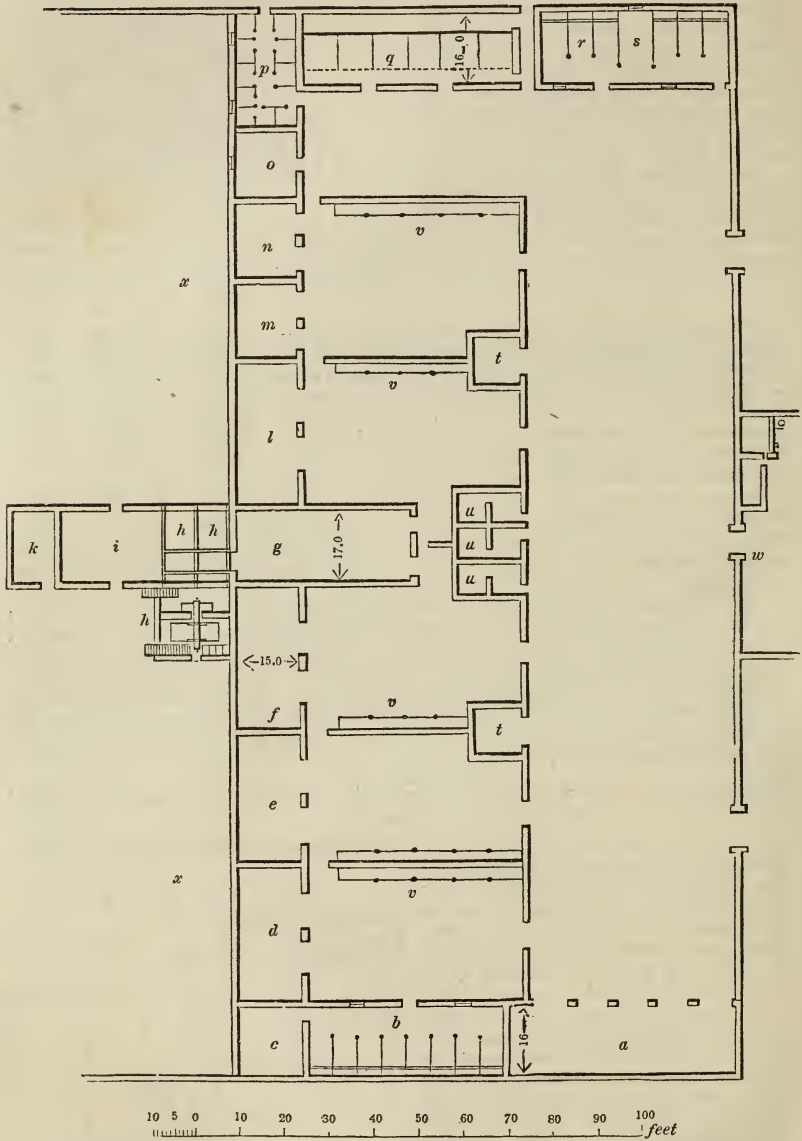

964. *Accommodation.* The ground plan of the farmery is shown in fig. 956; and the ground plan of the farm house in fig. 954.

The farmery contains a cart-shed, *a*; stable for eight horses, *b*; hay-house, *c*; hovels with yards, *d, e, f*; straw-house, *g*; water-wheel and machinery for threshing-machine, and place for threshed corn, *h h h*; corn-barn for unthreshed corn, *i*; tool-house, *k*; hovels with fold yards, *l, m, n*; foal-house, *o*; calf-house, *p*; cow-house, with stalls between every two cows, *q*; stable for six horses, *r*; hay bay in the stable, *s*; turnip-houses, *t t*; roofed part of the pigsties, *u u*; cribs for fodder in the fold yards, *v v*; kitchen court of the dwelling-house, *w*; and stack-yard, *x*. Fig. 954 is the ground plan of the dwelling-house, in which may be seen a porch, *a*; a sitting-room, *b*; parlour, *c*; dining-room, *d*; store-room, *e*; pantry, *f*; dairy, *g*; with a meat-safe indicated on one side at *p*; kitchen, *h*; back-kitchen, *i*; cleaning-shed, *k*; privy, *l*; place for ashes, *m*, and for coals, *n*. The surface drainage of the kitchen court, *o*, is to two iron traps, *q q*, as indicated

955

by arrow-heads; and the water thus collected passes under the privy into a drain, *r*, which also receives the water from the sink-stone, *s*.

965. *Construction.* The walls are of freestone; the exterior angles, and all the jambs of the doors and windows being worked, and the lintels and sills of one piece. Fig. 955 is an elevation of the front of the house, in which a porch is shown, which is formed of stone pilasters. Fig. 957 is a cross section of the stable, showing the manger, *a*; racks, *b*; and the floor, perfectly level, *c*. Fig. 958 is a section across the division walls, *d*, and double cribs of the fold-yard; by which it appears that the posts, *e*, into which are let the ends of the rails to which the spokes of the cribs are nailed, are of stone, and that the cribs are divided into short lengths by cross rails at top, let into the posts, *e*, and the wall, *d*. Fig. 959 is a section across a single crib.

957

966. *General Estimate.* The actual expense of building this farmery, exclusive of the farm house, was £1200; and, as it contains 168,560 cubic feet, the expense per foot is about  $1\frac{3}{4}d$ . The actual cost of the farm house, with the kitchen court and offices, amounted to the same sum; and, as these contain 86,704 cubic feet, the average per foot is  $3\frac{3}{4}d$ , or thereabouts.

967. *Remarks.* This Design, also by Mr. Green, is for a Northumbrian farm which pays a rent of from £1200 to £1400 a year; the rent being partly paid in money, and partly in the value of the produce, chiefly corn, wool, and butchers' meat. The circumstance of the threshing-machine being driven by water is favourable for the tenant, as requiring fewer horses. The cribs for the cattle in the fold-yards seem remarkably well executed, the posts being of stone. These cribs are two feet wide, and into them the turnips are thrown at one period of the day, and the straw at another. The stables are, as usual, divided into single stalls, and they are lighted by glass windows, which are always favourable for cleanliness. The house is spacious, and appears to contain most of the conveniences required. The connection of the dairy with the kitchen and back-kitchen is good; but the idea of a safe for meat in the dairy cannot be considered as favourable (see § 730). The manner in which the draining of the surface water of the yard is indicated is highly commendable, and ought to be generally adopted. The first points which should be settled, in determining the heights of the ground floors of any assemblage of buildings, are the levels of the underground and surface drainage.

Design XVII.—*A Farm House and Farmery for Fourteen Ploughs, suited to the Northumbrian Husbandry.*

968. *Accommodation.* Fig. 962 shows the general appearance of the whole; fig. 963 is the ground plan of the farmery; and fig. 960 the ground plan of the dwelling-house. The ground plan of the farmery shows a gig-house, *a*; harness-room, *b*; a stable, *c*, with a loft over it, and a man's sleeping-room over the gig-house and harness-room; a foal-house, *d*; bull-house, *e*; two cow-houses, for sixteen cows, each pair separated by a partition, *f f*; five hovels with fold-yards, *g*; calf-house for twelve calves, *h*; stable for a loose horse, *i*; straw-house, *k*; barn, *l*; steam-engine house, *m*; boiler-house, *n*; tool-house, *o*; poultry-house, *p*; outside stair to the barn, *q*; cart-shed, *r*; cartwright's shop, *s*; blacksmith's shop, *t*; hay-yard, *u*; stable for bailiff's horse, *v*; bailiff's cottage, *w*; turnip-houses, *x*; pig-houses, *y*; kitchen-court of the farm house, *z*; and rick-yard, &c. Fig. 960 is a ground plan of the dwelling-house, in which there are a lobby, *a*; a dining-room, *b*; drawing-room, *c*; parlour, *d*; office and library, *e*; passage, *f*; kitchen, *g*; back-kitchen, *h*; pantry, *i*; dairy, *k*; wash-house, *l*; place for ashes, *m*; for coals, *n*; best privy, *o*; and servant's privy, *p*. Fig. 961 is a front elevation of the house.

961

969. *Construction.* Native freestone, Baltic timber, and Westmoreland slate are, as usual, the principal materials; and the details of construction are common to all farmeries in Northumberland. We may remark, as not common, the practice of passing from one fold-

yard to another, over the separation wall, by ascending three steps on one side, and descending three on the other, as indicated by the section fig. 964. The fodder-cribs, fig. 965, have raised bottoms, grated, in order to let the dust and dirt from the turnips drop through. The hay, when there are cribs for the turnips, is given in racks, placed against the back wall of the hovels, as indicated in the plan, fig. 963. This practice seems a decided improvement.

964

965

970. *Remarks.* The threshing-machine here is driven by steam, which shows a great advance on the practice of employing horses, and one particularly suitable to a coal country, where fuel must be so much cheaper than horse-food. It will be observed in the plan, that the boiler-house, the cart-shed, the cartwright's shop, and the smithy are kept quite apart both from the fold-yards and the rick-yard; which is highly proper, as it prevents all risk from fire getting to straw, and all waste of litter, none being required for this department of the farmery. Taken altogether, this farmery appears one of the most extensive and well-arranged things of the kind that we have seen, and does the highest credit to its Architect, Mr. Green. One circumstance we cannot help remarking; and that is, the commodiousness of the farm house, which contains twenty-eight windows, and twenty-eight apartments; while the dwelling of the bailiff, or superintending hind, as he is called in Northumberland, consists of only one apartment, and one small window. The horses and cows, nay, even the swine, are incomparably better lodged, considering their scale in creation, than the unfortunate occupant of such a cottage as is here shown: but the farmers of Northumberland, like those of Scotland, are under the dominion of an all-powerful aristocracy, and their servants are little better than serfs; or, as it has been observed in the *Morning Chronicle*, the landlords are the slave-owners, the farmers the slave-drivers, and their servants the slaves.

Design XVIII.—*A Farm House and Farmery for Ten Ploughs, Ten Cows, Twenty Young Cattle, and other Live Stock, adapted to the Husbandry of Northumberland.*

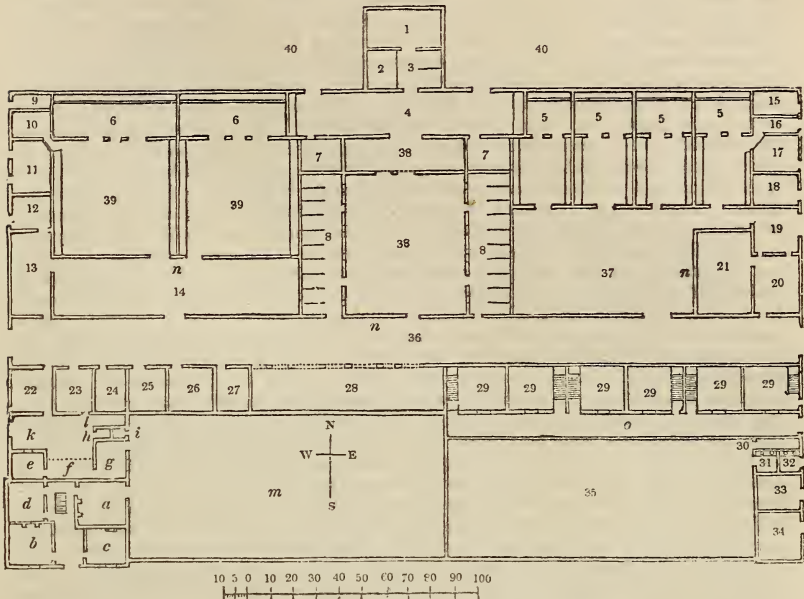

971. *Accommodation.* The general appearance is shown in fig. 966, and the ground plan in fig. 967. In the latter, the house contains a kitchen, *a*; dining-room, *b*; parlour,

966

*e*, separated from the dining-room by a large hall or lobby; office, or place of business, *d*; dairy, *e*; covered passage, open in front, *f*; back-kitchen, and dairy-scullery, *g*; privy for servants, *h*; best privy, *i*; kitchen court, *k*; place for ashes, *l*; and walled kitchen-garden, *m*. The farmery contains in the barn a compartment for unthreshed corn, 1; another for threshed corn, 2; a space for machinery, 3; and a large straw-house, 4. At one end of the straw-house is a stair to a granary which extends over the straw-house and cattle-sheds 5 and 6. The cattle-sheds, or hammels, are of three kinds; hammels for beeves upon turnips, 5; hammels for stirks, 38; and hammels for store cattle on straw, 6. Every hammel has its yard; those for the cattle on straw, 39, being largest, because

967

a number are put together; and those for the beeves being smallest, because they are understood to be fattening. The yard for the stirks, 38, is also the yard for the stables. There are two hay-rooms, 7 7; and two stables for ten horses each, 8 8; a poultry-house, 9; pigsty, 10; calf-house, 11; foddering-bay for cow-house, 12; cow-house for ten cows, 13; yard to the cow-house, 14; vacant house, to be used as a slaughter-house, or for pickling wheat, or for various other purposes, with a dovecot over, 15; store pigsty, 16; house for a bull, 17; house for a stallion, 18; feeding-house for cows, 20; and yard for cow-house, 21. There are a boiling-house, which also serves as a wash-house for the family, 22; a coal or wood-house, 23; stable for a riding-horse, 24; an hospital, 25; a carpenter's shop, 26; a tool-house, 27; cart-shed, 28; and six cottages for ploughmen, 29. Belonging to the cottages there are a place for such rubbish as cannot be turned into manure for the cottage gardens, 30; a privy for the women and children, 31; and a privy for the men and boys, 32. To complete the establishment, there are a blacksmith's shop, 33; and a cow-house for the six cows of the cottagers, 34. Each cottage has a garden in the enclosure marked 35. To supply all the animals with water, there are pumps at *n n n*, besides a pump in the kitchen court, and one at *o*, for the cottagers. There are a broad passage or roadway between those offices which are unconnected with working, feeding, or store animals, and the farm yard, 36; a yard for store turnips, 37; one for stirks, and for the stables, 38; two for cattle feeding on straw, 39; and an extensive rick-yard, 40.

972. *Remarks.* This Design has been sent us by one of the most extensive farmers in Northumberland, an enlightened and liberal-minded man, and a much valued contributor to our *Encyclopaedia of Agriculture, Gardener's Magazine, and Magazine of Natural History*, accompanied by the following remarks:—"This Design is sent to show you what we in Northumberland consider some of the essentials in the arrangement of a farm steading. It scarcely ever happens that a whole homestead has to be built at once; and the nature of the ground, or of the farm roads, frequently causes a variety of modifications in the different buildings here exhibited. In explaining what these essentials are, it may be necessary to state the reasons why the barn, in fig. 967, is made thirty feet wide, instead of sixteen or eighteen feet, which is the usual width. This is done that there may be sufficient space for a stack of unthreshed corn, and also two bays for threshed corn, in order to supply work for the men and horses, in weather so bad, that corn would be injured in carrying it from the rick-yard to the barn; and to contain a large quantity of threshed corn, when there may not be time, on account of out of doors work, to clean and measure it up, and raise it into the granary. The straw-house, 4, may

also seem large; but the advantage of having occasionally, or rather always, a store of dry straw is great; and in a large straw-house the different kinds for the keeping or feeding of cattle may be kept separate without inconvenience. The hammels, as well as the other cattle-houses, it will be seen, are so situated as to be supplied with straw from the straw-house with the least possible labour; they are also all made to front the south; as that aspect, in Northumberland, offers so much more warmth and comfort to the animals, as to render the food given much more effective in fattening them than it would be in houses facing the north, or even the east or west. The cattle wing is placed on the west side of the quadrangle, near the dwelling-house, as being more convenient for the cows and calves; and the stables are placed near the centre, with hay-houses, 7, 7, at their farther end, to which access may be had through large folding doors in the straw-house. The hay, may, therefore, be carried to the feeding stock dry, and may be lodged under lock and key, and given into the charge of a fodderman; under which circumstances, it is considered much less liable to waste; the expense of lofting the stables is also saved, and the stables are thus rendered more healthy for the horses. As a long range of buildings fronting the south might be exposed to a sweep of wind from the east or west, the stables are carried up close to the fodder-house, for the purpose of breaking such a current, and of rendering the folds more sheltered, particularly the middle one; which, on this account, and from its being the most convenient for receiving the stable litter, is particularly eligible for the yearling cattle (stirks), which the Northumbrian farmers think are less liable to the quarter ill, when allowed to eat the refuse hay and litter from the horses, of which they are very fond. The feeding cattle are now generally fed in sheds opening into a loose yard, three, five, and sometimes more, being placed together, with the exception, occasionally, of old cows, which are usually tied up; for these there is a feeding-byre, 20, in the east wing, which, however, may also be converted into a feeding-hammel. Both a turnip-house, 19, and a turnip-yard, 37, are given; the first is principally useful during winter frosts, though excellent beeves may be fed with turnips which have been stored in the open yard, when they have been well covered with straw. The cart-shed, which more farmers consider necessary than can boast of having, is placed near the stables, and fronting the north; that being considered the best aspect for preserving those implements. The tool-house is also near, and the remainder of this range to the west may be considered most conveniently situated. The dwelling-house is placed a little in advance of the west wing, and is as near the farm-yard as it will can be, without being subjected to its nuisances. The dairy is shown rather detached, because it is better at some distance from the heat of the kitchen; and its window is to the north, as that is requisite for preserving the milk sweet during the hot weather of summer. The cottages are to the east of the south range; and if built like Mr. Bardwell's, § 477, fig. 423, with sleeping apartments above, they will be of sufficient size. They are better placed together than detached, as, by their vicinity to each other, a dishonest servant is prevented from pilfering, from the fear of being detected and exposed by his neighbours. Their cow-houses, and the blacksmith's shop, are placed on the east, to complete the quadrangle, where also other conveniences may be added, if thought necessary. The wash-house, 22, at the west end, is intended either to boil horse or cow food; or where many harvesters (reapers) are employed and fed, it may be used as a cooking-house." We value this plan highly, knowing the competency of its author. We are gratified to observe that the cottages for the labourers are proposed to be formed, like Mr. Bardwell's, with one large room and two closets on the ground floor, and two bed-rooms over. The worst point about the Northumbrian farmeries, as well as those of Scotland, is the boothies, or little booths, for the single men, and the houses of one room for the married servants.

Design XIX. — *A Farmery for Five Ploughs, with Cows, Cattle, and other Stock in Proportion, suitable for the Northumbrian Husbandry.*

973. *Accommodation.* No farm house is here shown, but merely the offices of the farmery; the general appearance of which is exhibited in fig. 968, and the ground plan in fig. 969. The latter contains the barn bay for unthreshed corn, *y*; the bay for threshed corn, *z*; the machinery, *c*; and the straw-house, *d*: the stable, *e*, has separate stalls for ten horses; and connected with it is a hay-house, *f*. There are a tool-house, *g*; straw-yards, and hammels, *h*, *i*, *k*, *l*; calf-house, *m*; stable for a loose horse, *n*; cow-houses, *o*, *p*; hackney stable, *q*; and four feeding-hammels, with yards, *r*, *s*. There are a vacant house for an hospital, and for various other purposes, *t*; a cart-shed, *u*; turnip-house, *v*; a common yard, *w*; and rick-yard, *x*. There are pumps for supplying water, at *a' a'*; and upright racks along the divisions between the fold-yards, at *b' b'*, &c.

974. *Remarks.* On this Design, which has been sent us by the same experienced agriculturist as the preceding one, its author thus remarks: — "No dwelling-house or cottages are attached, nor a blacksmith's nor carpenter's shop; because these may be added

968

where deemed most convenient. Many of the observations made on the preceding Design will apply also to this one: the cart-shed, however, fronts the east, which is the next desirable aspect to the north."

969

Ft. 10 0 20 40 60 80 100 Ft.

Design XX. — A Farm House and Farmery for Three Ploughs, adapted to the North-umbrian System of Culture.

975. Accommodation. Fig. 970 shows the general appearance; and fig. 971 the ground plan. In the latter the dwelling-house shows an entrance-lobby and staircase, a;

970

parlour, *b*; kitchen, *c*; dairy, *d*; drying-shed, *e*; back-kitchen and dairy-scullery, *f*; servants' privy, *g*; best privy, *h*; place for ashes, *i*; pigsty, *k*; poultry-house, *l*; and kitchen yard, *m*. The offices show a stable for six cart-horses, *n*; hackney-stable, *o*; cow-house, *p*; calf-house, *q*; hammels and yards, *r*; house for a loose horse or bull, *s*; bay of the barn for unthreshed corn, *t*; threshed corn and machinery, *u*; straw-house, *v*; situation in which cattle-sheds may be extended, *w*, with yards, *x*. A pump, placed at *y*, will supply the whole of the farm-yard, and the kitchen court may have one in any convenient angle. The rick-yard is at *z*.

976. *Remarks.* This Design, by the same contributor, is for what is considered in Northumberland a small farm. "It is chiefly intended for keeping cattle, and may be extended towards the east, as shown by the dotted lines, *w, x*. The additional hammels, *w*, may be covered by corn stacks, as roofs, and especially with beans, a very general practice in Northumberland. There is a dwelling, but no buildings are shown, for servants or workmen. The cattle-sheds are all lofted, such lofts forming better granaries for keeping corn than those over close cattle-houses or stables; because the corn is not injured by the breath of cattle confined below. The whole range of building on the north side of this yard is shown two stories high, for the sake of sheltering the fold-yards. The stables in this Design, and in the two preceding ones, ought to be between sixteen and eighteen feet wide; and, if a recess with a small window in it were made behind each pair of horses, a convenient place would be formed there for keeping harness above, and for placing a corn or chaff bin below. The light and the ventilation which would be afforded by the window would admit of keeping the stable much more sweet and clean than is usual; for it is certain, as White observes, that 'there is nothing like light for exposing a negligent servant.'"

Design XXI.—*The Farm House and Offices for a Farm of Six Ploughs, called Hallington New Houses, on the Beaufront Estate, in Northumberland.*

977. *Accommodation.* The general appearance is shown in fig. 972, and the ground plan in fig. 973. The latter shows the farm house, containing a kitchen, *a*; parlour, *b*;

972

973

back-kitchen, *c*, with four bed-rooms and a closet over. There are also a dairy, *d*; coal-house and shed, *e*; ash-house and privy, *f*; and garden, surrounded by a wall, *g*. The farmery contains a stable for nine horses, *h*; a hay-house, *i*; three hovels with their fold-yards, *k*; a straw-house, with granary over, *l*; a barn, *m*; stack-yard, *n*; stable for four horses, *o*; foal-house, *p*; cow-houses, *q*; calf-house, *r*; piggeries, *s*; cart-shed, *t*; and two cottages, *u u*.

978. *Construction.* The walls are of the freestone found upon the estate; the timber is of Baltic fir, and the covering of the roofs of Westmoreland slate. There is nothing peculiar or specific in the fitting up of the buildings composing the farmery; and the interior of the dwelling-house is finished in the usual manner, as appears by the section, fig. 974. As a specimen of the manner in which the particular, or specification, of the work to be done in building a farm house and offices in Northumberland is made out, we are enabled, through the kindness of Mr. Green, to subjoin the following form, being that actually made for rebuilding this farm:—

974

979. *Specification and Description* of the several works to new farm buildings intended to be erected at Hallington New Houses, on the estate of J. Errington, Esq., of Beaufront, in the county of Northumberland, according to the plans, elevations, and sections hereunto annexed.

980. *The Contractors* shall, at their own cost and charge, provide all and every kind of material; labour, including the digging and quarrying stones; workmanship; tools; travelling, lodging, and every other expense attendant on the works, except cartage, which is to be supplied by the tenant. All the materials to be of good quality of their several kinds; and the mortar for building the walls to be composed of good well-burnt lime, mixed with clean sand; using not less than one cart-load of lime to three cart-loads of sand, and having them well mixed and beaten together with water. The stones to be got from a quarry which is to be opened on the farm; the contractor to find labour for opening and laying bare the stone; but the tenant to supply what cartage may be neces-

sary. The timbers for all the carpenter's work; viz., roofing, lintels, bond timber, stoothings (studwork, or quartering; that is, wooden framework for lath and plaster partitions), raggings (ceiling joists), joistings, external door-frames, posts and rails for stalls in stable, cow-byre, and calf-pens, to be all sawn out of Memel, Dantzic, or red pine timber. The deals for the external doors, windows, gates, stall partitions, mangers, and hay-racks, and for the steps and risers to stairs, to be all of red wood from the Baltic. All the floors of the house and granary to be laid with white-wood battens from Christiania. All the other inside joiner's work to be executed with deals, &c., cut out of Quebec yellow pine. The whole to be free from sap, shakes, loose knots, and every other defect. The materials of the present old buildings to be taken for the use of the respective contractors; and such of them as shall be deemed sound and good by the inspector, such as stones and timber, to be used in the new offices. The old buildings, however, are to be taken down only in such order of time as they can be spared by the tenant, so as he may not be put to unnecessary inconvenience thereby.

981. *Dwelling-House. — Mason's Work.* To open out, and lay bare the quarry where pointed out; and to get from it all the stones necessary for the mason-work; to dig proper trenches for all the walls, of the different thicknesses, and to the depth required for a good foundation, and also for sleeper walls to the parlour floor. To build stone footings to all the walls, from good foundations, of the different thicknesses described on the drawing; the first footing to be 3 feet, and the second ditto 2 feet and a half. To carry up all the external walls 2 feet thick, and the internal walls, and walls of coal-house, privy, &c., 20 inches thick, to the heights required, as shown by the elevation and section. The front of the house to be built with good blocking courses of hewn stone ("good blocking courses" does not mean, in Northumberland, hewn work, but only stones dressed with the pick end of the hammer, and laid in regular courses, which courses are generally of such a thickness, as that two of them range with one course of coins, as in fig. 975). The jambs of the doors and windows to be carried up in in and out tie (in and out tie, or in-bands and out-bands, are analogous to headers and stretchers in brick-work; and, in the case of windows and other openings, will be understood by fig. 976,

in which *a* is the in-tie, in-band, or heading stone; and *b*, the out-tie, out-band, or stretching stone; and *c*, the pulley style of the windows; the external elevation of in and out tie may be seen in fig. 977); checked (rebated) to receive frames; the inside of the jambs to be splayed; to have wooden bricks built in for fastenings of the beads, and recesses left for window seats. The gables of the house and back side to be built with good common walling; the whole of the walls to have a bond stone (binding stone) laid through the full thickness of the wall every superficial yard, and to be properly pointed outside. Windows and doors to have stone heads and sills, chiseled and set. The sills to have proper drips, and to project 2 inches from the face of the wall. The coins (corners) for all the walls to be chiseled, and to be from 12 to 14 inches deep, 20 inches long, and 10 inches in the bed. Two courses of blocking in the front wall to range fair with one of coins. The chimneys to be carried up with gables, as shown in the drawing. The vents (flues) to be well pargeted inside, with hair and lime; and the tops above the roof to be built with hewn stone, well jointed; each joint to have a wrought-iron cramp, three eighths of an inch square, and 5 inches long, run with lead. Stone water-tables to be laid up the gables on each side, and to be wrought with saddle top, chiseled and set; the first stone to be fixed with an iron stud, run with lead, into corbel coins (summer stones, as shown in fig. 977), also a stone ridge, wrought fair to a mould, well jointed and laid straight on the roof. To pave the two kitchens, dairy, pantry, passages, and closet under the stairs with flag-stones, 3 inches and a half thick, from Erring Craig: the whole to be dressed, jointed, and well bedded in sand. The front and back doors to have stone steps and thresholds, chiseled and set. The fireplaces in the front kitchen and back ditto to have stone jambs and mantels chiseled and set. The mantels not to be less than 15 inches deep, and the jambs the breadth required. Each fireplace to have a furnace pot (boiler) and oven (the front kitchen pot to contain 12 gallons of water; the oven to be 20 inches in diameter); and standard grates, (kitchen grates supporting themselves by feet in front,) 20 inches wide, set with hewn stone fronts, coved behind for the pot mouth (boiler mouth, as in fig. 978; in which *d* is the pot or boiler; *e*, the coving; *f*, the jamb; and *g*,

the bottom of the standard grates); the back-kitchen fireplace to have a standard grate, 20 inches wide, and the pot to contain 16 gallons of water. The whole to be properly set with cast-iron dampers and fire bricks; to have end plates and a hook fixed for the top bar to fall down. The fireplaces in the bed-rooms and parlour to have polished stone jambs, mantels, and fire slabs, and side slips where required; each to have a sham stove of the value of 15s. each, the parlour fireplace to have metal cove plates (metal side pieces, coved to the jambs above the stoves, as in fig. 979, in which  $h$   $h$  are the cove plates), and the whole to be properly set. To pebble-pave the yard to the house, coal-house, ash-house and shed; the privy to be flag-paved. The front and back doors to have flags laid in the front of the steps, 4 feet by 4 feet. To build the garden wall, as shown in the plan, with common walling, 20 inches thick, and 6 feet high, with coins at the angles, and to have the coins of the gate openings scappled (broached ashlar dressed roughly with the pick end of the hammer).

982. *Plasterer's Work.* To plaster all the walls of the house with two-coated plaster; and also all the jambs of doors and windows. The soffits of the same to be lath-plastered where required. The ceilings of all the rooms, passages, and of the staircase with stoothing partitions, to have two-coated lath-plaster; also the partitions forming closets to have the same. The privy to have two coats of wall-plastering, and the ceiling to have two coats of lath-plaster. The lime for the whole of the above to be well prepared, and mixed with a sufficient quantity of long beast's hair; the whole to be well smoothed off, and left free from blishes (blisters) and every other defect, when finished. The mason to cut all the holes necessary for the carpenter's and joiner's work, and for the smith's work, &c.; also to provide lead for running in ditto. Grooves to be cut, when required, for the slating; and the whole to be done to the satisfaction of Mr. J. Green, Architect, or whom he may appoint to inspect the same.

983. *Carpenter and Joiner's Work.* To provide and cut all the necessary wooden bricks; lintels for door and window openings, and wall plates for joisting, of such scantling as will be hereafter specified. The joisting for the chamber floor to be laid level at top, and fair underside for the ceiling, and not to exceed 16 inches apart, middle and middle (from centre to centre). The joists to have 12 inches hold on the wall at each end, and to be laid on wall plates; to be trimmed for the chimneys and staircase, as may be required; and to be of such scantling as will be hereafter specified. The joisting for the parlour floor to be laid on sleeper walls, not to exceed 18 inches apart, middle and middle. The fire hearths to be boxed with 1 inch and a quarter deal. The roof to be framed, as shown in the section, with four pair of principals (principal rafters); the common rafters to be laid so as not to exceed 18 inches apart, middle and middle, a course of five-eighths inch deal sarking (boarding), 9 inches broad, to be laid along the eaves and the ridge, on each side of the roof and chimney necks (shafts); also five-eighths inch deal sarking laid up the gables, 2 feet wide on each side, to meet the slate laths in the middle of the second spar from the gable. The beams to be laid on raising plates, (wall plates) with a proper bearing on the same. The ceiling joists to be fixed to the underside of the tie beams, and not to exceed 16 inches apart, middle and middle. A trap-door to be made and fixed in the ceiling where directed, to give access to the roof. Stoothing partitions to form rooms, pantry, closets, &c., to be fixed as shown on the drawing; the stoothings (quartering) not to exceed 16 inches apart, middle and middle, the scantlings to be hereafter specified. Partition door-frames to be beaded, rabbeted, and fixed with stoothings, where shown in the drawing. The closet door-frames to be beaded, and fixed with stoothings to form closets, as shown in the drawing. The chamber floors and parlour ditto to be laid with inch-and-quarter white-wood battens; dressed and jointed, and well nailed to joists; the battens to be dressed and jointed immediately after the contract is made, and horsed (set up on end in the open air to dry, against a horizontal spar or horse, the end of which is shown at  $i$ , in fig. 984), so as to be properly seasoned before laying down. The coal-house, shed, and privy, to be covered in with a pitched roof (a roof raised in the middle, and not at one side only, as in lean-to roofs), as shown in the drawing; scantlings hereafter specified.—Scantlings.

980

Chamber flooring joists, 9 inches by 2 inches and a half, 16 inches apart, middle and middle; sleeper joists for parlour, 6 inches and a half by 2 inches and a half; 18 inches apart, middle and middle; principal rafters, 9 inches by 3 inches; tie-beams, 8 inches by 3 inches and a half; king-posts, 11 inches by 3 inches and a half; ridge-pieces, 7 inches by 1 inch and a half; ribs, 5 inches by 3 inches and a half; struts, 5 inches by 3 inches; common rafters, 3 inches by 2 inches and a half; raggings, 3 inches and a half by 2 inches; stoothings, 3 inches by 2 inches and a half; wall plates under joists, 4 inches and a half by 1 inch and a half; raising plates under tie-beams, 6 inches and a half by 2 inches and a quarter; lintels for doors and windows, 4 inches

thick, by the breadth required; wall plate at foot of spars, 9 inches by 1 inch and a quarter; partition door-frames, 4 inches and a half by 3 inches and a quarter; closet door-frames, 3 inches and a quarter by 3 inches; external door-frames to house, 4 inches and three quarters by 3 inches and a half; principal rafters for shed and coal-house roofing, 6 inches and a half by 2 inches and a half; common rafters, 2 inches and a half by 2 inches and a quarter; ribs, 4 inches and a half by 3 inches and a quarter; wall plates, 6 inches and a half by 1 inch and a quarter; ridge pieces, 6 inches by 1 inch and a half; pan plate, wall plate, and lintel, 3 inches and a half thick. — Windows. All the windows for the house to have boxed sash frames of red-wood deal. The frames to have 1-inch pulley stiles (hollow stiles, containing the pulleys, lines, and weights, for balancing the sashes), outside linings of three-quarters-inch deal; and beaded inside linings of half-inch deal, with the sash sill double sunk (see fig. 981), 3 inches and a half thick by the breadth required. The heads to be of 2 inch deal, boxed out the breadth of the side frames; three-eighths-inch parting (separating) beads grooved into pulley stiles; inside beads, three quarters of an inch and seven eighths of an inch broad; the sashes to be 1 inch and three quarters, stuck (worked) with astragal and hollow; sash bar, five eighths of an inch thick; the stile of sashes to be 1 inch and three quarters broad. The whole to be single hung with cast-iron weights and proper sash line; and to have cast-iron framed pulleys; each window to have a brass sash fastener fixed, of the value of 1s. 9d. The low room (ground floor) windows to have inside shutters framed of inch-and-quarter deal, in two panels, planted (inlaid) moulding, plain back flaps of three-quarters-inch deal, clamped at the ends; shutters to be hung with two inches and a half metal butt hinges; and the back flaps with 1 inch and a half wrought-iron ditto, and screws. Each shutter to have a plain brass knob, and a window shutter bar, 2 feet and a half long, fixed to each window. All the windows to have inch-and-quarter deal bottoms, with plain backs and elbows (casings round the window seats) of 1-inch deal beaded; the upper edge and plain soffits to be of three-quarters-inch deal, grooved and tongued. The parlour window to have framed backs and elbows down to the floor, with a framed soffit of inch-and-quarter deal, to correspond with shutters. The plinth to be fixed round the window, 4 inches and a half broad. Framed grounds 4 inches and a half by 1 inch and a quarter, beaded and splayed inside, to be fixed round the windows in the parlour and in the two kitchens, with a three-quarters-inch ogee back moulding. The upper room windows to have a three-quarters-inch angle bead fixed round the jambs and heads. The dairy and pantry windows to be made with solid frames, 3 inches and a half by 3 inches; to have sliding trellises inside, with glass above, one square in height; and to have inch-and-quarter deal bottom made level with shelving. The jambs and heads to have a three-quarters-inch angle bead fixed. The dairy and pantry shelving to be fixed, as shown on the plan, by dotted lines; to have three shelves in height; their united breadths not to be less than 4 feet; and to have proper framed bearers. All the external angles of the chimney breasts, jambs, and heads of door openings to have three-quarters-inch angle beads fixed, and on such other places as require them. The closets to be fitted up, as shown in the drawing, with 3 shelves in height, of 1-inch deal; their united breadths not to measure less than 3 feet. The stairs to be fitted up in one flight, as shown on the plan, with inch-and-quarter deal steps and risers. The steps to have rounded nosings chimed (let in) at both ends into stringings, which are to be of inch-and-half deal, and 10 inches broad; with a dressed and beaded upper edge to answer as skirting. A wrought deal handrail to be fixed to stoothings on each side of the stairs. Moulded skirting to be fixed round the parlour of 1-inch deal, 6 inches broad; to be fixed to the wall with plugs. Plain skirting of three-quarters-inch deal, 4 inches and a half broad, to be fixed round the kitchen, back-kitchen, passages, bedrooms, &c. The parlour fireplace to have a plain pilaster chimney-piece, 4 inches and a half broad, with shelf and frieze. The bed-room fireplaces to have a single fire moulding, with a plain shelf and frieze. The two kitchen fireplaces to have each a chimney shelf of inch-and-quarter deal, fixed with ogee brackets. All the room door-frames to have a three-quarters-inch quirk ogee moulding, planted (fixed) round on each side, also round the closet door-frames, to cover the plastering. The upper room doors, and the dairy and pantry ditto, to be framed in four panels of inch-and-half deal, finished and planted on one side. To be hung on frames, with 3 inches and a half butt hinges, and each to have a good Norfolk latchet (latch). The cheese-room door and pantry ditto to have iron-rimmed locks of the value of 2s. 6d. each, with escutcheons. The low room doors to be also framed in four panels of inch-and-half deal finished, planted moulding, both sides hung on frames, with 3 inches and a half butts; the parlour door and kitchen ditto next to the stairs to have each an iron-rimmed lock

with Scotch springs, and plain brass knobs of the value of 5s. 6d. each. The closet doors to be framed in four panels of inch-and-quarter deal; with planted mouldings on one side, to be hung with 3-inch butt hinges, and to have closet door locks of the value of 2s. 6d. each. The front door to be framed 1 inch and three quarters thick, in 6 panels, bead and flush outside; and hung with 4 inches and a half butt hinges on frames beaded and rabbeted, with a light above. The back entrance door to be framed 1 inch and three quarters thick, in four panels, bead and butt, and hung on frames, beaded and rabbeted, with 4 inches and a half butt hinges. Each of the above doors to have a stock lock of the value of 6s., and a good Norfolk latchet. 20 feet run of pin rail (railing for hat or cloak pins) to be fixed in the kitchen where required. The trap-door, made for the ceiling, to be of half-inch deal, grooved and tongued, with beaded lining round the frame. The privy to have a boxed seat of inch-and-quarter deal, grooved and tongued, and a battened door of 1-inch deal, hung on frames, beaded and rabbeted, 4 feet by 3 feet, with T bands (hinges like fig. 982) 2 feet long, and to have a Norfolk latchet, with a small bolt inside. The coal-house door, and ash-house ditto, to be of inch-and-quarter deal, hung with bands (strap hinges) and crooks (hooks) run into stone cheeks (jambes), 2 feet 2 inches long, with two screw-bolts and nuts in each band. (N.B. No doors or window shutters to be hung on mouldings fixed in any part of the house where the plastering is unfinished, except on the window grounds and skirting.)

982

984. *Hardware* (Ironmongery). To provide all the nails, spikes, screws, &c., that may be necessary for the carpenter's and joiner's work; also all the hardware, as before specified; two dozen of iron crooks to be fixed in the ceilings of the kitchen, or in such other parts as shall be directed. To fix along the eaves of the roof on both sides half round metal spouts (see fig. 983), with two metal wall pipes. The whole to be fixed with a sufficient number of iron stays and holdfasts.

983

985. *Slater's Work*. To cover the roof of the house with Welsh slates called countesses, laid with a sufficient overlap, and well nailed, with two nails to each slate, to Memel laths 1 inch and a half by five eighths of an inch; the laths to be well nailed to spars (common rafters). The whole to be well pointed inside with good hair and lime mortar, and inserted into grooves at the chimney necks; also to be well pointed up the gables and along the ridge; the whole to be sound, and left perfectly watertight when finished.

