OF THE ROYAL COLLEGE OF PHYSICANS, LON-DON, PHYSICIAN TO CHELSEA HOSPITAL, OF THE UNIVERSITY OF LEYDEN, THE AMERICAN PHILOSOPHICAL SOCIETY, AT PHILADELPHIA: &c. &c. &c.

SIR,

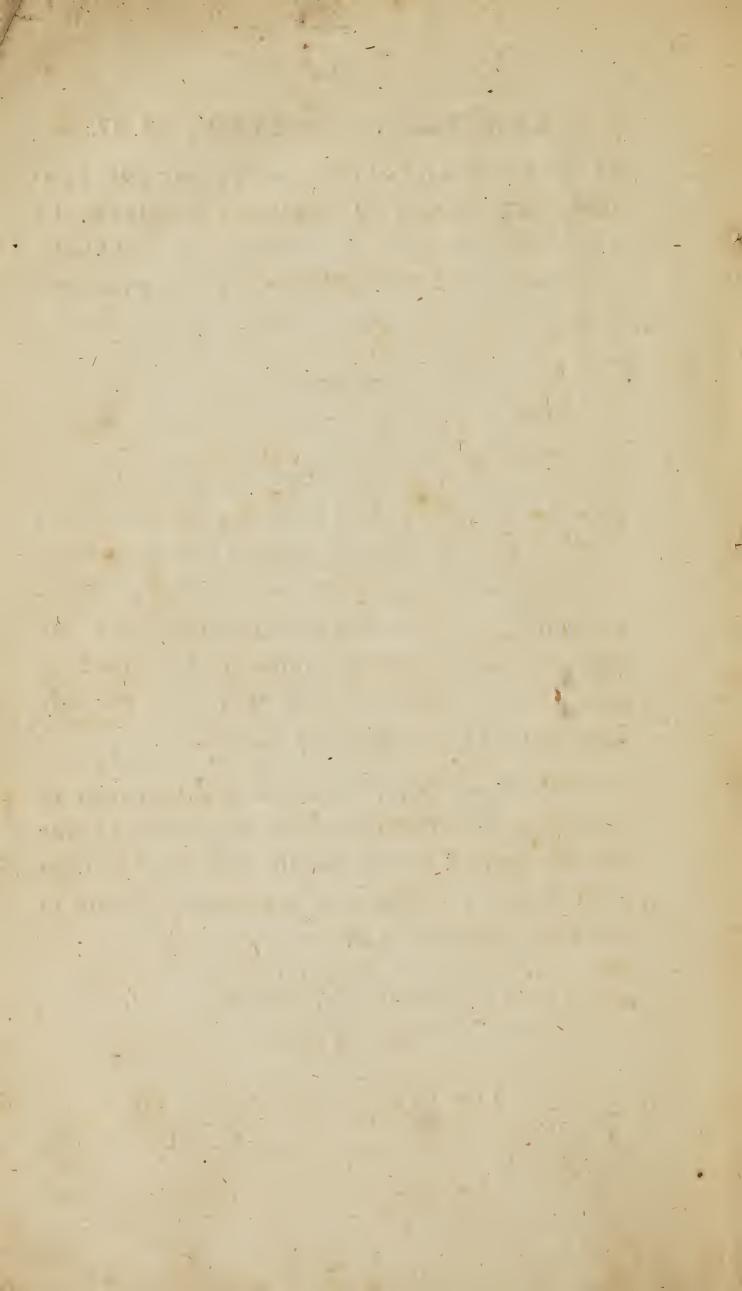

I Take the liberty of dedicating to you this MANUAL OF INOCULATION; confident that if it shall be found to deferve your notice, the patronage of a gentleman so eminently diftinguissed by abilities most useful and brilliant; by learning most varied and profound; by experience most acknowledged and extensive, will be duly appreciated and regarded by the public.

At the fame time I embrace the opportunity of presenting a refpectful acknowledgment of the benefits derived by the faculty and fociety, from your highly valuable and meritorious labours in the field of fcience, and

I have the honour to fubfcribe myfelf,

SIR,

Your obliged and obedient fervant, Frith Street, G. LIPSCOMB. Feb. 4, 1806.

MANUAL OF INOCULATION.

