Temperature.—There is a gradual increase of temperature in the rocks of the earth's crust, below the zone of uniform temperature which is found near the surface. The law of this increase in temperature is not clearly established. It is certainly much affected by the chemical reactions which may go on in the rock. Mr. Robert Hunt, in his testimony before the British Commission, says that whatever may be the temperature of the atmosphere on the surface of the earth, there is in the Cornish mines a constant temperature throughout the year at the depth of about 150 feet. Below that point, he says, the increase is one degree Fahrenheit for every 56 feet down to about 750 feet; then one degree in every 75 feet down to about 1350 feet; and below that about one degree to 85 feet. Mr. Henwood (quoted by Prof. J. A. Church, in his paper published on the Heat of the Comstock Mines) gives for different kinds of rock the following distances in feet, corresponding with each rise of one degree: granite, 51; slate, 37.2; cross veins, 40.8; lodes, 40.2; tin lodes, 40.8; tin and copper lodes, 39.6; copper lodes, 38.4. These figures show how great is the variation due to local causes. Assuming the increase in granite to be least affected in this way, and applying also Mr. Hunt's formula for the rate of increase, we may adopt as a probable standard of comparison a scale of depths and rock temperatures, as follows:

Depth—Feet.	Temperature of rock.
150, . .	60°
300, . .	62°
600, . . .	66°
1350, . . .	76°
2000, ...	84°

It will generally be admitted that most mines are hotter than this, the fact being that the heat given off by lights, explosives, animals, and men is not immediately removed by the ventilation, and hence the rock is perceptibly cooler than the air. But chemical reactions and hot springs in the rock may very greatly raise its temperature; and when this is the case the miners, finding that the rock feels hot, in comparison with the air, say that the lode or the wall "makes heat." Even when the air is still somewhat the warmer, the rock may seem to be so when touched with the hand.

One of the United mines in Wales is mentioned by Prof. Church, in the paper already cited, as possessing springs which discharge water at 116° Fahr., the depth being 1320 feet. The heat of the air in the workings is given at 100° to 113° Fahr. The hottest mine in Cornwall is, or was in 1862, the Wheal Clifford, concerning which the superintendent, John Richards, testified that the temperature was 102° fifty-one feet below the 1200 feet level, and a "pretty deal hotter" (120° he guessed) at the 1380 feet level. At one time, in a confined working, the temperature was known to rise as high as 128°. Mr. Robert Hunt, speaking apparently of the same mine, says that, by his personal measurement, the air showed 110° in the deep level, and the tests of the rock, made by leaving a thermometer for two hours in a bore-hole, gave from 112° to 114°. He reports the maximum with which he was acquainted as 117°. Mr. Richards says the workmen can endure 120° perhaps half an hour, but cannot continue to work for an hour at 102°, while they can make a four-hour shift without interruption at 95°. Mr. Hunt gives the average time of working at twenty minutes, and says that on retreating, the men washed themselves in water at 90°, to cool off. Six sets of men were employed, so that each set had one hour and forty minutes to recover from the effects of the twenty minutes' exertion. Four turns of twenty minutes, thus distributed through an eight-hour shift, constituted a day's work. It is not surprising that, under these circumstances, the labor account was heavy. It is said that three guineas per inch was paid for driving a cross-cut in this mine.

These remarkable statements are even surpassed by the recent experience of the deep mines of Comstock Lode in Nevada. For many data on this subject, corroborating and completing my own hasty observations and recollections, I am indebted to the paper of Professor John A. Church, already mentioned, and to the unpublished memoranda of that gentleman, generously placed at my disposal. In the lower levels of these mines (say about 2000 feet below the croppings of the Gould & Curry, the usual datum-line) the temperature of the rock is generally about 130°. In freshly opened ground the air usually varies from 108° to 116°; but higher temperatures are not unfrequently reported, as, for instance, 123° in the 1900 feet level of the Gould & Curry. The water, which enters the drift from the lode and the country rock, is, however, often much hotter. The vast body which filled the Savage and the Hale and Norcross mines for many months had the temperature of 154°. But the water, like the rock and the air, varies in this respect in different portions of the mines. The ordinary range of "hot drifts" is 105° to 110° air-temperature. The ventilating current is delivered at a temperature of 90° to 95°, which seems to be most conducive to comfort. It is blown upon the men through zinc pipes by means of powerful mechanical blowers. The question of present interest being the effect upon the health of the miners of working under such conditions, further description of the peculiar phenomena of the case will be unnecessary. Before considering the health of the Comstock miners, it should be noted that by no means all, or even the majority of them, are employed in the hot drifts, and, moreover, that these mines are provided with arrangements which enable every miner to bathe and change his clothing immediately upon emerging from underground. The diseases of the Comstock miners are mainly typhoid and mountain fever, rheumatism and erysipelas. There is little or no consumption, bladder, kidney or liver disease. The superior ventilation (apart from the question of temperature) in the mines, the hearty and abundant diet of the miners, the constant enormous activity of their perspiratory functions, and the personal cleanliness resulting from their daily baths, seem to have abolished among them the disease, supposed elsewhere to be characteristic of their avocation. It is admitted by all observers that they are healthier than their wives and children.

As to the immediate effect of the high temperature upon those who work in them, it must be confessed that while actually working, the men display apparently undiminished vigor, delivering with seven, eight or even nine pound hammers, very rapid and effective blows. Perhaps a third of the time is lost in resting and cooling. In very hot drifts, a relief gang is employed; and, in extreme cases, four and even six men to the pick have been found necessary. In the main, however, the rapid progress in the hot drifts is remarkable, and shows that the heat does not greatly lessen the power of work, except by necessitating longer or more frequent rest. At the usual temperature of 108°, three shifts of three men each, working in turns of eight hours, advance three to five feet daily in hard rock. This is so much better than the efficiency reported from the hot lode in Cornwall, that we are led to infer that the method of delivering air to the Comstock drifts affects the temperature and perspiration of the miners in such a manner as to protect them to a large extent from the otherwise distressing action of the heat. My own sensations, as I recall them, in a deep and very hot level of the Crown Point (about 116°, I believe), were not specially uncomfortable on the surface of the body, except when a drop of still hotter water fell upon me. The principal feeling of distress was internal, and was caused by the inhalation of the scorching air.

The question whether those who labor in such places are permanently injured, is more difficult to decide. One of the physicians at Virginia City has declared that "there is not a sound heart in any man on the lode who has worked in a hot drift for two years." This statement is perhaps too strong, though it is possibly true that many of the miners are organically affected. Yet this appears not to interfere with ordinary and equable work, though it may, perhaps, develop into distinct disease under special strain or excitement. After long work in the hot drifts, the men have a waxen color, and are known as "tallow-face." Prof. Church noticed some men who, without being lazy, showed unusual care in handling their work, and two or three of them told him that they were "broken down" in hot drifts. In the only instance in which the time required for "breaking down" was given, the workman had been employed underground six years.

The actual effect of the heat on the men is, first, excessive perspiration, and, if this is not removed by evaporation with sufficient rapidity, great faintness. The pulse increases, as is shown in the following interesting data, obtained by Prof. J. D. Whitney and Prof. Church, in the 1800 feet level of the Julia Mine, the drift being about 1200 feet long, and having an air temperature of 108° to 110°, while the air temperature at the station or junction of the drift with the (downcast) shaft was only 84°. The following observations were made:

	Pulse-beats per minute.
Carman, after bringing out car, say 1200 feet	140
Carman, after resting at station	64
Carman (another case), after partial rest	128
Prof. Whitney, after walking through drift	120
Prof. Whitney, normal rate	60
Prof. Church, after moving about, without exertion	88

A case of death is reported as follows: A powerful man, accustomed to hot drifts, returned to work after a rest of three months, and entering the Imperial Mine as carman, pushed his first car to the end of the drift, in the 2000 feet level—say 1000 to 1200 feet—loaded it, and brought it back to the station, where another man was waiting to relieve him. But, instead of taking his turn, he dumped the car and started back without cooling off. He loaded the car again at the end of the drift, and proceeded to return, but was found a few minutes later hanging senseless to his car, and died, I believe, before he could be got to the surface. Another died in the Imperial incline while that was sinking. Three such deaths in all are reported from this mine, which is an excessively hot one. Sometimes accidental deaths may be the indirect result of the faintness caused by the effect of the heat on the circulation. Thus a man fell down the Imperial (upcast) shaft last year, who was probably overcome by the heat while putting in timbers. In these worst places, strong and healthy young men are employed. Fat men seem to stand the heat best, and, among visitors, women endure it better than men. Some men wilt under the work, and are said to have "no pluck." Drinking habits unfit the miner for this severe test. Unaccustomed men are often unable at first even to reach the end of the drift where they are to work. An intelligent miner told Prof. Church that the first month of such work after a long rest is hard; then comes three months of brisk feeling; and then follows a "dragged-out" sensation.

The underground use of machine-drills, operated by compressed air, is an important aid to ventilation and cooling, since the expansion of the escaping air absorbs much heat from the immediate neighborhood. But when, as in the Comstock, the heat radiated from the whole surface of exposed rock is far in excess of that which men and lights supply, nothing can sensibly reduce it, or mitigate its effects, except abundant mechanical ventilation. This is carried to a large extent in the Comstock mines; and to the fact that, in counteracting the high temperature, the impurities of the air are thus removed, the remarkable good health of the Comstock miners may be partly ascribed. Other causes have been already mentioned, such as the healthy mountain climate, the good food, and the comfortable dwellings. Finally, the fact must not be omitted from consideration that the miners of our Western regions are emigrants, and presumably men of such bodily vigor and health as their adventurous spirit would imply. Incidental to the question of temperature is the effect of sudden changes of temperature, such as are experienced on coming suddenly from the depths of a mine to the surface. The hygienic conditions here do not differ from those which any similar change of temperature produces; and since they may easily be counteracted by the product miner, they need not be set down as sources of disease inherent in his occupation.

Another kindred question relates to the effect of barometric pressure, which varies in mines with the depth of the openings, and also with the changes of the outside weather. The general experience is that high barometric pressure, though it permits a greater inhalation of oxygen with each breath, causes a feeling of distress, and affects the heart unfavorably. Dr. Bernays says that undoubtedly the most injurious, as well as the most unpleasant, condition of mine air is that in which a high temperature is accompanied with excessive barometric pressure and great humidity. The effect of the pressure alone can best be studied in the records of work in highly compressed air, as in the sinking of the caissons for the East River and other bridges. It may be affirmed, as a general rule, that sound men are not permanently injured by it. In ordinary mines the chief sensible effect of the barometric pressure is the variation it may cause in the natural ventilating current. Where the ventilation is wholly or partly artificial, these changes may be controlled. The introduction of compressed and cool air by machinery tends powerfully to reduce to a minimum the humidity of hot mines, and thus (as in the Comstock) to give an atmosphere in which free perspiration, rapidly evaporating, cools and refreshes the body. A comparison of the statements above made, as to the Comstock miners and the miners in the hottest mine of Cornwall, shows how much more can be endured and accomplished by workmen when thus protected from vitiated or over-humid air. The injurious effect of working under artificial light, instead of sunlight, has been often asserted; but there is no definite proof of it. Where other conditions are wholesome, and the habits of the workmen are regular, this is not likely to have a traceable effect. At all events, it is subordinate to many other causes.

General Conclusions.—The British Commission, to which reference has been made, summed up its voluminous report in a few conclusions and recommendations, the substance of which I quote below, in order to point out how far they are applicable to miners in the United States. The Commission finds that a large proportion of the diseases affecting miners in the metal-mines is to be ascribed to defective ventilation only. However various the opinions of physicians concerning the causes of the disease so well known under the name of miners' consumption or miners' asthma, there is in one respect a remarkable unanimity among all the experts, namely, that the health of the miner is chiefly affected by the quality of the air in which he works. This conclusion is emphasized by the results of very wide inquiry on the part of the Commission. In the coal-mines, where special attention is paid to ventilation, on account of explosive gases, the mortality of miners, apart from accidents, is lower than in the metal-mines. Starting from this significant fact, the Commission recommends that some of the methods of artificial ventilation employed in the former should be more generally introduced into the latter, and favors particularly the use of furnaces in "upcast" shafts, to accelerate the natural current by heating the upward-moving column of vitiated air, and to prevent the stagnation or reversal of the current by change of season or weather.

With reference to other causes of disease, the Commission recommends that every mine be provided with a conveniently situated, separate house, in which the workmen may change and dry their clothes; that boys under fourteen be not permitted to work under-ground; and that mechanical means be adopted for transporting the miners into and out of the mines. The man-engine is praised; but the system of hoisting the men in skips and cages is also pronounced satisfactory provided the machinery be properly constructed and carefully tended. These recommendations are as timely now as they were ten years ago, except that the increasing use of compressed air in mining has furnished an aid to ventilation not then considered. There is no proof that the metal-miners of America are less healthy than other laborers, and there is no need that they should ever become so. In my judgment a wise regard for financial economy alone will cause capitalists to do all that philanthropic considerations would require in dealing with the problem of hygiene in mines—a problem which contains, as the foregoing discussion shows, no fatally insuperable difficulties, and no insoluble mysteries.

—*A paper by R. W. Raymond, M. E. Ph. D., Transactions American Institute of Mining Engineers.*

PROVISION FOR THE HEALTH AND COMFORT OF MINERS.—MINERS' HOMES.

WHEN we consider the efforts made in Europe to promote the physical and moral well-being of the working classes, the question is suggested whether in this country, where, theoretically, every man is peculiarly the arbiter of his own destiny, we may not be too prone to expect every man to take care of himself, and neglect to make those provisions for the welfare of the employed, demanded alike by enlightened economy and humanity. In the older countries, where the disproportion between capital and labor is greater, and the working classes are more dependent, their welfare largely occupies the attention of employers. The subject is involved in the problem of the just relations of capital and labor, and we are rapidly approaching the time, if we have not already reached it, when a generous paternal interest in the welfare of the employed should be more generally manifested. It is a subject which is of special importance to mine-owners and engineers in this country, especially to those located in the coal regions. My own attention has been particularly directed to it by a visit made to the Hassard collieries, a few miles from Liège, Belgium, under the direction of M. Andrimont. This celebrated engineer has established a generally known. The miners wear a special dress into the mine, and remove it on coming out. When they reach the hotel at the end of the shift they go to the bathroom and bathe, each in a small compartment. Hot and cold water are plentifully supplied in movable tubs. The soiled mining clothes are removed to the laundry, and are neatly washed and ironed in the course of the next day, and placed in the miner's room. The miners wear sabots in the mine, and leather boots or shoes above ground. These are nicely blacked daily at the hotel, and kept in readiness for the miner when he dresses for the surface. The men are not allowed in the restaurant or other apartment of the hotel until their toilet is made. Meals are furnished at a fixed rate. The food is wholesome, well selected, and well cooked, as I can testify from actual trial. The miner is charged only with the meals that he takes; that is, he does not pay by the day or week, but is furnished with a printed card upon which each meal taken is registered, and at the end of the time named the account is squared. These cards or tickets are in the subjoined form, and entitle the holder to the privileges of the hotel for the eight days, of which the dates are given, by stamping in the figures when the card is issued. New cards are issued at the end of the time, and the old ones are surrendered. Whenever a meal is taken the clerk of the hotel punches a hole through the proper square under the date. At the end of the time the card shows exactly how many and what meals have been taken. Upon the back of this ticket the miner is informed, by a printed notice in French and in German, that no workman is permitted to lodge at Hôtel Louise unless he works regularly for the company, and conducts himself honestly and properly toward his fellow-workmen and the officers of the establishment. The hotel has proved a success. Its comforts are prized by the men, and it helps to secure an excellent class of miners for the company. The moral effects are important. The library is an excellent one; the books are well selected, are substantially bound, and are well used. The total cost of all this wholesome comfort was stated to me as only one franc and twenty centimes a day (25c.).

comfortable home for the miners near the mouth of the shaft of the mine. It has been highly successful and beneficent in its results, and may to a great degree be regarded as a model for such undertakings.

It is known as "Hotel Louise," this being the name of Madame d'Andrimont, who laid the corner-stone of the building April 4th, 1871. The structure is of brick, upon three sides of a square, and is three stories high. The ceilings are high; it is thoroughly well ventilated, and is fireproof. It has lodgings for 200 men, and all above the first floor. The first or ground floor is used for the restaurant, the coffee-room, the reading-room, library, store, and the office. The basement is divided off into kitchen, laundry, bathing-room, store-room, etc. Each miner has a separate room, with separate bedding and clothing, all marked with the number of his room, by which number the occupant is

At the store connected with the hotel the men can purchase any clothing or delicacies of which they have need at very low rates. The cheapness of sabots, of boots and shoes, and of well-made Cornish hats was surprising. But this is only one of many prominent examples of provision for the health and comfort of workingmen abroad. To give only a general view of what has been accomplished at the great industrial and metallurgical establishments would require more space than can appropriately be given in conjunction with the technical papers of the Institute. The subject is a broad one, and much has been written upon it since the lamented Prince Consort more fully aroused the attention of the public to it by the model dwellings which he erected at the Great Exhibition in 1851. Those who visited the Paris Exhibition in 1867 will remember the miner's cottages, with their furniture, shown by the Blanzy

Coal Mining Company as examples of the 676 cottages of the kind which they had erected at the works, and rented for 45 francs a year, including fuel and a garden privilege.

Prof. Egleston.—The improvement of the condition of workmen, which is the subject of Prof. Blake's paper, is one in which every one must feel the greatest interest. There is, however, something beside their mere physical welfare, which is the topic of Prof. Blake's paper, which requires the most earnest attention. I do not know of any place where laundry privileges seem to be carried out in so great perfection, or where such special attention is given to the restaurant department as in the hotel which he has described. These are, however, only insignificant items, so far as the general well-being of the men is concerned. Something requires to be done to elevate their moral as well as physical condition; and unless it is done, it is impossible to keep up their *morale* for any great length of time. To ameliorate their condition, it is not sufficient to provide restaurants and laundries, although good food and cleanliness are very important moral as well as physical correctives. But the world cannot generally depend upon unmarried men, for whom these provisions are made at Hôtel Louise. It is generally conceded that, to keep a skilled or even an ordinary workman for any length of time in the same place, he must be married. He should be able to hope that his family, which is as dear, and, perhaps dearer to him, than that of persons occupying higher stations in life, will be reasonably provided for in case of his death; or that, if he is disabled by accident, there will be some expectation that he will either receive treatment which will cure him, or, at least, will render him as capable as possible, under the circumstances, of supporting his family. He wishes to be assured that his family will be provided for in case of sickness, that his children will be educated, that his dead shall have a decent burial. In those establishments where the best work is obtained, some kind of rational amusement is provided, which not only elevates the tone of the society which surrounds him, but keeps him with his family, and, what is quite as important from worse things. It is not always possible to combine all this in any one institution; nor are they anywhere combined, but each one separately does exist in the highest state of perfection in different parts of Europe. As a student, my attention was very early called to this subject, and the condition of the working people has been a subject of great interest to me ever since. The establishments for ameliorating the condition of workmen differ in different countries. Most of them have been founded for the sake of keeping the men quiet and satisfied where they are. No one is applicable in this country as it exists abroad. There are too many races here, each one of which has its own national customs and amusements, and they refuse as persistently to blend as oil and water.

In the Georg-Marien Hütte, in Hanover, each workman is provided, at a low rent, with a house built of slag brick, which is of a gray color, and is light and singularly free from dampness, and makes a house of exceedingly pleasant exterior aspect. These houses are arranged for families of different sizes, and their interior is in every way comfortable and commodious. They have each a cellar, and are one story and an attic high. Every attention is given to their proper sanitary condition, and their arrangement in streets is most convenient. The plans of these houses attracted very great attention at the Vienna Exposition, and I think, on the whole, are the best of their kind, furnishing a comfortable, commodious home, where more than ordinary sanitary regulations are carried into effect. In certain parts of Austria there is a choice in such houses, the best being given to those married men who have been longest in the works, and who have had the least complaint made against them for abuse of the sanitary laws. Of the mere matter of houses, these form the two most conspicuous examples that have fallen under my notice. Under such conditions as these, where houses are furnished, the restaurant system becomes impossible; and it is doubtful whether it is desirable, except in the case of unmarried persons, who are, in Europe, almost always transient men, and, therefore, are not a very desirable class. The part of the old Guild system, which requires that the workman shall travel, is still in moral force, from the fact that it has become a custom, though the *Meisterstück* is no longer required, and there are consequently a considerable number of transient workmen who use the time they remain in works for their own benefit. With the modern system of rapid travel the transient workman is generally a very demoralizing element.

It is characteristic of almost all the German works, where the system of looking after the workmen is carried into effect, that they provide some kind of rational amusement. The best types of these are Georg-Marien Hütte, where the workmen have a small *Bier Garten*, and have beer furnished to them at cost price, and where they have also a theatre and a concert hall. The actors and musicians are composed exclusively of workmen. I visited this theatre and *Bier Garten*, and examined it in detail, and I was told by the director of the works that the musical and theatrical performances of the men were creditable in the highest degree, and that the families of the officers of the works were in the habit of visiting the theatre and concerts as a matter of amusement; and that since the erection of the theatre there was an appreciable elevation in the condition of the men. The bier-garten system, or the pleasure-garden of the Anglo-Saxon, is most extensively and completely carried out in Borsig's Works, in Silesia. A garden, comprising a number of acres, laid out in the most artistic style, and planted with trees and flowering shrubs, is provided by the works. It is arranged on the same general plan as the pleasure-gardens of the great European cities, but, of course, not so luxuriantly fitted up. This garden is provided with the ordinary amusements for children, and handsome arbors and shade-trees; and on holidays a band of music, composed of workmen, play at stated intervals. All kinds of amusements, for grown people as well as children, are provided, such as is usual in gardens of that character in Europe. All the buildings are decorated artistically, and are filled in the evening and on holidays with men, women, and children, including the families of the officers of the works. On special occasions there are grand demonstrations of music, and special decorations of the gardens, all of which are carried out by the men, under proper direction. Such a garden as this, filled with families engaged in all kinds of harmless recreation, goes far to make the men and their families respectable, and is certainly an interesting spectacle, which, unfortunately, cannot be seen in any country inhabited by Anglo-Saxons. Its influence is seen directly, in the product of the works. The men rarely leave of their own accord, and their general *morale* is no small part of the reason why the works turn out some of the highest grades of iron manufactured in Germany. The free hospital and school systems are carried out in their greatest perfection in England, where day and night schools have been established by the proprietors of some of the works, under the direction of clergymen and government schoolmasters. I became so much interested in some of these schools, that after examining them in a good deal more than the ordinary routine of arithmetic, etc., I offered a prize for a written examination on subjects which I proposed to them, and these examinations were afterwards sent to me. The children of this school, which was a day school, were none of them over thirteen or fourteen years of age. The examination would have certainly done credit to the lower classes in our colleges and the universities abroad. The night schools were attended principally by persons over the age of sixteen. The parts of these schools which principally attracted my attention were the drawing classes; they were organized to teach not only free hand sketching, but to some extent geometrical and mechanical drawing. The interest excited even among the older workpeople of both sexes was surprising, and their performances highly creditable. The school-houses are so arranged as to be easily transformed into a church on Sunday, and I certainly never saw a more quiet and devout congregation than that assembled there for worship. I visited the families in their homes with the clergyman in charge, and as is not unusual in England, I frequently found that the grandfather of the family had been a workman in these same works, and the grandson was looking forward to the same position. There was connected with these works a hospital system, a physician being paid by the works, and the men allowed the liberty, in all ordinary cases, of being treated in a hospital or in their own homes. A system, which I have seen nowhere else, was adopted here with reference to boys who had become maimed in the works so as to render them unfit to become workmen. They were specially trained to occupy office positions, or educated for occupations suited to their condition. One of the brightest boys I saw had lost a leg by some accident about the rolls, and was being trained to occupy the position of bookkeeper. My attention was specially attracted to these works because I had gone to Staffordshire to ascertain how their iron was made, as it was of superior quality, and much better than that of their neighbors who were using the same materials. My impression, of course, was that the superiority was owing to some peculiar process. After visiting the works carefully I saw nothing in any way different from the other works of the neighborhood, and I became convinced that the whole secret lay in these excellent arrangements for elevating the moral and physical tone of the workmen. The proprietor of these works informed me that he had spent £30,000 in the erection of the necessary buildings, and in carrying out the plans, which were the most perfect that I saw in England; and I am certain that every penny of the capital so invested came back to him, in the superiority of the work done in consequence, every few years.

In France the hospital system—for the school system was not formerly in favor—is carried out mainly by the workmen themselves. A society of the workmen is formed, of which the director of the works is president. Members chosen from among the workmen by ballot are associated with him as a council or board of trustees. A certain part of the funds necessary is subscribed by the company, the rest is raised among the workmen themselves, by means of a tax on wages or by fines. These fines are established for such things as coming to the works intoxicated, arriving late, unnecessary neglect, and, in some cases, for profanity, etc. The workman declared sick by the physician in the employment of the company receives so much per day from the common fund. In case of death a portion of the funeral expenses is paid by the society and the works together, and the widow receives a pension, graduated according to the position of her husband and the length of time he had been connected with the society or the works. Persons disabled by sickness or age receive a pension, to provide for which a certain percentage of the wages received by every workman is retained by the society to create a pension fund. Any workman discharged for incompetence or neglect, or who voluntarily leaves the works, loses all right to any part in the administration of this fund. In case he should return, he commences, except under special circumstances, as if he had never been connected with the works. I have been convinced for a great many years that the workman does the best where he is most kindly treated, and where he can look forward to some reasonable support for his family in case of his death or inability to work. When I first returned to this country I hoped to put some of these schemes into practice, and I commenced with more enthusiasm than judgment to apply a system drawn from my experience in England and the Continent to Celts, with not very fortunate results. They were suspicious of the houses that I built, were certain that I was personally deriving benefit from the fines that I proposed for the foundation of their fund; were jealous of their own members, raised to higher position than themselves, as they thought, by being brought more in contact with the officers of the company than they were, and caused so much trouble that in the interest of the company I was obliged to abandon any attempts to elevate the condition of the men, and I must confess that I have been obliged as conscientiously to abstain from acting as I was at first disposed conscientiously to act. The short time that can be allowed to the discussion of any question like this by the Institute is greatly to be regretted, not only because anything that can be done to raise the condition of the workmen, necessarily increases the product, but also because there is a greater humanitarian interest in elevating the moral and physical welfare of our own people and our adopted countrymen. Unfortunately our religious and political differences greatly aggravate the difficulty. I believe it, nevertheless, to be true that some plan may be devised which will work successfully with the various nationalities which we are obliged to employ as workmen. The chief trouble with them all, as far as they have come under my notice, is that, as a class, the men engaged in mining are improvident, and that they are addicted to the use of the stronger alcoholic stimulants. If they used good liquors in moderation there would be little objection. The difficulty, however, is that the liquor which they buy in preference is cheap, and that, as a general rule, even if they should try to purchase good liquor the cheap article would be furnished to them at a high price. This cheap liquor contains so much fusel oil as to endanger the constitution of the men and make them more unmanageable than they would be if inebriated simply by alcohol. To furnish the men with good liquor at a low price, or at least liquor which did not contain fusel oil, would strike me as being one of the means of remedying the real evil. I cannot pretend to say how this should be carried out or regulated in each particular case. The German would certainly be content with good beer, and if he understood that better beer was furnished to him for the same money he would take that in preference; while the Irishman would probably want something which scratched all the way down which could be furnished him without the poison. Whether it would be worth while for any company to undertake to inspect the liquor sold to their men is a question. Those who have large works have probably tried the experiment of regulating the sale, and know more about it than I can suggest, but it is a matter of real moral and physical importance that some method should be devised by which workmen should be prevented, if possible, from drinking liquors which, from their method of manufacture, must be more or less poisonous. We cannot prevent their use of stimulants and I therefore think it is better that, since they cannot be prevented from drinking, a good and always pure liquor should be furnished them, and that they should be furnished a better article than they can buy at the same price, which can only be done by those who have no interest in making money out of them.

I cannot pretend to give you a remedy for the improvident character of the miners, except to encourage marriage among them, and I do not feel certain that even this would be effectual; but it seems to me that some plan of furnishing them comfortable, commodious, well-drained and ventilated houses, provided with plenty of good water, would be an efficient means of keeping them at home. The question of education is provided for much better in this country under State laws than it is in any of the countries of Europe, and I do not know that it would be wise for any company to interfere further, than perhaps to see that the State system was really carried out. The matter of pensions, hospital relief, etc., has been taken up so much by societies among the workmen in this country that it would seem, perhaps, a difficult matter for any company to interfere in any way with it. I am satisfied, however, that if any plan could be devised by which the society could have its officers members of the company, who would show in their meetings a real interest in the welfare of the men, that would go far toward destroying the influence of demagogue workmen upon their fellows. I am not prepared to furnish any plan for such a society, nor am I at all sure that such an organization would be possible. This class of people are difficult to treat with, and my experience of many years' charitable work among the poor has shown that the great difficulty in reaching them is not so much the kind of treatment or the distribution of alms as their suspicion of you, for they are, as a general rule, slow to believe in disinterested motives. I make these suggestions with diffidence in presence of persons largely engaged in manufactures, and who have so many men working under them, on account of my great interest in the subject, because I have become convinced by long connection with charitable work that a great deal of our charity makes beggars, and that there is a great deal of misdirection in the philanthropic work undertaken to elevate or relieve the classes known as the working classes. It is much easier, I know, to find fault than to carry out plans for relief, or even to suggest some practical method for effecting the object in which we are all so greatly interested. Prof. Blake said that we, in the United States, were not without notable example on a considerable scale of care of working men, both unmarried and married, with suitable provision for their education, amusement, and morals.

—A paper (and discussion) by Prof. W. P. Blake "Transactions American Institute of Mining Engineers."

OUR NON-PRECIOUS MINERAL INDUSTRIES.

THE three great divisions of industry—agriculture, mining and the fisheries,—are usually classed together by writers on political economy, for the reason that they do not add a value to raw material, but draw it directly from the land or sea. They must be the primitive occupations of mankind, and in the subsequent development of society must remain the foundation industries on which manufactures, transportation and exchange are built. Therefore, though they may not occupy the largest space in the public eye nor in the marts of great cities, their growth is one of the surest criteria of the material progress and independeuce of a community. This is especially true of the coal and iron ore mining industries; for coal furnishes the power, and iron the lever, by which the work of modern civilization is accomplished, and a very rapid increase in their production has been one of the marked industrial features of the nineteenth century. A brief presentation of some of the leading facts made public by the tenth census of the United States, in its reports on the mining of the non-precious minerals, will prove that our country has never participated so fully in the movement as it has during the past decade, and may not be devoid of interest to the readers of this magazine. The table below is condensed from the official bulletins, which, though subject to final revision, will not be changed materially, —certainly, not enough to affect any of the important relations.

The coal and iron ore production referred to in the following table is that of the firms and individuals who make mining their regular business, and employ more or less capital and labor. To arrive at the total output of the country, there should be added to these figures 628,569 tons of coal and 909,877 tons of iron ore mined by farmers from shallow deposits which are worked in a desultory manner when the season for the operations of husbandry is ended. Obviously, such irregular production must be kept distinct from the returns of the industry at large. The copper comes exclusively from the part of the country east of the one hundredth meridian. Over three thousand tons of ingot were produced from mines west of that line; but a large portion of this is a by-product in the smelting of the precious metals, and the difficulty of determining exactly the labor and capital applicable to the copper alone has led to its rejection from the present consideration.

The minor minerals include asbestos, asphaltum, bismuth, barytes, chromium, emery, graphite, glass, sand, kaolin, manganese, mica, nickel, ochre, pyrites, etc., the production of which, though not individually of great importance, makes a respectable aggregate, which is rapidly increasing. The table, therefore, covers the mineral industries of the United States, with the exception of gold and silver, salt, petroleum, building stone and material, and the fertilizers, gypsum, marl, and the phosphates of South Carolina. Care has, of course, been taken to apply the same limitations to the summations from the ninth census before instituting comparisons.

In interpreting the figures, it must be borne in mind that they represent strictly raw material at its first point of shipment, and imply the existence of a vast body of secondary workers before the finished product is ready for the consumer. Thus, the value of the coal, which is given at one dollar and forty-seven cents per ton for anthracite and one dollar and twenty-five cents per ton for bituminous, is, as we have occasion to notice on our bills, more than doubled by the cost of transportation before it melts our iron or warms our houses. The iron ore, Mr. Swank tells us, in passing into its first manufactured state of pig and bar iron, is five-folded in value, and gives employment to a corps of the industrial army numbering over seventy-seven thousand men. The seventy-eight million tons of raw material dug every year from the earth are all worked up within our borders, with the exception of a little copper and a trifling amount of the minor minerals. An increase in mineral production means to us an increase in machine shops and artisans in all the metal-working trades. It is an increase in the hidden foundations of the industrial world, on which a broader and higher superstructure may safely rest. More iron and coal means to us more railroads, more steam-engines, more plows, more reaping-machines, more labor-saving implements of every description, which do not perish in the using, but cause a permanent gain in productive capacity.

Space will not permit us to refer to the geographical distribution of mineral production in the United States, further than to say that it is very wide. There are few large areas in our country that do not contain workable beds of coal or iron ore. All things considered, our Appalachian coal field, extending from Northern Pennsylvania to Central Alabama, is the largest and most valuable mineral deposit in the world. The next census will show a marked development of the coal and iron industries in the extreme North-west, a promising beginning having already been made at Washington and Oregon. Pennsylvania, Ohio, Illinois and Michigan will undoubtedly retain their leading positions as mineral producers for many years to come. Relative gains have been made, and will continue to be made, by the Southern States, West Virginia, Kentucky, Tennessee and Alabama.

Restricting the consideration to the United States as a whole, and comparing the figures in our table with the corresponding ones from the census of 1870, the great advance becomes at once evident. The gross weight of minerals

Production of the Non-precious Minerals of the United States during the year ending June 1st, 1880.

1880.	*No. of establishments.*	*Tons of 2,240 lbs. produced during census year 1880.*	*Value of product.*	*Value of materials consumed.*	*Total hands employed.*	*Wages paid annually.*	*Capital employed invested.*
Bituminous coal,	2,989	41,789,195	$52,316,868	$4,851,093	99,916	$32,535,460	$98,478,674
Anthracite coal,	275	28,640,829	42,172,948	6,729,477	70,669	22,664,055	154,399,796
Iron ore,	805	7,061,829	20,470,756	289,604	31,668	9,538,117	61,782,387
Copper ore,	32	*1,005,955	8,842,961	1,391,101	6,116	3,115,103	31,675,096
Lead and zinc ore,	234	†182,414	4,242,409	347,807	7,787	2,716,217	7,565,672
Minor minerals,	178	218,452	3 235,703	583,980	3,982	1,227,050	5,673,415
Total,	4,513	78,898,674	131,281,705	14,193,062	220,138	71,796,004	359,574,940

* Yielded 25,376 tons of ingots copper.
† Yielded about 27,228 tons of lead and about 26,812 tons of zinc.

The same remark applies to lead, which is largely yielded as a by-product in silver mining, and comes East with it in the form of base bullion. The entire amount of lead produced in the country during the census year varied but little from seventy thousand tons. The table, in a word, is confined to the statistics of what may be termed "regular mining establishments."

removed from the earth has increased one hundred and thirteen per cent., although, in consequence of a decline of thirty-three per cent. in the average price received per ton, owing principally to the resumption of species payments, the money received for it has increased only forty-one per cent. But the total number of employés has increased eighty-eight per cent. only, or considerably less than the result of their labor. This would seem, at first sight, to indicate a striking gain in the efficiency of labor,—so striking, indeed, as to suggest inaccuracies in the data; for it is hardly possible that the number of tons produced per man, yearly, can have increased as much as fifteen per cent. Most of this apparent gain is undoubtedly due to the fact that labor has been much more continuously employed than it was ten years ago, although it is impossible to determine accurately the proper allowance to be made for "short time" in 1870. The average number of full days worked by a miner in 1880 varied but little from two hundred and thirty. Strikes, slack demand, etc., probably caused a greater loss in 1870. From the best evidence attainable, it is safe to say, however, that the efficiency of mining labor has been increased not less than three per cent. in the past ten years by increased experience and the introduction of labor-saving machinery, when the effect is spread over the entire industry.* In certain cases, the use of the power drill and "high explosive" has enabled two men to do as much as three did before.

That increase in mineral production has been much more rapid than in population, is shown by the following comparative table:

Yearly Production Per Capita of Population.

	The United States, 1870.	*The United States,* 1880.	*The United Kingdom of Great Britain and Ireland,* 1881.
	lbs.	*lbs.*	*lbs.*
Coal, ...	1,608	2,818	9,30
Iron ore, ...	177	283	1,500
Metallic copper, .	0.7	1	—
Pig iron, . . .	—	141	492

Estimating the world's consumption of coal in 1880 at three hundred and fifty million tons,—the mean of several authorities,—the industrial standing of Great Britain and the United States is shown by the fact that of this total we produce twenty per cent. and England forty-seven per cent., leaving only thirty-three† per cent. to be distributed among the non-Anglo-Saxon populations. Any ideas based on the future scarcity of coal in England, may as well be dismissed at once, since the careful surveys of the royal commissioners show the available fuel yet in the ground, within four thousand feet of the surface, which they consider the limit of workable depth, is sufficient to keep up her annual output of one hundred and forty-seven million gross tons for ten centuries to come. The expense of English deep mining is shown by the high average price of coal at the pit's mouth, —one dollar and eighty-two cents,—the price per ton of bituminous coal in the United States in the same position being only one dollar and twenty-five cents. Nevertheless, the price in the London market was only three dollars and seventeen cents a ton, a cheaper fuel than is obtained by any great city here outside of the Ohio valley. Iron ore in England costs much less than it does here; but so large a proportion of it is argillaceous carbonate, that their furnace yield of pig iron is only thirty-three per cent. of the ore, whereas ours averages fifty-two per cent. Therefore, though Great Britain produces three and one-quarter times as much iron ore as we do, her output of iron weighs but little over twice as much as ours. The price of ore averages one dollar and fifty-nine cents there, against two dollars and ninety cents here; so that, admitting that her native ores can be cheaply brought up to a higher grade by calcination, the iron masters of the United States must, when they enter on the area of large production and moderate profits, become formidable rivals of their transatlantic brethren. When the day comes that we contend with her for the markets of the world in manufactured iron, our strong points will be richer ore, stronger iron, and more accessible coal, and hers, proximity of coal and iron ores to each other and to the ocean. In addition to her native ores, England imported, in 1881, from Spain, Elba, and Algeria, 2,632,601 gross tons of high grade ores, especially suitable for the manufacture of Bessemer steel; but in this regard the only advantage she has over us lies in our tariff of two dollars a ton, since such freight could be brought as cheaply here as ballast for return grain vessels as it can to Wales. We were restricted during the census year to the importation of four hundred and thirty-nine thousand, four hundred and fifty-one net tons of this valuable raw material.

Since 1870, the increase in our product of iron ore has been one hundred and eight per cent., in bituminous coal, one hundred and forty two per cent., and in bituminous and anthracite coal, together, one hundred and fourteen per cent.* The great increase in the demand for iron and steel is due to the extension of railroad building, as well as to the natural growth of the country. The production of coal bears, of course, an intimate relation to that of iron. That it has increased in a greater ratio, is due to the following causes: 1. The great relative growth of urban and village communities burning coal only. A strictly rural population is generally able to supplement its supply of coal with wood. 2. The increase of internal transportation, effected by that great consumer of coal, the locomotive. 3. The decreasing supply of wood, which is gradually forcing even the inhabitants of the agricultural districts to burn coal. 4. The increase of machine labor, energized by steam. This cause is intensified by the gradual failure of water-powers, owing to the shameless and wanton destruction of our forests in the absence of any intelligent State supervision. We may safely take the increased production of iron ore as one of the surest gauges of industrial advance, since its consumption is less likely to be influenced by science and the lesser economic changes. Iron enters into our industrial bone and blood. A thousand tons of ore, removed from the earth and converted into useful forms, become a possession of permanent value; whereas, the burning of a thousand tons of coal may mean only the substitution of one fuel for another. An English writer says that the consumption of sulphuric acid in a country is a measure of the development it has attained in the useful arts; but, surely, it is iron, which "breaketh in pieces and subdueth all things," that does the work of modern civilization, from "turning the furrow to reaping the grain."

The great consumption of copper in the United States is a remarkable economic feature. The world's annual yield of ingot copper is but little over one hundred thousand tons, of which we contribute more than one-quarter. Substantially, the whole of our product is worked up and used in our own country. Since the decline of wooden shipbuilding, its principal applications have been to articles, the use of which implies a certain degree of comfortable living, as clocks, ornamental hardware, modern household appliances, etc. It would be interesting, by the way, to know how much copper is shot away yearly by the American people in the form of metallic cartridges,—probably as much as any other people can afford to consume in all its forms. It is certainly a striking evidence of the distribution of wealth in our country, that we can absorb so large a quantity of this metal at its present high price; for, compared to iron, it may be called semi-precious. Possibly, the new demand for copper wire created by the development of electrical machinery is an important factor in fixing the price and consumption. It may not be considered too fanciful to say, that if we take the production of iron as a measure of industrial progress, we can regard that of copper as an indication of accumulating wealth. The engines that drive our great factories are built of iron, but ornamented with brass.

* Mr. Swank's bulletin on the manufacture of iron and steel shows a still more marked increase in the "effectiveness of labor." Mechanical applicances, however, pay a more important part in rolling-mills and furnaces than they do in mines; and improvements are much more likely to increase the product per head. But, in both cases, "steady work" is the important factor.

† Part of this last comes from the English colonies, Nova Scotia and Australia.

* Attention is again called to the fact that the "irregular product" of coal and iron is disregarded in all these computations, and that they are, therefore, safely within the mark. This product —at least in the case of iron ore,—is a part of the yearly addition to our national wealth; for it is created by labor that would otherwise be unoccupied. The reasons for omitting it are, first, the importance of keeping the "regular industry" distinct, since it is the labor-employer, and must more and more displace the farmer mines; second, the Superintendent of the Census reported that the ore product of 1870 was underestimated; third, more ore was produced in 1880 than was consumed, by about ten per cent., the active demand following the "ore famine" of 1879, stimulating production beyond the requirements of the market.

The following table, to return to more solid ground, shows the relative importance of the industries under consideration:

Comparative View of the Non-Precious Mineral Industries.

	Per cent. of total tonnage.	Per cent. of value of total yearly product.	Per cent of total employes.	Per cent. of total Capital.
Anthracite coal,	36.3	32.1	32.1	42.9
Bituminous coal,	53.0	39.0	45.4	27.4
Iron ore,	8.9	18.6	14.4	17.2
Copper rock and ore,	1.3	6.7	2.8	8.8
Lead and zinc ore,	.2	3.2	3.5	2.1
Ores of the minor minerals,	.3	2.5	1.8	1.6
Total mineral product of above	100.0	100.0	100.0	100.0

In anthracite coal, the figures approach nearest to equality, and it is the industry which has most fully entered upon an area of large establishments, ample capital, improved mechanical appliances and modern profits. Grouping together all the above industries, the average yearly product for a "full hand" is three hundred and eighty tons of material, ready for transportation, valued at six hundred and thirty-one dollars. Of this value, labor receives three hundred and forty-five dollars, and thirty-seven dollars and fifty cents more go to pay for the materials and supplies consumed. The number of boys below sixteen years of age employed about the mines has increased from ten for every one hundred men to twelve and one-half for every one hundred men. Mr. Swank's bulletin on the manufacture of iron and steel shows a still greater gain in the number of young boys allowed to work at an age when the community has a right to their time in the public schools it has provided for them. It is not an encouraging sign, though one of the results of an increased demand for labor.

The workingman is better off than he was in the days of paper money; for the average earnings reported in these mining industries in 1870 was only four hundred and eighty-nine dollars yearly, so that the purchasing power of his income is evidently greater now than it was then. A "full hand," too, produces forty-eight tons more, yearly, than he did ten years ago; but, as said before it is impossible to tell how much of this increased product is due to fuller time made during the year, and how much to increased effectiveness of the individual resulting from the use of improved labor-saving machinery. Steam-power certainly plays a more important part than it did, and has increased in a greater ratio than the number of employés.

The true test of the position of labor is, however, the proportion it receives of the value of the product, measuring in the units of the cost of living. In applying this test, however, we are met by the difficulty that the pay of miners usually includes varying allowances for powder, candles, etc., furnished by the men, which are not in any sense wages of labor, but expenditures for material. In the foregoing tables, this item has been carefully separated from the wages returns and added to the amount stated as the cost of supplies. This deduction was usually made when filling up the original census blanks, so that it is now impossible to state exactly how far it had the effect of changing the laborers' apparent income. Consequently, an exact comparison of earnings with those of 1870 cannot be made. The share retained by capital has increased one per cent. Labor received fifty-five per cent. of the product in 1880; and distributing the cost of supplies in 1870 as far as possible, it would appear to have lost at least one-half of one per cent. of its share, as compared with the earlier period. However, the comparison need not arouse the depressing reflection that the condition of labor is growing worse as civilization advances in our country; for the miner receives, on the average, fifty-five per cent. of his yearly product of three hundred and eighty tons, as against fifty-five and one-half per cent. of three hundred and thirty-two tons ten years ago; nor could any general deduction of this nature be safely drawn from the averages of only two periods.

The increase in the amount of capital in the mining industries referred to is one hundred and fifty-eight per cent. and is much greater than the corresponding increase in income. Still, the figure of $359,574,940 bears about the expected relation to the yearly productiveness of the property it represents, and contains no items of a speculative or unreal value. Mines individually should yield a larger profit than other fixed capital, because their income is always terminable. There is a time in the future—indefinite, perhaps, but always certain to be reached,—when any mine must be exhausted and the capital invested in it sunk. The net income of a mining property must, therefore, be applied to paying for the maintenance of the plant and to creating a sinking fund which will make good the original cost when the value has reached zero, besides paying interest charges and the expenses of the general management. These principles have been borne in mind in assessing the value of the "capital invested in mining establishments" for the census of 1880. That the sum total returned is so much greater than it was in 1870, arises from several causes in addition to natural growth. These are, first the ruling rate of interest has fallen, and the values of income-bearing properties have risen correspondingly; second, the steadiness of all prices brought by the return to specie payments further increases the value of all fixed productive capital; third, in 1870, the mine operators were simply asked to state the amount of their capital. When they did not own the land, but, as is true in many cases, worked it on a royalty, they naturally omitted any estimate of it in their answer. But the real estate forms seventy-five per cent of the capital of the industry. In 1880, the questions were: "What is the value of the real estate attached to the mine?" "What is the value of the plant and equipment?" and, "How much do you usually use as working capital to carry on your business?" None of these questions were resented, and, if the answers were palpably wrong, the agent could use his own judgment to correct them on the spot. Undeveloped mineral lands, which, from the economic standpoint, are the property of the next generation, were omitted entirely. Therefore, the capital returned is not a mere summation of share capital,—often fictitious,—but represents, at a fair valuation, productive wealth of a kind in which only one nation on earth can make any comparison with us.

On the "face of the returns," there is no evidence of any tendency to concentration in the hands of large operators. In fact, the number of separate establishments has increased rather more rapidly than production. This is owing to the great number of small mines of bituminous coal. The areas of mineral lands are so extensive, there are so many producers in widely distant localities, that it is not likely that combinations can ever be formed to create a monopoly in any of the leading mineral products. At the same time, the influence of large capital in the mining industries is greater than it was. Nineteen mines yield over one-third of our most valuable iron ore. One mine yields over one-half of our copper. The two hundred and seventy-five anthracite collieries are virtually owned or controlled by seven great corporations. Should the man ever appear possessed of force and tact enough to combine them, such a pool could easily lay the Eastern public under an annual contribution of several millions of dollars. Our experience with the Standard Oil Company proves that neither law nor public opinion affords the community any protection against oppressions of this nature. On the other hand, it must be admitted that large mining establishments pay higher wages than small ones, and even yield to labor a larger share in the division of the product, depending for their profits more on the volume of the business than on a large margin. Thus the average wages earned in copper mines reach five hundred and twenty-two dollars, while in the soft coal mines labor makes only three hundred and thirty-six dollars per annum, being subject to an average period of three months of enforced idleness.