986. *Glazier's and Painter's Work*. To glaze all the windows with the best Newcastle second crown glass, to be well fitted and bedded in good oil putty. The windows to be primed before glazing. Pantry and dairy windows to have glass above the trellises one square in height, also the same above the front door. To paint all the outside joiner's work, viz., doors, windows, &c., and all the metal spouts, with three coats of good white lead and oil; and all the inside joiner's work, viz. the doors, windows, mouldings, linings, skirtings, handrails, &c. &c., with two coats of white lead and oil, or with such other colours as may be required. The whole work to be well puttied up, and knotted (the knots smoothed and filled up) previously to painting.

987. *Farm Offices. — Mason's Work*. To dig proper trenches for the foundations of all the walls to the new buildings, the proper thicknesses, and to the depth required. To take off the covering, and pull down the walls of such of the old buildings as are to come down; the old stones to be used for the inside of the walls to the new buildings; and the new stones wanted, to be from the aforementioned quarry. To build stone footings to all the walls for the new buildings, as shown on the plans, 2 feet and a half wide, from good and sufficient foundations. The walls above the foundations to be 21 inches thick, with good common walling carried up to the height required, as shown in the plan, elevation, and sections. A proper bond stone to be laid through the full thickness of the wall every superficial yard (measuring on the face of the wall), and the face of the external walls to be well pointed. The coins for all the external angles of the walls to be scappled, jointed, and set; and to be 20 inches long, 12 inches deep, and 10 inches thick. Stone heads and sills to be chiseled for all the windows, the frames to be built in with the walls. The external doors to have also stone heads and sills chiseled; the jambs to be built in and out tie, scappled and checked; (hammer-dressed, as above explained, with a rebate cut out for the door to shut against,) the in-tie to go through the full thickness of the wall, and to be 12 inches in the head; the out-tie to be 20 inches long, and 10 inches in the head. Iron crooks to be run into stone cheeks while building for the door bands, which the carpenter will provide; the lead to be provided by the mason. The two byres at the west end of the present old farm house to be converted into two hovels, as shown in the drawing. The present slated cart-shed to be lengthened with a new

opening, arched, &c., as shown in the drawing. To build jambs and pillars to all the hovels and cart-sheds, with hewn stone in and out tie both sides, well jointed and set; the stones to be 20 inches long, 12 inches deep, and 10 inches and a half thick, and the space between the pillars to be carried up with good common walling. The arches to have pen stones (arch stones) to go through the full thickness of wall, and not to be less than 10 inches in the head; all the angles of the jambs to be cut off, making a 2-inch chamfer. The barn and straw-house to be flag-paved with flag-stones,  $3\frac{1}{2}$  inches thick, dressed and jointed, to be laid on a bed of rubblestones 8 inches thick, broken small; the flags to be bedded in sand, and the joints to be set with lime. To pebble-pave the byres and calf-houses with proper cribstone and saddle (the former, fig. 984, *k*, partitions off the crib; and the latter, *l*, the gutter behind) ditto, as shown in the plans. The cribs to be flagged at bottom. To pebble-pave the new stable, fowl-house, hay-house and pig-houses, with the yards to ditto. The stable to have proper stones mortised, and set for stall-posts. To pebble-pave a causeway 4 feet broad, with proper edge stones, in front of all the buildings inside the fold; also along the east side of the east wing, as shown by dotted lines on the ground plan. To build walls for the pig-houses, fold walls, stack-yard walls, and crib walls, as shown in the plan. Proper stone gateposts to be set into the ground, and those for the folds and stack-yard to have iron crooks run into the same with lead, for gates to be hung on; the whole to have scappled coins at the angles and gate openings. The walls to be carried up 5 feet and a half high above the ground, in common walling, with sloped coping. The ridge stone to be worked fair to a moulding, and laid on all the ridges and hips of the roofing. The first stone of each hip to be fixed with an iron spike. Stone water-tables to be laid on the pig-house gables; the first stone to be run into a corbel coin. The stone spouts to be wrought, and fixed into the walls of the pig-yards. The crib walls in the folds to have stone posts grooved to receive deal fronts, and to be flagged at bottom with common flags. The old cottage at Hallington Hill to be taken down; the byre to be converted into a cottage, and the barn into a hovel, opening into ditto. The latter to have jambs carried up with hewn stone and arch, as described for the other hovels. The chimney and fireplace in the cottage to be done as hereafter described for the new cottages. The flagging and plastering also to be the same. The walls for the fold and stack-yard to be done as before described for those at the farm house.

988. *Cottages.* To build two cottages adjoining the cart-shed, as shown in the drawing. The walls to be as before described. The chimneys to be carried up with proper vents 14 feet by 10 feet, and to be well pargeted inside with hair and lime; each to have hewn stone jambs, mantels, and chimney-top. The fireplaces to have each a cylinder oven, 15 inches in diameter; a furnace pot to contain eight gallons of water; and a pair (front and bottom bars) of common grates 17 inches wide: the whole to be set with hewn stone fronts, fire bricks, and dampers. The floors to be flag-paved with  $3\frac{1}{2}$ -inch flags, dressed and jointed, and well bedded in sand.

989. *Plasterer's Work.* To plaster the cottages with two-coated plastering; the sootching partitions of the dairy and lobby, in the new cottages, to be plastered with two coats of lath plaster. The granary and barn walls to be plastered with one coat wall plaster, 4 feet from the floor. The window-frames to be drawn about (pointed) with hair and lime mortar on both sides. The lime to be well prepared for all the plastering, and to be mixed with a sufficient quantity of hair. The mason to cut all holes for posts, iron crooks, grooves, and all others necessary for carpenter's and joiner's work, and the slating also; to clear away all the surplus earth from the inside of all the buildings, which are to be made level; the earth to be wheeled out to a considerable distance for carting away. The mason, also, to provide lead for running the ironwork into the stone; and to have the use of roofing timber, or any other old timber which may be spared, for scaffolding; but in case any of the same should thereby be broken or injured, to replace them, or else allow the value thereof to the carpenter for damages.

990. *The Carpenter's and Joiner's Work.* To provide and cut all the lintels for the doors and windows, of such scantlings as are hereafter specified; and so as not to have less than 12 inches hold on the wall at each end. The granary above the straw-house to have joisting laid 18 inches apart, mid and mid; and to have 12 inches hold on the wall at each end.—Flooring. The granary floor to be laid with inch-and-quarter white-wood battens, dressed and jointed: the battens to be laid loose, so as to take up and relay after pining (shrinking). The roofing for all the buildings to be framed and hipped, as shown in the drawing, with tie-beams laid on raising plates (wall plates), the scantlings to be hereafter specified; and the whole to have a sufficient number of principals to make the openings between not exceed from 7 to 8 feet.—Scantlings. Tie-beams, 6 inches and a half by 4 inches; principal rafters, 8 inches and a half by 2 inches

and a half; hip rafters, 10 inches by two inches; common rafters, 3 inches by 2 inches and a half; not to exceed 18 inches apart middle and middle; binders (tie beams) 8 inches by 2 inches and a half; ribs, 6 inches by 3 inches and a quarter; ridge, 3 inches and a quarter by 3 inches and a quarter; granary joists, 10 inches by 2 inches and a half; raising plates, 6 inches by 1 inch and a half; lintels, 4 inches thick by the breadth required for the low buildings. The lintels for the granary windows, 3 feet and a half by the breadth required. Hinder posts to stalls, 5 inches by 5 inches; fore posts, 5 inches by 3 inches. Sarking of five-eighths-inch deal, 9 inches broad, to be laid on the eaves and ridges of the roofing on each side. Gutter boards to the valleys to be laid with three-quarters-inch deal, covered with sheet lead, 18 inches broad, 6 pounds to the foot, which is to be provided, and laid at the carpenter's expense.—The stable to be fitted up with stalls, as shown on the plan and section. The stall partitions to be fitted up with inch-and-quarter deal, and to have a 9-inch batten placed horizontally about the middle of each side. The top and bottom rail, 4 inches by 3 inches and a quarter, to be grooved to receive the same. The rails to be tenoned into the stall posts; and the stall posts to be set into proper stones at the bottom, and fixed to girding pieces at top, 5 inches by 3 inches, nailed to the under side of the tie-beams. The hinder posts to be fixed at the top with a screw bolt. Mangers to be fixed between the stall partitions, with fronts and bottoms of inch-and-half deal; the back to be of inch-and-quarter, and the fronts to have a roller 2 inches and a quarter in diameter, grooved and fixed: each manger to have a wrought-iron ring and staple fixed. The hay-racks to be made 2 feet and a half wide; the rungs (spokes) of 1 inch and a half deal; the rack sides, 3 inches and a half by 3 inches; a harness rail 12 feet long, with proper pins, to be fixed in the stables.—The cow-byres to be fitted up with partitions and stakes, as shown in the drawing. The partitions to be cleaded (clothed) with inch-and-quarter deal, and proper posts of the old materials, provided any of them can be found suitable. The stakes to be let into the cribstones at bottom, and to be fixed at the top to joists, 8 inches by 4 inches, laid through for that purpose.—The calf-house to be fitted up with pens, as shown in the drawing; and the partitions to be formed with posts and rails, and paled. The posts to be 3 inches and a quarter square, let into stones at bottom, and fixed to a joist at top, laid through for that purpose. The partitions to have three rails in height, 3 inches by 1 inch and a quarter. The pales to be 4 feet high, 2 inches and a half by three quarters of an inch, and to be well nailed to the rails; each pen to have a small wicket, hung with small bands and crooks, and each having a hasp and staple for fastening.—Doors. All the outside doors of the farmery to be battened of inch-and-quarter deal, grooved and tongued. The barn and straw-house ditto to be hung in two halves. The whole to be hung with bands and crooks, run into stone cheeks. To provide and fix on the same a common wrought-iron sneck (latch), fig. 985, and catch, with ring handle to hang down. The barn, straw-house, granary, and stable doors all to have stock locks of the value of 5s. 6d. each, and proper iron bolts and staples to be supplied for all the other doors. The cottage outside doors to have each a thumb sneck and catch, and a stock lock of the value of 4s. The cottage inside doors to be made of 1-inch deal, battened, grooved and tongued, and hung on frames with 3 bands; and each to have a Norfolk latchet. The stable door to be hung in the middle with strap hinges, to allow the door to fall back against the wall. The door between the straw-house and barn to be of 1-inch deal, battened, grooved, and tongued; hung on frames with 7 bands, 22 inches long, and to have a sneck the same as the stable doors, with an iron bolt and staples.—Windows. The cottage windows to be made with casements, and iron bars, forming small panes, about 6 inches by 4 inches, to be fitted into solid frames, leaded and rabbeted; 4 feet three quarters of an inch by 3 feet 7 inches inside of frames; scantling of frame, 3 inches and a half by 3 feet: one casement in each to be made to slide. The above to have outside shutters of three-quarters-inch deal, grooved and tongued, hung on frames with small bands and crooks. Each window to have an iron cottler (a spring wedge, fig. 986) and an iron turn (a fastening, see Index) to keep it back. The small windows for the cottage dairies to be made with inside sliding trellises, 22 inches square. The windows for the stable, granary, and foal-house to be made 3 feet high, 2 feet 10 inches wide; and to have inside sliding trellis frames, 3 inches by 2 inches and a half. The stoothing partition and raggings to be fitted up so as to form a dairy and lobby in the cottages, with door-frames for ditto, 4 inches by 3 inches; and stoothings, 2 inches and a half by 2 inches and a half. The dairies to be shelved, with two shelves in height, each 12 inches broad, of inch-and-quarter deal, with brackets. The cottage windows to have inch-and-quarter deal bottoms, and 1-inch deal backs. The jambs and heads of the doors and

985

986

windows to have a three-quarters-inch angle bead for plastering. A chimney shelf of 1-inch deal, with brackets, to be fixed above the fireplace in each of the cottages. The windows in the granary to have inch-and-quarter deal bottoms, to project 1 inch over the wall, and to be nailed to the window sill.—The hay-racks to be the same as those in the stable, and to be fixed in each hovel the full length; as are the rack and manger in the foal-house. The hovel at Hallington Hill to have a partition put across it with posts and rails; and the gates to be hung with loops and crooks for young cattle. The stairs in the straw-house to be fitted up with inch-and-quarter deal steps and risers, and proper strings: the stairs to be partitioned off with stoothings, and three-quarters-inch deal cleading next to the straw-house; with inch-and-quarter batted door at the bottom, hung on frames 4 inches by 3 inches and a quarter, with T bands, and to have a stock lock and sneek as before described. A rail to be fixed round the opening of the granary stalls, with skirting at the bottom of three-quarters-inch deal, 12 inches broad. The skirting to be fixed round the barn and granary of 1-inch deal, 4 inches and a half broad, and to be well nailed to plugs.—Gates. Nine gates to be made for the folds and stack-yards, including those at Hallington Hill. Each to have 5 bars, and to be braced. The bars to be 4 inches by 1 inch and a half, and the stiles to be 4 inches and a half by 3 inches and a half. Also, 5 wickets, with 5 bars and braces, for the inside of the folds, &c. &c. The bars to be 3 inches and a half by 1 inch and a quarter; and the stiles, 3 inches and a half by 3 inches. The whole to be hung with proper iron loops, and crooks run into stone posts, in the coins of walls, where necessary; and to have proper hasps and staples. Crib-boards to be fixed in all the stone cribs in the folds; to be 10 inches broad, and 2 inches and a quarter thick; and to be made to take out and in by grooves cut in the stone posts. Centres for the arches of the hovels and cart-shed to be provided, and posts for setting ditto.

991. *Smith's Work, and Hardware.* To provide and fix all spikes, nails, screws, &c., necessary for the carpenter's and joiner's work; and all the other hardware and smith's work before specified.

992. *Slater's Work.* To cover the roofs of all the buildings of the farm offices, as shown on the plan, with slates of the same kind, and done precisely in the same manner, as before specified for slating the dwelling-houses.

993. *Glazier's and Painter's Work.* To glaze the casements of the cottage windows with second crown glass; the panes to be 6 inches by 4 inches, neatly puttied on each side, and the casements to be primed before glazing. (N.B. The casements will be provided; and are, therefore, not to be estimated. To paint all the external doors and frames; also, the granary windows, the cottage ditto, and the stable ditto; also, the inside doors of cottages, and the window backs, with two coats of white lead and oil, on both sides. The windows to have one coat before being built into the walls.)

994. *All the Works,* as before specified, to be done in a sound and workmanlike manner, subject to the approbation of Mr. John Green, Architect, or whom he may appoint to inspect the same; and it is to be understood that, should it be deemed advisable that any of the work before specified, for the dwelling-house or farm offices, should be dispensed with during the progress of the building, the value of such work is to be deducted from the amount of the contract; and, on the other hand, should any alteration or additional work be required, which is neither expressed nor understood by the plans and foregoing specification, the expense of such alteration or additional work is to be paid to the contractor, and agreed for previously to its being done, or else left to the valuation of the inspector. (N.B. The iron-barred casements for the cottage windows will be provided; therefore the joiner need only estimate for the outside frames for ditto, as specified.)

995. *General Estimate.* The following form was sent us with the foregoing specification:—

	£	s.	d.
Building new farm-house, fig. 977, <i>a, b, c, d</i> .....	453	12	7
Building corn-barn, <i>m</i> .....	95	11	2
Building straw-house with granary above, <i>b</i> .....	125	3	1
Building foal-house, <i>p</i> ; two cow-byres, <i>q q</i> ; and calf-house, <i>r</i> .....	176	6	3
Building two stables, <i>h</i> and <i>o</i> ; and a hay-house, <i>i</i> .....	189	3	10
Building one hovel, <i>k</i> .....	48	13	11
Building two cottages, <i>u u</i> .....	130	8	0

We have formed a rough estimate of the cubic contents of the farm house, which, we find, contains 31,570 feet, which gives about 3½*d.* per foot as the price of this description of building in Northumberland. The cottages estimated in the same manner cost 2¾*d.* the cubic foot; and the farm buildings 2*d.* These prices are not much more than half what such farm houses and farmeries would cost in the neighbourhood of London,

as will be evident by comparing them with the estimate of the Bury Hill Designs, § 863 and § 880. One reason of this is, that in Northumberland stone is got for the working, and the carriage of the greater part of the materials is found by the tenant.

996. *Remarks.* This Design is another of those so obligingly furnished us by John Green, Esq., of Newcastle, the first Architect, as we are informed, for farm buildings, in the extensive counties of Northumberland and Durham. It is one of twenty plans and estimates which he made, in the year 1824, for renovating the farm buildings and cottages on the estate of Beaufront, lying on the river Tyne, between Newcastle and Hexham. By the advice of a kind friend, in the north of the county, we applied to this gentleman through our esteemed correspondent Mr. Falla, the eminent nurseryman at Gateshead, near Newcastle, and he has liberally permitted us to examine many of the plans (accompanied by their specifications and estimates) which he has designed and executed on different estates. From these we have selected seven, of which this is the last, and they will give a complete idea to the Architect of the mode of arranging farm houses, farmeries, and the dwellings of farm labourers, in that first of all English agricultural counties, Northumberland. We must say, that, highly gratified as we have been with these farm houses and farmeries, we have been proportionately shocked by the scanty accommodation provided for the farm labourers. While the master is lodged in a house which is fit for any gentleman of independent fortune, and the horses and cattle have as ample accommodation as can be desired, the poor ploughman and hind are put into single rooms, each generally about 22 feet long by 16 feet wide, with one door and two small windows. At one end of this room a closet or dairy, 5 feet by 5 feet, is partitioned off, and lighted by one of the windows; and a corresponding space serves as a sort of lobby to the outer door. This reduces the room to 16 feet by 16½ feet, which must serve the occupant for every purpose to which a dwelling-house can be applied. The reader may turn to the plan of two of these cottages, marked *u u*, in fig. 973, p. 487, which he may rest assured are fac similes of all the cottages built in Northumberland for ploughmen and farm-labourers. Among Mr. Green's plans, we have met with none with two rooms; and only with two or three that have privies or places for a pig. These last cottages, we are informed by Mr. Green, were built for labourers to be employed by the landlord in different parts of his estate. To the cottages marked *u u*, in fig. 973, there is attached no privy or exterior appendage whatever; though this is not much to be wondered at, since there is none to the farm house. We are tempted to enquire by what strange circumstance it happens that the art of farming should be carried to such a degree of perfection as it is in Northumberland, while the farmers, and more especially their servants, live in a state of comparative destitution of many of the comforts enjoyed by the same class in the south of England, where the art of agriculture is at the lowest ebb; and we can only account for it from the general ignorance both of the labourers and their employers, and from the remaining habits engendered by the oppression of the feudal system. The truth is, that almost the entire produce of the land, beyond the mere subsistence of the farmer and the labourer, is paid to the landlord in the form of rent; because the landed capitalists, like the great capitalists in trade and manufactures, enjoy a complete monopoly of the market, and they can command their own price for their land, as the others do for the use of their capital. Thus, in the country of great landholders, in the same manner as in the great manufacturing districts, the operative is scarcely able to exist. This evil can only be remedied by time, and a better system of government, which will effect a more equal distribution of land and capital. In submitting these remarks to the reader, we intend to make no reflections, in this or in any other case, on the Architect, who must necessarily conform to the customs of his locality; but we conceive it to be the duty of an author, who is under no local influence, to express his opinion freely on this, as on every other subject that comes within the range of his work. We may add, that the chief point in which the farmeries of Northumberland excel those of Scotland, is in the subdivision of the fold-yards into smaller yards; which, instead of being mere manufactories for manure, serve as enclosures for the growth, improvement, or fattening of cattle. Weak and young cattle always suffer much when many are placed together in the same yard; and this, more especially, when the animals are brought from mountainous or partially enclosed districts; or even districts where the enclosures are very large. Cattle fed loose in small enclosures or hammels of this kind have their hair sleek and unbroken, and their feet are never so tender as to prevent their travelling some distance to market. Nine tenths of the beeves or young cattle of Northumberland, we are informed by one of the most intelligent farmers in the county, are fed in small fold-yards, such as are represented in the ten preceding Designs, to the number of from three to six, or even more, together, accordingly as they are found to agree. In the rich flat pastures of Lincolnshire, Leicestershire, and other counties of England, the larger breed of cattle, from their constitutional tameness and docility, will

fatten together in large open yards, by dozens; but this not the case with Scotch cattle, more especially those from the Highlands. In looking over the specification, § 979 to § 995, the reader will observe that many of the building terms used in Northumberland differ from those in use about London; and some even from those employed in the south of Scotland, as given by Mr. Newall in his specification, § 907. We have shortly explained these terms, each when it first occurs; but there are some of them which will require to be more minutely defined, and compared with other local terms, in the Glossarial Index. This specification will be found of great use to all persons intending to build farmeries where stone is employed, and it also shows the practical man what is considered, in a highly cultivated district, the best mode of finishing racks, mangers, cribs, partitions, &c. The construction of the cribs is worthy of notice; the sides and bottom are formed of boards two inches and a quarter thick, which fit into grooves and notches in stone posts. This seems an excellent plan, because the boards may be taken out at any time, and cleaned, and at seasons when the cattle are not kept in the yards they may be taken out altogether, and placed under cover, in a dry airy situation, till again wanted. All the stables are fitted up with stalls and full-length partitions, so that every horse securely enjoys the food placed before him. There appear to be a few inches of slope from the head of the stall to the gutter behind, which is now generally disapproved of in the best stables in England and France, though still continued in the farm stables in Scotland, as appears by an article in the *Highland Society's Transactions*.

Design XXII. — *The Farmery at Calley in Kirkcudbrightshire, suitable for a Galloway Crop and Pasture Farm of 400 Acres.*

997. *The Object* of this Design is to afford accommodation for wintering young cattle, and fattening others, as much or more than for affording stable room for horses. In Galloway, we are informed by the contributor of this Design, Mr. Brown, the factor or land agent at Calley, that the half of the rents is generally paid from the corn crop, and the other half from black cattle; so that a considerable proportion of the farmery is required to be laid out as cattle-sheds, for wintering the animals when young. The oldest and best Galloway cattle are generally wintered in the fields; which, in Galloway, where the winters are very temperate, are mostly well sheltered by hedges and plantations. Cattle wintered in this way are less tender in the feet, have a finer skin in the spring, and are in better condition to go to the English markets at that season, than those wintered in sheds and yards.

998. *Accommodation.* The cattle sheds here shown at *a*, in fig. 987, with the yard in front, *b*, are sufficient for the accommodation of forty or fifty-two head of cattle. There are a feeding-house, *c*, in which six cattle may be fed in stalls; a cow-house, *d*, 32 feet long, in which ten Galloway cows may stand without stalls; and at their heads there is a foddering-passage, *e*, which communicates with the straw-house, *f*, the feeding-house, *c*, and the cattle-sheds and yard, *a, b*. There are a barn, *g*, with a threshing-machine driven by water; a room for horses' corn and cut straw, *h*; a stable, 33 feet by 17 feet, for six horses, *i*; a cart-shed with a loft over, *k*; a small office or counting-house, *l*; a boiling or steaming house, *m*; and a tool-house with a smith's forge for occasional use, *n*. One part of the yard is left open,

and the other part is enclosed by a fence of pales, *o, p*, as a fold for the wintering of cattle. The general appearance of this Design is shown in the isometrical view, fig. 988.

999. *Construction.* The walls are chiefly of the slate-stone of the country, a cold and disagreeable stone for cottages and human dwellings, but less injurious for buildings for cattle and for sheds. The roofs are of Baltic fir, covered with slates; a covering cold in winter, and too warm in summer; and therefore, however fit for sheds, not to be commended for stables without lofts, or for cattle-houses. It is true that the prevailing prejudice, in the west of Scotland, is in favour of slates indiscriminately, from their durability; but even if thatch should be found less durable, and this is not always the case with the thatch composed of chips, shavings, and spray, or heath, we consider the latter as decidedly preferable for all buildings in which animals are to be lodged. But, in Galloway, improvement is not yet so general, that long heath and broom cannot be found; and these, even the natives will allow, are nearly as durable as any slate or tile whatever; or, at all events, they are sufficiently so for constructions which are undergoing the progressive improvements and changes which those of agriculture constantly are.

1000. *Remarks.* This Design has been furnished us by one of the most enlightened agriculturists in the west of Scotland, and therefore it may be considered as a fair specimen of a farmery for the agriculture of that district. It would be easy to add a farm house; but we have given so many good plans of this description of dwelling, that we consider it unnecessary to add one on the present occasion. No arrangement for the collection of liquid manure is shown; because the farmers of Galloway, as those of most other districts of Scotland, have not yet arrived at that degree of scientific refinement to be fully aware of the advantages to be obtained by this important part of a perfect farmery.

Design XXIII. — *A Farmery for a small French Farm, as given by Morel-Vindé.*

1001. *The requisite Farm Buildings for a small Farm,* our author observes, are the same as for a large one, almost the only difference being in their magnitude. The plan exhibited in the following figures is therefore to be considered as conveying the rudimental idea of all farmeries whatever, where the objects of cultivation are those common to the temperate regions of both hemispheres. The same constructions, which in the annexed plans are only a width of two bays of ten feet each, by forty feet in length, might be extended to many bays of the same size. The following is the general type of this building: — 1. The stable and cow-house are in the same space without separation; because by this arrangement, on small farms where there are few or no servants and not much litter, the animals are more easily looked after; the litter from the horses is with little trouble thrown under the cows, and the dung of both, being mixed, produces a better manure. 2. The poultry-house is placed alongside of the cow-house, and only separated from it by an open grating in order to admit the heat of the former to the latter. 3. The barn is sufficiently large for containing one rick of 3000 sheaves, with additional

space, in order that a part of it may be used, if necessary, as a cider-house, for wine vats, or for storing roots. The space covered by the entire building is eight hundred superficial feet.

1002. *Details.* Fig. 989 is the surface ground plan, showing the barn for unthreshed corn, *a*; the cellar end of the same barn, *b*; the threshing-floor, *c*; the stable for three horses, *d*; cow-house for three cows, *e*; harness-house and general magazine, *f*; poultry-house, *g*; pigsty, *h*; place for hatching poultry, *i*; open shed for large implements, *k*; and two porches, *l*. Fig. 990 is a plan of the foundations. Fig. 991 is a plan of the flooring over the barn, stable, &c., which is used for containing unthreshed corn. Fig. 992 is the side elevation showing the door of the porch. Fig. 993 is the elevation of either of the ends. Fig. 994 is a longitudinal section; and fig. 995 is a perspective view.

994

six inches on the side. The panels are filled in with studwork or quartering, and covered with weatherboarding or plaster.

1004. *General Estimate.* The actual cost, in the neighbourhood of Paris, was £150; that for the departments of France, £92. A bay may be added, in the neighbourhood of Paris, for £42; and in the departments, for £25.

1005. *Remarks.*

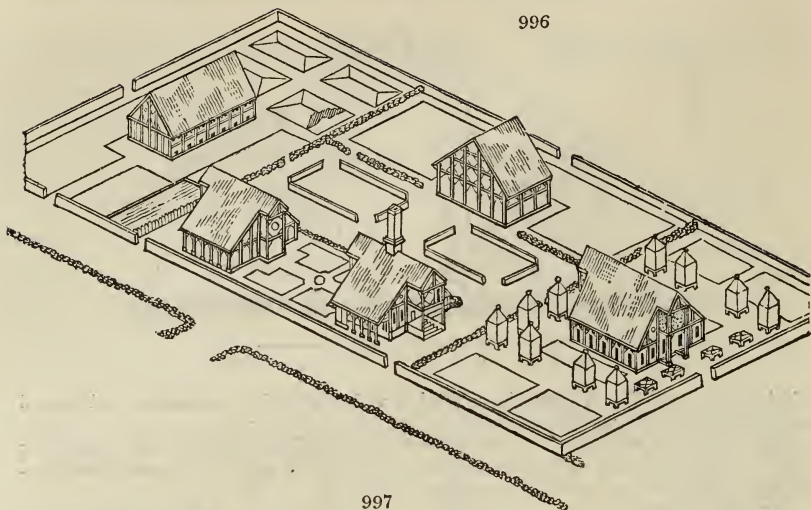

995

The great economy of this construction must be obvious. This economy results from the four cross walls being used on both sides; and from two short lines of eaves serving for the whole structure. To be convinced of this, it is only necessary to imagine the threshing-floor, corn-bay, stable, cow-house, the two implement-houses, the two poultry-places, and the pigsty, arranged as separate buildings round a square or parallelogram farm-yard, as in Britain. Add to this, the great advantage of the accumulation of heat during winter, and the exclusion of heat during summer. The steepness of the roof not only renders that part of the structure more durable, by preventing it from ever being soaked with moisture, but it actually reflects off the heat more powerfully in summer, and receives it more effectually, because at a larger angle, during winter. If eaves-gutters are considered necessary, they are only required at the two ends, and even the tubes for conducting the water from these gutters to the ground are as short as it is possible to conceive them to be. We have examined all the French and German works on Rural Architecture, and though we have found much to approve of in Lasteyrie's *Rural Architecture* and the *Landes Verschönerung*, published periodically at Munich, which, through the kindness of our friend Count Hazzi, we receive regularly, we have found nothing at all worthy of being put in competition with the *Architectur Rurale* of Morel-Vindé. We say this with the more confidence, having seen most, or all (for we cannot bear all the circumstances exactly in our mind), of his designs in actual execution, on his own beautiful estate, at Celle, in 1828. — In a wine or cider country, or on a farm where potatoes were raised in great quantities, a cellar might be made both under the threshing-floor and the bay for unthreshed corn. The two porches convey an idea of shelter and comfort, and, in fact, produce both in every building to which they are judiciously attached. We particularly recommend this Design to our American and Australian readers, and, indeed, to those of all countries where timber is the principal building material.

Design XXIV. — *A Farm House and Farmery suitable for a Farm of from Three Hundred to Five Hundred Acres in France.*

1006. *The object* of the following Design, which is taken from the work of Morel-Vindé, is to show what is considered by one of the first agriculturists in France a model farm

997

house and farmery for a large farm. Like all Morel-Vindé's designs, it will be found to be the result of much consideration, both in point of arrangement and accommodation, and of economy of construction; altogether it is eminently worthy of imitation, in countries where small timber forms the principal building material.

1007. *General Arrangement.* The farmery with its different courts, yards, and gardens stands on a space of about two acres: the general appearance is as in fig. 996, and fig. 997 is the general ground plan. This plan is arranged in four divisions. In the first may be seen the dwelling-house, *a*; an open shed on posts, *b*, under which linen is washed and dried, and maize, tobacco, onions, herbs, and various other garden productions are hung; the kitchen-garden, *c*; and part of a large pond, *d u*, for supplying water for washing, for watering the gar-

Fl. 20

10 Ft.

den, &c. The second division contains a large building, including a barn, stable, and cow-house, *e*; stands for ricks, *f*; plots of turf, *g*; and oblongs planted with apple and pear trees for cider and perry, *h*. The third division contains the sheep-house, *i*; four farm compost heaps, *k*; the pit for stercorac, *l*; two plots for cider fruits, *m*; and a part of the pond, *d*, which is divided by a fence, *u*. The fourth division contains the cart and implement shed, with granary over, *n*; a plot planted with fruit trees, *o*; two dung-pits, *r*; and the situations of open gutters, *p p p*, which collect the surface water, and deliver it either into the dung-pits at *q q*, or into the pond, *d*, as may be considered most desirable. These four divisions are surrounded by a wall, *t*; and they are separated from each other by hedges, *v*. The advantage of placing the different buildings which compose the farm house and farmery in four divisions, Morel-Vindé states to be as follows:—the absolute security against the communication of fire from one to another; the facility of maintaining an orderly administration of the business of the farm; and the thriving better of the different kinds of animals, as from their being kept distinct, they will run less risk of being injured by each other. We shall now give the details of each of these divisions.

998

1008. *The Farm House* is a model of excellent contrivance and economy. Its general appearance is shown in fig. 998; and its details, which are given with such distinctness and accuracy that the simplest country carpenter may build from them, are exhibited in

999

figs. 999 to 1008. The plan of the house is formed on the same general model as that detailed in § 742; but it is necessarily larger, in order to afford the additional accommodation required. The living-apartments are raised on four cellars, which give a bake-house and wash-house, a beer and cider cellar, a cabbage or green vegetable cellar, and a cellar for potatoes and other roots. All the living-rooms and bed-rooms for the family are contained on one floor over these cellars; and on the floor above are the bed-room for servants, and a place for drying linen. The only luxury which may be said to distinguish this plan from that

before given is, that there is a bed-room for strangers. Fig. 999 is a plan of the cellar floor, in which *a* is the wine, cider, and beer cellar; *b*, the cabbage or green vegetable cellar; *c*, the bakehouse and wash-house, with a square supporting post; and *d*, the potato-cellar, also with a post. In the bakehouse there are an oven, *e*, and a stove, *f*, which might be employed for heating the whole house. The foundations of the stairs to the principal entrance, and for descending to the cellars, are shown at *v*; those of the back door and staircase at *w*; of a small storehouse or fruit-room at *p*; of the implement-shed at *q*; of the shed for wood at *r*; and of the cesspool of the two privies at *t*. Fig. 1000 is a plan of the principal floor, in which *g* is the kitchen, with its dresser

and post, *z*, and sink stone, *u*; *h* is the parlour, with its double-sized or best bed, which in French farm houses is but seldom used, the whole family sleeping together in one large bed-room, *l*; or the master and mistress using the stranger's bed-room, *m*; *i* is the master's office, or place of business, the window of which ought to command the entrance gate to the farmery, and does so in the plan, fig. 997; *k* is a clothes-press, or linen and china closet; *l*, the children's bed-room, and room for sewing-work (*chambre de couture*); *m*, stranger's room; *n*, light closet; *o*, pantry; *p*, fruit-room; *q*, shed for all the agricultural implements used on the farm; *r*, shed for wood and other domestic purposes; *s s*, privies; *v*, entrance porch, with stair down to the cellar and stair up to the kitchen; *w*, staircase to the upper floor. In the centre of the building may be seen the octagonal funnel which receives the heated air from the stove in the cellar, and communicates with the parlour and the two bed-rooms through the lateral openings. Fig. 1001 is a plan of the upper floor, in which are seen the sleeping-room for servants, and general lumber-room, *v*; place for drying linen, *w*; and reserve bed-room, *x*. Fig. 1002 is the plan of the joists of the principal floor. In this plan the situation of the upright posts may be observed, from which it will be evident that neither girders nor joists are required of a greater length than ten feet. Fig. 1003 is an elevation of the entrance front. Fig. 1004 is an elevation of one side, in which may be seen the entrance porch, and stair to the principal floor, *c*, and the projection behind containing the staircase, *d*. Fig. 1005 is a longitudinal section through the bed-rooms, in which may be seen two stoves, *e e*, one in each bed-room; the door of the oven, *f*, and of the ash-pit under it, *g*; the stairs up to the principal floor, *h*, and down to the cellar, *i*; the inside stair to the beer-cellar, *k*; the stair to the principal floor, *l*; and to the floor above, *m*. In showing in what manner this dwelling is but an extension of that detailed in § 742, Morel-Vindé remarks that the kitchen has the addition of a pantry; that the stove in the centre, which ought to warm, dry, and ventilate the whole house, is enlarged in proportion to the dimensions of the rooms which it has to heat; and that the air which supplies combustion in this stove,

1005

must always be drawn from the exterior, which it will be, if the bakehouse door does not fit very accurately, or if the window be left partially open. Instead of the ladder for ascending to the garret in the smaller house, we have here a staircase; and the garret, which in the smaller house was intended chiefly as a granary, has now a ceiling and boarded sides, and forms a servants' room, a room for drying linen, and the reserve bedroom.

1009. *Estimate.* This building, with its two porches and sheds, covers 1580 superficial feet; and it costs, at Paris, £546: 15s.: 10d.; or, in the departments, £328: 2s.: 6d. As the cubic contents of the buildings amount to 25,280 feet, it thus appears that 5d. per cubic foot is something near the rate from which to form an estimate for this description of farm houses in the neighbourhood of Paris, and 3d. in the provinces.

1010. *Remarks on the Dwelling-house.* A superficial observer, deeply imbued with the prejudices common in Britain, and especially in Scotland and other stone countries, against wooden buildings, and not taking into consideration the fitness of means to ends, will be apt to despise the simplicity and homeliness of this farm house; but to us, who have entered into all the details of this Design, it appears perfect of its kind. The accommodation is ample for the country and state of society for which it is designed; and it is contained in a form as near as practicable to that of a cube. The mode of heating is the most perfect that could be devised; and the room for drying linen is a great source of comfort to the housewife, in rainy weather or in the winter season. It may be thought that there are too few bed-rooms, and too many beds in one room; and the bed in the parlour will no doubt appear shocking in the eyes of an Englishwoman. It should be recollected, however, that the manners of the French are materially different from ours in this respect; and that, with apparently less delicacy, they have not less moral rectitude. Whoever has travelled much by the public conveyances in either France, Germany, or Italy, must have frequently found himself going to bed in the same room with strangers of different sexes.

1011. *The Barn, Stable, Cow-house, Calf-house, Dairy, Cheese-room, Poultry-house, Pigeon-house, Piggery, &c.,* for this large French farm, are all contained in the same building. The problem to be solved is, to unite under the same roof, at the least cost, and in the manner in every respect the most suitable, a stable for twelve horses, a cow-house for as many cows or cattle, a calf-house, a dairy, a cheese-room, a poultry-house, piggeries, a harness-room, and pigeon-houses, with a barn sufficiently large for containing 6000 sheaves of grain at a time, and with two threshing-floors for threshing it. This

1006

problem is solved in the plan, fig. 1007, which presents the best possible construction of each particular requisite, and the best mode of uniting them together at the least possible expense. Fig. 1006 shows the general appearance of this building, and fig. 1007 its ground plan. The latter contains a barn with two threshing-floors: one for wheat and rye, *a*; and another for oats, peas, and barley, *c*; with a space for either straw or unthreshed corn between them; the corn being either brought in from the ricks in small quantities, as wanted to be threshed, and the straw piled up; or in entire ricks, and threshed by degrees as the straw is consumed in the stable, cow-house, &c.; *b* and *d* are porches, over which are pigeon-houses; *e* is a stable for twelve horses, fitted up with separate stalls, and a rack and manger; *f* is a cow-house for twelve cows, with separate stalls, and a manger, but

no rack, for reasons given § 757; *g* is a dairy with two windows to the north, and two doors to the east and west; *h* is a cheese-room; *i*, a calf-house; *k*, a poultry-house, grated on the side next the stable, with a view of admitting to it the heat from the horses; *l*, a harness-room; and *m*, piggeries. There is a lobby to the north at *N*, and another to the south at *S*. Fig. 1008 is a plan of the foundations. Fig. 1009 is a plan of the flooring over the

1008

stables, cow-houses, and porch; the threshing-floor being left open to the roof. Fig. 1010 is an end elevation. Fig. 1011 is a cross section. Fig. 1012 is a longitudinal elevation. Fig. 1013 is a longitudinal section through the threshing-floor. Fig. 1014 is an elevation of the racks and mangers of the stable; and fig. 1015 a section, showing the construction of the rack and manger. Figs. 1016 and 1017 contain an elevation and section of the feeding-trough in the cow-house.

1012. *Estimate.* The actual cost of this building, in the neighbourhood of Paris was £438: 17s.: 8d.; and the price for the departments of France is £263: 5s. As the cubic contents of the building are 24,052 feet, this gives 4¼d. per foot as a fair price for estimating this description of building in the neighbourhood of Paris, and 2¼d. per foot for estimating it in the provinces.