HE following directions for Small-Pox-Inoculation, and the treatment of patients; felected from the most authentic and respectable fources of information, and recommended by experience, are offered to the public with great respect, but with equal confidence.

It is prefumed that they will be found to concentrate all the most useful remarks which have hitherto appeared on this important subject; and afford fome affistance to individuals and private families, as well as to those professional gentlemen who may have either neglected, or been deprived of the opportunity of becoming experimentally acquainted with those circumstances in the practice of Inoculation, and the management of patients under it, on which the fafety and the lives of their fellow-creatures for greatly depend.

Subjects favourable for Inoculation.

Children under two years of age, who have had the thrush and red-gum; of placid cheerful dispositions; subject to slight cuticular eruptions; fat and fleshy; with mottled skin: those

A

who are nourifhed by wholfome milk, from temperate healthy nurfes; having regular bowels, moderate perfpiration, moift and coarfe skin; accuftomed to partake of the ordinary provifions of common tables; and who have not been confined to a precife regimen, or too rigid reftraints with regard to diet and exercife.

Young perfons and adults, grofs, flefhy, and difpofed to perfpire; not liable to the exertions of hard labour, or the influence of fudden heat or cold; in a word, perfons of all ages, from infancy to the remoteft period of life, who are of good ftamina.

Unfavourable Subjects.

Children pot having had the thrush or redgum; peevish and irritable in disposition; during the time of dentition; lean; with a dry and parched skin; habitually costive; fed with acid or impure milk, such as that of dram drinkers; narrow chested; ricketty; those who have been too scrupulously confined to a particular species or quantity of food: subject to worms; or having been recently exposed to the infection of the measures or any other difease.

Perfons more advanced in life; of very delicate irritable habits; acutely fenfible; gouty; rheumatical; accuftomed to be exposed to the heat of blaft-furnaces, forges, glafs-houses, &c. failors, and others who have been long confined to falted and unwholfome provisions, or having been fuddenly removed from a cold climate to a more temperate one.

Subjects more unsafe, and even dangerous.

Perfons whofe conftitutions have been injured by intemperance, and abound with corrofive humours. Women in advanced pregnancy. No one would think of inoculating perfons while fuffering acute or dangerous difeafes; farther cautions on this head are therefore unneceffary.

The enumeration which has been made is not intended to deter perfons from Inoculation: but that a cure of fuch complaints may be effected previous to the introduction of the Small-Pox.

Time of Inoculation.

There is no reafon for declining Inoculation at any feafon of the year, unlefs in the extremes of fummer's heat and winter's cold: the conftitution being free from difeafe, and epidemics not remarkably prevalent.

The difadvantage of not being able fecurely. to inoculate children during the time of dentition is confiderably diminished by the facility with which at that period of life, they may be fecluded from the influence of contagion. Experience convinced Mr. DAN. SUTTON that the average number of puftules which followed Inoculation performed in the evening, was as five to one more than occured to perfons inoculated in the morning; and the increase of febrile fymptoms, proportionable; this is mentioned as matter of experience, not of reasoning.

On the Choice of Matter.

It is preferable that variolous matter for the purpose of Inoculation be selected from persons free from constitutional diseases.

It fhould be taken invariably in the moft early ftage of the eruption; while in a pellucid ftate; either from the inoculated part, or what is preferable in the opinion of the moft experienced, from the natural Small-Pox puftule, as foon as any fluid can be obtained from it.

It is of great importance to remember that matter taken from the most benign fort of puftules, after complete maturation, generally produces a later and more untrastable difease, than clear active matter selected from a vesicle in its earliest stage.

It is defirable to introduce the matter fresh, immediately from one subject to another; but when this is impracticable, and it is necessary to preferve it for future use, it may be kept between two pieces of glass, from which heat and air are excluded, by enclosing them in goldbeaters skin.

When dry matter, which has been either fo preferved, or kept on the point of a lancet, is to be ufed, it fhould be liquified with cold water, but not with fleam or hot water, as is the general practice.

Attention to the matter is of great confequence, becaufe on that depends the certainty of producing infection; and confequently the reputation of the practice and the Inoculator.

Performance of the Operation.