The industrial returns of the tenth census must, of course, be interpreted with reference to the time they cover. The year ending June 1st, 1880, marked the termination of a period of depression. There can be few, who were engaged in active business during the five years previous, who have forgotten how economy and industry seemed powerless against some malign cause which paralyzed effort and made each successive balance-sheet more discouraging than the last. There are few now who do not understand that the hidden sinister influence was a currency "based on the faith of the nation," but divorced from a direct connection with objective value, which caused the prices of commodities to "peak, dwindle and pine," while the debts incurred for purchases remained unaffected. Many can, no doubt, recall the day when the relation between buyer and seller changed —when a guardedly written letter brought an unstinted order and disclosed the fact that price was less an object than promptness. The productive energies of the country were released from their bonds and came into action with a sudden spring which carried them, for a time, beyond their normal power. Every department of industry was infused with a feverish energy. The census year covered this period of "boom," as it was not inaptly called, and the census statistics, no doubt, reflect the sanguine feeling then prevalent.

Making all possible allowances for this and every other imaginable cause, it is evident that the United States have made and are making wonderful progress in mining, as in all other industries. This progress is in no sense fictitious. It is a gain in tangible and comparatively indestructible property; but, after all, it is only a gain in material things. Corresponding advance in the world of ideas—of ideas embodied in institutions and in definite habits of action—must, in the end, determine whether material progress prove a blessing or a curse to the nation at large. Our growth on the material side is so rapid as to be alarming. It suggests undefinable dangers, and should be as much a source of uneasiness as of congratulation. It renders the responsibilities of the American citizen, educator and legislator graver and more complex. The coming years may not call for passionate loyalty and sacrifice, but they will call for a thoughtful patriotism and a broad comprehension of the organic life of a great republic. The more rapidly we grow rich, the sooner we shall be called upon to settle the question of equitable distribution. The sudden accumulation of wealth is as trying to national character as it is to that of an individual. It is an increase of power. The philosophers of the twentieth century, from the vantage-ground of recorded history, must determine whether in our hands it proved a power for good or for evil.

—A Paper by C. F. Johnson, Jr., in the Penn Monthly.

THE GERMAN SPELTER INDUSTRY.

AT the present time, when considerable quantities of spelter are imported from Germany, and the sales for future delivery indicate an increasing strength in this movement, some data concerning the spelter industry of the most formidable rival of our common Western metal in Eastern markets are of value. In a recent issue of the *Verhandlungen des Vereins zur Beförderung des Gewerbfleisses*, Herr Oskar Bilharz, of the Altenburg Company, treats of the Western or Rhenish District, while Herr E. Althaus, a well-known authority, reports elaborately on the Silesian District. Though both reports relate to the year 1880, the technical questions involved and, to a certain extent, the commercial status are unchanged. Herr Bilharz gives the following valuable estimate of the production of Europe, the figures being in metric tons:

	1879.	1880.
Germany	96,360	99,405
Belgium	63,007	65,010
England	16,750	22 000
France	14,467	13,715
Austria, Poland, etc.	3,200	3,200
Total	193,784	203,330

Silesia produced 63,476 tons in 1879, and 65,437 tons in 1880, leaving 32,884 and 33,968 tons respectively to the rest of Germany. Up to the present time, the supply of German zinc ores keeps pace with the increasing production; but the use of blende instead of calamine, carbonates and silicates is steadily increasing. In the Aix la Chapelle District, for instance, the quantity of blende treated has, in three years, reached a quantity double that of the calamine used. The following figures may serve to illustrate the increase in that district:

	1879. *Tons.*	1880. *Tons.*
Calamine	21,800	19,690
Blende	31,790	34,580
Total	53,590	54,270

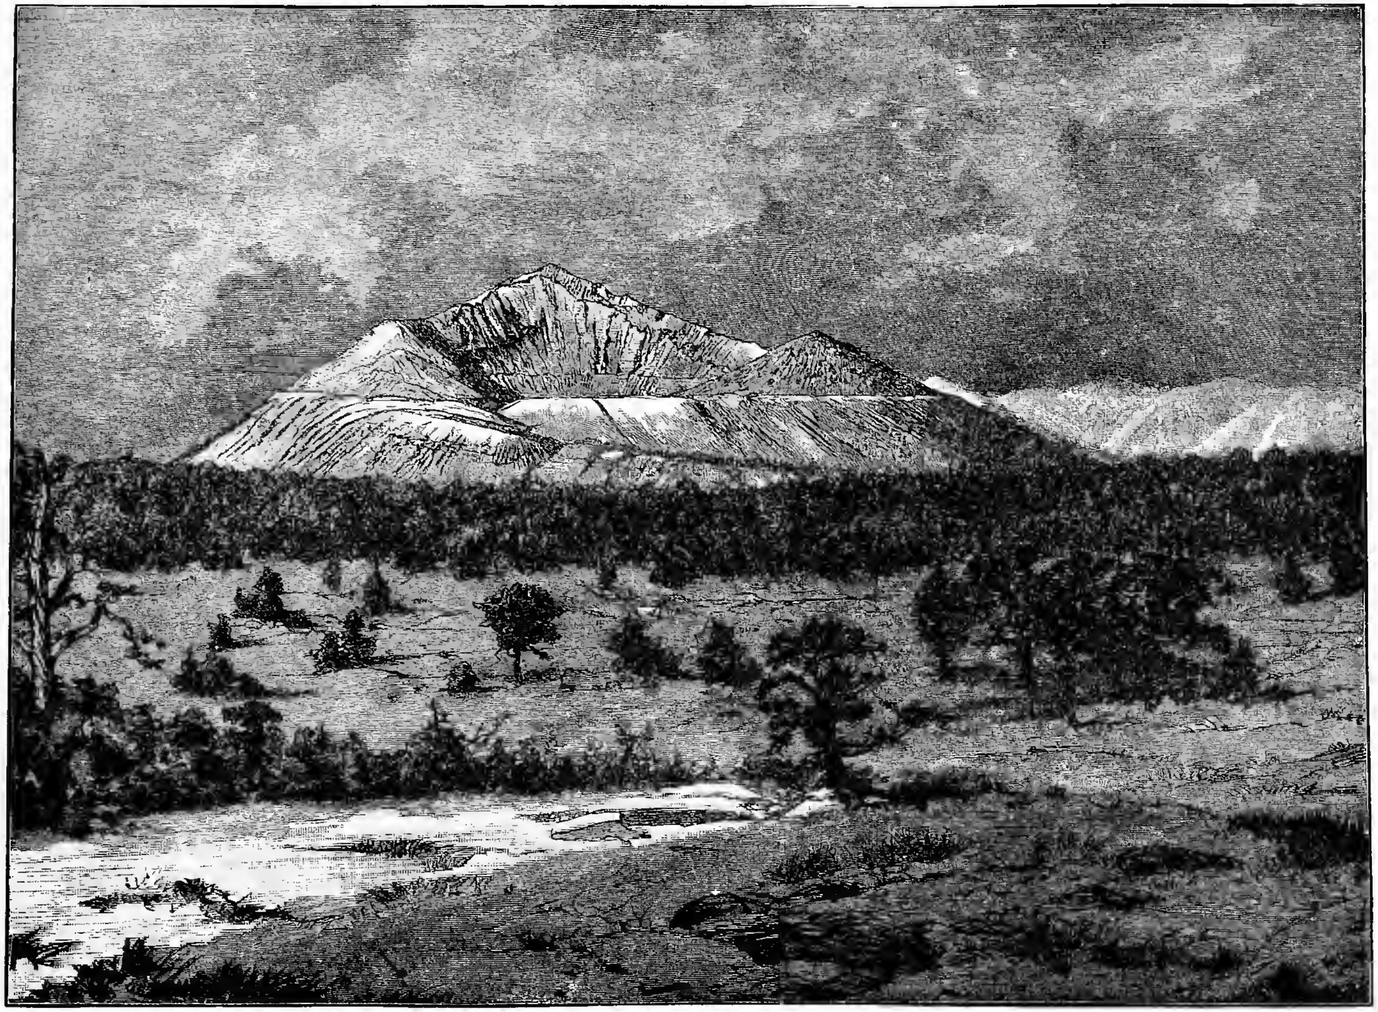
Besides the German ores, the works of the Rhenish District draw largely upon the northern and southwestern coast of Spain, and upon Sardinia. Quite recently, the mines of Laurium, in Greece, have sent rich ores running as high as 62 per cent. Herr Bilharz states that, while no trouble is at present experienced concerning the supply of calamines, he seems to fear that in a few years, when the Mediterranean mines, now worked to full capacity, approach exhaustion, the question will become a serious one, because the manufacture of zinc from blende is not alone more expensive, but also furnishes a poorer grade of metal. Some of our Western works which are contending with the same difficulties will appreciate the importance of this confession. Herr Bilharz gives the following interesting figures concerning the articles into which the spelter made by the Vieille Montagne Company of Germany and Belgium, the largest producer of the world, is manufactured. It will be seen that sheet-zinc is in that district the most important article:

	1879.	1880.
Production of spelter	43,750 tons	44,690 tons
Manufactured into:		
Sheet-zinc	41,882 "	37,522 "
Zinc-white	6,016 "	5,583 "

Herr Althaus, who reports on the great Silesian District, goes into the questions at issue much more at length. The causes which gave that district such a commanding position, notwithstanding its remoteness from the markets of the world and the low grade of the ores, are that the zinc mines are located in close proximity to the coal mines, and that mines and works are in the hands of a few strong parties. The cost of the raw materials is, therefore, very low. While the older calamine mines are gradually becoming exhausted, blende, which predominates in the lower workings, is more and more superseding calamine. The necessity of roasting it and the difficulty of handling the gases of the roasting process increase the cost of working. The manufacture of sulphuric acid from the gases is less profitable than in other districts, because the market for acid is limited and the blende contains arsenic. Only one works is making sulphuric acid, and that one has not introduced it for an extension of the plant recently made. The other works are forced to adopt some means of getting rid of the roasting gases, and generally use towers in which the sulphurous acid is absorbed by milk of lime. It may be of interest to state that one of the largest of our Western works is now putting up a sulphuric acid plant in connection with blende roasting. The lead ores associated with the zinc ores of Silesia have hitherto paid for a part of the cost of mining. It is found that they are not only much more difficult to separate by dressing from blende than from calamine, but also that in the former they are poorer in silver than in the latter. The large producers are, on the other hand, favored by the large extent and the regularity of their deposits, and by the cheapening of freights by the construction of narrow-gauge roads between the mines and the works. The production of zinc ores in 1880, the quantities taken from (—) or added to (+) the stocks at the works, and the actual consumption of the latter are given in the following table:

Kind of ore.	*Production.*	*Drawn from or added to stock.* *Tons.*	*Total supply of works.* *Tons.*	*P. c.*
Calamine	449,672	+22,865	462,537	84·6
Blende	81,322	— 8,516	72,806	14·6
	530,994	14,349	545,343	99·2
Excess of imports and exports of ore			3,185	0·8
Total			548,528	100·0

The following table will serve to show the development of the Silesian zinc industry since 1810:



WESTERN SCENERY—PAVANT BUTTE—A SUBMARINE VOLCANO—UTAH.

—FROM U. S. GEOLOGICAL SURVEY REPORT.

Period.	Average annual production of — Ore.	Average annual production of — Spelter.	Value of ore in per cent. of value of spelter.	Pounds of coal per — Pound of ore.	Pounds of coal per — Pound of spelter.
1810–1819	2,600·0	680·0	23·1	6·300	20·20
1820–1829	27,984·0	7,466·0	34·0	4·200	15·80
1830–1839	37,445·5	8,190·6	51·0	. .	. .
1840–1849	94,779·1	17,068·0	21·9	3·284*	14·75*
1850–1859	180,915·1	30,352·0	42·5	2·594†	14·15†
1860–1869	275,938·1	38,155·4	35·3	2·557	19·03‡
1870–1879	392,988·8	45,224·3	38·5	1·807	14·00
1880 . . .	630,904·0	65,443·0	36·6	1·529	12·40

* 6·5 per cent. being slack. † 18·4 per cent. being slack. ‡ 46·6 per cent. being slack.

The reduction in the consumption of fuel is due to the introduction during the years 1870 to 1880 of gas firing, either in the shape of step grates with upper and lower blast or the Siemens regenerative system with natural draught. The former is economical, because it allows the use of otherwise unsalable slack; while the latter, notwithstanding high first cost, is cheaper still, although market sizes of coal must be used. Herr Althaus says that, in consequence of the almost general introduction of the gas firing, the smoke is almost entirely disappearing. He expresses his surprise that the recuperative system introduced by Dr. Wedding at the small Friedrich works at Tarnowitz has not been more generally adopted, as it combines the advantages of both of the above methods. The upper blast is heated in a cast-iron hot stove. The following table will best illustrate the effect of the introduction of these improvements:

	Production of spelter. Tons.	Yield of ore. Per cent.	Consumption of coal per pound of — Ore.	Consumption of coal per pound of — Spelter.
1860	40,354	15·3	2·699	17·63
1870	36,444	12·8	2·455	19.16
1871	31,971	12·1	2·040	16.80
1872	32,502	9·6	1·425	14·80
1873	30,719	10·0	1·342	13·40
1874	41,518	11·3	1·575	13·97
1875	43,194	11·4	1·666	14·60
1876	49,377	11·0	1·553	14·14
1877	57,423	12·0	1·526	12·70
1878	59,619	11·8	1·509	12·78
1879	62,476	12·7	1·420	11·21
1880	05,443	12·3	1·529	12 41

Herr Althaus gives the following estimate of the cost of manufacture of spelter, the cost of the ore, which is generally mined by the smelting companies themselves, being placed at the assessed valuation of the government for the purposes of taxation:

	Per metric ton of ore.	Per metric ton of spelter.
Assessed valuation of ore	15·23 Marks.	129·45 Marks.
Freight to works, unloading, etc.	1·70 "	14·45 "
Fuel	6·78 "	49·10 "
Wages	6·29 "	45·00 "
Other expenses	2·94 "	25 00 "
Interest and sinking fund	3·06 "	26·00 "
Total cost	34·00 "	289·00 "
Average selling price	39·77 "	338·00 "
Average profit	6·77 "	49·00 "

Spirek gives the following figures for four Silesian works:

	1.	2.	3.	4.	Average.
Cost of ore at works	203·8	209 0	200·0	195·0	202·0
Cost of fuel	82·0	60·4	40·0	38·0	52 6
Other expenses	80·0	67·7	67·8	65·0	70·1
Total cost	365·8	337.1	307·8	298·0	324·7
Average selling price	338·0	338·0	338·0	338·0	338·0
	—27·8	+0·9	+30·2	+48.0	+33·1

The German imports and exports of spelter and sheet-zinc during the year 1880, were as follows, in metric tons:

	Imports from. Spelter.	Imports from. Sheet-zinc.	Exports to. Spelter.	Exports to. Sheet zinc.
Bremen	47.7	3·2	. . . .	156·3
Hamburg	620·4	36·5	17,388 9	6,007·6
Denmark, Sweden and Norway	64·2	. . .	. . . .	1,248·3
Russia	. . .	. . .	488·3	993·4
Austria-Hungary	705·8	2·3	6,845·3	499·3
Switzerland	. . .	2·2	. . . .	173·1
France	. . .	10·5	1,956·0	. . .
Belgium	1,755·4	66·9	1,290·5	235.3
Netherlands	76·2	2·3	3,158·4	1,254·2
Great Britain	631·3	. . .	8,573·4	2,772·4
United States	. . .	. . .	. . . .	134·0
Other countries	98·8	0·9	921·6	50·9
Total	3,989·8	114.8	40,622 4	12,524·8

It will be noted that a very considerable portion of the exports are to Hamburg, which, being a free city, is outside of the German customs union. Hamburg is really the main distributing point for spelter exported, the other figures being only shipments from other German ports. To a certain extent, the metal that goes into the Netherlands is really only in transit. It is not, therefore, correct to assume that the figures given under "United States," represent all of the German spelter and zinc which has come to this country.

—*Engineering and Mining Journal.*

COPPER SMELTING IN THE MANSFELD DISTRICT.

ONE of the old established and successful mining industries of Germany has been that of Mansfeld, where a thin stratum of cupriferous slate has been worked for centuries. The miners of the district, by nice distinctions divide the bed into a series of nine layers, the whole of which do not aggregate more than from 13.5 to 22 inches. Only a few inches are worth mining, and yet the working of this deposit for copper has been profitable. The average percentage of copper in the slate between Gerbstadt and Eisleben, the principal district, is from 2 to 3 per cent. with an average of half a per cent. of silver in the copper. In the Sangerhausen District, silicious ores run as high as 5 and sometimes even 10 per cent. of copper, but contain only one-half the quantity of silver. The average of the ore smelted is 2.5 to 3 per cent., and 0.015 per cent. of silver. The Mansfeld copper slate contains a considerable quantity of bitumen, and it is, therefore, first calcined in open heaps, the operation taking four to six weeks, and occasioning a loss of weight of from 8 to 12 per cent. The calcined ore is smelted in five works in cupolas or shaft-furnaces. In the older establishments, the furnaces have a fore-hearth into which the melted cinder and matte flow directly, thus separating outside of the furnace. They do not put through as large a quantity as the more modern furnaces, closely modeled upon iron blast furnaces, but they possess the advantage that there is less danger of the formation of salamanders, bodies of metallic iron reduced from the ore. Their maximum capacity is 100 tons per day, while the larger modern furnaces, from which slag and matte are tapped at intervals, can put through 160 tons per day, being run with a higher pressure of blast, which ranges between 1.9 and 5.2 inches of mercury. Generally the ore is fluxed only with impure slag from the furnaces themselves, or with slag from smelting roasted matte. The coke used holds only about 5 per cent. of ash, 3.5 to 4 cwts. being used per ton of charge. The slag contains 48 to 50 per cent. of silica at one works, and 53 to 57 per cent. at another, and its contents of copper vary from 0.2 to 0.3 per cent. of copper, the loss of that metal being, therefore, very nearly 10 per cent. The gases escape from the tunnel-head with a temperature of 100 to 300 degrees C., and are partially utilized under steam boilers or in hot-blast stoves. By analyses, the gases of two works contained:

	1.	2.
Carbonic acid	10·8	15·0
Oxygen	0·4	0.1
Carbonic oxide	16·8	14.0
Nitrogen	72·0	70·9
Total	100·0	100·0

The matter produced by four works held:

	1.	2.	3.	4.
Copper	30·500	44·900	36·400	44.815
Silver	0·152	0·230	0·180	0·225
Lead	1·210	0·690	1·046	0·643
Iron	26·600	20·000	25·900	23·778
Nickel	0·590	0·350	0·485	0·488
Cobalt	0·180	0·010	0 055	0·146
Zinc	9·149	4·570	5.550	3·012
Total	68·381	70·750	69·616	72·135

The rest embraces 23 to 27 per cent. of sulphur, and generally some manganese. This first matte is roasted in kilns 10.4 feet high, 4 feet wide, and 5 feet deep on the level of the grate, and somewhat larger in section on the top. One kiln will hold ten tons, and calcines 1.25 to 1.50 tons of matte per day, 85 parts of partly roasted matte being added to the raw matte, in order to prevent sintering. The access of air is so regulated that the roasting gases contain from 4.5 to 5.5 per cent. of sulphurous acid. The latter is conducted into lead chambers for the manufacture of sulphuric acid. The kiln is so run that a layer of sintered matte is formed about three feet above the grate, so that the roasting material can be drawn without causing the unfinished material above to mix with it. After drawing, this sintered layer is broken through, and the matte above it descends quite uniformly. One ton of raw matte yields 1.015 to 1.070 tons of roasted material. The latter is worked in reverberatory furnaces, built after the English model. They are fired with coal, though recently a Groebe-Lauermann gas producer is on trial. The Kupferkammer works has ten furnaces, and the Eckardt works six, the charge being respectively 2.8 and 2.5 tons of roasted matte, 616 and 440 pounds of sandy ores, and 308 and 220 pounds of quartz, and some richer scrap, the time for a charge being seven to nine and six to seven hours respectively. After three to three and a half hours strong firing with luted doors, the charge is rabbled three times, until there are no accretions on the hearth. Then a portion of the slag is drawn out of the working-doors, and the rest of it is tapped, together with the matte. In 1880, the average working of the two establishments referred to was as follows, respectively; Daily capacity, 8.02 and 9.34 tons; yield 902 and 1,188 pounds of second matte, and 1,250 and 1,100 pounds of slag. The matte held 74.391 and 74.375 per cent. of copper, and 0.427 and 0.433 per cent. of silver. The consumption of coal per ton of first matte was 2,174 and 1,888 pounds respectively. The slag drawn from the furnace held 9 per cent. of copper, and 0.036 per cent. of silver, and the slag tapped 4 and 2.943 per cent. of copper, and 0.01 and 0.0085 per cent. of silver respectively. The slag held from 17 to 20 per cent. of silica and as high as 50 per cent. of protoxide of iron, and being so basic is used as flux in smelting raw ore. The percentage of the second matte is roughly determined by its density; 74 per cent. matte having a specific gravity of 5.76, and 75 per cent. matte, 5.80. Recent analyses of the second matte gave the following result:

	1	2.
Copper	73·320	73·512
Silver	0·427	0·429
Lead	0·816	0·557
Iron	2·590	2·870
Nickel	0·536	0·304
Cobalt	0·178	0·187
Zinc	1·378	0·514
Manganese	0·011	0·010
	79·256	79·383

The matte contained besides about 20 per cent. of sulphur. It is desilverized by the Ziervogel process, being groud in mills and roasted in 13 reverberatory furnaces with three hearths, one above the other, which together have a capacity of 15,000 tons of matte per annum. The silver is extracted after careful roasting as sulphate of silver, and is precipitated as metallic silver by copper. The precipitated silver is treated with silver solution, to dissolve the copper, washed, pressed, and melted into bars 999 to 999.4 fine. The residues from this leaching process, when they have less than 0.023 per cent. of silver, are worked for copper directly. If they hold more, they are roasted over again and are again extracted, then yielding residues carrying 0.018 per cent. of silver. The residues, which contain 74 to 75 per cent. of copper as oxide, are mixed with 10 per cent. of coal slack, dried and charged in lots of 10 tons into reverberatory smelting-furnaces. In 9 to 9½ hours the copper is reduced and melted down, and a thick slag is drawn off. Refining then begins with open doors, and large quantities of sulphurous acid and zinc oxide escape. Iron, zinc, lead, and finally nickel are slagged, the operation taking from 1½ to 2 hours. The copper then begins to boil, in consequence of the escape of sulphurous acid, which continues for 2 to 2½ hours, at the close of which samples show a convex surface and little porosity. Two hours afterward, the copper is ready for poling, which is followed by toughening, the latter operation taking about 2 to 2½ hours. The copper refined in this way is better than that made by first smelting the residues of the Ziervogel process for "blister copper," and then refining the latter. This was formerly done in the Mansfeld District, and the following range of analyses will show the difference fairly, No. 1 being the present metal, and No. 2 that made between 1864 and 1868:

	No. 1.	No. 2.
Copper	99·394 to 99·550	99·120 to 99·277
Silver	0·028 " 0·030	0·024 " 0·031
Lead	0·043 " 0·103	0·169 " 0·316
Iron	0·025 " 0·132	0·044 " 0·069
Nickel	0·239 " 0·275	0·337 " 0·468

The drosses from refining the copper are smelted in a blast-furnace, and are toughened in a reverberatory. In 1880, the composition of this copper ranged within the following limits:

Copper	99·110 to 99·270
Silver	0·015 " 0·020
Lead	0·134 " 0·259
Iron	0·019 " 0·024
Nickel	0·314 " 0·405
Arsenic	0·101 " 0·144

By adding lead or phosphor-copper, this metal is made fit for rolling purposes.

—Engineering and Mining Journal.

THE COAL-FIELDS OF GREAT BRITAIN.

In briefly calling attention in our last issue of Coal to the work just issued by Mr. Richard Meade, Assistant Keeper of Mining Records, we stated that we would endeavor to gather the main data of general interest in a series of articles. The information at the disposal of Mr. Meade is so extensive and in many points reaches so far back that we can only attempt a brief summary. The following is the area of the coal-fields of the United Kingdom:

Coal-fields.	Area in Square miles.
England:	
Durham and Northumberland	796
Yorkshire, Derbyshire, and Nottinghamshire	800
Cumberland	25
Lancashire and Cheshire	220
Leicestershire	15
Warwickshire	30
Shropshire	28
North Staffordshire	75
South Staffordshire	93
North Wales:	
Anglesea, Denbighshire, and Flintshire	90
South Wales:	
Monmouthshire	104
Glamorganshire	518
Brecknockshire	74
Caermarthenshire	228
Pembrokeshire	76
Gloucestershire (Forest of Dean)	34
Somersetshire (Bristol)	150
Scotland	1,720
Ireland	2,800
Total	7,876

According to the returns of the Inspectors of Mines, the following was the product of the various coal-fields in the years 1860, 1870, and 1881, the figures for the latter year having been substituted by us for those of 1880, given by Mr. Meade, the data for 1881 not having been published at the date of his report:

England:	1860.	1870.	1881.
Northumberland, North and South Durham	18,244,708	27,613,539	35,592,420
Cumberland	1,171,052	1,408,235	1,769,213
Westmoreland	.....	.....	1,860
Cheshire	750 500	929,150	782,000
Lancashire, North, East, and West	11,350,000	13,810,600	18,500,810
Yorkshire, North Riding	......	......	7,036
" West Riding	9,284,000	10,606,604	18,287,141
Derbyshire }	4,940,000	{ 5,102,265	8,508 923
Nottinghamshire }		{ 2,115,372	4,758,060
Warwickshire	545,000	647,540	1,133,419
Leicestershire	730,000	599,450	1,145,265
Staffordshire, North and South, and Worcestershire	7,648,300	13,230,062	14,858,070
Shropshire	850,500	1,343,300	892,500
Gloucestershire, Somersetshire }	5,503,400	1,955,910	1,361,396
Monmouthshire }		4,364,342	5,412,840
North Wales:			
Flintshire, Denbighshire	1,750,500	2,329,030	2,670,597
South Wales:			
Glamorganshire, Brecknockshire, Pembrokeshire, and Caermarthenshiro	6,254 813	9,299,770	1,584,886
Gloucestershire	....	..	15,257,050

Scotland:			
Eastern District, Western District	10,900,600	14,934,553	20,823,055
Ireland	119,425	141 470	127,586
Total	84,042,698	110,431,192	154,184,300

The following statistics will show the development of the production of coal in the United Kingdom:

Year.	Production.	London consumption.	Exports.
1660	2,148,000	. . .	. . . .
1700	2,612,000	. .	. . .
1750	4,773,000	. . .	. . . .
1770	7,205,400	. . .	. . . .
1780	6,424,976	. . .	. . . .
1790	7,618,760	. . . . .	. . . .
1800	10,080,300	. . . . .	. . . . .
1816	27,020,115	1,500,000	237,667
1854	64,661,401	4,376,770	3,359,575
1860	84,042,698	5,070,515	7,412,575
1865	97,160,587	5,903,271	9,283,214
1870	110,431,192	6,759,100	11,702,649
1872	123,497,316	7,556,422	13,198,494
1874	125,067,916	7,423,488	13,927,205
1876	133,344,766	8,451,375	16,265,839
1878	132,607,866	8,794,516	15,483,816
1879	134,008,228	10,058,811	16,442,296
1880	146 969,409	9,915,488	18,702,551
1881	154,184,300	. . . . .	. . . . .

The quantity of coal available in 1880 is estimated to be 135,288,613,038 tons, or, at the present rate of production, fully 900 years supply. Of this quantity, 79,015,613,038 tons exist at depths not exceeding 4000 feet in known coal-fields, and 56,273,000,000 tons as the probable amount of coal, under Permian and other overlying formations, at depths of less than 4000 feet; 40 per cent. being deducted for loss and other contingencies. The following are the data:

England and Wales	69,192,056,317
Scotland	9,669,172,642
Ireland	154,384,079
Total known coal-fields	79,015,613,038
Concealed coal-fields	56,273,000,000
Total coal available, 1880	135,288,613,038

The Great Northern Coal-Field.—The earliest record of the use of coal of this great field is the receipt, in 852, of twelve cart-loads of coal by the abbey of Peterboro'; and in 1239, Newcastle coal was sent to London. The field comprises an exposed area of 460 square miles and a concealed area of 225 square miles, its length being nearly fifty miles, while its greatest width is twenty miles. Beyond the area above referred to, there is extending under the German Ocean another area of 111 square miles known to be available. The coal measures are about 2000 feet thick, and they are much intersected by faults in the immediate neighborhood of which the beds have a high dip. Through the greater part of the measures, however, the seams lie at a gentle inclination. The principal seams are the High Main and the Low Main or Hutton, both averaging six feet of coal. It is an interesting fact that the latter seam, in different parts of the field, has the best description of those varieties of coal suitable for purposes not at all similar to each other, namely, the best household, the best gas, and the best steam coal. The household coals of this field, of which the choicest kinds are known as Wallsend coal, may be illustrated by the following analysis:

	Haswell.	Hartley.	Original Hartley.
Carbon	83·47	84·284	81.18
Hydrogen	6·68	5·522	5·56
Nitrogen	1·42	2·075	0·72
Sulphur	0·06	1·181	1 44
Oxygen	8·17	6·223	8·03
Ash	0·20	0·715	3·07

The gas coals of the Northern field are obtained from the lower seams on the Tyne, Wear, and Tees, and yield from 10,000 to 11,000 cubic feet of gas per ton. The following analyses show the character of this coal:

	South Peareth.	Bowden Close.	Willington.	Garesfield.
Carbon	81.41	84·92	86·81	86.9
Hydrogen	5·33	4·52	4·96	
Nitrogen	2·05	0 96	1.05	5·4
Sulphur	0.74	0·65	0·38	
Oxygen	7.90	6·66	5·22	5·2
Ash	2·07	2·28	1·08	2·5

The steam coals of the field are found in the northern part, the constituents of the fuel being shown by the following analysis:

	Buddles Hartley.	Newcastle Hartley.	Haswell Sunderland.	Seaton Burn.
Carbon	78 69	81·81	83·71	78·65
Hydrogen	6·00	5·60	5·30	4·65
Oxygen	10·07	2·58	2·79	13·06
Nitrogen	2·37	1·28	1·06	. .
Sulphur	1·51	1·69	1·21	0.55
Ash	1·36	7·14	5·93	2·49

The best coking coal of the district is obtained from the lower seams of the Tyne and South Durham: together with the ironstone of the region, it forms the basis of the development of the great Cleveland iron-making district, the greatest in the world. In South Durham alone, the production of coke exceeds four millions of tons, and the total number of oveus in Durham is estimated to be nearly 14,000 bee-hive ovens. The following analyses will indicate the nature of the coal.

	Durham best.	Average Durham.	Busty upper.	Busty lower.	Brockwell.
Carbon	93·150	84·92	81·22	78·46	83·40
Hydrogen	0·721	4·53	4.70	4·42	4·40
Nitrogen	1·276	0·96	9·45	8·82	7·18
Oxygen	0.905	6·66			
Sulphur	. .	0·65	0·81	1·83	1·00
Ash	3·948	2·28	3·28	6·17	3·50
Water	. .	. .	0·85	0·99	0·99

The yield of coke varies widely, running from 53 to 72 per cent., the average, however, being 60 to 65 per cent. The coke is very pure, the average of the best varieties being 6 per cent. of ash and 0·6 per cent. of sulphur. The time of coking ranges from 18 or 19 hours to as high as 96, according to whether a light, soft, or hard and compact coke is to be made. During the past years, efforts have been made to save the gases given off in the ovens; but the success so far has not been equal to what could be desired. At several places, however, the waste heat of the coke ovens has been utilized. Mr. Meade says that experience at Durham has taught him that to have good coke it is necessary that the gases should have a free outlet and the ovens kept burning in the ordinary way. To secure this object, ovens were erected at Brownley Colliery, and the results attained have been most favorable. The ovens were built back to back, but with larger flues than usual between them. To each stack—about 116 feet in height—were connected about 100 ovens, an equal number on each side, there being four flues and boilers so arranged that the heat was carried past, when cleaning or repairs were carried on, the connecting flues being built compact and tight. There was great freedom from smoke, owing, no doubt, to the air-tight and perfect character of the flues, the small proportion of air present not cooling the gases to a point below, by which the hydrocarbons escaped imperfectly burnt. This was shown to be the case by admitting the air, when flame was at once seen. By this arrangement, no coal whatever was used for the boilers, and the produce of the pits was drawn from a depth of 600 yards and the water pumped, for which purpose, before the new system was adopted, 600 tons per fortnight were wasted. The amount of heat available for evaporative purposes was found to be very large. Mr. Stevenson, of Durham, in speaking of these ovens, states that 50 of them coked at the rate of 230 tons of coal in 84 hours, which yielded 50 per cent. of coke composed of 132·7 tons of carbon to 5·3 tons of ash. He found the composition and the weight of the material lost in coking to be: Carbon, 62·6 tons; hydrogen, 10·3 tons; nitrogen, 2·3 tons; sulphur, 1·4 tons; and oxygen, 15·3 tons. At several places in Durham, the coal is crushed to powder before going into the oven, and this has been found to be beneficial, producing a larger percentage of coke with less refuse.

The Midland Coal-Field.—The second coal-field described by Mr. Richard Meade, in his work on the Coal and Iron Industries of the United Kingdom, is the Midland or Yorkshire coal-field which has a known area of about 800 square miles. It extends from Bradford and Leeds, on the north, for sixty-six miles, to Derby and Nottingham, on the south, Sheffield occupying a position in its center. Its breadth varies from 5 to 20 miles, and it is the most continuous of the British coal-fields. In a section of 4500 feet are fifteen seams over two feet thick, their aggregate being 43 feet of coal. Besides, there are numerous veins less than two feet, equal in all to 53 feet of coal. Mr. Meade, following his plan, has given three widely-separated chapters on the various parts of this field: one covering that portion in Yorkshire; another that in Nottinghamshire; and a third in Derbyshire. This division has little or no significance for American readers, and we shall therefore consider these portions together. The lower coal measures contain only unimportant veins of coal, but are remarkable for the occurrence of seams of ganister, a highly siliceous rock, which, when ground down and mixed in some cases with powdered fire-brick or similar materials, forms one of the best fire-resisting materials known. The middle coal measures are those which are particularly rich in coal, the seams of the upper measures being less numerous and valuable. In the northern part of the field, a number of veins, varying from 2 to 3 feet thick, are worked; while in the southern part of Yorkshire, the great seam is that of Barnsley, which so far exceeds in thickness and value the other seams that, with the exception of the Silkstone, it is the only one likely to be touched until they are exhausted. This Barnsley coal, which is about from 6 to 9 feet thick, derives its great value from the fact that the middle portion of the vein is semi-anthracite or steam coal, and is particularly adapted for use in locomotives, ships, and iron-smelting, on account of its high heating-power. This portion of the bed is made up of alternating layers of dull and bright coal. The "Silkstone," or, as it is called in the northern part of Yorkshire, the "Blocking Bed" coal, is remarkable for its purity. It is largely sent to London as a house coal, and is also employed for steel-making in Sheffield, as coke, and for gas manufacture. In the Derbyshire and Nottinghamshire fields, which are the southern extension of the Yorkshire field, a number of veins, some of them averaging six feet, are worked.

The following analyses are given by Mr. Meade for the Yorkshire coals, the first five being from the Barnsley vein, while the last is from Silkstone coal:

Constituents.	Womburll	Darfield.	Oaks.	Elsecar.	Marsboro' Park.	Silkstone.
Carbon	80·500	81·390	82·520	81·30	82·190	80·46
Hydrogen	5·500	5·500	5·025	5·19	5·173	5.08
Oxygen	6·205	7·451	6·915	8·21	8·144	6·80
Nitrogen	1·862	1·496	2·120	1·89	1·730	1·67
Sulphur	1·833	2·100	1·144	1·21	1·537	1·65
Ash	4·100	2·063	2·276	2·20	1·226	3·30
Specific gravity	1·266	1·270	1·270	1·29	1·268	. .
Coke, per cent	63·130	63·190	65·620	62·00	63·600	. .

The composition of the Derbyshire and Nottinghamshire coals appears from the following analyses, the first three belonging to the former field and the last two to the latter:

Constituents.	Stavery.	Loscoe.	Langley	Shireoaks.	Portland.
Carbon	79·85	77·490	77·970	77·40	80·410
Hydrogen	4 84	4·860	5·588	4·96	4·650
Nitrogen	1·23	1·640	0 800	1.55	1·590
Sulphur	0.72	1 300	1·140	0·92	0·860
Oxygen	10·96	12·410	9·890	7·77	11·260
Ash	2·40	2.300	4·050	3·90	1·230
Specific gravity	1·27	1·285	1·264	. .	1.301
Coke, per cent	57·86	52·800	54·900	63·18	60·900

The acreage of this Yorkshire or Midland coal is estimated at 7,970,156 acres, of which 7,783,610 remain unworked, which contain an estimated quantity of 18,406,799,433 tons available for future supplies, or a total of 32,721,198,832 tons. The production of the Midland coal-field has increased from 17,824,241 tons to 29,804,763 tons. The average quantity raised per man was 295 tons in 1880.

Cumberland Coal-Field.—A small though, in some respects, an important field is the Cumberland, in the northwest of England. It is only twenty miles long, and at its greatest width five miles broad. The coal measures in this area attain a thickness exceeding 2000 feet, the middle division containing seven workable seams of coal. In the Workington District, the most important are the cannel, from 4 to 6 feet, and the Bannock band, 5½ feet thick; the Lower Main, from 3 to 4 feet; and the Main, from 9 to 10 feet thick; the total workable thickness being estimated at 35 feet. In the Whitehaven and, to some extent also, in the Workington District, the colliery workings extend as far as two or three miles under the sea. Mr. M. Dunn, describing the dangers attending these under-sea operations from inundation, gives an account of a calamity which occurred in this district in July, 1837, when 36 men and boys were killed, the water having filled up the whole of the extensive workings to the level of the sea in a few hours. The scene of the accident was the Workington colliery, where the two pits were sunk 90 fathoms deep, close to the seashore, and the coal was worked to the distance of 1500 yards under the Irish Sea, in a ten-foot seam. The workings were driven considerably to the rise, at the rate of one in three, which brought them within 15 fathoms of the bottom of the sea. The bed of the sea gave way, flooding the colliery.

The following analysis of cannel coal from this field, made with special reference to its adaptability for gas manufacture:

Volatile matter	Gas, tar, etc	52·65	
	Sulphur	0·66	
	Water (212° F)	1·16	54·47
Coke	Fixed carbon	26·25	
	Sulphur	0·92	
	Ash	18·36	35·53
	Total		100.00

The quantity of gas per ton at 60 degrees Fahr. and 30 inches barometer was 10,765 cubic feet; the illuminating power, in standard sperm candles, by union jet consuming 5 cubic feet per hour at 0.5 inch pressure, being 40.48 candles. In 1880, the production of the Cumberland coal-field was 1,680,841 tons, of which 654,763 were shipped coastwise.

The Lancashire Coal-Field—This important coal-bearing tract, most irregular in outline and greatly disturbed by faults, has an estimated area of 217 square miles. The chief centers of activity are Prescot, St. Helen's, Wigan, Bolton, Bury, and Manchester, and the isolated tract of Burnley. The South Lancashire area of the coal-field is 32 miles in length, its average breadth being about six miles. The number of seams of workable coal, as also the character of the strata in which they occur, vary considerably in the different parts of the area; thus, in the neighborhood of St. Helen's, the number of coal seams exceeding two feet are 13, compared with 17 in Wigan, and 18 in the Manchester districts. A general thickening out of the coal measures takes place toward the north-northeast, the same coal seams being found farther apart at St. Helen's than at Prescot, and at Wigan than at St. Helen's. The middle coal measures, with a section of 3,500 feet, contain all the important seams of coal, which vary from 3 to 9 feet, and under different names can be traced over the whole district. The Burnley basin lies to the north of the main coal-field: it is small but rich. The Manchester field, farther south, is only four and a half miles long, and its greatest breadth does not exceed one and a half miles. The coals of this field are chiefly used for steam and domestic purposes, and cannel coal for gas making. The following are a number of analyses:

Constituents.	Bal-carres.	Blackley Hurst.	Ince Hall.	Pember-ton.	Cannel.
Carbon	83 54	82·01	77·010	76.160	79·23
Hydrogen	6·24	5·55	3·930	5·350	6·08
Nitrogen	0·98	1·68	1·400	1·290	1·18
Sulphur	1·05	1·43	1·050	1·050	1·43
Oxygen	5·87	6·28	5 520	10·130	7·24
Ash	3·32	4·05	11·090	6·020	4·84
Specific gravity	1·26	1·26	1·2760	1·283	1·23
Coke, per cent.	62·89	57·84	67·100	56·100	60 33

The production of the Lancashire coal-field, which was 9,080,000 tons in 1854, was 19,120,294 tons in 1880. Of this large quantity only 753,804 tons were shipped coastwise, and 610,572 tons were exported in 1880, thus showing that the consumption is almost entirely local. The coal area available for future supplies is estimated at 5,264,787 acres, in which it is computed there are 5,436 millions tons, enough to last 275 years at the present rate of production. The Cheshire coal-field lies south of the Lancashire field, and is closely allied with it.

The Leicestershire Coal-Field.—This lies to the south of the Midland field, and is irregular in form. It has been divided into three districts. The middle measures are the most productive, containing many seams of coal, ten of which, exceeding two feet in thickness, are workable and give a total average of from 40 to 45 feet of coal. The central part of the measures is that containing the principal beds. The main vein of the western or Moira District is from 12 to 14 feet thick, while that of the eastern field is 6 to 8 feet. The following two analyses may serve to show the character of some of these coals:

Constituents.	Ibestock.	Whitwick.
Carbon	74·970	69·00
Hydrogen	4·830	4.35
Nitrogen	0·830	10·78
Oxygen	11·880	
Sulphur	1·450	0·78
Ash	5·990	5·42
Specific gravity	1·291	. .
Coke, per cent.	50·800	58·14

The production of this field has increased from 425,000 tons in 1855 to 1,063,382 in 1880, the total tonnage still available for consumption being estimated at 836,799,634 tons.

—From Coal.

THE GOLD FIELDS OF NOVA SCOTIA.

THE gold-fields of Nova Scotia occupy a district extending along the Atlantic coast from Cape Canso to Yarmouth, and varying in width from 10 to 40 inches. The total area assigned to the auriferous strata and the rocks most intimately connected with them is estimated at from 6500 to 7000 square miles, of which about one half is occupied by what is known as "granite" rocks. The shore presents a low, rugged front, and the land rises gradually to a height of 560 feet.

Geology.—The "granite" rocks of Nova Scotia may be divided into two sections. The western one extends from Halifax to Windsor, a distance of forty-five miles, and stretches in a great belt, interrupted by occasional patches of auriferous measures, nearly to Yarmouth. To the eastward, another band of less width stretches with several interruptions from Waverly to the Cape of Canso. These great masses are but little known and have never been mapped. Some ingenious theories have been advanced as to their being really of Laurentian age, based, it would appear, chiefly on the fact that they have in contact with them at many places bands of gneisses, mica schists, etc., which have been set down as Huronian, as they are more metamorphosed than the ordinary auriferous strata. So far, however, as these granites have been studied in their relation to auriferous and newer strata, they serve to confirm the view entertained by Dr. Dawson, that they are intrusive masses. Near Sherbrooke, as remarked by Dr. Dawson, the quartzite at the point of junction with the granite, is slightly changed in character, having apparently minute hornblende and mica crystals developed in it; but the granite sends numerous veins into it, and in them becomes coarser in texture, and presents beautiful aggregations of plumose mica. At Cochran's Hill, auriferous measures are found lying close to one of the most persistent of the granite ranges, and are penetrated by bands of granite from one inch to six feet in thickness. The measures have exhibited a metamorphism equal to that found anywhere in the coastal range. The slates have become perfectly crystalline. Mica schists, or micaceous gneisses, with crystals of chiastolite, staurolite, have been developed in them.

Dr. Dawson similarly describes the granite of Nictaux, as altering the Devonian beds and converting them, for a short distance away from the junction into gneissoid rocks holding garnet. The granite sends veins into the strata, and, near the junction, holds numerous angular fragments of altered slate. In the case of both the auriferous and Devonian strata, the gradual passage from gneissoid rock into the normal metamorphosed quartzite and argillite can be frequently observed The Nova Scotia granite has all the characters of a plutonic rock in its want of stratification, its frequent porphyritic appearance, its passage into graphic granite, etc., and closely resembles in lithological characters the intrusive granites of the Eastern Townships of Quebec and of New England, some of which belong to the Montalban series of Hunt, while others are later than the Upper Silurian; and it differs materially from the typical Laurentian of Canada. In the latter, the gneisses are usually hornblendic, laminated, and interstratified with diorites, pyroxene rock, limestone, serpentine, etc. These granites are evidently older than the Carboniferous; for at Horton their *debris* is found in the Lower Carboniferous. At Nictaux, they penetrate rocks of Oriskany age. They are therefore much more recent than the auriferous strata to which, as will be shown, a greater age must be assigned. Around and between these granite masses, the gold-bearing strata are spread, with a general strike parallel to the line of the shore, and are now presented in a series of undulations, such as would be expected from a pressure acting against the trend of the coast. Denudation on an immense scale has swept away the crests of the anticlinals, and presented the strata in a succession of elliptical curves, the axes of which are variously inclined. The gold-bearing strata may be divided into two great sections. The upper is composed principally of black earthy pyritous slates with few beds of quartzites, and not many quartz veins. These veins are auriferons when exposed in the anticlinals similar to those in the lower section, to be described farther on. An instance of this auriferous character of the veins is met at Lunenburg, but it is not known at what horizon they occur. Its thickness has been estimated by Professor Hynd to be about 3000 feet. The lower section is composed of alternating beds of quartzites and compact sandstones, sometimes felspathic, and argillites, and is estimated to be 9000 feet thick. It is to be regretted that the age of these rocks can not as yet be definitely determined. There has been no systematic survey of the district, and the strata can not be continuously followed into connection with well-defined horizons farther west. Mention has been already made of the anticlinal folds of the auriferous measures, and their denuded summits. The veins of auriferous quartz, more particularly the subject of this paper, occur in them, and run parallel to the strata, having usually quartzite on one side and slate on the other. They follow the dips and turns of the incasing rocks, and to a casual observer appear to be really beds of quartz, formed at the same time as the beds containing them. They have, therefore, been considered by numerous writers to be true aqueous sediments. Others, again, who have considered the reason of their formation, and the characteristics of the deposits, affirm with great show of reason that they are true veins. Imagine these alternating layers of slate and quartzite ridged up under the influence of a pressure acting in a horizontal direction, and possibly to some extent confined by the more unyielding granite masses, it will be readily conceived that, at points of least resistance, which would be the crests and sides of the flexures, the strata would separate most readily at the junction of beds of differing toughness, leaving fissures closely following the outlines of the undulations. Denudation has swept away the crests of these anticlinals, and now presents these concentric fissures filled with quartz. A different effect, however, is noticed when the ends of the anticlinals are penetrated. Here the pressure acting on the layers not capable of escaping the pressure by flexure as readily as those already described has caused the beds to form corrugations, accompanied, doubtless, in many cases, by a slight movement of one bed on another. The larger of these corrugations, when filled with quartz, present the appearance of logs of wood laid side by side and connected by threads of the same mineral, and are called "barrel quartz." One of these corrugated lodes, worked last year at Moose River, varied in thickness from three quarters of an inch to four inches, and presented the apex of an anticlinal dipping to the east. The lode was accompanied by a similar one a few inches below it. Both lodes carried gold, iron, and lead sulphides, and a little calcite, and gold showed through the intervening slates. The corrugations of the slates were parallel to those of the lodes, and extended as far as a section was exposed by the excavations. Similar but less strongly marked corrugations occur in many of the straight-running lodes, and in some instances their transverse axes point to the line of pressure. Other effects are recognizable as caused by this pressure. Thus, veins called "anglers" are observed breaking abruptly across the quartzites and obliquely across the slate-beds, and in some instances proving rich sometimes in one rock and sometimes in the other. Numerous feeders, sometimes auriferous, radiate from the lodes into the surrounding beds, and in some cases connect them. The thin layers of slate found in most instances on one side of the lode are frequently so soft and broken as to be readily removed by the miner's pick. The wider beds of slate are frequently penetrated by several irregular veins, sometimes uniting and again diverging, and the whole mass is filled with a network of spurs and threads of quartz.