1013. *Remarks on the Building containing the Barn, Cow-house, &c.* The author observes on this plan, that the greatest care has been taken to adjust every part with a view to sufficient strength and economy. The stables and cow-houses are 14 feet 6 inches wide, and 53 feet long, inside measure; which, he says, is the smallest space that ought to be allowed for 12 horses and 12 cows. The mangers, racks, and troughs are of the proper dimensions, and are placed at the precise heights from the ground at which they ought to be. No racks are placed in the cow-house; because, if they were put sufficiently low, they would only incommode the animal when eating out of the trough; and, if they were placed as high as the racks of horses or nearly so, they would oblige the animal to

1010

raise its head, and thus endanger abortion. All the doors to the stables and cow-houses are grated, or formed with luffer-boards, in order to admit through them a continual

1011

current of air. For the same purpose, and for light, there are four windows to the threshing-floor, and one window at each end of both stable and cow-house, as may be

seen in the plan. The partition which separates the poultry-house from the stables is of trellis-work or luffer-boarding, in order that the heat may enter the former, for the

benefit of such hens as are laying eggs. The threshing-floor is 12 feet wide and 50 feet long, which allows a considerable bay for unthreshed sheaves in the middle, and space for two threshers at each of the ends. Over the spaces for the two threshers at the ends, may be floorings of joists for receiving sheaves. The middle of the threshing-floor, the two floors over the stable and the cow-house, exclusive of the spaces over the threshers, will hold two stacks of unthreshed corn, each containing 3000 sheaves (see § 815). The two porches at the two extremities of the threshing-floor are for protecting the latter from the weather; and, at top, one of them contains a pigeon-house for wild or common pigeons, and the other a cot for stockdoves. Morel-Vindé concludes by observing, that, if any one will take the trouble of examining this Design with the most severe attention, he will find that it leaves little to desire, unless the farm were of an extraordinary size. We may add, that in this case the chief addition that would be necessary would be a

threshing-machine, which might be placed at one end of the threshing-floor, and driven either by water, or by a gin-wheel under a porch sufficiently large to cover the horse-course. The building is composed of five bays 10 feet wide by 56 feet long, exclusive of the porches; hence, the expense of the two gable ends being already incurred, any number of additional bays may be introduced, at the sixth part of the first cost of the whole building. By this means the barn, stable, cow-house, &c. may be extended to any degree of accommodation required.

1014. *The Rick-stands* for this farm, which are placed around the barn in the manner shown in fig. 996, have already been described under § 815 and § 816.

1015. *The Cart-shed and Granary*, also shown in fig. 996, have been described in § 779.

1016. *The Sheep-house* has been described in § 767.

1017. *General Estimate.* The actual cost of the house, barn, stable, cow-houses, &c., and of the cart-shed and granary, in the neighbourhood of Paris, amounted to £1427, and the average for the provinces would be about £855. The expense of the rick-stands and of the drying-shed is not taken into this account.

1018. *Remarks on the Farmery as a whole.* To the eye accustomed to admire only the extensive quadrangles of stone covered with slate, common in the best agricultural districts of Britain, neither beauty nor convenience will be seen in the scattered disposition of the objects in fig. 996; but let such consider the very different circumstances which exist between a country where timber is the sole or principal building material, and another where easily worked stone is abundant. The great object, in all agricultural constructions, is, to attain the end in view in the most effectual manner, by the simplest and most economical means; and this result will be found to be as completely attained in the French farmery as in the British one. With respect to the scattered appearance of the building, that is fully justified by the security which it affords from the spread of fire; and if we imagine the whole surrounded by fruit trees, as Morel Vindé proposes, and as is generally the case in France, we shall find as much or more beauty, though of a different kind, as in any of the farmeries of Britain. We have already observed, that we have introduced this Design and others by Morel-Vindé, chiefly with a view to new countries, for which they form admirable models.

Design XXV. — *For a Court of Feeding-houses, built for the late Thomas Hibbert, Esq., at Chalfont Lodge, Buckinghamshire.*

1019. *The object* of these feeding-houses was, to fatten cattle and swine at the least possible expense; and with the greatest product of manure, consistent with a due economy of straw for litter. For this purpose, arrangements were made by open gutters in the feeding-houses and pigsties, and by underground drains communicating with them, to convey all the urine to one tank or pit. In furtherance of the same object, the dung, consisting of the litter and droppings of the animals, was conveyed from the feeding-houses, and sties directly to a dunghill under a roof, and there it was watered, by means of a pump and spouts, with the liquid from the manure tank. Fig. 1018 will give a general idea of the whole.

1018

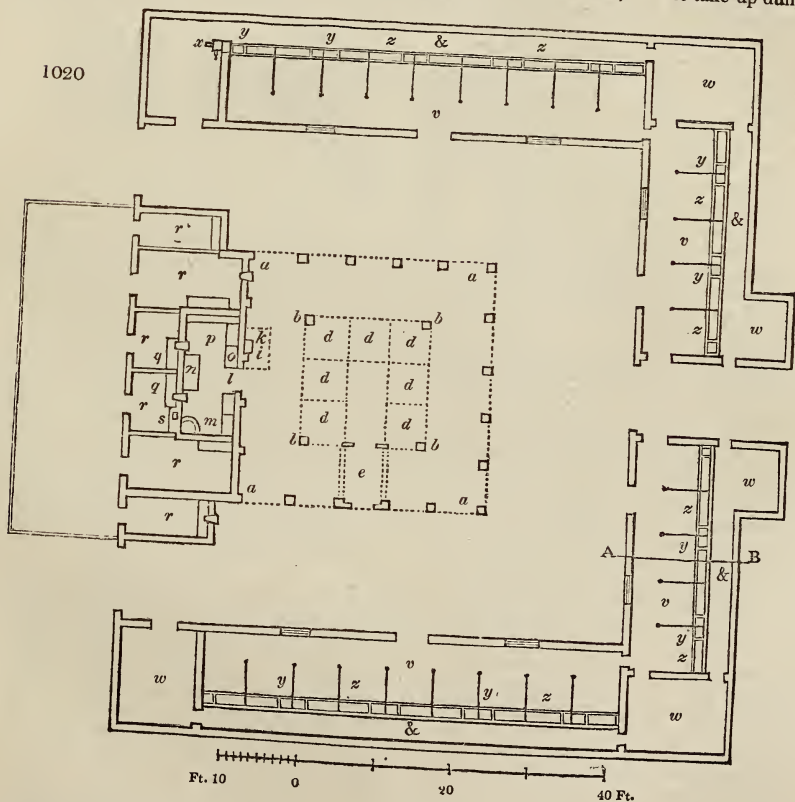

1020. *Details.* Fig. 1020 is a ground plan, in which *a a a a* form the area of the dunghill, which is covered with a lean-to roof on all sides as far as *b b b b*, which letters mark the situation of oak posts, 16 feet apart, and 8 feet high above the surface, supporting a granary floor, over which there is a pigeon-house, with the boxes for the pigeons fixed to the rafters of roofs, as indicated in the section fig. 1019, at *c c*. The floor of this granary is divided into 7 bins, indicated by the dotted lines forming the squares marked *d*, and by the same letter in the section. There is a porch, *e*, for receiving and delivering corn by means of a crane and pulley, as indicated at *f* in the section. In the upper part of this porch there is a small door to the pigeon-house, *g*, and the ascent is by an outside step-ladder, *h*. Under the porch carts or waggons may enter, and pass completely round or through the area roofed in, so as to take up dung

1019

1020

at any point. There is a cesspool, *i*, with a pump to it, rising 8 feet above the surface at *k*; and there are a number of spouts, which can be joined one to another, from the pump all over the dunghill, so as to convey the liquid of the tank to all or any part of the latter. This operation was performed at Chalfont Lodge every morning. There is a pigs' kitchen, *l*, which has a copper, *m*; hog-tank, *n*; bins, *o*, feeding hoppers, *p*; hog-troughs, *q*; and sties, *r*. The flue and chimney of the hog's copper are seen at *s* in the plan and at *t* in the section. From two of the bins in the granary there

are spouts, indicated in the section at *u u*, for shooting down corn from the granary to the bins, *o*, there to be mixed up, or used, as required. The cattle-feeding houses, *v v*, are fitted up with stalls, racks, and mangers, like stables, and there are foddering-bays, at each end, and at the angle, *w w w*, for hay, oil-cake, turnips, &c. In one of these there is a pump, *x*, which supplies water to the divisions, *y*, in all the mangers, by means of a spout, *z*, at the back of the mangers, and between them and the partition which separates the stalls from the feeding-passage, *g*. Fig. 1021 is a cross section of the feeding-houses, in the line A B, in which are seen the passage behind the stalls, *a*; the partition between the cattle, *b*; manger, *c*; water gutter, *d*; partition separating the foddering-passage from the stalls, *e*; foddering-passage, *f*; hay-rack, *g*; fodder-bay, *h*; and roof over the gateway, *i*. Fig. 1022 is a section, taken across two stalls in the feeding-house, in

which are shown, *a a*, oak posts, 5 inches square, let into the ground; *b*, a cistern for water, 3 feet in length, 12 inches wide, and 15 inches deep, placed between two stalls so as to supply water to each, and being raised 3 inches above the manger; *c c*, mangers for dry meat, 3 feet long, 12 inches wide, and 12 inches deep; and *d*, the situation of the spout or trunk of wood, 2 inches square, which runs along the back of the manger, for supplying water to the cisterns. This line of spouts is on a perfect level; so that, when water is pumped into it at one end, it runs along it to the other, supplying all the cisterns in its course. Where the spout crosses the foddering-bays and the gateway, it passes under ground, rising up again to the same level on the opposite side. These cisterns are intended to be pumped full every day, and the person pumping is rendered aware of the cisterns being full, by the water first becoming stagnant in the trunk, and afterwards running over the end immediately under the spout of the pump, which is purposely made one inch lower than the top of the cisterns. The hay-racks are shown at *e e*; *f f* are the doors through which the cattle are fed; *g g*, the boards of the partition between the stalls and the foddering-passage; and *h h*, the brickwork on which the mangers and cisterns are placed. In the construction of these feeding-houses, granary, and pigsties, all the posts which are fixed in the ground, and all the sills into which the uprights are framed, are of oak; and all the other scantling and boards are of Scotch pine, grown on the premises. The granary and piggeries have tiled roofs; but the feeding-houses are thatched with straw.

1021. *Remarks.* We received this Design from Mr. Main, who informs us that it was built in 1796, by the late Mr. Howes, land steward at Chalfont Lodge, and who was succeeded in that capacity by Mr. Main, a few years afterwards. We have made some trifling alterations and additions, for the purpose of completing the square, and giving the whole a more symmetrical form; but we have in no respect altered the dimensions of the stalls, or the different details. The arrangement and contrivance of the whole we think most excellent in theory, and Mr. Main informs us that it was found to be not less so in practice. The mode of conveying water to the different stalls may seem too expensive for common commercial farms; but it is not unfrequent on feeding farms in Lincolnshire, where oil-cake is much in use for feeding cattle. Instead of a wooden gutter, we have observed in the neighbourhood of Gainsborough, gutters, and also mangers, and stall partitions, of freestone. In most other situations, lead or iron piping would be found cheaper than wood. An immense quantity of dung, we are informed, was produced by means of the tank, from which the dunghill was kept constantly moist, and the roof over it, which prevented evaporation. We should have thought that the exhalations from the dung would have affected the air, and consequently the corn in the granary; but we are assured that this was by no means the case; because the latter was double-floored and thickly covered, on the outer side, with several coatings of boiling pitch.

Design XXVI. — *A Farmery for extensive Iron-Works, erected at ———, in South Wales.*

1022. *The object in view, in this establishment, is, to prepare food and supply lodging for fifty working horses, and the men who manage them. It was sent us by our esteemed friend, Mr. Samuel Taylor, at once a practical and scientific farmer, and a literary man.*

1023. *Accommodation.* Fig. 1023 shows the general appearance of the quadrangle;

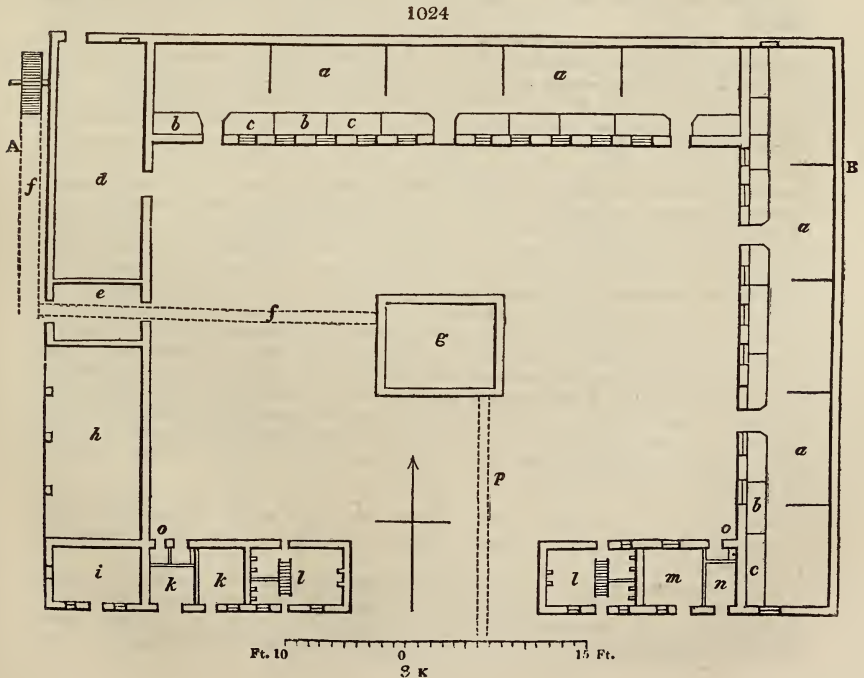

fig. 1025 is the elevation of the north side, and the section of the east and west sides, as taken on the line A B; and fig. 1024 the ground plan. The stabling for fifty horses is

in ten divisions, marked *a*, containing five horses in each. In every division there is one chaff-bin, marked *b*, and one harness cupboard, marked *c*. These bins and cupboards are formed of boards in the manner of lean-tos, as shown in fig. 1025, at *c*. They are lighted

1025

by the lower panes of the windows, their roofs being carried high enough for that purpose. The upper panes light the stable over the lean-to slope. There is a barn, *d*, in which is a threshing-machine driven by a water wheel; which wheel also drives a straw-cutter, a machine consisting of a pair of rollers for bruising oats, and one for washing turnips or potatoes. There is a turnip-house, *e*, in which turnips are washed by the tail dam, or water from the overshot wheel, which is led through the house, in the underground drain marked *f*, to the washing-pond in the centre of the yard, marked *g*. This pond is about two feet and a half deep, and is paved at bottom, for the purpose of washing the horses' legs. There is a cart and waggon shed, with a granary over, *h*; a sick-horse stable, *i*; implement-houses, *k*; two comfortable cottages, *l*, with six rooms each, three having fireplaces, and three being without; a workshop, *m*; a tool-house, *n*; and three privies, *o*. The water from the overshot wheel, after passing through the horse-pond, *g*, runs off by the underground drain marked *p*.

1024. *Construction.* The walls are of the slate stone quarried on the spot, the mortar used being made from the limestone of Aberthaw, which was considered by the late celebrated engineer Smeaton as the best in Britain; and, when mixed with clean sharp sand, as equal to any cement known in his time. The roofs are of fir covered with slate. The floors of the stables are perfectly level, with underground gutters, and gratings over them under each horse. There are no partitions between the horses, except those between every five; but the space allowed for each horse is six feet, which is more than is found in most farmeries. There are mangers of double the usual size, but no racks; the horses being fed with straw and hay cut into chaff, and mixed with corn, roots, salt, and water, and given in a semifluid state. No horses ever thrive better than those so treated; and the expense was found to be less than that of the common mode of feeding in use among farmers.

1025. *Remarks.* Little care seems to be taken, in this farmery, of the dung or liquid manure; but it is most gratifying to observe the striking difference between the labourers' cottages shown in this Design, and those on the Scotch and Northumbrian farms. The truth is, that the Scotch and Northumbrian farmers have the fear of their landlords continually before their eyes, and dare not venture to increase the comforts of their labourers, lest they should be thought too comfortable themselves. In every country, all the comforts which the labouring classes without fixed property enjoy above the starvation point, they owe to the commercial classes. Where landed property is in immense masses, farms are necessarily large, small properties few, and manufactures or commerce scarcely known. Under such circumstances, there being only a demand for one description of labour, and that of the rudest kind, the mass of the population are easily kept in a condition little better than if they were the slaves of their employers. Hence the low state of the agricultural labourers in the farm districts of Scotland and the north of England, and, indeed, of all the purely agricultural districts of Britain, compared with their state in the manufacturing, commercial, or mixed districts, where the different kinds of labour required necessarily produces different degrees of remuneration, and where the laborious classes of every description acquire higher tastes, and rise in the scale of comforts. All the comforts which the lowest class of society enjoy, they owe to the introduction of manufactures and commerce; and it gives us pleasure to pay a tribute of respect to this great Welsh Iron Company, for the comfortable cottages which they have built for their carters, as we did before (§ 481) to Messrs. Jones and Wilcox, the eminent builders, for the dwellings they provided for their workmen.

Design XXVII. — *A Farmery for a Farm of 250 Acres in the Valley of Strathmore, where a Rotation of Seven Crops is followed, the Grass Division being pastured the Second Year.*

1026. *Accommodation.* Fig. 1026 shows the general appearance, and fig. 1027 is the ground plan. In the latter are seen three cow-houses, *a*; with foddering-bays, *b*; barn, *c*; horse-course for threshing-machine, *d*; straw-barn, *e*; stable for ten horses with a foddering-bay in the centre, *f*; house for potatoes or grass, *g*; two-stall stable, *h*; cow-

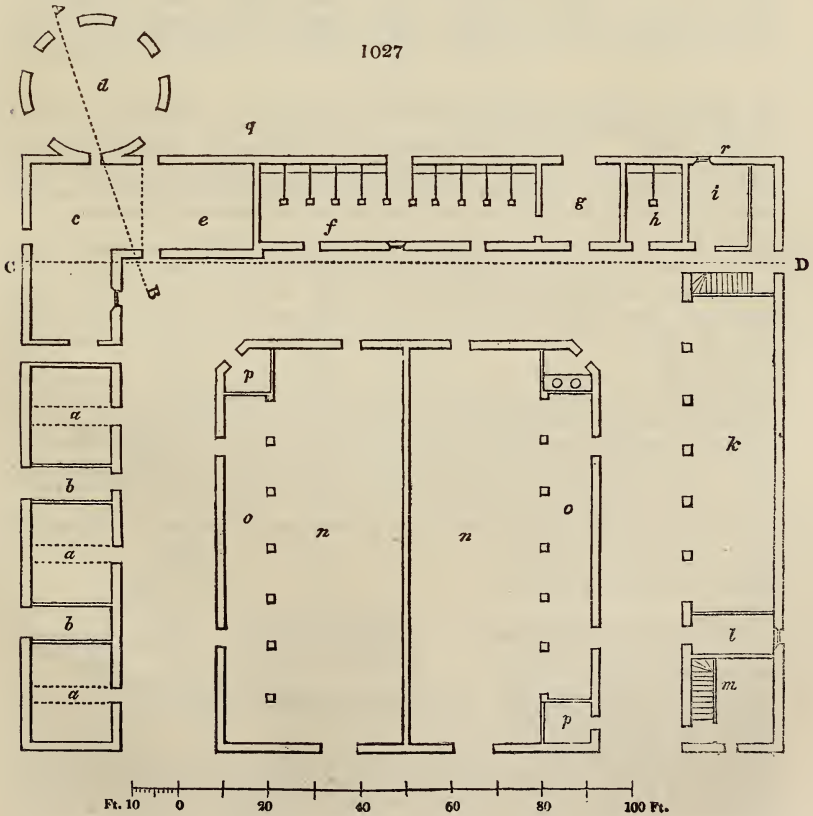

1026

house, *i*; cart-shed, with granary over, *k*; carpenter's shop, *l*; tool-house, with spare room over, *m*; cattle-yards, *n*; open sheds for cattle, *o*; pigsties, *p*; and rick-yard, *q*.

1027

A place for poultry is supposed to be formed over the cow-house, *i*; and entered by an outside stair at *r*.

1027. *Construction.* The walls are of stone, and the roof slated. All the doorways and window-openings have facings, sills, and lintels of dressed stone, and all the doors are hung by strap hinges on hooks leaded into the stone; and they shut into rebates in the jambs. The feeding-houses have ventilators in the roof; one upright tube, about a foot square, with a cover to protect it from the rain, being placed in the ridge over each stand of four cattle. Fig. 1028 is a section across the mill-shed and barn, on the line

A B; and fig. 1029 is an elevation and two sections on the line C D. In the latter, the stable window, *s*, is shown with the upper part of glass and the lower part of spars for

the admission of air, with an inside shutter for occasional use. The stable-loft windows over are shown luffer-boarded.

1028. *Remarks.* This Design has been sent us through our esteemed friend and valuable correspondent Mr. Gorrie, by Mr. James Chalmers, land surveyor, and land steward at Muithly, in Perthshire. Mr. Chalmers is evidently a good Architect as well as land-surveyor, the Design being well arranged, and the elevation architectural.

Design XXVIII. — *A Farmery for a particular Situation, suitable for Eighty Acres of arable Land, and Three Hundred Acres of Pasture, in the Carse of Gourie.*

1029. *This Design* is calculated for a steep declivity; so much so, that the floor of the granary and straw-loft, which is on a level with the ground on one side of the range, is ten feet above it on the other. The general appearance is shown in the isometrical view, fig. 1031.

1030. *The Accommodations* are seen in the plan, fig. 1032, in which *a* is a cart-shed with a granary over; *b*, the threshing-mill course; *c*, the dressing-barn; *d*, a stable; *e*, a feeding-house for cattle; *f*, a cow-house; *g*, a poultry-house; *h*, a boiling-house; *i i*, ploughmen's cottages, each sixteen feet by seventeen feet, and two stories high; *h*, a privy; *l l*, cattle-sheds; *m m*, open yards for cattle; *n*, pigsty of the farmer; *o o*, pigsties of the two cottagers; and *p p*, the gardens of the cottagers; each containing twelve falls, or about one thirteenth of an acre.

1031. *Construction.* The walls are of the common stone of the country, and the roofs slated. Fig. 1030 is a section taken on the line A B, which shows the steepness of the situation.

1032. *Remarks.* This Design has been sent us by Mr. Gorrie, accompanied by the following remarks: — "The dung from the stables, and cow and cattle houses, is thrown into the cattle-yard across the road, by which means it becomes mixed with the litter of the yards in which young cattle are kept during winter and spring, and enclosed in summer and autumn. The advantage offered by this form of farmery, when the

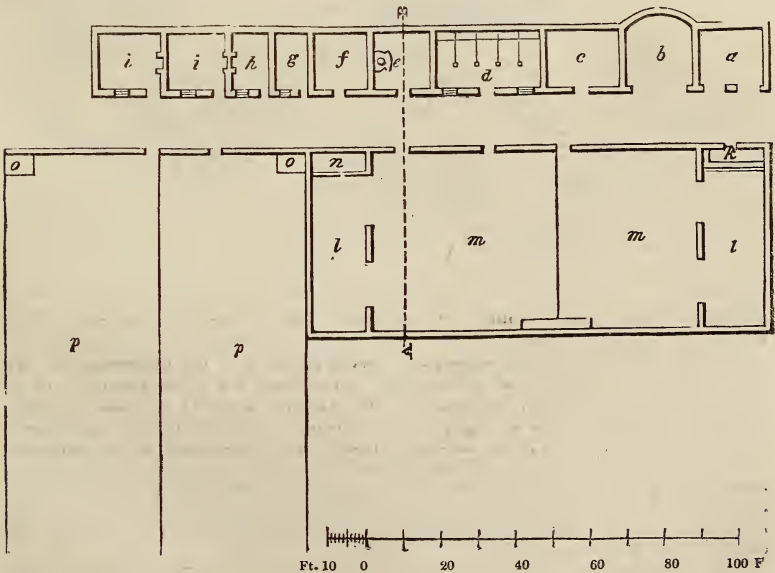

1031

buildings are not of sufficient extent to enclose three sides of the straw or cattle yard, and where the surface of the ground is a declivity, is, the facility of carting in corn to the threshing-mill loft in winter, and turnips for the byres in sharp seasons; and clover for the stable and byres in summer. The disadvantages of adhering strictly to this plan, which is taken from an old steading, are the narrowness of the threshing-mill course for a

103

mill of four-horse power. The machinery, too, being across the house, is too much confined, admitting of only one shaker (a part of the machine), which throws the straw on the loft, imperfectly freed from the grain. In the present instance the ground occupied by the steading is on a dry freestone rock, and the lower part of the range does not suffer from damp, to prevent which expensive draining would be necessary for a similar range on humid soils. A turnip-house placed at the back of the feeding-byre is a desideratum

in this Design, but was not thought of in laying it out; the culture of turnips not being extensive when it was built. Potatoes are for the most part kept in pits, and a house for that article is often dispensed with in this district." We consider this Design of considerable value, as indicating how to manage farm buildings on declivities. In such situations, where there is a stream, very favourable opportunities frequently occur of driving the threshing-machine by water, with very little expense in forming the head-dam or tail-dam. At Underley Park, in Westmoreland, there is a very complete farmery, built on the margin of a stream, the barn stretching across it, and the wheel of the threshing-mill so contrived as to meet the whole of the water of the stream. The banks being thirty or forty feet high on one side, and not much above the level of the water on the other, the corn is carted from the ricks into the barn, and shot down at the feeding-board of the machine; it is cleaned in the floor below, from which, through a trap-door, it is dropped into the ground floor, or into carts to be taken to market. We saw this farmery in 1811, and then considered it, in this and in various other respects, as remarkably complete.

Design XXIX. — *The Farm House and Farmery of Starston Place, near Harleston, in Norfolk, suitable for a Farm of 350 Acres under the Norfolk System of Culture.*

1033. *Accommodation.* The general appearance is shown in fig. 1033, and the ground plan in fig. 1034. The house contains a vestibule, *a*; two parlours, *b*, *c*; an office, *d*;

1033

a lobby, *e*; store-room, *f*; pantry, *g*; kitchen, *h*; back-kitchen and bakehouse, *i*; back entrance, *k*; a dairy, *l*; and larder, *m*. In the farmery there are: — 1 1, barns; 2 2, porches to ditto; 3 3, cattle-sheds; 4 4, cattle-yards; 5 5, turnip-houses; 6, cart-horse yard; 7 7 7, cart-horse stables; 8 8, hay-houses; 9 9 9, chaff-houses; 10 10, horse-sheds (open to yard); 11, yard for colts; 12, shed to ditto; 13, stable to ditto; 14 14 14, pens for sheep or pigs; 15 15, pigsties; 16 16, swill-house and cistern; 17, cow and sheep yard; 18, cow-shed (open); 19, cow-house; 20 20, calf-cribs; 21 21, hay and turnip-houses; 22, horse-pond; 23, sheds for waggons, carts, and implements, with granary over; 24, stack-yard; 25, house for horse-wheel; 26, chaff engine-house; 27, shed for implements; 28 28, &c., passages; 29 29, &c., lock-up gates; 30, riding-horse stable, chaise-horse, carpenter's shop, tool-house, &c.; 31, garden and orchard; and 32, kitchen-garden.

1034. *Construction.* All the walls of the buildings and yards are of flintstone, as are those of the barns, to the height of 6 feet, above which they are of studwork, boarded, 14 feet higher. The house and all the farm buildings are covered with slates.

1035. *Remarks.* This Design was contributed by Mr. Samuel Taylor, the nephew of the proprietor of Starston, Meadows Taylor, Esq., of Diss. The general arrangement seems good; all the cattle-houses and cattle-yards being conveniently situated with regard to the two barns; and the cart-shed, 23, and carpenter's shop, tool-house, chaise-

1034

house, &c., 30, being detached from the buildings and yards for animals; and, consequently, being free from straw, the obligation of opening and shutting gates, and the risk of letting out cattle, &c. The farm house has the most ample accommodations. Mr. Taylor has sent us a plan of Starston farmery, as it appeared some years ago, when the same accommodation was scattered about in all directions, to the great inconvenience of the occupant. In reply to some questions respecting the construction of the racks and mangers, and the farm-yard management of Norfolk, Mr. Taylor has sent us the following valuable information:—

1036. "The Norfolk System of Farming Management differs materially from that pursued in most other counties of England, in not having any stalls or divisions in the stables, save, perhaps, one for a vicious or troublesome horse; the rest stand close to each other, each tied to the manger by a halter, at the end of which is a log of wood, as in fig. 1035, sufficiently heavy to draw down the halter after its being raised by the horse, in lifting up his head; and thus, by keeping the line stretched, preventing the horse from getting his feet entangled therewith. The horses are not confined to the stable, except at feeding and cleaning times, when they are tied up; at other times they are turned into a dry well-littered straw-yard, between the stable and the horse-sheds, 10 10, which, being open to the yard, they can resort to for shelter. The door of the stable is left open every night. This is done in all seasons, and in all weathers; and it is a well-known fact, that, be the weather ever so rough, the horses generally prefer lying in the open air. Of course, in pursuing this yard system, it will be desirable to keep a good look-out, especially in the first instance, that no horse of a quarrelsome, domineering temper be suffered to mix with the

rest. Again, in some stables, there may be a horse of a particularly timid disposition, who seems a sort of butt of the whole stud; and who, if he could speak, would doubtless exclaim with Falstaff, ‘Nags of all sorts take a pride to gird at me.’ All such should be separated from their fellows, or accidents will very likely happen. It is not well to put too many horses together in one yard. In Lancashire and other parts of the north of England, the farm horses are clothed up in warm close stables; the consequence of which is, that if a horse stand any little time in a cold wind, even though his cloth be on, he is almost sure to catch cold, and be laid up. Now, a Norfolk man never clothes his horses; unless, perhaps, in very severe weather, when a carter throws a sack, or some such covering, over the horse’s loins, while corn or other articles are loading or unloading. This is proper enough, but anything beyond it tends to make the animal tender, and susceptible of cold.” With respect to the keep of farm horses, Mr. Taylor is decidedly in favour of cutting their fodder, whether it be hay, straw, or a mixture of both. The best criterion of the excellence of this plan is the fact, that, in seasons when the hay crop is unusually short, farmers invariably resort to it as a measure of economy, in order to make their stock of fodder hold out.

1037. *The Norfolk System of managing Cows and Cattle* is the same as that for horses; except that in the cow-houses and cattle-sheds there are no racks, but only troughs or mangers from which they eat their food.

1038. *The Sheep System of Norfolk* is very simple; though some persons go to a great expense for movable racks and feeding-troughs. Mr. Taylor thus describes, in the *Country Times*, a movable fold, with a sheep-rack attached, which he used for a number of years:—“It is well known that, in setting and striking a fold in frosty weather, there is not only great difficulty, but that the wear and tear of the hurdles is considerable; to say nothing of the loss of time incurred by the frequent repetition of this operation. Wicker hurdles are made on a frame, with holes bored for the upright stakes; and around and between which, the smaller wood is woven or wattled. The frame is usually six feet long, and of course this is the length of each hurdle. Instead of a six-foot frame, get a larch pole, or oak stand that will square about five or six inches, and is about eighteen or twenty feet long. Bore holes in this similar to, and at the same intervals as, those of a hurdle frame; then fix it on a pair of axletrees about four feet long; each axle-tree having attached to it a pair of cast-iron wheels, just high enough to carry the hurdle when finished; the whole presenting an appearance like that of fig. 1036. For greater strength, the end uprights may be of iron, fastened to the bottom with nuts and screws. Fig. 1037 is an end view of the hurdle on its axle, with the addition of a small, or bank,

hurdle, as it is sometimes called, sloping outwards, and forming the economical hay-rack of which we have been speaking. Being low, the strain on the main hurdle is but trifling, and it is easily kept in its place by tar-line. The hay forms not only food but shelter for the sheep. About a fourth of the total length of the movable fold may thus be made into hay or straw racks in a very few minutes; and the whole fold can be shifted by a man and a horse in the tenth of the time it would take to remove it if formed of common hurdles and stakes. Iron rings or staples are provided at the end of each division of the fold, to which the horse is fastened when it is wanted to be moved. There being but little wear on the hurdles, they will last treble the time of those in general use, and, even when the wickerwork decays, it may be replaced at the cost of a few shillings. A fold on the same principle was invented by the late Mr. T. Plowman of Broome, near Bungay, but it was made of sawn stuff, painted, and of course vastly more expensive in its construction.” (*Country Times*, vol. i. p. 27.) Mr. Taylor has suggested a still cheaper sheep-rack and fold, which may be formed in a few minutes, of wicker hurdles (which cost about 10s. or 11s. per dozen), set sloping round a yard, as represented in the section fig. 1038; the yard itself being supposed to be fenced in with bush faggots (faggots composed of thorns from the hedges, which, when wanted for yard fencing, ought to be cut with the leaves on, and stacked flatwise previously to using, in order to render them close and compact; thus treated, they will also go further, and make a better fence); *a* represents the line of hurdles, and *b* the faggot fence. The hurdles may be secured at top to the stakes of the faggot fence with a piece of tar-

line, *c*. Between the hurdle and the faggots is placed the fodder, which serves the triple purpose of food, shelter, and protection to the sheep from the thorns of the faggots.

1039. *The Norfolk System of managing Swine* has nothing in it which requires any variation of construction from the form of pigsties in use in other districts.

1040. *A Substitute for Rickstands*, the invention of the late ingenious and excellent Robert Paul (see his humane rat trap, *Gard. Mag.* vol. vi. p. 584.), Mr. Taylor recommends as being equal for ingenuity and utility to any of the more costly inventions that have been published, having practised it himself for several years. "At harvest time the stack, as soon as up (every thing depends on this), is cut under a little at bottom; and immediately a coat of mortar, or clay and horse-dung mixed, is applied round the bottom to the height of about two feet and a half; the stack, when finished, presenting the appearance of fig. 1039; in which *a* is the upper line of the composition spread round the foot of the stack. If the soil on which the stack is placed be soft and sandy, it may perhaps be advisable to form a bottom projecting from the stack, as shown at *b*, covered with the same composition as the space between *a* and the ground; but this need not occupy the whole area of the stack bottom, but only a circle round its edges, formed somewhat like a quoit, as at *c*. It must not be forgotten that the complete success of this plan depends on its being executed as soon as the stack is built; an hour must not be lost, otherwise vermin may get possession. Too much caution cannot be taken to suffer no straw, ladder, nor stays, to remain near the stack, and in contact with it; for by them mice may get in, and if once there, they are not to be got out; for they do not, like rats, leave the stack for drink, not requiring it: they breed fast, and do a vast deal more harm to wheat than rats. This plan of Mr. Paul's is adopted by Mr. Coke at *Holkham*. The expense is only a few shillings for even a large stack." Perhaps to some it may appear a deviation from Architecture to enter into the uses of structures to the extent which we have done here, and in other instances: but we are decidedly of a different opinion; feeling confident, from experience, that no real improvement will ever be made in any class of buildings, with the uses of which the Architect is not thoroughly acquainted.

Design XXX. — *A Farmery for a Farm of 300 Acres of arable Land, and 500 of Pasture, in the West Highlands.*

1041. *Accommodation.* The general appearance is shown in the isometrical view, fig. 1040, and the ground plan in fig. 1041. The latter shows a pigsty, 18 feet and a

1040

half by 12 feet, *a*; a room for the corn-chest and horse-harness, *b*; a working-horse stable 16 feet wide, and 48 feet and a half long, for ten horses, *c*; a riding-horse stable, with two

spare stalls, *d*; a place for general purposes, *e*; a tool-house, *f*; cattle-sheds, *g*; straw-house, *h*; a barn with a granary over it, *i*; a stair to the granary, *k*; a horse-course under the mill-shed, *l*; the turnip-house, *m*; cow-house, *n*; cart-sheds, *o*; cheese-room, *p*; milk-house, *q*; calf-house, *r*; and poultry-house, *s*.

1042. *Construction.* The walls are built of the local stone, 2 feet thick where the buildings are two stories high, and 18 inches thick where they are only one story in height. The stable and cow-house doors are 3 feet and a half wide, and the others 3 feet. The door in the end of the stable is 4 feet wide, and those of the pigsties, poultry-house, and calf-house are 2 feet and a half. The mill-shed is 30 feet in diameter, outside measure; and the horse-course is 4 feet wide. The timber of the roofs is Highland fir, and the slate is from Westmoreland. Other particulars of construction will be found in the specification of a succeeding Design.

1043. *Estimate.* Cubic contents 114,912 feet; which, at  $1\frac{3}{4}d.$  per foot, the price which it appears such buildings cost in the Highlands, is £837 : 18s.

1044. *Remarks.* This Design, and the three which follow, have been sent us by William Ross, Esq., Architect, Bristol; a native of that part of Scotland for which these farm buildings are intended, or in which they have been executed. The arrangement of the ground plans of the whole, and the details of the specification given with the fourth Design, show an intimate acquaintance, on the part of Mr. Ross, with the accommodations required; and we therefore consider them as well deserving a place in this collection. Mr. Ross observes that the prevailing winds in the neighbourhood of Tarbat, in Ross-shire, are from the N. W.; for which reason he has put the low side of the square, and the entrance gate, on the S. W.; and generally placed the buildings which require to be two stories high on the N. W. and N. E. sides. These are obviously judicious arrangements. — In the Design before us, the barn and straw-house are centrally placed; and the feeding-passages from the latter are convenient. We should have preferred reversing the position of the large stable, with those of the tool-house and turnip-house, for the sake of connecting it with the feeding-passage; but Mr. Ross informs us that it is placed in its present position, agreeably to Waistell's maxim, that the stables and cattle-houses should be near the dwelling-house, to hear when any thing is wrong among the cattle. In a cold country like Ross-shire, it is very desirable to have the pigsties entirely roofed in, as they are in this Design; and we think the poultry-house should always be placed adjoining the cow-house or stable, for the sake of heat. The corn-chest and harness-room, connected with the stable, is good and convenient; the horses are in separate stalls, which ought always to be the case where they are fed on corn, unmixed with cut straw or chaff; because, otherwise, a fast-eating horse, when near a slow-eating one, will take part of his share. Where horses are fed on oats, or succulent food, mixed with chaff or cut straw, they may stand without stalls, as in Norfolk.

Design XXXI. — *A Farmery for 200 Acres of arable Land, and 300 of Pasture, in the West of Scotland.*

1045. *Accommodation.* The general appearance is exhibited in fig. 1042, and the ground plan in fig. 1043. In the latter are shown, in the house, a lobby, *a*, 10 feet 4 inches by 4 feet 6 inches, with a staircase and passage; a parlour, *b*, 11 feet and a half square; a dining-room, *c*, 13 feet and a half square; a bed-closet, *d*; a pantry, *e*; and a kitchen, *f*. On the floor above are four good bed-rooms and a bed-closet. In the

1042

farm-yard are two cattle-sheds, *g g*; a stable, *h*, with 12 stalls, 5 feet wide each; a tool-house, *i*; straw-house, *k*; barn, *l*; shed, *m*; hen-house, *n*; pigsty, *o*; cart-shed, *p*; calf-house, *q*; and cow-house, *r*, 20 feet by 18 feet, for ten cows. The construction is the same as in the preceding, and in the two following, Designs.

1046. *Estimate.* The cubic contents of the house are 19,200 feet; which, at 3*d.* per foot, is £240; those of the farmery are 97,370 feet; which, at 1½*d.*, is £608 : 11*s.* : 3*d.*

1047. *Remarks.* The arrangement of the farm buildings is compact, though we do not approve of the cattle-sheds fronting the N.E.; and as much is made of the house as could well be desired: the only circumstance in it that we regret is, the placing of the fire-places in the outside walls. But this plan of putting the fire-flues in the outside walls is not without some advantages: it renders thick walls wholly unnecessary in the interior of the building; in which case, as all the divisions between the rooms can be formed of quartering, lathed and plastered, such houses necessarily cost much less than those which, having thick outside walls at any rate, have also one or more thick walls inside, for the sake of the chimneys. It may also farther be observed, that, in countries where fuel is abundant, it is a matter of much less consequence whether the fireplaces are in the outside walls, or in the interior ones. In most parts of the Highlands of Scotland the fuel is peat, and hitherto it has been to be had in abundance. The idea of incurring any expense in construction therefore, with a view to saving fuel, is entirely out of the question. Equally so, we might add, is the idea of incurring expense to free the occupant from the risk of a smoky house; peat smoke being familiar to every inhabitant of the Highlands, more especially to the farmers and the working classes. In fact, houses regularly built of stone and lime mortar, are, comparatively speaking, luxurious in that part of the island. The reader who wishes full information on this subject, may consult *Lock's Account of the Improvements made on the Marquess of Stafford's Estates in Sutherland and Ross-shire.* In this work it is stated that numbers of the inhabitants refused to live in the new houses prepared for them, and others required some years to be reconciled to the clean and cold appearance which they alleged was produced by the want of smoke.