A lancet, the point of which has been charged with the fmallest perceptible quantity of pellucid matter, should be introduced as soon afterwards as possible, obliquely through the cuticle so as to wound the skin, but in such a manner as if possible not to produce blood.

The puncture fhould be performed deliberately; and it would be proper to make it higher up than the infertion of the deltoid mufcle (or, in common language, the midway between the elbow and the fhoulder) on account of the expofure to which the arms of females are now liable, in confequence of the influence of fashion in modern drefs.

It is unnecessary and improper to pat or wipe the lancet on the incision or puncture: a practice which may alter the form of it, and confuse the judgment subsequently to be made on its appearance.

MR. SUTTON remarked that in perfons who were inoculated a fecond or third time, the fkin exhibited a paler appearance, when elevated by the point of a lancet, than in those who had not previoufly undergone the Small-Pox.

The introduction of fresh active matter, in the manner here described, instantaneously produces a flushing or slightly suffused appearance round the punctured part, which soon disppears, leaving the skin in about an equal degree paler than in its natural state.

This is not known to happen to perfons who have already had the Small-Pox, nor is it equally difcernable in those who are fusceptible of infection, being in some cases rendered obscure by a certain opacity or coarfeness of the skin; by its peculiar colour, or the unusual minuteness of its vessels.

A flight pain alfo is fometimes felt in fome remote part of the body; and a fmarting in the puncture, fenfibly different from that more obtufe fenfation which accompanies the introduction of the point of a perfectly clean lancet into the fkin. This has been obferved by perfons of mature age.

After Inoculation the puncture is not to be

covered with any kind of ointment or plaister; and as experience proves that the Small-Pox is most favourable when the smallest possible quantity of matter be employed in Inoculation; the practice of inoculating in both arms, or in more places, or by more punctures than one, must evidently appear to be improper; and has been found always prejudicial:

Food proper for Inoculated Patients.

Much of the fuccefs of Inoculation muft neceffarily depend on a ftrict regard to articles of diet. In this particular, as in every other connected with fo delicate and important a practice, the moft rigid and exact attention to medical directions, and a conftant and uniform fubmiffion to the regulations here fuggefted, will be found abfolutely and indifpenfibly requifite.

For breakfast—Tea with dry toast, milk-porridge, skimmed milk, rice-milk, water-gruel, water-pap, honey and bread, or bread made with the addition of sugar and currants.

For dinner—Bread-pudding, boiled rice or millet, rice-pudding, fago or apple-pudding, rice-milk, and vegetables with or without fugar, falt, vinegar or lemon juice.

For supper-Any of the spoon-meats above-

mentioned, roasted apples or potatoes. For children, weak tea, or milk and water, with dry toast, at an early hour.

Stewed prunes, tamarinds, or roafted apples; may be freely or occafionally used.

SUTTON recommends that perfons moft favourable for Inoculation be reftrained to a vegetable diet, of which they fhould eat only about as much as three-fourths of their accuftomed quantity of food, at a meal; and that others lefs favourable fhould diminifh their allowance to two thirds. Patients thus dieted are not to eat any thing between their regular meals, unlefs bread or fruits.

The drink fhould be toaft and water; milk and water; barley-water; lemonade; water which when previou fly boiling was acidulated with cream of tartar, and fweetened to the tafte: or barley-water agreeably acidulated with vitriolic acid: unlefs in cale of conftitutional objections.

A liberal use of these is highly refreshing, particularly whenever the fever be confiderable.

Clothing, Air, and Exercife.

As heat applied to the furface of the body, or generated in confequence of fuperabundant clothing, is liable to occasion numerous pustules, great precaution on this head is necesfary, particularly in the nurfery: moderate and frequent exercife in temperate air invigorates the digeftive powers, and promotes that gentle relaxation of the ikin, which is most favourable to the progress of a mild difease.

The patient fhould be kept out of bed; and as much as possible in the open air; particularly during the eruptive fever. In this circumftance, the employment of purgatives, and the ufe of *mercurial* alteratives, confifts the *fecret* of the most famous modern Inoculators, to which they have been indebted for their great fuccess in practice; and the neglect of which can alone account for the mortality of the natural Small-Pox in the hands of others.