It is found, as a rule, that in wide bands of slate the veins are feebly auriferous, as is also the case in massive sandstones, or in sections composed principally of quartzites. The most productive veins are found where bands of quartzite and slate of moderate thickness alternate. This may possibly be due to the slates being readily penetrated by solutions, owing to their original lamination, and its increase by the pressure alluded to above, and to the fact that the original deposition of the gold may have been dependent on this alternation of beds of differing minerals. These remarks apply to the lower section of the auriferous measures. The overlying slates, although pyritous and containing numerous quartz lodes, indistinguishable from those already considered, have not yet yielded any containing enough free gold to warrant working by the present systems of milling. The worked veins vary in thickness from half an inch to six feet, the usual width being from four to eight inches. A twenty-inch vein is considered a large one. The length varies from a few hundred feet to over two miles. They show frequently a banded structure with cavities filled with quartz and calcite crystals. Other veins show a compact oily quartz or are slightly granular, and break most readily across the vein. Pieces of slate constantly occur in them, and there are also "horses." The fissures have been seen to extend after the quartz filling them has run out. The undulations of the auriferous strata were subsequently disturbed on numerous faults. The Waverley gold-field is disturbed by two heavy faults, running north and south, and throwing the measures 180 to 570 feet. Numerous small faults are met, and they are found, as a rule, to belong to either of two sets of faults, the one having a north and south, and the other an east and west course. These heavy faults seldom hold veins; but there have been disturbances, subsequently to the filling of the veins, which have produced fissures also holding veins, sometimes themselves auriferous, and generally influencing the gold values of the veins they intersect or touch. There seems to be but one true igneous dike cutting the gold measures This occurs at Strawberry Hill, Tangier, and is about 40 feet wide, and runs at right angles to the measures, cutting the veins, without, to any appreciable extent, influencing their positions or metallic contents. Bedded diorite dikes are met in the Lunenburg District.

The period at which the veins were filled can not be precisely ascertained. From its occurrence in the Lower Carboniferous conglomerate, to be referred to, it would appear that the greater part had been deposited previous to that era. The date of the subsequent faults and of the filling by quartz, etc., of the fissures they formed is not clear. There are no measures in the province of date later than the Triassic sandstones of Truro, and it is not known if they are faulted by the extensions of the sets of dislocations in the gold-fields which have been described. It is known that the strata succeeding the Carboniferous limestones up to a period as late at the Upper or Permo-Carboniferous are intersected by sets of faults corresponding to those of the gold districts. It may, therefore, be conjectured that the filling of the second set of fissures was not earlier than the latest period to which can be referred these systems of faults.

The minerals usually associated with the gold are sulphides and arsenides of iron, galena, blende, copper pyrites, oxide of iron, copper glance, molybdenite, native copper, sulphur, chlorite, feldspar, garnet, mica, calcite, felsite, etc., not, however, in quantities of economic importance. The presence of these minerals, especially of the sulphides and arsenides of iron, appears to be essential to the value of the lodes. It is true that numbers of lodes have been worked, causing but trifling quantities of pyrites, etc.; but if not present in the vein, they are found in the inclosing walls, which, in this case, are sometimes rich enough to warrant crushing. The gold occurs chiefly as free or coarse gold in grains, visible to the naked eye, and in strings or filaments between the planes of the quartz. A considerable quantity is inclosed in the nodules and nests of the associated minerals, as well as noticed farther on. Crystals have occasionally been found not exceeding one-third of an inch in diameter. One from Tangier was a rhombic dodecahedron with beveled edges, and brilliant, finely striated faces. Others are octahedra, sometimes elongated and flattened, with dull and rounded faces. The distribution of the gold in the veins is to a certain extent capricious. Few lodes carry a uniform yield over a space exceeding 500 feet. There is in almost every vein one or more zones or "pay-streaks" of quartz much richer than that surrounding it. These zones do not appear to be the effect of any law that has yet been applied to our mines. They lie at every angle, and appear to be of very varied length and width. At the Wellington mine, in Sherbrooke, one of these streaks has been followed nearly 600 feet from the surface without showing signs of exhausting. The surrounding quartz varied from 2 to 6 dwts. to the ton, while the "pay-streak" ran as high as 20 ounces.

Mining.—In the earlier operations, many companies were started with schemes too ambitious for their means, and broke down before they could get into working order. Others paid large dividends for a few years; but having no reserve funds, abandoned the work, when they encountered the trial of poor ore, which must be faced by every mine sooner or later. Other properties, again, have been continuously worked and have made handsome returns. On the failure of many of the large companies, their properties were sub-let to tributers, some of whom have done well by systematic mining, and others have effected little beyond robbing the richer parts of the lodes within a few yards of the surface.

During the past two years, a number of the more promising properties have been purchased by American capitalists, and it is expected that their mining experience, gathered in the Western States, will lead to a much larger output than has been obtained for some years past. When it is determined to work a vein, a mine shaft is sunk, at first, to a depth of about 60 feet, and a shaft on each side from 50 to 150 feet from the central one. At a depth of 40 feet, these shafts are connected by levels, and stoping started from six points, and continued, in some cases, to the surface. Then commencing 15 or 20 feet below the levels, a breast of two or more underhand stopes is carried from shaft to shaft. Frequently, when it is not desired to work to any depth, shafts are sunk at close intervals, and the rock raised through several of them. All these shafts are sunk on the vein, so that they vary from perpendicular sinkings to slopes at various angles, as low as 45 degrees.

This work is continued as long as the quartz pays, and some of the mines have reached a depth of 600 feet. Usually, in the more systematically worked mines, each stope has the following scaffold low enough to permit of convenient stowage. Formerly, it was customary to take out at one operation the lode and enough of the slate, etc., to allow working room of from two to three feet. This was found to lead to serious loss of gold, both by theft and by mixture of the quartz with the rock, which had nearly all to be sorted at bank. Now, the slate, etc., on one side of the vein is first taken out, and the vein allowed to stand untouched until several hundred square feet of it are exposed. Then it is removed at one operation, and sent directly to the surface. This method costs rather more, as the width of the ground removed is increased by the thickness of the lode; but the quartz is uot so much exposed to the workmen, and very little of it is lost. As might be expected from the nature of the strata, the mines are as a rule very free from water. It may be said that at a depth of 300 feet they are perfectly dry whenever proper care has been taken to puddle the shafts on the rock-beds, and not to carry the stopes too near the surface. The most noticeable exception to this rule that has come under the writer's notice occurred recently at the Rose mine, Montagu, where, at 150 feet, the main shaft struck a flat throw to the south of three feet. This throw evidently came to the surface under an adjacent swamp, and passed the water so rapidly that the men had immediately to leave their work, which was not resumed until more powerful pumps had been set up. The pumps used are of every variety, from Cornish patterns to steam ejectors.

The explosive used is chiefly powder; but in many of the lodes narrow slate bands, or very tightly bound, dynamite is used. Formerly, English dynamite and powder were exclusively used, but local factories now supply both these requisites at fair rates and of good quality. The drilling is entirely two-handle, and the system of single-hand drills never succeeded in establishing itself here. Machine drills are but little used, and the narrow inclined workings which necessarily characterize our gold mines almost forbid their application except for driving levels, etc. They will, however, be found economical when attention is turned to the broad belts of banded slate quartzite which are met in many of the districts, and offer an abundant supply of low-grade ores. The cost of extracting a ton of ore varies between wide limits. In the narrow veins, it frequently costs as high as $15 per ton of 2000 lbs., while in veins three feet wide and upward, it is raised for $1.50 a ton, and in slate bands from three to ten feet wide, the cost has been known not to exceed 95 cents; the wages of miners being $1.25, and of laborers 90 cents to a dollar a day.

Milling.—The quartzite from the mine is passed directly to the stampmill. At the commencement of gold mining here, attempts were made to roast the ores before they were stamped; but as the ordinary circular open kilns were used, with wood for fuel, the heat was not more than sufficient to drive off part of the sulphur in combination with the iron, and to coat the free gold with arsenic from the almost omnipresent mispickel, and they were abandoned. The fineness to which the quartz is crushed varies in different mills, from a size passing through a mesh of 150 holes to the square inch, down to one of 400 holes. The following estimate of the cost of crushing is from actual performance, and a mill of ten stamps driven by steam-power, which is also utilized for driving a small pump:

Quartz crushed to pass through finest Twilled Wire Cloth.

Wood 2⅛ cords at 75 cents	$1.57
One man by day, to fire and feed batteries, at	1.50
One man by night at	1.50
One man by night at	1.25
Chemicals and oil	.50
Wear and tear	.75
Total	$7.07
Quartz crushed in 21 hours, 8 tons.	
Cost per ton	$0,88⅜

The above is for quartz alone; when, as is frequently the case, slate is crushed with the quartz, the cost per ton would be materially reduced. At the Ophir mill, at Renfrew, some years ago, the cost per ton for quartz was 60 cents per ton crushing at the rate of 600 tons per month.

In some mills, the use of plates in the "batteries" is not adopted, but mercury is added at regular intervals to the ore undergoing pulverization; the resulting amalgam accumulates around the circular dies on which the stamps fall, and is taken out at the week's end. The use of mercury traps and blankets is not as general as it might be. As the gold is generally coarse, much of it is retained in the batteries, and the loss is in the fine gold not caught by the plates. Excluding the gold found in a state of minute subdivision in the sulphurets, the mills as a rule do not extract over 75 per cent. of the gold. The causes of this are the casing of the gold by grease from lamps, dynamite, etc., and the powdered silicates of alumina, which form an unctuous slime, as well as the vibratory motion of the stamps, inducing a crystalline condition of the gold unfavorable to amalgamation, in addition to the flouring of the gold by the stamping, so that it floats too rapidly over the plates to permit of its being caught by the mercury. No process has yet been found equal to the task of recovering the gold thus lost. As already stated, considerable quantities of arsenical pyrites and sulphurets of iron, lead, and copper are found in the veins, usually in close connection with the gold. The percentage present of these minerals varies very much. Some veins and the incasing rocks are heavily loaded with them up to a proportion, as high as 60 per cent.; while in other veins, equally auriferous, the quantity will not exceed one per cent. The average amount may be estimated at not less than 5 per cent. They are presented as scattered crystals, as films in the bands of the veins, and as irregular masses or pockets frequently connected by threads. As an almost universal rule, they contain gold. A marked exception has been noted at Mount Uniacke, where a number of small veins containing large amounts of mispickel yielded but mere traces of gold and silver. Beautiful specimens of gold are frequently secured by treating nodules of pyrites with acid, which presents the metal in curiously interlaced plates and films, when by a previous examination no gold could be detected. As yet, the treatment of these pyrites has been of the most superficial character; they are passed through the mills together with the quartz, and allowed to run away with the tailings. The following assays of these ores, freed from quartz, will show their value:

Locality.	*Area.*	*Ore.*	*Yield per ton of 2000 lbs.* Gold.			Silver.		
			Oz.	*Dwt.*	*Gr.*	*Oz.*	*Dwt.*	*Gr.*
Mine Harbor	Provincial Co.	Arsenical pyrites	11	8	16	.	.	.
Sherbrooke	Boulder area.	Arsenical pyrites and galena	4	1	16	8	19	10
"	Coburg "	Arsenical pyrites	1	12	15	6	10	16
"	Canada Co.	Mispickel and iron pyrites	45	0	0	.	.	.
"	Meridian Co.	Mispickel and iron pyrites	1	12	16	9	0	0
Montagu	O'Connor area	Mispickel and iron pyrites	12	12	22	1	0	0
"	Belt lode	Mispicket	100	0	0	.	.	.
Ovens	McCulloch lot	Mispickel and iron pyrites	242	16	10	16	5	0

These results are confirmed by the assays of the same ores from various districts made by the writer, who, on several occasions, has found nickel and cobalt present up to 2 per cent. The following assays of pyrites which have been concentrated from tailings show the inadequacy of the ordinary process of stamping to extract the gold from them:

District.	*Area.*	*Yield per ton of 2000 lbs.* Gold.			Silver.		
		Oz.	*Dwt.*	*Gr.*	*Oz.*	*Dwt.*	*Gr.*
Tangier	New York Co.	6	5	0	2	4	0
"	Leary lode	4	14	4	. . .	. . .	. . .
Waverley	. . . . . .	6	14	1	0	10	0
Sherbrooke	Average lots	2	10	0	. . .	. . .	. . .

The following table shows the assay values of several samples of tailings and pyrites taken from waste-heaps not concentrated, showing that much pure gold is lost in addition to that carried away by the various pyrites, as already alluded to:

District.	Area.	Ore.	Yield per ton of 2000 lbs. Gold.			Silver.		
			Oz.	Dwt.	Gr.	Oz.	Dwt.	Gr.
Waverley	. . . .	Tailinge	0 oz. 7 dwt. 4 gr.					
"	Barrel quartz.	"		15	0			. . .
Montagu.	Belt mill	"		16	13			. . .
"		Tailings natural concentration.	3	0	0			. . .

It would seem that no regular system of assays of the values of the ore and pyrites before and after milling has ever been carried out here. A few such experiments would afford valuable data to replace the empirical and haphazard method of treating the ores too frequently seen among our miners. At Montagu, a Frue vanner has been erected to treat the tailings of that district, which are said to yield pyrites averaging $60 to the ton. It is yet too soon to speak of its practical working; but should it equal the expectations of the builder, there is a good field for this work, as about 412,700 tons have been crushed since gold mining began here. Nova Scotia gold, like that of other countries, is an alloy, of which silver forms the chief impurity. As a rule, it is of a high degree of fineness. The following analyses represent the character of the bullion:

Locality.	Authority.	Composition.				Total.
		Gold	Silver	Copper.	Zinc.	
Mooseland	O. C. Marsh	98.13	1.76	0.05	. . .	99.94
Tangier, Field lode	B. Silliman, ...	97.25	2.75	. . .	. . .	100.00
" Leary "	U. S. Assay Office .	96.60	. . .	. . .	. . .	. . . .
Waverley	H. Howe	94.69	4.74	0.39	0.16	99.98
Ovens	A. Gesner	93.06	6.60	0.09	. . .	99.75

Doubtless, the chief attention of the miners here, who as a rule, possess little capital, will continue to be directed to the small rich veins yielding quick returns, and it is to be regretted that as a rule their operations are confined to working out the more accessible parts of the pay-streaks, and no systematic scheme of work is attempted. It is anticipated, however, that in the future the greatest reliance will be placed on the low grade ores. There are numerous belts known to contain many thousands of tons of quartz and slate, yielding by mill test up to seven pennyweights (6-70 dollars) of gold to the ton. From the costs of extraction and milling already given, it will be seen that in many cases these ores would yield good returns if worked on a fairly large and careful system. This experiment is now practically being testing in the Sherbrooke District by parties who propose adopting the usual treatment in stamp mills to secure the coarse gold, and a systematic concentration of the trailings which will yield considerable quanties of arsenical and other pyrites. These would find a ready sale at the reduction-works of the Eastern States, and form an important item in the returns.

The gold is held by the provincial government, which grants areas of 250 by 150 feet for a term of twenty-one years, with option of removal, for a fee of two dollars, and a royalty of two per cent. on the gross value of the smelted gold produced, which is valued at nineteen dollars an ounce (from 20 to 60 cents less than its market value). The royalty is collected from the mill owners, who are obliged to give bonds, and make sworn returns of the quartz crushed and the yield of gold.

Nova Scotia Gold-Fields—General Annual Summary.

Year.	*Total ounces of gold extracted.*			*Stuff crushed.*	*Yield per ton of 200 lbs.*			*Total days labor.*	*Average earnings per man per day and year of 300 days at 18 dollars per oz.*

Total	321,362	18	7	422,741	. . . .			3,157,391	. .	. .

It is computed that about 8000 ounces were produced before that date, which would make the total amount to the present date about 330,000 ounces. In addition to the amount legitimately mined and crushed, there is reason to believe that in every district a very considerable quantity is stolen by the miners, theft being assisted by the common occurrences of the gold in small nuggets or "sights" in the quartz. Much of the richest quartz from numerous veins worked by two or three men is known to be reduced in hand-mortars, and the resulting gold is surreptitiously sold, so that the returns made to the department of mines may be considered as by no means fully representing the amount of gold extracted.

The tables also show the number of mills, which it may be remarked, work only at intervals; also the number of days' labor performed at mining, prospecting, and surface work, from which it would appear that business, although small, is fairly remunerative. From the foregoing remarks, it will be seen that the area containing gold is very large, and that the little work that has hitherto been performed has shown that there are numerous lodes that have yielded good returns. The district as yet has not shown the extensive alluvial deposits characterizing those countries which have become famous for their production of gold, and the future development will, so far as can be judged at present, be due to more extensive working of the veins. The district affords good openings for men having capital and experience, and as a rule such men have done well. Companies have done equally well whenever their operations have been controlled by competent agents, who have learned to work on the systems experience has shown best adapted to the country, and have not maintained the rules of mining learned in wide lodes, etc. When cheapness of labor, the abundance of water-power, a favorable climate, and the accessibility of the district are considered, it may be fairly anticipated that gradually the attention of miners and capitalists will be turned to Nova Scotia gold-fields: and that with improved methods of treatment and accumulation of experience in detecting and following the richer deposits, this industry will become a leading one in the province.

—Compiled from a paper by Edward Gilpen, Inspector of Mines, read before the North of England Institute of Mining and Mechanical Engineers.

RARE MINERALS OF CALIFORNIA.

PROF. WM. P. BLAKE has contributed the following paper to the Mining Bureau of the State of California.

New Mineral Localities.—*Erythyrite:* Cobalt Bloom.—In minute mammillary incrustations, showing, when broken, radial aggregations of silky, fibrous crystals. Color: deep carmine or rosy red, also, peach blossom red. Streak, the same color, but blue after the mineral has been heated. It gives the usual reactions for cobalt, arsenic and water. Occurs, also, in massive earthy aggregations, of small fibrous crystals of a rose-pink color. It was associated with an ore of silver and cobalt in dark colored earthy masses, a mechanical mixture, assaying at the rate of 5,000 to 6,000 ounces of silver to the ton, but the precise nature of which is not yet ascertained, in a gangue of heavy spar, containing, also, nodular masses of chalcopyrite (yellow copper ore). From the Bernardino range, Southern California. This is believed to be the first observation of the occurrence of this species in the United States.

Rubellite—Rose-colored Tourmaline.—This very interesting mineral is now observed for the first time in California, in the form of long tender crystals from one sixteenth to one-eighth of an inch in transverse diameter, with the usual triangular section. Color, a beautiful rose pink, contrasting well with matrix of white lepidolite. When ignited the color disappears and the mineral becomes perfectly white. Infusible. Locality, Bernardino range Southern California.

Lepidolite—occurs with the above in massive aggregations of minute pearly scales, both colorless and purple-red in color. It is traversed by the crystals of tourmaline. It fuses readily to a white enamel and colors the flames next to the assay a dark crimson-red for a moment.

Cassiterite—"Wood Tin."—A single specimen of wood-tin, a segment of a botryoidal mass, with concentric structure and dark brown in color, was found by Mr. Thomas Lane, of Laporte, in the bed of the middle fork of the Feather river, about three miles above Big Bar, Plumas County. The mass is about five-eighths of an inch in diameter, and closely resembles the wood-tin brought from Durango, Mexico, and that found in Idaho. The attention of Placer miners should be directed to this, as other fragments may be found in cleaning up sluices, and thus lead to the discovery of the source of this valuable ore of tin.

Bornite—Variegated Copper Ore.—This beautiful ore copper is found upon the claim of Mr. A. J. Ford, at Light's Canyon, Plumas County, in a vein affording massive specimens three inches or more thick. In the same region there are veins of yellow copper ore and of massive Hematite.

Section from Merced to Coulterville and Big Oak Flat.—From Merced station upon the Southern Pacific railroad, the line of section described in this contribution extends in a northeasterly direction, nearly transverse to the line of strike of some of the most interesting gold-bearing rocks of the Sierra Nevada. Merced is situated upon the alluvial plains of the San Joaquin. The level and clay soil, noted for its fertility and adaptation to cereals, extends without change to the Six-mile house, where gravel begins to show itself and the soil is poorer and more arid. Another six miles over a gentle rolling gravelly plain brings us to the banks of the Merced. Crossing by ferry to the right bank, we travel along the broad and rich bottom lands to Snellings and Merced Falls, passing plantations of India corn and cotton.

At Merced Falls, the first outcrop of the older rocks is observed. It is a hard bar of compact black clay slate, like roofing slate, very uniform in texture, in broad flat plates, standing vertically on edge, trending in remarkably straight lines northwest and southeast. This hard outcrop forms a natural dam, upon which the rapidly flowing water of the Merced has made but little impression. There is a fine water power at all seasons, which is partially utilized by a woolen mill. We here leave the river and ascend the hills to the northeast. The black slates carry numerous veins of white quartz which have not been much prospected. A few miles beyond the falls, the surface rises rapidly, and the slates give way to harder rocks. These are light bluish-green in color, weathering in places almost white. They are evidently of sedimentary origin, though much altered and changed from their original condition. They form the outlying belt of a series of heavily bedded conglomerates, sandstones, and shales, which, being harder and less susceptible to erosion than the slates, form the high hills and ridges. These elevations trend northwest and southeast, and are probably the northwestern extension of the Mount Oso range, which traverses a large portion of Mariposa County, and forms the western wall of Bear Valley, on the Mariposa estate. The heavy and bold outcrops of the massive conglomerates composing this range are not readily recognized as conglomerates. Their composite character is obscure. Generally it is scarcely possible to recognize that the rock is made up of rounded boulder-like masses. The boulders which form these rocks are so much compressed, welded, and united in one apparently homogeneous plasma, that the dividing lines and contact surfaces are obliterated, and cannot be seen except upon surfaces that have been weathered, and sometimes upon broad surfaces of fracture. Occasionally, where the metamorphic action has not been as strong as in other places, the original forms of the boulders can be made out, and the masses stand out from the general surface. In decomposing, these old conglomerates reveal their origin by yielding a vast amount of hard boulder-like masses, elongated and lens-shaped spheroids, which are utilized for fencing. These rocks are generally known and described as "greenstone," the color being light bluish-green, and the mineral composition of the boulders being like the green stones. They offer a very interesting subject of study to the lithologist and to the student of dynamical geology. They border on each side the belts of slates in which most of the quartz veins are found and have, next to the granites, best withstood the denuding and wearing forces of the elements, and thus have to a great extent determined the topography of the Piedmont region of the Sierra Nevada. Upon the line of the section herein described, such conglomerates occur in a number of parallel outcrops with slaty rocks between and belts of sandstone, the exact succession of which cannot be determined without painstaking investigation. The whole series occupies a breadth of about twenty miles between the slates of Merced Falls and the similar slates of Coulterville Valley. It includes at least two bodies of well-defined pebbly conglomerates, in which the pebbles are small—not much larger than beans. These conglomerate beds lie parallel with bodies of argillaceous slate, and clearly demonstrate a succession of deposits formed in alternating deep and shallow waters. Approaching Coulterville we descend the hills of greenstone conglomerate and pass suddenly upon the black slates of the valley. They greatly resemble the outcrops at Merced Falls, and probably are a repetition of that series. Here, however, they are especially interesting, as the matrix of the two chief lines of gold-bearing veins in California, the so-called "mother lode" of the State. In this valley, as also upon the Mariposas and farther north, there are two nearly parallel lodes of great size, the croppings of which are so bold and prominent, crowning the hills, as to be visible for miles. The western lode rises between walls of black slate, and carries films and sheets of the slates in its mass, giving to it a more or less stratified form and a striped appearance when seen in cross sections, or as it stands in the mines. Such quartz is technically known as ribbon quartz, and is a great favorite with quartz miners. In the mother lode proper, a short distance farther east, the quartz is more massive and solid, and is in close proximity to a belt of serpentine, and for a great part of its course follows and penetrates a stratum of magnesian rock, referable to ankerite and magnesite. It is characterized by rusty outcrops and an abundance of a foliated, bright green mineral to which the name "Mariposite" has been given. It appears to owe its green color to chromium and iron rather than to copper or nickel. The quartz penetrates this magnesian rock so thoroughly as to form in many places a complete network of veins branching off from the chief body. Beyond the veins and magnesian belt the slates are seen again for a short distance, and are succeeded by greenstone conglomerates. Beyond these, on the road to Big Oak Flat, there is a heavy body of syenite forming a hilly region traversed by the road for ten miles north and east to Priest's, on the Yosemite road. From Priest's, westward, there is a region of massive, hard black slates, which appear to belong to the series of formations in which the limestone belt of Sonora and the Hite group of veins occur. I regard them as older than the mother lode series of slates, and believe that they belong to the period of the carboniferous; the reasons in part for this belief being their stratigraphical relations to other formations and the abundance of carbonaceous matter which they contain.

The mother lode slates have been shown to correspond in age to the jurassic period. I am inclined to refer the greenstone conglomerate series to the trias. The whole series of formations embraced in the section give satisfactory evidences of extensive plication and subsequent erosion. The dips are generally eastward and at a high angle.

Coulterville to Chinese Camp.—Leaving for the present a notice in detail of the mother vein, we follow its course approximately to Chinese Camp, near Sonora, in Tuolumne county. Crossing the line of the great vein at Coulterville, the road leads for a short distance over an outcrop of the heavy greenstone conglomerate, bordering the slates on the west. From that point to Priest's hotel, on the Yosemite road, a distance of ten miles, the rock formations are entirely different from those of the valley, being granite and syenite. The hills rise higher and the topography changes. The altitude at Coulterville is about 1,700 feet, and the road, upon the granite formation, is about 2,500 feet. Priest's is between 2,300 and 2,400 feet in altitude. The hills are but sparsely timbered and generally are wholly covered by a dense growth of chemisal. When this is in blossom, it never fails to remind one of the heather-covered downs of England, although it is comparatively gigantic in growth. These high hills, which have been generally regarded as barren and worthless, are now being sought for and utilized for grain-growing and vineyards. Wherever water can be distributed over the surface, the granite soil yields excellent crops of wheat. The vine takes kindly also to this soil and particularly where there is an excess of iron oxide, giving a red color to the earth. Probably the greenstone conglomerate hills are better than the granite. It is said that wherever the vines get well started they do not afterwards require irrigation. The fact that these hills can be covered with vineyards is extremely important as greatly extending the area of the vine-producing region of the State. About midway between the points mentioned, the syenitic granite gives way for a short distance to a thin belt of gneissic rock and a metamorphic slate. These formations are bordered by felsites, which, in decomposing, have formed banks and layers of kaolin, cut through by the graded road. Near Priest's some gold-bearing quartz seams, or veins, have been found traversing the granite. These probably hold about the same relation to the veins of the slate belt as the veins in the granite at West Point, farther north, do to the veins in the slates of Amador county. At Priest's we pass upon another and heavier belt of slaty rocks, which are more massive, harder, and appear older than the jurassic slates of Coulterville. This formation extends east and southeast from this point, and is probably the same body of hard black slates reaching southeast to Hite's Cove and beyond, carrying the celebrated Hite vein and others. These slates are regularly stratified, and appear to be traversed by dykes of trap or greenstone.

From Priest's to the Tuolumne river at Stephen's Bar the road leads in a northwesterly direction. The granite and syenite appear to thin out, for directly after leaving Priest's the greenstone conglomerate takes its place. The road descends rapidly between high chemisal covered hills, underlaid by the conglomerates, to Culbertson's in the valley, only a mile west of Priest's, and 1,300 feet lower. At this point we are again upon the mother lode formation, and follow it down Moccasin creek to the Tuolumne. Looking back toward Coulterville, the view is interrupted by the Peak of Penyon Blanco, the crest of which is formed by the massive blocks of white quartz of the mother vein. About Culbertson's the vein is split up, and does not come boldly to the surface. Lower down the valley it appears in the foothills on the right bank, and on the left bank there are heavy outcrops of serpentine, extending nearly to the Tuolumne, where the slates are found largely developed. The mouth of Moccasin creek is only about 700 feet above tide. Running parallel as it does with the great vein for several miles, it might be expected to be rich in gold, which was the fact. It has been worked and reworked with profit, but now the gravelly bed is being leveled, and vineyards and orchards cover its surface and give a perpetual bonanza to the appreciative sons of Italy. The wonder is that more of our American young men and women do not avail of the many opportunities to make charming and profitable homes in the forsaken gold fields of California.

We cross the river in a boat and follow the left bank for about two miles to Jacksonville, noted years ago for its figs and oranges. The general direction of the river corresponds with the strike of the formations, but it soon turns abruptly to the west and cuts across the slates and sandstones of the chief gold belt. Conglomerates and outcrops of serpentine with traces of the mother lode are also found; and these rocks continue, with a regular northwest trend, to Chinese Camp, eight miles southeast of Sonora. This place is situated in an open, gently rolling country, at an altitude of about 1,300 feet. Surface gold washings were very extensive in this vicinity, and sustained a large population of miners for many years, but the diggings are now overgrown with grass, and many of the once well-filled stores are vacant.

Chinese Camp to Sonora.—In my last communication the course of the lode was followed from Coulterville to Chinese Camp, and it was shown that for most of the distance northwest of Penyon Blanco the lode does not crop out strongly, and appears at intervals only. The formations, however, continue unchanged, and the line of the lode is east of Chinese Camp. Leaving Chinese camp, and passing northeastward at right angles to the strike of the rocks, we first cross the eroded outcrops of the conglomerates, and then over a belt of slates standing on edge, but presenting an almost flat surface, greatly resembling the outcrops at Merced Falls. This smooth, and apparent planed-off outcrop is in strong contrast with the sharply serrated edges of the slates standing above the soil like tombstones, generally known among the miners as "grave-stone slates." The difference of surface is very likely due to a difference of internal grain; the absence of the elongated structure made by pulling or stretching the strata during the period of plication, to which we may refer the sharp ellipsoidal outcrops of the slates in a great part of the gold region. Beyond these outcrops, north and west, there is a belt of greenstone conglomerate, succeeded by serpentine; apparently the prolongation of the serpentine belt traced northwestward from Coulterville and along the Tuolumne. Pliocene gravel also makes its appearance in remnants of a tableland formation; and a short distance beyond, the lava-capped beds of Table Mountain bound the view from north to west.

Thinly-bedded clay slates come to the surface east of the serpentine, and continue up to the outcrop of the mother lode, about one mile west of Jamestown. The lode of this place crops strongly, and forms the crest of a ridge, upon the flanks of which there are heavy deposits of quartz gravel, evidently derived from the disintegration of the vein. The many pits and trenches in this gravel clearly indicate its valuable auriferous character, and at the same time, show that the vein is not a mere barren outcrop of quartz. The vein is accompanied by many branches and veinlets penetrating the adjoining slates in various directions. It follows the formation and trends northwest towards Table Mountain, under which it disappears. It would be interesting to ascertain what the fineness of the Table Mountain gold is, compared with the fineness of the gold from the vein. There can be little doubt that the Table Mountain deposit was greatly enriched below the mother vein by the gold broken from its croppings upon the banks and in the bed of the ancient river, along which the deposits and lava overflow of the present mountain were formed.

The lode is in the midst of the clay-slate formation which extends to and beyond Jamestown. East of this place the slates become harder, more massive, and are traversed occasionally by quartz veins. All the formations trend toward Table Mountain, and are there covered from view. As the slates become harder, the surface of the country rises from 1,400 feet elevation at Jamestown to nearly 1,800 feet at Sonora. This may be due in part to a very hard dyke of dioritic rock just west of the town. Sonora is built upon hard, massive black slates, resembling those beyond Priest's, and at the Hite mine, belonging, I believe, to the most eastern belt of slates of the Sierra; these black argillaceous slates are firm and hard enough to be quarried for building purposes. They are gold-bearing, and at the present time, there is a most notable development of a vein within the town limits, from which fabulous amounts of gold are taken by two men, the metal being so abundant that but little crushing in a hand mortar is required to free it from quartz.

The limestones at Sonora, bordering the slate formations on the east, constitute one of the most interesting geological formations of the State. They are here developed over a considerable area and stretch for many miles to the northwest, to Columbia, Shaw's Flat, Murphy's and beyond; and southeastward it is believed to reach to Hite's Cove and beyond it, though I have not traced them in that direction. In a section which I shall hereafter give, from Mariposa to Hite's Cove, I shall show the similarity of the formations; that there are several distinct strata, or beds, and that some of them abound in fossil encrinites. The Sonora outcrops have failed, so far as I know, to give any evidence by fossils of their age or place in the geological scale. There is no doubt, however, of their deep-sea marine origin. They show distinct stratification and alternate layers of gray, white, and blue color. The stratification is nearly vertical and the beds being of differing degrees of solubility now present a very extraordinary and uneven surface, especially where in the flats and valleys they were covered with alluvial gravels and clays. In such places, notably in Columbia and Shaw's Flat, the outcrop consists of a succession of sharp, irregular bodies of limestone, separated by deep, fissure-like chasms. The masses, in many instances, seem like loose boulders, and where the soil and gravel were removed by mining, they toppled over. Such a surface proved to be wonderfully retentive of placer gold, and the harvest from this strangely irregular surface of limestone was very great. Miners have worked the crevices to great depth, and there is reason to believe that the bottom of many of the chasms has never been reached. A similar formation occurs in the Ural mountains, and was described by Sir Roderick Murchison. A reference to this and a more complete notice of the Sonora deposits, with figures, will be found in my report to the United States Government in 1853 to 1855. The cause of the uneven surface is not as generally supposed, mechanical wearing away, or erosion, but is chiefly chemical. It is due to the solvent action of carbonated water percolating through the soil or standing in the undrained and swamp-like flats. As the rock was dissolved the gravel and gold sank down into the cavities and crevices far below the surface upon which they were originally laid down.

At the time of my first visit, in 1854, the whole limestone belt was populous with miners, and many relics of the Pliocene age were brought to light and were often lost to history and science. These for the most part consisted of teeth of elephants, the mammoths, and of the mastodons of primeval days, when they roamed through the forests and glades of California with the tapir and hipparion. Whether the progenitors of the modern Digger Indians were "there to see" is still an open question, though some cracked skulls are thought to bear evidence on this part.

The late Dr. Snell, of Sonora, was an enthusiastic collector of aboriginal stone implements and relics which have been peculiarly abundant about Table Mountain, and were supposed by the doctor to be of great age, even antedating the lava flow. This, however, is very doubtful. As the subject is very interesting, and the facts are important in the discussion of the antiquity of man upon the globe, I propose to make them the basis of a second paper. Since the death of Dr. Snell, his collection appears to have been scattered. I did not find in Sonora any one who could give me an account of it. Casts of soms of the specimens have been sent to the Smithsonian Institute; and the doctor presented me with a collection of specimens some years before his death. At the same time, I made exact drawings of some of the more important pieces.

Occurrence of Vanadates of Lead at the Castle Dome Mines.—The occurrence of the rare metal *vanadinite* at the Castle Dome mines is sufficiently interesting to receive a special notice in this series, although the locality is just beyond the line of the State, across the Colorado river, and in the Castle Dome district, Arizona. Vanadinite, which occurs in considerable abundance in the claim known as the "Railroad," is a rare mineral, and has not hitherto been found in the United States, if we except some minute microscopic crystals mixed with Wulfenite found in the ores of the Wheatley mines, at Phœnixville, Pennsylvania, and referred to the species Descloizite, also a vanadate of lead. The vanadinite occurs in groups of hexagonal prismatic crystals with curved sides, tapering at each end, and closely resembling pyromorphite in form and grouping. These crystals are rarely over one-sixteenth of an inch in diameter, being generally half that size and less than three-sixteenths long. They are in confused aggregations, forming crusts and filling cavities in the decomposing ores of lead, and also on fluor-spar. Some of the crystals are cavernous, presenting the appearance often seen in phosphate of lead. One side of a crust of crystals is often in distinct hexagonal crystals, and the other consists of an aggregation of minute crystals grouped in arborescent forms, and differing in color from the coarser crystals. The larger crystals are generally light-brown in color, with a bronzy luster. The smaller crystals are lighter, and are of various shades of orange-yellow, becoming in places nearly white with a silvery wax-like luster, due possibly to a pellicle of some other mineral covering the surface. The yellowish brown crystals have a wax-like appearance and luster. The difference in appearance in the crystalline crusts, their difference of aggregation and color, suggest the probability of several species. It is possible that Dechenite, Descloizite and Mimetite are represented; also Eusynchite. The behavior with nitric acid is different, some crystals showing a distinct separation of red vanadic acid, and others giving but a slight reaction. The Wulfenite crystals in association are extremely brilliant and light-yellow in color, presenting a beautiful appearance upon a background of green fluor-spar, or white crystalline carbonate of lead. There is great need of investigation of the composition of the many varieties of yellow, red, and brown crystals from Castle Dome and silver district, now usually referred to Wulfenite, though it is probable that several species are represented.

The Castle Dome vanadinite is totally different in appearance from the red crystals of Silver district. At Castle Dome the vanadium appears to be present in varying proportions in the crystals of different appearance, though all hexagonal, and to be associated with arsenic acid in the mineral species, Mimetite.

Some of the specimens giving strong arsenical odors on coal and having the external characters of mimetite or arsenate of lead, give also characteristic reactions for vanadic acid though not to the same degree, or so distinctly as other crystals where the arsenical reactions are weaker. The strongest reactions for arsenic, so far obtained, are from the crusts of small aggregated crystals of a light brown or straw-yellow color and wax-like luster. The deportment with nitric acid varies, but all the varieties disolve and give finally yellow solutions, which become green and blue where deoxidized by organic acids or alcohol, The occurrence of vanadic acid in mimetite is not unknown, Domeyko having found it in mimetite from Mina Grande, Chile. In all of the specimens so far examined, whether the light yellow, barrel-shaped crystals, or the long, tapering, hexagonal prisms, or the dendritic aggregates, reactions for chlorine are obtained, and the yellow nitric solutions become green by heating with alcohol. It is interesting to note here that recent researches by M. Bertrand go to show that the hexagonal crystals of mimetite are compound crystals, made up by twining of orthorombic crystals. This has been shown by the study of the optical characters. While pyromorphite is truly hexagonal, showing only one axis of symmetrical polarization, mimetite was found to have two optic axes. It is possible that we may find crystals large enough from Castle Dome or Silver district to examine with the polariscope, and ascertain whether they are in reality compounded or single.

Vanadinite also occurs in beautiful crimson red crystals in the Hamburg mine at Silver district. These crystals are small, but are beautifully distinct hexagonal prisms or "berylloids," being similarly shaped, and are terminated by a flat plane at right angles with the planes of the prism. The terminal edges are replaced by a minute brilliant plane, and in one or two of the crystals a plane replacing one of the solid angles has been observed. The material at hand is insufficient to give me the best specimens for examination by the goniometer, so as to accurately measure the inclination of these terminal planes to the base or sides. I have, however, mounted one of the minute crystals in hand, and the angles of the prism apparently equal, so there is little doubt of its truly hexagonal form. The seemingly partial termination or modification of the terminal edges in some crystals raised the question whether, though apparently hexagonal, the true form might not be rhombic. The streak or powder of this mineral is salmon-colored or orange red. It dissolves completely in dilute nitric acid, but in strong nitric acid, if added in small quantities, there is a separation of a red powder, which floats off in the acid and is then dissolved, giving a yellow solution, which, after standing some hours, becomes green. It is also turned green in a few moments by the addition of a small quantity of alcohol, and this green solution, on boiling, turns blue. These reactions are characteristic of vanadic acid. With microcosmic salt in the outer blowpipe flame, we obtain a yellowish green glass, which in the reducing flame is changed to an emerald green when cold. With borax in the outer flame an olive brown bead results. Strong reactions for chlorine are obtained by the silver test. Some of the crystals are light amber colored and are transparent, and some of them are much darker in color near the terminal plane than at the foot of the prism where it adheres to the gangue.

In the Red Cloud mine at Silver district and likewise at the Silver Glance mine numerous fine specimens of tabular crystal of Wulfenite have been procured from time to time for the past two years. These crystals are often half an inch across, and are from one sixteenth to one eighth of an inch thick. The chief peculiarity is their fine red color, very different from that of ordinary molybdate of lead and contrasting strongly with the yellow Wulfenite crystals from the same localities, and from those also of Castle Dome. These red crystals I provisionally refer to the vanadiferous variety of Wulfenite. A complete analysis is, however, needed to show the composition of this and other allied varieties found in other claims at Silver district, notably at the mines opened by Bamber & Sons—"The Oakland Boys' claim." The first red crystals of Wulfenite observed in the United States were extremely small, being almost microscopic, and were implanted on the ores from the Wheatley mine, at Phœnixville, Pennsylvania. They were found by the writer, and the red color was at first supposed to be due to chromic acid, but when the mineral was procured in quantity sufficient for analysis, Professor J. Lawrence Smith showed that the red color was due to the presence of vanadic acid. The Silver district specimens now afford sufficient material to permit of a quantitative determination of the constituents.

Beautiful octahedral crystals, of a reddish-brown color, are obtained at the Oakland Boy's claim. I regard these as another vanadic mineral, possibly a vanadic variety of Wulfenite; though the form and the color are so different from the form and color of undoubted Wulfenite in the district, I am inclined to regard it as a distinct species, or, at least, a well characterized variety. I am indebted to Mr. William P. Miller, the general superintendent of the Castle Dome mines and the smelting works at Melrose, for assistance in procuring some of the specimens which I have been describing. Some were obtained by me at the mines, April, 1880, and others at the time of my last visit to the mines in 1881.

INTERESTING STATISTICS FROM FOREIGN COUNTRIES.

IN Part III we have thought it advisable to introduce certain statistics from foreign countries; that while not properly belonging to the mining interests of the United States are still of deep interest and necessary to know. We begin the compilation with tables on the foreign iron trade, from the admirable report of Mr. James M. Swank, Secretary of the American Iron and Steel Association, a gatherer of statistics, who can always be relied upon.

General Summary for 1881 and 1882.—In our Annual Report which was published in the summer of 1881 the statement was made that the foreign iron and steel industries had been generally prosperous since the latter part of the year 1879, when the influence of the revival of American prosperity began to be felt abroad. This favorable condition continued, although in a modified degree, throughout the whole of the year 1881, which, as has already been stated, was also a year of great prosperity in the iron and steel industries of our own country. Without a single important exception every European country produced more iron and steel in 1881 than any preceding year, while prices were in the main satisfactory to producers. They were not, however, so high as in 1880. The production of British iron and steel in 1881 was enormous, and exports were well maintained all through the year, the latter being slightly in excess of the extraordinary exports of 1880. Among Continental countries France, Germany, Belgium, Austria, and Sweden could boast of active and prosperous iron and steel industries in 1881. The iron and steel manufacturers of France especially enjoyed a very prosperous year. It is an interesting coincidence that in many European countries—France, Germany, and Austria particularly—the increased demand for iron and steel in 1881 was largely due to the same activity in railway building which prevailed in that year in our own country. Iron and steel rails and railway rolling stock were required in larger quantities in these countries in that year than in any preceding year since 1872 and 1873. During the first five months of the present year these requirements were continued without serious abatement. Naturally the stimulus imparted to general business by the activity in railway building extended to other forms of iron and steel than those mentioned.

While we are without positive information concerning the probability of continued activity in the building of Continental railways, various other circumstances, already developed, point to the conclusion that the European iron and steel industries will not as a whole be so actively employed in 1882 as they were in 1881. The most important of these already developed circumstances will readily occur to the reader. The decline in the American demand for foreign iron and steel unfavorably affects all foreign markets, but it particularly affects the British iron market, compelling British ironmasters to lower their prices, and leading them to more sharply and severely compete with native manufacturers in the supply of the Continental markets. We obtain a hint how severe this competition may be from a remark recently made by the English metallurgical authority, *Iron*, in referring to the influence of the Protective policy in Germany. It said: "The Protective tariff which Germany adopted in 1879 is unable to check the steady importation of English pig if that description of metal is low enough in the English market to bear the import duty and thus to make its importation into Germany profitable." As the German duty on pig iron is only $2.50 per ton, our American readers will see that British pig iron at its present low prices is altogether likely to find its way into German markets in large quantities, or else it will so depress the price of German pig iron that its manufacture can not be profitable. The plain truth is that the German tariff, although nominally protective, is really too low to afford sufficient protection to German iron and steel manufacturers whenever their British rivals find it necessary to enter German markets. Some other Continental countries do not have even so highly protective duties as Germany. British ironmasters, therefore, lacking the large American demand this year to which they have for two or three years been accustomed, will crowd their products on Continental purchasers, to the injury of native manufacturers. Even France, by its new duties, is not free from the influence of British competition. The general adoption of the Protective policy on the Continent has, of course done much to develop Continental industries, but duties are as a rule still too low to afford adequate protection in periods of great depression. In many Continental countries they too much resemble the duties imposed by American statesmen upon foreign commodities in the early years of our history, which for purposes of protection were more ornamental than useful.

The action of France, in generally reducing duties on imports by the law of May 7, 1881, is a reactionary step which was certainly not expected from a country which has been so pronounced an advocate of Protective policy, and which has, as all the world knows and admits, been so greatly benefited by it. The education in the duties on certain forms of iron and steel is very marked, and this reduction has been emphasized by the conclusion of a new treaty with Belginm, whereby the duty on pig iron from that country has been still further reduced five francs per ton. The same rate of duty will apply to German pig iron, under "the most favored nation clause" in a treaty between the two countries. It will also, by the spontaneous act of the French Government, apply to British pig iron. The effect of the new duties on the French iron and steel industries can easily be conjectured. The French journal, *L'Ancre*, in a recent issue, thus describes it:

> What cannot be denied is that foreign competion causes home iron manufacturers to be constantly on the look-out, and that they are compelled to keep their eyes upon Germany, Belgium and England, and to follow the movements and the tendency of the markets of those countries. England and Luxemburg for pig iron, and Germany and Belgium for manufactured iron, become to some extent regulating markets which we must consult. The general position, for instance, of our foreign neighbors does not inspire apprehension of a reaction; nevertheless, we must not forget that competition has been made easier by the recent modifications of the customs tariffs. We may expect them to take part, and be sometimes even successful, in competitions for contracts given out both by the government and private firms.

France, therefore, in lowering her duties on iron and steel invites competition from all her neighbors—an experience to which she has not been much accustomed. It is entirely safe to predict that the new policy will not be well received by the great iron and steel interests of France, and it is, we think, equally safe to predict that it will not long continue to receive the approval of the French Government itself. The French iron and steel trades are now, however, very active. The most recent information we have received from other Continental countries represents a weakness in prices and some difficulty in securing orders in the Belgian iron markets; activity in the manufacture of Bessemer steel rails in Austria, but dullness in its finished iron markets; depression in the pig iron trade of Germany, in consequence of British competition, and a lack of animation in some other branches of its iron trade, but continued activity in its various steel works; and stagnation in the Swedish iron markets, relieved, however, by a decided improvement, originating a year or two ago, in the Bessemer and Siemens-Martin steel industries of the country. In the manufacture of locomotives, railway cars, and machinery generally Austria, Belgium and Germany are well employed, as is also France. Sweden is fortunate in having received numerous orders for iron and steel ships for Russia, Denmark and Norway. The iron trade of Russia does not prosper, but the manufacture of steel is supposed to be increasing. In the remaing Continental countries comparatively little iron or steel is ever made. The condition of the British iron trade in the early part of May was described by the London *Times* in a leading article from which we take the following extracts.