1043

Design XXXII. — *A Farm House and Farmery for 200 Acres of arable Land, and 300 of Pasture, in Ross-shire.*

1041

1048. *Accommodation.* The general appearance is shown in fig. 1044, and the ground

plan in fig. 1045. In the latter, the house contains a living-room, *a*; small office or business-room, *b*; and kitchen, *c*. On the garret floor are two bed-rooms, *d*, *e*, lighted from windows in the gable ends, and with closets partitioned off under the roof. The farmery shows a place for hogs, *f*; potato-house, *g*; boiling-house, *h*; washing-house, *i*; cattle-shed, *k*; spare stable, *l*; work-horse stable, *m*; straw-house, *n*; barn, with granary over, *o*; mill-shed, *p*; cow-house, *q*; tool-house, *r*; dairy-scullery, *s*; dairy, *t*; cattle-shed, *u*; cart-shed, *v*; calf-house, *w*; temporary enclosure for calves, *x*; poultry-place, *y*; and privy, *z*. The construction is the same as that of the two preceding, and of the following Design.

1049. *General Estimate.* The cubic contents of the house are 13,376 feet; which, at 3*d.* per foot, is £167 : 4*s.*: those of the farmery are 112,708; which, at 1½*d.*, is £704 : 9*s.* : 4*d.*

1050. *Remarks.* This is a compact well arranged Design, as far as respects the farmery; and the washing-house appears to be a substitute for a back-kitchen to the dwelling-house; the latter being on a very confined scale, and, we suppose, intended for the residence of the grieve (bailiff). The cattle-sheds, *k* and *u*, are judiciously contrived so as to shelter the cattle both from the north-east and south-west winds, according to the prevalence of either; these winds being most severe.

Design XXXIII. — *A Farm House and Farmery for 500 Acres, half Pasture and half arable, erected at ———, in the Parish of Tarbat, Ross-shire.*

1051. *Accommodation.* The general appearance is seen in fig. 1051, and the ground plan in fig. 1046. In the latter the house shows a dining-room, *a*; parlour, *b*; bed-

room, *c*; kitchen, *d*; and pantry, *e*; and on the floor above are four garret bed-rooms. The farmery shows a pigsty, *f*; place for calves, *g*; corn-chest, and harness-room, *h*; stable, *i*; privy in the same, *k*; spare stable, *l*; barn, *m*; covered horse-course, *n*; stair to granary over the straw-house and cattle-sheds, *o*; straw-house, *p*; cattle-shed, *q*; pump and water-trough, *r*; cattle-shed, *s*; poultry-house, *t*; cart-shed, *u*; cow-house with feeding-passage, *v*; boiling-house and dairy scullery, *w*; dairy, *x*; and coal-house, *y*.

1047

1048

1409

1050

1052. *Construction.* The materials and kind of workmanship will be found detailed in the following specification, obligingly sent us by Mr. Ross; and which is intended to be elucidated by fig. 1047, a section and elevation on the line A B of fig. 1046; by fig. 1048, a section on the line C D; by fig. 1049, an elevation of the north side of the same figure; and by the section across the stables, fig. 1050.

1053. *Specification of the Carpenter's, Mason's, Plasterer's, and Painter's Works, intended to be done in building and finishing a Farm Steading for* \_\_\_\_\_, tacksman (tenant on lease, a lease in the north of Scotland being called a tack) of \_\_\_\_\_, Parish of \_\_\_\_\_, Ross-shire, under the direction and to the entire satisfaction of William Ross, Architect, of No. 11. Pritchard Street, Bristol; and which is further explained by drawings made for that purpose.

1054. *It is to be understood that the following conditions apply to each trade respectively.*

1055. *The Contractor is to find and provide every kind of materials, labour, hoisting, carriage, scaffolding, rules, moulds, tools, and tackle necessary for the due execution of the works, correspondent with this specification and drawings, to the full intent and meaning of both, as no extra-charge or day-bill will be allowed for any thing implied, expressed, or set forth, in either of them.*

1056. *The Materials are to be the best of their respective kinds, and the Architect, or his agent, shall have full power to reject any materials that may be brought on the premises which he may consider unfit for the purpose, or different from those described to be used in the works; and likewise the power to cause any unsound work to be altered, at the contractor's expense, or any works that are not executed according to the true intent and meaning of this specification and drawings, and to the directions which may be given from time to time by the Architect or his agent.*

1057. *The Care of the Building is to be with the contractor, as* \_\_\_\_\_ (the proprietor) will not be accountable for any thing that may be damaged, destroyed, or removed; but the whole must be left clean, perfect, and complete, in every respect, at the conclusion of the works. \_\_\_\_\_ will not be bound to accept even the lowest tender, nor to proceed with the works, unless the amounts of the estimates are satisfactory.

1058. *The Contractor must not allow any alteration to take place from this specification or drawings, without first obtaining a written order for the same from the Architect, or the proprietor, particularly describing such alteration; but if* \_\_\_\_\_ (the proprietor) or his Architect think proper to make any addition or omission, or to deviate in any manner from the drawings and this specification, such alteration, whether an addition or omission, shall not invalidate or make void this agreement, but the same shall be ascertained in the usual and customary way by admeasurement, and either added to or deducted from the amount of the contract (as the case may be), according to the list of prices herein after mentioned; and all extras or omissions not included in such list will be monied out (calculated) in proportion to such list.

1059. *Tenders must be delivered in separate amounts for each trade; and it must be distinctly understood, that in each case a detailed bill of every article contained in the*

estimate, together with the price at which each article was monied out, must accompany such tender sealed up, or it will not be accepted; and all variations from this specification and drawings, which may be ordered, shall be monied out from such list, and which is to remain in the hands of the Architect for that purpose.

1060. *The Works to be executed* in the most sound, substantial, and workmanlike manner; and, that the contractor may not consider himself in any way aggrieved, he must take special notice that *every circumstance* appertaining to the well-doing of the works will be *most strictly* insisted on, to the full intent and spirit of this specification and drawings; and that no indulgence will be allowed for any breach of covenants; and if any difference of opinion shall arise as to the quantity or quality of the workmanship or materials, or upon any other matter connected with the works, the contractor must in all cases be bound by the decision of the Architect.

1061. *The Works to be immediately begun* by taking down those parts of the present buildings that are intended to be removed, in the most careful manner; shoring up as will be necessary the adjoining walls, &c., which will be at the contractor's risk, until they are fully secured; repairing and making good all the walls, &c., that may be disturbed in consequence of this contract.

1062. *The Contractor may see the Site*, and he is expected to provide for every thing required to execute the works, without any extra-charge whatever, for any thing omitted in this specification or drawings.

1063. *The Money* is to be paid at the rate of £75 per cent on the amount of work done, by certificates to be signed by the Architect, and payable at fourteen days' sight; but the Architect will not certify for any sum less than £60, and the balance will be paid upon the certificate of the Architect, that the works are completed to his satisfaction, by bill at four months.

1064. *Carpenter*. The timber (unless where otherwise particularly described) is to be the best natural-grown Spey timber (Scotch pine, grown in a native forest on the banks of the Spey, and generally considered of superior quality); and, together with every other species of timber which may be hereafter described, for carpenter's and joiner's work, is to be well seasoned, for which affidavits must be given, if required by the Architect. The whole to be perfectly sound, free from sap, shakes, dead parts, and large knots.

1065. *All the Materials will be carted* from Portmahomack by the proprietor; but the contractor must not delay the carts unnecessarily, otherwise the proprietor will charge for such detention, and will deduct the amount from the balance in his hands.

1066. *All Timbers* to be coggged (notched) down, so as to have a solid bearing on the walls and plates; no joist, standard (quarter), or rafter, &c., to be more than 18 inches apart in the clear. All lintels, and filling in lintels (lintels behind the front lintels), to be not less than 2 feet longer than their respective openings, and 1 inch thick for every foot the opening is wide, and shored up where requisite. All bridlings (trimmings) and bridling joists to be one eighth of an inch thicker than the other joists, for every joist they support. The joists to be bridled (trimmed) for wells of stairs, for fire-places and vents, and stiffened with herring-bone strutting, at distances not exceeding 4 feet apart. All scantlings and other dimensions given, must hold good, when the works are completed, cleaned off, and finished. No panels to be, when cleaned off, less than five eighths of an inch thick. To provide for all centring for arches, &c.; also, all blocks, studs, beads, stops, fillets, bilgets (wooden bricks). None of the flooring-boards to be more than 6 inches wide, and they must be prepared, and brought on the premises five weeks before they are laid. All the framing, such as doors, sashes, &c., must be got out in six weeks from the date of the contract; but not to be wedged up until the Architect or his agent directs. The door-frames are to be built in the walls, with horns (the lintels with projections beyond the styles) and side arms (side pieces to bond in), and tenoned into stone sills. The roof is to be formed as shown in the drawings, and of the several scantlings thereon figured, and well nailed with double garron (6-inch spikes) nails. All plates to be in long lengths, and chacked (notched or halved); or dovetailed together, and well spiked. To lay the floors throughout (unless where otherwise directed) of 1½-inch Tarlogie (a native forest) deals, straight-jointed, ploughed, and feathered. The stairs to be formed as shown in the plan, of 1½-inch Tarlogie deals, glued and blocked, complete, with 1¼-inch wall string and torus on upper edge; and where an open well is shown, to have 1½-inch front strings. All the treads and risers to be ragged (housed) into strings, and the whole to have strong carriages complete; handrail to be put from the barn to the threshing-floor, as shown, with ¾-inch balusters, with three iron balusters, flanged and screwed complete: the handrails to be of Spey fir. The locks, bolts, and fastenings to be found by the proprietor; and the contractor will find screws, and fasten them on without any extra-charge for the same. The roof must be ready to receive the covering on or before the day of , and the whole of the works finished and completed on or before the

day of \_\_\_\_\_, or else the contractor shall and will allow the sum of £5 per week, as liquidated damages, for each week he may exceed the time allowed for being ready with the roof, for covering in, or for the completion of the works; and which sum or sums will be deducted from the balance due to the contractor, remaining in the hands of the proprietor.

1067. *Joisting.* All the wall plates to be 7 inches by 1 inch and a half. The sleepers in the dressing-barn (the part of the barn appropriated for dressing corn) to be 6 inches by 2 inches and a half, built in as described in the mason's work. The joisting of the barn and granary floors to be 10 inches by 2 inches and a half, with 1 foot of wall hold. The cart-sheds to have a joist 8 inches by 2 inches and a half, built into the wall at each pillar, and chucked to the lintling beams, 9 inches by 12 inches, and screwed to the same with a half-inch bolt, the other end of the same joist to be chucked to the wall plate in the same manner.

1068. *Doors.* The whole of the doors to be made of Tarlogie deals, not more than 6 inches wide, and 1 inch and a quarter thick, ploughed and beaded on the joists, with three  $1\frac{1}{4}$ -inch cross bars, and well nailed. The stable, byre, and barn doors to be hung in two leaves. The whole of the doors to be hung with crooks and bands; the crooks to be laid on the bed of the rybats; the crook to be split in the tail (in order to serve instead of a rivet), and to have 7 inches hold of the stone, and to be well batted (run) in with lead; the pin of the crook to be 1 inch and an eighth in diameter; each crook to weigh 3 pounds and a half. The bands to be 22 inches long, three eighths of an inch thick at the neck, and 2 inches broad, with  $\frac{3}{8}$ -inch screw-bolt to the neck of each; each band to weigh 4 pounds and a half. The band nails to have counter-sunk heads, and properly riveted; sunk ring latches to all the doors, and 8-inch stock locks to the granary, barn, poultry-house, milk-house, and coal-cellar doors only.

1069. *Windows.* The frames of the barn and milk-house windows to be 2 inches thick, and filled in at bottom with boards 16 inches high, hung to frames on cross-tailed bands, and glazed above with third crown glass; those in the granary, stables, &c., to be filled in with weather-boards 6 inches wide and 1 inch thick, chamfered on the outer edges, hung with iron pivots in a frame 3 inches by 2 inches, having a strap of iron attached to the inside, and movable up and down, to admit air when wanted.

1070. *Stables.* The hind posts of the trevises (partitions) to be octagons of 6 inches and a half in diameter above the pavement, and sunk in solid masonry, as shown in the section, fig. 1050; the part built in to be charred, and the tops to be rounded. The fore posts to be 4 inches and a half by 2 inches, the foot set in a stone;  $1\frac{1}{2}$ -inch trevise-boards to be mortised into the hind post, which must be set 8 feet from the front wall. The trevises to be 6 feet high at the front posts, and 4 feet and a half high at the hind posts; to have angle warpings (braces) 4 inches by 1 inch and a half, and to be nailed with double double nails (20d.). Mangers to be, as shown, of  $1\frac{1}{2}$ -inch Tarlogie deals. The under racks to be 2 feet 3 inches high, and to have a run beam 4 inches by 3 inches, rounded on the upper edge, with rings for fastening the horses. A piece of bond timber, 4 inches by 3 inches, to be built into the walls for harness-pins.

1071. *Gates.* The posts to be as the hind posts of the stables, and to stand 9 inches above the gates; the hinge post of the gate to be 5 inches by 4 inches; the front post, 4 inches by 3 inches; the angle spar, 1 inch and a half by 3 inches; the spars to be three quarters of an inch by 3 inches and a half; the top spar will be  $1\frac{1}{4}$ -inch square iron, with shoulder and eye at the hinge post, diminishing to three quarters of an inch square at the front post, with a screw and nut. The crooks to be put into the gate-posts with a screw and nut.

1072. *Sundries.* The linteling beams to the horse-course to be 12 inches square, and to be tied at the angles with iron straps 2 inches and a half by three eighths of an inch, and 20 inches long, and to be chucked together; the rafters to be 6 inches and a half, and 6 inches by 2 inches and a half, with 2 balks in height, chucked and spiked together with double garron nails, and mortised into the octagonal post at top 6 inches in diameter;  $\frac{3}{4}$ -inch square cat bars (a cat bar is an iron bar three quarters of an inch square, for keeping a folding-door fast when shut; it has a ring at one end for fastening to the wall with a staple, and is bent at the other end, so as to hook into the door by another staple on the inside) to all the two-leaved doors; to provide a seat and riser to privy, and a ventilator over the boiler in the milk-house.

1073. *Mason.* All the excavating will be done by the proprietor. The whole of the stones used to be from the quarry of Balnascarrish. The mortar to be made of good well-burnt English lime, and landed at Portmahomack, with sharp sand in the proportion of two parts of lime to three parts of sand, the whole being well tempered and beat before being used. The foundations to be laid with flat-bedded stones laid in regular courses, and to be taken in by regular scarcements (sets back) as shown in the sections; all the internal gables to be carried up to the roof; the sleepers to be laid and built into the

same, and the dwarf walls to be 14 inches thick. The walls to be built of the heights and thicknesses shown and figured in the drawings, and the whole to be beam-filled at the top. No wall to be at any time more than 3 feet higher than the other walls, until each wall has been raised to its intended height. The door soles (sills) to be laid six inches above the causeway (or pavement) outside; the soles of the stable, byre, &c., to be laid 3 inches above the same, and the whole to be beveled (sloped outwards) on the top.

1074. *Hewn Work.* All the external corners to be droved (tooled) with broached tails (a regular breadth on each side of the angle of the corner stones to be hewn smooth, and the remainder of the stone to be rough-hewn, like the rest of the wall). The rybats (reveals), soles, and lintels of the doors and windows to be droved, with broached tails; all the rybats and corners to be 2 feet long at least, and the inband rybats (headers) to pass through the thickness of the walls; all the skews and tabling to be droved, and the shed-pillars, arches, and the chimney-tops to be broached; the shed and gate pillars to be chamfered 3 inches on the angles.

1075. *Causewaying.* The whole of the stables, byre, sheds, &c., to be laid with whinstone set in sharp sand; the settles (gutters or channels) to have 2 inches fall in 10 feet; the stable channels to be 10 feet from the front wall, and the rise from them to the rack to be 5 inches. All the doors, windows, &c., to be saved with rough arches (to have discharging arches) over the same. All the spurs (lower stones of the raking part of the gable, called in England the summer stones) to be 2 feet and a half long each. The whole of the rough walls to be pointed and harled (roughcast) outside, and the whole to be pointed inside.

1076. *Plasterer.* To plaster the walls of the granary and the dressing-barn with one coat of plaster with pounded glass mixed in the mortar, to prevent vermin from getting in.

1077. *Painter.* The whole of the doors, windows, gates, and all exposed wood and iron work, to have three coats of oil paint, of a colour to be chosen by the proprietor.

*Detailed Estimate of the Expense of erecting the Farm Steading of ———, referred to in the above Specification.*

1078. *Mason.*

308 roods (36 square yards in each rood) rough walls of the standard thickness (2 feet), and harled .....	
433 yards of causewaying with whinstone, laid in sharp sand.....	
47 yards of paving with flags in the straw-house.....	
365 superficial feet of droved hewn work (labour only) .....	
200 superficial feet of broached do. (do. do.) .....	
9893 superficial feet of run 4-inch tabling and skew stones; the materials only; the labour being included in the droved work.....	
96 superficial feet of door and window soles and lintels, do. ....	
16 lineal feet of vent .....	
1 copper and furnace to set .....	
21 posts built in solid work, 3 feet in diameter .....	
18 steps broached to the gangway to the granary.....	
Tools, tackle, scaffolding, &c. ....	

£ 274 : 10 : 0

1079. *Plasterer.*

417 yards of one-coat plaster .....	£ 14 : 5 : 0
-------------------------------------	--------------

1080. *Painter.*

428 yards of three-coat paint and knotting .....	£ 21 : 8 : 0
--	--------------

1081. *Carpenter.*

169 cubic feet in lintels, &c. ....	
1227 yards of roofing and cabers (laths for thatch) .....	
271 yards of flooring and joists .....	
264 yards of 1½-inch three-barred doors (ledged doors with 3 backboards) .....	
193 yards of windows .....	
56 yards of gates.....	
43 yards of sleepers and flooring .....	
45 yards of trevises, &c. complete .....	
55 yards of racks, &c. ....	
41 yards of do. in byre .....	
75 yards of do. in cattle-sheds .....	
93 yards of centres for arches .....	

105 yards of paling in the fold-yard .....	
15 yards of water-trough and pump .....	
29 yards of shelves and divisions for nests in the poultry-house .....	
10 feet superficial 1 seat and riser in the privy .....	
61 feet superficial of stairs .....	
57 feet superficial run bond timber, and harness pins .....	
48 pairs of large crooks and bands .....	
14 pairs of small cross-tailed bands .....	
4 8-inch stock-locks .....	
8 cat bands and socket hinges (see fig. 1059, p. 533.) .....	
20 iron straps for the cart-sheds and horse-course .....

£ 821 : 11 : 0

1083. *General Estimate.* As the cubic contents of this farmery are 78,468 feet, the above gives 2½*d.* per foot as the data for forming guess estimates for the north of Scotland.

1084. *Remarks.* We have given the foregoing specification and estimate chiefly on account of some peculiarities in the details of construction, and of some local terms. The first twelve paragraphs were taken from a printed form, which, being applicable to specifications generally, is calculated to save the Architect a good deal of trouble. Such forms, both for specifications of buildings, agreements for leases, and even leases themselves, are often printed, in the case of large estates, for the convenience of the agents. The farm house to this farmery is remarkably small, and, with its chimneys in the gable ends, it has the usual commonplace air of Scotch farm houses; cold, formal, and comfortless. There is a privy in a recess off the stable, which is all exceedingly well for the men, but quite useless for the women, who ought, at least, to have had a similar convenience, equally private, near the byre, but by no means in it, as cows are, in relation to such places, much more delicate than horses. The barn here is remarkably well placed, connected, as it is, with the stables on one hand and the cattle-sheds on the other.

Design XXXIV. — *The Farmery at Greendykes, in Haddingtonshire, consisting of 500 arable Acres under a Six-Course Shift.*

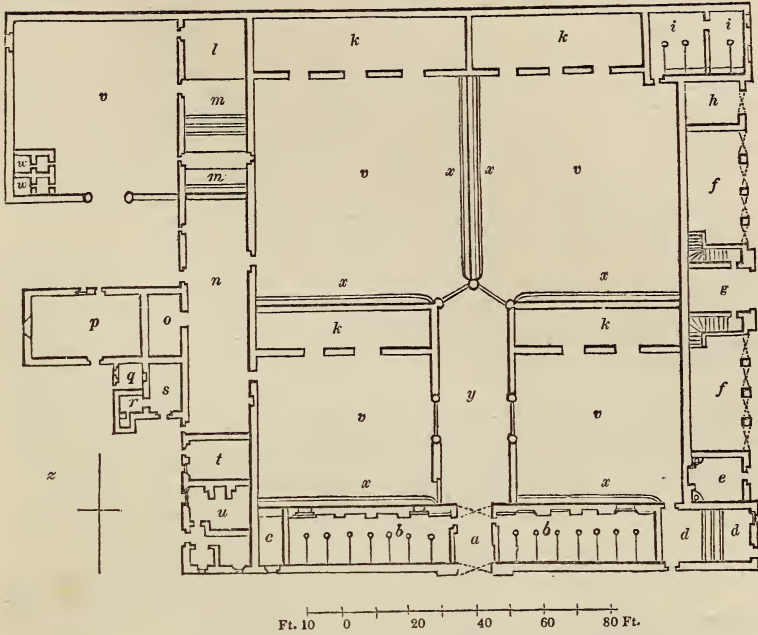

1085. *Accommodation.* The general appearance is shown in p. 535, and the ground plan in fig. 1054. In the latter are seen an entrance gateway, *a*; two stables for eight horses each, *b b*; hen-house, *c*; two loose horse places, *d d*; a boiling-house, *e*; two cart-sheds, *f f*, with granaries over; the tool-house with stairs to the granary, *g*; gig-house, *h*; two riding-horse stables, *i i*; four cattle-sheds, *k*; potato-house, *l*; two cow-houses, *m m*; straw-barn, *n*; chaff-house, *o*; corn-barn, *p*; engine-house, *q*; boiler, *r*; coal-house, *s*; smithy, *t*; bailiff's house, *u*; open courts, *v*; piggeries, *w*; feeding-troughs, *x*; passage, *y*; and rick-yard *z*. Fig. 1055 is a plan of the roofs, and of those parts of the buildings which are two stories high. In this plan are shown the two granaries, *a*; boiling-house, *b*, hayloft to the riding-horse stables over the gig-house, *c*; barn, *d*; and chimney to the boiler of the steam-engine, *e*.

1086. *Construction.* The walls are of local freestone, and the roofs of Baltic timber, covered with slate. Fig. 1052 is an elevation of the west front, and fig. 1053 is an

1054

elevation of the north front. All the various details of construction will be found clearly set forth in the following specification:—

1087. *Specification of a Plan for building the new Farm Offices at Greendykes, near Haddington.*—*Foundations.* The foundations to be dug down until a firm and solid

1055

stratum is obtained for founding upon, and to be at least 18 inches below the level of the door soles (sills). The foundation to be laid with large flat-bedded stones on a bed of lime, and to be laid in 12 inches wider than the thickness of the walls, as figured in the plan, and to be reduced to their regular thicknesses at the surface level.

1088. *Rubble-work.* The whole of the walls to be executed of the best rubble building, with the stones laid all on their flat and natural beds, and properly hearted and packed (the interior filled in solid with mortar and chips) with well prepared lime and sharp sand; and all the joints to be clean, and neatly drawn in with the edges of the trowel, particularly the west elevation, which will be done in coursed work with the very best picked stones from Bangley quarry. The whole of the external elevations to be executed with new materials, and all the old stones to be used in the inside walls. All the gable tops (upper parts of the cross walls) to be carried close up to the slates.

1089. *Hewn Work.* The whole of the corners, door and window rybats (reveals), soles and lintels, stair-steps, crow-steps (barge-stones rising above one another like stairs, see fig. 1053), balls and points (ornaments; see the figures), chimney-tops, skews, pillars and arches, and arches of cart-shades (cart-sheds), archways for the gateway and bailiff's house, the jambs and hearths, also the pavement in the riding-stable, gig-house, and at the stair foot, to be all executed in broached work, with droved margins (or draughted and broached; that is, worked round the joints with a chisel, about

1056

three quarters of an inch on the face, and the remaining part of the face, roughly done with a pick, as in fig. 1056: common broached ashlar is without the draughted or droved edges, and is simply dressed with the pick, or

pointed or chisel edge of the hammer, as in fig. 1057) as will be directed.

1090. *Heelpost Stones.* The stable posts, and posts in front of the feeding-troughs, to have heel-stones 12 inches square and 18 inches long, properly squared, and droved on the top; with a hole for receiving the posts 2 inches deep.

1057

1091. *Causewaying (Paving).* The stables, loose-house (stable or place for a sick horse, mare and foal, cow about to calve, &c.), byres, and piggeries to be all neatly causewayed (paved) with good rubble causeway; and all these apartments to have proper declivities

and channels for carrying off the water into the open courts.

1092. *Wall Coping.* The walls in the open courts to have semicircular hammer-dressed (dressed with the chisel end of the hammer) freestone copes (coping), and the tops of the pillars or piers to the gateway openings to be finished with a square plinth and semicircular droved stone; the top stones (the course of stones immediately under the coping) to be in single blocks.

1093. *Troughs.* The feeding-troughs to be built up solid with stone and lime to a proper height; and the soles to be laid with droved pavement close joined, and not less than 3 inches thick.

1094. *Engine-house.* The engine stalk (shaft or chimney) to be carried up with brick from the level of the wall heads to the height of 45 feet from the level of the engine-house floor. The flues to be 20 inches square inside, and the sides of the flues to be built with quicklime, and the floor of the engine-house to be laid with clean droved pavement. A tunnel to be built for the engine 10 feet long, 6 feet deep by 2 feet 3 inches wide, the sides and ends of the tunnel to be built with rubble-work 2 feet thick, and lined upon the face with droved ashlar, and the bottom to be laid with droved pavement. The tradesman to build in the boiler for the engine, and to furnish what fire and other bricks may be required for that purpose. The whole of the external corners of the pillars of the cart and cattle sheds to be neatly rounded.

1095. *Corn-barn.* The floor of the corn-barn to be sunk down 15 inches deeper than the level of the door sole, and dwarf walls built every five feet apart, and 12 inches thick, for supporting the sleepers; the whole space below the floor to be filled up close to the under bed of the flooring, with small broken stones, and to be run full of thin grout lime, on purpose to prevent vermin from getting through the floor.

1096. *Stables.* The wall heads of the stables, corn-barn, granary, hayloft, and cow-house to be beam-filled close up from the top of the walls to the roofs. Recesses are to be left in the stable wall behind the horses, seven feet high, as shown by the drawing, for the reception of the harness, and of the corn-chest.

1097. *The Ventilators* to be put through the front wall of the stable, as shown by the

plan, 6 inches square, with a droved hewn stone on the outside of the wall 16 inches square, with a 6-inch hole cut through it to ventilate the stable.

1098. *Servants' Houses.* The vents (chimneys) of the servants' houses and boiling-houses to be carried up at 11 inches square inside, and to be properly plastered.

1099. *Stonework generally.* In building the pillars for the gates to the open courts, proper care must be taken that large weighty stones be put at their proper places for fixing in the iron crooks. The tradesman to get the old stones at Greendykes and Arniston which will be pointed out by Mr. C. The tradesman will also furnish the whole of the other stones, and the lime that will be required for finishing the building; the hewn and rubble stones are to be taken from the Jerusalem quarry, the whinstones for the west front from Bangley, and the pavement from the quarries at Salton limeworks. All to be of the best quality the several quarries will produce; and Mr. C. to furnish the whole of the carriages of every description; but the tradesman must take down and clear out the old stones, and prepare them for carting, and also furnish bricks for the engine vent of the best quality.

1100. *Carpenter's Work.* The soles and lintels to be 3 inches thick, with a wall-hold (their ends deeply inserted into the wall) on each end of the head and sill of the frames, 9 inches in length, and of width sufficient to fill up the space required. The whole of the joisting for the granary and barn to be 11 inches by 2 inches, and 16 inches apart, with a wall-hold on each end of 9 inches; and the joisting to be laid on wall plates 7 inches by 14 inches. The joisting over the mill-loft (floor for the unthreshed corn, from which, being fed into the upper part of the machinery, it comes out separated into corn and straw, in the floor below) and granaries to be covered with a flooring of boards not exceeding 6 inches and a half broad, and 1 and one eighth of an inch thick, and to be ploughed and tongued on the edges. Two strong joists to be in the mill-loft, 11 inches by 6 inches, and three cross framings of the same size on each side of the shaker, and one at the spur-wheel (a wheel on the main shaft with the cogs or teeth standing outwards, which operates on a pinion), as shall be directed by the millwright.

1101. *The Corn-barn* to be laid with sleepers and flooring; the sleepers to be 5 inches by 2 inches and a half, and 16 inches apart; the flooring to be the same as above specified; the wall-plates below the sleepers to be 7 inches broad by 14 inches thick.

1102. *Roofing.* The scantling for the roofing to be 6 inches at bottom by 5 inches at top, by 2 inches and a half thick, and placed 18 inches apart. Wall-plates to be 7 inches by 1 inch and a quarter; baulks (tie or collar beams) to be 6 inches by 2 inches and a quarter. The sarking to be three quarters of an inch thick, and close-jointed on the edges. The flank-trees (valley rafters) to be 7 inches at bottom and 6 inches at top, by 3 inches and a half thick; and the pien-trees (hip rafters) to be 7 inches broad and 2 inches thick. The partition in the corn-barn to be of standards (quarters) 4 inches by 2 inches, 18 inches apart, and covered on one side with deals a quarter of an inch thick, clean-planed, beaded, grooved, and tongued on the edges; with a door through to the chaff-hole. A trap-stair and wood-rail to be put up to the same, and round the opening at the landing from the corn-barn to the mill-loft. There is to be also a wooden trap from the straw-barn to the mill-loft, 2 feet wide, and of proper strength for carrying up the refuse from the shaker. There are to be two skylights put into the roof of the mill-loft, 3 feet long by 2 feet wide, for giving light to the machinery; and these are to be glazed, having flashings of lead round the slates weighing 4 lbs. and a half per foot.

1103. *Working-Horse Stables.* The working-horse stables to be fitted up with racks and mangers, and trivess boarding. The trivess boarding to be 7 feet high in front, and 8 feet at the back end; with hard-wood (oak, ash, elm, &c.) coping on ditto. The top of the coping to be 2 inches and a half by 2 inches, and the boarding to be 1 inch and a half thick, and doweled on the joints. The mangers to be 10 inches wide at bottom, and 14 inches wide at top, by 10 inches deep, and the boards 1 inch and a quarter thick. A breast-tree (horizontal rail) to be put in front of the manger, 4 inches by 2 inches and a half, rounded in front. This tree to be of oak, with proper iron rings and staples for fixing the horses. The rack sides (top and bottom rails) to be 4 inches by 2 inches and a quarter, and to be fitted in with turned rack staves, 2 inches in diameter, with a rail 6 inches broad, opposite each trivess, and the rack staves to be made of beech; the back posts of the trivesses to be made of oak 6 inches square, rounded on the angles, and mortised into a run-tree (a rail fixed along the tie-joists) at top, and let 2 inches into the stone at bottom; the front posts to be 4 inches by 2 inches and a quarter, and one on each side of the trivess to be rounded on one side. There are to be 16 tie-joists across the stables, 7 inches by two inches and a half; and clean-planed for fixing the run-tree. The run-tree to go the whole length of the stable, to be 6 inches by 3 inches, and clean-planed. There are to be a sufficient number of harness-pius and saddle-trees put up behind the horses and on the posts.

1104. *The Riding-Horse Stable* to have a manger the same as the other stables, with circular racks in the angles. The stable to be divided in the middle with a deal partition 2 inches thick, clean-planed, beaded, and doweled on the joints, with a door of communication formed in it. The door-framing to be 4 inches by 3 inches; the door to be hung with strong cross-tailed hinges (strap hinges with a cross, sometimes shaped like a trefoil at the tail), and to have a sunk thumb sneek (a latch with the handle sunk flush with the surface of the door), the partition to go the whole way up the height of the ceiling. The front wall to be lined up with  $\frac{3}{4}$ -inch deal from the top of the manger to the top of the rack, and to be planed, grooved, tongued, and beaded.

1105. *Stable Arches*. Elliptical arches to be put across between the back posts and over the horses, with neat wood impost mouldings at the springings; and a thin plate of wood bent round the soffit of the arches.

1106. *Trivess (Partition) Boarding*. The trivess boarding to be of the same height and thickness as in the other stables, and finished on the top with an ogee and sweep, and hard-wood cope. The joists to be of the same materials, and the workmanship the same as in the other stable. The stone wall next the west front to be lined with 1-inch deal, and finished the same as the other trivesses. The ceiling to be lathed from the beam-filling, round the couples, and back; and the whole walls and ceiling to be finished with three-coat plaster. There are to be two wood pipes made 6 inches square, to go up through the ceiling, and 2 feet through the roof above the slates; with a flashing of lead put round the pipes to cover their joining with the slates. The 2 feet of pipes above the slates to be bored full of holes on all the four sides, and covered on the top with a moulded capital, on purpose to ventilate the stable. The bottom of these pipes to project below the ceiling of the stable, on purpose to admit of a shifting board to shut them up when required.

1107. *Poultry-houses*. A wooden stair to be put up from the turkey-house to the hen-house, as shown by the plan; and this hen-house and the hayloft to be joisted and floored with the old materials, &c. The stair to be covered in round the sides up to the ceiling in the turkey-house, and a door to be put up on the foot of the stair to keep the two places separate. The hen-house to be fitted up with a wooden roost, and nests on the north and east sides; and the tops of the nests to be covered with a sloping thin deal cover, on purpose to keep them clean from the roosts. The ceiling of the hen-house to be lathed from the top of the walls, round the couples (rafters), and back; and to be finished with two coats of plaster; and the walls both of the hen-house and of the turkey-house to be plastered with one coat of plaster. A skylight to be put in the roof of the hen-house, 3 feet by 2 feet, glazed, and made watertight with flashings of lead.

1108. *Doors*. The doors to be plain deal, and 1 inch and one eighth thick; the boards to be 6 inches and a half broad, and ploughed, tongued, and beaded on the joints, with three bars on the back of each; to be all hung with strong cross-tailed hinges (hinges like fig. 1058, which, of course, can only be used where there are wooden door-frames, or hanging posts, on which to nail the tail part, *a*, of the hinge) with an iron bolt through the neck, *b*, of each; except the doors for the straw-barn, which are to be hung with strong crook and band hinges. The door-frames to be 6 inches by 2 inches and a half, and strongly battened into the cheeks of the rybats; the whole to have keeps (stops) three quarters of an inch thick, and of proper breadth.

1109. *The Servant's (Bailiff's) House* to have a lath and standard partition on both sides, and two doors inside, 1 inch in thickness, with hinges and sneek (thumb latch).

1110. *Glazier's Work*. The windows of the stables and byres to be glazed on the top half; the under half to be made to open with boards, and hinges and sneeks. The sashes to be 2 inches thick, with proper facings, keeps, and frames. The windows of the riding-stable, boiling-house, servants' house, corn-barn, engine-house, potato-house, and turkey-house to be made with sashes and cases; and to be glazed with good crown glass. The whole to receive one good priming coat of white lead before being glazed.

1111. *The Beams (Lintels) for the Cattle Sheds* to be 12 inches by 6 inches; to be all clean-planed on the front and under sides, and to have 12 inches of wall-hold on each end.

1112. *The large Entrance Gate* to be framed with  $2\frac{1}{2}$ -inch wood; styles 6 inches and a half broad, with cross rails 9 inches, and cross angular (diagonal) braces to the same, to be covered on the face with 1-inch deal grooved, tongued, and beaded on the joint, and to be made in two leaves; a wicket door to be in one of the leaves, to be framed in a similar manner. The gates to be hung with centre-point hinges at the bottom, and crook and band hinges at the top; and fixed at top and bottom with a very strong sliding bolt, and large thumb sneek. (Centre point, or swing hinges, appear to be of two kinds; one with the pivot of the hinge turned down, to work in an iron socket let into a stone,

as in fig. 1059; the other with two pivots, working on two hooks, as in fig. 1060, in which *a* is the hanging style of the gate, with the double pivot hinge attached, *b b* being the pivots; *c* is the hanging gate-post; and *d d*, the two pivots leaded into it. The

object common to both is, to make the point of rest of the gate the same as the shutting point; that is, the line in which the gate remains when it is shut.)

1113. *The Gig-house Door* to be made with  $1\frac{1}{4}$ -inch deal, with three bars across each half, 1 inch and a half thick, and with angular braces; to have hinges and bolts of a proper strength, the same as the large gate, and a good stock lock and sneck. This door to be made with an opening three quarters of an inch wide between each deal (board), for the admission of air, the deals not being more than 6 inches broad.

1114. *The Byres* to be fitted up as shown in the drawings; the sole trees to be eight inches by four inches; the top tree six inches by three inches; and the stakes to be of hard wood.

1115. *The whole of the Doors* to have good and sufficient locks, bars, and bolts, where necessary; and all to have strong Scotch-made thumb snecks, with folding handles (handles to hang down, or fold aside) to the same.

1116. *The Gates* for the open courts to be hung on two leaves, and framed with  $1\frac{1}{2}$ -inch thick framing and angle braces; and to be covered on the outside with 1-inch thick deal, ploughed, tongued, and beaded on the joints; and finished on the top with a cope 1 inch and a half thick. The gates to be hung with strong crook and band hinges (in fig. 1061, *a* is the band, and *b* the crook; the former is used in the case of boarded doors, which have no hanging styles; the latter is either leaded into stone, or sharpened and driven into wood), and the hinges to be made so that the gate may open on the outside, and fold back to the court walls; and be fixed together, when shut, with a hardwood swivel bar, and iron bolts and staples of sufficient strength.

1117. *Granary Windows.* The windows of the granary to be fitted in with wooden frames and round iron rods three eighths of an inch in diameter, and three fourths of an inch apart. The frames to be 2 inches and a half broad, and 2 inches thick; the sole for the frame to be 3 inches and a half by 2 inches and a half, and to be washed off (sloped) on the outside to carry off the rain. There are to be inside shutters five eighths of an inch thick, ploughed, tongued, and beaded on the joints, with a water verge on the bottom (a slip nailed on, to throw off the rain), hinged on the two halves, and fixed inside with a cross shifting hard-wood bar, and iron staples. There is to be a standard and deal partition put round the top of the stair in the granaries 3 feet high. Standards 3 inches square, and the boarding 1 inch thick, ploughed and tongued.

1118. *The Hayloft* to have a door 1 inch thick, with frames, hinges, and folding thumb sneck; the openings for putting the hay down to the horses to have doors three fourths of an inch thick, with frames, hinges, and bars; there is to be a light movable trap-ladder to go up to the hayloft by the front door of ditto; and saddle-trees and pins to put up in the stable.

1119. *The Gig-house* is to be lathed on the ceiling, and to be finished on the walls and ceiling with two coats of plaster. The floors of the straw-barn, servants' house, potato-house, turkey-house, chaff-hole, and boiling-house to be all laid with a composition of lime, sand, and engine ashes (coal ashes), three inches thick; to be laid on in due proportions, and properly rubbed and smoothed on the surface. Frames of wood

are to be fixed to the inside of the front wall of the cart-stable, opposite the openings of the ventilators, with shifting boards, to slide and close them as may be required.

1120. *Beams.* Two strong Memel planks will be required in the engine-house, to be built into the walls, and to be 9 feet long and 12 inches by 5 inches on the sides, for fixing part of the machinery.