The effects of cool air are fo falutary and refreshing, that it should never be dispensed with, unless the weather be extremely inclement or the patient remarkably delicate: and whatever reluctance may be felt to comply with such injunctions, experience shews that those who have been prevailed on to rise out of their beds and go into the open air, even when unable to walk without affistance, have had their spirits revived, their appetite restored, and their fleep rendered far more comfortable and refreshing than before:—afterwards a gentle relaxation of the shin comes on accompanied by a favourable eruption, and the fever entirely disappears.

The illustrious Sydenham who may be con-

fidered the great founder of modern and rational practice in the Small-Pox, well knew the advantages of an open skin at the period of the eruption: and has alfo expressly recorded the *exhilaration which his patients experienced from the admission of fresh air, and being taken out of bed,*—a remark which however it may have been disregarded, is fufficient of itself to entitle the author of it, to eternal renown.

REMARK.

The fame good effects being observable under the cooling regimen, whether preparatives were or were not employed, it has been fupposed that the mildness of the disease depends on the use of brisk cathartics : it seems however more probable that the mercurial preparation possesses an important influence in the fystem, and is capable of controling the variolous fever; for purgatives, exhibited without mercurials, are not found capable of fubduing the unfavourable fymptoms though they readily yield to these remedies united with mercury. It appears that the introduction of a certain quantity of mercury is necessary, and that it is highly important to excite the fever of the fmall pox at that period when the mercury is most powerfully exerting its influence: hence matter fo

inert as to remain feven or eight days before it produces fever, ufually occasions a more unfavourable disease; because the action of the mercury being then over, the system is deprived of that opposing power with which the mercury when present so constantly resists severe symptoms. This remark explains at once the propriety of employing the mercurial alteratives, and points out the advantage of inoculating with the most active matter, obtained in the earlieft stage of the disease. The utility of antimonials is very obvious. They bring on that gentle relaxation of the skin, which ever fince the days of SYDEN-HAM, has been well known to be greatly conducive to the occurrence of the mildest and most favourable eruption.

DIMSDALE'S Preparative Powder.

vel

Sulph. Antimon. præcip. Gr. ij. M. f. Pulvis.

This dofe was calculated "for a healthy ftrong man:" to be diminished for perfons advanced in years, and for women and children in due proportion.

It was the cuftom of DIMSDALE to prepare his patients for Inoculation by exhibiting three dofes of the powder, either formed into pills or mixed with fyrup or jelly, at equal intervals; beginning "nine or ten days before" the time appointed for the operation.

Another dofe of the powder was to be exhibited in the evening of the fecond day after Inoculation, and repeated once or twice previous to the occurrence of eruptive fymptoms. On the morning following, a laxative draught, composed of Infusion of Senna, with Manna, and Tincture of Jalap was directed: particularly when the fymptoms indicated a fevere difeafe.

MR. SUTTON laid afide the preparative mode; exhibited one of his alterative powders, every night at bed time, beginning on the day of Inoculation; and one of the cathartic powders every other morning, beginning on the day next following that of the operation.

R-Syrup. e Spinâ Cerv. Ziß. Tinct. Cardom. comp. ziß. M.

Mr. SUTTON prefers the use of Glauber's Salts for perfons who can be induced to take that preparation, on account of their cooling quality, and the copious fecretion which they induce in the glands of the intestines.

These medicines are found to subdue preternatural heat; to cleanse the first passages; to dispose the skin to a state of gentle relaxation; and in conjunction with the cooling antiphlogistic plan of diet, occasion a gradual reduction of corporeal power or vascular action, previous to and during the eruptive fever.

In SUTTON'S formula it is evident that the emetic tartar bears too great a proportion to the whole, unlefs for ftrong robust perfons, and fuch as are accustomed to a laborious life; for although it be a most defirable point to produce a state of nausea, and its usual accompaniment, a relaxed skin, it is not the object required, to excite vomiting: although vomiting will be excited if the state of the stomach from bile, &c. should require it.

The following preparation is better adapted to more delicate conftitutions.

LIPSCOMB'S POWDER.

Take of Calomel and prepared Crabs'-Eyes, each 4 drams, Emetic Tartar, 6 grains:

Mix them perfectly, fo as to form an impalpable powder.

				given.