"The iron trade of the United Kingdom is in an anomalous condition at present, and much attention is, therefore being directed to this enormous industry. The year opened with a strong buoyant feeling, full of hope and expectation of a general expansion of our home and foreign iron industries, great stress being laid on the certainty of another 'boom' from America. As a consequence of that feeling consumers and merchants bought all kinds of iron freely and in large quantities in anticipation of the good time coming. Scotch pig iron warrants in the beginning of January were quoted 53s., Bessemer iron 65s., and Cleveland pig 43s. To-day the respective prices are 47s. 6d., Scotch, 52s. 6d., Bessemer, and 43s. Cleveland. It will be noticed that a serious fall in values has occurred in the two former, but the price of Cleveland remains the same. The present depression in iron and steel is undoubtedly traceable to the disappointment in the American demand.

Since the beginning of this year stocks of iron in Scotland have increased by about 25,000 tons. Stocks of Bessemer iron have also increased considerably. As a further indication of the demand having to a large extent been overtaken by supply, it may be stated that steel rails which were lately selling freely at £6 5s. can now be purchased at 15s. per ton less and manufactured iron is from 10s. to 15s. per ton cheaper than the highest point touched this year. The unprecedented demand for steam shipping alone remains as the prop of the great iron industries of the North of England. Her iron rail trade is a blank. But even in this important branch of trade we do not hear of the same number of new steamers being placed on the Tyne, Wear, and Teas, or on the Clyde, as there was at the opening of the year. It is evident that if shipbuilders do not get fresh work at the same rate as they launch vessels their order-book which has been so full will diminish, and bring about a change before long."

Since *The Times* gave these facts and opinions to the world the price of Bessemer steel rails has fallen in England to £4 15s. per ton. It is by constantly lowering her prices as occasion demands that Great Britain succeeds in sending such large quantities of her iron and steel products to other countries. Her manufacturers are first to see and to act upon any tendency to reaction from prosperous times. In this country manufacturers frequently insist on holding up prices when every sign indicates that the tide has turned.

Great Britain.—*Coal.* Great Britain's production of coal in 1881 was the largest in her history. According to the statistics of the Inspectors of Mines it amounted to 154,184,300 gross tons. In 1880 the production, according to Mr. Robert Hunt, Keeper of Mining Records, was 146,818,622 tons. The production of coal in each of these years was twice that of the United States. The production of coal in Great Britain from 1854 to 1880 is given as follows by Mr. Hunt, to which we add the figures of the Inspectors of Mines for 1881. (We may state here that Mr. Hunt is the official government statistician, but that his statistics do not usually appear annually until after the issue of our annual report.)

Years.	*Gross tons.*	*Years.*	*Gross tons.*	*Years.*	*Gross tons.*	*Years*	*Gross tons.*
1854	64,661,401	1861	84,013,941	1868	103,141,157	1875	131,867,109
1855	64,453,079	1862	81,638,338	1869	107,427,557	1876	13[illegible],344,765
1856	66,645,450	1863	86,292,215	1870	110,431,192	1877	134,910,763
1857	65,394,707	1864	92,787,873	1871	117,352,028	1878	132,607,866
1858	65,008,649	1865	98,150,687	1872	123,497,316	1879	134,008,228
1859	71,979,785	1866	101,630,544	1873	127,016,747	1880	146,818,622
1860	80,042,698	1867	104,500,480	1874	125,042,757	1881	154,184,400

The exports of coal from Great Britain to foreign countries in 1881 amounted to 19,591,598 gross tons. In 1870 they amounted to 11,702,649 tons. The increase from 1870 to 1881 was gradual. France is the leading importer of British coal—Germany, Italy, Russia, and Sweden and Norway coming next in the order named.

Iron Ore.—Mr. Hunt gives the quantity of iron ore produced in Great Britain in 1880 as 18,026,049 gross tons, to which were added in that year 427,730 tons of "burnt ore" from cupreous pyrites, and 2,632,601 tons of imported iron ore. The approximate total of iron ore smelted in Great Britain in 1880 was, therefore, 21,086,380 tons. The production of iron ore in Great Britain in 1881 is not yet obtainable. The imports of iron ore into Great Britain in 1881 aggregated 2,449,277 tons, the average cost of which to consumers was from 15s. to 16s. per ton. Of the importations of the year two million tons came from Spain. The imports of iron ore in 1880 were, however, larger than in 1881, being 2,632,601 tons, of which 2,278,962 tons came from Spain. Mr. J. S. Jeans, the Secretary of the British Iron Trade Association, says that in 1866 British imports of Spanish iron ore amounted to only 27,619 tons, and that in 1870 they amounted to only 179,083 tons.

Pig Iron.—Great Britain's production of pig iron in 1881 exceeded the production of any previous year, even of 1880, a year which saw a great advance upon any previous yearly record. In 1880, according to Mr. Hunt, the production amounted to $7,749,233 gross tons, while in 1881, according to Mr. Jeans, it rose to 8,377,364 tons. To realize how enormous was the production of pig iron by Great Britain in these two years we need only to reflect that in each year the production was more than twice that of the United States, and yet our production in these two years far exceeded all our previous achievements. The following table, compiled from statistics prepared principally by Mr. Hunt, shows the growth of the pig iron industry of Great Britain from 1740 to 1881. The figures for 1881 are by Mr. Jeans.

Years.	*Gross tons.*	*Years.*	*Gross tons.*	*Years.*	*Gross tons.*	*Years.*	*Gross tons.*
1740	17,000	1835	1,000,000	1858	3,456,604	1870	6.963,515
1788	98,009	1839	1,347,790	1859	3,712,904	1871	6,627,179
1796	125,009	1840	1,396,400	1860	3,826,762	1872	6,741,629
1806	259,000	1842	1,099,138	1861	3,712,390	1873	6,666,451
1818	325,000	1844	1,999,608	1862	3,943,469	1874	6,991,408
1820	400,000	1845	1,512,600	1863	4,510,040	1875	6,365,462
1823	454,866	1847	1,999,608	1864	4,767,901	1876	6,555,997
1825	681,367	1852	2,700,000	1865	4,819,254	1877	6,608,664
1827	690,000	1854	3,069,838	1866	4,623,897	1878	6,381,051
1828	703,184	1855	3,218,151	1867	4,761,023	1879	5,995,337
1830	678,417	1856	3,586,377	1868	4,970,206	1880	7,749,233
1833	700,000	1857	3,659,477	1869	5,446,767	1881	8,377,364

Cleveland (Durham and North Yorkshire) and Scotland, which are leading pig iron producing districts in Great Britain, both increased their production in 1881, notwithstanding an agreement by the ironmasters of both districts to restrict production 12½ per cent. for six months commencing on the 1st of October. The production of Scotland was 1,176,000 gross tons in 1881, against 1,049,000 tons in 1880; the production of Cleveland was 2,670,339 tons in 1881, against 2,510,853 tons in 1880. In the West Cumberland district there was a large increase in 1881 as compared with 1880—the production in 1881 being 077,871 tons, against 751,371 tons in 1880. This district produces Bessemer pig iron, and a large part of the increase in its production in 1881 was due to the increase exports in that year of this class of pig iron to the United States. Mr. Jeans says that the manufacture of spiegeleisen in Great Britain is largely increasing, and now amounts to nearly 100,000 tons annually, of which the largest quantity is produced in South Wales. He also says that nearly 3,000 tons of charcoal pig iron are still made annually in Great Britain—all by one firm with a few furnaces, which, as we learn from another source, are located in Scotland and "over the border" in Cumberland and Hampshire.

The stocks of British pig iron in the hands of makers or in warrant stores at the close of 1881 were very large, amounting to 1,736,262 tons—an increase of 194,851 tons on the quantity held at the close of 1880. Some of the unimportant districts decreased their stocks in 1881, but Scotland increased its stocks 201,000 tons during the year, or from 739,-

000 tons to 940,000 tons. Cleveland stocks increased 47,046 tons, or from 331,124 tons to 378,170 tons. With the exception of Scotland, stocks were reduced in all the leading districts during the second half of 1881, but notwithstanding this reduction they still amounted at the close of the year to 20 per cent. of the year's production. The exports of British pig iron in 1881 were 152,147 tons less than in 1880. In 1880 they amounted to 1,732,343 tons, and in 1881 to 1,480,196 tons.

Prices of Pig Iron.—Prices of pig iron in Great Britain varied greatly in 1881. Messrs. William Fallows & Co. say of prices in the Cleveland district: "The year opened with No. 3 at 41s., and the price gradually receded until 36s. was accepted in May. From this time there was a slow but gradual recovery until 43s. 3d. was reached by the close of the year." Of prices in Scotland they say: "The condition of the pig iron trade in Scotland was unsatisfactory. In previous years this market had been very much stimulated by the American demand, and as this was disappointing in 1881 there was a corresponding amount of depression. The year opened with G. M. B. warrants at 53s. 9d., but the small shipments and restricted demand soon told upon prices, and 45s. was reached by the end of May. A slight rally took place in June and July, but in August the price had receded to 45s. 6d. In September the expectation of some reduction in the output of Cleveland and Scotland led to a considerable advance, and 51. 10½d. was paid on 23d September, when the agreement was finally concluded. The result of this movement was to draw out buyers all round, both for pig and manufactured iron, and the former advanced to 53s. 6d. in October. After some reaction 53s. 6d. was again reached by 9th December, and, after touching 50s. 9d., the year closed at 51s. 10d." Mr. Jeans says that the average range of prices for pig iron in 1881 was lower than for many years, with the exception of 1878 and 1879, and submits the following table of average prices of Cleveland and Scotch pig iron in the ten years from 1872 to 1881.

Years.	Average price of Middlesbrough No. 3.	Average price of Scotch warrants.
1872	£4 18 5	£5 1 10
1873	5 8 0	5 16 11
1874	3 9 10¾	4 7 6
1875	2 14 2	3 5 9
1876	2 7 4½	2 18 6
1877	1 1 10	2 14 4
1878	1 19 2	2 8 5
1879	1 17 6	2 7 0
1880	2 4 11	2 14 6
1881	1 19 2	2 9 1

Mr. Jeans adds that in the statistics of the Scotch iron trade it is necessary to go back to 1852 before as low an average of prices can be found as ruled in 1881, the years 1878 and 1870 excepted. "The average price of Cleveland No. 3 iron over the last ten years has been £2 19s. 9½d. per ton, which is £1 0s. 7½d. above the average of last year. The average price of Scotch warrants over the same period has been £3 11s. 9½d., being £1 2s. 8½d. above that of 1881." Manufacturers of pig iron in this country will now understand more fully than heretofore why Great Britain was able to send us so many tons of pig iron in 1881 and in the first months of 1882. British ironmasters were not only burdened with heavy stock, but their prices had fallen much lower proportionately than the prices of American pig iron.

Manufactured Iron.—Mr. Jeans has been unable to obtain complete returns of the production of manufactured iron in Great Britain in 1881 or preceding years. The total production of iron rails in 1881 was about 150,000 tons, of which South Wales produced all but about 30,000 tons. Nearly all the rails made were exported. Mr. Jeans publishes a very interesting series of tables which show the variations in the quantities of each of the leading forms of iron rolled in the Cleveland district in the ten years from 1872 to 1881 namely, rails, plates, bars and angles. The changes in these ten years are clearly indicated in the following summary of the percentages of total sales of these products at the beginning and end of the decade mentioned. The decline in the iron rail-trade of the district almost amounts to its annihilation.

Articles—Percentage of Sales.	1872.	1881.	Difference.
Rails	49.01	2.62	46.39
Plates	29.16	66.41	36.25
Bars	12.28	11.76	.52
Angles	9.52	20.19	10.67

Prices of Manufactured Iron.—Mr. Jeans gives the following comparative statement of the prices of manufactured iron in 1881 and preceding years in the Cleveland district:

With the exception of 1879 the past year has witnessed a lower average range of prices than any twelve months since 1870. In the former year the lowest prices realized for iron rails were those of the second and third quarters. when £4 14s. 5d. and £4 14s. 8d. respectively were brought out. Last year an average of £5 1s. 9d. per ton was realized during the second quarter, being only 7s. more. The lowest price realized for plates in 1879 was £5 4s.; in 1881 it was £6 1s. 8d., or 17s. 8d. more. Bars touched their lowest quotation at £5 5s. 9d. in the third quarter of 1879; in 1881 their lowest average was £5 15s., so that the difference was 9s. 3d. in favor of last year. Angles were £4 16s. 11d. at their lowest in 1879, and £5 8s. 5d. in 1881, giving an increase of 11s. 6d. in the latter year.

Bessemer Steel.—As we have already stated in the first part of this report, devoted to the iron and steel industries of the United States, and there used for comparison, the production of Bessemer steel ingots in Great Britain in 1881 was 1,441,719 gross tons, and the production of Bessemer steel rails was 1,023,740 tons. In 1880 the production of ingots was 1,044,382 tons, and that of rails was 739,910 tons. The increase in the production of ingots was 397,337 tons, and in the production of rails it was 283,830 tons. In each year 70 per cent. of the ingots produced was manufactured into rails. The largest increase in the production of both ingots and rails was in the Cleveland district, but every other district except Staffordshire also increased its production. The leading Bessemer steel districts in Great Britain now are, in the order named, Sheffield, South Wales, Cleveland, Lancashire, and Cumberland. Staffordshire makes an inconsiderable quantity of Bessemer steel. At the close of 1881 there were 82 Bessemer converters at work in Great Britain, 27 unemployed, and 14 in course of erection. The average yield of the converters at work was 17,582 tons. Mr. Jeans selects from the whole number 21 especially well-managed converters which produced 533,000 tons, or an average of 25,400 tons for each converter. The best results obtained were 64,861 tons with two converters, and 140,000 tons with a four-vessel plant. Of the production of 1,023,740 tons of Bessemer steel rails by Great Britain in 1881, more than the half, or 594,419 tons, was exported, the remainder being taken for home consumption. The statistics of the production of Bessemer steel ingots and rails in Great Britain in the last five years, compared with similar statistics for the United States in the same period, are as follows:

Years.	Gross tons.			
	Great Britain.		United States.	
	Ingots.	Rails.	Ingots.	Rails.
1877	750,000	508,400	500,525	385,865
1878	807,527	633,733	653,773	491,427
1879	834,511	519,718	829,439	610,682
1880	1,044,482	739,910	1,074,262	852,196
1881	1,441,719	1,023,740	1,374 247	1,187,770

The following additional details of interest concerning the Bessemer steel industry of Great of Britain in 1881 are taken from Mr. Jeans's report for that year:

No real progress has been made during the past year in the direction of employing Bessemer steel for shipbuilding purposes. The total quantity of Bessemer plates made was 21,989 tons, being an increase of only 489 tons on the preeding year, and an advance of 12,838 tons on the production of 1879.

Of the 400,000 tons of ingots which were used for other purposes than rails in 1881 a large part took the form of blooms for export to the United States. The production of blooms in 1881 was about 100,000 tons in excess of that of any former year. About 500,000 tons of ingots were manufactured into tires, axles, and general forgings; and 15,000 tons were made into angles for shipbuilding purposes, and so forth.

The course of prices has been much more uniform in 1881 than it was during the preceding year. Statistics with which we have been furnished from some of the principal works show that in 1880 steel rails were sold as low as £5 7s. 6d., and as high as £9 15s. per ton. During last year, however, the minimum was £5 11s. 4d., and the maximum £6 10s. per ton, so that between the two limits there was a difference, by increase, of only 17 per cent., as contrasted with the difference of about 70 per cent. in the previous year.

Prices of Bessemer Steel Rails at the Works in Wales.—Mr. Jeans gives the following table of the average net realized prices of Bessemer steel rails during the last twelve years at the works in Wales. It shows that the average of last year was the lowest of any year in the series except two, and the average over the whole period was £9 12s. 11d., or £3 12s. 11d. more than that of 1881.

Years.	*First half.*	*Second half.*	*Average of year.*
1870	£10 2 6	£10 17 6	£10 10 0
1871	11 12 6	12 5 8	11 18 9
1872	13 17 6	13 17 6	13 17 6
1873	15 5 0	15 10 0	15 7 6
1874	13 18 6	9 17 6	11 17 6
1875	9 7 6	8 18 6	9 2 6
1876	8 7 6	7 15 0	7 15 0
1877	6 15 0	6 8 6	6 11 3
1878	5 15 0	5 10 0	5 12 6
1879	5 0 0	5 5 0	5 2 8
1880	7 10 0	6 10 0	7 0 0
1881	5 15 0	6 5 0	7 0 0

Open-hearth Steel.—The production of open-hearth steel in Great Britain in 1881 was 338,000 gross tons; in 1880 it was 251,000 tons. Of the whole quantity produced in 1881 Scotland produced nearly one-half. South Wales is now the next most important open-hearth district in Great Britain; in 1870 it was the leading district. The growth of the open-hearth steel industry of Great Britain since 1873 is shown in the following table.

Years.	*Gross tons.*	*Years.*	*Gross tons.*	*Years.*	*Gross tons.*
1873	77,500	1876	128 000	1879	175,000
1874	90,500	1877	137,000	1880	251,000
1875	88,000	1878	175,500	1881	338,000

The total number of open-hearth furnaces constructed in Great Britain at the close of 1881 was 149, but, all of these were not at work. Twelve additional furnaces were at that date in course of construction. The average production of the furnaces which were at work in 1881 was 2,925 tons, according to Mr. Jeans. The Landore Siemens Steel Company, in South Wales, and the Steel Company of Scotland, with 24 and 34 furnaces respectively, together produced 179,280 tons of open-hearth steel in 1881, or 53 per cent. of the total product of the year. Open-hearth steel is put to a great variety of uses in Great Britain. It is largely used for plates, but much of it is used for rails, angles, forgings, springs, castings, and tin plate.

Crucible Steel.—The statistics of the production of crucible steel in Great Britain from year to year are not given by Mr. Jeans, nor are they obtainable from any other source.

Tin Plate.—The statistics which Mr. Jeans gives of this branch of the British iron trade are tantalizing, if not exasperating, to an American reader who remembers that his own country does not make a single box of tin plate. Its manufacture forms an important branch of the British iron trade. The business employs over one hundred works, which consumed in 1881 fully 225,000 tons of iron. But the worst remains to be stated. The production of tin plate in Great Britain has doubled since 1872, and doubled solely to supply the American demand. The United States has for many years taken annually about three-fourths of the tin plate exported by Great Britain. In 1874 it imported 1,585,944 boxes out of a total exportation of 2,143,468 boxes. The American demand has since steadily increased. In 1880 we imported 2,959,380 out of an exportation of 4,089,160 boxes.

Iron and Steel Shipbuilding.—We abbreviate from Mr. Jeans's report the following information under this head.

The total tonnage of new vessels constructed in the United Kingdom during 1881 was, 1,013,208, as compared with a total of 796,221 tons launched in the preceding year, being an increase of 216,987 tons. These figures not only represent the largest amount of shipbuilding yet launched in any twelve months, but they also indicate the greatest stride that the industry has made in a single year.

The statistics already available do not indicate what proportion of the total tonnage launched during 1881 was of iron and what of timber; but inasmuch as the statistics compiled by Lloyd's Registry showed that, of 843,000 tons of new shipping contracted for at the beginning of the year, only 8,769 tons, or 1.4 per cent. of the whole, were of timber, it may be assumed that wooden shipbuilding has now practically ceased to be carried on.

The effect of this process of change upon the iron trade has, of course, been very important. In 1850 the total quantity of iron plates required in the construction of the hulls of the 12,000 tons of vessels built of that material would not exceed 7,000 tons. Last year the quantity of ship-plates and angles used in the construction of the hulls of the vessels built of iron and steel would not be less than 600,000 tons, while nearly 200,000 tons more would be employed in the construction of the boilers, engines, and other machinery.

The chief advance made during 1881 has occurred on the Clyde, which shows an increase of 104,244 tons over the preceding year. The Wear follows with an advance of 31,732 tons, then the Tyne with an increase of 28,183 tons, and Barrow with an advance of 18,661 tons—the last-named figure being more than double that of 1880.

Next to the enormous volume of work turned out, and the decay of wooden shipbuilding. the most notable feature of the trade is the tendency to increase of size in ocean-going vessels. The total number of vessels launched during the past year has been 662, which divided into the 1,013,208 tons constructed, gives an average of 1,530 gross tons for each vessel. The port producing the largest average size of vessel appears to be Barrow, which turned out ten vessels, each of over 3,200 gross tons capacity.

The use of steel for naval construction has made substantial progress during the past year. Thirty-seven vessels in all were built of this material, representing an aggregate of 71,533 tons. This is an increase of 33,369 tons, or nearly 100 per cent., on the steel tonnage launched in the previous year. The total number of vessels that were being built of steel on the 1st January, 1882, and are likely to be completed this year, was, however, largely in excess of the total tonnage launched during the preceding ten years: their tonnage will amount to 183,818 tons. The number of vessels under contract to be built of steel during the current year is 61,000 tons more than the total tonnage of iron vessels launched in 1862.

At the beginning of the present year there were under construction 736 vessels of iron and steel, representing a gross aggregate tonnage of 1,264,603 tons.

Exports.—The total exports of all kinds of iron and steel from Great Britain from 1871 to 1881 were as follows, in gross tons.

Years.	*Gross tons.*	*Years.*	*Gross tons.*
1871	3,169,219	1877	2,346,370
1872	3,382,762	1878	2,296,860
1873	2,957,813	1879	2,883,484
1874	2,487,162	1880	3,792,993
1875	2,458,309	1881	3,818,338
1876	2,224,470		

The exports of iron and steel from Great Britain to the United States in the last three years are given in the following table.

Articles.	1879.	1880.	1881.
	Gross tons.	*Gross tons.*	*Gross tons.*
Pig iron	277,939	614,005	391,784
Bolt and rod	29,648	51,413	18,957
Rails	44,919	221,131	294,378
Hoops, sheets and plates	10,447	45,237	36,125
Tin plates	155,595	164,167	179,744
Old iron for manufacture	188,705	197,653	99,974
Other iron	10,437	20,464	6,222
Steel	9,296	44,066	135,275
Total	717,986	1,358,136	1,162,459

Germany.—*Production.*—It appears, according to the German Mining Bureau, that the production of pig iron in the German Empire was 2,613,795 metric tons in 1880, and 2,784,037 tons in 1881; the increase in the latter year over the former was therefore 170,242 tons. This statement of production we find accompanied by another, in these words: "It is officially estimated, however, that if complete returns had been received from all the works last year's production of pig would have really stood at 2,907,000 tons, while the production for 1880 ought to be increased to 2,729,000 tons. We do not know whether these statements include Luxemburg. The production of steel of all kinds in 1881 appears to have been 890,000 tons, of which 745,000 tons were Bessemer, 121,000 tons were open-hearth, and the remaining 24,000 tons were made by minor processes. The production of steel in 1880 is stated to have been 650,000; the increase in 1881 was therefore 230,000 tons, or about 35 per cent. The Bessemer steel industry of Germany has steadily grown since 1871, when the production was 143,305 tons. The production of coal in Germany in 1881 amounted to 48,598,000 metric tons, and the production of lignite 12,843,000 tons, making a total of 61,541,000. In 1880 the production of coal was 46,972,000 tons, and the production of lignite was 12,136,000 tons; total, 59,108,000 tons. The increased production of these two classes of fuel in 1881 over 1880 was 2,433,000 tons. The following statistics of the production of coal alone in Germany from 1854–1881 are published by authority of the Department of the Minister of Public Works at Berlin. We would be glad to see an equally authoritative statement of the production of pig iron and various kinds of steel in Germany in recent years.

Years.	*Metric tons.*	*Years.*	*Metric tons.*
1856	8,634,200	1869	26,774,000
1857	9,841,200	1870	26,397,000
1858	10,721,600	1871	29,373,000
1859	11,419,000	1872	33,306,000
1860	12,347,800	1873	36,392,000
1861	14,133,000	1874	35 918,000
1862	15,576 300	1875	37,436,000
1863	16,906,700	1876	38,454,000
1864	19,408,900	1877	37,629,000
1865	21,794,700	1878	39,689,000
1866	27,629,700	1879	42,025,000
1867	23,808,000	1880	46,972,000
1868	25,704,700	1881	48,698,000

Prices.—Dr. Gurlt, of Bonn, has contributed to the London *Iron* a paper on the metallurgical progress of Germany in 1881, from which we compile the following general view of the range of prices of iron and steel in that year.

We must remember that 1880 had begun with fair prices, which, however, gave way in an alarming manner in the middle of the year, and that they improved again in the last quarter. There were, therefore, in the beginning of 1881, fair average prices with a tendency upwards. In the middle of February a retrograde movement set in with slight occasional oscillations, until the lowest point was reached in June. Just at that time, when the German ironmasters, in order to stay the downward current, had concluded the convention to blow out a number of blast furnaces and to reduce the output, another and healthier movement, with the rising tide, set in from the other side of the Atlantic. It was followed by fresh orders from home and abroad, so that many steel works have secured contracts which will give them work up to and even after the middle of this year, 1882. The prices went gradually upward, and by the end of the year they stood about the same as at the beginniug, or even slightly better; during the first part of 1882 they have rather continued in that tendency.

Iron Shipbuilding.—The Imperial Chancellor, Prince Bismarck, addressed an important memorial to the Reichstag on the 6th of April, 1871, in relation to the necessity of extending government aid in building up the shipbuilding and navigation interests of Germany. The immediate occasion of the transmittal of this memorial was the passage by the French Legislative Assembly on January 30, 1881, of an act for the encouragement of the shipbuilding and navigation interests of France. The Chancellor took the most advanced ground in favor of bounties to German shipbuilders and ship-owners. We may expect some positive action to result from the Chancellor's recommendations, especially as the action of France would seem to render similar action by Germany absolutely necessary as a measure of protection.

Luxemburg.—We are indebted to the London *Iron* for information from which we glean the following summary concerning the character of the iron industry of Luxemburg.

The grand-duchy of Luxemburg, situate to the east of the Belgian province of the same name, is 998 square miles in extent, and has a population of 210,000. The inhabitants are chiefly of German origin, and speak a German patois. The use of French or German is optional, but the higher education is carried on in the latter language. Although the King of Holland is also Grand-duke of Luxemburg, the duchy is in no way connected with Holland, but has its own government, consisting of a responsible ministry and a chamber of deputies. By virtue of a treaty with Germany, Luxemburg forms part of the Zollverein. The chief mineral wealth of Luxemburg consists in its deposits of oolitic limonite or ferruginous schorl, which are divided by the river Else, or Alzette, into two basins. It is estimated that there remain altogether about 270,000,-tons of ore still to be extracted, which will admit of a production rather over that of 1880 for a hundred years to come. About two-thirds of the ore extracted is exported to neighboring countries. Hitherto Belgium has been the largest consumer; but now German ironmasters are offering higher prices, and thus driving their Belgian competitors out of the market. Besides five small furnaces for reducing ore called *fourniquets*, erected at the tool and machine factories, and producing 1,579 tons of pig, there exist in the grand-duchy twenty regular blast furnaces, sixteen of which were in blast at the beginning of the present year, while one has since been blown in. Besides the oolitic iron ore there are some deposits of alluvial ore which form two distinct groups. These deposits are, however, to a considerable extent worked out or abandoned.

From the same source we gather the following statistics of the production of iron ore and pig iron in Luxemburg since 1877.

Years.	*Iron ore—Metric tons.*	*Pig Iron—Metric tons.*
1877	1,262,825	215,388
1878	1,407,617	248,377
1879	1,623,392	291,236
1880	2,173,463	260,666
1881	2,166,881	293,616

France.—*Production.* The production of pig iron in France in 1871 is officially stated to have been 1,894,861 metric tons. The production in 1880 was 1,725,293 tons; the increase in 1881 was therefore, 169,568 tons. The production of finished iron in France in 1881 was, 1,019,170 tons, against 965,751 tons in 1880, an increase of 53,419 tons. Of the finished iron produced in 1881 there were 28,411 tons of iron rails; in 1880 there were 42,325 tons of iron rails produced. The production of all kinds of steel in France in 1881 was 418, 094 tons, against 388,693 tons in 1880, an increase of 29,401 tons. The statistics of Bessemer and Martin (or open-hearth) steel in France are not kept separately; hence we cannot tell how much of each was produced in 1881, but other details are at hand. Of Bessemer and Martin steel the product was 300,580 tons of rails; 71,385 tons of bars; and 17,075 tons of plates: total production of Bessemer and Martin steel, 389,040 tons. The remaining 29,054 tons of steel produced in 1881 embraced puddled, cemented, and crucible steel, but principally puddled steel.

Imports and Exports.—The *Bulletin du Comitê des Forges de France* gives the following statistics of the imports and exports of iron ore by France in 1880 and 1881:

Countries.	*Imports—Metric tons.*		*Exports—Metric tons.*	
	1881.	1880.	1881.	1880.
Algeria	242,494	326,363	......	...
Germany	348,488	279,286	37,427	39,098
Belgium	130,822	97,961	29,065	52,148
Spain	419,097	332,207	......	...
Italy	121,920	1:6,314	...	...
Other countries	25,049	4,375	21,803	23,550
Total	1,287,870	1,166,506	88,292	114,796

The imports of iron and steel by France in 1881 were much larger than in 1880. They amounted in 1881 to 361,-046 tons, and in 1880 to 228,172 tons, a difference of 132,-874 tons. The details are as follows:

Articles.	1881.	1880
	Metric tons.	*Metric tons.*
Pig iron	271,532	169,137
Finished iron	65,337	60,208
Steel	24,177	8,827
Total	361,046	228,172

The exports of iron and steel to all countries in 1881 were very nearly the same as in 1880, being 121,324 tons in 1881, against 121,895 tons in 1880.

Coal and Coke.—From the *Bulletin*, above quoted, we learn that the production of coal in France was 19,361,564 metric tons in 1880 and 19,909,057 tons in 1881. In 1881 the production of coal in the Pas-de-Calais was 5,320,616 tons, against 4,844,323 tons in 1880, an increase of 476,293 tons. The Nord production, however, was 3,668,733 tons, against 3,701,589 tons in 1880, a decrease of 32,856 tons. The total output of the two districts in 1881 was 8,989,349 tons, against 8,545,912 tons in 1880, an increase of 443,437 tons.

The following table gives in metric tons the imports and exports by France of coal and coke in the last three years.

Years.	Coal.		Coke.	
	Imports. Metric tons.	*Exports. Metric tons.*	*Imports. Metric tons.*	*Exports. Metric tons.*
1879	8,662,385	513,938	760,529	20,589
1880	8,451,129	646,455	943,416	40,905
1881	8,106,761	724,885	1,110,974	24,514

Nearly all the coal and coke imported by France is derived from Great Britain, Belgium, and Germany.

Steel Rails.—The growth of the steel-rail manufacture in France is shown in the following table.

Years.	*Metric tons.*	*Years.*	*Metric tons.*
1866	3,687	1874	102,227
1867	10,967	1875	120,660
1868	25,759	1876	130,681
1869	50,225	1877	136,549
1870	41,189	1878	196,240
1871	22,613	1879	253,742
1872	62,104	1880	279,847
1873	64,097	1881	300,580

Railroads.—The New York *Railroad Gazette* calls attention to the fact that the railroads of France have been very prosperous in 1880 and 1881. It adds: "If our railroads had earned as much per mile in 1880 as the French lines, their gross receipts would have been $592,000,000 greater than they actually were."

Shipbuilding.—The provisions of an act of the French Government, passed January 29th, 1881, for the encouragement of the shipbuilding interests of France, by the granting of bounties or subsidies, need not be recited in these pages. The policy adopted has already given a decided stimulus to the enlargement of the French mercantile marine.

The New French Tariff.—A new general tariff was approved by the President of the French Republic on the 7th of May, 1881, and formally promulgated on the 8th. We give at the foot of this page the clauses which relate to iron and steel, compared with corresponding clauses in the old tariff and in the conventional, or treaty tariffs. The treaty tariffs are practically superseded by the new tariff. The famous British commercial treaty, negotiated with France by Mr. Cobden, has at last come to an end.

Belgium.—*Production.*—The production of pig iron in Belgium in 1881 was 631,764 metric tons, against 595,704 tons in 1880, an increase of 36,060 tons. The production of pig iron in Belgium in any one year has never reached 700,000 tons, and since 1865 has not fallen below 400,000 tons. The mining of iron ore in Belgium has gradually declined in the last ten years, mainly through the competition of the cheaper iron ore of Luxemburg. The production of finished iron in Belgium in 1881, including rails and plates, is reported to have been 493,200 tons, against 489,366 tons in 1880. The production of steel of all kinds in 1881, according to M. Max Goebel, of Liège, was 138,076 tons. We are without like statistics for 1880. The manufacture of steel is increasing in Belgium, and the low price at which it can be sold threatens serious interference at no distant day with neighboring steel producers. A new Bessemer plant, owned by Messrs. Caramin & Company, has recently gone into operation at Thy-le-Chateau, the company rolling its first steel rails in March last. These works are adapted to either the acid or basic process.

Imports and Exports.—The total imports of pig iron, other iron, and steel by Belgium in 1881 amounted to 242,747 metric tons, against 260,388 tons in 1880, a decrease of 17,641 tons. The total exports in 1881 were 384,599 tons, against 363,769 tons in 1880, an increase of 20,830 tons. The sidururgical imports of Belgium consist principally of pig iron, and the exports consist principally of finished iron and steel.

Coal.—The statistics of the production of coal by Belgium in 1881 are not yet accessible. In 1880 the production

Denomination of articles. [Duties in francs & centimes. One franc=19.03 cts. One centime=19 cts. One kilo=2.2 lbs.]	Old general tariff. Per 100 kilos.	Conventional tariff. Per 100 kilos.	New general tariff. Per 100 kilos.

Old and scrap iron	9.98	2.75	2.00
Old and scrap cast iron	4.99	2.00	2.00
Iron dross and slag	1.04	Free	Free

was 16,866,698 tons. The production in the ten years ending with 1880 was as follows;

Years.	Metric tons.	Years.	Metric tons.
1871	13,733,176	1876	14.329,578
1872	15,658,948	1877	13,938,523
1873	15,778,401	1878	14,899,175
1874	14,669,029	1879	15,417,292
1875	15,011,331	1880	15,866,698

In 1880 Belgium exported 4,525,085 tons of coal, and 850,346 tons of coke. In the same year it imported 917,033 tons of coal and 19,217 tons of coke.

Austria and Hungary.—Herr Wilhelm von Lindheim, of Vienna, reports to the London *Iron* that 1881 was a year of greater animation in the Austro-Hungarian iron trade than 1880, the construction of more miles of railway being under way in 1881 than in 1880. Complete statistics of the production of iron and steel in 1881 are, however, wanting. Owing to a continuance of the activity in railway building, and to the benefits expected to result from a slight increase in the duties on iron and steel, to go into effect in June, the production of 1882, especially of steel rails, is expected to be larger than that of last year, although, in anticipation of the increase in the duty on pig iron, Great Britain has since the beginning of the year shipped large quantities of that article to Austrian ports. From a report made to our Government by Consul-General Weaver, of Vienna, we obtain the following interesting statistics of the production of Bessemer and Martin (open-hearth) steel in Austria and Hungary in recent years.

Products.	1878.	1879.	1880.
	Metric tons.	Metric tons.	Metric tons.
Bessemer steel ingots.	103,590	86,465	101,369
Martin steel ingots	25,888	35,222	27,368
Total	129,478	121,587	129,007

The first Bessemer steel works in Austro-Hungary were erected in 1872, in the province of Styria, and in 1880 there were eleven works in operation, producing as has been seen, over 100,000 tons of Bessemer ingots. The production of Martin steel dates from 1870, with two works, which in 1880 had increased to seven, with an aggregate production of nearly 30,000 tons. The total production of Bessemer and Martin steel in Austro-Hungary down to the close of 1880 is given in the following table.

Years.	Martin steel.	Bessemer steel.	Years.	Martin steel.	Bessemer steel.
	Metric tons.	Metric tons.		Metric tons.	Metric tons
1864	...	305	1873	3,782	76,611
1865	..	3,545	1874	3,422	85,339
1866	.	7,921	1875	3,481	99,250
1867	..	8,766	1876	4,504	93,668
1868	.	14,479	1877	13,468	104,119
1869	...	20,717	1878	25,888	103,590
1870	298	29,076	1879	35,222	86,365
1871	9,118	49,724	1880	27,638	101,369
1872	5,746	55,444			

Sweden.—*Production.*—Professor Richard Akerman, of Stockholm, furnishes in *Iron* the following details of the production of iron and steel in Sweden in 1879 and 1880. The statistics for 1881 are not yet published.

Products.	1879.	1880.
	Metric tons.	Metric tons.
Iron	645,365	775,344
Pig iron	342,547	405,713
Bar iron, rods, and rolled wire	208,606	219,234
Plates	10,581	11,909
Nails	6,567	7,445
Bessemer steel	20,723	30,013
Siemens-Martin steel	6,720	7,718
Blister and crucible steel	2,129	1,550

Professor Akerman adds the following interesting comments upon the above statistics, and particularly with reference to the increased production of Bessemer steel in 1880.

The production of ore was indeed somewhat greater in the middle of the decade beginning 1870 and 1880, and the make of bar and fine-grained iron also in one year, 1877, when it amounted to 224,818 metric tons, somewhat exceeded the figures of 1880, but the make of pig iron and ingot metal during the last-named year considerably exceeded the largest amount of production hitherto attained in Sweden. Comparatively, it appears, the production of Bessemer metal has most increased in Sweden during 1880. As there are no rails made in the country, the Bessemer metal produced there is only used for nicer purposes, and it is in this circumstance that we have to seek for the reason why the Bessemer manufacture has increased so slowly as compared with what has been the case in the countries where enormous quantities of rails have been made of Bessemer metal. As the amount of 21,303 metric tons of Bessemer metal produced in 1874 was not again reached during any of the five following years, it even almost appeared as if the Bessemer manufacture of Sweden was not to undergo any further development. Of this, however, there cannot now be any question, for the Bessemer manufacture in Sweden, in 1880 exceeded by 54 per cent. the annual make during the years 1875–'79, which, as has been stated, was somewhat less than that of 1874. The great increase during 1880 depends, in incomparably the greatest degree, on an augmented use of Bessemer iron within the country, above all for boiler and ship plates; but also on an increased sale of Bessemer ingots and blooms abroad, especially at Sheffield, where they now at least appear to be beginning to find out that a Bessemer steel so pure as the Swedish may not only equal but even surpass many a less pure crucible steel.

Professor Akerman expresses the opinion that the production of both Bessemer and Siemens-Martin steel in 1881 will be found to have been larger than in 1880. He then adds:

The production which otherwise of recent years has made most progress in Sweden is that of rods and rolled wire, but no exact figures on this head can unfortunately be given. Yet this follows, among other things, from the annually increased export of such fine iron. The export in 1880 was, for instance, fully double that of 1875, viz., 52,162 metric tons, against 24,047 tons in 1875, when it was, besides, considerably greater than in any of the preceding years.

The old wooden shipbuilding of Sweden is now only in a languishing state; but, on the other hand, our iron shipbuilding yards in recent times have to felicitate themselves on full employment not only on native orders, but also on orders from the neighboring countries—Russia, Denmark, and Norway. It is also this fortunate circumstance which has conduced most of all to the present improvement of the Swedish Bessemer manufacture. For incomparably the greater part of both ship and boiler plates are now made here of ingot iron, [steel] and only a very small quantity of puddled plates is for the present manufactured in Sweden.

Exports and Imports—The exports of iron and steel from Sweden during the last three years are shown in the following table:

Articles.	1879.	1880.	1881.
	Metric tons.	Metric tons.	Metric tons.
Iron ore	12,570	29,662	24,432
Pig iron	34,569	61,585	55,289
Blooms	10,470	8,860	8,842
Bar iron	110,325	131,218	135,856
Rods and rolled wire	41,776	48,713	52,162
Plates	2,022	2,174	2,362
Nails	781	876	1,052
Ingot iron and steel	8,519	8,155	7,465

The imports during 1881 are not yet known; but in 1879 and 1880 they were as follows:

Articles.	1879	1880.
	Metric tons.	Metric tons.
Pig iron	11,314	15,972
Rails	19,804	9,971
Bar iron	1,514	2,464
Hoop iron, etc.	2,180	2,821
Plates	2,166	3,080
Tinned plates	1,067	369
Nails	522	1,665
Steel	484	552

Coal.—The mining of coal in Sweden is making some progress. In 1879 over 200,000 tons were mined, and in 1880 almost as many tons were mined. We presume that the mining operations were restricted to the district of country in the southwestern part of Sweden, opposite the Sound, Helsingborg, being the principal town.

Spain.—*Iron Ore Exports.*—In 1881 there were exported from the district of Bilboa, according to the authority of Mr. William Gill, in a paper read before the British Iron and Steel Institute at its May meeting at London, 2,500,532 tons of iron ore. From all the iron ore districts of Spain, including Cartagena and Malaga, the exports in 1881 slightly exceeded 3,000,000, tons. The exports from Bilboa in 1880 amounted to 2,345,598 tons; in 1879 to 1,117,836 tons; and in 1878 to 1,224,730 tons. In the first two months of the present year the exports from Bilboa reached 458,000 tons, against 390,000 tons in the corresponding period of 1880, a gain of 68,000 tons. It is not probable, however, that this year's exports from Bilboa will greatly exceed those of 1881; they may not, indeed, equal them.

Prices of Iron Ore at Bilboa for Twelve Years.—In the following table Mr. Gill gives the average prices of iron ore, free on board, in Bilboa river, from 1870 to 1881. (The average price is not a mean of highest and lowest, but is that which prevailed during each year.)

Years.	Prices per ton.			Years.	Prices per ton.		
	Maximum.	Minimum.	Average.		Maximum	Minimum.	Average.
	s. d.	s. d.	s. d.		s. d.	s. d.	s. d.
1870 . .	6 6	5 6	5 10½	1876 . .	10 0	6 3	8 0
1871 . .	6 6	4 8½	5 8	1877 . .	8 0	6 3	6 10
1872 . .	10 0	6 2	6 7	1878 . .	7 11	6 2	7 0
1873 . .	12 0	7 1	9 0	1879 . .	6 6	5 9	6 0
1874 .	Carlist	Carlist	Carlist	1880 . .	15 9	6 0	9 0
1875 .	War.	War.	War.	1881 . .	9 9	6 7	7 0

Manufactures.—Spain makes but slow progress in developing the manufacture of iron and steel. The country is largely dependent upon other countries for its supply of these articles.

A National Exhibition.—An official notice has been published relative to a mineralogical and metallurgical exhibition which is to be opened at Madrid on April 1, 1883, under the auspices of the Spanish Government. It may be expected that the display of the extraordinary riches of the country in iron ores will be complete.

Italy.—*Production.*—The most recent statistics of the iron industry of Italy that we have noticed do not come down to a later period than 1877, in which year the total production of iron and steel is stated to have been about 76,000 tons. The most of this production was bar iron, made principally in Catalan forges. We find the production of 1877 classified as follows: bar iron, 49,000 tons; cast iron, 4,600 tons; rough iron, 20,278 tons; steel, 2000 tons. Of the total production 32,000 tons are credited to Liguria. The following details we take from a European technical journal: "The iron works of Vobarno, near the lake of Garda, now yield 8,000 tons of iron per annum, fused in Siemens furnaces, as against 3000 tons in 1872. The fuel used at these works is chiefly peat, procured either in the neighborhood or from the peat beds of Fiavé, the Trentino. The works belonging to Messrs. Masson, at Colle di Val d'Elsa, are also provided with Siemens furnaces."

Coal.—The French journal, *La Houille*, briefly describes as follows the poverty of Italy in lacking a supply of coal as a basis on which to build up manufacturing enterprises, especially of iron.

"The kingdom of Italy and the islands dependent upon it are very poor in mineral fuel. Coal, properly speaking, does not exist, and the very rare carboniferous layers consist of anthracite and lignites. These deposits of anthracite possessed by the country are not very productive, and the chief of them are situated in the Valley of the Piedmont. According to a recent report of the Belgian Consul at Savona, the total production does not exceed 2000 tons. The layers of lignite are more numerous, and all belong to the tertiary formation. The largest basins are found in Tuscany, Sardinia, Liguria, Vicentino, and Lombardy. M. Cappa, the Belgian Consul, estimates their annual production at about 100,000 tons. In addition to this about 90,000 tons of peat are extracted annually. If Italy were as rich in mineral fuel as in iron ores it would be able to rival the most favored nations with respect to metallurgical industry, but fuel being in default it is reduced to exporting most of its production of iron ore."

United States Consul Crain, of Milan, in a recent communication to the Department of State makes the following more hopeful statement of the prospects of Italian manufactures.

The development of the manufacturing industries of Italy is seriously impeded by the great cost of coal for steam-power. This fuel not being produced in the country is brought principally by sea from England, and is so heavily burdened by Italian railway freights as to discourage the erection of factories requiring steam power. Hence, an active agitation is being carried on by capitalists for some measure of relief, and the Milan Chamber of Commerce has taken the initiative in making important recommendations. All signs point to a rapid growth of manufacturing in this country, and this, with the extension of the railway system must, in the near future, vastly augment the consumption of coal.

The Chamber of Commerce of Milan states that Italian manufacturers pay for coal three times as much as it costs the competing English industries, and twice as much as it costs these of France. The importation of coal into Italy in recent years is increasing. In 1878 it amounted to 1,325,245, in 1879 to 1, 523,676 tons; in 1880 to 1,737, 746 tons; and in the first nine months of 1881 to 1,646,249 tons, against 1,256,249 tons in the corresponding period of 1880. England and Wales supply most of the coal imported by Italy.

Iron Ore.—The quantity of iron ore mined in Italy 1877 amounted to 237,931 tons. The iron mines of the Island of Elba are reported to have been lately transferred to an Italian company represented by the National Bank of Rome. The royalty to be paid to the government has been fixed at 5.25 fr. per ton of ore extracted. A communication which we have just received from F. Regolini, of Turin, dated May 20, 1882, informs us that it is proposed to establish in Italy a company of bankers, merchants, and other capitalists for the manufacture of Bessemer steel from Elba ores, and that the enterprise only awaits the engagement of a competent director for the technical department.

Russia.—*Imports and Exports.*—Notwithstanding its high tariff Russia still remains a large importer of many raw and manufactured products. The following table gives the imports of iron and steel and coal in 1880 and 1881, in metric tons.

Articles Imported.	1880.	1881.
	Metric tons.	Metric tons.
Pig iron . . .	243,854	234,864
Bar iron, etc . . .	105,109	71,761
Plates and sheets . .	49,183	30,530
Iron rails	4,628	776
Bessemer steel rails	50,728	15,385
Machines	65,778	23,226
Coal	1,929,799	1,790,368

The exports of iron from Russia in 1880 were 133,371 tons; in 1881 they probably amounted to about the same quantity.

Production.—The following statistics of the productions of iron and steel and coal in Russia in 1879 are extracted from a report by Mr. Skalkofski, sub-director of the Russian Department of Mines. No later statistics of production are available.

Products.	Metric tons.
Pig iron	429,865
" " castings	50,974
Blister and puddled steel	3,084
Bessemer and Simens-Martin steel	203,636
Crucible steel . .	4,284
Iron bars, angles, etc.	206,438
" sheets and plates . .	69,325
" rails . . .	6,131
" wire	1,899
Bituminous coal .	2,378,138
Anthracite "	477,972
Brown " . .	16,157

Of the total quantity of Bessemer steel produced in 1879 there were 144,801 tons of rails. As compared with the statistics of production in the five years preceding 1879, Russia had not in that year made any progress worthy of note in the manufacture of pig iron, and no progress at all in the manufacture of finished iron, but in the manufacture of steel her progress had been very rapid. From 1874 to 1879 the production of steel was as follows, in metric tons.