1121. *Plaster-work.* The working-horse stable, granaries, corn-barn, and mill-loft to be finished with one coat of plaster on the walls; and the corn-barn, mill-loft, and granaries to have a skirting of Roman cement 8 inches round the floors.

1122. *Slaters' Work.* The roofs to be covered with the best dark blue slate, from Mr. Bell's quarry near Dunkeld; to have a sufficiency of cover, to be well shouldered in haired lime (the lower part of each row bedded in lime); and to be nailed on with nails at 12 lbs. per thousand, well steeped in linseed oil when in a heated state (to prevent, or at least diminish, oxidation); the slates to be all close-mitred (when two planes meet against a diagonal line, they are said to be mitred) in the angles of the flanks.

1123. *The Ridge* to be covered with lead 12 inches broad, and weighing 5 lbs. per superficial foot; the piens (hips) with lead 10 inches broad, and 5 lbs. per superficial foot; and the flanks with lead 8 inches broad, and 5 lbs. per superficial foot, to be all properly dressed down to the slates, and firmly nailed to the wood battens.

1124. *Description of Timber.* The timber for the roofing, joisting, sarking, soles, lintels, sleepers, gates, windows, trivess-boarding, racks and mangers, beams, and sole and top trees, feeding-troughs, &c., to be all of the best Memel timber, and all the flooring and doors, &c., to be of drawn (selected) battens.

1125. *Feeding-troughs.* The front of the feeding-troughs, in the open courts, to have a plank of wood 9 inches by 3 inches set on edge; and to have a post every 10 feet 4 inches by 3 inches, and put 2 inches into a stone in the bottom, and fixed at top with a long strong iron bat (stud) fixed into the stone sole, and a large screw-nut on the outside of the posts. The planks to be all fixed to the posts, with two iron screw-bolts into each.

1126. *The Tradesman* to furnish the whole of the material and workmanship, as particularised in the foregoing specification. Also the sea carriage of the slates, which must be shipped to the harbour nearest Greendykes, and Mr. C. (the tenant) will furnish the whole of the land carriage.

1127. *The whole Work*, of every description and kind, must be finished in the most substantial and workmanlike manner, and be liable at all times to the inspection of the proprietor, or Mr. C., or any other person they may choose to appoint for that purpose. The carpenter to furnish all the centring and moulds for the mason-work.

1128. *Estimate.* The actual cost of this building, exclusive of the old materials, and the expense of carriage, was about £2000; but it is estimated that if all the materials had been new, and the carriage had been included, the total amount would have been £3000; which, at 6 per cent, would have been equal to an addition of £180 a year to the rent of the farm. The expense of the farm house is not included in either of the above sums; but as that for such a farmery would cost nearly £700, this, at 6 per cent, would give at least £200 a year of additional rent, or 12s. an acre. The total number of cubic feet in the farmery, including court and fence walls, is 208,600; which gives 2½d. per cubic foot as the guess price for estimating buildings of this description in East Lothian.

1129. *Remarks.* This Design was procured for us by our much valued contributor, Patrick Shirreff, Esq., of Mungoswells, near Haddington, well known as one of the most scientific farmers in Scotland, as a specimen of one of the best farmeries in East Lothian. It was designed by — Swinton, Esq., Architect, Haddington; and built, under his superintendence, at Greendykes, for David Anderson, Esq., of St. Germain's. It will be observed that, considering its extent, the courts or fold-yards are fewer in number, and smaller in size, than those of the Northumberland Designs; and that there are none of these courts which are entitled to the appellation of hammels or fold yards. Hammels, indeed, Mr. Shirreff informs us, are out of repute in East Lothian; that is, what are called hammels in Berwickshire, which differ from those of Northumberland in being much smaller. "My idea of a hammel," says Mr. Shirreff, "is a range of shed-buildings divided by parallel partitions from ten to twenty feet asunder, and projecting beyond the building, so as to form courts two or three times the size of the space included within the building. Such hammels, within long narrow open courts, have gone out of use in Haddingtonshire, and in Scotland generally; and justly so, on account of the expense of littering them, supplying them with food, and removing from these long narrow spaces the accumulated manure. To a farmer who fattens short-horned cattle, so tame that several of them may be put together in a very small space, hammels may be of use; but where, as with us, young active cattle from the Highlands and other northern districts are put up to feed, it is often a month or more before only two or three cattle, bought

XXXIV.

XXXV.

XXXVI.

promiscuously in a market, agree when put together into a hammel; and the loss, in consequence, is often considerable. In the neighbourhood of Haddington, there was a set of excellent hammels erected about fifteen years ago, but open sheds with large courts are now substituted for them. Well sheltered courts are almost every where employed, in Haddingtonshire, for fattening cattle; but it must be remembered that with us, it is generally a difficult matter to convert straw into manure, from the abundance of it, and the dryness of the climate." The ample details in the specification of this Design will give a very complete idea, to the Architects of other districts, how farm buildings are executed in the first agricultural district in the island; and they cannot fail to observe the substantial and durable nature of the materials and the workmanship employed. There are two or three minor conveniences and comforts which we could wish to introduce; and that prominent feature, the chimney to the steam-engine, might, we should hope, be placed centrally with reference to the range or side to which it belongs. But, whether the shaft of the steam-engine can be placed centrally or not, we sincerely hope that the landed proprietors of Scotland will not suffer their country to be disfigured with the inelegant forms of engine-chimneys, which have hitherto been erected in those farmeries where steam has been adopted. We have little doubt that it will soon be preferred to either horses or wind, on all large corn farms on every part of the island. Tall engine chimneys, therefore, promise to be as common in the corn districts, as they are now in Lancashire, and we have only to point out the latter as beacons to be avoided. Under the head of Exterior Finishing of Farmeries, in Section III., we shall give some to be imitated. Since it is so difficult to turn straw into manure in East Lothian, we could wish to see all that is used for fodder cut into chaff, and mixed with succulent food, salted and watered; and we could wish also to see the liquid manure collected in tanks, and pumped up daily, or twice a day, and distributed over a covered dunghill, in the manner which has been already described, § 1019. It will, no doubt, be considered presumptuous in us to find fault with any agricultural practice prevalent in East Lothian: let it be recollected, however, that great improvements have, within the last twenty years, taken place even in this district, and that farther advances may be made. The dryness of the atmosphere appears to us a strong argument in favour of covering the dunghills, as well as of collecting liquid manure to moisten them; and feeding horses and cattle with cut straw and some liquid food, in order, among other advantages, to increase the quantity of liquid manure. It will be observed that several local terms are spelt differently in this specification from what they are in those of Mr. Newall, § 907, Mr. Green, § 979, Mr. Ross, § 1053, and even the Committee of the Highland Society, § 1200. We have deemed it better to give the spelling, in each specification, as we received it, hoping to be able to discover and insert that which is preferable, and also to generalise many of the local terms in the Glossarial Index.

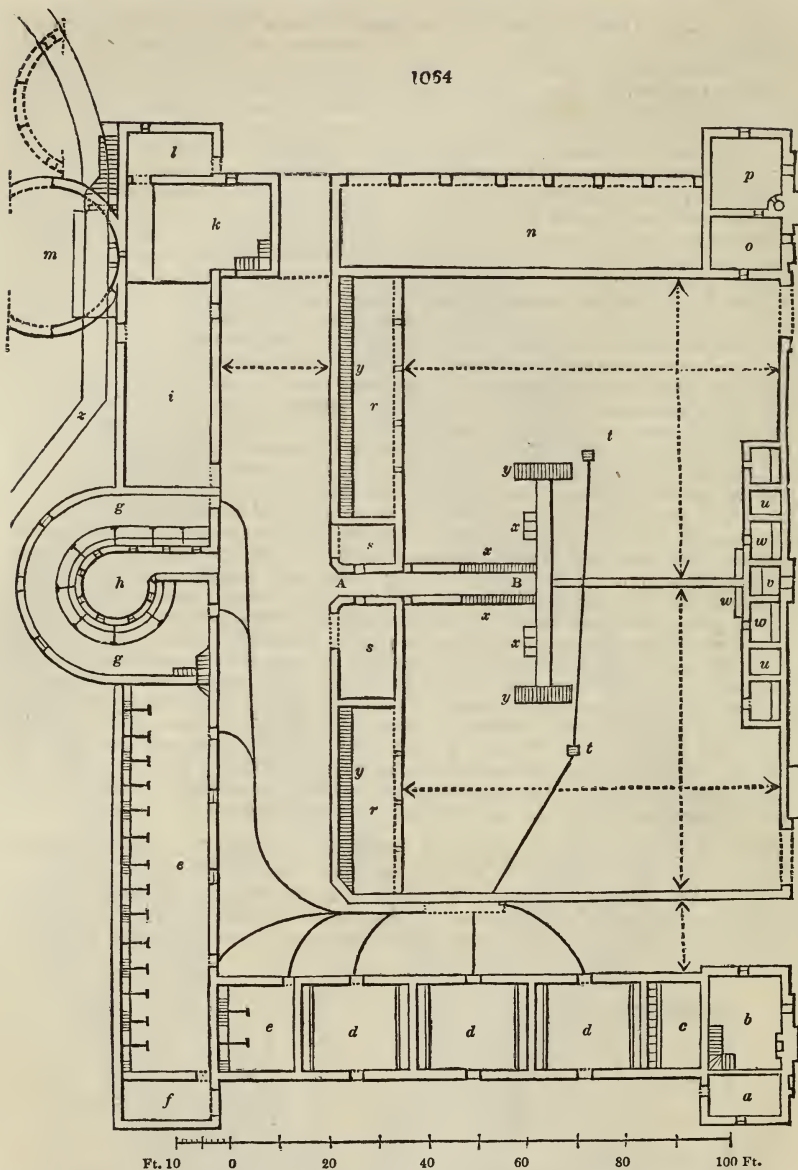

Design XXXV. — *A Farm House and Farmery at Elcho Castle, Perthshire, adapted for a Farm of Six Ploughs, under the Turnip Husbandry.*

1130. *The General Appearance* is shown in the isometrical view, page 535; the ground and chamber plans of the house in figs. 1062 and 1063, and the ground plan of the farmery in fig. 1064. Figs. 1065, 1067, 1068, and 1069 are geometrical elevations.

1131. *Accommodation.* The ground plan of the house, fig. 1062, shows two parlours *a a*; a family bed-room on the same floor, *b*; kitchen, *c*; wash-house, *d*; lobby and staircase, *e*; pantry, *f*; coal-house, *g*; dairy, *h*; and cellar, *i*. The chamber floor, fig. 1063, contains four good bed-rooms, *k*; and a servant's bed-room, *l*.—In the farmery, fig. 1064, *a* and *c* are poultry-houses; *b* is a boothy, or single men's lodge, with a bed-

1054

room over; *ddd* are houses for milch cows; *eee*, stables, with hay and straw lofts above; *f*, house for grass, or other green food for the horses; *g*, house for feeding cattle; *h*, feeding-chamber; *i*, straw-house; *k*, corn-room; *l*, chaff-house; *m*, mill-shed; *n*, cartshed, and granary above; *o*, potato-house; *p*, boiling-house; *r r*, cattle-sheds; *s s*, turnip-houses; *t t*, straw yards; *u u u u*, piggeries; *v*, water-cistern; *w w*, water-tank; *x x x x*, turnip cribs or boxes; *y y y y*, straw racks, and *z*, watercourse for driving the water-wheel of the threshing-machine, when water is abundant.

1065

1132. *Construction.* The walls are of stone, eighteen inches thick, and those of the barn, and of all the other buildings of two stories, two feet thick at the surface of the ground, and eighteen inches at top; the roofs are covered with slate. Fig. 1065

is a front elevation of the farmer's dwelling-house. Fig. 1066 shows the position of the house relatively to the farmery, in which *a* is the house; *b*, the kitchen-

garden; *c*, a grass field planted with fruit trees as an orchard; *d*, the farmery; and *e* the rick-yard. Fig. 1067 is an elevation of the farmery from the south. Fig. 1068

is an elevation from the east, and fig. 1069 is a west elevation. Other particulars of construction will be found in the following descriptive particular, sent by W. M. Mackenzie, Esq. Architect, the author of the Design:—

1133. *The Situation* fixed upon was nearly level, and the straw-yard was cut out hollow in the centre, of a basin figure, that form being most advantageous for retaining the moisture among the manure.

1134. *In the General Arrangement*, the highest of the buildings front the north and east, as best suited for the purposes to which those parts of the steading are to be applied, and at the same time adding to the comfort of the cattle in the sheds and straw-yards, by sheltering them in the directions which are generally the coldest. The pigsties on the south, and the byres, &c., on the west, being low buildings, do not shade the straw-yard and cattle-sheds, but admit the rays of the sun to all parts of them. The farm house is situated on the south-west of the steading with the kitchen court adjacent to the cow-byre, calf-ward, &c.; thus keeping the offices which are managed by the house servants in the one division, and those under the management of the farm servants in the other division, of the establishment.

1135. *The Threshing Machinery* being placed in a corner of the square, discharges the threshed corn into the clean-corn room, in the direction of the granary which occupies the upper story of that side of the square, and the straw is thrown from it into the straw-house, which is in the direction of the straw chambers, over the feeding-byre, stables, &c., on the other side of the square. By this arrangement the clean-corn room communicates with the granary, which comes three feet over it, and extends from this point over the cart-shed and boiling-house. In this three feet of the granary which comes over the corn-room is placed a trapdoor, through which the sacks are drawn up by means of a wheel and axle, and are then placed in a miller's barrow, and wheeled into the granary. In this way the clean-corn room occupies a side of the square apart from the offices allotted for the bestial (beasts), and other apartments connected with them; and, as the corn-room can be locked up the moment the operation of threshing is finished, no opportunity is left for the grain being pilfered or injured. The granary, in this situation, has not only the advantage of the ventilators in the side walls, but it has also the benefit of the free air in the open cart-shed under it, which acts upon the grain through the joints of the floor. The cart-shed under the granary, besides being beneficial to it for air, is convenient, particularly where a farm is situated at a considerable distance from a market town; or, in the winter season, when the carts are required to be loaded on the evening preceding the market day, as it can be done before yoking, and without moving the carts from under their cover, by means of the trapdoor in the centre passage of the granary, which passage is at all times kept clear from grain. In the straw-house a trapdoor is placed over the straw-rack, and when the lower part of the house is packed full, this trapdoor can be shut, and the straw carried along the upper floor to the straw-chambers over the stables and feeding-byre. These apartments will contain the straw of three large ricks, which will enable the farmer to keep different kinds under cover, and in separate divisions. A door five feet square is placed opposite the passage which extends along the centre of the straw-yard for taking out straw for the cattle-sheds, cow-byres, &c., if at any time required, but in general these are supplied from the low straw-house. The threshing-machine is one of six-horse power, and is impelled by water, but is so planned that horses can be employed if the water run short: in this Design, however, the horse-shed is not executed.

1136. *The circular Feeding-byre*, which will contain eighteen cattle, is by far the most commodious and convenient arrangement for a farm of this extent. The figure of the stalls being broad behind gives more space for the cattle when lying; and, as a greater quantity of bedding (litter) is requisite, more manure, of course, will be made; at the same time admitting a more abundant supply of fresh air, by having the advantage of one large ventilator in the centre of the circle serving the whole. The eighteen cattle are put up in double stalls in pairs; they are bound up one on each side of the travis (partition, probably from *traverser*, Fr. to cross), which is made high enough to prevent the horned

cattle from touching one another, at the same time keeping the heads of each pair at such a distance apart as not to be able to injure, or eat, one another's turnips. The bands are fixed to upright iron rods about three quarters of an inch in diameter, which are screwed together through the travis. The lower part of the windows in the back wall of the byre are filled with louvre (luffer) boarding, which can be opened to any degree for admitting air, or shut altogether, at pleasure. The feeding-ports (openings), which surround the feeding-chamber, have small doors hung with pulleys, lines, and weights, similar to a common window, which by moving upwards, do not interfere with, or occupy, any part of the feeding-chamber. The wall at the cattle's heads, surrounding the feeding-chambers, is built to the full height of the joists, which keeps the turnip-barrow out of the view of the cattle, and does not disturb the one division of them while the man is in the act of feeding the other. This is important, as the quieter the cattle are kept the better, quietness being no doubt essential to quick fattening.

1137. *A commodious Straw-chamber* is got over the byre, in a connected range with the straw or hay chamber over the stable; the roof, which is of considerable height, serving the double purpose of covering the feeding-byre, and containing a very large quantity of straw immediately over it. Racks are placed over the several stalls, which are filled from the straw-chamber above. By this arrangement, the cattle have it in their power to eat straw and turnips alternately, if inclined. The access to the straw-chambers over the byre and stables is by a stair which is common to both, and upon the plate (first landing-place) of the stair is placed a door, which divides the stable from the feeding-byre; the upper flight of the stair is understood to be a hanging one, leaving a useful space under it for holding the byre implements. By the whole arrangement half the labour of feeding and attending the cattle will be saved.

1138. *The Stabling* consists of eighteen stalls, three of which are separated from the general farm stable, but are so situated as to admit of the racks being supplied from the general straw or hay chamber over the common farm stable. They are understood to have two sets of racks; the upper one for hay or straw, and the under one for grass. Although the under racks appear the most natural for the horses to eat from, it is found that they do not eat the straw or hay so clean out of them as they do out of the upper racks; but these under racks are the most convenient for the grass, as it should always be put in from the stall below, without passing through the hay-chamber; being, in its damp state, very hurtful to the wood floor above.

1139. *The Turnip-shed*, which is right opposite the feeding-byre, is also conveniently situated for supplying the cattle in the straw-yard; and, as it is not required for turnips in summer, it may be used for, and serve the double purpose of, a grass-house.

1140. *The Cow-byres* have ventilators placed over each line of heads; they cross the ridge, and are formed of lead of a triangular figure, the sill-piece being overlapped by the sides far enough to prevent the rain from getting in. The calf house and ward, and the cow-byres, which fall under the class of offices more immediately connected with the house, have doors facing the kitchen court, which makes the access to them convenient and clean. The opposite doors are used for driving out the cattle, and for wheeling the dung into the straw-yard. The causewayed court in front of the byres, besides being convenient for carting in the turnips, affords space for the cows to move about in, or to stand in for a short time; and, as the cattle always make dung when they are driven out, by allowing them to remain for a few minutes in this passage or court, the dung that might otherwise be wasted on the roads is preserved, and thrown into the straw-yard.

1141. *The several Drains* leading from the byres, stables, and straw-yard have such declivities as to discharge the liquid manure into the tank, which is constructed on one side of the straw-yard, in a central situation for the byres, stables, &c. It is twenty-one feet long, five feet broad, and seven feet deep; and, if the nature of the soil be porous, it should be plastered over with Roman cement, to prevent the thin liquid manure from escaping. Being of this long and narrow figure, the tank can easily be covered with pavement, which is much cheaper than arching, and takes up less space. The drains should have cast-iron plugs placed at about fifteen feet apart, and at these openings a jointed rod fifteen feet long could be put into the drain with a hough (hoe), or piece of plate iron the figure (shape) of the drain, fixed to one end of it; by which means the drains may be cleaned without breaking up any part of the causewaying; but, if the drains are properly constructed, they will not require cleaning for several years. They should have a fall towards the tank of at least four inches to the ten feet, and be nine inches wide, six inches deep at the sides, and nine inches at the centre. By having this kind of triangular bottom, the smallest quantity makes a run (current) and forces every thing along with it. The drains through the straw-yard should have openings, with grates over them, situated in the lowest part of the straw-yard, to draw off the surplus water after falls of rain or snow. When these drains are not required, the grates may be

easily covered over with dung; and if, at any time, the dung is found too dry, movable spouts may be attached to the pump which is placed in the tank, by which means the liquid manure can be regularly spread over the whole straw-yard. A waste drain extends from the tank to an open ditch in front of the steading; by which means the liquid manure in the tank, if neglected, is carried off when it rises to that level, and is thus prevented from injuring the drains.

1142. *The Cattle-sheds*, from their situation, face the south, which is of great advantage to the cattle, though often overlooked in laying out farm buildings; and they are divided in the centre by a passage adjoining the turnip-shed, and opposite the straw-house. This passage rises like an inclined plane, 4 feet from A to B, the side walls or parapets being built up to that height, and forms a fence to both yards. All the dung from the feeding-byre and stable is wheeled into the straw-yards by this passage; which, from its central situation, admits of the stable dung being equally distributed through both yards, and this by the rising passage can be done without opening a door, which prevents the one class of cattle from intermingling with the other, or getting out. Straw-racks are placed in the sheds; but, by also having them in the centre of the yard, and connected with this passage, they can be conveniently filled, and the cattle are induced to divide, which mixes the dung more generally through the yards. The racks on the extremities of the passage are understood to be movable, and can be laid aside when carting out the dung. The piggeries, from their situation, may be conveniently supplied from the kitchen or boiling-house, and are in both yards. Pigs are very beneficial to the dung, from their turning it over and mixing it: they also eat up any particles of corn among the horses' dung that may not be digested. One small enclosure is provided in each yard, with a trough for feeding young pigs; thus protecting them from the cattle while eating: but they have no house or sty, which induces them to go out among the cattle, and to lie about the sheds. By this arrangement they have healthy exercise, enabling them at the same time to provide a part of their food, and be beneficial to the dung in both yards. Other two sties are provided for putting up two pair to feed. The gates to the straw-yard may either be of the common form, or be hung with stout ropes, pulleys, and weights. This last is perhaps the best plan, as it secures them from the risk of damage when the dung is being carted out of the yard, and they can be also raised as the straw in the yard rises.

1143. *The Cistern-house* is of such a height that pipes may be taken from it to the dwelling-house, boiling-house, calf-ward, &c. It may be either supplied from a fountain, if one can be found in the neighbourhood; or a well may be dug, and a pump placed within the cistern-house. A water-trough is placed in the division wall between the straw-yards; and a ball-cock is fixed in the centre of the said trough, and shut in by boarding, overlapped by the upper part of the wall, protecting it from injury from the cattle. The cock opens and increases running as the water falls low in the trough, and when the trough is full, the floating ball shuts the pipe. By this self-acting supply, the cattle at all times have the command of water, and none of it is wasted; if supplied from a fountain no attention is necessary, as the cistern will also shut itself in like manner, and the overflow, if any, will go off at the fountain head. Two troughs are placed on the outside for the horses, or the milch cows, and supplied with ball-cocks in the same manner.

1144. *The Roof Water*, in the inside of the court, is carried round with eave spouts, and with rain-water pipes at the south extremities leading it into drains. It is a material object to carry off the roof water without allowing its admixture with the manure in the courts.

1145. *The Dwelling-house* consists of the following apartments; viz. upon the ground floor two parlours, a bed-room, kitchen, servants' bed-closet, dairy, scullery or wash-house, with a small cellar, which may be got under the stair, and a coal-house. The upper floor consists of four bed-rooms and a servants' bed-room; but, in cases where more bed-rooms are required, an additional attic room could be got over the wash-house, having access from the same stair. The upper rooms go partly into the roof.

1146. *Estimate. — Mason's Work.*

	£	s.	d.
54 roods of rubble building, at 30s. ....	351	0	0
810 feet of rybats, soles, and lintels, at 1s. ....	40	10	0
302 feet superficial of hammer-dressed pillars in cart-sheds, at 4d....	5	4	0
60 feet lineal of cart-shed arches, hammer-dressed, at 1s. 6d.....	4	10	0
98 feet lineal of cattle-shed ditto, at 2s.....	9	16	0
52 feet lineal of squares droved, at 1s.....	2	12	0
378 yards of causeway in stables and byres, at 1s.....	18	18	0
476 feet superficial of flag division at cattle's head, at 8d.....	15	17	4

1147. *Wright's and Slater's Work.*

1589 yards of wood roofing, at 5s. 3d. ....	417	10	0
---	-----	----	---

51 roods 6 yards of slatework, at 75s.....	190 : 0 : 0
728 feet superficial of lead ridges, piens, and flanks, at 1s.....	36 : 8 : 0
149 yards of sleepers in flooring in low barn, at 5s. 6d. ....	40 : 19 : 6
511 yards of joisting in granaries and stable lofts, at 6s. 6d.....	161 : 1 : 6
390 feet cubic for safe lintels (inside lintels) and beams, at 3s. ....	58 : 10 : 0
1523 feet lineal for skirting in granary and cow barn, at 4d. ....	8 : 14 : 4
140 feet superficial of weather-boards in ventilating the byres, at 6d.	3 : 10 : 0
108 yards of plain doors, with 3 bars each, at 3s. 6d. ....	18 : 18 : 0
192 feet superficial of luffer board windows, at 6d. ....	4 : 16 : 0
126 feet superficial in straw-yard gates, at 6d. ....	3 : 3 : 0
24 feet cubic in frames of hung gates, at 3s. 3d. ....	3 : 18 : 0
4 pulley chains and weights.....	2 : 5 : 0
36 feet cubic in beams at cattle heads, at 3s. 3d. ....	5 : 17 : 0

22 stock locks, at 2s. 6d.....	2 : 5 : 0
8 sliding bolts of a large size, at 2s. 6d.....	1 : 0 : 0
9 ditto of a smaller size, at 2s.....	0 : 18 : 0
45 feet superficial of three glazed windows, at 2s. 3d. ....	5 : 1 : 3
175 feet superficial of stair, at 6d. ....	4 : 7 : 6
46 yards of division walls in the poultry-house, piggery, and necessary, at 2s.....	4 : 12 : 0
153 yards of plaster in granaries, at 5d.....	3 : 3 : 4
46 feet cubic of anchor beams and posts in cart-shed at 3s. ....	6 : 18 : 0

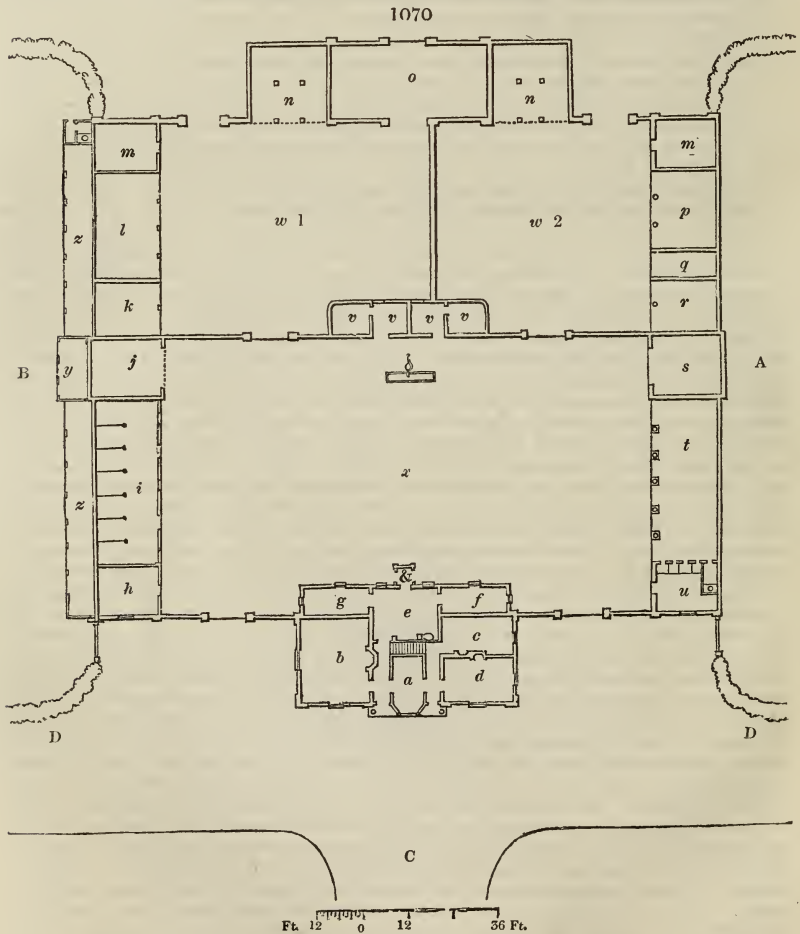

£1478 : 3 : 9

1148. *Remarks.* This Design was procured us by our much esteemed friend Mr. Gorrie, who informs us that it is built exactly on the model of one which obtained a premium for its author from the Highland Society of Scotland. "The farm of Elcho, where the above farmery stands," Mr. Gorrie remarks, "is partly clay and partly black land, and may be considered as a fair medium average of Carse of Gowrie farms, as to size, soil, and mode of cropping. Many of the best farms in the Carse of Gowrie contain a proportion of black land, which admits of turnips being raised for feeding. On Elcho, and such Carse farms, the whole is under tillage; clover, standing only one year in the course, admitting of little pasturage. On black lands, a pair of horses with a plough are equal to the labour of 40 acres; 6 ploughs with 12 horses, and a few supernumerary, are equal to the working of 240 acres. On farms wholly clay, 8 ploughs are necessary for the same extent, under the same rotation of cropping; and, on such farms, feeding-byres and additional stabling would be requisite. In other respects the plan of Elcho farmery would be suitable, holding out many advantages. Several mills go by water near the northern banks of the Carse, and this element is available near the river Tay. Elcho is situated near the west end of the Carse of Gowrie, and on the south side of the Tay." To us this Design appears decidedly the most perfect of upwards of a hundred which have been sent us from different parts of the country, and from which we have chosen those given in the present section. Its excellence evidently depends on two things; first, on the Architect being a thinking and ingenious man, really intent on carrying improvement into every department of his profession; and, secondly, on his knowing thoroughly the uses of a farm yard. He is, or appears to us to be, among the builders of farmeries, what Mr. Fowler of London is among the builders of public markets, — an Architect of reason, and not a mere follower of precedents; a man, in short, anxious to do something more than leave his art exactly where he found it. No Architect can improve the arrangement of a building of which he does not thoroughly understand the use; for which reason, in all our Designs, we have endeavoured to show the uses of all their different parts; and we have also enlarged on this subject when treating of Fundamental Principles and Model Designs, in a manner which, in a work professedly devoted to Architecture, must, no doubt, have surprised many. This we have done, because we are convinced that the knowledge of the uses of any building constitutes the essential foundation of all architectural improvements in it, beyond that of mere design and taste; which, it must be remembered, are to an edifice only what dress is to a man, not the man himself. In perusing Mr. Mackenzie's description of his plan, we find in every sentence evidence of his intimate acquaintance

with the business of the farm yard; and we cannot help being delighted with the improvements which he has introduced. The circular feeding-house is a new and excellent idea, the whole arrangements of the barn and straw-house are admirable, and, as the author observes, must save a great deal of labour. The inclined plane, and its right and left level elevated branches, for wheeling the manure from the stables into the middle of the cattle courts, without the necessity of opening a gate, is excellent; as is the idea of the pump and general supply cistern being placed in a house, to protect them from the frost. In a country where flag-stone abounds, long, narrow, liquid manure tanks are, as shown, preferable to circular or square forms covered by arches, on account of their cheapness. On the whole, we strongly recommend the young Architect to make himself master of this Design in all its details; because there are several points in it which he may introduce in the very humblest of farmeries, and because most, or all, of them should be included in all extensive ones.

Design XXXVI.—*A Public House and Farmery; the Publican being, at the same time, a small Farmer and a Butcher.*

1149. *Accommodation.* The general appearance of this public house and farmery is shown in p. 536; the ground plan in fig. 1070; and we have received from the

author, William Thorold, Esq., Architect and Engineer, of Norwich, the following explanatory details:—"The words, 'Good entertainment for man and horse,'" Mr. Thorold observes, "formerly appeared on the sign-board of every country alehouse;

and, in order that we should maintain the character of 'good,' it is necessary to make the accommodations and appearances correspond with modern refinement, which we have endeavoured to do in the present Design. In fig. 1070, to a scale of 48 feet to an inch, the bar, *a*, is represented with a bow window, overlooking the road, and is surrounded on the other sides by the entrance lobbies and staircase, being warmed from the back of the kitchen range. The dining or club room, *b*, is proposed to be occasionally used as a magistrates' petty sessions room; the two small parlours, *c* and *d*, have cellars under them; the kitchen, *e*, is approached from the yard, *x*, by a small porch; and this kitchen should have a cooking-range, copper, oven, &c., and must be used also as a back-kitchen; but the family washing can be done in the brewhouse, *s*. There is a dairy, *f*; pantry and store-room, *g*; and there are six sleeping-rooms on the first floor. There is a butcher's sale-shop, *h*; a lock-up stable, *i*; a coach and gig-house, *j*; a slaughter-house, *k*; and an open stable, *l*; with hay-houses, *m m*. Two open lodges are shown at *n n*, with stack saddles over their flat stone roofs. There is a barn, *o*, with a wicket at each end to pitch in the stacks. There is a cart-house stable at *p*; a loose box for a hackney, *q*; a cow-house, *r*; brewhouse, *s*; cart-lodge, *t*; place for fowls, fuel, and women's privy, *v*; a yard for driven cattle, *w 1*; a yard for farm cattle, *w 2*; and a paved yard, *x*, with pump and water-trough. The house and brewhouse are supposed to be supplied by underground pipes. There is an orchestra at *y*; and two verandas for playing at skittles, or for separate alcoves or pavilions for taking refreshments in, *z z*. There is a kitchen-garden, *A*; a bowling-green and tea-garden, *B*; a parish road, *C*; and a turnpike road, *D*.

1150. *Construction.* The walls may be of rubblestone, bricks, or clay lumps; and the roofs covered with slate.

1151. *Remarks.* This Design is supposed to be in the plainest possible style; and it is intended to introduce drains, manure tanks, and every other economical arrangement, in its details." We consider this a very complete Design of its kind; its author is not only a scientific Architect and engineer of considerable practice, but he has also had much experience in farming, in the county of Norfolk.

Design XXXVII. — *A House and Out-buildings for a Cheese Dairy Farm of from 300 to 350 Acres, in Cheshire.*

1152. *Accommodation.* The ground plan of the house, which we have not given, contains a parlour, dining-room, kitchen, or, as it is called in Cheshire, a house-place,

staircase; pantry, with a cellar under; dairy, with cheese bench; situation for cheese-presses, and boilers, there are a milk-room, with a cheese-room over it; and a salting-house, also with a cheese-room over it. The farmery contains four cow-houses for six cows each, *m*; and two for twelve cows each, *o*; with foddering bays, *n*, and cleaning-passages, *p*, between. There are in the barns two corn-bays, *q*, and a threshing-bay, *r*, where the machinery would be placed if a threshing-machine were employed. There

is a stable for six horses, *t*, an hospital for sick horses, *u*; a wheelwright's or carpenter's shop, *v*, with a store-room over it; a steaming-room, *w*; a reservoir for liquid manure, *x*, with a pump, *y*; four inner pig-cots, *z*, with outer pig-cots and two poultry-houses, *aa*; with a poultry-yard, *bb*. The stack-yard is in the situation, *cc*, and it contains sixty feet in length of hay-sheds, twenty feet wide, and twenty-two feet high, in one or more lengths, as may be most convenient. There are three calf-cots, *dd*, and sheds may be continued at *ee*, with a wall at *ff*; so as to form an additional straw or fold yard to that in the centre of the farmery marked *gg*.

1153. *Remarks.*—This Design has been made, at our request, by Alexander Ogilvie, Esq., of the Mere, near Knutsford, Cheshire. Mr. Ogilvie was a pupil of the late Dr. Coventry, and has since had extensive practice both as a land steward and as a farmer. We saw his crops and his dairy when we visited him at Mere, in July, 1830, and found them greatly superior to any in the neighbourhood. His dairy practice was also of an improved description; and, at our request, he has furnished us with plans and elevations of his improved cheese-press, which we shall give under the head of Farm House Furniture. The plan of the farmery was accompanied by the following observations:—“This plan is something near what I should think a house and set of offices *ought* to be on a farm of from 300 to 350 acres, in Cheshire; but I am sorry to say that the poor tenants of this district are obliged to put up with buildings of a very different description; partly owing to the landlords not liking to see a gentleman farmer in their neighbourhood, and partly owing to the class of men who, in this country, generally have the charge of landed property being incompetent to judge of the best system to be adopted for the ultimate and permanent benefit of the estate. There are several things of minor importance that have been omitted in this Design; such as a coal-yard, &c.; but these will not affect the general merits or demerits of the plan. If I occupied such a farm myself, with similar out-buildings, I should certainly have a threshing-machine, and that one to be moved by a steam-engine of about six-horse power, by which I could thresh my corn, cut my hay, straw, turnips, &c., and steam my potatoes and other articles. The machine would stand in the one corn-bay, on a loft or platform raised eight feet from the ground, with a winnowing-machine, &c., under it; then the threshing-bay, shown in the plan, would be the place where the straw would be deposited when thrown from the shaker of the machine, and the other corn-bay would become the straw-house. Behind the cow-houses there might be a straw-yard, if required, with sheds for young cattle and young horses during the winter months. This is shown by the dotted lines *ee* and *ff*.”

Design XXXVIII.—*A Mixed Stock Farm, in a high (lilly) Country, employing only One Pair of Horses.*

1154. *Accommodation.* In the ground plan, fig. 1072, are shown a potato-house, *a*; spare-house, or place applicable for different purposes, *b*; house for young cattle, *c*; cow-house, *d*;

larger cow-house, *e*; small cow-house, *f*; corn-barn, *g*; part of the barn to be floored and lofted, *h*; house for holding wool, to be floored with boards, *i*; hay-house, *k*; stable, *l*; cart-shed, *m*; poultry-house, *n*; two sheep-sheds, *o o*; two pigsties, *p*; sheep-yard, *q*; and yard for dung, *r*.

1155. *Construction.* The walls are of stone, and the roof is slated. The surface on which this farmery stands is supposed to have an inclination to one point, to which all

the rain water which falls on the roofs of the houses and on the yards, and all the liquid manure, are drained by open gutters, or underground conduits, formed in the manner shown in the section fig. 1073,

1073 which are discharged into a tank, of which fig. 1075 is a ground plan, and fig. 1074, a longitudinal section.

This tank is about forty-four feet long by twelve feet wide; the water may enter at one end, and there may be a waste gutter at the other, in case it should at any time be allowed to overflow. "The sediment is supposed to settle in the basin. The chaff, or other dry substances, that it is wished to convert into manure, and that are difficult to rot, may also be put in here; and it is intended that the width and slope of the basin should admit of carts passing through it for carrying off the sediment. On one side, fig. 1075, *u* is supposed to be sunk about four feet deep below the bottom of the basin, and the water to be drained thence through a close grating, *g*. A pump is proposed to be put into the well, and to stand sufficiently high above the ground to throw the water into a barrel on a cart, which may then be taken to the field, and discharged on the soil, in the same way as the streets are watered in towns. If the grating should not make the water sufficiently free from mud, a small bundle of wheat straw, well drawn, and loosely tied, put up against it, will be found to answer the purpose. A hatchway, or manhole, should be made in the cover of the well, in order to admit of a person going down occasionally to clear it out." (*Highland Soc. Trans.*, vol. viii. p. 388.) The soil in which this tank or basin is formed is supposed to be rocky or gravelly, in which case a layer of clay puddle should be placed underneath the causewayed bottom, and a vertical stratum of the same material should be put at the backs of the side walls; but in clay soils this will not be necessary. In fig. 1075, *s s* are the side walls; *t t*, vertical strata of clay puddle; *u*, the well; and *g*, the grating. In fig. 1074, *v* is the layer of clay puddle under the causeway; *w* is the grating before the opening to the well; *x*, the point at which the water enters; *y*, that at which it escapes; and *z*, the coping of the side walls. Fig. 1076 is a suitable plan for a gate

for this description of farm yard. "The right side pillar is intended for a situation where free-stone can be easily obtained; and the left side represents the finishing in a situation where inferior stone only is to be got, or where the expense of better finishing is not approved of; but, if it should be thought preferable, a round pillar may be formed of any kind of inferior stone. The gate-posts are supposed to be ten inches in diameter, circular, or in the octagon form, and sunk in the ground. As it frequently happens that gates into straw-yards are obstructed in their opening, when the courts are becoming filled with dung, it is proposed to hang this gate about nine or ten inches clear of the surface; and to make up the space between the surface and the gate by laying a piece of coarse wood below the gate, about six or eight inches in diameter, which can be taken out, so as not to obstruct the wheels of carts when the dung is removed from the court. A gate put together in this way is very substantial; and is easily repaired, when any part of it fails. As a means of preserving the gates in spring, when the cattle leave the yards, they should be all taken off, and put into the sheds, where they may remain till they are again required.