A pleafant mode of exhibiting the powders is mixed with coffee fweetened with fugar; but they may be given in any thing elfe.

The operation of each dose of the purgative is expected to extend to four, five, or fix lax motions; according to the ftate and conftitution of the patient; the degree of evacuation being always regulated by the index of the arm, and the prognostic afforded by it, of a favourable or fevere difease.

It is particularly defirable that the dofe which immediately precedes the cruptive fever, be of due ftrength: and whenever it happen that a powder be rejected by vomiting, another must be given immediately, or a fufficient dofe of fome other laxative lefs difagreeable to the ftomach, to produce the requisite evacuations.

The operation of the physic is well promoted by the copious use of water-gruel, or other diluents.

# Progress of the Disease, Indications, and Mode of Treatment.

The days of Inoculation, of the fever, and of the eruption are calculated from that day inclufive on which the matter was introduced, the fever commenced, and the eruption appeared.

1. On the day of Inoculation no alteration is discoverable.

2 and 3. The puncture being viewed through a lens, a kind of orange-coloured stain appears, and the furrounding skin seems contracted.

4. These appearances more evident.

B 2

5 and 6. Some degree of hardnefs is to be felt. The puncture itches, is flightly inflamed, and a little pellucid fluid is feen under a kind of vefication; the part refembling a fuperficial burn.

Itching accompaning the irritation is a favourable indication.

But if the colour of the skin near the puncture remain pale, the edges of the wound clofed and flat; no itching nor uneafinefs be felt; either infection has not taken place (which however feldom happens if fresh pellucid matter have been carefully inferted) or the enfuing difease will be very severe.

7, or 8. Pain and ftiffnefs in the axilla, which foretel the near approach of the eruption, and indicate a favourable progrefs of the difeafe: for as DIMSDALE obferved " an early progrefs " of the arm, and an early commencement of " the eruptive complaints portend that the dif-" temper will be mild and favourable; and on " the contrary, where both are late, the fymp-" toms are ufually more irregular and unto-" ward."

During this period of the difeafe, if reftleffnefs prevail, a moderate and fuitable dofe of opium may be advantageoufly exhibited at bed time.

9, or 10. Slight remitting pains in the head, which are greatly increased by the impetus of the blood in the vessels of the brain when the patient is confined to an horizontal polition: the bed therefore fhould be avoided; and children, who at this period of the difeafe, fometimes fuffer great diftrefs, manifeft almost immediate tranquillity on being taken out of the cradle and carried into the air. Pain in the back, fucceeded by transfient shiverings and alternate heats: these continue till the eruption be completed, with an unpleafant taste in the mouth, and a foetor of the breath, peculiar to the Small-Pox.

The fymptoms here defcribed fometimes occur earlier, and fometimes later, but more ufually at this period, which is the moft important in the whole difeafe. "No ignorance" fays the experienced SUTTON) "no inattention to what " is paffing on the arm muft now be fuffered : " on the contrary, a just and accurate diferi-" mination between the indications afforded by " it, is abfolutely indifpenfable, in order to enfure " a regular and favourable Small Pox."

It must be remembered that many of the indications depend on the mode of practice, which has been previously observed; and are subject to variation in confequence of the future treatment pursued: that an unfavourable indication which depends on natural habit may be converted into a favourable one by skilful practice; but that neglect or ignorance may render it the fure harbinger of danger and diffres.

B 3

When the fymptoms of eruption have taken place, as foon as the cathartic medicine has operated, the patient fhould go abroad into the open air (be it ever fo cold) as much as he can bear, always cautioufly avoiding to ftand ftill. He fhould alfo drink cold water if thirfty, or the acidulated barley-water, before mentioned.

A ftrict attention to the regimen, and the enjoyment of cool air at the period of the eruption, almost always prevent either dangerous fymptoms or numerous pustules.

Perfons who have experienced this mode of treatment are in general fo fenfible of the advantage evidently derived from it, that were it always practicable, it *would be* always highly defirable to commit the fuperintendance of inoculated patients to them; for they commonly encourage the fick to bear the apparent hardfhip of quitting their room, and walking about in the open air during the eruptive ftage, by recounting the benefit which they themfelves have reaped from the practice here recommended.