Years.	Metric tons.	Years.	Metric tons.
1874	8,466	1877	43,446
1875	12,684	1878	93,242
1876	17,577	1879 . . .	211,004

MISCELLANEOUS.

At about 150 miles from the mouth of the Bosphorus, on the Asiatic coast of the Black Sea, there is a coal basin of considerable extent and richness, known as the Heraclea Basin, and near the Heraclea Pontia of the ancients. Surveys have been made, which show that the beds extend over an area of about 450 square miles, and are estimated to contain 60,000,000 tons. During the Crimean war the British Government operated these mines to supply the allied squadrons operating against Sebastopol and their numerous steam transports, and the works undertaken in the mountains south of Zougal Daugh, 60 miles east of Heraclea, furnished nearly all the coal consumed during the siege. After 1856 the working of the mines was left to the Ottoman Government. The best quality of coal is obtaned at Koosloy, in the district of Heraclea, where it is found in seams varying from 3 to 18 feet in thickness. The mines are the property of the government, and in 1880 yielded about 33,000 tons. Turkey imports annually from Great Britain about 20,000 tons of coal.

The annual consumption of coal in India by railways, manufactories, and steamers amounts, in round numbers, to 1,500,000 tons, of which over one-third, or 600,000 tons, is imported from Europe and Australia, and the remaining two-thirds, or 1,000,000 tons, are raised in the country.

Coal is found in the Colony of New Zealand, and its production is steadily increasing, while the importation of foreign coal is decreasing, as will be seen by the returns for the years 1878, 1879, and 1880, which are given in the following table:

Years.	*Raised in the Colony.*	*Imported.*
	Tons.	*Tons.*
1878	162,218	174,148
1879	231,218	158,076
1880	299,923	123,278

At the Esk Bank Iron Works in New South Wales, the only works of their kind that are now in operation in the colony, 1,200 tons of pig iron and 800 tons of bar iron and rails were made in 1880. This production is reported to have exceeded that of any previous year by these works, which are well managed but operated under difficulties. The pig iron produced in 1880 was valued at $20 per ton, and the rolled iron at $50 per ton.

There has been organized in the United States a company of capitalists which proposes to develop the iron ore deposits of the celebrated iron mountain of Durango, in Mexico. Hon. W. L. Helfenstein, of New York, is the president of the company. Mr. John Birkinbine, civil engineer, of Philadelphia, has recently accompanied Judge Helfenstein to Durango, and since his return has published an elaborate description of the company's property. It is expected that steps will be taken to utilize the vast resources of the iron mountain, and this expectation is strengthened by the probability of railway communication between the United States and Durango being soon accomplished.

Mr. Birkinbine tells us in the *Journal of the United States Association of Charcoal Iron Workers*, of which he is the editor, that during his visit to Durango he could not gather much definite information concerning the iron industry of Mexico. He says that bar iron and ordinary iron castings are sold at Durango and in Northern Mexico generally at 12½ cents per pound. He adds:

> We made diligent search for information concerning the charcoal iron works of Mexico, but were able to obtain no reliable data. There are several works which have been long in existence in Southern Mexico; but the only one above the Tropic of Cancer is that near Durango, described below.
>
> Five miles south of Durango, on the bank of the Rio Tunal, is the plant of the Piedra Azul (Blue Stone) Iron Works, consisting of a blast furnace, 35 feet by 8 feet; a heating furnace; a puddling furnace; one train of rolls; two sinking fires; one wooden helve hammer, and three smith fires. Power is obtained from a masonry dam across the Rio Tunal, giving a head and fall of seventeen feet. There are four water-wheels—two over-shot, one under-shot, and one turbine. The blast furnace is built of stone.

In our last Annual Report allusion was made to an enterprise for the manufacture of both pig and bar iron, with mineral fuel, which had been projected and undertaken in the State of Boyaca, in the United States of Columbia. We now learn that this enterprise, after absorbing a large amount of capital, said to be $400,000, has been abandoned, at least for the present.

STATISTICS OF MINERAL PRODUCTION.

ALTHOUGH the following figures are a little more than a year old they will be found necessary often in reaching such conclusions as the latter tables of Mr. Swank's report will suggest. They are compiled from "The Progress of the World" by Michael G. Mulhall, F. S. S., an exceedingly careful authority.

Minerals of the World.—During the present century the mineral resources of the world have been developed on a scale surpassing anything in history.

Coal.—Seventy years ago the world produced annually 9,000,000 tons of coal, or one-thirtieth of the present quantity, the only coal-fields then working being those of England, although the mineral was known to exist in France, Germany, and North America. Coming down to the year of Queen Victoria's accession, we find the production had then risen to 40 million tons, of which Great Britain stood for four-fifths. Since the introduction of railways and steamers the quantity raised has quintupled, viz.—

	1842. Tons.	1878-79. Tons.
Great Britain	35 million	135 million
United States	2 "	55 "
Germany	11 "	42 "
France	3½ "	17 "
Belgium	3 "	15 "
Austria		12 "
Russia		7 "
China, Spain, Australia	1½ "	7 "
	56 "	290 "

In the last ten years the exports from Great Britain have doubled, and the consumption increased 30 per cent. According to the report of the Parliamentary committee in 1871, there are still 90 milliard tons available, going no deeper than 4000 feet:* at an average consumption of 150 million tons there is, therefore, enough for 600 years to come. Electricity is, meantime, coming to supply in many ways the place of coal, which will doubtless tend to reduce the consumption. The average output per miner is greater in England than in other countries, viz.—

	Output.	Miners.	Per miner.
Great Britain	135,000,000 tons	440,000	306 tons
United States	55,000,000 "	190,000	288 "
Germany	42,000,000 "	160,000	262 "
France	17000,000 "	92,000	185 "
Belgium	15,000,000 "	81,000	185 "

Great Britain exports 20 million tons, which would suffice to freight all the merchant navies of the world. In the best years of California or Australia the yield of gold in either of those countries never exceeded £15,000,000, whereas the coal-fields of Great Britain produce £47,000,000 per annum.

Iron.—Men still living can remember when the world produced annually but 450,000 tons of iron: at present the production reaches 14 million tons which is equivalent to 35 million tons iron ore, the ordinary yield being 40 per cent. There is hardly a part of the globe in which iron is not found, but it can be advantageously worked only where fuel is cheap and transport easy. So plentiful is the iron ore of England that the Cleveland district possesses as much as would take all our coal-fields to smelt. The production as compared with population, is greatest in England, but the relative increase in other countries, since 1850, exceeds ours; we produce, nevertheless, as much pig-iron as all the rest of mankind collectively, and manufacture 40 per cent. of the steel of the world. In the

* The deepest coal-mine now working in Great Britain is Rosebridge, 2500 feet; the Lambert mine in Belgium goes down 3490 feet.

subjoined Table is shown the production of pig-iron for population:—

	1850.	1877.	Increase
Great Britain	182 lbs. per inhab.	225 lbs. per inhab.	24 p. c.
United States	55 " "	132 " "	140 "
Germany	27 " "	88 " "	224 "
France	27 " "	96 " "	250 "
Belgium	80 " "	190 " "	137 "
Sweden	105 " "	170 " "	62 "
Austria	18 " "	30 " "	67 "
Russia	8 " "	11 " "	37 "
Average	44	110	150

Copper.—In the Waterloo period the world depended on Cornwall for this mineral, until the Chilian copper-fields rose into importance. Subsequently, in 1842, some buffalo hunters discovered a rich mine near Lake Superior, which yielded 100,000 tons copper in twelve years. At present the production is as follows:—

Chile and Peru	34,000 tons
United States	15,000 "
Australia	14,500 "
Russia	5,600 "
England	5,200 "
Other Countries	19,000 "
	93 300 "

The price of copper has fallen 33 per cent. since 1870, and the industry seems rapidly declining. There is nothing of copper manufactures in modern times to compare with the Colossus of Rhodes, the metal of which formed 900 camel-loads on its removal.

Lead.—The world produces 140,000 tons per annum, of which Cornwall gives one-half. The Spanish mines, near Cordoba, are worked by English companies, yielding over 30,000 tons. Missouri first produced lead in 1854, and gives at present 18,000 tons. This metal abounds in Bolivia and the lower ranges of the Andes.

Tin.—Cornwall has now to compete with Australia and Malacca in the production of this mineral. The tin factories of the world consume 24,000 tons annually, of which Great Britain stands for five-eighths.

Zinc.—Germany produces 60 per cent. Russia and Belgium the rest.

Quicksilver.—The Almaden mines in Spain have been famous since the time of the Romans, but are now surpassed by the California mine. The annual production is as follows:—

California	2,000 tons
Spain	1,000 "
Other countries	300 "
	3,300 "

Summary.—The mining industries of all nations (not including precious metals) give employment to 1,500,000 miners, as shown in the following Table:

	Miners.	Products.	Per miner.	Output.
United Kingdom	475,000	£66,000,000	£139	325 tons.
United States	280,000	46,000,000	165	220 "
Germany	204,000	16,000,000	75	230 "
France	206,000	13,000,000	63	105 "
Austria	92,000	8,000,000	87	135 "
Belgium	105,000	9,000,000	85	160 "
Russia	80,000	4,000,000	50	100 "
Spain and Portugal	48,000	6 000,000	125	50 "
Italy	36,000	2,000,000	60	10 "
Scandinavia	29,000	1,000,000	34	34 "
	1,555,000	£171,000,000	£110	206 "

It appears from the above that Great Britain stands for one-third of the mining industry of the world. The mortality of miners in this country in 1879 was 3 per 1000, say 1 killed for 103,000 tons of coal or iron extracted.

Great Britain.—*Hardware.*—There are 530,000 operatives engaged in hardware, cutlery, and the manufacture of machinery. The raw material is valued at £20,000,000, and the manufactured goods reach £100,000,000, of which one-third is exported, the rest being kept for home consumption. Until recently the hardware industry of Great Britain was equal to that of all the rest of the world put together. Although no longer without a rival, she is still far ahead of all competitors. It was supposed that the invention of Bessemer steel would be almost fatal to our trade, but the returns for 1877 show that out of 94 Bessemer factories in the world, there are 21 in Great Britain.* Such has been the progress of steel, cutlery, and all species of hardware † manufactures, that Sheffield and Birmingham have quadrupled their population in a life-time—

	1811.	1880.
Sheffield	53,000	284,000
Birmingham	86,000	380,000

The export of hardware and machinery has risen as follows:—

1820	£1,920,000
1840	3,793,000
1878	37,200,000

The iron consumed in our manufactures is about 2,500,000 tons, or less than half the quantity we produce, the rest being exported. We also use about 30,000 tons of superior Swedish iron, and an equal quantity from Biscay, especially suited for steel. Our copper manufactures consume £4,500-000 sterling of this metal, which is imported from Chile and United States. Our tin factories require 15,000 tons, worth £3,000,000 sterling, two-thirds of which is imported from Australia, East Indies, or Prussia. The total value of hardware manufactures in 1801 was £16,500,000; it follows, therefore, that the industry has multiplied six-fold. It appears that the total manufactures of the kingdom amount to £665,000,000, the work of 2,930,000 operatives, say £224 per head. Deducting the exports, the balance for home consumption is about £460,000,000, or £14 per inhabitant. The above, of course, includes minerals.

Minerals of Great Britain.—The value of coal and iron extracted from the mines of Great Britain in twenty-five years (1854–1879) has been £1,076,000,000, or nearly equivalent to the yield of the gold and silver mines of Spanish America in three centuries. The development of our mineral resources has been as follows:—

	1800–1805.	1835 to 1840.	1875 to 1879.
Coal	£3,000,000	£10,000,000	£47,000,000 per ann.
Iron	2,000,000	7,000,000	16,000,000 "
Copper, tin, salt, etc.	1,000,000	3,000,000	3,000,000 "
Total	£6,000,000	£20,000,000	£66,000,000

Coal.—The production has increased thirteen-fold, more than keeping pace with our manufactures, which have grown eleven-fold since the beginning of the century. The output in 1801 to 1805 averaged 10,000,000 tons, of which one-fourth was shipped at Newcastle and Sunderland, the rest conveyed inland. The duty of 75 per cent. imposed by William III. on coal, even for consumption in England, was such an obstacle to the manufacturing and general industry of the kingdom, that it was abolished in 1830. This caused the price in London to fall from 50s. to 17s. per ton, whereupon the consumption rose rapidly. At the same time the invention of steamboats and railways increased the demand, and in 1853 the output reached 54,000,000 tons. As foreign countries constructed railways, the exportation of English coal increased year by year, while the onward march of British manufactures gave equal impetus to the home consumption. At present the annual demand reaches 135,000,-000 tons, viz.—

British factories	46,000,000 tons.
Railways and steamers	25,000,000 "
Gas and water companies	14,000,000 "
Domestic use	30,000,000 "
Exportation	20,000,000 "
	135.000,000 "

Great Britain raises one-half the coal consumed in the whole world. It has been supposed that our coal-fields will hardly last more than 200 years longer, but the result of the Parliamentary inquiry rather indicated a sufficient supply for six centuries to come. A new coal-field of Durham is now worked some miles under the sea. Moreover, electricity has begun to supplant coal-gas, and also to take the place of steam as a motive power, which will reduce the demand upon our coal-fields.

* Before Bessemer's invention the annual production of steel in Great Britain was only 51,000 tons; in 1873 it rose to 480,000 tons.

† The manufacture of pins averages 50,000,000 daily, or nearly three times the quantity produced in 1840.

Iron.—In the earlier part of the century (1801-1805) we imported 20 per cent. more iron than we exported. The invention of Nelson's hot-blast, in 1828, gave an extraordinary impulse to the industry, by cheapening the production of pig-iron from ore. Previous to that time it required four tons of coal for a ton of pig-iron; but this was reduced by Nelson almost one-half, and subsequent improvements have caused a still greater economy of fuel. The iron ore of England gives about 40 per cent. metal—that is, 2½ tons ore equal to 1 ton pig-iron. The relation which Great Britain bears to the world is as follows:

	Ore.	Pig-iron.
Great Britain . .	16 million tons	6½ million tons
Rest of World . . .	22 "	8½ "
	38 "	15

The production of pig-iron in Great Britain has grown as follows:

1802 .	227,000 tons.
1848 .	1,998,000 "
1877 .	6,608,000 "

This enormous increase was chiefly due to the construction of 150,000 miles of railway, in all parts of the world. It was also, in some measure, caused by the building of steamers and sailing vessels of iron instead of wood. The annual consumption of iron in the United Kingdom is much greater per inhabitant than in any other country. The weight of coal and iron annually exported by Great Britain is over twenty million tons—enough to freight all the vessels in the world.

Copper, Lead, Tin.—These minerals are of secondary importance, and their annual production may be briefly noticed as follows:

	1801-1806. Annual average.	1877-1878. Annual average.
Copper .	£600,000	£340,000
Tin .	300,000	700,000
Salt	100,000	1,500,000
Lead, Silver, etc. .	500,000	2,460,000
	£1,500,000	£5,000,000

Previous to 1823 salt was subject to a duty thirty times its own value. Since the repeal of the duty the production has increased tenfold, being now close on three million tons. The average output of miners is increasing as shown thus:—

	Mineral extracted.	Miners.	Per head
1878	149 million tons	515,000	290 tons.
1878	146 " "	475,000	307 "

The above includes not only coal and iron, but all other minerals.

Australia.—In the last thirty years the population has multiplied five-fold, chiefly owing to the discovery of gold in 1851, from which date, down to 1878, Australia produced £247,000,000 of the precious metal, viz.—

	Production	Per annum.
1852-1862	£110,760,000	£10,070,000
1863-1873 .	101,310,000	9,210,000
1874-1878 . . .	34,930,000	6,980,000
	£247,000,000	£9,200,000

During the last five years the gold fields* employed 48,500 miners and 1100 steam-engines, representing 24,000 horse-power: the average product per miner was £144 per annum. Gold-digging is now superseded by sheep-farming, as shown by the exports of wool and those of gold in 1877.

Value of wool exported . .	£19,460,000
Do. of gold "	7,499,900
Surplus for wool . . .	£11,860,100

New South Wales has produced more than £50,000,000 of gold, or one-fifth of the total exported. Wool has been, however, in the last ten years, a more valuable staple than gold:—

	Ten years.
1868 77 exported gold . .	£18,200,000
" " " wool .	30,410,000

Victoria.—A wandering party of sheep farmers from Tasmania, attracted by the beauty of the Yarra-Yarra river, settled on its banks in 1835, on the spot where the superb city of Melbourne now stands. Only a year before gold was discovered the settlers obtained permission to constitute themselves into a separate colony, for they now numbered 77,000 souls, and thus the colony of Victoria was established in 1850, with a territory of 88,000 square miles, or twice the area of the kingdom of Portugal; this being the smallest of all the Australian colonies except Tasmania. The gold fields in 1851 gave an extraordinary impulse to everything, the quantity of gold dust extracted in twenty-five years exceeding £170,000,000 sterling. The gold fields produced in 1879 over £3,000,000 sterling. Comparing the value of gold dust and of wool exported in the last ten years, we find as follows:

	1868-77.
Gold dust . .	£49,000,000
Wool	51,000,000

At present the latter item stands for three times as much as the former.

France.—*Minerals and Metals.*—These industries, which were insignificant in the time of Buonaparte, now amount to £36,000,000 per annum. The greatest development, strange to say, has taken place since the removal of the oppressive tariff against English coal and iron.

Coal.—In 1836 there were 170 coal-fields, employing 24,000 miners, who raised annually 3,000,000 tons, worth £1,200,000. At that time the supply of coal from England averaged 1,000,000 tons. But, with the introduction of railways, an increased consumption imparted vigor to the home production, as also to the imports, which have grown as follows:—

	Native coal.	Imported.	Consumption.
1830-1840	2,700,000 tons	900,000 tons	3,600,000 tons per an.
1860-1865	10,200,000 "	7,300,000 "	17,500,000 " "
1875-1877	17,100,000 "	7,600,000 "	24,700,000 " "

The number of coal-fields now working is 623, which employ over 100,000 men. The value of coal raised is little short of £10,000,000 per annum.

Iron.—Prohibitory duties upon foreign iron obliged people to extract it from the mines at double the cost for which English iron might have been imported. During many years the average price of iron in France was £26 a ton, or three times the price then ruling in England (£9 : 10s.) In this manner the farmers and others lost £1,500,000 sterling per annum for about thirty years, say £45,000,000. In fact, iron was so dear that the peasants used wooden ploughs until 1840. The production of iron rose to its highest in 1860-64, but it has since fallen away one-fourth.

1820-25 .	80,000 tons per annum.
1840-45 .	150,000 " "
1860 64 .	1,530,000 " "
1871-75 . . .	1,170,000 " "

There are over 2,000 iron mines and 1100 furnaces (including 600 blast-furnaces), employing 120,000 workmen. The production of steel averages 260,000 tons per annum. The various branches of this industry, from the extraction of the ore from the mines to the finer classes of cutlery, represent more than £20,000,000 sterling per annum. France produces one-fourth of the quantity of iron that England does.

Lead.—This metal was imported, although known to exist in France, until about 50 years ago, when some quantities were extracted. In 1839 there were forty mines, producing in the aggregate a value of £22,000 sterling, and employing 900 workmen. In late years the industry rose, until 1860-64, when the average yield was 86,000 tons lead, but the production since 1871 has been under 70,000 tons yearly.

Copper.—Another metal that was utterly neglected for half a century. In 1839 there were two mines, employing 130 men, who produced 90 tons copper.

The returns since 1860 may be summed up thus:—

1860-64	54,000 tons copper ore per ann.
1871-75	108,000 " "

The ore is of inferior kind, say 5 per cent. copper, since it takes 20 tons ore to produce one ton of copper. France produces 6 per cent of the copper of the world.

Quarries.—There are 24,000 in the various Departments, employing altogether 88,000 workmen, and yielding about £2,000,000 per annum.

* Some of the mines are very deep—the Magdala, for example, 1990 feet.

Salt.—For an interval the duties were removed, and the consumption rose to 1,000,000 tons yearly, but when they were re-imposed the consumption fell to 100,000 tons, on which the State levied the enormous tax of £18 per ton. This industry, under modified duties, has so far recovered, that it now employs 24,000 workmen, who produce 350,000 tons per annum, valued at £400,000.

Germany.—Ironworks and foundries are 1200 in number, and employ 120,000 workmen, who produce merchandise worth £28,000,000 per annum. The quantity of iron and steel of all descriptions manufactured is over 2,400,000 tons yearly. Krupp's factory at Essen covers 10,000 acres, and employs 10,000 men, 286 steam-engines (9230 horse-power), and 71 steam-hammers of 220 tons weight. Germany imports 500,000 tons pig iron yearly, besides 2,000,000 tons produced from native ore. This iron is used for the manufacture of 400,000 tons steel rails, plates and wire, and 2,000,000 tons of castings, rolled iron, etc. After supplying her own requirements, Germany has still a surplus of steel and iron merchandise for exportation, especially railroad bars, viz:

	1872-75.	1876-77.
Exported	90,000 tons per annum.	185,000 tons per annum.

The exportation in 1877 was 225,000 tons, at a period when the iron trade in Great Britain and the United States was under great depression.

Coal.—The production is over 42,000,000 tons yearly, including 9,000,000 tons brown coal or lignite. The following table shows how rapidly this industry has advanced:

1805	300,000 tons
1822	1,270,000 "
1864	16,200,000 "
1873	42,300,000 "

More than two-thirds are raised in Prussia, the rest in Alsace and Saxony. There are 920 pits, which employ 160,000 miners, the output being valued at £10,000,000, including £1,500,000 for brown coal. The home consumption is 40,000,000 tons, leaving a surplus of 2,000,000 tons for exportation.

Iron.—The production has multiplied fifteen-fold in half a century. In 1830 the ore extracted gave but 120,000 tons pig iron. At present there are 1071 mines, yielding over 4,500,000 tons ore, from which are obtained 2,000,000 tons of iron. The miners number 20,000 hands, nine-tenths of the iron mines being in Prussia.

Copper.—In 1830 the production barely reached 2,000 tons, or one-fourth of what it is at present. The mines are in Prussia and Saxony. The ore is not very rich, 260,000 tons giving about 1,000 tons pure copper, say 3 per cent. The 69 mines employ about 8,000 men, and the annual output is valued at £300,000.

Zinc is produced by Prussia on a larger scale than in any other part of the world, the production having multiplied fifteen fold since 1830. There are 77 mines, worked by 11,000 miners, who raise 350,000 tons ore per annum, worth £1 per ton. The ore gives 17 per cent. zinc, that is, 58,000 tons.

Lead and Silver are produced by Prussia and Saxony, the former country standing for three-fourths. There are 168 mines, employing 11,000 miners, who raise 125,000 tons ore, or six times the quantity raised in 1830. Almost half the ore is lead, say 46 per cent.

Salt.—Actual production 1,000,000 tons, or seven times what it was in 1830.

Summary.

The mineral industries have grown as follows in thirty years:—

1846	68,000 miners
1866	148,000 "
1876	205,000 "

The value of the minerals at the pit's mouth is about £15,500,000, or £75 for each miner. Prussia represents 80 per cent. of the minerals produce of Germany, employing 160,000 miners.

Belgium—*Minerals and Manufactures.*—These branches of industry employ 760,000 persons, Belgium having come to rival Great Britain in certain manufactures, and employing comparatively more operators, with reference to population, than any other country in the world.

Coal.—The production has multiplied six-fold in forty years:—

	Tons.	Miners.	Tons per miner.
1836	2,100,000	32,000	70
1850	6,200,000	49,000	126
1878	14,900,000	81,000	185

The value was 17s. per ton in 1873, but has now fallen to 11s. The average profit is 3d. per ton, although it appears that 82 mines do not cover expenses. Miners' wages have been reduced from £46 to £37 per annum. The highest output yet attained was at Hainault in 1872, say 206 tons per miner.

Iron.—Mr. John Cockerill, from England, introduced the system of smelting with coke in 1816, and established at Seraing one of the finest ironworks in Europe. This gave such an impetus to the trade that it grew as follows:—

	Ore.	Pig-iron.	Operatives.
1836	460,000 tons	150,000 tons	12,500
1860	900,000 "	320,000 "	25,000
1873	1,700,000 "	607,000 "	42,000
1878	1,300,000 "	464,000 "	24,000

Notwithstanding the depression in this trade, it is worthy of remark, "that in so adverse a season of three years (1874-77) not a single ironmaster in Belgium failed." The operatives accepted a reduction of 60 per cent. in wages, and thus enabled their masters to import pig-iron from England, make it into girders, send it back to England, and sell it at a profit.* Belgian ironmasters explain that they can undersell the British because their workmen are more thrifty and live on lower wages, the price of provisions being also less than in England. The value of the hardware industry of Belgium may be measured by the fact that the exports average £4,000,000 sterling, whereas ten years ago they were barely one-third.

Liege has grown up to be one of the great factories for arms. The value of this manufacture in 1829 was only £120,000, and now it falls little short of £1,000,000.

There are manufactures of zinc, copper, and lead, amounting in the aggregate to £2,000,000 per annum.

Glass has lately risen to great importance, as shown by the exports of this article:—

1867-68, average	£590,000 per annum
1877-76	1,550,000 "

Sweden.—The decree of 1765 prohibiting all manufactures, with the view of promoting agriculture, had a very disastrous effect. Factories of steel and of silk were closed, and the skilled artisans took refuge in Russia. After an interval of twenty years the insane law was repealed, but the country did not soon recover the blow. Prohibited duties upon foreign merchandise existed in full force till 1828. No sooner were they abolished than manufacture increased in a surprising manner. In 1839 the official returns showed an increase of 35 per cent. over ten years before. In 1876 the Swedish manufactures reached £10,250,000 sterling, counting merely the products of 2825 factories.

Coal abounds in Sweden, but costs more to raise than the price of coal imported from England. Swedish iron has long been considered the best in the world, and especially suited for making Bessemer steel. This is partly from the quality of ore, partly from the smelting with wood instead of coal. The supply of iron is inexhaustible. Tuberg, a hill of 370 feet high, is simply a mass of magnetic iron; it is described as "a source of riches to remotest posterity," although the ore is not very pure, yielding from 20 to 30 per cent. (which is considerably below the average of England). Persberg is another mountain of ore, containing thirteen mines; but the best ore is that of Dannemora, which produces 4000 tons of iron annually, the shaft (500 feet deep) being worked by blasting. The production of iron has increased as follows:—

1812	65,000 tons
1850	140,000 "
1870	292,000 "
1876	340,000 "

* In 1877 Belgium imported from Great Britain 68,000 tons pig-iron, and sent it back in the form of 46,000 tons of girders.

This does not include 78,000 tons Bessemer steel. The total number of miners and hands in the 200 mines and 1400 smelting-works usually ranges from 18,000 to 20,000. Copper-mines in Dalecarlia have been worked for a thousand years, especially those at Fahlun. The yield, however, has steadily declined, from 4000 tons per annum in the seventeenth century to 500 tons in recent years. The Fahlun mines now count but 500 workmen; the ore is inferior. All the copper-fields of Sweden now produce about 1400 tons, say one per cent. of the copper-crop of the world. Silver exists in many parts of Sweden, mixed with lead. Konigsberg was reputed the richest silver mine in Europe, having produced a block, almost pure, weighing 600 lbs., and worth £1800 sterling. At present, the total yield of silver in Sweden is under one ton per annum, say £6000 worth, or one day's produce of the Nevada or Peruvian silver-fields. Zinc is of some importance, the yield being over 40,000 tons yearly. There are numerous mines of lead, iron, and copper in Lapland, which can only be worked in midsummer, as the cold at other times congeals the engines.

Russia.—*Manufactures and Minerals.* From the beginning of the century until 1815 the industry of Russia was seriously checked by the Napoleon wars, but not altogether paralyzed. In 1808 there were 640 factories, chiefly at Moscow, Kazan, and Tula, for the manufacture of cottons, linens, woollens, leather, canvas, and cutlery, without counting the iron-works of Perm and Olonetz, or the mines of Siberia. The Ural mountains were said to be "the Potosi of Europe," yielding in minerals £6,000,000 per annum, of which one-third consisted of gold and silver. The iron of Dougua was esteemed equal to the best Swedish, however little developed owing to the difficulty of transport, sometimes taking three years to reach St. Petersburg. A second epoch may be said to date from the opening of three main canals between the Caspian, the Baltic, and the White Sea, almost coincident with the accession (1825) of the Emperor Nicholas. Shubert, in his report of 1828, sums up the total manufacture of Russia thus:—96 million yards of cotton, woollen, and linen fabrics, 16,000 tons of sugar, 7000 tons of soap, 15 million glass bottles, and £800,000 worth of silk manufactures. He took no account of hardware, although thousands of operatives were employed in the iron industries of Perm, Viatka, and Nijni, which counted 900 furnaces, while Tula and Olonetz produced large quantities of cutlery, arms, and artillery. Tula was already known as the Sheffield of Russia, its 600 workshops and 7000 artificers being specially famous for cutlery and snuff-boxes. At that time (1827–1832) iron was so dear that the horses were unshod, and even the farming implements were entirely made of wood. So rapidly did industry progress after the peace with Turkey (1828), that we find in 1840 there were 6850 factories, employing 413,000 operatives, besides 280,000 men engaged in the mines and ironworks. A separate report on the cotton factories (1842), shows 620 factories, of which 63 moved by steam, the whole employing 47,000 looms and 96,000 operatives, whose yearly product was over £5,500,000 sterling. The iron and copper works at Perm counted 7400 furnaces, and the annual production in all Russia was 4000 tons copper and 170,000 tons iron. Mining industry was still far from being adequately understood; the coal-beds of Taganrog were said to be not worth working, and salt was imported from England because the carriage from Orenburg was so expensive. The first time Russian coal came into use was in 1847, the yield being only 50,000 tons. Tegebolzki the same year estimated the manufactures of the empire at £72,000,000 sterling, but this seems to have been above the reality, as we find that in 1856 the amount was only £35,000,000, not including the minerals and metals. The production of iron between 1840 and 1850 averaged 150,000 tons per annum.

The production of coal has in late years risen to 7,000,000 tons, or two-thirds of the required quantity for consumption, the importation being close on 3,000,000 tons yearly. Gold-digging usually employs 20,000 miners in Siberia; the annual yield varies from £3,000,000 to £6,000,000 sterling. The iron-fields have yet to be fully opened up, the supply being so far short of the demand that the importation of iron and steel has grown six-fold in ten years, and now averages 300,000 tons per annum. The salt-works produce yearly about 1,000,000 tons, besides which 250,000 tons are imported. The progress of internal industry may be measured by the returns of the great annual fair at Nijni-Novgorod, viz.—

	Goods offered.	Goods sold.
1841	£8,000,000	£7,000,000
1857	13,000,000	12,000,000
1876	30,000,000	28,000,000

The merchandise disposed of between the 100,000 traders at this fair in 1876 consisted of:—

Cotton, linens, silks	£8,000,000
Ural metals	7,000,000
Flax, furs, leather, etc.	7,000,000
Flour, fish, brandy, etc.	3,000,000
Tea and luxuries	3,000,000
	£28,000,000

Austria-Hungary.—Exports have doubled in the last ten years, silk factories consume 2,000,000 lbs. silk, of which one-sixth is grown in the Tyrol, the rest imported. The factories are unable to supply enough silk fabrics for home use, although the manufacture has multiplied five-fold in ten years. The import of raw silk shows as follows:—

Average.	Raw silk.
1865-66	£292,000
1870-72	1,350,000
1875-76	1,490,000

Besides the home-made goods, Austria consumes imported silk fabrics to the value of £3,000,000 yearly.

There are 100 glass factories in Bohemia, and 70 in other provinces, producing wares to the value of £1,000,000 sterling, three-fifths of which are exported.

Bohemia has 1000 breweries, and the other provinces in proportion. The total product is 270,000,000 gallons, an increase of 60 per cent. on the returns for 1852. The exportation averages 4,000,000 gallons, leaving 266,000,000 for home consumption, or $7\frac{1}{2}$ gallons per head.

The sugar industry has increased as follows in twenty years:—

	1857.	1878.
Sugar-mills	91	217
Beet-root	410,000 tons	3,700,000 tons.

The annual production of beet-sugar is over 300,000 tons, worth £6,000,000 sterling, of which one-half is exported.

The growth of Austrian manufacturing industry in forty years is shown by the consumption of coal.

1839	500,000 tons
1864	3,500,000 "
1878	14,300,000 "

Minerals.—At the beginning of the century Transylvania was called "the gold-mine of Europe," the yield of the Kremnitz for 100 years averaging £300,000 per annum. Various mines of iron, copper, etc., were also carried on with such activity that Hungary had 45,000 miners, and at least as many more were employed in Illyria, Bohemia, and the salt-mines of Galitzin. Thus the annual yield of mines was not far short of £3,000,000 sterling in 1830, since which time it has more than doubled. The mining interest reached its highest point in 1873, when the total product was up to £9,000,000; but since then the iron industry has so much declined that the minerals do not sum up £7,000,000:—

Coal	£3,320,000
Iron	1,710,000
Sundries	1,770,000
	£6,800,000

Coal is increasing, the output now averages 12,000,000 tons, or 20 per cent. more than in 1873. The supply is, nevertheless, insufficient, and Austria has to import 3,000,000 tons yearly. The production of iron, in like manner, is so far short of the requirements, that the importation in the last ten years averaged 400,000 tons per annum. Styria ore is considered equal to Swedish in quality, and yields about 45 per cent. of metal. In the last century the Idria quicksilver mines averaged 600 tons per annum, but now they do not reach one-third of that quantity. These mines formerly exceeded the yield of the Almaden mines in Spain. Copper-mines in Hungary were advantageously worked before the present century. Most of the works, however, had been destroyed, the mines lying idle for several years. The ore is not rich, barely 4 per cent. being pure metal.

MINING LIFE—EXPLOSION OF FIRE DAMP.

—FROM "LA VIE SOUTERRAINE" BY L. SIMONIN.

Tin is extracted in Bohemia, and lead in Illyria. Sixty per cent. of the lead ore is metal. The salt mine of Wieliczka in Galitzia, at the base of the Carpathians, is the greatest in the world, extending six hundred miles, and seeming inexhaustible. For six centuries it has given prodigious quantities of salt. The Government has a monopoly, and sells the salt at £10 for home consumption, or £1 per ton for exportation. The works occupy 9,000 miners. The various mining and furnace works employ 84,000 men, 6,000 women, and 2,100 children, the distribution of hands being as follows:—

	Hands.
Coal	62,650
Iron	13,360
Silver	5,380
Lead, etc.	10,710
	92,100

The coal miners raise 12,000,000 tons a year, which represents £72 per miner. The iron miners and founders turn out twenty tons, worth £120 a head. The product of the lead mines is £80 each; and the general average of all mining £87 per head. Notwithstanding the depression, especially in iron, which has prevailed for a couple of years, it is likely mining will take strength, owing to the better economy in working. Each miner now produces much more than the average of 1873:—

	Coal.		Iron.	
	Miners.	Per head.	Operatives.	Per Head
1873	66,742	153 tons.	20,823	17¾ tons.
1876	62,650	192 "	13,360	20½ "
Increased yield per head		26 per cent.		16 per cent.

In like manner the production of silver has in several years increased 65 per cent. per head. The royalties on all the mines in the empire were £70,000 in 1869, and at present exceed £124,000 sterling. The miners have, in the last seven years, constructed seven hundred miles of railway. Steam power is aiding efficiently in the development of the mines, the number of engines at work having nearly doubled in seven years.

	1869.	1876.
In coal mines	447 engines	842 engines.
In other "	63 "	118 "
	510	960

Spain.—The miners are a prosperous and thrifty class of people. The masters provide them with schools, libraries, hospitals, etc., besides which the men have 355 joint stock banks, holding an aggregate capital of £717,000 sterling.

Hardware.—Toledo swords are still unequalled for temper, which some ascribe to the water of the Tagus. The royal factory usually employs about 300 operatives. Firearms are made at Valencia, artillery at Seville, nails, horseshoes, and copper utensils in Biscay. The muleteers of Vittoria convey weekly a ton of horseshoes to the inland provinces.

Minerals.—No country of Europe is richer in minerals, yet the total number of miners employed is only 43,500. There is no return of the value of minerals extracted, which will probably reach £7,000,000 as the exports are over £5,000,000. This branch of industry has trebled in twenty years, the exports of minerals in 1860-61 not exceeding £1,400,000. The returns for 1875 to 1877 average as follows:—

Lead	£2,050,000
Copper	1,650,000
Quicksilver	780,000
Iron	460,000
Zinc	240,000
	£5,180,000

The iron of Biscay, being specially suited for Bessemer steel and Krupp guns, is mostly exported to England and Prussia. The largest iron works are those of two English companies, and of Messers. Ibarra at Bilboa. The English companies at Cordova and Grenada have extracted such quantities of lead in the last twenty years, that other countries have had to suspend working their mines. The most productive coal-fields are those of Belmez and Seville, employing 10,000 miners, who extract only 300,000 yearly; this is barely one-third of the consumption in Spain, the rest being imported from England and Belgium. Previous to the discovery of quicksilver in California this article was almost a monopoly of Spain; the Almaden mines have been worked from the time of the Romans, and belong to the State; they employ 4000 miners, who raise 1500 tons yearly. Rio Tinto, near Sevill, is the most productive copper mine. There are 2000 silver mines, but the yield is trifling; even the Sierra Morena mines give less than in the eighteenth century.

Brazil.—There are various mining companies, but the most successful is that of San Juan del Rey, the annual output being 70,000 ounces of gold-dust, worth £220,000. The average dividends for the last thirty-three years have been 23 per cent. per annum; shares usually sell at four times their nominal value.

THE MINERAL PRODUCTION OF ITALY.

AMONG those countries on which we rarely obtain statistics is Italy. We are indebted to a memoir written by MM. Jean Beco and Lean Thouard, two well-known Belgian engineers, for the following data taken from quite an elaborate table, accompanied by many explanatory notes. The figures given are averages for the period of 1875 to 1879 for the production, exports, and imports:

	Production.	*Exports.*	*Imports.*
Iron ore	215,000	185,000	...
Pig-iron	16,000	.	56,000
Wrought-iron	46,000	.	66,980
Rails	...	...	47,470
Manganiferous iron ore	11,800	8,400	..
Ferro-manganese	3,000	3,000	.
Manganese ore	6,000	3,000	.
Copper ore	23,400	9,200	.
Copper (imports include brass, etc)	400	...	4,542
Zinc ores	65,200	65,200	...
Zinc	....	....	1,780
Lead ores	35,600	25,000	....
Lead	10,000	....	3,500
Silver ores	750		.
Silver, kilos	15,000	. .	..
Gold, kilos	100	..	.
Quicksilver	109	112	..
Iron pyrites	4,000	1,000	.
Graphite	740	710	70
Coal and coke	...	.	1,340,000
Anthracite	700	.	....
Lignite	120,000		..
Asphalt	6,000		12,500
Sicilian brimstone	282,000		
Romagnes refined sulphur	31,000	216,600	.
Other brimstone,	9,000		
Salt	321,000	102,800	.
Boracic acid	2,680	2,680	...
Sulphuric acid	13,000	..	510
Soda	15,900	472	13,400
Niter	1,700	...	3,520
Superphosphates	4,500	..	...
Powder and dynamite	1,500	....	....
Marble (Carrara, Masas Seravessa)	132,000	78,570	.
Marbles, other localities	45,000		
Pozzolana, cubic meters	230,000		
Talc	7,300		
Strontianite	1,000		
Ordinary lime	680,000	31,100	....
Hydraulic lime	60,000		
Cement	10,000		
Plaster	130,000		

—*Engineering and Mining Journal*

Great Britain's Coal and Iron Output in 1881.—The following statistics of the production of coal and ironstone (from the coal measures only) in the United Kingdom in 1881, has been supplied by the Home Office to the British Iron Trade Association. The total number of hands employed in and about the mines of the United Kingdom in 1881 was 495,477 as compared with 484,933 in 1880. The number of mines at work in 1881 was 3,847 as compared with 3,904 in 1880.

District.	*Coal.* *Tons.*	*Ironstone.* *Tons.*
Northumberland, Cumberland and North Durham	15,830,720	705
South Durham and Westmoreland	21 532,773	...
North Riding of Yorkshire and Cleveland	7,036	6,474,464
North and East Lancashire	9,326,722	....
Ireland	127,585	....

West Lancashire and North Wales	11,843,685	23,569
Yorkshire	18,287,141	171,146

Derbyshire, Leicestershire, Nottinghamshire & Warwickshire	15,545,667	47,137
North Stafford, Cheshire and Shropshire	6,473,900	2,113,600
South Staffordshire and Worcestershire	10,058,670	198,069
Monmouth, Somerset, and parts of Glamorgan and Breconshire	8,318,821	32,128
South Wales	16,008,525	111,984
Scotland, East	14,148,880	778,994
Scotland, West	6,674,175	1,816,381
Total	154,184,300	11,858,766
Ditto in the preceding year	146,969,409	11,664,726

—*Coal Trade Journal.*

Consumption of Coal in France.—For the year 1880, the consumption of coal in France was distributed as follows, according to *La Houille.*

Railroads	2,499,000 or	9·6	per cent.
Ocean steamers	450,000 "	1·8	" "
River steamers	112,000 "	0·4	" "
Mines	1,112,000 "	4·4	" "
Other industries	3,819,000 "	15·1	" "
Iron and steel-works	4,546,000 "	17·9	" "
Other metallurgical works	141,000 "	0·6	" "
Salt-works	115,000 "	0·5	" "
Domestic fuel	12,606,006 "	49·7	" "

Quicksilver Production in Spain.—Through the kind attention of his correspondent at Almaden, Spain, Mr. J. B. Randol, general manager of the New Almaden mines, Santa Clara county, California, is enabled to place at our disposal the accompanying statement of the production of quicksilver at the famous Almaden mine for the year 1881. As usual there was no work in June, July, August and September on account of hot weather. It will be observed that the production is given in kilograms, as 1,737,571,600 and dividing this amount by the number of flasks—50,353, we have as the contents of each flask 34,507 kilograms, which, at 2.2046 lbs. avoirdupois to the kilogram, gives the contents of the flask or bottle in English weight 76.07 lbs., or .403 of a pound less than is contained in the New Almaden "A" brand, which latter have a guaranteed weight of 76.50 lbs. net. To large consumers and close buyers this difference of weight and quantity in favor of the product of the New Almaden may be found worthy of note and we therefore call attention to the fact.

Quicksilver Production of the Almaden Mine (Spain) during the Year 1881.

Months.	*Production in Kilograms.*	*Equal in Flasks.*
January	251,503,400	7,288
February	223,961,100	6,490
March	273,743,200	7,933
April (29 days)	250,873,200	7,270
May (19 days)	192,490,200	5,578
June	......	..
July	......	..
August	......	..
September	......	..
October (12 days)	96,550,300	2,798
November	220,876,700	6,401
December	227,573,500	6,595
Total	1,737,571,600	50,353

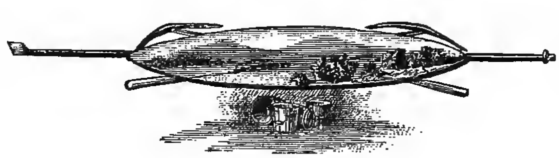
Equal to 34,507 Kilograms per flask.

N. B.—34,507 kilograms at 2.2046 lbs. avoirdupois=76.07 lbs. avoirdupois. 75 lbs. Spanish at 1.014331 lbs. avoirdupois=76.07 lbs. avoirdupois.—*Mining & Scientific Press.*

Russian Coal Statistics.—M. K. Shalkowsky, of the Russian department of mines, has officially published the following statistics of the production of coal in Russia for the year 1879. We have converted the figures on the basis of 36.116 pounds to the Russian pound.

	Pounds.	*Net tons.*
1874	78,813,137	1,423,245
1875	104,348,067	1,884,313
1876	111,302,028	2,009,941
1877	110,120,054	1,988,547
1878	154,024,302	2,781,363
1879	178,238,013	3,218,661

—*Coal.*



PART IV.

THE DISSEMINATION OF KNOWLEDGE, CONCERNING MINING INTERESTS—COURSES OF ENGINEERING—SCHOOLS OF MINES—MINING JOURNALS—U. S. GEOLOGICAL SURVEY.

KNOWLEDGE was defined on one occasion by one of the Argonauts of '49 to be "the possession of everything." Following out the Californian's idea the MINES, MINERS AND MINING INTERESTS OF THE UNITED STATES would not be complete unless it supplied its readers with an outline or panoramic view of what is being done in the country to forward a true knowledge of mining matters and to prepare the mining engineers for the duties before them. When in 1869 Professor R. W. Raymond, who has done so much for the honest growth of American mining, urged upon Congress the necessity of government founding a national mining school, it was done because he saw the great need of the hour, and was afraid that private initiative would not gratify it. Since then, though the government has taken no steps in the matter, the American colleges have come to the rescue, and where twelve years ago, a good outfit in mining education was difficult to obtain, to-day there is apparently some danger of overcrowding in the professions of Mine Engineering and Metallurgy.

Their courses are full and complete, and thoroughly practical. The wisdom of the old world has been drawn upon wherever it would aid the altered condition of the new. The student can, too, have his education for nothing. If circumstances have given him only an heritage of poverty the fullest and best courses in high technical education are still to be obtained at the cost only of hard work and earnest study.

In Part IV of our volume we furnish a good idea of the course of instructions in our various colleges as far as we have been able to obtain direct information from the colleges, also some notes on Education at Freiburg; Information Concerning the American Institute of Mining Engineers, the pioneer institution of its character; a list of prominent mining papers, the work of the U. S. Geological Survey, the Denver Mining Exposition, and some topics of kindred interest are touched upon.

TECHNICAL EDUCATION.

IT is no doubt to the interest of a metallurgist to employ a skilled laborer who will prevent waste by properly proportioning his materials; by regulating the supplies of air and fuel; by arranging his plant in the most economical manner, and by disposing of his products to the greatest advantage. The engineer is benefited by selecting for his assistant a person able to determine the values of his factors of safety for the same materials in different forms and positions, avoiding expensive suits for damages and cost of reconstruction; he should be able to so locate a road as best to fulfil the requirements of a through traffic, and yet develop local industries. But I need not multiply instances to show what all will readily concede, viz.; the advantages of a *theoretical* education; that was fully demonstrated at the previous special meeting, but it is still an open question whether the practical instruction should precede, accompany, or follow the theory.

In carefully canvassing the opinions of the members* who committed themselves on this subject, I find that *eight* were inclined to favor the first arrangement, *twelve* the second, and *eight* the last—giving a plurality in favor of the synchronal combination of the two departments of study of thirty-three per cent. over either of the other systems. Most of the advocates of this middle course are men of experience in both practical work and professional duties, and whose faith in the ability of the schools to make it a practical success is founded upon their knowledge of the requirements of both theory and practice. Numerous precedents are established in the technological schools of Russia, Germany, France, England, Sweden, and other countries; and so decided has been the impression made in this country by the exhibits of such institutions at the late Exhibition, that many of our instructors and their enterprising boards of trustees are using every effort to modify their rosters so as to embrace as large a proportion of practical work as possible in their curricula. A combined course conforms to the order of nature. From the very inception of knowledge, the sound or name and the thing are associated; the senses and mind are co-laborers—the first to glean, the second to direct, arrange, digest and utilize the information thus obtained. The mind and hand are essential to the engineer, and they are constantly called upon to assist each other, and this interpreter of the mind, the hand, gives exact expression to the imaginative and inventive faculties in the only universal language, that of form, as exemplified in drawings. But that the mind may direct the hand intelligently, it must itself be cultivated, and thus taught to know what is right or wrong, good or bad, safe or

* Members of the American Institute Mining Engineers.

unsafe, practical or visionary, and such knowledge can only be obtained by an intimate association with materials and tools, and the methods of using them, by which is developed their physical properties. To educate the mind simply by reading, as in a purely theoretical course for a number of years, and then to develop the practical requirements of one's nature, is abnormal, and a waste of time; the two assist each other by giving substance to the idea and weight to the formulas that may be used.