1156. *Remarks.* This Design, and those of the six following farmeries, have been taken from a collection published in the *Transactions of the Highland Society of Scotland*, vol. viii. These Designs were composed by Mr. Waddell of Berwickshire, an Architect of great experience in the laying out of farm buildings, under the superintendance of the committee of the society; and we are informed by our much esteemed friend, David Low, Esq., Professor of Agriculture in the University of Edinburgh, that he considers

them, though capable of improvement, yet the best which have hitherto been published. In consequence of our having received this opinion from such high authority as that of Professor Low, we have deemed it our duty to make a selection, such as we consider will render our series complete. The Designs in the *Highland Society's Transactions* are prefaced by a general specification, and some accompanying remarks, from which we have made the following extracts and abridgments.

1157. *The Designs published by the Highland Society* are contrived solely with a view to utility, and to correct the prevailing errors in this description of buildings; viz., that of crowding them together, under the idea of giving them greater compactness; and that of not giving them a sufficient extent of shelter-sheds for the feeding of cattle. "The last is a fault so universal, that it is only on the larger class of breeding and feeding farms, in the border counties of England and Scotland, that experience has taught builders fully to avoid it." "In giving designs of the outhouses of a farm," it is judiciously observed, that "little more can be done than to present useful examples. Although a certain similarity must exist in the form and arrangement of the parts of all such buildings, yet these must be modified according to the circumstances of the farm itself, the nature of the soil, the situation with regard to markets, and the particular kind of management to be pursued. No one rule that can be given is of general application; and the judgment of the Architect must be shown in adapting the size, form, and arrangement of the buildings to the nature of the farm, and the wants of the occupier. While every suitable accommodation should be afforded to the tenant, it is the province of the Architect to take care that the heavy cost of such buildings be not unnecessarily enhanced, either by erecting buildings that are useless, or by giving unnecessary dimensions to such as are requisite. It may be particularly remarked, that the giving unnecessary breadth to the buildings adds materially to the expense, by increasing the dimensions of the timbers, and adding to the size of the roofs. At the same time, care must be taken that, in the cow-houses and stables, the animals shall not be cramped from the want of necessary room." (*Ibid.*, p. 368.)

1158. *The most convenient Arrangement of a Farmery* "is in the form of a rectangle, the side to the south being open; and the farm house being placed at some convenient distance in front of it. The most approved mode of keeping and feeding the larger and finer kinds of cattle is in small sheds, with open yards attached, each capable of holding two animals. In the Designs which follow, the sheds are of larger dimensions, but they can be subdivided where this mode of managing the feeding stock is adopted."

1159. *In arranging this, and the Eight following Designs*, "wherever uniformity and convenience could not be combined, the preference has been given to the latter; and nothing has been proposed but what has been found, from experience, to be useful and practicable. But it is quite impossible, especially in the largest class of farm buildings, to get all the apartments arranged so conveniently as could be wished, consistently with any degree of regularity; nor does it seem to be possible to lay down a plan that will suit the wish of all farmers, there being so great a diversity in the modes of occupation, kind of management, situation, soil, &c."

1160. *Drainage*. "It is recommended that the liquid manure from the stables, cow-houses, and yards should be carried off, by causewayed open channels, to a pond or tank near to the buildings. This mode of conveying away and receiving the urine and dung-water is conceived to be better in ordinary cases than conduits below ground, which, even when executed in the best manner, will be subject to be choked up from the want of necessary attention to cleaning; further, such sewers become nurseries for rats, notwithstanding every precaution that can be taken. Conduits may be made through the ranges of building, below the floors, at proper places, so as to discharge the liquid into a pond or tank exterior to the farmery."

1161. *Water*. "With respect to watering the cattle in the yards, no indication of the mode of doing so is given in the Designs, as this must depend on whether the water is got from a stream, or from a well. If a stream cannot be obtained, there are few situations where water cannot be got by sinking a well; and the best way is to raise the water into a cistern, which may be placed in any of the shelter-sheds or other houses, seven feet above the ground; or, if the water will not rise so high, a small apartment may be made for it, and from this it may be conveyed to cisterns with ball cocks, in the different yards and places where it is wanted; care being taken to lay the pipes so as that they may be easily emptied on the approach of frost."

1162. *The Shelter-sheds and Yards* "should always be open to the south; and the sheds, unless where they are very large, will be found to answer better with only one opening in front; as by this means they afford more warmth to the cattle. The usual objection to this is, that one ill-natured beast will keep out the rest: this, however, seldom happens. A farmer of much experience recently told Mr. Waddell that last year he built up all the openings, except one, in one of his sheds, and that he knew a great

difference in favour of the stock in that yard, as compared with those in which there were three or more openings in the sheds. The animals were finer in the skin, and, in other respects, in better condition."

1163. *Passages.* "It may appear, in several of these ground plans, that the passages and the entrances to the different apartments are wider than necessary; but it is a matter of great consequence to have open and free access, where a number of carts and cattle frequently come in contact."

1164. *Turnip-house.* "As it is necessary to lay up a stock of turnips as a supply when they cannot be got from the field either on account of frost or wet weather, a turnip-house is delineated in some of the plans; though it is to be observed that these turnip-houses are of no great utility, since it is found that turnips keep much longer when put together in a sheltered place in the open air, well covered with straw, than they will do in a close house."

1165. *Threshing-mills.* "No Design has been given either of a water-mill or steam-engine house for the threshing-machine; as the erection of these is subject to circumstances, and their size and position are naturally under the direction of the millwright."

1166. *Gates.* "In all the plans here designed, the gates are shown to be hung on wooden posts, which are not so easily knocked down by carts as common stone pillars. But this does not prevent the adoption of hewn-stone pillars, which both have a better appearance and are much stronger."

1167. *All the inside Gables* "are intended to be carried to the top."

1168. *With regard to ventilating the Stables and Cow-houses,* "it is recommended that openings of about six inches high, and the same width as between the rafters, shall be made in the roofs, and fitted up with boards, about three inches broad, suspended by pivots, and moved by a crank, in the same way as the luffer-boards in a granary window. One, two, or three of these, in a stable or cow-house, according to the length of the apartment, will, if attended to, be found to be of great service."

1169. *Boiling-houses and Stables.* "In all the boiling-houses the roofs should be lathed and plastered in the inside, round by the back of the cupple (couples, or rafters), and should have a large ventilator to let off the steam. The saddle-horse stables should be plastered in the same way."

1170. *In the Construction of these Buildings,* "the corners, ribbets (reveals), arches, and skews are supposed to be of hewn stone; the wood of Memel fir; the slates from Easdale; and the ridges of flanks (gutters in the valleys) covered with lead. The cost and workmanship of all the materials are included in the general estimate, except the prime cost of stones. In most of the plans, metal pillars are designed for the cart-sheds; but, where stones can be easily procured, it is recommended that they should be made use of, in preference to metal. The stones for the bases of the metal pillars should be one foot eight inches broad, and one foot two inches thick." (*Ibid.*, 372.)

1171. *The Plan, fig. 1072,* "being intended for a hill farm, principally in pasture, it is supposed that only one pair of work-horses is employed; but the stable is made to hold four, because, on a farm of this sort, there should always be a third ready to be employed occasionally, frequently a breeding mare; and the fourth stall is required for a riding-pony. It is supposed that three or four cows are to be kept, and their calves brought up till they are two or three years old, which will consume all the fodder produced by this extent of arable culture. Should more horses be employed, or the farm produce much meadow hay, more cattle might be kept; and, consequently, the houses for cattle would then require to be enlarged. A room is designed for holding wool, which by some may be thought unnecessary, as the barn or cow-house is frequently made use of for holding it till sold; but it sometimes happens that, in bad markets, the wool is kept over the year; and in this case a house for it is necessary. There are also added shelter-sheds, and a yard for handling sheep, which may be subdivided by hurdles, as required. Shelter of this kind for ewes in lambing is of great service in bad weather. It is thought, on the whole, that in this Design there is as small an extent of building as should be erected on a considerable-sized farm of this description." (*Ibid.*, p. 387.)

1172. *General Estimate.* The probable expense of executing this plan, exclusive of the carriage of materials and prime cost of stones, will be about £410; and, if covered with tiles, £322.

Design XXXIX. — *A Farmery for a Garden Farm of 200 Acres, situated near a Town, employed wholly in Tillage, where no Stock is kept but Horses and Family Cows, and where the whole Produce is sold.*

1173. *Accommodation.* The general appearance is shown in fig. 1077, and the ground plan in fig. 1078. The latter contains a potato-house, *a*; cart-shed, the pillars of which are of iron, with stone bases and caps, *b*; cow-house, *c*; calf-house, or place for a mare and

foal, *d*; straw-barn and dressing-barn, *e*; situation of the granary, or outside inclined plane, up which the unthreshed corn is carried to the feeding-board of the threshing-machine, *f*; spare house, *g*; stable, *h*; hay-house, *i*; riding-horse stable, *k*; poultry-house,

*l*; house for boiling or steaming food, *m*; two pigsties, *n*; dung-pit, *o*; and open court, *p*; privy, and place for a dog, *q*. One pump may be conveniently placed in the boiling-house, and the other in the hay-house.

1174. *Remarks.* This farmery is supposed to be situated on the side of a public road, near a town. The doors on that account are placed on the inside of the court, with a wall in front eight feet high, that they may be locked at night; but in other situations this wall will be unnecessary. The accommodation here shown will be found sufficient for most situations. The dressing-barn might answer a few feet shorter than it is represented; and, if the straw-barn should be thought too short, the space thus gained could be thrown into it. It is proposed to make the straw-barn ten feet high to the joists, which would hold a sufficient quantity of straw, and give room for putting it up in bundles for the market, &c. The granary above this will be four feet six inches high from the floor to the top of the wall, which, with six inches of beam-filling, will give

five feet from the floor to the intersections of the cupples (rafters). If these offices were not on the side of a public road, it would be an improvement to make the boiling-house and poultry-house face the south.

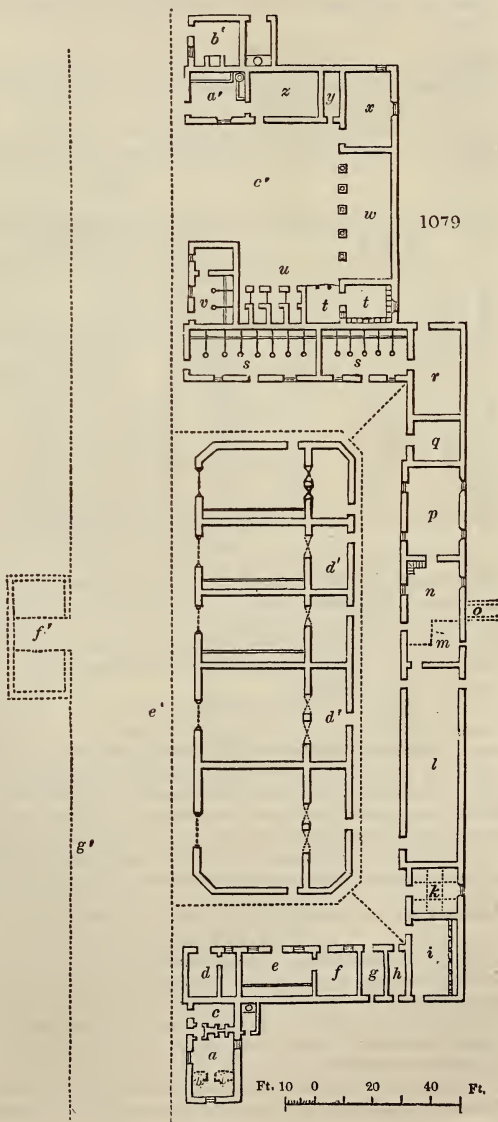

1175. *General Estimate.* This Design, exclusive of the carriage of materials, and the prime cost of stones, will cost, in the south of Scotland, about £550; and, if covered with tiles instead of slates, the expense will not exceed £400. Dividing these sums by the number of cubic feet, we have, in the first case,  $2\frac{1}{2}d.$  per foot, and, in the second,  $1\frac{3}{4}d.$  per foot, which may be considered the guess prices for this description of buildings in Scotland.

Design XL. — *A Farmery for a Farm of 500 Acres, kept in a Rotation of Corn Crops and Pasture, producing Turnips, and employed partly in breeding, and partly in feeding Stock.*

1176. *Accommodation.* The ground plan, fig. 1079, shows an overseer's house, with

a kitchen, *a*; two box-beds, *b b*, partitioning off a light closet, or bed-room: there is besides, a small parlour, *c*. Adjoining this are a gig-house and harness-room, *d*; cow-house, *e*; house for hay or turnips, *f*; mare and foal house, *g*; house for a bull, *h*; servants' cow-house, *i*; calf-house, *h*; straw-barn, *l*; threshing-machinery, *m*; dressing-barn, *n*; gangway, or inclined plane, from the rick-yard to the floor for unthreshed corn, *o*; undergranary, *p*, with a granary over; spare house, *q*; hay-house, *r*; stables, *s s*; poultry-house and yard, *t t*; pigsties, *u*; stable for riding horses, and saddle-room, *v v*; cart-shed, *w*; carpenter's shop, *x*; foal-house, *y*; potato-house, *z*; house for boiling and steaming food, *a'*; smithy, *b'*; open yard, in which no litter or manure is placed, *c'*; shelter-sheds, and fold-yards, with cribs in the latter, *d'*; paved gutter for collecting and conveying away the surface water, *e'*; place for storing turnips, *f'*; and supposed line of fence, *g'*.

1177. *Remarks.* This is a very complete plan, though we could wish some more accommodation to the overseer's house. The separation of those houses which require no litter into a square by themselves, *c'*, is very judicious. The poultry-house here, *t*, ought to have a communication with the stable, for the sake of heat. The pigsties we would remove, and add the space they stand on to the poultry-yard. Places for pigs might be formed in

the central shelter-shed. The following observations on this plan are by the committee of the Highland Society: "The shelter-sheds are placed within the square; and, should they be thought too small for a farm producing a great quantity of straw, they may be enlarged by throwing them a few feet forward. There are also designed an overseer's house, and a smithy and carpenter's shop. Should these not be required, the cart-sheds could be placed where the overseer's house is; the boiling and potato houses at the west end of the riding-horse stable, and the west wing done away with altogether. A poultry-house could be taken off the straw-barn. By these means a considerable expense would be saved. The lower and upper granary would still make an extent of seventy feet by eighteen feet, which would be a suitable size for such a farm." (*Trans. High. Soc.*, vol. viii. p. 382.)

1178. *General Estimate.* To execute this plan, exclusive of the overseer's house, smithy, and carpenter's shop, and of the carriage of materials, and the prime cost of stones, will cost about £1300 covered with slates; if covered with tiles, it will cost about £1020.

Design XLI. — *A Farmery for a Farm of 500 Acres of arable Turnip Land, kept under alternate Corn and Pasture, and employed in breeding and in feeding Stock, as well as in sending Corn to Market.*

1179. *Accommodation.* The ground plan, fig. 1080, shows pigsties, *a*; a poultry-house, *b*; house for boiling or steaming food, *c*; potato-house, *d*; foal-house, *e*; stables

for seventeen horses, *f*; hay-house, *g*; spare house, *h*; straw-houses, *i*; threshing-machinery, *k*; dressing-barn, *l*, with loft for unthreshed corn, &c., over it; lower granary, *m*, with another granary of the same size over it; calf-house, *n*; cow-houses, *o*; house for bull, *p*; cart-shed, *q*; gig-house, *r*; shelter-sheds, *s*; shed for young horses or cattle, *t*, with a yard in front; feeding-yards, *u*; yard for young cattle, *v*; and yard for store cattle, *w*.

1180. *Remarks.* The committee observe that this plan will be found extremely convenient, though it does not contain near so much accommodation as the preceding one. The small yard, *t*, in the middle will be found to be very useful for different purposes. On some farms the length of the straw-barn would be quite sufficient, were it to terminate in a line with the front of the shelter-sheds. The cart-sheds would be better arranged if they opened to the exterior of the yard, as the cows going out and in are apt to be rambling among the carts, and injuring themselves.

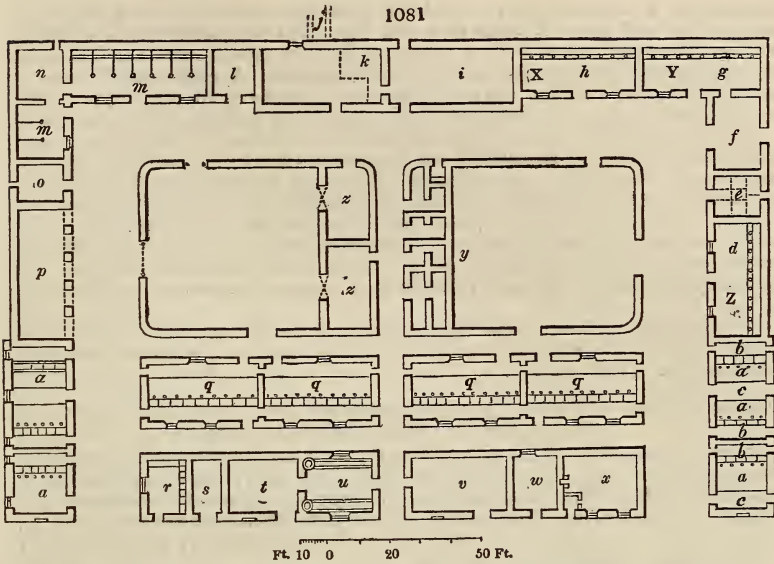

1181. *General Estimate.* Exclusive of carriages, and prime cost of stone, this farmery will cost about £1190, covered with slates; and, if covered with tiles, about £940.

Design XLII. — *A Dairy Farm of 500 Acres, kept in a Rotation of Corn Crops and Grass: one half being supposed to be in Hay or Pasture.*

1182. *Accommodation.* The ground plan, fig. 1081, shows four cow-houses, *a*, with feeding-passages, *b*, and cleaning-passages, *c*; another cow-house, *d*; a calf-house, *e*; turnip-house, *f*; cow-house, *g*; another cow-house, *h*; straw-house, *i*; situation of the inclined plane from the rick-yard to the unthreshed corn-floor, *j*; and machinery, *k*; There are a spare house, *l*; two stables, *m*; hay-house, *n*; place for a bull, *o*; cart-shed, *p*; four cow-houses, *q*, each with a feeding-passage on one side, and a cleaning-passage on the other; a poultry-house, *r*; gig-house, *s*; potato-house, *t*; boiling-house, *u*; turnip-house, *v*; store-house, *w*; superintendant's house, *x*; pigsties, *y*; and shelter-sheds, *z*.

1081

1183. *Construction.* Fig. 1082 is a section across the dressing-barn, by which the space between the dressing-floor and the ceiling of the unthreshed corn floor appears to be eight feet. Fig. 1083 is a section across the straw-barn, with granary over; showing the height from the floor to the ceiling of the straw-room to be ten feet. Fig. 1084 shows two sections across the boiling-house and cow-house, exhibiting the cooling or scalding troughs of the boiling-house, *a a*; the feeding-passage of the cow-house, *b*; and the situation of the cleaning-passage behind the cows, *c*. Fig. 1085 is a plan of the corn-loft, or floor for unthreshed corn, of the barn; in which is shown the entrance for bringing in the sheaves by an inclined plane from the rick-yard, *d*; the opening for the

admission of the horizontal shaft, connecting the outside gin-wheel with the inside spur-wheel of the threshing-machine, *e*; the hatchway or trapdoor for descending to the dressing-floor of the barn, *f*; the situation of the machinery, *g*; the opening by which the straw is dropped by the shaker to the straw-house, *h*; and steps from the corn-loft to the granary, *i*.

1184. *Remarks.* "This plan is designed for a dairy-farm, and it is considered that a great proportion of the cows are fed on boiled or steamed food. There are two boilers, one being intended for steaming, and the other for boiling in the common way. The stalls, except those in the cow-houses marked X, Y, Z, are designed for the cows fed on boiled or steamed food, and may be fitted up with troughs of flat stones. On the supposition that a part of the cows are not giving milk, some of the cow-houses are designed with stalls in the common way, that the cows may be fed with straw, hay, or turnips. These cow-houses are marked X, Y, Z. In farm offices of this kind, a turnip-shed may be necessary, in order that a supply of turnips may be obtained, free from frost, in winter. Those cow-houses intended for the cows feeding on boiled or steamed food are all placed as near as possible to the boiling and store houses, with large open passages for conveying the food to the different places. The dung-pits are also constructed as near the cow-houses as possible. The walls round these pits need not be higher than three feet. A

shelter-shed is designed on the west side, for a few young cattle. If this should be required, the wall around it should be six feet high. On a farm of this kind, a considerable number of pigs may be kept; a number of sheds for them are therefore laid out in a convenient situation, and more can be added if necessary. A good supply of water to a steading of this description is of great importance; and the cistern may be put up over the gig or store house. A superintendent's house is also designed, it being necessary that such a person should be near the establishment at all times. It will also be proper to attend particularly to the architectural arrangements for cleaning and ventilating the cow-houses. In some farm buildings of this description, the dairy is connected with the outhouses; and the same power that drives the threshing-machine gives motion to the churn; but it is conceived that it would be more convenient to attach the dairy to the farm house at a little distance from the outhouses, where there would be purer air, and where the work is to be performed under the eye of the mistress of the farm. As the dairy does not, in the present Design, form a part of the houses, no plan of it is given."

1185. *General Estimate.* This plan, exclusive of the carriage of materials and the prime cost of stones, will cost about £1300, covered with slate; if covered with tiles, about £1000. (*Ibid.*, p. 385.)

Design XLIII. — *A Farmery for a Clay-Land arable Farm of 500 Acres, not producing Turnips, and kept chiefly, or wholly, in Tillage.*

1186. *Accommodation.* The ground plan, fig. 1088, shows a cart-shed, *a*; tool-house, *b*; gig-house, *c*; stable, *d*; harness-room, with a flue for a stove, *e*; three stables, *f*; hay-house, *g*; spare house, *h*; straw-barn, *i*; dressing-barn, *h*, in which are indicated the place for the machinery, and the stair to the corn-loft; granary, *l*; two cow-houses, *m*; house for bull, *n*; calf-house, *o*; potato-house, *p*; boiling-house, *q*; poultry-house, *r*; two pigsties, *s*; shelter-sheds, *t*; yard for young cattle, *u*; yards for feeding cattle, *v v*; situation of the gangway, or inclined plane to the corn-floor, *w*; and rick-yard, *x*.

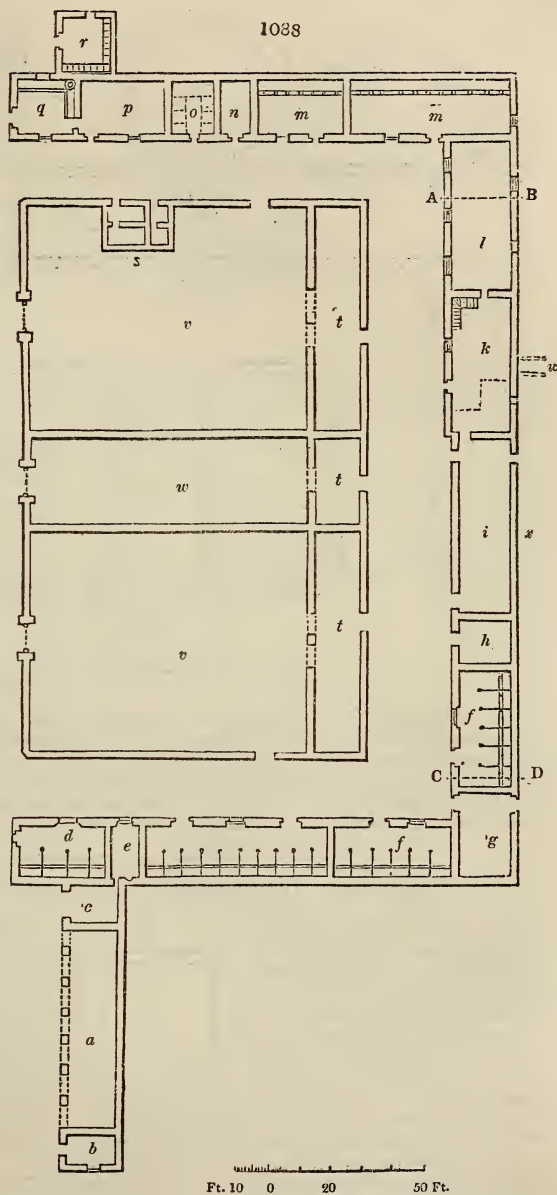

1187. *Construction.* Fig. 1086 is a section, A B, across the barn, or granary. Fig. 1087 is a section, C D, across the stable. With the exception of the barn and granary, all the out-buildings are only one story high; the walls of the straw-house are 10 feet high, and those of all the others 8 feet.

1188. *Remarks.* "In this plan, the stables and cart-sheds are conveniently situated, and the barns are well placed for supplying the courts or yards with straw. The dung from the stables and cow-houses is designed to go into the yards by the small gates. The yards here may be differently divided, if it be thought expedient. The extent of granaries above and below, together, is 88 feet by 18; perhaps more than in some, but not more than in other cases, might be required. The boiling-house, in this plan, is not so near the stables as could be wished; but, as there is not room for it and the potato-house in the same range where the stables are, and it being necessary to keep it near the outside of the square, and as far from the barn yard as possible, there is no other part where it could be so properly placed, except it were placed where the cart-sheds are, and the cart-sheds were made in the west range, which would be found to be attended with inconvenience. The flue of the boiling-house here may go round the back of the poultry-house, and the chimney be erected on the west side of it. There is also a plan for a small stove in the harness-room, next the saddle-horse stable, which will be found to be of great use in winter or damp weather." (*Trans. High. Soc.*, vol. viii. p. 384.) We have not, either in this case, or in most of the others, copied the elevations given by the Highland Society; because they are all of the very plainest description, and without the slightest pretension to architectural style. We must say, we deeply regret this circumstance; because a public body, so influential as the Highland Society of Scotland, might easily effect important improvements, not only in the economical arrangements, but also in the architectural taste, of farm houses, farm buildings, and cottage dwellings. Indeed, the farm buildings, and especially the farm houses, of the northern half of the island, are as far behind those of the south in point of architectural taste, as they are before them in point of arrangement. Where, for example, shall we find, in Scotland, a farm bailiff's house like that at Bury Hill, § 847; or, in the south of England, a farm-yard like that of Elcho? It is true that a mere farmery affords but slight opportunities of displaying architectural style; but, slight as these are, they are such as would render the most common-place arrangement of walls and roofs as different from the external appearance which they now present, as a wall of mud is from one of hewn stone.

Besides, there are always the gable ends: and every farmery must have one of three things highly susceptible of architectural style; viz. a shed to the gin-wheel of a threshing-machine; a water-wheel; or a chimney to a steam-engine. Most farmeries have a boiling-house; and many have a ploughman's lodge; both of which give rise to chimney-tops, which may always be rendered sources of conferring style. Neither should it be forgotten that there are such things as ventilators in the ridges of the roofs, respecting which the same remark may be made. As to the farm house, and the cottages of the married labourers which are commonly to be found adjoining the farmery; it is clear that, if the landlord wishes it, they can be rendered as beautiful as any other dwellings. But the grand feature of the modern farmery, on a large scale, is the chimney to the steam-engine; and to its form we would particularly direct the attention of Architects, and their employers; and, also, that of the Highland Society, which among its other committees, ought to have one of taste.

1189. *General Estimate.* "This plan, exclusive of the carriage of materials and the prime cost of stones, will cost, if covered with slates, about £1260; and, if covered with tiles, about £1020." (*Ibid.*)

Design XLIV. — A Farmery for a Farm of 150 Acres, kept in a Rotation of Crops and Pasture, producing Turnips and Potatoes; and employed partly in feeding and partly in breeding Stock.

1190. *Accommodation.* The ground plan, fig. 1089, shows a potato-house, *a*; house for storing turnips, *b*; two cow-houses, *c*; calf-house, *d*; house for mare and foal, *e*; straw-barn, *f*; dressing-barn, *g*; machinery, *h*; gangway, or inclined plane to the corn-loft, *i*; horse-course, 30 feet in diameter, and covered with a conical roof, *k*; cart-shed, *l*; hay-house, *m*; stables, *n n*; spare house, *o*; poultry-house, *p*; pigsty, *q*; shelter-sheds, *r*; and yards, *s*.

1191. *Remarks.* "This plan will afford all the accommodation that could be wished

for in a farm of this size. The form of a horse-course is here added; for, unless sufficient water can be easily procured for turning a wheel, a farm of this extent will not afford the expense of steam or a wind power, and horses must be employed. The stables, containing but 4 horses, will answer very well at 15 feet wide."

1192. *General Estimate.* "This plan, exclusive of the expense of carriage and prime cost of stones, will cost about £600; if covered with tiles, about £476." (*Ibid.* p. 383.)

Design XLV. — *A Farmery for a Cottage Farm of 25 Acres.*

1193. *Accommodation.* The general appearance is shown in fig. 1091, and the ground plan in fig. 1090. The latter exhibits a court for calves, *a*; poultry-house, *b*, open to the cow-house, in order to partake of its heat; calf-house, *c*; cow-house, *d*; calf-crib, *e*; cart-shed, *f*; stable, *g*; barn, *h*; part of the barn to be lofted over, *i*; potato-house, *k*; pigsty and yard, *l*; and dung-pit, *m*.

1194. *Remarks.* "This Design for a cottage-farm is plain and simple, and calculated for a country situation where ornament is not required. It is proposed to joist and floor a small part of the barn, laying the joists about 1 foot below the top of the walls. This will be found very useful, by admitting a draught of air near the bottom of the roof, for drying wet corn, grass seeds, &c." It would be easy to render this Design ornamental, by giving the openings the character of the old English style; but we can hardly think it in good taste to bestow much ornament on this class of buildings, which may be truly said to be, "when unadorned, adorned the most." With a comfortable cottage and garden

in front, which, however may, and indeed ought to be, ornamented, and with an orchard and rick-yard behind, what object can harmonise better with the sentiments called forth by the appearance of a simple tract of cultivated country?

1195. *General Estimate.* To execute this plan, we are informed, will require, exclusive of the carriage of materials and the prime cost of stones, about £164, covered with slates; if covered with tiles, about £130.

Design XLVI.—A Farmery for a Cottage Farm of 30 Acres, with Remarks showing how it may be extended so as to serve for a Farm of 50, 80, or 100 Acres.

1196. *Accommodation.* The general appearance is shown in fig. 1093, and the ground plan in fig. 1092. In the latter is seen a potato-house, *a*; stable, with a bay at one end for hay, *b*; cart-shed, *c*; barn, *d*; part of the barn to be lofted at the height of ten feet from the ground, *e*; house for turnips with a pump, *f*; cow-house, *g*; calf-crib, *h*; poultry-house, *i*; pigsties, *k*, with yards, *l*; and dung-pit, with liquid manure tank under, *m*.

1197. *Remarks.* This plan resembles the preceding one, but the different apartments are somewhat larger. The same arrangement, with a small additional increase, will serve for a farm of fifty acres, and double the extent of barn and stable room, with the same accommodation in every other respect, might serve for a farm of eighty or a hundred acres, under a course of alternate grass and corn. In this case the turnip-house, *f*, would serve as a second cart-shed, and there might be a lean-to formed by the farmer himself, placed against the stable and potato-house wall, as a shelter-shed for cattle, and there might be a fold-yard in front of it, formed of bush faggots in Mr. Taylor's manner, § 1038

1198. *Estimate.* This plan, exclusive of the carriage of materials, and prime cost of stones, will cost about £190, covered with slates; covered with tiles, it will cost about £150.

1199. *General Estimate applicable to the Nine preceding Designs.* On calculating the cubic contents, and on comparing these with the actual estimates, it appears that the average price per cubic foot, exclusive of the carriage of materials and the prime cost of stones, is, when the buildings are covered with slates,  $2\frac{3}{4}d$ , and when they are covered with tiles,  $2d$ .

1200. *General Outlines of a Specification to the Nine preceding Designs.*—*Digging.* The trenches for the foundations to be 2 feet below the surface of the floors, or more, if necessary, to obtain a good solid foundation.

1201. *Mason's Work.* The foundations to be laid with flat-bedded stones laid in regular courses, breaking joint alternately, and to be taken in by regular scarcements, as shown in the sections. The whole area of the dressing-barn and low granary floors to be laid

over with small broken stones, forming the thickness of 9 inches. The sleepers to be laid on the inside scarcements, and the whole remaining space of 14 inches to be filled up with solid mason-work of stone and lime properly packed; to have a coat of plaster three fourths of an inch thick on the top, the surface of the plaster being kept one fourth of an inch below the top of the sleepers; care to be taken that the sleepers are resting on flat stones, at short distances; the lime which is applied next the walls all round, to be mixed up with a portion of broken glass. This, if carefully done, will keep the barn-floor clear of vermin, and also prevent it from sinking, as frequently happens. This under-building to be properly dry before the boards are laid on the top. The straw-barn to be done in the same way, with this difference, that the rubble-building above the small stones is to be only 12 inches deep, and to have a composition floor laid above of 3 inches thick, 9 feet broad, and, where the straw falls from the rakes, to be laid with large flags. The foundations of the low buildings to be 2 feet 9 inches at the bottom, and taken in by regular scarcements.

1202. *Door-Soles.* The door-soles of the barns to be laid 6 inches above the surface of the causeway, on the outside; those of the stables, cow-houses, &c., to be laid 3 inches above it, and beveled on the front.

1203. *Walls.* The thickness of barn-walls above the door-sole to be 2 feet 3 inches; above the second floor to be 2 feet, and beam-filled at the top. The thickness of the walls for the low buildings above the door-sole to be 2 feet, and likewise beam-filled at the top. The division walls to be 1 foot 6 inches thick, and carried to the top. The foundation of the walls of the courts or yards to be at least 1 foot below the general surface, founded 2 feet 3 inches at the bottom.

1204. *Hewn Work.* All the external corners in the houses and gate-pillars to be droved, with broached tails. The ribbets (rybets, rebates, or reveals), soles, and lintels of doors and windows to be droved with broached tails; all the ribbets and corners to be at least 2 feet long, the inband ribbets to pass through the thickness of the wall. The ribbet heads (outside facings or architraves) for barn windows to be 9 inches; the skews to be droved. The shed-pillars, arches, and chimney-tops to be of broached ashlar. The shed and gate pillars to be champhered (chamfered) or rounded on the corners 3 inches. The yard walls to be coped with flat, hammer-dressed, or Galloway cope (large irregular stones, projecting on both sides of the wall), as stones can be procured. The cooling-troughs, and the feeding-boxes for the cows on the dairy-farm, to be constructed with pavement.

1205. *Conduits.* If the water be carried away by under-drains or conduits, the great common sewer, or discharging conduit, to begin in a central part of the offices, to be 2 feet 3 inches wide, and 3 feet 6 inches high, so as to allow a person to go up to clean it. It may be arched or covered, as shall be most convenient; and the size of the side conduits to be according to the distance from the common sewer, namely, from 1 foot to 1 foot 6 inches wide, and from 1 foot 6 inches to 2 feet high, with chisel-jointed angle bottom, according to the sketch fig. 1073.

1206. *Causewaying.* The whole of the stables, cow-houses, calf-houses, pig-houses, &c., to be laid with whinstone causeway set in sharp sand. The settles (gutters) for carrying off the urine to have 1 inch and a half fall to 10 feet, or 2 inches to 10 feet, if the situation admits, or all the fall which can be had. The run channels (gutters) for stables to be 10 feet from the wall, and the rise from the channel to the rack to be 5 inches. The channels for cow-houses to be 9 feet from the wall; the rise from the channel to the sole-tree (the sill into which the posts to which the cows are tied are mortised) to be 4 inches. The area round the yard to be causewayed, and to have proper channels, with 2 in. declivity to the 10 feet, so as to carry the water to the settling-pits (liquid manure tanks). In situations where the extent of causewaying in the areas round the offices is considerable, by making the causewayed channels 4 feet broad, that is, 2 feet on each side of the run, the space between that and the buildings will answer nearly as well to be made up with small broken stones 9 inches deep, and blinded (the interstices filled up) on the top with small clean water sand. This, in a short time, will become a smooth hard substance, and will be obtained at less expense; or, if conduits are adopted, gratings must be made at proper places to communicate with the conduit: the gratings should be strong, and have the ribs well bent upwards, as in that form they are not so liable to be choked up.

1207. *Carpenter's Work.—Roofing.* The cupple (couple or rafter) sides for the houses of 15 or 16 feet wide, to be 6 inches and a half at bottom, 5 inches and a half at top, and 2 inches and a half thick, with a balk (balk or tie-beam) 6 inches by 2 inches and a half, fixed as near the middle of each cupple as possible with double garronnails, and properly riveted. The cupple sides for houses 18 feet wide to be 7 inches at bottom, 6 inches at top, with a balk or scantling to each, 6 inches and a half by 2 inches and a half, fixed as above. The cupples to be set at 20 inches from centres, on a wall-

plate 7 inches by 1 inch and a half, the sarking to be three fourths of an inch thick, well seasoned, and jointed closely. The sarking on the granaries to be half checked on the joints. Ridge-bottoms to be 2 inches by 1 inch and a quarter, fixed to the roof with iron spikes 3 feet apart.

1208. *Joisting and Flooring.* The sleepers in the dressing-barn and the low granary floors to be 6 inches by 2 inches and a half, built as described in the mason-work. The joisting in the loft for unthreshed corn and granaries to be 10 inches deep by 2 inches and a half thick, with 1 foot of wall-hold. Joisting and sleepers laid at 20 inches from centres, all covered with Dram timber battens (battens from Drammen, a sea-port in Norway, supposed to be of spruce fir); under floors to be plain-jointed, and doweled with iron dowels; the upper floors to be tongued and feathered on the joints, and fixed down with good flooring sprigs. The cart-sheds to have a joist built into the wall at each pillar, 8 inches by 2 inches and a half, and the wall-plate nailed down on the top of it. Those that have metal pillars should have linteling-beams 9 inches by 12 inches broad and the end of the joist tenanted 2 inches into the lintel to have an iron strap, split on the end, and put on the top with screw bolts, to fix the joist and the lintel together; the joist going through the back-wall; and the under side to be checked into a piece of wood 3 feet long, 2 inches and a half thick, and about 6 inches broad, built into the middle of the wall; also the wall-plate nailed on the top: this will keep the pillars firm in their position.

1209. *Safe-Lintels.* The whole of the safe-lintels (inside lintels) to have a wall-hold of 1 foot, to be 1 inch thick for each foot of the openings they cover, and from 9 inches to 12 inches broad; the whole breadth filled in like manner behind, and arched above where there is room.

1210. *Doors.* The whole of the doors to be made of deal not more than 6 inches and a half broad, 1 inch and a quarter thick, beaded on the edges, and grooved and tongued on the joints; with three cross bars to each, 9 inches broad, 1 inch and a quarter thick, and well nailed. The stable, cow-house, and barn-doors to be 3 feet 6 inches wide, and hung in two leaves where necessary, which is the case in some of the stables. The straw-barn and granary doors to be 4 feet wide, the whole of the doors to be hung on crooks with bands, the crooks to be laid on the bed of the ribbet. The crook to be split in the tail, to have 7 inches hold of the stone; the pin of the crook to be 1 inch and an eighth in diameter, each crook 3 pounds and a quarter in weight, well batted in with lead; and for 4-foot wide doors the crooks to be 4 pounds each, and the pin to be 1 inch and a quarter in diameter. The bands for 3 feet 6 inches doors to be three eighths of an inch thick at the neck, and 2 inches broad, 22 inches long, having a proper taper, both in breadth and thickness, from the neck to the tail, and to have a  $\frac{3}{8}$ -inch screw bolt to the neck of each, the weight of each to be 4 pounds and a half. Those for 4-foot doors to be 23 inches long, half an inch thick by 2 inches and a half broad at the neck, with a bolt as above, and to be 5 pounds and a quarter weight each. The band-nails to be counter-sunk, and properly riveted. The latches for the doors to be of the kind which has a sunk ring, but stronger made than in general. Locks to be selected according to the use of the different places where they are applied.