In young children, if the veficle about the feventh or eighth day after Inoculation be depreffed, and contain but a fmall portion of fluid, having its edges fharp and irregular, and exhibiting a number of appearances refembling the impreffion of a pin's point, the colour being whitish and pale; convulsions will most probably foon enfue, unless feasionably prevented.

For that purpose SUTTON recommends a glyster with as a factida, and a dose of fyrup of poppies: the belly should be well rubbed with hot flannel, and the circulation promoted on the furface of the body and limbs by friction. During this violent constitutional agitation, the extremes of heat and cold must be carefully avoided.

9 or 10. The inflammation fpreads rapidly on the arm, and the punctured part when viewed through a glafs, appears to be furrounded by a number of fmall confluent puftules, which gradually increase in fize and extent.

11 or 12, or even later. An efflorefcence is feen round the vehicle extending to the fize of a fhilling, and fometimes much larger. It is fmooth and not painful. The general crifis of the arm follows: the contents of the puftule becoming difcoloured (after which it is recommended not to take matter for the purpofe of inoculating other patients) the inflammation fubfiding, the fever going off, and the appetite returning.

During the eruptive stage, the complaints are usually very trivial; the patient eats and sleeps well; a few pustules appear irregularly difperfed : sometimes the inflammation of the arm

B +

fpreads confiderably, and is furrounded by a few puftules.

The powders are to be difcontinued. Cool air feems the only cordial required; medicines being feldom neceffary, unlefs on account of coftivenefs: but in cafes of peculiar languor and delicacy, or to perfons in extreme old age, a bafon of weak broth, or a glafs of wine, may be allowed; or a little white-wine-whey at bed time.

Sicknefs and vomiting fometimes occur during the eruption, in which cafe the difcharge of the offending matter is to be promoted, either by drinking plentifully of warm water, or by a finall dofe of tartarifed antimony, mixed with abforbent powder; this fymptom is alfo eafily removed by the exhibition of a cathartic, which appears to be preferable.

It may be fometimes neceffary to exhibit a folution of Epfom-Salts by way of glyfter, particularly to infants, who fuffer much pain in the head, or flufhing of the face, about the time of the appearance of the eruption. The proportion for a child of twelve months old is about 3ij with 9ij of nitre, in a quarter of a pint of hot water.

In cafés of unufual reftlesses, or pain, during the maturation of the puscules, a few drops of tincture of opium may be given at bed time, but for children, fyrup of poppies is preferable; the dofe of which for a child of two or three years old, is a tea-fpoonful. When the puftules are very numerous, the patient fhould not be exposed to very cold air, particularly to currents of it: on the other hand, he ought not to be kept in a close room, nor on any account near a fire.

Coftiveness must be rigidly guarded against; for which purpose either occasional doses of the purging powder may be given, or a glyster of warm water-gruel and Epsom-Salts dissolved in it.

Eryfipelatous appearances and a rafh fometimes accompany the ficknefs above mentioned: thefe to an experienced practitioner are not alarming, as they go off fpontaneoufly, not being accompanied with those dangerous fymptoms which constantly attend the approach of the confluent Small-Pox.

The patient fhould refrain from cold water, and keep in the houfe: but not in bed. After two or three days the florid colour of the fkin changes to a darker or dufky hue, while the eruption is advancing to maturity, without farther trouble, from fo formidable an appearance.

The errors which have been propagated by those who have miltaken such symptoms for the approach of the confluent Small Pox, deferve the more serious attention; because a fatal accident may be the confequence of adopting an improper mode of treatment at this critical period of the difeafe; and the well-deferved fame of Inoculation may be injured, as well as the reputation of the practitioner.

For the fame reafon a careful and frequent examination of the nurfes and attendants muft be ferioufly inculcated, for prejudice and ignorance under the difguifes of cunning and tendernefs, are too often employed to deceive the faculty refpecting the exhibition of medicines to inoculated patients : and moft of the dangerous fymptoms which have been known to occur after Inoculation may be very rationally attributed to this fertile fource of mifchief and diforder. The greateft care is neceffary in the choice of nurfes, and the moft acute difcernment required in thofe whofe duty it is to fuperintend their conduct.

After the abatement of the fever, and the apparent completion of the eruption, fresh puftules sometimes make their appearance for four or five days successively.