Another important consideration is the physical benefit conferred by a small amount of labor. The diligent student, without exercise, may graduate well, but it will be with an impaired constitution, caused by constant confinement and continuous and sometimes severe mental strain, which overtaxes and hence weakens the intellect; on the contrary, a due percentage of shopwork not only furnishes recreation and physical exercise, but enables the student to appreciate much better the practical advantage of his theory. It is urged by some of the advocates for separating the courses, that it is impossible to meet fully the requirements of practice in the schools. While this is undoubtedly true, much more may be taught in a practical direction than is generally imagined. All practical knowledge is progressive, and the sooner a student begins the better will be his chance of success. It is only by knowing what has been done and what has failed, with the reason why, that he can proceed rapidly to add to the general fund of invention or discovery. The greater the number of elements he possesses, the larger will be the number of possible practical combinations; and if the practical men will not furnish these elements, they must not expect from the schools such men as they desire to assist in developing their industries. The statement has been made that "before eighteen or twenty years of age the body is not generally sufficiently developed to endure the physical hardships of engineering." My own experience was so totally at variance with this, that I hope I may be excused the egotism of remarking that I was but a boy fourteen years old, only four feet nine inches high, and hardly more than an animated shadow, from the effects of intermittent fever and too much study, when my father took me from school and gave me a level rod, almost as heavy as myself (at least so it seemed), and so tall that I could not reach the target at the top, to operate on the Troy and Boston and Troy and Greenfield Railroads, in Massachusetts, during some severe fall and winter weather. Had I consulted my own comfort and convenience I should have preferred anything else, but I was obliged to weather it through whether I would or not, and it was, doubtless, the best school I ever attended.

A fellow-member remarks, of a blast furnace manager, "though he may have efficient subordinates in various departments, he must be able to understand and check their work, and he will find it extremely useful to be something of a mason, bricklayer, and carpenter, largely a surveyor, engineer, and mechanic, and well up in the general principles of chemistry and metallurgy." This I can heartily indorse, but I do not entirely approve the method proposed for acquiring such varied knowledge, that has been: "After the school *practice.*" Graduates, as a rule, are above mixing mortar, laying bricks, framing timbers, etc., but all this they can be made to do willingly, if incorporated in their course, and their tutor is the right sort of man, and will *show* them how. But this introduces the difficult element of finding capable teachers. It requires that they shall be practical men as well as scholars, and it is one of the chief obstacles to the successful establishment and operation of technical schools. If a man is a successful practitioner, and has the requirements of a good teacher, there are no schools that can hold out sufficient inducements for him to close his business and consent to teach. Again, there are many who are *too practical* to teach, having, as they say, "grown rusty on their mathematics," and most of those now engaged in teaching have not the experience required to do justice to so expanded a course of instruction. For the present, however, the difficulty may be met by calling in the service of some expert or foreman to explain the tools and their uses, and to direct students in their efforts to use them. A few weeks of such practice, with carefully prepared notes and sketches, would give them a fund of information they could never gather from books, and would do much towards breaking the ground for further cultivation by the professors. To accomplish this would require a small endowment, to be disposed of in a manner similar to the Whitworth scholarships in England.

Besides his practical knowledge, the engineer must be a man of integrity and good judgment, with experience in the management of men, and a financier. Most of these requirements can only be taught by combining theory and practice, organizing students into squads, gangs, or parties, and appointing one of them foreman, who directs the workmen in their several duties. By comparing the cost of a piece of finished work with the estimates, they learn the value of labor and materials; and so, in many other ways, can the workshop be made to supply a great defect in the older methods of education. With reference to æsthetics and art instruction, the greatest obstacle to progress arises from the apathy of the class intended to be benefited, the manufacturers, who, to protect themselves from competition, hesitate to furnish the information required to make such instruction practical. Hence it is that the remark is often heard that the designs of certain schools are pretty but impracticable. To overcome this defect to a certain extent, the Franklin Institute sent out the following circular to such of its members as would be most apt to respond favorably, but in return only a few drawings were received from a single firm:

HALL OF THE FRANKLIN INSTITUTE,
PHILADELPHIA, September, 1875.

Dear Sir: In view of the great demand for a better class of designs in our American manufactured articles, it is proposed to give especial attention to this subject in the Franklin Institute Drawing School during its coming sessions. In furtherance of this object, it has been decided to request from manufacturers of textile fabrics, paper-hangings, porcelain, etc., the donation of such articles as will exhibit the necessary elements of design, such as structure, form, color, etc., with any suggestion they may be pleased to make as to any special requirement which must be fulfilled to make a design of *practical* value. Donations are also requested from manufacturers of machinery of all kinds, of drawings or models that will serve as examples of mechanical drawing, representing modern practice in machine building. Any services that you may render the Institute, either by donation or information, will be properly acknowledged.

Respectfully yours,
J. B. KNIGHT,
Secretary.

Until we can have a better understanding and more perfect co-operation between manufacturers, engineers, and teachers, we cannot expect to make much progress in our efforts to educate men who may practice successfully from the date of their graduation. In conclusion, I have only to suggest that it would be a step in advance if such organized societies as this were to identify themselves with the educational institutions teaching kindred subjects, and by the appointment of a committee on Technical Education see that such information was placed within reach of those institutions as would assist them in keeping up with the progress of the age, and enable them to introduce, explain and exemplify the latest advance in methods and processes, by giving publications, pamphlets, drawings, photographs, models, ores, or manufactured articles to such schools; prevailing upon manufacturers to open their doors for visits of inspection by students, and assisting the latter to secure positions after graduating, by keeping a register of their names and addresses.

—Compiled from a paper by Lewis W. Haupt, Professor of Civil Engineering, Transactions American Institute of Mining Engineers.

THE UNIVERSITY OF PENNSYLVANIA

STUDENTS of Mining and Geology who aspire to an education fitting them to the duties and trials of the Mining Engineering profession will find a good course of study easily available in the Towne Scientific School, of the University of Pennsylvania. Students are practically under the supervision of Prof. George A. König, who writes us concerning the course of study as follows:

"Special students for the course of three years, must be thorougly prepared in the whole of Geometry, plane Trigonometry and

Algebra, including quadratic equations. Other knowledge outside of plain English, is *not required*, however desirable. But I place special stress upon a sure mathematical foundation, without which no satisfactory result can be obtained in matters belonging to Mining Engineering. Another feature of my course, is the absence of recitations from text books. My teaching is direct, as far from mechanical learning as possible. Mineralogy in all its branches is treated thoroughly, and altogether practically. My lectures on ore deposits I consider as very valuable facts, the specimens having all been collected by myself on the spot. Ore dressing and the metallurgical treatment of ores, I have made a specialty of, and recommend to the attention of all aspirants to the profession. Whilst the course and its success rely mainly upon my personal exertion, they are freely and wholly given to the earnest student."

The University of Pennsylvania is the outgrowth and successor of the College of Philadelphia, which was founded chiefly through the influence of Dr. Benjamin Franklin and Dr. William Smith. Dr. Smith was the first Provost, and he is conspicuous in American college history as having established here in 1757 the curriculum of study which was adopted substantially by all the colleges of later foundation, until scientific departments were attached to them. The College of Philadelphia was chartered in 1755, and is therefore the sixth in the order of succession of American Colleges. Instruction is now given in eight different departments, viz.:—

The Department of Arts, established in 1755; the Department of Medicine, established in 1765; the Department of Law, established in 1789; the Auxiliary Department of Medicine, established in 1865; the Towne Scientific School, established in 1872; the Department of Music, established in 1877; the Department of Dentistry, established in 1878; the Wharton School of Finance and Economy, established in 1881.

Public commencements are held—(1.) For the Towne Scientific School, on June 15th, or if this day falls on Saturday or Sunday, on the previous Friday. The following degrees are conferred: Bachelor of Science (B.S.) with mention of special course of study pursued. The latter degree is awarded to graduates of the Towne Scientific School. Post-Graduate Degrees—Civil Engineer (C.E.), Mechanical Engineer (M.E.), Mining Engineer (E.M.), to graduates in Science of three years' standing; Bachelor of Science (B.S.), in Sciences Auxiliary to Medicine, by the Auxiliary Faculty of Medicine.

The college year in the Towne Scientific School is divided into three terms: the first beginning on the 15th of September, and ending on the 24th of December; the second beginning on the 2d of January, and ending on the Wednesday before Easter; and the third beginning on the Tuesday after Easter, and ending on the 15th of June (Commencement Day). The annual tuition fee is $150, payable to the treasurer of the university in three instalments, on October 1st, January 1st and April 1st. The graduation fee is $20. A separate charge of ten dollars per term is made to the chemical and geological students of the junior and senior classes in the Towne Scientific School, for chemicals and gas, and a like charge of five dollars per term to students of the sub-junior class. Students are required to have their own apparatus. Examinations are held by the faculties of these departments, partly in the month of January, and partly, for the senior class in May, and for the lower classes at the close of the college year in June. During the first and second terms, private examinations by way of review may be held by each professor. At the end of each term students who attain distinction are classed in order of merit. Students shown by their term average to be deficient in any of their studies, may be conditionally attached to their class until they prove on re-examination that said deficiency has been fully made up. In case of persistent neglect of study, great irregularity of attendance, or evident inability to keep up with the class from any cause, the student must be dropped from the rolls.

The Towne Scientific School occupies a building that has a front on Locust street (between Thirty-fourth and Thirty-sixth streets, Philadelphia) of 254 feet, by 102 feet 4 inches in depth, exclusive of towers, bay windows, buttresses, &c., with an additional projection of the center 21 feet 10 inches beyond the wings. The cellar is arranged for the storage of coal, and an apartment in connection, outside the building, is provided for the boilers of the steam-heating apparatus. The basement on the sides and rear is entirely above ground, 15 feet high. There is an entrance in the rear for students to the assembly-room, 44 feet by 50 feet, and entrances on the east and west ends to a wide corridor, which extends the whole length of the building, in all the stories. The eastern wing contains: Laboratory, 30 by 45 feet, apparatus and store-room, 24 by 29 feet, metallurgical laboratory, 30 by 50 feet, a fire-proof furnace-room, 24 by 34 feet, balance-room, 14 by 17 feet, as well as smaller rooms for silver and gold assaying. The western wing contains: Laboratory, 30 by 45 feet, and apparatus and diagram room, 24 by 29 feet, for the chemical-lecture room on first floor, one laboratory, 30 by 50 feet, and one, 24 by 34 feet, for the physical department. Apartment for janitor and assistants are arranged on this floor, and for machinery, storage, dumb-waiters, water-closets, &c. The first or principal floor is 16 feet high. On the eastern side of the main entrance is the faculty-room of the scientific department, 13 by 22 feet, professors' laboratory, 19 by 45 feet, preparing laboratory, 21 by 24 feet, qualitative laboratory, 30 by 45 feet, quantitative laboratory, 30 by 50 feet, laboratory for organic analysis, 24 by 34 feet, two balance-rooms and two assistants' rooms. On the western side is the reception and secretary's room, 13 by 22 feet, trustees' and faculty-room, 19 by 37 feet, provost's recitation-room, 24 by 33 feet, and private room, 14 by 18 feet, chemical-lecture room, 30 by 45 feet, physical-lecture room, 30 by 50 feet, and apparatus-room, 24 by 34 feet. The library in center of rear, 44 by 50 feet, is entered from a hall 34 by 40 feet. This part of the building is fire-proof. The second floor is 15 feet 6 inches high. The chapel 50 by 80 feet, occupies the front of the center building, and is 28 feet high. The eastern side contains lecture-rooms for civil engineering, mining and metallurgy, and mineralogy, and a large museum for these departments. The western side and center of rear is divided into six large recitation-rooms, with adjoining private rooms. The third floor is 14 feet high, and contains three large recitation-rooms, lecture and model rooms for mechanical engineering, three large rooms for the study and practice of drawing in the departments of civil and mechanical engineering, architecture, &c. A large examination-hall is in the rear of the chapel. The fourth floor, over the chapel, has two society-rooms for students, each with an adjoining library. The design is in the collegiate gothic style; the material used is Lieperville stone, for the basement, with base course of Hummelstown brownstone. The walls above are serpentine marble, with cornices, gables, arches, &c., of Ohio stone. The entrance-porch is of Franklin stone, with arch supported on polished red-granite columns, with enriched capitals of Ohio stone. The windows of chapel and gables are decorated with geometrical tracery. The space devoted to the sciences more immediately connected with mining and metallurgy is one-half of the building. The chemical departments were planned by the late Prof. Wetherell, of Bethlehem.

THE FACULTY.—William Pepper, M. D., LL. D., Provost of the University, and *ex-officio* President of the Faculty. Rev. Charles P. Krauth, D.D., LL. D., Vice-Provost, and Professor of Intellectual and Moral Philosophy. E. Otis Kendall, LL. D., Dean of the Faculty, Professor of Mathematics. J. Peter Lesley, LL. D., Professor of Geology and Mining. Oswald Seidensticker, Ph. D., Professor of the German Language and Literature. John G. R. McElroy, A. M., Professor of Rhetoric and the English Language. Rev. Robert E. Thompson, A. M., Professor of Social Science. Frederick A. Genth, Ph. D., Professor of Chemistry and Mineralogy. George F. Barker, M. D., Professor of Physics. Lewis M. Haupt, C. E., Professor of Civil Engineering. Thomas W. Richards, A. M., Professor of Drawing and Architecture. George A. Koenig, Ph. D., Assistant Professor of Chemistry, Instructing in Metallurgy, Technical Chemistry, and Mineralogy. Samuel P. Sadtler, Ph. D., Assistant Professor of Chemistry, instructing in General and Organic Chemistry. Joseph T. Rothrock, B. S. M. D., Professor of Botany. William D. Marks, Ph. B., C. E., Whitney Professor of Dynamical Engineering. Otis H. Kendall, A. M., Assistant Professor of Mathematics. Andrew J. Parker, M. D., Ph. D., Professor of Comparative Anatomy and Zoölogy. John Welsh, Centennial Professor of History and English Literature.

INSTRUCTORS AND ASSISTANTS.—Morton W. Easton, Ph. D., Instructor in French and in Elocution. Henry W. Spangler, Assistant Engineer U. S. N., Instructor on Marine Engineering and Naval Architecture. Carl Hering, B. S., Instructor in Dynimical Engineering. Frederick A. Genth, Jr., M. S., Assistant in Analytical Chemistry. Herman A. Keller, B. S., Assistant in Geology and Mining Engineering. Lawrence B. Fletcher, Ph. D., Assistant in Physics. John G. McElroy, Secretary.

In order that this professional training shall be complete and systematic, and rest upon a broad basis, so that the student at its close may not be a mere *specialist*, but a man of liberal education as well, the course is comprehensive, extending through five years.* The students are divided into five classes,—Senior, Junior, Sub-Junior, Sophomore, and Freshman. The first two years are devoted, not merely to a thorough training in the preparatory and elementary Mathematics, Chemistry, and the methods of scientific research in general, but (for a considerable portion of the time) to instruction in History, English Composition, and Rhetoric, as well as to the Modern Languages and to Mechanical and Free-hand Drawing. At the close of these two years, the student is presumed to be prepared for studies of a strictly professional or technical character, and he then selects one of six parallel courses, in which instruction is given in this department. During the last three years, his work is confined mainly to the studies of one or another of these courses, in accordance with the plans he may have formed in regard to his future profession.

Terms of Admission and Degrees.—Candidates for admission to the Freshman Class must pass an examination in the following subjects:

GEOGRAPHY.—Ancient and Modern Geography. (Mitchell's *New Ancient Geography* and *Ancient Atlas* are recommended.)

ENGLISH.—Grammar, Composition, and Etymology (*Greek and Latin Roots.*)

Abbott's *How to Parse* indicates the amount required in Grammar, and Sargent's *Manual* the amount in Etymology. A composition, one (foolscap) page long, will be required on a theme to be set at the time of the examination.

MATHEMATICS.—Arithmetic (*including the Decimal System of Weights and Measures*), Algebra (*through Quadratic Equations,*) Geometry (*the first four books of Chauvenet or Wentworth*).

The professional courses from which a student may select are at present—I. A course in Analytical and Applied Chemistry and Mineralogy. II. A Course in Geology and Mining. III. A Course in Civil Engineering. IV. A Course in Mechanical Engineering. V. A Course in Drawing and Architecture. VI. A Course Preparatory to the Study of Medicine.

On the completion of any one of these professional courses, in addition to the studies pursued by the whole class during the five years of the curriculum, and on the presentation of a satisfactory thesis, the student is graduated BACHELOR OF SCIENCE. Special students, not candidates for a degree, may be received into any of the professional courses, when the Professor in charge of that course is satisfied of their competency to profit by his instruction. They take all the studies that the Professor thinks necessary to the completeness of the course, together with such others as the faculty may require. At the end of the course, upon passing the examinations required and presenting a satisfactory thesis, they will receive a Certificate of Proficiency. Application should be made to the Professor in charge of the department in which the student wishes to study; and definitive arrangements may be made with him,—subject, however, to the approval of the Faculty.

Course, Methods, and Means of Study—Instruction is made as practical as possible. It is given by lectures and recitations,—and by daily exercise in the Laboratories and the Drawing and Model Rooms. These are open to the students all day, work being required of the higher classes in the afternoon as well as in the morning hours.

* The four years' curriculum heretofore in force has been found too short for the work required of undergraduates in this Faculty, and it has accordingly been lengthened to five years. The statements in the catalogue have been adapted to the new arrangement; but the Seniors, the Juniors, and one section of the Sophomore Class, are pursuing the four years' course, whose requirements will be found in the catalogue of 1879-80.

In the Department of Chemistry, the Sophomores have a course of fully illustrated lectures, covering the whole ground of Inorganic Chemistry. In the Sub-Junior year, their work commences in the Analytical Laboratories, while they also attend lectures on Mineralogy and Metallurgy. In the Junior and Senior years, Qualitative and Quantitative Analysis and the making of Chemical Preparations are combined with lectures on Organic Chemistry and practical work on Metallurgical and Technical Subjects.

Students in Geology and Mining Engineering are trained in drawing-rooms in the platting of original field-notes, in contouring, in making relief maps of mineral properties, and in constructing sections on an equal vertical and horizontal scale, converting thereby their maps into clay and plaster models, with coloring to show the structure of the country. Solid models of underground work are made to show the position of the veins and beds, and the connection of these with the surface. To these are added illustrative diagrams and pictures, calculations of quantity, and whatever else is needed for the preparation of professional reports.

Students in Civil Engineering are instructed by recitations, lectures, and practical work, so as to develop to the best advantage the qualities required of the practical engineer. The afternoons and Saturdays are devoted to drawing and practical work in the shop, or to the surveying or visiting public or private works, manufactures, etc.

The *Course of Drawing* includes the projection of maps; various methods of representing Topography; conventional signs; problems in shades, shadows and perspective; details of framing; composition; general drawings for constructions in wood, stone, and iron; special designs; working drawings for modelling; platting; and drawing of profiles and cross-sections.

In *visiting shops and manufactories*, students are required to collect all the practical information possible, and to embody it in a written report, noting particularly any new or special features for economizing time or materials, improved methods of assembling parts, etc., as well as the general plant, apparatus, and facilities for receiving and shipping materials.

The *field practice* embraces the various problems in chain surveying, the measurement of areas, and the computation of results; line surveys and location, cross-sections and levels for estimating quantities, hydrography, topography with the plane-table, and the solution of such geodetic problems as relate to the orientation of maps.

Students of Dynamical Engineering are required to give particular attention to the kinematics of mechanism, to the conditions under which work and power act, and the means of regulating and transmitting the same; to the problems of hydraulics or hydraulic motors, and to the mechanical theory of heat, with its applications to the steam engine, etc., as will appear from the detailed course of study given elsewhere.

Special attention is given to the execution of drawings, first from designs and models, and afterwards from calculations; and also to the methods of casting and working in iron, and of making and using machine tools. The recent appointment to this department of an Instructor in Marine Engineering and Naval Architecture provides for instruction in these subjects. Weekly visits of inspection will be made during two years of the course to blast furnaces, foundries, machine shops, iron and steel rolling-mills. The instruction in Physics extends over three complete years. In the Sub-Junior year, the subjects treated are Elementary Mechanics and Sound, the exercises consisting of recitations from a text-book, illustrated by experiments, with occasional lectures. In the Junior year, the subjects treated are Heat and Light, the instruction being by lectures, with recitations and examinations. In the Senior year, lectures are delivered on Electricity, and on Astronomical and Terrestrial Physics. The Senior Class receives also practical instruction in the Physical Laboratory throughout the year. The education of the eye and hand which is thus given, secures familiarity with apparatus and the knowledge of methods of precise measurement.

The Rogers Engineering Library is composed of standard works on the various sub-divisions of the profession, treating of drawing, mathematics, astronomy, physics, surveying and explorations, technical works on the roads, and strength and properties of materials, railroads, tunnels, canals, water-supply, drainage, architecture, mechanics, navigation, harbor improvements, park and landscape engineering, with a valuable collection of Reports of American, English and French Engineering Societies, and periodicals, Coast Survey and hydrographic charts, maps, diagrams and drawings. Letters of inquiry may be addressed to Professor E. O. Kendall, Dean of the Faculty, or to Professor J. G. R. McElroy, its Secretary, at the University.

COURSE OF STUDY.

FRESHMAN YEAR.—*History.*—Freeman's *General Sketch of History.*
English.—Abbott's *How to Write Clearly,* and McElroy's *System of Punctuation.*
French.—Collot's *Pronouncing French Reader.* Bregy's *Compendium of Grammatical Rules* (First Part).
Mathematics.—Thompson and Quimby's *Algebra.* Chauvenet's *Geometry.* Chauvenet's *Plane Trigonometry.*
Drawing.—Geometrical and Isometrical Drawing (Minifie), and Drawing from the Flat. Free-Hand Sketching. Use of the Scale and Protractor. Shading in India Ink. Graphical representations from Geometry.
German.—Schmitz's *German Grammar; Elementary German Reader.*
SOPHOMORE YEAR.—*English.*—Elements of Rhetoric (Lectures). Haldeman's *Outlines of Etymology.* Lounsbury's *English Language.* Compositions and Declamations.
German.—Hodge's *Course of Scientific German.* Storm's *Immensee. Guide to German Conversation.* Translations into German.
French.—Souvestre's *Un Philosophe sous les Toits.* Bregy's *Compendium of Grammatical Rules.* (Part II).
Mathematics.—Chauvenet's *Spherical Trigonometry.* Bowser's *Analytical Geometry.* Descriptive Geometry.
Drawing.—Linear Perspective. Geometric and Isometric Drawing. Projection of Shadows. Architectural Detail and Ornament. Gothic Tracery. Shading in India Ink. Free-Hand Drawing.
Chemistry.—Inorganic Chemistry (experimental Lectures).

STUDIES PURSUED BY THE WHOLE CLASS.

SUB-JUNIOR YEAR—*Chemistry.*—Exercises in Analytical Chemistry and recitations in analytical and general Chemistry.
Physical Science.—Mechanics (including Hydrostatics and Pneumatics), Sound.
Mineralogy.—Crystallography and General Description of Minerals.
Mathematics.—Descriptive Geometry. Differential Calculus.
German.—*Der Mensch und die Natur* Lessing's *Nathan der Weise.*
French.—Racine or Corneille.
English.—Critical Reading of English Authors. Compositions and Declamations.

1. *Studies pursued by the Chemical Section.*

Mineralogy.—Special description of species, and practical exercises in determining minerals by their physical properties.

2. *Studies pursued by the Geological and Mining Section.*

Mineralogy.—Same as in 1st section.

3. *Studies pursued by the Civil Engineering Section.*

Engineering.—Spherical Projections. Graphical Statics.
Mathematics.—Differential Calculus.
Drawing.—Topographical Charts. Problems in map projections. Perspective. Details of frames, joints, etc.

4. *Studies pursued by the Dynamical Engineering Section.*

Mathematics.—Differential Calculus.
Statics.—The application of the principles of Statics to Rigid Bodies. The Elasticity and Strength of Materials. Forms of uniform strength. Theory of framed structures. Stability of structures. Theory of the arch. Strains in parts of mechanism. The Equilibrium and Pressure of fluids, as water, air, steam, etc. The equilibrium of fluids with other bodies, stability of vessels; determination of specific gravity; use of Hydrometers, Manometers, Gauges, etc. The Equilibrium of Funicular Structures.
Drawing.—Copies of bolts and nuts; riveting; gudgeons, pivots, axles, shafts, couplings, pillow-blocks; shaft-hangers, pulleys, sheaves, and gear-wheels; connecting rods and cranks, working-beams, crossheads, pipe-connections, valves, steam cylinders, pistons, stuffing-boxes, glands, etc., etc.

STUDIES PURSUED BY THE WHOLE CLASS.

JUNIOR YEAR.—*Physical Science.*—Heat and Light. Lectures and Recitations.
Philosophy.—Atwater's *Logic.* Intellectual and Moral Philosophy.
English.—Compositions and Declamations.
Descriptive and Determinate Mineralogy.
Elements of Geology.
Metallurgy.—Theory of Metallurgical Processes. Construction of Furnaces. Dressing and Mechanical Treatment of Ores.

1. *Studies pursued by the Chemical Section.*

Organic Chemistry—Lectures and making of organic chemical preparations and organic analysis.
Qualitative analysis by the blowpipe, in connection with reactions in the humid way for the rapid determination of Minerals and Ores.
Introduction to Metallurgy.—Theory of Metallurgical Processes; theory and construction of furnaces and other metallurgical apparatus. Dressing of ores considered theoretically and practically.
Assaying of ores and fuels, with special application of volumetric analysis.
Demonstration of the principal metallurgical processes by furnace practice.
Instruction in the practical production of chemical salts, preparations, and simple substances in their greatest perfection and purity; and also according to the principles which govern their manufacture on a large scale.
Qualitative Analysis of more complex substances, with practice in determining the color and condition of products and in the determination of minerals.
Qualitative Analysis and detection of the rarer elements and organic constituents of bodies. Introduction of Quantitative Analysis. Use of the spectroscope in qualitative determinations.

2. *Studies pursued by the Geological and Mining Section.*

Lithology and Palæontology.—Examination and determination of Rocks and of Fossil Organic forms.
Mining Engineer.—Methods used in searching for and developing deposits of valuable Minerals. Sinking of Shafts. Drifting and Stopeing.
Drawing and Modelling.
Dynamical Engineering.—Statics and Dynamics of rigid bodies. Determination of centres of gravity; moments of flexure, rupture, etc. Practical exercises in constructing and drawing machines.
Surveying.—Same as Section 3. At the beginning of summer vacation a complete mine survey will be executed in the coal regions.
Analytical Chemistry, Metallurgical Practice and Assaying.—The same as the Chemical Section.
Field excursions into the neighboring mineral districts for the demonstration of practical Geology.

3. *Studies pursued by the Civil Engineering Section.*

Mathematics.—Differential and Integral Calculus.
Surveying.—*Field-Practice;* including Chain Surveying, Use of Compass, Transit and Plane-Table in measuring lines and areas, Traversing and Location of Roads, Drains, etc., on Topographical Charts. Recitations from Gillespie's *Land and Higher Surveying,* Henck's *Field-Book for Engineers,* and *Earthwork Formulæ.*
Drawing.—Topography in ink and colors, Studies in Contours. Platting field-notes; Shades, Shadows, and Perspective.
Architecture.—Ornament. History of Architecture. Decorations and Shading.
Engineering.—Mechanics of Engineering, embracing the Statics of Rigid Bodies, Determinations of the Centres of Gravity, Moments of Flexure, Rupture, Resistance, Torsion, Analysis of Bridge and Roof Trusses, Strength and Properties of Materials, etc.
Modelling.—Construction of Scarfs and Joints used in Framing, Centres, Caissons, Coffer-Dams, Trestles, Bents, etc., from working drawings.

4. *Studies pursued by Dynamical Engineering Section.*

Mathematics.—Differential and Integral Calculus.
Statics.—The application of the principles of Statics to Rigid Bodies. The Elasticity and Strength of Materials. Forms of uniform strength. Theory of framed structures. Stability of structures. Theory of the arch. Strains in parts of mechanism. The Equilibrium and Pressure of fluids, as water, air, steam, etc. The equilibrium of fluids with other bodies; stability of vessels; determinations of specific gravity; use of Hydrometers, Manometers, Gauges, etc.
Kinematics.—Laws of motion. Elementary combinations of Pure Mechanism. Pulleys and belts. Trains of gearings and forms of teeth of wheels. Parallel motions. Link and valve motions, with a consideration of the various forms of valves, illustrated by working models.
Drawing.—From the model and original design.
Construction and Practical Applications.—Weekly visits of inspection will be made to blast-furnaces, foundries, iron and steel rolling-mills, ship-yards, steam and hydraulic forges, etc.

5. *Studies pursued by the Section in Drawing and Architecture.*

Mathematics.—Differential and Integral Calculus.
Drawing and Architecture.—The Study of Executed Works and of Buildings in Progress. History of Architecture, illustrated by

views of structures of all ages. Ornament. Shading in India Ink.
Engineering.—Same as Section 3.

6. *Studies in the Course preparatory to Medical Studies.*

Chemistry.—Laboratory Practice in Qualitative Analysis. Organic Chemistry (Lectures and practical analysis.)
Botany.—Systematic Botany and Special Morphology.
Zoology.—Invertebrate Zoology and Embryology.
Latin.—Reading of Latin Authors.

SENIOR CLASS.—STUDIES PURSUED BY THE WHOLE CLASS.

English.—Compositions. Declamations.
History.—Mediæval History. Lectures.
Social Science.—International Law. Thompson's *Social Science and National Economy.*
Astronomy.—Gummere's *Astronomy.*
Physical Science.—Electricity, Astronomical Physics, Practical Physics (Instruction in the Physical Laboratory.)
Geology.—Structural Geology of North America with reference to that of Europe, and with the principal minerals and fossils, distribution of metals and fuels. History of Geology.

1. *Studies pursued by the Chemical Section.*

Lectures on the applications of Organic Chemistry in the useful arts.
Quantitative Gravimetric Analysis of the simple and complex salts and minerals. Volumetric Analysis and preparation of normal solutions. Gas Analysis. Manufacture, graduation, and use of eudiometers.
Determination of the constituents of cast-iron and steel. Practice in Agricultural Chemistry, and Analysis of Manures.
Determination of small amounts of impurities (adulteration and poison in food and drink). Analysis of water of mineral springs. Practice in production of Chemical preparations. Quantitative Blowpipe Analysis.
Special Metallurgy—Gold, Silver, Lead, Copper, Zinc, Cobalt, Nickel, etc. Metallurgy of Iron and Steel treated with special attention. Metallurgical practice. Construction of plans for metallurgical works, with estimates of cost.
Practical determination of minerals by their physical properties.

2. *Studies pursued by the Geological and Mining Section.*

Geology.—The ore and Coal deposits of the United States in their topographical and structural relations.
Mining Engineering.—Ventilation and Drainage of Mines. Description and construction of Mining Machinery.
Dynamical Engineering.—Motors and Principles of Mechanism.
Surveying.—The survey made during the previous vacation will be mapped.
Metallurgy, Analytical and Didactic Chemistry.—with Section 1.
Practice in Lithological Determination by means of microscopic sections and microchemical tests.
Construction and Application of Geological Sections relating to problems of mining.

3. *Studies pursued by the Civil Engineering Section.*

Engineering.—Nomenclature of and Constructions in Masonry, Timber, Iron and Steel, as applied to Lighthouses, Bridges and Roofs, Depots, and other engineering structures. Strains in Girders and similar structures. Equilibrium of Arches and Retaining Walls. Tunnelling and Earthworks, with the required plant and organization. Sea-Coast and Harbor Improvements. Canal and River Improvements. Transportation. Hydraulics. Preparation of estimates and contracts. Reports on Tours of Inspection. Thesis, etc.
Drawing.—Details of Engineering Works, Composition, Plans, Sections, Elevations, Profiles and Cross-Sections. Working drawings. Platting field notes and computations from data.
Surveying.—Field Practice. Reconnoissance, Use of Prismatic Compass, Level, Solar Transit, Repeating Theodolites, and Heliotropes, Sketching; Preliminary Surveys for and Locations of Roads, Railroads or Canals; Hydrography; Laying Out of Parks; Use of Sextant, etc.
Geodesy.—Measurement of Bases, Triangulation, Determination of Meridian, Latitude, Longitude, Time, and Azimuth.
Visits of Inspection to public and private works, with reports thereon.
Architecture.—Shading, Decorations. History of Architecture (continued).
Metallurgy.—Technical Chemistry and Metallurgy.
Modelling.—Construction of trusses for bridges and roofs, girders, etc. Conducting experiments on strength of beams and trusses, Problems in stone-cutting. Tunnels.

4. *Studies pursued by the Dynamical Engineering Section.*

The Analysis and Synthesis of Mechanism.—Machine Tools and their principles. Lectures on forging, riveting, pattern-making and moulding.

Dynamics.—Lectures on the conditions under which work and power act, and the means of regulating and transmitting the same. The Efflux of Fluids. The Flow of Fluids through pipes. The Impulse and resistance of Fluids. Theory of Oscillation of Fluids. Lines of least resistance. Hydraulic Motors Turbine, overshot, breast, and undershot water-wheels.

Thermodynamics.—Value of Fuels. Strength, safety, and evaporative power of boilers. Steam and its properties. The Mechanical Theory of Heat. Stationary, locomotive and marine Steam Engine. Lectures on the proper proportions of the various parts of the Steam Engine.

Lectures on, and Use of Instruments.----Steam Engine Indicator. Planimeter. Dynamometer. Odontograph. Slide Rules. Arithmometers. Trammel and Testing Machines. Peaucelier's Compound Compass.
Construction and Practical Applications.—Weekly visits of inspection will be made to blast-furnaces, foundries, machine shops, iron and steel rolling-mills, ship-yards, steam and hydraulic forges, etc., etc.
Drawing.—Original designs. Designs and calculations for special machines. Detailed working drawings with specifications.
Metallurgy.—Chemical Technology and Metallurgy.

5. *Studies pursued by the Section in Architecture and Drawing.*

Engineering.—Calculation of the strength of roofs and bridges. Foundations, retaining walls, arches. Same as Section 3.
Architecture.—Elements of designs and principles of composition. Ornament of all styles. Sketching and measurement of works executed and in progress, building materials and processes. Specifications. Contracts.
Drawing.—Plans, Elevations, and Sections of original designs. Exercises with perspective views. Water-color.

The students of the school for the academical year 1882-3 are as follows: Post-Graduate, 1; Seniors, 24: Juniors, 23: Sophomores, 42; Freshmen, 49; Special Students, 33. Total Matriculates in Towne Scientific School, 171.

The Lehigh University.—The Hon. ASA PACKER of Mauch Chunk, during the year 1865, appropriated the sum of Five Hundred Thousand Dollars, to which he added one hundred and fifteen acres of land in South Bethlehem, to establish an educational Institution in the rich and beautiful Valley of the Lehigh. From this foundation rose THE LEHIGH UNIVERSITY, incorporated by the Legislature of Pennsylvania in 1866. In addition to these gifts, made during his lifetime, Judge Packer by his last will secured to the University an endowment of $1,500,000, and to the University Library one of $500,000. The original object of Judge Packer was to afford the young men of the Lehigh Valley a complete technical education for those professions which had developed the peculiar resources of the surrounding region. Instruction was to be liberally provided in Civil, Mechanical and Mining Engineering, Chemistry, Metallurgy, and in all needful collateral studies. French and German were made important elements in the collegiate course. A School of General Literature was part of the original plan, together with tuition in the ancient Classics. The Institution was freely opened to pupils from every part of the country and the world. It will be observed that all these educational facilities are provided without charge. Through the generosity of the Founder, the Trustees were enabled, in 1871, to declare tuition free in all branches and classes. The Lehigh University is open to young men of suitable talents and training from every part of our own land and of the world. To this fact the attention of the pupils of our public schools and of the graduates of classical institutions is especially called. Thus is offered *without charge*, every facility for studying the professions of the Civil, Mechanical and Mining Engineer, and of the Metallurgist and Analytical Chemist. In the Classical and Scientific departments of the School of General Literature instruction is given to those who wish to become lawyers, clergymen, physicians, editors, or merchants.

Expenses.—Tuition is FREE in all branches and classes. Books, materials, paper, pencils, chemical materials used in the analytical laboratory, and drawing instruments, are furnished by the student. Rooms and board can be had in University buildings, under the following rules:

1. The room-rent, for each term, must be paid in advance to the Treasurer of the University. The price for board must also be paid monthly in advance.

2. The charge for board and room-rent shall be $5 per week. Where two students occupy a room jointly, the charge shall be $4.50 per week for each. The charge for

room without board shall be $2 per week for each room. These prices include gas and heat.

3. The choice of rooms shall be in order of the classes; in any class the first applicant to have the first choice.

4. Students may retain their rooms from year to year by giving notice of their intention so to do at the close of the academic year, and by procuring their tickets therefor on or before the first day of the next term.

5. Students are required to keep their rooms in order, or to employ some proper person to do so for them.

6. No furniture for rooms will be provided by the University.

7. The use of kerosene, coal oil or burning fluid, in any of the buildings, is prohibited. The following is an estimate of the necessary expenses for the collegiate year, clothing and traveling not included:

Board for 40 weeks	from $100	to	$200
Room rent, with fuel and lights	" 40	"	80
Care of room and use of furniture	" 5	"	20
Washing and incidentals	" 15	"	30
Books, stationery, etc.	" 20	"	45
Total	$240	to	$375

NOTE.—If clubs be formed the cost of board need not exceed $3.50 per week.

Admission.—Application for admission into the University should be made to the President, from whom all information may be obtained. Candidates for the Freshman class are examined orally and rigorously. All candidates must be at least sixteen years of age, must present testimonials of good moral character, and satisfactorily pass in the following subjects: 1. *English Grammar*, including composition, spelling, and punctuation. It is recommended that candidates have a knowledge of Latin Grammar, although an examination in it is not required for any other course than the classical. 2. *Geography*, general and political. 3. *History of the United States*. 4. *Physical Geography*, Mitchell's or Guyot's, or an equivalent. 5. *Arithmetic*, including the metric system of weights and measures. 6. *Algebra*, through equations of the second degree. 7. *Chauvenet's Geometry*, or Davies' Legendre, six books, (Chauvenet preferred).

All applicants for regular standing in the classes or schools must be prepared to pass an examination according to the programme of studies. A student may be admitted at any time if able to pass a satisfactory examination in the studies already pursued by the class that he proposes to enter. The only exception will be in the case of a young man who is very nearly but not thoroughly prepared to enter in full standing and who may, at the discretion of the Faculty, be admitted conditionally, to make up his deficiencies by extra study. When they are made up, he will be received in full standing into his class. Young men who do not desire to take a full regular course may enter, upon a satisfactory examination, and select special shorter courses, with the sanction of the Faculty.

Programme of Studies.—The following is presented as the general programme of instruction, subject to such modifications from time to time as the Faculty may deem expedient, with the approval of the Trustees. The names of the text-books studied are generally mentioned. The number of exercises per week in each subject is indicated by the figure in parenthesis immediately following. Two hours of Drawing, three of work in the Laboratory, or three of practice in the field, are equivalent to a recitation or lecture of one hour's duration.

Faculty. — Robert A. Lamberton, LL.D., President. Henry Coppée, LL.D., Professor of English Literature, International and Constitutional Law, and the philosophy of History. William H. Chandler, Ph.D., F.C.S., Professor of Chemistry and Director of University Library. Benjamin W. Frazier, A.M., Professor of Mineralogy and Metallurgy, H. W. Harding, A.M., Professor of Physics and Mechanics. James P. Kimball, Ph.D., F.G.S., Professor of Economic Geology. C. L. Doolittle, C.E., Professor of Mathematics and Astronomy. W. A. Lamberton, A.M., Professor of the Greek Language and Literature. Mansfield Merriman, C.E., Professor of Civil Engineering. S. Ringer, U.J.D., Professor of Modern Languages and Literatures and of History. Henry C. Johnson, A.M., LL.B., Professor of the Latin Language and Literature. The Rev. Frederic M. Bird, A.M., Chaplain and Professor of Psychology, Christian Evidences and Rhetoric. Edward H. Williams, Jr., E.M., A.C., Professor of Mining and Geology. J. F. Klein, D.E., Professor of Mechanical Engineering. LECTURER.—Traill Green, M.D., LL.D., Lecturer on Physiology and Hygiene. INSTRUCTORS.—Spencer V. Rice, C.E., Instructor in Drawing and Civil Engineering. E. H. S. Bailey, Ph.B., Instructor in Chemistry. A. E. Meaker, C.E., Instructor in Mathematics. Lester P. Breckenridge, Ph.B., Instructor in Drawing and Mechanical Engineering. A. W. Sterner, Clerk to the Director of Library.

Calendar—1882-83.

1882.

Sept. 4-5,	Monday and Tuesday		Examinations for Admission.
Sept. 6,	Wednesday	. . .	First Term begins.
Oct. 12,	Thursday	. . .	Founder's Day.
Nov. ,	Thursday	. . . .	Thanksgiving Day.
Dec. 20,	Wednesday	. . .	First Term ends.

1883.

Jan. 10,	Wednesday	. . .	Second Term begins.

THE SCHOOL OF TECHNOLOGY.—This school includes four distinct courses: I. The Course in Civil Engineering; II. The Course in Mechanical Engineering; III. The Course in Mining and Metallurgy; IV. The Course in Chemistry. These have the same curriculum of studies for the first three terms (one year and a half.) At the end of that time the student selects his course and follows its programme.

FIRST TERM.

FRESHMAN CLASS.—*Mathematics.*—Chauvenet's Geometry, (completed). (5)

Physics.—Mechanics, with Lectures. (2)

German.—Otto's Grammar. Writing in German Text. Translations into English. (3) Or *French.*—Fasquelle's Introductory Course. Chouquet's Reader. (3)

Drawing.—Elementary Projections, Shading and Lettering. Free-Hand Drawing. (4)

Physiology and Health.—Lectures. (1)

English.—Essays and Declamations. (2)

SECOND TERM.

Mathematics.—Olney's University Algebra, Part III. (3) Plane and Spherical Trigonometry and Mensuration. Use of Logarithmic Tables. (2)

Chemistry.—Lectures. Fownes' Elementary Chemistry. (3)

German.—Otto's German Grammar. Translations. Ahn's Second German Reader. (3) Or *French.*—Languillier and Monsanto's Practical French Course. Translations. Keetel's Analytical Reader. (3)

Botany.—Lectures and Practice. Gray. (1)

Drawing.—Projection Drawing. Descriptive Geometry. (2)

English.—Essays and Declamations. (2)

THIRD TERM.

SOPHOMORE CLASS.—*Mathematics.*—Analytical Geometry. Olney's General Geometry. (4)

Chemistry.—Lectures and Laboratory Practice. Galloway's Qualitative Analysis. (5)

Physics—Heat, Meteorology, Magnetism and Statical Electricity. with Lectures. Laboratory Practice in these branches and Mechanics. Barometrical leveling and Measurement of heights. (3)

German.—Otto's Grammar. Oral translations. Ahn's Reader. (2) Or *French*—Languillier and Monsanto's Practical French Course. Translations. Keetel's Analytical Reader. (2)

Drawing.—Isometric Drawing. Architectural Drawing. (2)

English.—Essays and Declamations. (1)

The Course of Civil Engineering.—The general scope of this Course comprises the higher branches of the applied mechanics and mathematics, together with the principles of construction and exercises in mapping, drawing and designing. The student is made acquainted with the strength of materials, including the theory of elasticity or flexure, the principles of construction of roof-trusses, beams, girders and bridges, the determination of their proper dimensions and the preparation of working-drawings. Under this head belong also the theory of the stability of structures, including the theory of the arch and of retaining walls; the principles of hydrostatics and hydraulics with their applications to vertical water-wheels and turbines. The theoretical priciples are in all cases illustrated by examples from actual engineering practice. Much time is devoted to surveying operations and to actual practice in the field. Profiles, plans of topographical surveys, contour maps, and railroad charts are made. The practical operations connected with the reconnaissance, location and survey of roads, canals and railroads, are fully illustrated in the field. Thorough instruction is given in drawing, the construction of working drawings of structures, topography and hydrographical charts.

Attention is also paid to the application of the general principles of the science of engineering, or to engineering construction, incluing the composition and qualities of materials; their dressing and preservation; foundations, earth and rock-work; the drainage, collection and distribution of water. Visits of inspection to engineering structures in the Lehigh Valley and vicinity are regularly made. So much of Mechanical Engineering is necessarily included, as refers to the construction of bridges, and the special machinery and appliances used in the erection of structures. There is also thorough instruction in mineralogy and geology. The course in astronomy in the Senior year includes practical work in the observatory. Designs for and reviews of special structures, specifications and estimates of quantities and cost, and the preparation of a graduation thesis giving evidence of satisfactory attainments, complete the course of study. The graduate in this course will receive the degree of Civil Engineer. (C. E.)

SECOND TERM.

SOPHOMORE CLASS.—*Mathematics.* — Differential and Integral Calculus: Olney. (4)

Physics.—Galvanism, Acoustics, Light, with Lectures and Laboratory Practice. (5)

German.—Systematic Readings. Translation. Dictation. (2) Or *French.* — Wall's Student's Grammar. Systematic Readings. Dictation. (2)

Drawing. — Line Shading. Sketching. Drawing of Structures from actual measurement. (2)

Surveying.—Use of Compass, Level and Transit. Maps of Farm Surveys. Profile and Contour Maps. (3)

English. Essays on Scientific subjects. Declamations. (1)

FIRST TERM.

JUNIOR CLASS. — *Mathematics.* — Integeral Calculus: Courtenay. (2)

German.—Systematic Readings. Lectures on Syntax. Compositions in German. (2) Or *French.*—Readings. Translations. Dictation. (2)

Mechanics.—Smith. Mathematical Theory of Motion. Science of Motion in General. Statics. Dynamics and Statics of Fluids. Lectures on the Theory of Centre of Gravity and Momenti of Inertia. (5)

Surveying.—Triangulation. Leveling. Topographical Surveys and Maps. (4)

Construction.—Materials of Construction. Carpentry. Masonry. Foundations. (1)

Crystallography.—Lectures, with practical exercises in the determination of Crystals. (2)

English.—Essays on engineering subjects. Declamation. (1)

SECOND TERM.

German—Systematic Readings. Compositions. (2) Or *French.* Systematic Readings. Compositions. (2)

Strength of Materials.—Elasticity and strength of wood, stone, and metals. Theory of columns, shafts, and beams. Testing of materials. (3)

Surveying.—Railroad Reconnoissance and Location. Survey of a Line, with profile, map and estimate of cost. (3)

Stone-Cutting.—Working drawings of piers and arches. (2)

Construction.—Methods of construction and maintenance of roads and railroads. (1)

Prime Movers.—Steam Engines and their accessories. (3)

Mineralogy.—Descriptive Mineralogy, with practical exercises in the determination of minerals. (3)

Essays and Original Orations.

FIRST TERM.

SENIOR CLASS.—*Astronomy.*—Descriptive Astronomy: (3)

Roofs and Bridges.—Theories and calculation of strains in trusses. (3)

Graphical Statics.—Analysis of roof trusses and arches. (2)

Surveying.—Use of plane table and sextant. Hydrographic surveys and charts. Gauging of streams. Geodetic surveying (3)

Construction and Design.—Study of bridge details. Reports on stability of bridges. Design for a simple structure. (3)

Geology.—Lithology, with practical exercises in determining rocks. (3)

SECOND TERM.

Astronomy.—Practical Astronomy as applied to Geodesy and Navigation. Lectures and Observatory work. Determination of Latitude, Longitude and Azimuth. Practice with the Sextant, Transit and Zenith Telescope. (2)

Surveying.—Mine Surveying, with practical work. (1)

Hydraulics. Flow of water in pipes and rivers. Water supply engineering. Hydraulic motors. (3)

Construction and Design. Specifications and Contracts, with Designs and Estimates for Engineering Projects. Patent office Rules and Regulations. (2)

Practical Dynamics. Machinery for transporting, handling, and lifting materials. (2)

Geology. Historic, dynamic and economic. Dana. (3)

English Literature. Lectures. (2)

Christian Evidences.—Lectures. (1)

Preparation of Theses.