1211. *Windows.* The frames of the lower windows of barns, stables, cow-house, &c., to be made 2 inches thick, with boards below 16 or 18 inches high, hung on the frames with cross-tailed bands, and glazed above with second crown-glass; those in the granaries, and other places where glass is unnecessary, to be filled with weather-boards 6 inches broad, 1 inch thick, chamfered on the outer edges, hung with iron pivots, in a frame 3 inches by 2, having a strap of iron attached to the inside, and moved up or down to admit air into the places when required. All the lower windows of the barn to be secured by iron bars 1 inch square, and not more than 5 inches apart, batted into the sole and lintel, and to have a cross bar in the middle, and the upright bars passing through it. The dressing-barn and granaries to have skirting-boards, 8 inches broad by 1 inch thick, nailed on bond timber built in the walls.

1212. *Trevises, Racks, and Mangers.* The hind-posts of the trevises to be 8 feet 6 inches long, 6 inches and a half square, made in the octagon form above the level of the pavement; to be sunk 3 feet and a half below the level of the pavement, and to be solidly built round, 3 feet in diameter, with stone and lime mortar; the parts of the posts to be properly charred on the ends, as far as they go below the ground, their tops to stand 6 inches above the trevis-boards, and to be rounded. The height of the fore-posts to be 9 inches above the top of the racks, 4 inches and a half by 2 inches, the foot of each to be set in stones, one on each side of the boards, and a piece of wood the thickness of the trevis-boards fitted in between the posts above the trevis-boards. The trevises to be 8 feet long from the wall to the outside of the hind-posts. The trevis-boards to be 1 inch and a half thick, mortised 1 inch and a half into the hind-post, and properly nailed into the fore-posts with 20d. nails; and the boards to be put together on the joints with iron dowels, at 2s. to the hundred. The trevises to be 4 feet 6 inches high at the hind-

posts, and 6 feet high at the front posts, and to have angle spars or warpings (diagonal braces) on each side 4 inches by 1 inch and a half, and properly nailed.

1213. *Racks.* The racks to be 2 feet 10 inches broad, the sides to be 6 inches by 2 inches and a half, and the spars to be 2 inches and a quarter by 1 inch and a quarter, sunk five eighths of an inch into the sides, at the distance of 3 inches and a quarter apart, and well nailed.

1214. *Mangers.* The mangers to be 20 inches at the top by 16 at the bottom, and 10 inches deep; the wood to be 1 inch and a half thick at the bottom, and the sides to be 1 inch and a quarter thick. The under racks (standard racks, or racks standing on the ground) to be 2 feet 3 inches high; the rails at the top and bottom to be 3 by 2 inches and a half, and to have a run-beam (front rail) rounded on the top, 4 by 3 inches, fixed along the top of the racks, with rings for securing the horses. Each box or manger to have a back lining or skirting on the top, where it joins the wall, sloping backwards, to prevent any of the corn from being lost. A piece of bond wood, 5 by 3 inches, to be built into the wall for fixing the harness-pins.

1215. *Plaster-work.* The stables for saddle-horses and the boiling-houses to get all one coat of plaster on the walls, and the ceilings to be all lathed and plastered round the back of the cupples and balks with two coats of plaster. A ventilator to be made in the ceiling of the boiling-house. The front walls of the work-horse stable also to get a coat of plaster, to prevent the harness from being injured by rubbing against the rough wall. The dressing-barn and granaries all to get one coat of plaster, and especial care to be taken to have the plaster applied close down to the floors, and close up to the under side of the boards over the joists, to prevent vermin from being admitted.

1216. *Slate-work.* The whole of the roofs to be covered with Easdale or Ballachoulish slates. The slates to have 2 inches of cover over the nail at bottom, and diminishing gradually to 1 inch and a half at the top, all being put on with nails of 12 lbs. to the thousand, and boiled in linseed oil. The whole of the ridges and flanks to be covered with milled lead 12 inches broad, 6 lbs. to the superficial foot. The piends (piens, or ridge pieces) to be covered with lead 10 inches broad, 6 lbs. to the superficial foot.

1217. *Court or Yard Gates.* The gate-posts to be sunk 3 feet into the ground, and burned or charred as far as they go into the ground; the posts to be 9 inches square, chamfered on the corners, and set 3 inches clear of the pillars, and to stand 9 inches above the gate, rounded on the top, and built in the ground with stone and lime 4 feet in diameter. The hanging style of the gate to be 5 by 4 inches; the falling style to be 4 by 3 inches; centre piece to be 3 inches and a quarter by 2 inches and a quarter; angle spar to be 1 inch and three eighths thick, 4 inches and a half broad at the foot, tapering to 3 inches and a half at the top. The uppermost spar to be of 1½-inch iron at the end next the hanging style, diminishing to the falling style to three quarters of an inch; to go through the posts with a shoulder and an eye at the hanging style, and a screw nut on the end at the falling style. The crooks to be put into the gate-posts with nuts on the ends. The spars of the gate to be 4 inches broad at the hind end, diminishing to 3 inches and a half at the front, by 1 inch and a quarter thick; the intersections put together with ¾-inch screw bolts.

1218. *Painting.* The whole of the outside doors, windows, and gates to get three coats of oil paint, the windows to get a coat before being glazed.

1219. *Wood.* The whole of the wood used to be of Memel timber, well chosen. The barn and granary floors may be laid with Dram battens.

## SECT. II. *Examples showing the Manner of displaying Architectural Style in Farm Buildings.*

1220. *To display Style in Farm Buildings,* the main resource is the expression of the walls; and, as these are for the most part only one story high, it is chiefly to be effected by the vertical bond; or, in other words, by the supports of the roof. The form of the roof is also another source of style; and that of the openings, or doors and windows, a third source. Something also may be effected by the display of the ornaments peculiar to different styles; but this resource is altogether unsuitable for buildings of so simple a character as those in use for carrying on the business of a farm. The three styles most easily displayed in farm buildings are, the Grecian, the Roman or Italian, and the Gothic.

1221. *A Farmery in the Grecian Style* is represented in the perspective view, fig. 1094, the ground plan in fig. 1095, and the exterior elevations in figs. 1096 to 1098. On inspecting the ground plan, it will be found that, instead of common walls, the foundations of the different buildings consist of pillars, either equidistant, or at double distances from each other. The smallest distance between these pillars or piers is such as is considered suitable for the opening of a door or window; so that, by removing a pillar, an opening of a double width is formed, or one suitable for a cart or carriage way. In the plan before us, fig. 1095, we have adopted such a width as is not only

1094

suitable for a door or window, but also for a single stall in a stable or cow-house, viz., 5 feet and a half from centre to centre; but this is by no means necessary, and we have only adopted it for the sake of illustrating some observations on temporary and portable

1095

farmeries, which will be found in our succeeding subsection. The buildings on the north side of the square are two stories high; and the foundations of the pillars are

1096

1097

shown larger, and at exactly double the distance apart, centre from centre; because the lower part of this building, on the exterior side, is chiefly appropriated to cart-sheds, and on the inner side to cattle-sheds. The elevations show at once, to an architectural eye, how much is to be made of these piers. That of the east side is not given; but a glance at the plan will show to every Architect that it will be by far the handsomest. The panels, or spaces between the piers, may be filled up in various ways, according to the kind of materials which the locality affords; the plinth or base on which they are placed being, in every case where permanency is any object, formed of brick or stone. On the supposition that brick is the material employed, all the small piers may be 14 inches on the side, all the large ones 18 inches, and all the panels filled in with brick in bed, or 4-inch work. This 4-inch work may be either kept in the middle of the line of piers, as in the plan, fig. 1098, or, what would be preferable, as showing the pillars on the external elevation in bolder relief, ranging with the inside pillars. In countries where freestone is the cheapest building material, the small piers may be of the same width on the face; but instead of projecting from the panels 5 inches, as in the case of the brick piers, they may be flush with the walls in the inside, and only project 3 inches on the outside; the piers being of hewn stone, and the panels of common ashlar, in regular or irregular courses, as may be most convenient. Where a coarser and more unmanageable stone than freestone is used, the piers may be 18 inches or 2 feet in thickness, and the thickness of the panels may be 18 inches or 20 inches. In this case, in order to obtain the same room in the interior, all that is necessary is to place the piers a few inches farther apart, in order that the spaces between them may be of suitable dimensions for common doors and windows, and two of the spaces of suitable width for gateways for carts. The plinths below and the architraves above should always be of stone; the latter worked in the same manner as the piers or pillars, and the former in a coarser style. In countries where timber is the principal building material, the plinth ought to be of stone or brick, the piers and architraves of squared timber, and the panels filled in with studwork, either lathed or plastered on both sides, or covered with weather-boarding outside, and lathed and plastered inside. The roofing to a farmery in this style should, of course, be at a low or Grecian pitch; and we should prefer slight iron rafters, judiciously combined of cast and wrought metal, with rebated laths, in Tugwell's manner, or a corrugated iron roof. In cold climates, prepared paper, or, in warm climates, composition or cement may be used. If the roof were to be made perfectly flat, tiles covered with Roman cement in three coats and courses, would be found to form one of the most efficient and durable of roofs. As we prefer slates, and Tugwell's manner of laying them appears to us a decided improvement on that in common use, we shall here shortly describe it.

1098

1222. *Tugwell's Mode of Slating.* The chief peculiarity of this mode consists in using rebated laths; the upper half of the lath rising above the lower half, as much as the thickness of the slate; by which means the slate incumbent on the upper part can be nailed in its middle. The laths are 2 inches wide and an inch thick. Fig. 1099 is a section of part of a roof slated in this manner: in which *a* is a rafter; *b*, the laths; and *c*, the slates. Fig. 1100 is a plan, or vertical profile, of a portion of the

1099

1100

same roof. "The laths, in the mode of slating generally practised, are made of deal only an inch in width; and, as a nail piercing the slate lying on such inch-wide laths will appear to have fastened it to the middle of that inch, the slate, with the wind lifting at its lower end, becomes a lever, with its fulcrum at the head of the nail; its short arm being only half an inch in length above the nail, and its longest arm (supposing the slates as in the figure, to be 18 inches long) 17 inches and a half below it; thus giving the wind a power to raise the slate as 35 to 1. In the method here proposed, that power will be only as 11 to 7; the short arm of the lever, in this case, being 7 inches long, and the other arm only 11 inches; which will, in all probability, enable the slate to resist the most violent hurricane or tornado ever experienced in Europe." (*Bath Society's Papers*, vol. x. p. 269.)

1223. *That, in point of accommodation*, no inconvenience will result from rendering a farmery architectural, will, we think, be obvious from going into the details of fig. 1095; in which are shown, a family potato-house, *a*; poultry-house, *b*; family cow-house, *c*; gig-house, *d*; gig and riding-horses table, *e*; gateways, *f*; tool-house, *g*; carpenter's shop, *h*; smith's shop, *i*; bailiff's house, *k*; house for boiling or steaming food for the pigs, family cows, and saddle-horses, *l*; cart-sheds, *m*; unthreshed corn barn, *n*; straw-room, *o*; place for boiling horse food, *p*; loose horse stable, *q*; stables for eighteen horses, *r*; fodde ring-bay, *s*; house for a bull, *t*; hospital or house for a sick animal, *u*; implement-house, *v*; cattle-sheds, *w*; pigsties and calf-pens, *x*; open space between the

cattle-sheds and straw-room for loading a cart with straw, *y*; and ramp or inclined plane for ascending to the unthreshed corn floor with loaded carts from the rick-yard, *z*. On examining this plan, it will be found as convenient as any of those which are composed without any regard to architectural style. It is intended for an arable farm under a six-course shift, in such a county as East Lothian. It will be observed that we have placed the chimney of the steam-engine centrally, for effect; a result that can easily be attained by a little contrivance in the disposition of the machinery, the engine-house, and the fuel-room. On the supposition that a farmery of this kind were occupied by the proprietor, it would be found to combine a certain degree of elegance with a convenience of inspection not commonly to be met with in farmeries. The master may enter at *a'*, and proceed down the passage to *y*, having the cribs for the cattle of the yards on both sides; he may then enter the straw-barn, and ascend to the floor for unthreshed corn, out of which doors open to the granaries over *l*, *m*, *w*, and *p*; having visited these, he may either descend and return by *l*, inspecting all the houses on the west side; or he may enter *p*, and proceed through the stables, and the other houses on the east side. The bailiff's house will be found very conveniently situated, as he may enter *l*, and proceed by *u* to *n* and *o* (where the most important part of his charge lies), under cover, and with great facility. We have shown the barn with a portico and a semicircular ramp; knowing, from experience, that it is a great saving of labour to be able to cart in a rick direct from the rick-yard to the threshing-floor. The floor for unthreshed corn has two bays, *b'*, *c'*, where two different kinds of unthreshed corn may be kept, while a third sort may be stored, or carted in, as passed through the machinery at *d'*. We suppose that all the straw intended to be eaten is carried by a travelling shaker to a straw-cutting machine, and cut into lengths of from three to six inches, in which state it is supposed to be partially steamed, or moistened with salt and water, or both, before being put in the cattle-cribs or horse-mangers. There is abundance of room under the floor for unthreshed corn, not only for the clearing-room, chaff-house, engine-house, boiler, and coal-house, but also for a room for crushing bones for manure, bruising grain, cutting turnips, &c. Of the three small doors shown in the elevation, fig. 1097, at *e*, the centre one is to the places connected with the steam-engine, and the others to places in which bones may be crushed, or turnips sliced, &c. It may be observed, in favour of displaying architectural style in farm buildings consistently with good arrangement, that there are certain houses or places in every complete farmery, the situation of which may be varied considerably, and which may therefore be always placed where they will contribute most to symmetry or regularity: these are the houses for loose cattle or horses, the hospital, and the open shed or shelter for cattle. Should the yards in this farmery be thought too large, which they probably would in Northumberland, though not in East Lothian, they may be divided by walls or hurdles at *f'*.

1224. *With respect to the extra-expense of displaying Architectural Style in a Farmery*, much will depend on the kind of building material. In the case of bricks, the plan, fig. 1095, would obviously cost less than if the walls were solid, and nine inches thick; and, in the case of pillars of squared wood and panels of studwork, the expense would not be greatly increased; but in the case of stone the hewing of so many pillars would no doubt be attended with considerable outlay. From this, however, would have to be deducted the expense that would otherwise have been bestowed in hewing door and window coims, lintels, and sills. The roof, as we have already observed, need not be more expensive than in any common farmery. Half the expense of the ramp to the portico of the barn may be saved by carrying out, instead of the curved roads, one road in a straight line from the centre opening of the portico, as indicated by the dotted lines *g'* in fig. 1098, and the same letter in fig. 1095; the barn being wide enough to allow a cart to turn within it. The chimney to the steam-engine is shown higher than may be necessary; but as such chimneys are built of brick with a simple description of scaffolding carried up inside (the invention, we believe, of our friend Charles Capper, Esq., engineer, Birmingham), the expense is much less than might be supposed. The spire of the Tron Church, Edinburgh, was rebuilt, in 1831, in a similar manner. The ventilators over the stables and cow-houses are formed to imitate chimney-tops, in order to harmonise with actual chimneys in the bailiff's house and the smithy.

1225. *A Farmery in the Roman or Italian Style* would differ little from the preceding Design. The piers might either support architraves or arches; for both would be alike Roman or Italian. The roofs ought to project farther, for the sake of shade to the windows and doors; and the windows ought not to be carried down so far as in the Grecian Design, but rather to exceed in breadth than in height; the architrave, or, in the case of arches, the soffit, forming the lintel of both doors and windows. To complete the idea, whether of the Roman or Italian style, the semicylindrical tile of Mr. Peake, fig. 24, § 50, may be used. An improvement on this tile, by Mr. Peake, and a

beautiful pattern for the joint tile to be used at the eaves, will be hereafter figured and described.

1226. *The Gothic style* may be displayed, in farm buildings, either by piers in the place of the Grecian pillars, with the heads of the panels pointed, and high steep roofs, as in fig. 788, § 752; by angular piers, terminating in low roofs; by buttresses, with parapets, and a moderately high roof; or by pointed openings and parapets, with battlements.

1227. *The Old English Cottage Style* of building might be easily conferred on farm-eries by steep roofs, covered with plain tiles, with barge boards at the gable ends, and latticed windows.

1228. *The Swiss Style* would require far-projecting roofs, and there might be a continued gallery or veranda round both the exterior and the interior of the low buildings, which would also be found useful in various ways.

SECT. III. *On constructing temporary, portable, and ambulatory Farmeries, and on altering Mansions, Monasteries, Manufactories, and other Buildings, so as to render them fit for agricultural Purposes.*

1229. *A complete Farmery* can seldom be required to be constructed either in a temporary or portable manner, or for the purpose of being readily moved from place to place; but in all countries where the farms are large, and the farmers men of considerable capital, it will, occasionally, be desirable to thresh out corn on the spot where it grew, and to consume the straw, or to convert it into manure there.

1230. *The Construction of a Temporary Farmery* is founded on the same principle as that of the Grecian Design, § 1221; that is, all the walls are formed of props at regular distances, and these distances are such that the space between the props is of suitable width for a door, a window, or a stall for a horse or cow; while the removal of a prop affords a suitable opening for a cart or carriage. The panels between the props may be filled in with wattled work, faggots, straw, hurdles or matting, or clay nogging; or with slight horizontal rails, to be clothed with fronds of spruce fir, furze, broom, holly branches, &c. All the doors may be formed of wattled hurdles, as may also the shutters for the openings to be left as windows. The props, or posts, may be formed of young trees of any kind, more particularly larches, or spruce fir, with the bark on, and the lower ends charred; or, if the bark be removed, the extreme ends may be charred, and the entire prop kiln-dried and smoked with wood, so as to have its exterior surface powerfully impregnated with pyrolignous acid. The spray of hard-wooded trees, such as beech, elm, oak, ash, birch, &c., is preferable to that of resinous trees for producing this smoke; and if the kiln be close at top, with no other opening than the door, a very few faggots will suffice to keep it filled with smoke for several weeks. All the tie-beams may consist of young straight spruce fir trees, and they ought to project so far at the eaves, as completely to protect the side walls; across them may be laid branches, and thatch over the whole, to be held on with turf. In some cases, a roof of shingles, tiles, or prepared paper laid on thin boards, or of corrugated iron, § 420, may be preferable to those of a more temporary description. In Poland, America, and other countries where timber is abundant, farmeries of this kind, if proper pains were taken to char the ends of the props, and to put on a roof that would completely exclude the weather, would last as long as the oak-built farmeries of England, some of which have stood for centuries.

1231. *A Portable Farmery* might be easily formed by having the props made to stand on stone, slate, or tile plinths, and the tie-beams of the roof made to fix on the tops of the props by wooden pins. All the rest is easy and obvious. Instead of wooden props and tie-beams, slight props of cast iron might be used with tie-rods of wrought iron, and all the roofing and panels might be formed of corrugated sheet iron. Well tarred or painted, such a farmery would last at least during a twenty-one years' lease; and the time may probably come when farmeries of this kind will be erected by the tenant, as being cheaper than paying a high interest to the landlord for fixed buildings. In some parts of the country it might be cheaper to form the panels and doors of slate, or boards, or of wattled hurdles plastered, or the interstices stuffed with moss; or they might be formed of clay nogging or straw matting; but nowhere, we believe, could roofing of a durable nature be found cheaper than of corrugated iron.

1232. *An Ambulatory Farmery* may seem to some a visionary structure; but there are already ambulatory covers to ambulating threshing-machines, and there seems no reason why there should not be ambulatory barns, granaries, and shelter-houses for cattle. In France the shepherds have ambulatory houses, which are placed on wheels, and dragged from one part of the farm to another, as the pasturage of the flock or herd is changed. We have seen, § 1038, Mr. Taylor's ambulatory sheepfold; and it is evident that the sides of any building might be formed and placed on wheels in a similar manner. The floor, where a boarded floor was necessary, and also the roof, could be

transported on wheels; or every particular building or apartment requisite might be framed and placed on wheels, so as to be dragged from place to place by horses or steam, in the manner of our ambulatory cottages, § 516. When steam shall once be employed in agriculture, not only for threshing, but for cutting all the straw not to be used as litter or thatch, into short lengths, and for ploughing, harrowing, hoeing, &c., great changes will be required in the arrangement and construction of farmeries; and the hints in this subsection are thrown out to give Architects some idea of their resources.

1233. *Substitutes for the Walls of Straw Yards*, Mr. Taylor has shown, § 1038, may be formed in the most economical manner of bush faggots; and, indeed, in countries where capital is scarce among farmers, bushes, furze, straw, and clay form almost the only materials used in the construction of farmeries. This is a good deal the case in some parts of Huntingdonshire. The timber for the roof, in such cases, consists of willow or poplar trees, with the bark on. In Norfolk, Suffolk, Kent, and various other parts of England, the straw-yards are enclosed by wattled fences, and sometimes even by wattled hurdles. The low price of labour, and the circumstance of wood being the sole or principal fuel, render temporary means of this sort more economical than may at first sight appear. At all events, in a work like the present, intended for new countries as well as old ones, different means of effecting an end ought to be pointed out; not always as subjects for imitation, but for the sake of leading to comprehensive views.

1234. *The Alteration of Buildings of different Kinds, so as to render them suitable for agricultural Purposes*, though very uncommon in Britain, is yet frequent on the Continent. Monastic buildings of every kind, even churches and chapels, have been converted, not only into manufactories, barracks, and dwelling-houses, but into barns, stables, cattle-houses, and other buildings requisite for carrying on the operations of agriculture, in almost every part of the Continent, from Riga to Naples. As these buildings are seldom more than two stories high, and as they generally spread over a considerable surface, and are placed in the form of a quadrangle open to the south, they make, at little expense, very excellent farmeries and farm-houses. The ground floors are employed for lodging animals, and for storing roots and other food, and the floors above are used as granaries, for the farmer's dwelling-house, and as lodgings for his servants. The upper floors are sometimes, in Poland, used as hay and corn barns, the window openings being, in that case, left without glass. In one instance we recollect having seen the upper floor converted into a sheep-house, the sheep entering by an inclined plane, formed from a ruined part of the building, at one end. It is much to be regretted that large buildings, erected at enormous expense, should not be converted, when their owners can no longer afford to dwell in them, or when, from any other cause, they are obliged to be sold, to some useful purpose, rather than suffered to go to decay, or be pulled down. For this reason we shall briefly point out how mansions of different kinds may be converted to agricultural purposes.

1235. *To convert Mansions into Farm Buildings*, the first object is, to consider whether the accommodation is contained in several stories in height, or spread out to a considerable extent in length and breadth. The former class of buildings include most Gothic and Elizabethan mansions, which, it must be acknowledged, are much better adapted for being changed into manufactories, colleges, inns of recreation, schools, or cooperative dwellings, than farmeries. Still, however, the ground floor, and the kitchen and stable offices, might be used for the latter purpose, and the upper parts of the building converted into a manufactory; in which case, one large steam-engine on the ground-floor might suffice for both establishments. But, even where it was necessary to use the second and third floors of houses of this description for agricultural purposes, they might be ascended by inclined planes, either formed on the outside of the building, or in the interior. In some of the large inns in London the horses are lodged both on the cellar floor and on the first floor, the carriages being on the intermediate or ground floor. The ascent and descent are by inclined planes, at an angle of from twenty-five to thirty degrees, kept well covered with litter. In country houses, however, where there is ample space, the inclined planes need not be so steep, and they ought not to be covered with litter; which is a clumsy contrivance, and, in London at least, renders the air of stables of this description intolerable. The upper floors of lofty houses should be used as wool-lofts, and for storing other bulky yet light articles; the next floor for poultry, rabbits, or other small animals; the floor below for ewes and lambs, or swine; the first floor for cattle and horses; the ground floor for barns, cart-sheds, tool-houses, &c.; and the cellar floor for storing roots. Where the mansion consists of only two, or, at most, three stories, as in most Grecian buildings, and some of the old English houses, the conversion is easy, and may follow in the manner common in Poland. We must confess we should deeply regret to see any fine specimens of Architecture occupied as farmeries; but as we have not a doubt that, with the progress of society, many such buildings in England will be sold by their present owners, we have thought it a duty to throw out these hints, with a view at least

of preventing them from being rashly pulled down. In comparatively uncivilised ages and countries, all great changes are accompanied with destruction; and much of the accumulated labour of mankind is lost for ever to society; but under a higher degree of civilisation, conversion takes the place of destruction, and things merely change their owners or their uses.

SECT. IV. *Designs for various Buildings, such as Corn-Mills, Kilns, Malt-houses, Cider-houses, &c., connected with Agriculture and rural Economy.*

1236. *The Designs to be included in this subsection* are such as do not necessarily belong to a common farmery; but which, nevertheless, form prominent structures in particular districts. We might have added considerably to their number, by including buildings for carrying on different manufactures of agricultural produce; such as crushing seeds for oil; extracting dyes from wood, weld, madder, &c.; preparing hemp and flax; making flour or starch, or distilling spirit from potatoes; making sugar from beet root, &c.: but such buildings come much more within the province of the engineer than the Architect, being altogether subordinate to the machinery which they are to contain. We have limited our designs to such as are of a more general description, and which are required in every country where corn and fruit are grown. These are the wind and water corn-mills, the hop-kiln, the malt-house, and the cider-house. We have also added an improved limekiln, as of essential importance in limestone countries; a brick or tile kiln, which will enable every farmer to burn his own bricks, and also to burn clay or lime, and even to serve for a malt or hop kiln, on a small scale, and for a variety of other purposes; and a poultry-house for farms where poultry are kept on a large scale. Among the letter-press accompanying these designs we have been fortunate enough to be able to include some of the best directions for the manufacture of cider, for the management of hop and malt kilns, and for the care of poultry, which have yet been published. The directions for managing poultry are from the pen of Mr. Main; and, we think, from their great simplicity, and from their being founded entirely on his own experience, that they will be found particularly valuable. We have added to the article some remarks, accompanied by Designs, relating to the management of poultry by cottagers, and especially by the wives of farm labourers, being particularly anxious to direct the attention of our readers to this subject. We may observe generally, respecting the Designs of this subsection, that we have confined our attention chiefly to economical arrangement, or, in other words, to fitness for the end in view. It would have been a most agreeable recreation to us to have bestowed more attention on the architectural style of the different buildings, but we feared that this would have drawn the attention of our readers from the ground plans. Almost all of them, however, might be rendered highly architectural, and this every Architect will readily assent to when he finds that the ground plans of the chief of them, when constructed on the best principles, such as the windmill, malt kiln, hop kiln, &c. are circular. There is nothing in the nature of a circular kiln to prevent it from assuming the forms and proportions of the temples at Tivoli, or the Temple of the Winds at Athens; that is, if such models ought to be imitated in such cases.

Design I. — *The Construction of a Building for containing the Machinery of a Corn-Mill to be impelled by Water, with introductory Observations on Buildings for Mills generally, on Flour-Mills, and on the different Kinds of Water-wheels.*

1237. *Buildings for containing Mills* require to be of greater strength than ordinary farm buildings, chiefly on account of the vibratory motion communicated by the action of the machinery. This vibratory motion differs materially in different descriptions of mills. Where the machinery is in a great measure independent of the building, and is placed on the ground floor, as in the case of the threshing-machine, it is trifling; but where the machinery is so connected with the structure as to be inseparable from it, or is in an upper story as in the case of the windmill, the vibration is considerable. In cases of the latter description, the side walls of the buildings must be securely tied together by the system of flooring, and the walls must be thicker than in a common house of the same height; they must be begun on solid foundations, and carried up in the most substantial manner, with the best materials. As in this part of our work, it is chiefly our object to illustrate by example, we shall make no further observation, but refer to the plans, elevations, and specifications of Unsted mill, which forms the main object before us, previously introducing some remarks on mills generally, on flour-mills, and on water-wheels, most obligingly prepared for us by our valuable contributor, Mr. Varden.

1238. "*Mill*, in its most general signification, applies to all machines whose action depends on a circular motion. Of these there are several kinds; and, according to the various methods of applying the moving power, they are called windmills, water-mills, horse-mills, or steam-mills. All of these kinds are employed for numerous purposes,

and are named according to their several uses; as corn, snuff, bark, colour, fulling, gun-powder, cotton, linen, oil, paper, sawing, sugar, or threshing mills, &c. Of these, corn-mills are the most important, as they are requisite to convert corn into flour, the state in which it is most fit for the food of man, and they are on that account indispensable in all civilised countries.

1239. "*Corn Mills.* Few persons are ignorant that corn is ground between two stones placed one above the other without touching. The lower millstone is immovable, but the upper one turns upon a spindle. These stones are usually from about 4 feet to 6 feet in diameter, and vary in thickness from 12 to 18 inches. The opposite surfaces of the two stones which are to grind the corn are not plane or fiat; but the upper one is hollowed about an inch, and the under one swells up about three fourths of an inch, so that the two millstones come nearer and nearer towards the circumference, whereby the corn that falls from the hopper has room to insinuate itself between them, as far as two thirds of the radius, which is the place where it begins to be ground, and where it makes the greatest resistance it is capable of; the space between the two stones being in that place about two fifths the thickness of a grain of corn. But as the millers have the power of raising or sinking the upper stone a little, they can proportion the distance from the lower one according as they would have the flour finer or coarser. The stone used for grinding corn was formerly brought from France, and was called burr stone; but, latterly, stones proper for this purpose have been discovered in different parts of Britain. From a quarry near Conway, great quantities are dug every year; and when first cut out, they are much softer, and more easily worked than when they have been exposed to the air; even a single day makes a difference. From Abbey Craig, near Stirling, a great number of millstones are sent to various parts of the kingdom, that are considered to be in some respects superior to the French. In order to cut and grind the corn, both the upper and under millstones have channels or furrows cut in them, proceeding obliquely from the centre to the circumference; and these furrows are each cut perpendicularly on one side and obliquely on the other, into the stone, which gives each furrow a sharp edge. In the two stones they come against one another like the edges of a pair of scissors, and cut the corn so as to make it grind the easier when it falls upon the plane between the furrows. These are cut the same way in both stones when they lie upon their backs, which makes them run crosswise to each other when the upper stone is inverted by turning its furrowed surface towards that of the lower. When the furrows become blunt and shallow by constant wear, the running stone must be taken up, and both stones new dressed with a chisel and hammer. But, by this operation being often repeated, their thicknesses, and consequently their weight, are diminished; and it has been observed, that, when they have lost one fourth or one half of their original thickness, they produce but three fourths or one half the flour which they did when new. The circular motion of the upper millstone brings the corn out of the hopper by jerks, and causes it to recede from the centre towards the circumference, where, being quite reduced to flour, it is thrown out by the centrifugal force of the stone through a hole provided on purpose. Millstones will commonly last from thirty to forty years.

1240. "*Water-Mills.* In water-mills the moving power is the momentum of the water, communicated to the wheel; and it is used in three different ways: first, where the force of the water is applied from below the wheel, which is called an undershot wheel; secondly, where the water strikes nearly against the middle of the wheel, which is called a breast wheel; and, thirdly, where the water is applied above the wheel, which is called an overshot wheel. Of these, the first is the least, and the last by far the most, powerful."

1241. "*Undershot Water-wheels* in a great measure act by the impulse of flowing water and are considered to be the most ancient form of water-wheel. At first they were wheels provided with vanes or wings on the circumference, called floats (see *d*, in fig. 1101), and were placed in a river or running stream; the floats at the lower part of the wheel being placed so as to dip into the stream in such a manner as to intersect the water. But, in wheels constructed thus, when the planes of the floats become perpendicular to the direction of the current, or nearly so, they will resist or oppose the motion from it, in proportion to the quantity of motion they have abstracted from the water of the stream. The power thus obtained will be found to be only a small proportion of the power of the stream; because the water easily escapes sidewise from the floats, particularly if it should be attempted to take away any considerable share of its velocity by resisting or loading the wheel, so as to make it move slowly. This being discovered, it became an obvious improvement to contract the stream to the exact size of the float-boards of the wheel, or to make a close channel into which the wheel might exactly fit. The next improvement was, to intercept the river or stream of water by a dam or obstacle, in order to make it pen up or accumulate, till it had risen to the greatest height which could be obtained; and to let the water out of the dam or reservoir into the

channel or wheel-course through an aperture level with the bottom of the wheel course. In this way the water is urged by the pressure of the water in the dam, and rushes out from the aperture in a stream or spout, with a velocity proportionate to the perpendicular pressure, striking the float-boards of the wheel, so as to urge them forward. Such is the form of the undershot wheels still generally employed in France and other parts of the Continent; but in England they have long been superseded by more effectual applications of the water, and are very rarely met with. Undershot wheels of this description are generally called groundshot wheels, because the water shoots along the ground or floor of the channel in which the wheel works. Fig. 1101 is the vertical

section of an undershot wheel, as now in use; in which *a* is the axis, which, if not of metal, should be made of hard and durable wood, of a length and size proportioned to the size and weight of the wheel. Into each end of this axis a gudgeon or centre-pin should be fixed, for the wheel to turn upon. There are two methods of fixing the gudgeon into a wooden axis: one is by forming the gudgeon with a cross, which is let into the end of the tree, and fastened by screws, the wood being compressed round the cross by two or three iron hoops, fitted on the end of the tree, and wedged. The other method is, to make a strong iron box in a piece with the gudgeon, into which box the end of the tree is received and secured with wedges: in the latter case, the box being of an octagonal shape, and the wood being cut to the same form, it cannot slip round with the box. Of late years it has been usual to make the axis of water-wheels of cast-iron tubes, which is a very good plan if they are of sufficient dimensions. In an iron axis, it is advisable to make the bearings of the axis close to the side of the water-wheel; and to leave the ends of the axis projecting beyond the bearing, in order to attach the cog-wheel. This diminishes the length of the axis between the bearings, and renders it much stronger. The arms supporting the circular rim of the wheel *b b*, are usually eight in number, framed together so as to intersect each other at right angles, and leaving a square opening in the centre for the reception of the axis; the corners round which being filled up by adding pieces of wood to it, and the wheel being fastened on by wedges. The only objection to this mode of framing is, that the arms are weakened by intersecting each other; and support the circular rim of the wheel in unequal segments: but on the whole it is considered superior to the method of mortising diverging arms into the axis, because by so doing the axis is much weakened, and the water, being admitted into the centre of the tree, soon causes it to decay. Another objection is, that an arm cannot be easily replaced without taking all the wheel to pieces. The very best method of uniting the arms to the axis is to have a cast-iron centre-piece, or strong hoop, to fit on the axis, with a broad projecting flanch round it, against the flat surface of which the arms of the wheel are applied, and the intervals between them are filled up by wooden blocks or wedges: the arms and blocks are firmly bound to the iron flanch by iron rings applied to the arms on the opposite side to the flanch with screw bolts to go through the whole. The circular rim, *c*, is made of wood put together in two or three thicknesses, the joinings of one ring not coinciding with those of the other; and there being eight or ten segments in each thickness, according to the size of the wheel. The thicknesses are united by rivets. The arms are attached to the ring by notching them into it, and securing them by bolts. Cast-iron rings are now generally used, and with great advantage; because the necessary mortises can be made in the iron without weakening the ring, but the strength of a wooden ring is greatly impaired by the mortises through it. The number of rings in a wheel must depend on its breadth; when the wheel is 4

feet wide, two rings will support the float-boards; but the rings should never be more than 5 feet asunder, or the float-boards may bend. Each ring is formed with its separate set of arms, so that every one derives its strength from the axis. When a wheel is of very great breadth, much additional strength may be gained by bracing it obliquely. The float-boards, *d d*, are twenty-four in number: they are formed of wood, and are nailed to pieces of wood called starts, which are fixed into mortises in the rings, and project outwards for that purpose. The velocity of the float-boards should be about equal to half the velocity of the stream; not more than one half of the float should ever be below the water, and from three to five should be immersed at once, according to the size of the wheel. When the stream is very rapid, the float-boards should be inclined towards the rim, so that the water may heap upon them, and act by weight as well as impulse. When the velocity of the stream is 11 feet per second or upwards, the inclination should not be less than 30 degrees; but as the velocity lessens so should the inclination diminish. When the velocity is only 4 feet per second or less, the floats should not be inclined at all, but should point to the centre of the wheel. To prevent backwater, the floats should be made to rise from the water as perpendicularly as possible. The circular sweep of masonry, *e*, is to prevent the escape of the water; the float-boards approach it as nearly as possible without touching. Beyond this sweep should be a step, or fall, *f*, of not much less than 9 inches, having a slope of about 45 degrees; in order that the tail-water may run off quickly, and not retard the motion of the wheel: beyond this step, the bottom of the tail-water channel should be paved for about 50 feet, having a declivity of an inch in every 6 feet: beyond this the bottom should slope about 4 inches the first 200 yards, 3 inches the second 200 yards, and decreasing gradually to the usual fall of the river. In places liable to floods, this fall must be increased so as to prevent the water running back upon the wheel. The tail-water course must be wider than the wheel. The slope *g* must be paved. The pen-stock is marked *h*. The diameter of the wheel should be the largest of which circumstances will admit; and, as it is of great importance that none of the water should escape without contributing to turn the wheel, either below the float-boards or at the sides, the breadth of the float-boards should be greater than that of the sheet of water that strikes them.

1242. "*Breast Wheels* are very commonly called also undershot wheels, because the water runs beneath the wheel; but they differ essentially, since the principal power is derived from the weight of the water, and not from its impulse. A breast wheel partakes of the nature of both over and under shot wheels, and is constructed as represented in fig. 1102. The lower part of the wheel is surrounded by a sweep of masonry,

1102

which is made concentric with it; the float-boards are exactly adapted to this masonry, so as to pass as near as possible to it without touching, and the side walls are, in the like manner, adapted to the ends of the float-boards; the intention being, that as little water as possible shall be able to pass by the float-boards, without causing them to move before it. The water is poured upon the wheel over the top of the breasting at *a*; the efflux from the mill-dam, *b*, being regulated by the sluice or shuttle, *c*, which is placed in the direction of a tangent to the wheel, and is provided with a rack and pinion, *d*; by which

it can be drawn up, so as to make any required degree of opening, and admit more or less water to flow on the wheel. The framing of this wheel is all of cast iron; and the floats are forty-two in number. The water first strikes upon the float, and urges it forward by impulse; but when the floats descend into the sweep, they form, as it were, close buckets, each of which will contain a given quantity of water, and from which the water cannot escape except the wheel moves; at least this is the intention, and the wheel is fitted as close to the race as it can be with this view. The float-boards are inclined to the rim, and there are other boards, *e e e*, placed obliquely, which extend from each float-board to the rim of the wheel, and nearly fill the space between one float and the next. These are called rising boards, and the use of them is to prevent the water flowing over the float-board into the interior of the wheel. The edges of these boards are not continued so far as to join to the back of the next float, because that would make all the boards of the wheel close, and prevent the free escape of the air when the water entered into the spaces between the floats. In breast wheels, the greatest constant height of water should be made use of for the fall; as water acts with much more effect by its weight than by its impulse. Any greater height that the water in the mill-pool may attain in wet seasons can only be employed in the way of impulse, unless a shuttle be used, which would allow of the water being discharged at different levels: this is sometimes done, and it is considered to be a great improvement. The velocity of the floats of a breast-wheel should be from three to four feet per second.