Thefe are ufually not very numerous, and feldom come to maturity; but fome inftances happen in which their number is confiderable; a circumftance undoubtedly dependent on the peculiar ftate of the conftitution at the time; and probably controlable by the due ufe of cathartics, and proper attention to the cooling regimen: Thefe fecondary eruptions, which, it must be observed always appear within the time commonly allowed for the progress of the Small-Pox, have unfortunately given rife to many erroneous reports of perfons who had been inoculated, having subsequently undergone the natural Small Pox : and have thus created more alarm than danger.

The pain and ftiffness in the axillary glands fublide, and the matter contained in the vesications, appears yellow and concocted; dries up, and forms a rough cicatrix.

#### Small-Pox Puftule.

There is a fpecific difference between the Small-Pox, and every other puftule. From its appearance it arifes above the fkin, and when mature is elevated to a confiderable height, fomewhat conically: the middle of the top or point being marked by a flight dent, depression, or concavity. As this infallible characteristic occurs in no other defcription of eruption, no doubt can arise in the mind of any experienced practitioner respecting the nature of the disease, when an opportunity is afforded him of feeing or even feeling the pustule.

The criterion afforded by this peculiarity has been highly advantageous: and even early in the practice of Inoculation, it enabled the fa-

culty to pronounce politively on the cafe of the Honourable John West (afterwards Lord de la Warre) who was erroneoufly fuppofed to have caught the Small Pox a fecond time, until the gentlemen who attended him publicly and de-.cidedly opposed that affertion, and expressly particularifed that the dent or depression on the head of the eruptions was wanting. Mr. West was attended during the Small-Pox, and alfo during the fecond difease by my grandfather, Mr. Lipscomb, of Winchester, and a narrative of the cafe is still preferved in the hand writing of my father, Mr. Lipscomb, Surgeon, of Quainton, in Buckinghamshire, of whom let me respectfully record, that in the course of forty years, he never lost a patient under Inoculation; an honourable proof of his merit as a practitioner, and well known in the neighbourhood in which he lived; where his memory is gratefully and affectionately revered.

When the eruption is complete, reft may be requisite; but heat should be avoided.

A change of diet is now proper. A fmall quantity of light animal food, as chicken, veal, or mutton, may be occafionally permitted; but patients fhould alter their courfe of living gradually; and return by regular degrees to their ordinary diet, it being neceffary that they fhould govern their appetite for folid food and fermented liquors, with the greatest prudence and caution.

When the food is permitted to be changed, the patient may be indulged alfo with a moderate quantity of his usual beverage.

The difease having been thus passed through, it has been usual to exhibit two or three doses of the cathartic medicine : in consequence of a mistaken idea that some purification of the system was necessary : this practice has more of fashion than philosophy to recommend it.

The cutaneous eruptions and excoriations. which fometimes take place foon after patients. have recovered from the Small-Pox, may be accounted for more rationally, if we reflect on the fudden increase of appetite which usually follows fevers of every description, and the consequent excessive indulgence in improper quantities of food. It is therefore very proper to exhibit cathartic medicines to convalescents after the Small-Pox, particularly whenever they may have been suspected of irregularities in point of diet: and more benefit will be derived from fuch attentions than is ufually experienced from a compliance with the fashionable practice of giving phyfic immediately on the termination of the disease.

By the method of treatment thus concilely defcribed, all the mifchiefs of that dreadful difeafe, the natural Small-Pox may be prevented: a fact fully established on the authority of the united experience of DIMSDALE and ARCHER, who in the course of their long lives and extensive practice, never lost a single patient; and by the immense experience of Mr. DAN. SUTTON and his brothers who are still living to prove that they have inoculated more than *five hundred thousand* persons with uniform fucces.

It is inconfiftent with the fcheme of thefe fhort remarks to enter more particularly into the confideration of any of the fymptoms which relate to the natural Small-Pox, befides thofe which belong to it in common with the immediate effects of Inoculation : they muft be left to the judgment of practitioners at the period of their occurrence :—but it is hoped that this little Manual of plain directions in the Inoculated Small-Pox, as it ufually appears, will be found of real utility to Inoculators, and their Patients, to whofe confideration it is very refpectfully prefented.