THE COURSE IN MECHANICAL ENGINEERING.—The object of this course is the study of the Science of Machines; the principal subjects taught are: the nature, equivalence and analysis of mechanisms, the mechanics or theory of the principal classes or types of machinery, Mechanical Technology and the principles and practice of Machine Design.

That the students may obtain the practical engineering data which they will most need when beginning their work as mechanical engineers, they are required to pursue a course of Shop Instruction which does not necessarily involve manual labor and manipulation of tools but is principally devoted to familiarizing them with those points in pattern-making, moulding, forging, fitting and finishing, which they need to know as designers of machinery. Particular attention is therefore directed to the forms and sizes of machine parts that can be readily constructed in the various workshops, to the time that it takes to perform and the order of the various operations, to the dimensions most needed by workmen (in order that the students may learn to dimension working drawings judiciously) and to the various devices—ordinarily escaping the beginner's notice—for increasing the accuracy of the work, durability of the parts, conveniences of manipulation and safety of the workmen. This involves acquaintance with the processes and machinery of the workshops, but it is the foreman's and superintendent's knowledge which is required rather than the manual dexterity and skill of the workman and tool-hand. The acquirements peculiar to the latter are by no means despised, and students are encouraged to familiarize themselves therewith during leisure hours, but manual work in the shops forms no regular part of the course. On the contrary, the student enters the shop with hands and mind free to examine all the processes, operations and machinery, and ready at any moment at the call of the teacher, to witness an operation of special interest or to examine into the causes of and remedies for any sudden break down. Dressed in overalls and provided with note-book, pencil, calipers and measuring rule, the student sketches the important parts of the various machine-tools, notes down the successive steps of each of the important shop-processes as illustrated by the pieces operated upon, and, having first obtained a clear idea from the working drawings of what is about to be constructed, follow pieces of work through the shops from the pig or merchant form to the finished machine.

That the students may learn to observe carefully and be trained to think and observe for themselves in these matters, there is required of them a full description of the various processes, operations and tools involved in the production of each one of a series of properly graded examples of patterns, castings, forgings and finished pieces which are not being constructed in the shops at the time and the drawings or blue prints for which have been given to them on entering the shops. The student's work is directed not only by these drawings and by the printed programme given him at the start, but also personally by a teacher, who accompanies him into the shops, gives necessary explanations, and who tests the extent and accuracy of his knowledge by examining the sketches and notes, and by frequent questioning. Finally the results of these observations and the sketches made are to be neatly embodied in a memoir.

During the course there are frequent visits of inspection to engineering works, both in and out of town, with special reference to such subjects as Prime Movers, Machinery for lifting, handling and transporting, and Machinery for changing the form and size of materials. It is intended that each of these excursions shall have some definite purpose in view which must be fully reported by the students. The instruction in Machine Design, during the second term of Junior year, consists in determining rational and empirical formulas for proportioning such machine parts as come under the head of fastenings, bearings, rotating, sliding and twisting pieces, belt and toothed gearing, levers and connecting rods, also, in comparing recent and approved forms of these same parts with respect to their advantages as regards fitness, ease of construction and durability, and in making full sized working drawings of these parts; all the dimensions are determined by the students from the above mentioned formulæ, the data being given as nearly as possible as they would arise in practice. Duriug the first term of the Senior year, the students undertake the calculations, estimates and working drawings involved in the design of a simple but complete machine, each student being engaged upon a different machine. From the finished drawings of each machine, tracings are to be made and then "blue prints" taken for distribution among the other members of the class. During the latter part of the term the whole class take up the design of a steam engine, every dimension being determined by the students, and complete working drawings made. In the case of the simple machines and of the steam engine, the general plan or arrangement will be given to the students in the form of either rough sketches, photographs or wood-cuts. This work will continue to the middle of the last term of the Senior year. From this time on the students are expected to make original designs for simple mechanisms, whose object has been fully explained. Throughout the course the work in the draughting room is carried on as nearly as possible like that of an engineering establishment, and special attention is paid to methods of expediting the work of calculation by means of simple formulæ, tables and diagrams. The graduate in this course will receive the degree of Mechanical Engineer (M. E.)

SECOND TERM.

SOPHOMORE CLASS.—*Mathematics.*—Differential and Integral Calculus: Olney. (4)

Physics. Galvanism, Acoustics, Light, with Lectures and Laboratory Practice. (5)

German. Systematic Readings. Translation. Dictation. (2) Or *French.* Systematic Readings. Dictation. (2)

Drawing. Line Shading. Sketching, Drawing of Machines from actual measurement. (2)

Kinematics. Nature and equivalence of mechanism. (3)

English. Essays on scientific subjects. Declamations. (1)

FIRST TERM.

Mathematics.—Integral Calculus: Courtenay. (2)

German. Systematic Readings. Compositions. (2) Or *French.* Systematic Readings. Compositions. (2)

Mechanics. Smith. Mathematical Theory of Motion. Science of Motion in general. Statics. Dynamics and Statics of Fluids. Lectures on Theory of Centre of Gravity and Movement of Inertia (5)

Mechanical Technology. Shop instruction. Examination of the processes and appliances involved in pattern making, moulding, forging, fitting and finishing, with sketches and reports. (7)

Essays and Declamations. (1)

SECOND TERM.

German—Systematic Readings. Compositions in German. (2) Or *French.*—Systematic Readings. Compositions. (2)

Strength of Materials.—Elasticity and strength of wood, stone and metals. Theory of beams, shafts and columns. Experimental tests. (3)

Prime Movers.—Steam Engines and their accessories.

Machine Design.—Proportioning of such machine parts as come under the head of Fastenings, Bearings, Rotating and Sliding Pieces, Belt and Toothed Gearing, Levers and Connecting Rods. (5)

Metallurgy.—Metallurgical Processes. Furnaces. Refractory. Building Materials. Combustion. Natural and Artificial Fuels. Metallurgy of Iron. (4)

Essays and Original Orations.

FIRST TERM.

SENIOR CLASS.—*Thermodynamics.*—General principles; application Steam Engines and Air Compressors. (3)

Graphical Statics.—Geographical analysis of roof trusses and girders. (2)

Machine Design.—Calculations and working drawings for the following machines: Drills, Hoists, Pumps, and Shearing, Punching and Milling Machines. Design for a Steam Engine begun. (5)

Kinematics.—Diagrams of the changes of position, speed and acceleration in mechanisms. Link and valve motions. Quick return Motions. (3)

Practical Dynamics.—Machinery for lifting, handling and transporting materials. (2)

Mechanical Engineering Instruments.—Appliances and apparatus for gauging, recording and testing employed in shops and in experimental work. (2)

SECOND TERM.

Practical Dynamics.—Machinery for lifting, handling, and transporting materials. (2)

Machine Design.—Design for a Steam Engine completed. Original Designs. (5)

Hydraulics.—Flow of water in pipes and channels; hydraulic motors. (2)

Measurement of Power.—Indicating of Steam Engines; determination of evaporative efficiency of boilers; dynamometer experiments. (1)

Mill Work.—Setting of Machinery and transmission of power. (1)

Specifications.—Contracts.—Requirements of Patent Office. (1)

English Literature.—Lectures. (2)

Christian Evidences.—Lectures. (1)

Preparation of Theses.

The Course in Mining and Metallurgy.—In addition to the physics, chemistry, literature, higher mathematics and mechanics necessary to all technical education, the scheme of studies comprises courses in mining, metallurgy, geology, mineralogy, dynamics, qualitative and quantitative analysis, blowpipe analysis, topographical and mine surveying and drawing. On account of the great number and scope of the studies necessary to the completion of this course, it is five years in length. The graduate in this course will receive the degree of Engineer of Mines. (E. M.) At the completion of the fourth year of this course, the student will receive the degree of Bachelor of Metallurgy. (B. M.)

In the courses of mineralogy, geology and analytical chemistry, much attention is paid to the practical instruction of the student in determining minerals by their crystallographical and physical properties, and, by the aid of blowpipe analysis, in the determination of rocks; in the qualitative and quantitative examination of ores and metallurgical products and in the rapid methods of assaying ores by the dry and wet ways employed in metallurgical laboratories. The location of the University in the vicinity of the iron works of the Lehigh Valley and especially of the extensive establishment of the Bethlehem Iron Company, affords unusual facilities for the practical study of iron metallurgy. The processes for the manufacture of spelter and oxide of zinc may be studied at the Bethlehem Zinc Works. The facilities for the practical study of mining and economic geology are not excelled by those of any other Institution in the country. The zinc mines at Friedensville and the brown hematite and slate deposits of the Lehigh Valley are in the immediate vicinity, while within easy reach by rail are the anthracite coal fields of Pennsylvania, the iron and zinc mines of New Jersey, and the celebrated iron mines at Cornwall, Pa.

SECOND TERM.

SOPHOMORE CLASS.—*Mathematics.*—Differential and Integral Calculus: Olney. (4)

Physics.—Galvanism, Acoustics, Optics, with Lectures and Laboratory Practice. (5)

German.—Systematic Readings. Translation. Dictation. (2) Or *French.*—Systematic Readings. Translation. Dictation. (2)

Assaying.—Including the Assay by the dry methods of Gold, Silver, Copper, Lead, Iron and Tin ores. Laboratory Work. Ricketts. (1)

Chemistry.—Quantitative Analyses: Laboratory Work. Fresenius. (5) The following analyses are executed by the students.

1. Iron Wire (Fe)
2. Bronze (Cu, Sn, Zn)
3. Silver Coin (Au, Ag, Pb, Cu)
4. Zinc Ore (Zu) By both Gravimetric and Volumetric Methods.
5. Copper Ore. (Cu)
6. Speigeleisen (Mn)
7. Lead Ore (PbS)
8. Ilemenite (TiO^2)

FIRST TERM.

JUNIOR CLASS.—*Mathematics.*—Integral Calculus: Courtenay. (2)

Mechanics.—Smith. Mathematical Theory of Motion. Science of Motion in general. Statics. Dynamics and Statics of Fluids. Barometrical Leveling and Measurement of Heights. Lectures on Theory of Centre of Gravity and Movement of Inertia. (5)

Chemical Philosophy.—Cooke. (5)

Kinematics.—Diagrams of the changes of position, speed and acceleration in Mechanics. Link and Valve motions. Quick Return motions.

German.—Systematic Readings. Compositions in German. (2) Or *French.*—Reading. Translation. Dictation. (2)

SECOND TERM.

Metallurgy.—Metallurgical Processes. Furnaces. Refractory Building Materials. Combustion. Natural and Artificial Fuels. Metallurgy of Iron. (4)

Blow-pipe Analysis.—Lectures with Practice. Plattner, Brush, or Nason and Chandler. (1)

Prime Movers.—Steam Engines and their accessories. (3)

Strength of Materials.—Elasticity and strength of Wood, stone and metals. Theory of beams, columns and shafts. (3)

Surveying.—Use of Compass, Level and Transit. Maps of Farm Surveys. Profiles and Contour Maps. (3)

German.—Systematic Readings. Compositions in German. Or *French.*—Systematic Readings. Compositions. (2)

Drawing.—Elements of Machine Design. Plans and Elevations of Furnaces. (2)

FIRST TERM.

SENIOR CLASS.—*Metallurgy.*—Of Copper, Lead, Silver, Gold, Platinum, Mercury, Tin, Zinc, Nickel, Cobalt, Arsenic, Antimony and Bismuth. (5)

Crystallography.—Lectures with Practical Exercises in the determination of Crystals. (2)

Thermodynamics.—General Principles: Applications to Steam Engines and Air Compressors. (3)

Practical Dynamics.—Machinery for lifting, handling and transporting matter. (2)

Roofs and Bridges.—Theory and calculation of strains in framed trusses. (3)

Chemistry.—Fresenius' Quantitative Analysis. (2) The following analyses are executed by the students:

9. Iron Ore (Complete Analysis)
10. Limestone (Complete Analysis)
11. Coal (Volatile Matter,—Fixed Carbon, Ash, (H_2O, S, P)

SECOND TERM.

Mineralogy.—Descriptive Mineralogy, with Practical Exercises in the Determination of Minerals: E. S. Dana. (3)

Blow-pipe Analysis—Practice. (1)

Hydraulics.—Flow of water in pipes and channels; hydraulic motors. (2)

Practical Dynamics.—Machinery for lifting, handling and transporting matter. (2)

Measurement of Power.—Indicator Cards. Determination of Evaporative Efficiency of Boilers. Dynamometer Experiments. (1)

Mill Work.—Setting of Machinery and Transmission of Power (1)

English Literature—Lectures. (2)

Christian Evidences.—Lectures. (1)

Chemistry.—Fresenius' Quantitative Analysis. (3) The following analyses are executed by the students:

12. Slag. (Complete Analysis).
13. Manganese Ore (MnO_2)
14. Pig Iron (Complete Analysis)
15. Nickel Ore (Ni. Co)
16. Gas Analysis (Complete Analysis of Illuminating Gas)

Projects.—On Metallurgical Subjects. (1)

FIRST TERM.

FIFTH YEAR.—*Astronomy.*—Descriptive Astronomy; Loomis. (3)

Mining.—Modes of Occurrence of the Useful Minerals. Searching for Mineral Deposits. Examination of Mining Properties. Boring. Mining Tools, Machines and Processes. Timbering and Masonry. Callon. Andre. (4)

Geology.—Lithology, with practical exercises in determining Rocks. Cotta. Rutley. General Geological Definitions and Principles. Dana. (4)

Zoology—Lectures. (2)

Surveying.—Triangulation. Levelling. Topographical Surveys and Maps. (4)

SECOND TERM [TO EASTER.]

Mining.—Methods of Working. Underground Transportation. Hoisting, Drainage and Pumping, and Lighting. Ventilating. Mechanical Preparation of Ores. Coal Washing. (3)

Geology.—Historic, Dynamic and Economic. (4)

Mine Surveying.—Practice in the mines. Map Drawing. (2)

Astronomy.—Practical work. (2)

Drawing.—Mining Plant. System of Timbering. Geological Maps and Sections. (4)

Projects.—In Mining, Geology and Metallurgy. (2)

THIRD TERM [AFTER EASTER.]

Astronomy.—Practical work. (2)

Notes on mining costs.

Excursions.

Theses.

THE COURSE IN CHEMISTRY.—This course of instruction continues the subject of Theoretical Chemistry from the general course of the two previous terms, the subject of Chemical Philosophy and Organic Chemistry being taught by daily recitations in the Junior and Senior years. In analytical Chemistry, the course of Qualitative Analysis in the first term of the second year is followed by preparation of Chemical Compounds and purification of Chemicals.

Subsequently, Quantitative Analysis is pursued to the end of the course, including the Dry Assaying of Ores of gold, silver, copper, lead, iron and tin, and the Wet Analyses, included in the appended schedule. In addition, courses of Lectures on Medical, Agricultural and Technical Chemistry are given, and various industrial establishments in the neighborhood and in Philadelphia and New York are visited in the company of an instructor. The course also includes thorough instruction in Physics and Mechanics, Mineralogy and Blow-pipe Analysis, Metallurgy, Geology and Descriptive Astronomy. The last term of the Senior year is mainly devoted to the preparation of a Thesis on some subject, selected by the professor, involving practical work in the Laboratory, in addition to the literary labors, and each graduate will thus make a contribution to the progress of the science as a preliminary to the reception of his degree. The course is thus seen to include thorough instruction in theoretical and applied chemistry, in their various branches, as well as in those cognate sciences of such great value to the chemist.

The Laboratories are under the immediate charge of the Professor and his Assistant, and together with the Lecture-room, are unsurpassed in excellence by any similar establishment in the country, being supplied with all the modern improvements. The collections of apparatus, specimens and models, illustrating theoretical and applied chemistry, are already important and rapidly increasing.

Students are charged for the chemicals and apparatus consumed. If the student is moderately careful, this expense need not exceed $60 per year

The graduate of this course will receive the degree of Analytical Chemist. (A.C.)

SECOND TERM.

SOPHOMORE CLASS.—*Mathematics*, Differential and Integral Calculus; Olney. (4)

Physics.—Galvanism, Acoustics, Light: with Lectures and Laboratory Practice. (5)

German Systematic Readings, Translations. Dictation. (2) Or *French.* Systematic Readings. Translations. Dictation. (2)

Chemical Preparations. Including the Preparation of Chemical Compounds and the Purification of Chemicals by Distillation, Sublimation, Fusion, Crystallization, Precipitation, etc. (2)

Assaying. Including the Assays by the dry methods of gold, silver, copper, lead, iron and tin ores. Ricketts. (1)

Blow-Pipe Analysis. Lecture with Practice. Plattner, Brush, or Nason and Chandler. (1)

Essays and Declamations. (1)

FIRST TERM.

JUNIOR CLASS. *Chemical Philosophy.* Coke. (5)

Toxicology. Otto on Poisons. (1)

Quantitative Analysis. Fresenius' Quantitative Analysis. (6) The following analyses are executed by the students:

1. Iron Wire(Fe)
2. Potassic Dichromate (Cr_2O_3)
3. Baric Chloride (Ba, Cl,H_2O)
4. Magnesic Sulphate (MgO,SO_3, H_2O)
5. Hydro Di-Sodic Phosphate (P_2O_5)
6. Bronze (Cu, Sn, Zn)
7. Rochelle Salt (K_2O, Na_2O)
8. Volumetric Determination of Chlorine.
9. Acidimetry (HCl, H_2SO_4, HNO_3)
10. Alkalimetry (KOH, NaOH, NH_4OH)
11. Chlorimetry (Bleaching Powders)
12. Silver Coin (Au, Ag, Pb, Cu)
13. Zinc Ore (Zn)

Crystallography.—Lectures, with Practical exercises in the Determination of Crystals. (2)

German.—Systematic Readings. Compositions in German. (2) Or *French.*—Systematic Readings. Compositions. (2)

Anatomy and Physiology.—Lectures. (1)

SECOND TERM.

Organic Chemistry.—Wohler. (3)

Quantitative Analysis.—Fresenius' Quantitative Analysis. (7) The following analyses are executed by the student:

14. Copper Ore (Cu)
15. Spiegelcisen (Mn)
16. Lead Ore (PbS)
17. Ilmenite (TiO_2)
18. Iron Ore (Complete Analysis)

20. Coal (Volatile Matter,— Fixed Carbon, Ash H_2O, S, P)
21. Slag. Complete Analysis.

Metallurgy.—Metallurgical Processes. Furnaces. Refractory Building Materials. Combustion. Natural and Artificial Fuels. Metallurgy of Iron. (4)

German.—Systematic Readings. Compositions in German. (2) Or *French*—Systematic Readings. Compositions. (2)

Mineralogy.—Descriptive Mineralogy, with Practical exercises in the Determination of Minerals. E. S. Dana. (3)

FIRST TERM.

SENIOR CLASS. *Metallurgy.*—Of Copper, Lead, Silver, Gold, Platinum, Mercury, Tin, Zinc, Nickel, Cobalt, Arsenic, Antimony and Bismuth. (5)

Quantitative Analysis.—Fresenius' Quantitative Analysis. (8) The following analyses are executed by the student:

22. Guano (NH_2, P_2O_5, H_2O)
23. Clay (Complete Analysis)
24. Manganese Ore (MnO_2)
25. Mineral Water (Complete Analysis)
26. Pig Iron (Complete Analysis)
27. Nickel Ore (Ni, Co)
28. Organic Analysis (C, H, O, N)
29. Gas Analysis (Complete Analysis of Illuminating Gas)

Astronomy.—Descriptive Astronomy: Loomis. (3)

SECOND TERM.

Chemistry Applied to the Arts.—Lectures. (3)
Medical Chemistry.—Lectures. (1)
Agricultural Chemistry.—Lectures. (1)
Geology.—Historic, Dynamic and Economic Geology. Lectures. Dana. (4)
Christian Evidences.—Lectures. (1)
English Literature and History.—Lectures. (2)
Preparation of Theses.

Graduating Theses.—Every student will be required to present a thesis upon some topic connected with his special course, as a necessary portion of the exercises for his final examination for a diploma. These theses shall be accompanied by drawings and diagrams, when the subjects need such illustration. The originals will be kept by the university, as a part of the student's record, for future reference; but a copy may be retained by the student, and be published, permission being first obtained from the President.

Diplomas and Certificates. The diploma is given only to those who have passed all the examinations in a regular course and is signed by the President and Secretary of the Board of Trustees and by the Faculty of the University. For all partial courses a certificate is given showing what the student has accomplished, and is signed by the President and Secretary of the Faculty.

Graduate Students.—Graduates of the University wishing to remain a year or more and pursue a course of studies as candidates for another degree may do so with the sanction of the Faculty. Graduates wishing to take special courses of study will be afforded every facility in so doing.

Post Graduate Degrees.—M. A. —The Faculty will recommend for the degree of Master of Arts candidates otherwise properly qualified, who after taking at this University the degree of Bachelor of Arts, shall pursue for at least two years, at the University, a course of liberal study approved by the Faculty, pass a thorough examination in the same, and present satisfactory theses. *Ph. D.*—The Faculty will recommend for the degree of Doctor of Philosophy, candidates otherwise properly qualified, who, after taking at this University either of the degrees of Civil, Mechanical or Mining Engineer, or Analytical Chemist, shall pursue, for two years, at the University a course of advanced scientific study in the line of their profession, pass a thorough examination in the same, and present satisfactory theses. *D. Sc.*—The Faculty will recommend for the degree of Doctor of Science, candidates otherwise properly qualified, who, after taking at this University, the degree of Bachelor of Science, shall pursue for at least two years, at the University, a course of scientific study, embracing two subjects approved by the faculty, pass a thorough examination showing in one of the subjects special attainments, and shall present satisfactory theses in one of the subjects, based upon original scientific investigation. Candidates for any of the above post graduate degrees, who are not graduates of this University, must give satisfactory evidence of having fulfilled the requirements for graduation in the corresponding undergraduate course; the acceptance of a certificate as evidence of proficiency, in lieu of examination, is at the discretion of each professor as to the subjects in his department. The requirement of residence may be omitted in special cases by the Faculty.

Students' Societies.—The Chemical and Natural History Society.—This Society was organized in the Fall of 1871, as "The Chemical Society," but was afterwards expanded, as its present title indicates, and admits by election students from all departments of the University. The collections of Chemical Preparations, and Botanical and Zoölogical Specimens belonging to the Society are already important. During the past years persons have been sent to Texas and Brazil to collect specimens for these cabinets. The Society has organized and maintained several courses of public scientific lectures. Among the honorary members of the Society are more than one hundred of the most distinguished scientists in Europe and the United States.

The Engineering Society—This Society was organized in 1873, and admits by election students in the Junior and Senior Classes. Its meetings are held monthly.

LAFAYETTE COLLEGE, EASTON, PA.

THIS College furnishes in its Scientific Department an opportunity to the student of acquiring that education that will be the most useful to him in his encounter with mining and metallurgy. The faculty is as follows:

Rev. William C. Cattell, D. D., LL. D., President, and Professor of Mental and Moral Philosophy. (The Hon. John I. Blair Foundation.) Traill Green, M. D., LL. D., Professor of Chemistry. (William Adamson Professorship of Analytical Chemistry.) Francis Andrew March, LL. D., Professor of the English Language and Comparative Philology. Rev. John Leaman, A. M., M. D., Professor (Emeritus) of Human Physiology and Anatomy. Rev. Lyman Coleman, D. D., Professor of Latin and of Biblical and Physical Geography. Rev. Thomas C. Porter, D. D., LL. D., Professor of Botany and Zoölogy. (Jessie Chamberlain Professorship of Botany.) Rev. Augustus A. Bloombergh, Ph. D., Professor of Modern Languages. Rev. Robert Barber Youngman, Ph. D., Professor of the Greek Language and Literature. Rev. Selden Jennings Coffin, Ph. D., Professor of Mathematics and Astronomy. (George Hollenback Professorship of Mathematics.) James W. Moore, A. M., M. D., Professor of Mechanics and Experimental Philosophy. Justus Mitchell Silliman, M. E., (George B. Markle Professorship of Mining Engineering and Graphics.) Joseph G. Fox, C. E., Professor of Civil and Topographical Engineering; Rev. Addison Ballard, D. D., Professor of Moral Philosophy and Rhetoric; Joseph Johnston Hardy, A. M., Adjunct Professor of Mathematics; David Bennett King, A. M., Adjunct Professor of Latin; Wm. Baxter Owen, A. M., Adjunct Professor of Greek; John G. Diefenderfer, A. M., Adjunct Professor of Modern Languages; Edward Hart, Ph. D., Adjunct Professor of Chemistry; Allen P. Berlin, C. E., A. M., Adjunct Professor of Mathematics; Addison B. Clemence, B. S., Assistant in Chemistry; Traill Green, M. D., LL. D., Dean of the Pardee Scientific Department; Francis Andrew March, LL. D., Librarian; Rev. R. B. Youngman, Ph. D., Clerk of the Faculty; Wm. H. Weaver, Janitor.

Pardee Scientific Department.—This department was organized by the Trustees of the College in 1866, to carry into effect the conditions of a donation from A. Pardee, Esq., of Hazleton, Pennsylvania. In July, 1867, in response to the growing wants of the Department, the original donation was increased to $200,000. In1871 Mr. Pardee made another and still larger donation for the erection of a building designed for the use of the Scientific Department. This building, costing with its scientific Equipment, nearly three hundred thousand dollars, was completed in 1873, and upon the 21st of October of that year was formally handed over by the munificent donor to the Trustees.

It consisted of a centre building five stories in height, fifty-three feet front and eight-six feet deep, and a lateral wing on each side of the centre building, measuring sixty-one feet in length and thirty-one feet in width, four stories in height, including a mansard roof, the whole terminating in two cross wings forty-two feet front and eighty-four feet deep, and four stories in height, the entire length of front, in a straight line, being two hundred and fifty-six feet. In determining what rooms were needed and the best arrangement of them, similar buildings in Europe, as well as in this country, were carefully studied, and liberal provision has been made in all the departments of instruction for every aid which has been devised for the most thorough and attractive teaching, and also for the prosecution of original researches. The original building was burned on the evening of June 4th, 1879. It has been rebuilt on the same site, of the same dimensions and external appearance. The arrangement of the interior has been much improved as experience with the former building suggested. In addition to its strictly scientific provisions, it contains suits of rooms for the Literary Societies, and an Auditorium for the oratorical exercises of Commencement and similar occasions.

The reopening was celebrated with appropriate ceremonies by a great concourse, on the 30th of November, 1880. An assembly so distinguished has rarely gathered in honor of any educational foundation in this country. His excellency, Rutherford B. Hayes, President of the United States, with members of his Cabinet, the General of the army, and the Commissioner of Education, His Excellency, Henry M. Hoyt, Governor of the Commonwealth of Pennsylvania, the State Superintendent of Education, the Moderator of the General Assembly of the Presbyterian Church, and the Moderator of the Synod of Philadelphia, with many other dignitaries of Church and State, took part in the addresses of thanks and congratulation to the Founder of the Hall and the friends of the College.

The Board intend that the whole Scientific Department shall be impressed with the Christian character of the College. In addition to the systematic and thorough study of the Word of God in all the classes, special attention will be given to the harmony of Science with revealed religion. The Scientific Department of the College leading to the Degree of B. S., is designed for those who wish to study the Natural Sciences, Mathematics, Modern Languages and Literature, History, Rhetoric, Logic, and Mental and Moral Philosophy, as thoroughly as they are studied in our Colleges, and who would be glad to enjoy the cultivation and learned habits and associations of College life, but who will not study Greek and Latin. The Trustees of the College are deeply impressed with the thought that our present collegiate system has grown up under the fostering care of the church, and that the relations of our old collegiate studies to manly culture and religious training have been studied by generations of Christian educators. They have, therefore, taken care that the new course shall not be removed from the old landmarks, and that, as far as possible, the old approved methods of instruction shall be used in all the departments of study. It will be found that the new course includes all the studies of the old, except the Ancient Languages, and it is believed that the method of teaching English and other modern Classics, which has been for some years in use in the College, gives, in a good degree, the same kind of discipline that is derived from the study of Greek and Latin. Latin, however, may be taken in this department if the student elect; the course then leading to the Degree of Ph. B.

Technical Studies.—Still further demands have been made on this institution on account of its peculiar relations to the *industrial resources* of our country. Lafayette College is in the midst of the great mining and manufacturing region of the Middle States. Every process used in the *mining* and *working* of the various ores of iron, and in the manufacture of iron into the thousand forms in which it is used, is going on almost within sight. Near by are the coal mines which supply the markets of Philadelphia and New York. Mineral wealth abounds on all sides. The expert is continually called on to examine new tracts of land, to analyze new ores, and to devise new ways of working and handling them. Here every resource of engineering is displayed in the works connected with the preparation and transport of lumber, and the carrying of railroads and canals through the mountains and over the rivers. Those who wish to prepare themselves to be working engineers in any of these departments, come from all parts of the country to observe and study these works, and it is most desirable that adequate means should be provided for the prosecution of scientific studies in the midst of them. In addition, therefore, to the GENERAL COURSE of the Scientific Department, which is designed to lay a substantial basis of knowledge and scholarly culture, courses have been arranged for those who may wish to devote themselves to studies essentially practical and technical.

I. ENGINEERING, CIVIL, TOPOGRAPHICAL AND MECHANICAL.—This course is designed to give professional preparation for the location, construction and superintendence of Railways, Canals and other engineering works; the design, construction and use of Steam Engines and other Motors, and of machines in general; and the construction of geometrical, topographical and machine drawings.

II. MINING, ENGINEERING AND METALLURGY.—This course offers the means of special preparation for exploring undeveloped mineral resources, and for taking charge of mining and metallurgical works.

III. CHEMISTRY.—This course includes text-book study, lectures, and laboratory practice, every facility for which is found in the Laboratories. Provision is made for advanced and special students who may wish to make original researches, or to study any particular department of Chemistry.

POST GRADUATE DEPARTMENT.—Resident Graduates, and others having suitable preparation, may pursue special studies in any branch, either of the Classical or the Scientific Department, under the Direction and Instruction of the Professor in that branch, and have the use of the Laboratories, Apparatus, Collections and Libraries, while prosecuting original researches. These studies and researches will not be confined to any fixed Course. Particular information may be obtained by addressing the President.

Admission.—SCIENTIFIC DEPARTMENT.—Candidates for admission to the Freshman Class for the Scientific Course are examined in English Grammar; Modern Geography; Arithmetic, including the metric system; Algebra, through Quadratic Equations; Plane Geometry, two books; (for Civil Engneers Plane Geometry entire,) the elementary principles of Natural Philosophy, and the outlines of History. Those who elect the study of Latin are examined also in the Latin required for admission to the Classical Course and in Ancient Geography. It is expected that all candidates for admission to the College will be acquainted with the general contents of the Bible.

TECHNICAL AND SPECIAL STUDIES.—Application for instruction in Technical or special studies are examined on such subjects connected with the study as have been gone over by the class which they propose to enter.

ADVANCED STANDING.—Candidates for advanced standing are examined in the preparatory studies, and also in the studies gone over by the class which they propose to enter. No student is admitted to the Senior Class after the beginning of the second term.

TESTIMONIALS.—Testimonials of good moral character are in all cases required; and those coming from other Colleges must produce certificates of dismission in good standing. All those who enter on scholarships must produce certificates for the same, and have their entrance endorsed thereon.

MATRICULATION.—No student is considered a regular member of College until he has been matriculated, after a probation of thirty days, during which time, however, he is subject to the laws of the College.

FIRST TERM.

Civil Engineering Course.—Freshman Year.—Algebra (completed), Elements of Industrial Drawing, English, March's Method, French, Chemistry, Lectures on Health.

SECOND TERM.

Geometry (completed), Surveying, Plane Problems, French, German, Problems in Division of Land.

THIRD TERM.

Surveying, Field Work, Elementary Projections, Trigonometry and Mensuration, French, German Analytical Chemistry.

Throughout the Year.—Declamations, Themes and the Bible.

FIRST TERM.

Sophomore Year.—Analytical Geometry (begun), Surveying, Field Work, Elementary Projections, Mineralogy, French, German, Study of Words, Trench.

SECOND TERM.

Analytical Geometry (completed), Topographical Drawing, Botany, Zoology, French, German, Mineralogy.

THIRD TERM.

Differential and Integral Calculus, Descriptive Geometry, Botany, Zoology, French, German, Determinative Mineralogy.
Throughout the Year.—Declamations, Themes and the Bible.

FIRST TERM.

Junior Year.—Descriptive Geometry (General Orthographic Projections), Triangular Surveying, Field Work, Adjustment of Instruments, French, Mechanics, Lithology, Practice with the Blow-pipe.

SECOND TERM.

Physics (begun). Road Engineering—Theory (begun.) Calculus (continued). Colored Topography. Shades and Shadows. Hydrographical Surveying.

THIRD TERM.

Linear Perspective, Physics (completed), Analytical and Applied Mechanics, Topographical Surveying, Map of Topographical Survey, Road Engineering—Theory (completed).
Throughout the Year.—Declamations, Themes, written Debates and the Bible.

FIRST TERM.

SENIOR YEAR.—Water Supply, Road Engineering—Practice, Plans, Profiles and Sections of Road Surveys, Astronomy, Machine Drawing, General Theory of Machines. Anatomy and Physiology.

SECOND TERM.

Stone Cutting, Machines and Motors, Strength of Materials, Stability of Structures, Supply and Distribution of Water, Astronomy, Geology, Mineralogy, Political Economy.

THIRD TERM.

Bridge Drawing, Foundations, Retaining Walls, River and Canal Improvements, Designs for, and Reviews of Engineering Works, Bridge and Roof Construction, Graphical Statics, History, Geology, Graduation Theses.
Throughout the Year.—Themes, Speaking and Biblical Studies.

FIRST TERM.

MINING ENGINEERING.—The Freshman and Sophomore years are essentially the same in this as in the Civil Engineering Course.

FIRST TERM.

JUNIOR YEAR.—Mechanics, Analytical Chemistry, Mine Surveying, Adjustment of Instruments, French, Lithology, Practice with the Blow-pipe.

SECOND TERM.

Physics, Colored Topography, Practice in Lithology, Analytical Chemistry, German, Assaying, Maps of Survey.

THIRD TERM.

Topographical Surveying, Map of Topographical Survey, Analytical Chemistry, French or German, Analytical and Applied Mechanics.
Throughout the Year.—Declamations, Themes, written Debates and the Bible.

FIRST TERM.

SENIOR YEAR.—Mining, Ore Deposits, Analytical Chemistry, Machine Drawing, General Theory of Machines.

SECOND TERM.

Mining, Analytical Chemistry, Machinery and Motors, Geology, Mineralogy, Political Economy, Supply and Distribution of Water.

THIRD TERM.

Mining, Metallurgy, Designs for, and Reviews of Special Metallurgical and Mining operations, History, Geology, Analytical Chemistry, Graduation Theses.
Throughout the Year.—Themes, Speaking and Biblical Studies.

WORKING SECTION.—Graduates of Schools of Science and Practical Engineers wishing to devote all their time to thorough preparation for professional employment in Civil Engineering, may enter, without examination the Senior Class, which is organized as an Engineering Corps, and goes though all the necessary operations for the construction of a Railroad from Easton to some selected terminus. Others wishing to enter the Section must pass an examination on the studies leading to the work of the section. Those completing the work of the Section may obtain from the Faculty a certificate to that effect. Further information may be had by addressing the Dean of the Pardee Scientific Department.

CHEMISTRY—The study in this department begins with a course of lectures on General Chemistry combined with the study of a text-book. In connection with these lectures each student is required to work in the laboratory, under the direction of the Professor; and he may pursue Analytical Chemistry through the rest of the course. The Chemical students of the General Scientific Course spend during their last two years the greater part of their time in the laboratory, electing such chemical and related studies or investigations as they may wish to pursue. The instruction is then mainly individual, and a student's progress depends on his ability and industry. Partial or special students may enter the laboratories at any time, provided they have the necessary knowledge of general chemistry to work advantageously. Advanced students will be afforded opportunity for continuing their studies, or for conducting investigations in organic or inorganic chemistry.

BOTANY, ZOÖLOGY, GEOLOGY.—*Freshman year*, Third Term, Mineralogy. *Sophomore year*, Second and Third Terms, Botany, Zoölogy. *Junior year*, First Term, Zoology. *Senior year*, First Term, Botany, Zoology. Second and Third Terms, Mineralogy, Geology.

The exercises of the Freshman, Sophomore and Junior years belong to the Scientific Course; those of the Senior year belong also to the Classical Course. The instruction includes structural and descriptive Science—field excursions for observations and collection, preparation and care of specimens, drawing, the use of microscope, and other means of refined observation. The collections in Botany are mcst ample. There has been lately added to the College Herbarium the extensive collection of Professor Porter, the fruit of thirty years' labor on his part, embracing the complete Flora of Pennsylvania. In GEOLOGY, besides the text-book study, Professor Porter delivers a course of lectures on the connections between Natural Science and Revealed Religion. In MINERALOGY the classes have the advantage of the admirable cabinets prepared for the Technical Course of Metallurgy and Mineralogy.

RELIGIOUS EXERCISES—All the students attend prayers in the College Chapel daily, and preaching on the Sabbath. A daily social prayer meeting has long been maintained by the students; it is under the auspices of the Christian Brotherhood of the College, an organization composed of professing Christians, having for its object mutual helpfulness in right living and usefulness. Thursday evening there is a divine service in Brainerd Hall, conducted by the President, or one of the Professors, to which all the students are invited.

DEGREES.—*The First Degree.* Graduates of the Engineering Course receive the degree of CIVIL ENGINEER. Graduates who have taken the special studies in Mining Engineering, Metallurgy and Chemistry may receive certificates of the same, or have the fact stated upon their Diplomas.

Certificates.—Students who have been admitted to any Department of the College, and have passed satisfactory examinations therein, may obtain certificates of the same, if they have been in attendance not less than one year.

LIBRARIES AND READING-ROOM.—The College Library is open Thursday, Friday and Saturday at nine o'clock, A. M.; the libraries of the Literary Societies, on Wednesday afternoon; of the Brainerd Society and of the Scientific Societies at the regular meetings. The Eastonian Hall is fitted up as a Reading-room; and is supplied with the best newspapers and periodicals of America, England, France, and Germany. Dictionaries, cyclopædias and other works of reference belonging to the Library are also placed in this room. It is kept open to all members of the College daily (Sundays excepted), for consultation during study hours, morning, afternoon and evening, and for general reading out of study hours. It occupies the first floor of the east wing of South College and the second story in galleries, making a spacious, light and airy hall. It is adorned with literary treasures and portraits of honored benefactors and officers of the College. Among these collections is a Papyrus Scroll, five feet long, from a mummy at Thebes, with a hieratic inscription pronounced by Seyffarth the finest he has seen, presented by Hon. John W. Garrett, of Baltimore. There is also a full-length portrait of Lafayette, painted by Healey at the Chateau La Grange, from Ary Sheffer's famous painting, and presented by Dr. Thomas W. Evans, of Paris.

College Societies.—The CHEMICAL SOCIETY has for its object the preparation and discussion of papers on chemical or allied subjects. Laboratory students have the opportunity of working on original investigations and communicating the results to the Society. The society of PHYSICS AND ENGINEERING, Professor Moore, President, has for its object the investigation and discussion of subjects connected with these departments.

Terms and Vacations.—The College year is divided into three terms, with intervening vacations. All the Classes are examined at the close of each term, and a report sent to the parent or guardian. Students are required to be present punctually at the beginning of each term, and are not allowed during term-time to be absent from town except by written permission from the president.

Expenses.—Tuition (to those not on scholarship) in the Classical or General Scientific Department, ... $15 00 a term

Tuition in Technical Studies or Chemical Sections, . .	25 00	"
General Expenses, ...	8 00	"
Library and Reading-room, ...	2 00	"

The annual College charges are therefore, for those who pay tuition in full, $75 for the Classical or General Scientific Course; and $105 for Technical Studies. Each student pays $5 when he is registered on entering college, and $10 when he is matriculated thirty days afterwards. These fees are appropriated to the Library fund, and to the increase of the scientific collections and apparatus. No fees are charged for diplomas. Apparatus for the use of students in the Chemical Laboratories will be furnished and charged in their account, and the charge canceled for that returned in good condition. Chemicals and all other materials will be charged according to the average cost. A deposit sufficient to meet these expenses is made on entering the laboratories. Members of the Classical Department are admitted to all the privileges of the laboratories while studying General Chemistry, and for the present, without charge for the aid of the Professor in attendance; each student will, however, pay for chemicals which he uses, and for any apparatus which he may break or injure. For the present the scholarships securing free tuition in the Classical Course will hold good for the Pardee Scientific department, unless the students shall select Technical Studies, in which case he must pay each term one-half of the regular fee for tuition. A number of scholarships have been placed at the disposal of the Faculty, for the benefit of young men of talents and good moral character. Applications for these scholarships should be made to the President. In all cases the place of boarding must be approved by the Faculty. The price of board in clubs managed by the students is from $2.00 to $3.50 per week.* Board, including furnished rooms in private families, is from $5 to $7 per week. Unfurnished rooms in the College building may be had at a cost of from five to fourteen dollars a term (average $8). Unfurnished rooms adjacent to the College premises can be rented for from twelve to sixteen dollars a term. Students obtain washing at 40 cents per dozen pieces. The College charges must be paid each term in advance, also the room rent, when the student occupies a room in the College buildings. The Treasurer also, on behalf of the Committee of Students, collects with the College bills at the beginning of the first term $5, and of the second term $7, for fuel. The unexpended balance is refunded by the Committee at the close of the year. For the last few years the average cost for fuel to those in double rooms was $6.75, to those in single rooms $10.07. A deposit of one dollar is also made, at the beginning of each term, to pay for public damages, the unexpended balance of which is returned to the students at the end of the year. Some money for books and other incidental expenses will be needed; but, with economy, the total annual expenses—exclusive of tuition, clothing and traveling expenses—need not exceed $250, as will be seen from the following summary:

College Charges.		
General Expense, ...	$24 00	
Library and Reading-room, ...	6 00	$30 00
Incidental Expenses.		
Fees and dues, Literary and Scientific Societies (estimated),	$ 8 00	
Text-books and Stationery (estimated), ...	20 00	
		$28 00
Personal Expenses.		
Board for 39 weeks (at lowest club rates, see note below)	$78 00	
Room Rent average as above	24 00	
Fuel (average as above)	6 75	
Light and Washing (estimated)	24 00	$132 75
		$190 75
Leaving a balance for contingencies,		59 25
Total as above,		$250 00

Board at the highest club rates, $3.50 per week, would add $58.50 to the above estimate, and still keep the annual expenses within the two hundred and fifty dollars. Parents or guardians at a distance may deposit funds with some member of the Faculty, who will pay particular attention to the pecuniary concerns of the student, settling his bills, and transmitting an account of the expenditure, for which services he will charge a commission. It is strongly recommended that parents furnish their sons with little beyond what will meet their necessary expenses.

Recent Additions.—An important addition has been made to the Mineralogical Cabinet through the liberality of Dr. Joseph Mixsell, of Easton, who has presented to the College the large and valuable collection known as the "Wagener Collection." This collection is the result of the labors of the late Jacob Wagener, one of the founders of the College, and is particularly rich in specimens of local interest, like the collection of Dr. Joseph K. Swift, which was purchased by the College in 1872. Mr. Wagener and Dr. Swift were warm personal friends, and for many years were interested in the same scientific investigations. It is believed that their combined collections completely illustrate the local mineralogy, while many of the specimens in Mr. Wagener's collection are of remarkable beauty and interest, and were obtained by him at a great expense. Another noticeable and valuable feature of his collection is the large number of minerals from Russia. This collection, upon the death of Mr. Wagener in 1859, became the property of his widow, who presented it to the donor, Dr. Joseph Mixsell. The Mineralogical Cabinet has also been increased during the past year by a valuable contribution of minerals from Rev. H. H. Beadle.

CALENDAR.—*Vacation of Nine Weeks.*

Sept. 12–13, Tuesday and Wednesday.—Examinations for admission.
Sept. 15, Thursday.—First term begins.
October 25, Wednesday—Founder's Day.
November 27, Monday.—Anniversary of the Franklin Literary Society.
November 30, Thursday.—Thanksgiving Day.
December 20, Wednesday.—First term ends.

Vacation of Two Weeks.

1883.

January 4, Thursday.—Second term begins.
March 21, Wednesday.—Second term ends.

Vacation of Two Weeks.

THE INDUSTRIAL SCHOOL FOR MINERS AND MECHANICS, AT DRIFTON, LUZERNE CO., PA.

AT the meeting of the American Institute, of Mining Engineers, in February 1879, Mr. Eckley B. Coxe, then president of the Institute, called attention in his address to the subject of Secondary Technical Education, and gave an outline of a scheme for a school for boys, which it was intended to start at Drifton, Pa., on the general plan of the Steigerschulen of Germany. This school was first opened on May 7th, 1879, when twenty-nine applicants for admission, from 12 to 24 years of age, were

* There are at the present time nine of these Clubs. The price of board per week in each is as follows: (1) and (2) $2.00; (3), (4) and (5), $2.25; (6), (7), and (8), $3.00; (9), $3.50.

examined. Of these eleven were admitted, the others being considered either too young or too deficient in primary education to profit by the instruction. In order that parents might be encouraged to send their children to the public schools, it was thought best not to receive pupils under 15 years of age. The number in each class was limited to sixteen, so that each boy might receive proper attention. Of the first class only eight passed through the full year's course. At the end of the year, on June 29th, 1880, a public examination was held with the most gratifying success.

The second year opened on the 1st of September, 1880. Nine candidates were then admitted after examination, and three more later in the course; one pupil has been dismissed. The school now comprises nineteen pupils, seven in the advanced and eleven in the preparatory class. There is also one boy in attendance at the drawing lesson who is too young for the other classes. Thus far the regular instruction has been given only for two hours each evening, Sunday excepted. At times when the pits are closed the pupils are requested to attend during the day from 9 to 12 A.M., and 2 to 5 P.M., the time being occupied in the drawing-room or in solving problems, or in review. If a sufficient number of boys from the regular classes are present, the regular studies are pursued. Attendance during the day is, however, voluntary. The limited, and to some extent uncertain time devoted to instruction is a disadvantage to the school, but it must be borne in mind that the school is as yet an experiment, and that the boys and their parents have to learn from experience that an education is worth the pecuniary sacrifice which would be involved in working half time and attending a day-school. The interest evinced by the pupils thus far is very gratifying, as is shown in the following figures, expressing their attendance and progress during the first three months of the session:

For attendance—Grades,	10	9½	9	8½	8	7½	6½
Number of pupils,	4	3	5	1	3	1	1
For progress—Grades,	9½	9	8½	8	7		
Number of pupils,	1	4	6	5	3		

A grade of 10 signifies "perfect" and 5 "indifferent." The plan of instruction is, in general, as follows:

I. *The Preparatory Class.*—In this class English branches are taught—spelling, reading, writing, grammar, the elements of composition, arithmetic, and geography. An assistant teacher has charge of these branches. Algebra is studied as far as involution and evolution. In teaching geometry, particular stress is laid on the names, properties, and relations of geometrical figures in connection with geometrical construction in drawing. Both freehand and mechanical drawing are taught with especial regard to developing artistic perception and the power of correct expression. Object lessons are also given to stimulate the reasoning faculties, which we often find but very imperfectly developed. In this preparatory class it is intended to admit boys under 15 years, that they may be well drilled in the elementary branches and better prepared for the next class.