1243. "An Overshot Water-wheel is simply a circular ring of open buckets, so disposed round the circumference of a vertical wheel, as to receive the water from a trough placed over it in such a manner as to have the buckets on one side of the wheel always loaded, while those on the other side are empty. The weight of water on the loaded side of the wheel will cause it to descend; and by this motion the water runs out of the lower buckets, while the empty buckets of the rising side of the wheel, each in their turn, come under the spout, and are filled with water. Fig. 1103 is a vertical section of an

1103

overshot water-wheel, the framing of which is of cast iron; *a a a a* are the buckets. As it is of consequence to have them so formed as to retain the water on the descending side as long as possible, much attention has been paid to their make: those in most general use are called elbow-buckets, because each partition is formed of two boards, which are put together with an angle or elbow; and this is the kind represented in the figure. It is a great advantage to make the partitions of the bucket thin; particularly the edges, which meet, and divide the stream of moving water flowing upon the wheel. If the edges are not sharp, they will splash the water about; and they are, therefore, generally finished by iron plate, or, what is better, all the inclined parts of the partitions are made of iron plate. The greater number of buckets, and the shallower they are, the more regularly the wheel will act. The mouth of the buckets should be of such a width as to allow the air to escape at the same time that the water flows in. To facilitate this, in some wheels, the buckets are made longer than the width of the stream of water acting on them, which allows the air to escape freely at the ends, and likewise affords

room for the water to spread. In this case, the buckets at the top of the wheel are not filled so completely as they otherwise would be, by which means less water is spilt when they first change their position, and, consequently, there is less waste of power, as the water is longer retained in them. The cast-iron trough for the water is marked *b*, and the sluice, also of iron, *c*. The inclined boards of the buckets should be exactly in a line with the stream of water when it issues from the spout, passing beneath it; and, if the edges are made thin, there will be but little splash. The velocity of the periphery of the overshot wheel should be from 6 feet and a half to 8 feet and a half per second, and the higher the wheel is in proportion to the whole descent of water, the greater will be the effect; provided the water, when it first impinges upon the wheel, has an equal or greater velocity than the bucket-boards; otherwise it will cause a splash, which will, in a slight degree, retard the motion of the wheel. A fall of two or three inches, in most cases, will be sufficient for this. A greater impulse in the water will of course accelerate the speed of the wheel; but the power will not be increased so much as if the diameter of the wheel were sufficiently enlarged for the water to act by its weight. In general, when the fall of water is between 4 feet and 10 feet, a breast wheel should be erected; an undershot should be used when the fall is below 4 feet, and an overshot wheel when the fall exceeds 10 feet."

1244. As an example of the kind of Building requisite for a Corn-Mill to be impelled by Water acting on a Breast Wheel, we shall give the following, erected at Unsted Lock. It is one of a number of Designs that have been furnished us by John Perry, Esq., of Godalming, Surrey, which have been executed by him in that county and the adjoining one of Sussex. Fig. 1104, to a scale of 9 feet to an inch, is an elevation of the up-stream end of the building, the down stream end being the same. In this figure the dotted line

*a b* represents the level of the water in the mill pond or head, below which the wall of the mill-house is of stone; *c* represents the thorough or space in which the water-wheel works; *d* is a stone wall; and *e e* brick checks, or facings, to confine the water to the wheel. (This Design, our readers will probably say, is plain enough; but in case they should wish to confer architectural style upon it, we shall show them how it is to be done. In the first place, more expression may be given to the walls by constructing them, or by exhibiting a style of construction founded, either on the wooden model or the stone model. By the wooden model, we mean the primitive style of building with timber, in which all walls are formed of a vertical bond of square pillars, and a horizontal bond of architraves or lintels placed over, or intersecting them. This may be exhibited with equal ease in a building constructed either of brick or stone; pilasters representing the vertical bond, and architraves the horizontal ties. The stone model is that in which small stones are used piled up in piers for the vertical bond, and forming arches in horizontal lines, or courses for the horizontal bond. This, it will be readily allowed, can be done with equal ease, whether the building is of brick or stone. Here, then, are the rudiments of two distinct styles of composition, of each of which styles there may be several varieties or manners, according to the kind of stone or brick used, and also according to the kind of timber imitated. We say nothing of the forms of the openings, or of the gable ends, which afford other sources of style and architectural interest, preferring, for the present, to leave the young Architect to develope and amplify the ideas which we have thrown out.) Fig. 1105 is an

1105

elevation of the building facing the thorough, in which the dotted line *f f f* represents the circumference of the wheel; *g g*, the position of the checks, or offset of brickwork,

two inches in projection, to confine the water to the breast of the wheel: the same space indicates the proportionate extension of the buckets, relatively to the circumference of the wheel; the square included in the dotted lines  $h h h h$  is to be faced or built to the depth in the wall of nine inches with Roman cement; the dotted line  $i i$  represents the head-water line; the parallelogram included in  $k k k h$  is to be built solid in Roman cement;  $l l l$  are inverted arches under the windows; the line  $m m$  represents the top of the pavement of the race for tail-water way;  $n n$  is a space technically called the sweep, which is to be built of Pulborough stone (a species of green sandstone, found to resist the action of water, and which is cheaper than any other freestone in the neighbourhood of Godalming);  $o$  is the axle of the wheel. Fig. 1106 is the front

1106

elevation, in which the line  $p p$  represents the level of the head water, the wall below which is built of stone, and the wall above of brick;  $q$  is the main entrance, and  $r$  a door by which corn or flour is taken up or let down by means of a crane and pulley tackle;  $l l l l$  are inverted arches, as in the preceding figure. (In these two elevations our readers will observe that there is naturally more expression than in the end view, fig. 1104, on account of the number of windows. We shall now show how this expression may be increased, independently altogether of either the pilaster and architrave, or the pier and arch styles. In the first place, there is always a degree of expression given to a building when the openings are on one axis, or series of axes, both horizontally and vertically; or, in other words, when all the windows and doors of the different stories are directly over one another, and when all those on the same story have their sills and lintels in the same plane. To be convinced that this gives expression, it is

only necessary to suppose a contrary position of these openings, and to imagine the doors and windows placed at random. Now, the expression, produced by uniformity and continuity of axis, whether vertically or horizontally, may be greatly increased by lines expressive of this uniformity and continuity; for example, by a continuity of the sills and lintels horizontally, and of the jambs vertically, somewhat in the manner shown in fig. 459, § 532. It surely will be allowed that this would give a marked expression to the two elevations before us, independently of every other resource. The angles or corners of all buildings, it will be admitted, contribute to expression by the mere circumstance of their furnishing vertical lines: now, the expression of these lines may be heightened by doubling them, or producing the appearance of a bold, massive pier, pillar, or pilaster at the angle; and this, again, may be varied and heightened by giving the expression of the individual stones which compose it; either simply, as of stones of the same size; or, compoundly, by showing stones of different sizes, as in what is called in and out bond. Here, then, are two distinct sources of expression, which may be added to plain walls varied by plain openings.) Fig. 1107 is a section from *c* to *d*

1107

on the plan fig. 1108. In this figure, *l l l l* are inverted arches, and *o*, the axle of the wheel, as in fig. 1105; *s s* is the ground floor; *t t*, the floor in which the millstones work; *u u*, the warehouse floor; *v v*, the floor in the roof. The spaces *w w w w* are left open. Fig. 1108 is a plan of the ground floor, in which *x* is the cog-pit, or place for the cog-wheel, on the lying or horizontal shaft of the water-wheel, paved with brick; *y* is the bed or bolster of the gudgeon of the cog-wheel; *z z z* are the upright posts which support the stone floor; *a* is the brick on edge paving of the race, or tail-water

1108

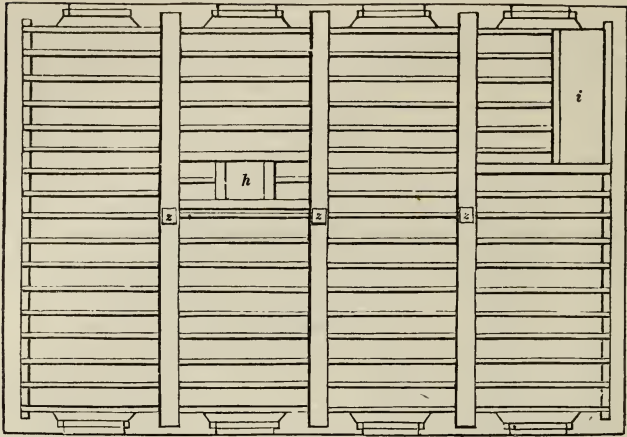

course; *b*, the Pulborough stone paving of the wheel sweep; *c*, the paving, forming the commencement of the sweep, under the buckets of the breast wheel, of Bargate stone (a species of hard limestone found in the neighbourhood of Godalming, more durable than the Pulborough stone, but not a freestone, and consequently worked by fracture, called heading or hammer-dressing, and not by the saw and chisel); *d*, *e*, *f*, and *g*, are pieces of oak for supporting the axle of the water-wheel. Fig. 1109 is a plan of

1109

the stone floor; *z z z* are the continuation of the posts for supporting the floor above, *h h h* are trap doors for raising or lowering sacks of corn or flour; *i*, the stair or step-

1110

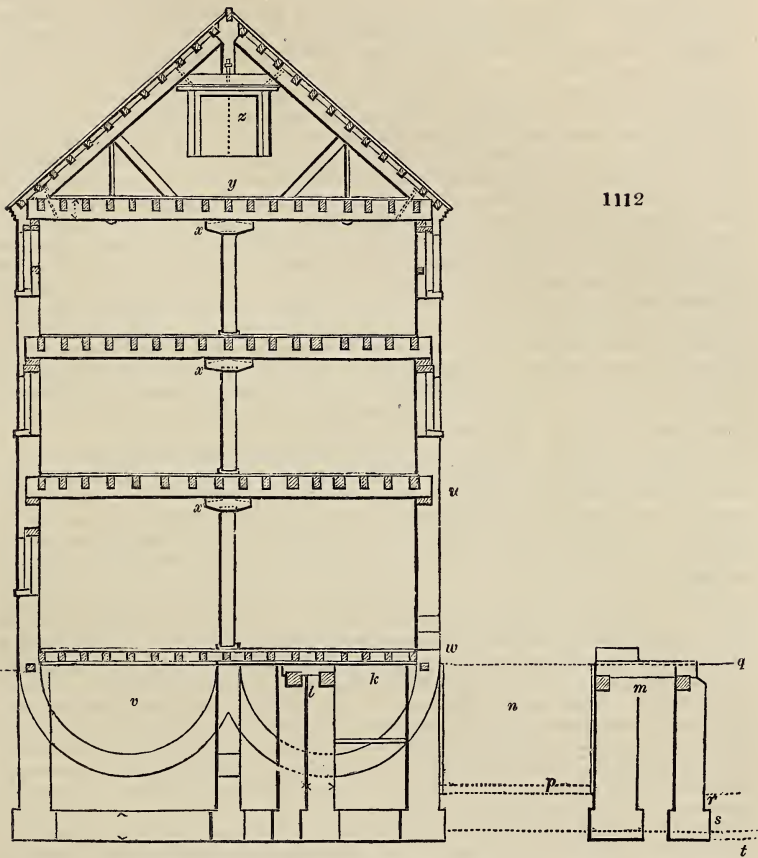

ladder. Fig. 1110 is the bin floor, in which may be seen the situation of the upright posts, the trapdoor, and the stair, as in the preceding figure. Fig. 1111 is a plan of

1111

the floor in the roof, showing a trapdoor, and a stair. Fig. 1112 is a section from A to B, in the plan, fig. 1108, in which *k* is the pit for the cog-wheel; *l*, the bolster for its axle; *m*, the bolster for the same axle, which passes through the water-wheel; *n*, the thorough, or place for the water-wheel; *o*, the centre of the axle of the water-wheel; *p*, the bottom of the water-wheel; *q*, the head-water line; *r*, the tail-water line; *s*, surface of a natural stratum of gravel; *t*, the bottom of the footings of the walls; *u*, the top of the water-wheel; *v*, the space between the inverted arches and the ground floor, filled in with masonry; *w*, the top of the stonework; *x*, caps to the upright posts; *y*, the floor in the roof; and *z*, the framing of the window in the roof. (As one great object which we have in view, in giving this plan of a watermill, and that of the windmill which follows, is to show the simplest mode of construction, with a view to their being adopted by residents in new countries, such as America and Australia, we may observe that the business of constructing the floors of mills is very much simplified, as well as their durability increased, where timber is abundant and cheap. In the interior of Poland we have seen windmills in which there were neither joists in the floors, nor standards nor quartering in the wall; both were formed of thick planking, closely joined by wooden pegs, or dowels, which served both for the skeleton and the covering; and in that country cost less altogether, than it would have done in Britain to saw up the same materials into joists, quartering, and boards.)

1245. *Particulars of the several works to be done in building a water corn mill at Unsted Lock, for J. S. Esq., according to the plans, elevations, sections, and details, and the conditions of the subjoined contracts severally signed by the parties undertaking the same.*

1246. *Bricklayer's Work.* The trenches for the foundations of the respective walls and cross walls are to be dug out of the proper depth and width, and the ground round the same properly secured, filled in, and rammed round the work. The water to be raised from the cavities, and carried therefrom as occasion may require. All the bricks to be used in the building, or brought upon the premises, to be sound and good well-burnt stocks, those to the external parts of the building to be of an even colour, and the whole laid and flushed solid in mortar of the several heights and thicknesses with the apertures specified in the drawings; and none of the bricks to be brought upon the premises shall be slack-burnt, or over-burnt, but all warranted to stand the frost. The mortar to be composed of the best well-burnt grey lime, and clean sharp river sand, well tempered together. The work of the foundations, and up to within one foot of the upper side of the ground floor, to be of Bargate stonework, grouted with hot lime and sand every two courses, and with brick coins. The external face of the whole of the brickwork to be laid in a close, neat, flat-ruled joint; and the inside of the mill to be worked fair for lime-whiting, with a three-course Welsh cornice under the eaves, and on the gables. Nine-inch brick discharging arches to be turned over all the apertures to within 4 inches of the face of the respective walls, and common skew-back arches to be turned over the several openings externally. Fourteen-inch brick inverted arches to be turned the whole thickness

indicates the proportionate extension of the buckets, relatively to the circumference of the wheel; the square included in the dotted lines *h h h h* is to be faced or built to the depth in the wall of nine inches with Roman cement; the dotted line *i i* represents the head-water line; the parallelogram included in *k k k h* is to be built solid in Roman cement; *l l l* are inverted arches under the windows; the line *m m* represents the top of the pavement of the race for tail-water way; *n n* is a space technically called the sweep, which is to be built of Pulborough stone (a species of green sandstone, found to resist the action of water, and which is cheaper than any other freestone in the neighbourhood of Godalming); *o* is the axle of the wheel. Fig. 1106 is the front

1106

elevation, in which the line *p p* represents the level of the head water, the wall below which is built of stone, and the wall above of brick; *q* is the main entrance, and *r* a door by which corn or flour is taken up or let down by means of a crane and pulley tackle; *l l l l* are inverted arches, as in the preceding figure. (In these two elevations, our readers will observe that there is naturally more expression than in the end view, fig. 1104, on account of the number of windows. We shall now show how this expression may be increased, independently altogether of either the pilaster and architrave, or the pier and arch styles. In the first place, there is always a degree of expression given to a building when the openings are on one axis, or series of axes, both horizontally and vertically; or, in other words, when all the windows and doors of the different stories are directly over one another, and when all those on the same story have their sills and lintels in the same plane. To be convinced that this gives expression, it is

of the walls below the ground floor under all the lower tier of windows, doors, and story-posts. Openings through the external walls to be left to admit air under the boarded floor, on the ground story of the mill, where directed. All the plates, lintels, and templets to be properly bedded level; and all the windows and door frames pointed with good lime and hair mortar. If any damage should happen to all or any part of the brickwork or stonework during the progress of the work, either from the inclemency of the weather or other causes, the same from time to time to be repaired and pointed. The mill wall against the thorough (the space in which the water-wheel works) to be set in Roman cement, where shown in the plan. The bricklayer is to find scaffolding, and the fixing and refixing the same, and all manner of ropes, boards, ladders, tackle, tools, and things necessary for the business, and all the bricks, lime, and sand, and the carriage thereof; and all the materials, workmanship, and ironwork required for the completion of his work, in the best, most substantial, and workmanlike manner, except the Bargate stone. The bricklayer is to find and lay a sweep of Pulborough stone, 8 inches thick, set in Roman cement, and laid on a proper foundation; and to pave the thorough above the sweep (a surface of masonry concentric with the wheel) with Bargate stone, and below with bricks on edge set in mortar. The employer is to find and deliver on the spot the Bargate stones for the foundations at his own expense; but the bricklayer is to head and prepare them at his expense.

1247. *Plasterer's Work.* To dub out and plaster the space from the edge of the wall-plates to the underside of the respective floor-boards. To lime-white twice over the whole of the interior of the walls of the mill. The plasterer is to find all kinds of materials, tools, and the carriage thereof; and all the workmanship required for the completion of his work, in a sound and workmanlike manner.

1248. *Slater's Work.* The roof of the mill to be covered with the best countess slates, nailed with wrought copper nails, 1 inch and a quarter long, the eaves laid double. The slater to find all kinds of materials, tools, and the carriage thereof, and the workmanship required for the completion of his work, in a sound and workmanlike manner.

1249. *Mason's Work.* To put Yorkshire stone quarry sills, 8 inches wide, beveled, throated, and tooled, to all the windows, finding all materials, workmanship, fixing, and carriage.

1250. *Memorandum of Agreement* made this twenty-fifth day of April, 1831, between J. S. of G., Esquire, of the one part; and W. M. the elder, and J. M. of G., Bricklayers, Plasterers, and Masons, of the other part: viz. ; In consideration of the sum of money, and the conditions herein after mentioned, the said W. M. and J. M. do hereby contract and agree to and with the said J. S. to perform the whole of the works described under the titles of *Bricklayer's, Plasterer's, Slater's, and Mason's Work*, in the foregoing particular, as the same are also exemplified in the plans, elevations, and sections, and details, which are identified by the signature of the parties hereto; and to complete the same in the best and most workmanlike manner, to the entire satisfaction of the surveyor appointed by the said J. S. to superintend the same, finding all materials, carriage, and workmanship of every kind soever, which may be required in the said works, except Bargate stone, and the carriage thereof, for the sum of two hundred and thirty-five pounds twelve shillings and sixpence; and to complete the whole of the said works as aforesaid, on or before the thirtieth day of July next ensuing the date hereof. And the said J. S. doth hereby agree to deliver upon the spot the Bargate stone required for the foundations, as described in the particular and drawings, and to pay unto the said W. M. and J. M. during the progress of the work, such sum or sums, on account of the said sum of two hundred and thirty-five pounds twelve shillings and sixpence, as the surveyor may direct; provided such sum or sums shall not exceed two thirds of the value of the work then done, and the remainder thereof on the thirtieth day of August next, provided that the said works are certified by the surveyor to be complete and finished according to the true intent and meaning of the foregoing particular and drawing referred to, and this agreement. And in case any difference or want of accordance shall appear between the drawings and the particulars, or any part thereof, the same shall be construed in the way most favourable to the substantiality of the work. And if any material shall be brought upon the premises which is disapproved by the surveyor, or any workman employed whose skill is considered insufficient by him, the said materials or workman to be removed or discharged immediately, upon the said W. M. or J. M. receiving notice from the surveyor so to do. And in case any alteration shall be directed by the said J. S. or his surveyor, in the nature of the work during progress, or any deviation shall be ordered by them from the foregoing particular and plans aforesaid, the same shall not vitiate or annul this agreement, but the difference shall be valued by J. P. of G., Surveyor, between the parties, and shall be added to or deducted from the amount of the present contract (as the case may be), and his decision shall be final. And further, if any or all of the said work should be performed in any way inferior to the description and intention of the

particulars and drawings, or shall be deteriorated below a fair standard of good quality or sound workmanship, the same shall also be valued by the said J. P. as aforesaid, and deducted from the amount of the contract by the said J. S., and his decision in this case shall also be final. Such parts of the work as affect or appertain to the machinery of the mill are to be done under the direction of W. B. of G., Engineer.

As witness our hands the day and year before written. J. M. for self and father.

Contract, £235 : 12s. : 6d.

1251. *Carpenter's and Joiner's Work.* The whole of the timber, except where otherwise mentioned, to be of the best yellow Dantzic, Riga, or Memel fir, of the several dimensions, scantlings, and framings as herein after described and shown in the drawings. The lintels to all the openings to be 4 inches and a half thick, with a 9-inch bearing on each pier beyond the splay of the jamb, and in width 4 inches less than the thickness of the respective walls. The wall-plates and rising-plate to be 5 inches by 3 inches, and 1 tier of bond, 4 inches and a half by 2 inches and a half, in the warehouse floor story, laid all round, properly halved and spiked at the laps, and dovetailed at the angles. An oak chain-plate is to be put in the centre of the external wall of the mill, all round, 5 inches by 4 inches, where shown in the drawings, well lapped and pinned at every length, and dovetailed and pinned at the angles. The centres to the arches, trimmers, and all other apertures, to be substantially made, fixed, and refixed, and left as long as may be necessary; and all moulds prepared and framed where requisite for the inverted arches, and other places where wanted.—Ground Floor. To have 2 oak front and back sills, 8 inches by 10 inches; 2 oak sleepers, 8 inches by 8 inches; 2 oak ground sills, 8 inches by 10 inches; fir joists not more than 12 inches apart, 7 inches by 2 inches and three quarters, laid on oak sleepers, 4 inches wide, and 1 inch and a half thick.—Out Doors. Oak front sill, 10 inches by 10 inches; oak back sill, 9 inches by 9 inches; and 2 oak sleepers, 8 inches by 8 inches.—Stone Floor. To have 3 girders, 14 inches by 12 inches, with joists framed into the same, and trimmed to the stairs and sack-hole, 9 inches by 3 inches, not more than 12 inches apart, with trimming joists and trimmers, 9 inches by 6 inches.—Warehouse Floor. To have 3 girders, 14 inches by 12 inches, with joists framed into the same, and trimmed to the stairs and sack-hole, 9 inches by 3 inches, not more than 12 inches apart, with trimming joists and trimmers, 9 inches by 6 inches.—Floor in Roof. To have joists, 8 inches by 3 inches, not more than 12 inches apart, framed into the tie-beams, trimmed to the steps and sack-hole with trimmers and trimming joists, 8 inches by 6 inches. All the girders to be laid on an oak templet at each end, 4 inches and a half by 9 inches, and as long as the respective piers will admit. All the floors to be of good well seasoned yellow deal, listed, free from sap, wrought, and edges shot; none of the boards to exceed 5 inches and a half in width. The ground floor and stone floor to be 1 inch and a quarter thick; the warehouse floor and floor in roof to be 1 inch thick, rebated. There are to be 3 wrought story posts, with chamfered edges in each story, 9 inches by 9 inches, with an oak cap properly stub-mortised, 2 feet 6 inches long, and 8 inches deep, and 2 pairs of oak wedges to each, with a cast-iron sole piece to each story post.—Roof. Tie-beams joggled to the plates, 7 inches by 12 inches; framed principals, 8 inches by 3 inches and a half at bottom, and 7 inches by 3 inches and a half at top; struts, 6 inches by 3 inches and a half; collars, 7 inches by 3 inches and a half; king posts, 9 inches by 3 inches and a half, with  $\frac{3}{4}$ -inch iron screw pins, 18 inches long, with nuts mortised through the king posts; common rafters, 4 inches by 2 inches and a half, 13 inches apart, notched on the back of principals, and laid horizontally. The principals to be fixed to the tie-beams, as also the collars at each end to be fixed to the principals, with iron screw pins and nuts, and to put  $6\frac{3}{4}$ -inch wrought-iron screw pins with nuts, &c., as queens. The ridge to be of  $1\frac{1}{2}$ -inch yellow deal rounded for lead, 9 inches wide. The roof to be covered with  $\frac{3}{4}$ -inch white spruce slate boarding match planed, together with a  $\frac{3}{4}$ -inch feather-edge eaves board, 8 inches wide. To put inch yellow deal wrought and rounded window boards to all the windows.—Note. The windows, doors, and frames are to be of iron, and will be provided by the employer. The step-ladders to each story to be of 2-inch wrought yellow deal, the sides 9 inches wide, with the steps housed into them with  $2\frac{1}{2}$ -inch wrought-iron screw bolts to each ladder. All the carpenter's and joiner's work to hold the several scantlings and thicknesses named in the foregoing particular when finished. The carpenter and joiner to find all the materials, and the carriage thereof, and workmanship, and tools, and ironwork required for the completion of his work in the best and most substantial and workmanlike manner. All the timber to be free from shakes, or sap, or large knots. Wood bricks to be found where necessary; and also all fillets, linings, beads, stops, &c., where required. The girders and tie-beams to be each in one length, without joint or scarf.

1252. *Memorandum of Agreement* made this twenty-sixth day of April, 1831, between J. S. of G., Esquire, of the one part; and H. B. of G., Carpenter, of the other part:

viz ; In consideration of the sum of money, and the conditions hereinafter mentioned, the said H. B. doth hereby contract and agree to and with the said J. S., to perform the whole of the works described under the title of *Carpenter's and Joiner's Work*, in the foregoing particular, as the same are also exemplified in the plans, elevations, and sections, and details, which are identified by the signature of the parties hereto ; and to complete the same in the best and most workmanlike manner, to the entire satisfaction of the surveyor appointed by the said J. S. to superintend the same, finding all materials, carriage, and workmanship of every kind soever, which may be required in the said works, for the sum of two hundred and forty seven pounds ; and to complete the whole of the works as aforesaid, on or before the thirtieth day of July next ensuing the date hereof. And the said J. S. doth hereby agree to pay unto the said H. B., during the progress of the work, such sum or sums on account of the said sum of two hundred and forty-seven pounds as the surveyor may direct, provided such advance shall not exceed two thirds of the value of the work then done ; and the remainder thereof on the thirtieth day of August next, provided that the said works are certified by the surveyor to be complete and finished according to the true intent and meaning of the foregoing particulars, the drawings referred to, and this agreement. And in case any difference or want of accordance shall appear between the drawings and the particulars, or any part thereof, the same shall be construed in the way most favourable to the substantiality of the work. And if any material shall be brought upon the premises which is disapproved by the surveyor, or any workman employed whose skill is considered insufficient by him, the said materials or workman to be removed or discharged immediately, upon the said H. B. receiving notice from the surveyor so to do. And in case any alteration shall be directed by the said J. S., or his surveyor, in the nature of the work, during progress, or any deviation shall be ordered by them from the foregoing particulars and plans aforesaid, the same shall not vitiate or annul this agreement ; but the difference shall be valued by J. P. of G., Surveyor, between the parties, and shall be added to or deducted from the amount of the present contract (as the case may be), and his decision shall be final. And further, if any or all of the said work should be performed in any way inferior to the description and intention of the particulars and drawings, or shall be deteriorated below a fair standard of good quality or sound workmanship, the same shall also be valued by the said J. P. as aforesaid, and deducted from the amount of the contract by the said J. S., and his decision in this case shall also be final. Such parts of the work as affect or appertain to the machinery of the mill are to be done under the direction and to the satisfaction of W. B. of G., Engineer.

In witness whereof, I the undersigned have hereunto set  
Contract, £247. my hand, the day and year before written. H. B.

1253. *Plumber's, Painter's, and Glazier's Work.* The ridge of the roof of the mill to be covered with cast lead, 7 pounds to the superficial foot, 18 inches wide, properly dressed, and nailed with lead-headed nails. All the sashes to be back puttied, and glazed with the best second Newcastle crown glass. All the sashes and frames, doors, shutters, and door frames to be properly primed, and painted three times inside and four times outside with the best white lead and oil colour, the doors and shutters lead colour.

1254. *Memorandum of Agreement* made this twenty-fifth day of April, 1831, between J. S. of G., Esquire, of the one part, and T. O. of G., Plumber, Painter, and Glazier, of the other part : viz ; In consideration of the sum of money and the conditions herein after mentioned, the said T. O. doth hereby contract and agree to and with the said J. S. to perform the whole of the works described under the title of *Plumber's, Painter's, and Glazier's Work*, in the foregoing particular, as the same are also exemplified in the plans, elevations, and sections, and details, which are identified by the signature of the parties hereto, and to complete the same in the best and most workmanlike manner, to the entire satisfaction of the surveyor appointed by the said J. S. to superintend the same, finding all materials, carriage, and workmanship of every kind soever, which may be required in the said works, for the sum of twenty-two pounds eight shillings and eightpence ; and to complete the whole of the said works as aforesaid, on or before the thirtieth day of July next ensuing the date hereof. And the said J. S. doth hereby agree to pay unto the said T. O. the said sum of twenty-two pounds eight shillings and eightpence, provided that the said works are certified by the surveyor to be complete and finished, according to the true intent and meaning of the foregoing particulars, the drawings referred to, and this agreement. And in case any difference or want of accordance shall appear between the drawings and the particulars, or any part thereof, the same shall be construed in the way most favourable to the substantiality of the work. And if any material shall be brought upon the premises which is disapproved by the surveyor, or any workman employed whose skill is considered insufficient by him, the said materials or workman to be removed or discharged immediately upon the said T. O. receiving notice from the surveyor so to

do. And in case any alteration shall be directed by the said J. S., or his surveyor, in the nature of the work, during progress, or any deviation shall be ordered by them from the foregoing particular and plans aforesaid, the same shall not vitiate or annul this agreement, but the difference shall be valued by J. P. of G., Surveyor, between the parties, and shall be added to or deducted from the amount of the present contract (as the case may be), and his decision shall be final. And further, if any or all of the said work should be performed in any way inferior to the description and intention of the particulars and drawings, or shall be deteriorated below a fair standard of good quality or sound workmanship, the same shall also be valued by the said J. P. as aforesaid, and deducted from the amount of the contract by the said J. S., and his decision in this case shall also be final.

In witness whereof, I the undersigned have hereunto set my  
Contract, £22: 8s.: 8d. hand, the day and year before written. T. O.

1255. *Remarks.* The foregoing mill was built as an auxiliary to a larger one close adjoining it; and, to make it complete as a district mill, another, viz., a dressing-floor, would be required to be added. The floors required in a complete mill are, the ground floor, the stone floor, the dressing-floor, the bin floor, and the stage floor in the roof.

Design II. — *The Construction of a Building for containing the Machinery and Apartments belonging to a Vertical Windmill, with Remarks on the different Kinds of Windmills.*

1256. *Windmills* are supposed to have been brought into France from the East in the sixth century. They are of two kinds, the vertical and horizontal; but the latter are rarely, if ever, used for commercial purposes, though they might sometimes be employed in gentlemen's grounds for raising water to supply the house, and other purposes, where the sails of the vertical windmill would be considered so unsightly as to render its erection inadmissible.

1257. *The Vertical Windmill* is the kind in most common use, and consists of an axis or wind-shaft, placed in the direction of the wind, and usually inclining a little upwards from the horizontal line. At one end of this, four long arms or yards are fixed perpendicularly to the axis, crossing each other at right angles; into these arms small cross bars are mortised at right angles, and other long bars are joined to them which are parallel to the length of the arms, so that the bars intersect each other in the manner of latticework; and form a surface on which a cloth can be spread to receive the action of the wind. These are called sails: they are in the form of a trapezium, and are usually nine yards long and two yards wide. The circular motion is produced by the obliquity of the planes of these surfaces from the plane in which all the four arms are situated. By these means, when the wind blows in the direction of the axis, it does not impinge upon the sails at right angles to the surfaces, but strikes obliquely: hence the effort of the sail to recede from the wind causes it to turn round the common axis, and the four sails are all made oblique in the same direction, so as to unite their efforts for the common object. For the wind to act with the greatest efficiency upon the sails, it is requisite for the wind-shaft to have the same direction as the wind; but as this direction is constantly changing, some apparatus is necessary for bringing the wind-shaft and sails into the proper position. This is done by turning the axis of the sails round in a horizontal direction. There are two methods of effecting this.

1258. *In the oldest windmills*, the whole of the building which contains the machinery is sustained upon a vertical post firmly fixed as a stand or foot, upon which the whole of the machine can be turned by a lever so as to present the sails to any quarter of the horizon whence the wind blows; and hence these are called post windmills, and are necessarily made of wood. They are of small size, and can only contain one pair of stones. The mill-house is of a rectangular form, but narrow in the direction which is presented to the wind. It is two stories high, the main shaft and millstones being in the upper chamber, while the lower is only used to contain sacks of flour, and to receive the post on which the mill turns round horizontally to face the wind. The whole building is turned by means of a lever, that also serves for a step-ladder into the upper chamber; and when it is wished to prevent the mill from turning, it is fastened to the posts by a cord. There is also a small windlass to assist in moving the mill round. These windmills are generally used for grinding corn or expressing oils; being unfit for other purposes, on account of there being so little room for machinery.

1259. *The other kind of vertical windmill* is called a smock, or tower, windmill, in which only the dome cap or head, which contains the axis of the sails, and covers the great cog-wheel, turns round horizontally; the other parts of the machinery being contained in a fixed building, which rises up in the form of a conical tower, and is composed of masonry, brick or timber framing; being surmounted by this movable cap or dome, which is supported on rollers, so as to turn round easily.

1260. *The Smock, or Tower, Mills* are considered the best, because the building which con-

tains the machinery may be made of any required dimensions, the sails and turning cap being all at the top of the house. Smock mills are built of timber, covered with boards; and tower mills are built wholly of brick or masonry. Fig. 1113 is a perspective view of

1113

a smock mill, as it appears with the sails spread to the wind. Fig. 1114 is a plan of the ground floor, showing the basement wall, which is of masonry, 20 inches thick, the cross wall for supporting the joists, and the story post, on the top of which rests the gudgeon pivot of the main axis or vertical shaft. This wall is of masonry, 14 inches thick; the joists are of oak 4 inches by 3 inches, and there is an oak sleeper on the cross wall 1 inch and a half thick and 4 inches wide. This floor is used for bolting and dressing the meal, and for filling the sacks with flour, &c. Fig. 1115 is a plan of the floor on which the mill-stones are placed, in which is shown the situations of the vertical shaft, *a*, the places of

1114

1115

the two pair of stones, *b*, and of the sack-hole, *c*, for allowing the corn to be raised by the tackle into the bin floor. The trapdoors of the sack-hole fold upwards, so as to give passage-way to the rising sack, and they fall close down again directly after it has passed. There is a hole between the two flaps for the chain to hang through; and *d* is the step-ladder. The framing is of foreign fir; the plate is 6 inches by 7 inches; and the joists, 12 inches apart, and 6 inches by 2 inches, are mortised into girders 10 inches by 10 inches; as also are the trimming joists which support the stones, and are 8 inches by 9 inches. Fig. 1116 is a plan of the bin floor, on which the corn to be ground is kept for supplying the stones, for which purpose the bottom of the bins slope to a centre, where there is a wooden trunk passing downwards through the floor, to convey the corn to the stones. The dotted lines represent the sides of these bins, which are generally about 3 feet 6 inches high, and are formed of inch wrought deal boarding nailed on fir bearers. The plate is 6 inches by 6 inches, the girders 8 inches by 10 inches, with the joists 5 inches by 3 inches mortised into them; *e* is the sack-hole. Fig. 1117 is the upper floor to

1116

1117

get at the machinery: the plate is 6 inches by 6 inches; the girders 9 inches by 8 inches; and the joists 4 inches by 3 inches. Fig. 1118 is a plan of the horizontal framework which carries the wind-shaft, and forms the base of the head or cap of the mill. The plates are 10 inches by 12 inches; the diagonal braces 7 inches by 6 inches; and the centre brace 10 inches by 8 inches. On the under side of this framing, and bolted to it, is a circular curb or wooden ring, *f*. There is a similar curb on the top of the fixed building. These curbs are to allow of moving round the head or cap; for it is necessary, as the wind changes its direction, to turn the sails about so that the axis or wind-shaft may be always in the direction of the wind. This motion is effected by turning the head of the mill round upon the fixed part on the curb at the top of the framing of the house of the mill, and is represented in section by *l*, in fig. 1119, between which and the movable curb, *m*, attached to the bottom of the frame of the head are fixed a number of rollers. The movable curb, *m*, of the cap lies upon these rollers, which are kept equidistant from each other by the centre-pins being fitted into a circular hoop. By these means, though the head of the mill with the wheels and sails weighs several tons, they can be made to turn round to face the wind by a slight force; *n* is the centre-brace of the head, turning on the pivot, *o*; *p*, the top of the vertical shaft on which, a short distance down, is a wheel called a trundle or lantern, which works into the cog-wheel on the wind-shaft, and so gives the rotatory motion to the shaft; *q* is one of the ribs of the head. In fig. 1118, the wind-shaft or horizontal axis, *r*, is made of cast iron, and is octagonal, thickest at the end next the sails, and having two cylindrical necks

1118

where it rests upon its bearings. It generally is placed a little inclined from the horizontal line; the highest end being towards the sails. At the end, it has a kind of box, which has two mortises through it in perpendicular directions to receive the sails. At the back of one of these mortises, and on the front of the other, a projecting arm is left in the casting to receive screw bolts which hold the sails fast in the mortises. The cogwheel, *s*, is fixed on by bolting its arms against a flanch cast on the vertical axis; *t* is the commencement of a curved piece of timber 10 inches by 12 inches at top, and 6 inches by 6 inches at bottom, being the lever by which the heads of the old-fashioned mills are turned round to the wind. Attached to the lower end is a windlass, a cord from which fastened to any one of the posts that are fixed round the mill in a circle (see fig. 1113) enables a man to move the head in the direction desired. There are also two pieces of wood affixed to the bottom of the lever by staples, made sharp at the lower end, to stick in the ground, and to steady the mill against any side-gusts. There are several plans now in use for making the head turn itself when the wind varies: this is done by having small sails at the back of the head that do not revolve while the head is in its proper position, but as soon as the wind varies, these sails are set in motion, and by machinery bring the head again into its proper direction. This is considered a great improvement; but, as all the plans for this purpose involve much machinery, a detailed description of them is omitted, as they may be considered to come more under the control of the millwright than the Architect.

Fig. 1121 is a section across the roof, showing the framing of one end of the

1121

head, where there is a door that may be opened to give light when any repairs of the machinery are going on.

1120

Fig. 1120 is an elevation of the east side of the structure, in which *t* is the commencement of the lever.

Fig. 1122 is an elevation of the north side, showing the front of the sails, the arms

of which pass through mortises in the end of the wind-shaft, and are bolted to projecting arms. The sails are clothed and unclothed by a line fastened to the upper corner of the canvass, passing over a pulley, and down the side of the arm to the bottom, where it is fastened. By these means, the canvass can be spread out at the end nearest the axis from below, in the same manner as a common window-curtain; the lower part is spread out by hand, and tied. When the mill is not at work, the canvass is gathered up in a roll over the arm. There are patent windmill sails now in use, in which a number of flaps or shutters of thin wood supply the place of canvass. They can all be moved from below, so as to present their edges to the wind when the mill is not at work. The computed power of a windmill, with four sails, measuring 66 feet French from the extremity of one sail to that of the opposite one, and 6 feet wide, or a little more, is, that it will raise 1000 French lbs. 218 feet in a minute, and is capable of working eight hours in a day upon an average. This is equivalent to the work of 34 men; 25 square feet of canvass performing about the daily work of one man.

Fig. 1123 is an elevation of the west side, in which *t* is the commencement of the lever, which serves for turning the sails to the wind.

Fig. 1124 is a transverse section of fig. 1118, from C to D, showing the framing of the mill. The corner or principal posts are 8 inches by 8 inches; the principal quarters and braces are 4 inches by 4 inches; and the common quarters are 4 inches by 3 inches. The clear height of the ground floor is 9 feet 8 inches; the clear height of the stone floor story is 7 feet 6 inches; that of the bin floor story 6 feet 8 inches; and

that of the upper story, to the under side of the frame of the head, is 4 feet 4 inches. The ribs of the roof are 4 inches by 3 inches, cut to a sweep. The roof is covered with  $1\frac{1}{4}$ -inch yellow deal feather-edge boarding, wrought on both sides, and the whole of the timber framing of the mill is likewise covered with  $1\frac{1}{2}$ -inch yellow deal feather-edge boarding, wrought on both sides, and having a quirked bead forming a drip (see fig. 1125) run on the lower edge of each board.

1125