II. *The Junior Class.*—In this class the English branches are continued, particular attention being paid to composition. The elements of bookkeeping are also taught, which serves, by the way, for an exercise in writing and arithmetic. Algebra is continued to equations of the second degree, with one or more unknown quantities, series and exponential equations including logarithms. The boys are also drilled in mental arithmetic and algebra to develop the power of quick perception and decision. The course in geometry is completed, including trigonometry, mensuration, and solid geometry. There is also provided an elementary course in analytical geometry, which is taught as algebraic projection in relation to geometrical projection and mathematical drawing. Geometry is divided into two parts—algebraic and practical geometry. In the first the subject is developed algebraically, with the aid of the trigonometrical properties of angles; in the second, the practical applications are seen in the solutions of problems and in construction of figures both on the drawing board and in the field. A course in geometrical projection aims to give the pupil facility in drawing any figure in plan, elevation, or section which may be called for, both with instruments and free-hand. In the course of mathematical physics, instruction is given in the elements of natural philosophy. To save time the mechanical portions, as for instance, the laws of motion, centre of gravity, the mechanical forces, etc., are treated mathematically, and the course becomes thus a combination of elementary mechanics and natural philosophy. Where feasible, experimental demonstrations are given. Chemistry is taught so that the pupils may become acquainted with names, properties, and combining proportions of the most important elements, particularly with those which enter into the composition of the common minerals. Simple chemical tests for minerals are also taught. The instruction in mineralogy and lithology is confined to the more generally occurring minerals and rocks, and those in which the miner or manufacturer has the most immediate practical interest. In this junior class a thorough knowledge of elementary mathematics and drawing is considered the basis for all subsequent instruction.

III. *The Senior Class.*—The course of instruction laid out for this class will include the writing of a plain, intelligent report upon some practical subject, either directly from investigation or from memory. This concludes the instruction in English branches. In the drawing-room the work will include the elements of construction in wood, stone, and metal, making working drawings, and designing simple structures and machinery. Lectures will accompany this course. The subject of mining is treated systematically under the following heads:

I. Mining; including:

1. The useful minerals and metals; their occurrence, and the methods for their exploration.
2. The various means employed for the extraction of ores, etc.
3. The opening and laying out of mines.
4. The method of exploitation.
5. The maintenance of mines in good order.
6. Transportation.
7. Drainage.
8. Ventilation.
9. Mine surveying and mapping.
10. Accidents in mines, and their prevention.
11. Mining accounts, contracts, and estimates.
12. Hygiene of mines, with the remedies to be adopted in case of accident.

II. Preparation of the useful minerals for smelting or for market, which will include the machinery used in ore-dressing and in the mechanical preparation of coal. During the senior year there will be practical exercises in the mine and in the field, which will involve the presentation of reports to the principal. It is possible that there may be formed a fourth class, to be known as

IV. *The Expert Class.*—This class will enable pupils and graduates at their leisure to continue their studies with the instructors outside of the regular classes, and thus perfect themselves in certain branches already gone over, or take up studies not provided for in the course. It is required that all the pupils must have regular work in the mines or in the shops, and, as far as possible, arrangements made to accommodate them. The instruction is entirely free, the pupils providing only their books and materials. Annual public examinations take place and prizes are awarded to the best scholars. The school-rooms are in Cross Creek Hall, a large building 106×51½ feet, having a basement room 12 feet high and an upper hall 42 feet high. In the basement are the office of the principal, 18×14 feet, two large class-rooms, 31×22 feet and 32×15 feet, and a drawing-room 28×18 feet. There are also a lecture-room, 49×30 feet, and a reading-room with a library the same size, all for school purposes. The reading-room is open every evening for the use of the employés. A separate building, 34×16 feet, contains the laboratory and lecture-room for chemistry and mineralogy. The school-rooms are open all day and until 9 o'clock in the evening. They are all lighted by gas and heated by steam. Collections of apparatus and minerals for the purpose of instruction have been commenced, and it is the aim to illustrate the lectures as far as possible by facts from every-day practice. The instruction is given by the principal, assisted by Mr. D. D. Davidson, a graduate of Lafayette College, who teaches the English branches, bookkeeping, and elementary mathematics. It is in the highest degree gratifying to record the praiseworthy conduct and punctual attendance of the boys; and the progress in their studies has been very fair, considering their previous ignorance. The nationalities represented in the school are as follows:

Americans (9 of Irish descent),	12
Welsh,	3
Irish,	2
Swede,	1
French	1

A noteworthy change is noticed in the pupils with regard to their appearance and dress, which are much improved by their attendance at the school. The effect of the school is also shown in the expressions of regret heard from many young men that they had not entered the school at the start, and some of the foremen deplore the fact that there was not such a school when they were boys. The success of this school, let us hope, will induce others in charge of large works or mines to try the experiment. It is to be recommended to start first, a preparatory class, say three evenings a week, and, in addition, to use the day hours when the mines or works are idle. When the boys are well prepared, a day-school, every afternoon for two years is desirable, the mornings being spent in practical work in the mines or shops. They should not, however, be employed in routine duties, such as picking slate, pushing cars, tending doors, etc. Such work tends to blunt the perceptions and stupefy the mind. If the suggestion above, of an expert class, is carried out for boys who have passed through the school, a very considerable technical training may be accomplished without taking an inordinate amount of time from working hours, or any considerable expenditure of money. The school must adapt itself to the works, which in turn must give aid and encouragement to the school. This co-operation is attained in some industrial sections of Europe, and I do not see why it cannot be introduced with us. The keynote of success, let me say in conclusion, is not to endeavor to turn out young engineers, but to raise up intelligent foremen.

The above paper is from the Transactions of the American Institute of Mining Engineers, and was written by Mr. Oswald J. Heinrich, principal of the school. In addition Mr. Heinrich writes us under date of June 22nd:

I give you in addition the following statement in regard to the "Drifton Industrial School for Miners and Mechanics." The second year's course was completed by an examination June, 1881, with the following results up to Sept. 1st, 1881.

For attendance, Grades,	10,	9½,	9,	8½,	8,	7½,	6½,	5.
Number of Pupils, 15	6,	3,	3,	—	1,	1.		
Grades for Progress	9½,	9,	8¾,	8½,	8,	7.		
Number of Pupils, 15,	2,	5,	2,	3,	1,	2.		

Seven prizes were awarded to the best scholars for attendanee and progress. The result of the third year's session is as follows: There were thirty-four [34] candidates, for admission, of whom twenty-six were Americans; five were Welshmen; one Scotch; one Irish; one Polander. Of these sixteen were admitted to the preparatory class, and two more joined during the session. Nine were admitted te the Junior class. The school, therefore, stands now:

Classes.	Admitted.	Remaining.
Preparatory	18	14
Junior	16	8
Senior	6	5
Total	40	27

One scholar has been dropped from the roll for irregular attendance. The balance were obliged to leave, either because of changing their plaee of work, or becoming discouraged on account of not being able to attend regularly because of their duties at the works. This last cause is one to be lamented, and a change for the better is to be hoped for. The preparatory class is now under the charge of Eugene B. Wilson, formerly of Yale College, in elementary, physics and algebra, and book-keeping for all three classes. The conduct and interest shown by the scholars is still the same as stated before, if not better, and all that is wanting is more time for recitations and tuition.

SCHOOL OF MINES—COLUMBIA COLLEGE, NEW YORK CITY.

THIS undoubtedly, one of our leading representative institutions, furnishes the student in mining and metallurgy as well as engineering, a most capital course of instruction. The faculty of the School of Mines is as follows:

FREDERICK A. P. BARNARD, S.T.D., LL.D., L.H.D.,
President of Columbia College.

PROFESSORS.—Thomas Egleston, E.M., PH.D., LL.D., Mineralogy and Metallurgy. Charles F. Chandler, PH.D., M.D., LL.D., Chemistry, Dean of the Faculty. William G. Peck, PH.D., LL.D., Mechanics. J. Howard Van Amringe, A.M., PH.D., Mathematics. Ogden N. Rood, A.M., Physics. John S. Newberry, M.D., LL.D., Geology and Palæontology. William P. Trowbridge, PH.D., LL.D., Engineering. William R. Ware, B.S., Architecture. Henry S. Munroe, E.M., PH.D., Surveying and Practical Mining (Adjunct). Frederick R. Hutton, C.E., PH.D., Mechanical Engineering (Adjunct).

OTHER OFFICERS.—John K. Rees, A.M., E.M., Director of the Observatory and Instructor in Geodesy. Frederick Stengel, A.M., Instructor in German. Jules E. Loiseau, A. B., LL.B., Instructor in French. Elwyn Waller, A.M., E.M., PH.D., Instructor in Quantitative Analysis. Pierre DePeyster Ricketts, E.M., PH.D., Instructor in Assaying. James S. C. Wells, PH.D., Instructor in Qualitative Analysis. Jasper T. Goodwin, A.M., LL.B., Instructor in Mathematics. Alfred D. Churchill, A.M., M.S., E.M., PH.B., Instructor in Drawing. Alexis A. Julien, A.M., Assistant in Analytical Chemistry. Charles A. Colton, E.M., Assistant in Mineralogy. Louis H. Laudy, PH.D., Assistant in General Chemistry. Nathaniel L. Britton, E.M., Assistant in Geology. Henry C. Bowen, Assistant in Quantitative Analysis. C. Herbert Torrey, PH.B., Assistant in Qualitative Analysis. Alford L. Beebe, PH.B., Assistant in Assaying. William W. Share, PH.B., Assistant in Physics. James L. Greenleaf, C.E., Assistant in Engineering. William G. Baker, Librarian. George F. Fisher, Registrar. Robert M. Ricketts, Assistant Registrar.

General Statement.—The School of Mines was established in 1864, for the purpose of furnishing to students the means of acquiring a thorough knowledge of those branches of science, which form the basis of the industrial pursuits that are to play the most important part in the development of the resources of the country. The system of instruction includes six parallel courses of study, viz.:

I. Mining Engineering.
II. Civil Engineering.
III. Metallurgy.
IV. Geology and Palæontology.
V. Analytical and Applied Chemistry.
VI. Architecture.

During the first year the instruction given to all the students of the First Class is the same; at the beginning of the second year each student must elect which of the six courses he intends to pursue, and must thenceforth abide by his election unless permitted by the Faculty to make a change. No student is permitted to pursue a special or partial course. The plan of instruction includes lectures and recitations in the several departments of study; practice in the chemical, mineralogical, blowpipe, and metallurgical, laboratories; field surveying; practice in operative mining; projects, estimates, and drawings for the establishment of mines, and for the construction of metallurgical, chemical, and other works; reports on mines, industrial establishments, and field geology. The course of instruction occupies four years. There is an advanced course for graduates of the school. The method of instruction is such that every pupil may acquire a thorough theoretical knowledge of each branch, of which he is required to give evidence, at the close of the session, by written and oral examinations. At the commencement of the following year he is required to show, from reports of works visited, that he understands not only the theoretical principles of the subjects treated, but also their practical application—a point that is insisted on with great rigor.

Admission.—Candidates for admission to the First Class, at its formation, must be of the age of seventeen years, complete; and, for admission to advanced standing, there will be required a corresponding increase of age. Candidates for the first class must pass a satisfactory examination in arithmetic, including the metric system of weights and measures; in algebra, on the first ten chapters of Peck's Manual of Algebra; in geometry, on the first six books of Davies' Legendre; in French, on the equivalent of twenty-five lessons of Jewett's Ollendorff Grammar; in German, on the equivalent of twenty lessons of Otto's German Grammar; in English grammar, on the equivalent of Quackenbos's English Grammar; in composition and rhetoric, on the equivalent of Quackenbos's Course of Composition and Rhetoric; in history, on the equivalent of Thompson's History of England and Doyle's History of the United States as contained in Freeman's Historical Course for Schools; in physical geography, on the equivalent of Guyot's Physical Geography; and in free hand drawing, including the ability to sketch, both in outline and with proper shading, ordinary objects, such as a tree, a house, a simple piece of machinery, a piece of flat ornament from a copy, a group of geometrical solids, etc. Candidates for advanced standing must pass a satisfactory examination upon the studies named above, and also upon those pursued by the class which they propose to enter.

From and after the beginning of the year 1883 candidates for admission to the First Class will, in addition to the requirements above specified, be examined on—

1st. Physics, equivalent to Ganot's smaller Treatise (Peck's Ganot's Natural Philosophy).

2d. The general principles of French Grammar, including an ability to read Montmahon's "Cours d' Histoire Naturelle," or its equivalent.

3d. The general principles of the German Grammar, including an ability to read Hans Andersen's "Märchen," or its equivalent.

Candidates for admission after the opening of a term will be required to pass satisfactory examinations on the part of the course already gone over by the class for which they are applicants. No candidates are admitted later in the course than the beginning of the third year. Graduates and students of colleges and schools of science, who shall have completed so much of the course as shall be equivalent to the requirements for admission, may be admitted at the beginning of the second year, or earlier, without examination, on presenting diplomas or certificates of good standing and honorable dismissal satisfactory to the examining officers. The regular examinations for admission are held annually, beginning on the Friday before commencement, and on the Wednesday preceding the first Monday in October. Candidates will, however, be examined during the session, but not in vacation. The annual tuition fee is two hundred dollars, payable one-half on the first day of each session.

Free Students.—Whenever it appears to the satisfaction of the President and the Treasurer of the college that a student, who is of good moral character and industrious habits, desires to pursue the studies of the school, but is unable to pay the usual fees for tuition, he may be admitted without charge. Candidates for free tuition must fulfil the following conditions:

1. He must present a certificate from some person of good repute, that the writer is acquainted with the circumstances of the applicant (his parent or guardian, if he has such) and knows him to be unable to bear the expense of his education if obliged to pay the tuition fee; also, that he (the writer) is not himself a relative of the applicant. A proper blank will be furnished ou application to the Registrar.

2. He must exhibit a proficiency in every subject of examination expressed by the number 6 of a scale in which 10 is the maximum.

3. He must maintain, subsequent to his admission, a standing in scholarship, also in every branch, expressed by the number 7 of a similar scale, failing which he will forfeit his privilege.

Apparatus Supplies.—I. Students may purchase apparatus of any of the dealers in the city.

II. To save inconvenience and expense to the students, and to secure a proper selection, the school undertakes, at considerable trouble and expense, to lend apparatus on the following conditions:

1. Each student must make a deposit with the Registrar, which deposit will be credited to him on the ledger. This deposit will be $25 for students of the Second Class, $40 for students of the Third Class, and $50 for students of the Fourth Class.

2. Each student will be entitled, on presenting his receipt at the supply room, to draw the regular set of apparatus for qualitative or quantitative analysis, or for assaying, according to his deposit, and from time to time to obtain ordinary articles which he may need, and these will be charged to him. At the end of the session he will be credited with those articles which he returns in good order, and the value of those which he has injured or broken will be deducted from his deposit.

III. The supply room will be open for issuing supplies every day at convenient hours.

IV. No charge is made for ordinary chemicals.

Excursions.—During the session, the students may visit the different machine shops and metallurgical establishments of the city and its environs. During the vacation, each student is expected to visit mines, metallurgical and chemical establishments, and to hand in on his return, a memoir on some subject assigned him. He is also required to bring collections illustrating his memoir, which collections are placed in the museum, reserved as a medium of exchange or made use of in the laboratories. During the vacation following the close of the second year, students of engineering may join a volunteer class in practical mechanical engineering under the supervision of the Adjunct Professor of Mechanical Engineering. During the vacation following the close of the third year, students of mining engineering visit a mine and engage in actual work or study under the superintendence of the Adjunct Professor in Surveying and Practical Mining. During the vacation following the close of the third year, the students of civil engineering are required to attend a summer class in Geodesy for six weeks. The class is under the supervision of the Director of the Observatory and Instructor of Geodesy.

Scholastic Year.—The year is divided into two sessions: The first commences on the first Monday in October; the second, on the first or second Thursday of February. The lectures close on the Friday of the fourth week before commencement.

Examinations.—There are two examinations every year, one commencing on the last Monday in January, and the other on the Monday of the third week preceding commencement. The latter is the final examination in each department of all the classes for the year. The former embraces such subjects only as have been completed during the first session. In addition to the examination above noted, examinations are held monthly in all the classes, and in every department, for the purpose of ascertaining the proficiency of the students in their respective studies.

Commencement and Vacation.—The annual commencement is held on the second Wednesday in June, on which occasion degrees are publicly conferred. A vacation of all the classes extends from the day of commencement until the first Monday in October, on which latter day the regular course of study commences. The exercises of the school are suspended on public holidays established by law, on such days in each year as may be recommended by the civil authority to be observed as days of fast or thanksgiving, and for two weeks from the third (or fourth) Monday in December.

Necessary Expenses.—Board, including room-rent, fire and light, and washing, may be had in the city from six and a half to nine dollars per week. Annual tuition fee, $200. Text books about $15 for the first class, $30 for the second class, $50 for the third class, and $20 for the fourth class. Drawing materials $15 to $25 for each of the first and second classes, and $5 to $10 for each of the others. Laboratory apparatus $30 to $60 for each of the three years. Travelling and board for summer class in Practical Mining (Mining Engineers only) and for summer class in Practical Geodesy (Civil Engineers only), $50 to $60. Graduation, including Diploma, $5. The fees required of graduates of the school, attending the school, are as follows:

1. Full fee, entitling the student to all the privileges of the school per annum, $150.

2. For use of the library and cabinets, $25.

3. For attendance on lecture-room and other special instruction, per annum for each hour per week of such instruction, $25.

Or for any number of hours per week as above specified, $150.

4. For the use of the drawing academy, $25.

5. For the use of the laboratories, or either of them, $50.

Should the amount of fees payable by any student not exceed $100, the entire amount is payable at the beginning of the academic year, or at the matriculation of the student. Should the amount exceed $100, payment is required in two equal instalments, one at the beginning of each session of the academic year.

BY-LAWS.—*Fulfilling Conditions.* 1. Conditional students must fulfill all conditions within two months of the date of their admission.

Attendance.—2. Prompt attendance is is required upon all the exercises of the school. Each instance of tardiness will be counted as half an absence.

3. Any student who shall have been absent from more than ten per cent. of the exercises in any subject shall not be entitled to examination thereon.

4. Any students who, being present at the school, shall absent himself from any exercise, or shall leave the grounds during the hours at which his attendauce is due, shall be liable to removal from the roll of his class.

5. Students are required to attend all the exercises and pass all the examinations of the class and course to which they belong, unless specially excused by vote of the Faculty.

6. Students who obtain on examination a mark of eight or more in any subject may be excused from attendance upon the exercises in that subject. This rule to apply to new students and also to those who repeat the studies of any year. Reports of such standing must be filed with the Dean of the Faculty, who alone is authorized to excuse students from attendance.

7. Any student who shall have passed a satisfactory examination in the School of Arts of Columbia College in any study forming a part of the regular course in the School of Mines, will not be required to pursue that study in the school.

8. EXAMINATIONS.—Examinations will be held each month, on all subjects taught in the school.

9. Examinations will be held at the end of the first term (semi-annual), or at the end of the year (annual), on all subjects taught in the school.

10. No student who absents himself from a regular examination is allowed to proceed with his class without a special vote of the Faculty.

11. Any student who shall fail to pass in any of his studies at the regular examination at the end of the academic year, may present himself for a second examination during the last week of the summer vacation. Failing to pass in this second examination, he can only go on with his class by special permission of the Faculty, and provided that he takes private instruction approved by the Faculty, and within two months from the beginning of the term, presenting to the Faculty a favorable report of his progress from his instructor. This will entitle him then to a third examination, failing in which his name shall be dropped from the roll of the class.

12. Examinations at times other than here designated are not held except by order of the Faculty.

13. Students deficient in any department are not allowed to go on with their classes without a special vote of the Faculty.

14. No student is entitled to a degree until he has passed satisfactory examinations in all the studies of the course in which he desires to graduate.

15. Any student who, at the close of the fourth year, may have failed to complete a course required for graduation, and desires to continue his studies in the school for a longer time, is permitted to do so; and, with the consent of the Faculty, may have an examination for a degree at the close of any subsequent term.

16. When a student fails to receive his degree with his class, and returns at some later period to present himself for examination for the same, he will be required to comply with all the requirements at the later date, and the same rule shall apply to students who have received one degree and make application for another.

17. STANDING.—Every officer keeps a record of the scholarship of each student.

18. The maximum mark is ten in each department, and six is required to pass a student.

19. Free students must maintain a standing of seven in every branch of study, failing which they will forfeit their privileges.

20. CHANGE OF COURSE.—No student shall be permitted to change his course till he has passed in every study of the course which he proposes to leave.

21. ANALYSES.—Analyses and Assays must be made on material supplied or authorized beforehand by the Instructor in charge of the laboratory, and the reports must be handed in on the completion of the work.

22. MEMOIRS.—Each student, at the commencement of his second, third, and fourth year, is required to present memoirs on such subjects as may be assigned to him by the Faculty.

23. Students of the Second, Third, and Fourth classes who fail to hand in, on or before November 1st, the memoirs, drawings, and other Summer work required of them under the rules, shall be dropped from the roll of their respective classes.

24. PROJECTS AND DISSERTATIONS.—Each student, before graduating is required to execute projects or dissertations on subjects assigned to him by the Faculty. These projects or dissertations must be illustrated by drawings made to a scale.

25. All memoirs, projects, dissertations, and drawings executed in the drawing academy, may be retained by the School.

26. DEGREES.—Every student who has passed satisfactory examinations in all the studies of a course, and completed the required number of projects, dissertations, memoirs, analyses, assays, and drawings, is recommended to the Board of Trustees for the degree of Engineer of Mines, Civil Engineer, or Bachelor of Philosophy.

27. Graduates of the school, who fulfil the following conditions, are recommended to the Board of Trustees for the degree of Doctor of Philosophy.

(1.) Each candidate shall pursue, for the term of at least one academic year, a course of higher study, at the school and under the direction of the Faculty, in two or more branches of science, and shall pass an approved examination thereon.

(2.) He shall also present an acceptable thesis or dissertation embodying the results of special study, research, or observation, upon the subject previously approved and accepted by the Faculty.

28. SPEAKERS AT COMMENCEMENT.—A list of members of the graduating class, from whom the speakers at commencement may be chosen, will be made by the Faculty and submitted to the class, who may select as speakers two of the number, subject to the approval of the Faculty.

29. LIBRARY.—The library is open to students from 9:30 A.M. to 4 P.M.

30. Books taken from the library must be returned within two weeks.

31. Students must give receipts for books taken, and are responsible for their return in good condition.

32. THE LABORATORIES AND DRAWING ACADEMY.—The analytical, assay, blowpipe, and mineralogical laboratories and the drawing academy, are open on week days, except Saturdays and during vacations, from 10 A.M. till 4 P.M.

33. No student will be allowed in the laboratory or the drawing academy at the time when his attendance there is not due. During hours assigned for practical work in each of the laboratories, in the drawing academy, and in practical surveying, the attendance of students will be required. A record of the daily attendance and of the progress of each student will be kept by the officer in charge.

34. ORDER.—Good order and gentlemanly deportment are required of all students, as a condition of attendance upon the exercises of the school.

35. Smoking is prohibited on the college grounds, as well as in the buildings.

SYNOPSIS OF STUDIES.

FIRST SESSION.

First Year. Common to all the Courses.—Geometry—Plane, volumetric, and spherical; Conic Sections. Text books: Davies' Legendre and Peck's Conic Sections.

Algebra—Text book: Peck's Manual of Algebra.

Physics—Doctrines of heat, viz., expansion, conduction, radiation, thermometry, latent heat, tension of vapors, steam. Lectures, and "Atkinson's Ganot's Physics."

Chemistry—The non-metallic elements, through carbon. Lectures, and "Roscoe's Elementary Chemistry."
Qualitative Analysis—Lectures, and "Fresenius' Manual of Qualitative Analysis."
French—Text books: Jewett's Ollendorff's French Grammar, Montmahon's Cours d'Histoire Naturelle.
German—Text books: Wershoven's Technical Vocabulary, Schoedler's Buch der Natur, Parts I., II.
Drawing—Use of instruments; lettering, instrumental drawing; projections, intersections, and developments. Text book: Binn's Orthographic Projection.

SECOND SESSION.

Trigonometry and Mensuration, as contained in Davies' Legendre.
Physics—Specific heat, magnetism, electricity static and dynamic, thermo-electricity, induction, magneto-electricity, the electric telegraph. Lectures, and "Atkinson's Ganot's Physics."
Chemistry—To the metals. Lectures, and "Roscoe's Elementary Chemistry."
Qualitative Analysis—Lectures, and "Fresenius' Manual of Qualitative Analysis."
French—Text books: same as first session.
German—Text books: same as first session.
Drawing—Same as first session.

1. COURSE IN MINING ENGINEERING.

FIRST SESSION.

SECOND YEAR—*Analytical Geometry*—Text book: Peck's Analytical Geometry.
Graphics—Descriptive Geometry. Text book: Church's Descriptive Geometry.
Chemistry—Metals. Lectures, and "Fownes' Manual of Chemistry."
Blowpipe Analysis—Qualitative.
Zoology—Lectures, and Nicholson's Manual of Zoology.
Botany—Lectures, and Gray's Botanical Text Book.
French—Fasquelle's French Grammar; Beudant's Geologie; La bouchee de pain.
German—Text books: Wershoven's Technical Vocabulary; Stoeckhardt's Schule der Chemie; Bernoulli's Vademecum des Mechanikers; Stoehr's Katechismus der Bergbaukunde; Gurlt's Bergbau- und Huettenkunde.
Drawing—Topographical drawing; tinting and grading; problems in graphics. Text book: Honey's Perspective.

SECOND SESSION.

Differential and Integral Calculus—Text book: Peck's Practical Calculus.
Graphics—Shades and shadows, perspective, isometrical drawing. Text book; Church's Shades and Shadows.
Stone Cutting.
Chemistry—Organic. Lectures, and "Fownes' Manual of Chemistry."
Crystallography—Lectures, and "Egleston's Diagrams of Crystals."
Zoology—Lectures, and Nicholson's Manual of Zoology.
Botany—Lectures, and Gray's Botanical Text Book.
French—Text books: same as first session.
German—Text books: same as first session.
Drawing—Problems in graphics: architectural drawing.

FIRST SESSION.

THIRD YEAR—*Mechanics of Solids*—Including forces, moments, equilibrium, stability, etc., and elementary machines; dynamics, including uniform, varied, rectilinear and curvilinear motion, rotation, vibration, impact, work done, etc.
Engineering—General principles relating to materials and structures, physically and mechanically considered.
1. *Materials*—Stone, cements, brick, metals, timber, treated in regard to strength, durability, mode of preparation, defects, tests of quality, and fitness for special uses.
2. *Structures*—Foundations and supports, superstructure, joints, stability, strength and stiffness of parts; special rules of construction for masonry of public buildings, bridges, retaining walls, arches, railroads, common roads, and canals.
3. *Theory of Strains and Strength of Materials*—Elasticity, mechanical laws, application of principles of mechanics to beams, girders and roof trusses, under various conditions of loading and supports.

Kinematics of Machinery—(1) General theory of motion, (2) uniform and varied motion, (3) compositions of motions, (4) instantaneous centre, (5) rolling centroids, (6) graphical and analytical representations of machine motions, (7) line of centres.
Surveying—Field work, with compass, sextant, hand level, and pacing, use of solar compass in land and mineral surveys, adjustments and use of transit and levelling instruments, triangulation and traversing.
Practical Mining or Miners' Work—Excavation, quarrying, drilling and blasting, tunneling.

Applied Chemistry—Air, water, fuel, artificial illumination.
Quantitative Analysis.
Stoichiometry.
Mineralogy—Determinative.
Geology, Lithological—Rocks and rock masses.
Metallurgy—General metallurgy, fuel, furnaces, etc.
Physics—Mechanical theory of heat, electrictiy.
Drawing—Constructions; machines, furnaces, plans, etc.

SECOND SESSION.

Mechanics of Fluids—Including pressure, buoyancy and specific gravities, motion in pipes and channels, undulation, capillarity, tension and elasticity of gases, the atmosphere, the barometer, barometric formulæ, and hypsometry.
Engineering—Theory of Strains and Strength of Materials continued—Graphical methods of determining strains, deflection of beams and girders; quantity of material in braced girders under various conditions of loading and supports; angle of economy for bracing torsion; of shafts; crushing and tensile strength of materials; working strains and working load; mode of estimating cost of girder work.
Dynamics of Machinery—Forces of nature employed or acting in all machines, dynamical laws, mathematical theorems, measure of forces, work of forces, elementary machines and their combintions, theory of efficiency, theory of flywheels, governors and brakes, strength and proportions of parts of machines, dynamometers.
Transmissive Machinery—
1. Transmission by rolling contact, friction gear, and cams.
2. Transmission by sliding contact, spur, bevel screw, and skew-bevel teeth, and cams.
3. Transmission by shafting.
4. Transmission by belts, ropes, chains, etc.
5. Transmission by links.
6. Transmission by fluids.

Practical Mining (*or Miners' Work*)—Excavation, quarrying, drilling and blasting, tunneling.
Surveying—Topographical work with plane table, magnetic survey, underground surveying.
Physics—Physical optics and the undulatory theory of light.
Applied Chemistry—Limes, mortars, and cements; building stones: decay and preservation; timber and its preservation: pigments, paints, essential oils, varnishes; glass and ceramics; explosives; gunpowder, guncotton, nitroglycerine, etc.
Quantitative Analysis.
Mineralogy—Determinative.
Metallurgy—Iron and steel.
Geology—Historical, including palæontology, or a systematic review of recent and fossil forms of life.
Drawing—Constructions; machines, furnaces, plans, etc.

WITHOUT DISTINCTION OF SESSIONS.

FOURTH YEAR—*Dynamics of Machinery completed*—Prime Movers, as driven by animal power, water power, steam power, compressed or heated air, wind power, comprising the theory of animal power, theory of water wheels, overshot wheels, undershot wheels, breast wheels, turbines, reaction wheels, centrifugal pumps; properties and laws of heat as applied to the generation of steam and the construction of boilers; properties of steam and air in their relation to prime movers; mechanical theory of heat applied to steam engines, hot air engines, compressed air engines; general description of heat engines of various forms; description and theory of ventilating fans or blowers.
Mining Engineering—
1. Considered in its widest sense as a course of study.
2. Considered in reference to the application of general principles of engineering to the development and working of mines.
3. Classification and nomenclature of mineral deposits; descriptions of lodes or veins, beds, masses, and irregular deposits, with illustrations of the disturbances to which they are subjected, as affecting the work of mining.
4. Graphical representations of deposits, with examples showing modes of occurrence and disturbances.
5. Prospecting or searching for mineral deposits.
6. Exploratory workings.
7. Establishing seats of extraction.
8. Description of typical methods of exploitation as applied to wide veins or lodes, to narrow veins, masses, to beds of various thickness and degrees of inclination.
9. General principles relating to subterranean transportation.
10. Methods and machinery employed for extracting minerals from the pits, and for facilitating ascent and descent of workmen.
11. Drainage of mines; theory of infiltration of water, methods of machinery for draining or freeing mines from water.
12. Ventilation of mines; causes of vitiation of the air of mines; quantities of fresh air required under various circumstances; natural ventilation; mechanical ventilation, by fires and by ventilating machinery; distribution of air through galleries and workings.

13. Graphical illustrations of exploratory workings; methods of exploitation; machinery for hoisting, pumping, ventilation, and transportation, including the use of steam engines and pumps, air compressors, air engines, pumping engines, winding engines, centrifugal and other ventilating machines.

Practical Mining—

1. Boring, earth augers, driven wells, boring with rods and cable tools, upward, inclined, and horizontal boring, diamond drill and its use in prospecting.
2. Shaft sinking, shaft timbering and spiling, boring of shafts, sinking of iron and masonry linings, cribbing, walling, and tubbing.
3. Drifting of adits and levels, timbering and walling in levels and working places.
4. Mining of coal and ores, coal cutting machines, hand and machine drilling.
5. Handling of coal and ores in working places.
6. Tramming, cars, tracks, locomotive and wire rope haulage, planes and gravity roads.
7. Accidents to miners, cause and prevention.
8. Organization and administration.
9. Time books, measurement of contracts, pay roll, analysis and dissection of accounts, and cost sheets.

Ore Dressing.

1. Introduction, theory of separation, hand and machine dressing, general principles governing crushing and sizing of ores of different character.
2. Jigging—theory of, description of different forms of jigs and methods of working, air jigs.
3. Slime treatment, classification of slimes in troughs, spitz kasten, etc., and treatment on buddles and tables.
4. Description of crushing machinery, jaw crushers, rolls, stamps, mills, etc.
5. Sizing apparatus, screens, riddles and trammels.
6. Description of coal washing plant; anthracite breaker.
7. Description of American ore-dressing works.
8. Foreign ore-dressing works.

Hydraulic Engineering—Application of principles of mechanics, of fluids to determining the discharge of water over weirs or dams; the dimension of conduit pipes; discharge of canals and rivers; the effect of varying forms and sections of channels and of obstructions to flow; the gauging of streams; retaining walls for reservoirs.

Mechanical Engineering—

1. Steam boilers—construction, wear and tear, fittings, setting, testing, care and management, firing, feeding, injectors, pumps, etc.
2. Mechanism of engines—Valve gearing, link motions, governors, etc.
3. Management of engines—Erecting, emergencies, special types of engines, etc.
4. Proportions of engines, etc.
5. Testing efficiency of engines and boilers, etc.
6. Pumps, hoisting engines, ventilating machinery, construction and management of hot air, gas, and petroleum, engines, etc.
7. Machine tools.

Surveying.—Railroad surveying, reconnoissance, location of line, calculation of cuttings and embankments.

Economic Geology.—Theory of mineral veins, ores, deposits and distribution of iron, copper, lead, gold, silver, mercury, and other metals; graphite, coal, lignite, peat, asphalt, petroleum, salt, clay, limestone, cements, building and ornamental stones. etc.

Assaying.—Ores of lead, silver, gold; and gold, silver, and lead alloys.

Metallurgy.—Copper, lead, antimony, iron, copper, silver, gold, zinc, tin, mercury, etc.

Drawing.—Graphic statics and project.

FIRST SESSION.

II.—Course in Civil Engineering.—*Second Year.*—*Analytical Geometry.*—Text book: Peck's Analytical Geometry.

Graphics.—Descriptive Geometry. Text book: Church's Descriptive Geometry.

Chemistry.—The Metals. Lectures, and "Fownes' Manual of Chemistry."

Blowpipe Analysis.—Qualitative. Text book: Plattner's Blowpipe Analysis.

Zoology—Lectures, and Nicholson's Manual of Zoology.

Botany.—Lectures, and Gray's Botanical Text Book.

French.—Text books: Fasquelle's French Grammar; Beudant's Geologie; La bouchee de pain.

German.—Text books: Wershoven's Technical Vocabulary; Stoeckhardt's Schule der Chemie; Bernoulli's Vademecum des Mechaniker's; Stoehr's Katechismus der Bergbaukunde; Gurlt's Bergbau und Huettenkunde.

Drawing.—Topographical Drawing; tinting and grading; problems in graphics. Text book: Honey's Perspective.

SECOND SESSION.

Differential and Integral Calculus—Text book: Peck's Practical Calculus.

Graphics.—Shades and Shadows, perspective, isometrical drawing. Text book: Church's Shades and Shadows.

Stone Cutting.

Chemistry.—Organic. Lectures, and "Fownes' Manual of Chemistry."

Crystallography.—Lectures, and Egleston's Diagrams of Crystals.

Zoology.—Lectures, and Nicholson's Manual of Zoology.

Botany.—Lectures, and Gray's Botanical Text Book.

French.—Text books; same as first session.

German.—Text books; same as first session.

Drawing.—Problems in graphics; architectural drawing.

FIRST SESSION.

Third Year.— Mechanics of Solids, including forces, moments, equilibrium, stability, etc., and elementary machines; dynamics, including uniform, varied, rectilineal and curvilinear motion, rotation, vibration, impact, work done, etc.

Engineering.—General principles relating to materials and structures, physically and mechanically considered.

1. *Materials*— Stone, cements, brick, metals, timber, treated in regard to strength, durability, mode of preparation, defects, tests of quality, and fitness for special uses.
2. *Structures* — Foundations and supports, superstructure, joints, strength and stiffness of parts; special rules of construction for masonry of public buildings, bridges, retaining walls, arches, railroads, common roads and canals.
3. *Theory of Strains and Strength of Materials*— Elasticity, mechanical laws, application of principles of mechanism to beams, girders, and roof trusses under various conditions of loading and supports.

Kinematics of Machinery—(1) General theory of motion, (2) uniform and varied motion, (3) composition of motions, (4) instantaneous centre, (5) rolling centroids, (6) graphical and analytical representations of machine motions, (7) line of centres.

Practical Mining—Excavation, quarrying, drilling and blasting, tunneling.

Practical Astronomy and General Principles of Geodesy.

Surveying—Field work, with compass, sextant, hand level, and pacing, use of solar compass in land surveys, adjustments and use of transit and levelling instruments, triangulation and traversing.

Applied Chemistry—Air, water, fuel, artificial illumination.

Mineralogy—Determinative.

Geology—Lithological, cosmical, and physiographic.

Metallurgy—General metallurgy; fuels, furnaces, etc.

Physics—Mechanical theory of heat, electricity.

Drawing—Constructions; machines, furnaces, plans, etc.

SECOND SESSION.

Mechanics of Fluids, including pressure, buoyancy and specific gravities, motions in pipes and channels, undulation, capillarity, tension and elasticity of gases, the atmosphere, the barometer, barometric formulæ, and hypsometry.

Engineering—Theory of strains and Strength of Materials continued—Graphical methods of determining strains; deflection of beams and girders; quantity of material in braced girders under various conditions of loading and supports; angle of economy for bracing; torsion of shafts; crushing and tensile strength of materials; working strains and working load; mode of estimating cost of girder work.

Dynamics of Machinery—Forces of nature employed or acting in all machines, dynamical laws, mathematical theorems, measure of forces, work of forces, elementary machines and their combinations, theory of efficiency, theory of flywheels, governors and brakes, strength and proportions of parts of machines, dynamometers.

Transmissive Machinery—

1. Transmission by rolling contact, friction gear, and cams.
2. Transmission by sliding contact, spur, bevel screw, and skew-bevel teeth, and cams.
3. Transmission by shafting.
4. Transmission by belts, ropes, chains, etc.
5. Transmission by links.
6. Transmission by fluids.

Practical Mining—Excavation, quarrying, drilling and blasting, tunneling.

Practical Astronomy and General Principles of Geodesy.

Surveying—Topographical work with plane table.

Physics—Physical optics and the undulatory theory of light.

Applied Chemistry — Limes, mortars, and cements; building stones: decay and preservation; timber and its preservation: pigments, paints, essential oils, varnishes; glass and ceramics; explosives: gunpowder, gun-cotton, nitroglycerine, etc.

Mineralogy—Determinative.

Metallurgy—Iron and Steel.

Geology—Historical including palæontology.
Drawing—Constructions; machines, furnaces, plans, etc.
Summer Vacation.—Memoir.

WITHOUT DISTINCTION OF SESSIONS.

FOURTH YEAR—*Dynamics of Machinery*—Prime movers, as driven by animal power, water power, steam power, compressed or heated air, wind power, comprising the theory of animal power, theory of water wheels, overshot wheels, undershot wheels, breast wheels, turbines, reaction wheels, centrifugal pumps; properties and laws of heat as applied to the generation of steam in steam boilers; properties of steam and air in their relation to prime movers; mechanical theory of heat, applied to steam engines; hot-air engines, compressed-air engines; general description of heat engines of various forms; description and theory of ventilating fans or blowers.

Civil Engineering—Hydraulic and Sanitary Engineering, embracing water supplies for cities and towns, for the purposes of irrigation and improvement of lands; quantity and quality of water required; rainfall, flows of streams, storage of water, capacity of water sheds, impurities of water; practical construction of water works, pumping machinery; clarification of water; systems of water supply.

Principles of Sanitary Engineering—As regards necessity of sanitary measures, different systems of removing refuse and decomposing matters, warming and ventilation.

Works of Sewerage—Rainfall and sewers; influence of geological and topographical features of the sites of towns and districts; discharge of sewers; intercepting sewers; forms, modes of construction, and materials used; flushing of sewers and ventilation; traps, outfalls, tide valves; subsoil and surface drainage of towns; house drainage; water closets; ventilation of houses, in connection with sanitary measures.

Improvements of Rivers and Harbors—Action of tides and currents in forming and removing deposits; methods of protecting and deepening harbors and channels.

Geodesy—Continued, with lecture on figure of the earth, and practical illustration in the use of geodetic instruments, such as measurement of base lines, measurement of horizontal angles for a primary, a secondary, and a tertiary triangulation; signals, astronomical determinations of time, latitude, longitude, and azimuth of a direction.

Railroad Engineering—Permanent way; rolling stock; motive power; administration, etc.

Hydraulic Engineering—Application of principles of mechanics of fluids to determining the discharge of water over weirs or dams; the dimensions of conduit pipes; discharge of canals and rivers; the effects of varying forms and sections of channels and of obstructions to flow; the gauging of streams; retaining walls for reservoirs.

Mechanical Engineering—(1) steam boilers: construction, wear and tear, fittings, setting, testing, care and management, firing, feeding, injectors, pumps, etc.; (2) mechanism of engines, valve gearing, link motions, governors, etc.; (3) management of engines, erecting emergencies, special types of engines, etc.; (4) proportions of engines, etc.; (5) testing efficiency of engines and boilers; (6) pumps, hoisting engines, ventilating machinery; (7) construction and management of hot air, gas, and petroleum engines, etc.; (8) machine tools.

Surveying—Railroad surveying: reconnoissance, location and survey of line with curves and slope stakes, calculations of cuttings and embankments.

Economic Geology—Theory of mineral veins, ores, deposits and distribution of iron, copper, lead, gold, silver, mercury, and other metals; graphite, coal, lignite, peat, asphalt, petroleum, salt, clay, limestone, cements, building and ornamental stones, etc.

Metallurgy—Supplementary lectures on iron and steel.
Drawing—Graphic statics and project.

FIRST SESSION.

III.—COURSE IN METALLURGY.—*Second Year.—Analytical Geometry*—Text book: Peck's Analytical Geometry.

Graphics—Descriptive Geometry. Text books: Church's Descriptive Geometry.

Chemistry—The Metals. Lectures, and "Fownes' Manual of Chemistry."

Quantitative Analysis—Lectures, and "Cairn's Quantitative Analysis."

Stoichiometry.

Blowpipe Analysis—Qualitative. Text book: Plattner's Blowpipe Analysis.

Zoology—Lectures, and Nicholson's Manual of Zoology,

Botany—Lectures, and Gray's Botanical Text Book.

French—Text books: Fasquelle's French Grammar; Beudant's Geologie; La bouchee de pain.

German—Text books: Wershoven's Technical Vocabulary; Stoeckhardt's Schule der Chemise; Bernoulli's Vademecum des Mechanikers; Stoehr's Katechismus der Bergbaukunde; Gurlt's Bergbau-und Huettenkunde.

Drawing—Tinting and grading: topographical drawing; problems in graphics. Text book: Honey's Perspective.

SECOND SESSION.

Differential and Integral Calculus—Text book; Peck's Practical Calculus.

Graphics—Shades and shadows, perspective, isometrical drawing. Text books: Church's Shades and Shadows.

Stone Cutting.

Chemistry—Organic, Lectures, and "Fownes' Manual of Chemistry."

Quantitutive Analysis—Lectures, and "Cairn's Quantitative Analysis."

Crystallography—Lectures, and illustrative diagrams.

Zoology—Lecture, and Nicholson's Manual of Zoology.

Botany—Lectures, and Gray's Botanical Text Book.

French—Text books: same as first session.

German—Text books: same as first session.

Drawing—Problems in graphics; architectural drawing.

Summer Vacation.—Memoir.

FIRST SESSION.

Third Year.—Mechanics of solids, including forces, moments, equilibrium, stability, etc., and elementary machines; dynamics, including uniform, varied, rectilineal and curvilinear motion, rotation, vibration, impact, work done, etc.

Quantitative Analysis.

Applied Chemistry—Air, water, fuel, artificial illumination.

Mineralogy—Determinative.

Geology—Lithological, cosmical, physiographic.

Metallurgy—General Metallurgy; fuel, furnaces, etc.

Physics—Mechanical theory of heat, electricity.

Drawing—Constructions; machines, furnaces, plans, etc.

SECOND SESSION.

Mechanics of Fluids, including pressure, buoyancy and specific gravities, motion in pipes and channels, undulation, capillarity, tension and elasticity of gases, the atmosphere, the barometer, barometric formulæ, and hypsometry.

Physics—Physical optics and the undulatory theory of light.

Applied Chemistry—Limes, Mortars and Cements; building stones; decay and preservation; timber and its preservation; pigments, paints, essential oils, varnishes; glass and ceramics; explosives; gunpowder, guncotton, nitroglycerine, etc.

Quantitative Analysis.

Mineralogy—Determinative.

Metallurgy—Iron and Steel.

Geology—Historical, including palæontology.

Drawing—Constructions; machines, furnaces, plans, etc.

FOURTH YEAR.—(*Without distinction of Sessions.*)

Machines, including prime movers, as driven by (1) animal power, (2) water power, (3) steam, (4) heated or compressed air, (5) the winds; comprising water wheels, turbines, and reaction wheels, steam engines in their various forms, and air engines.

Principles of Heat applicable to these Engines.

Steam Boilers.

Mechanism and Management of Engines.

Machine Tools.

Assaying—Ores of Lead, silver, gold, platinum, tin, antimony, bismuth, copper, nickel, cobalt, iron, mercury and zinc; and gold, silver and lead bullion; mattes, slags, etc.

Metallurgy—Copper, lead, silver, gold, zinc, tin, mercury, etc. Supplementary lectures on iron and steel.

Economic Geology—Theory of mineral veins, ores, deposits and distribution of iron, copper,, lead, gold, silver, mercury and other metals; graphite, coal, lignite, peat, asphalt, petroleum, salt, clay, limestone, cements, building and ornamental stones, etc.

Applied Chemistry—I. Chemical manufactures; acids, alkalies and salts. (1) Sulphur, sulphurous acid, hyposulphite, sulphuric acid, bisulphide of carbon, etc. (2) Common salt, soda ash, hydrochloric acid, chlorine, binoxide of manganese, bleaching powder, chlorimetry, etc. (3) Carbonate of potash, caustic potash, alkalimetry, acidimetry, etc. (4) Nitric acid and nitrates. (5) Iodine, bromine, etc. (6) Sodium, aluminium, magnesium. (7) Phosphorus, matches, etc. (8) Ammonia salts. (9) Cyanides. (10) Alum, copperas, blue vitriol, salts of magnesia, baryta, strontia, etc. (11) Borates, stannates, tungstates, chromates, etc. (12) Mercury salts, photography. (13) Electro-Metallurgy. (14) Oils, fat, soaps, glycerine. II. Food and drink; milk, cereals, starch, bread, meat, tea, coffee, sugar, fermentation, wine, beer, spirits vinegar, preservation of food, tobacco, etc. III. Clothing; textile fabrics, bleaching, dyeing. calico printing, paper, tanning, glue, India-Rubber, gutta percha, etc. IV. Fertilizers; guano, superphosphates, poudrettes, etc.

Drawing.—Project and Theses Work.

FIRST SESSION.

IV. COURSES IN GEOLOGY AND PALÆONTOLOGY.—*Second Year.—Graphics*—Descriptive Geometry. Text book: Church's Descriptive Geometry.

Chemistry—The Metals. Lectures, and "Fownes' Manual of Chemistry."

Quantitative Analysis—Lectures, and "Cairns' Quantitative Analysis."

Stoichiometry.
Blowpipe Analysis—Qualitative. Text book: Plattner's Blowpipe Analysis.
Zoology—Lectures, and Nicholson's Manual of Zoology.
Botany—Lectures, and Gray's Botanical Text Book.
French—Text books: Fasquelle's French Grammar; Beudant's Geologie; La bouchee de pain.
German—Text books: Wershoven's Technical Vocabulary; Stoeckhardt's Schule der Chemie; Bernoulli's Vademecum des Mechanikers; Stoehr's Katechismus der Bergbaukunde; Gurlt's Bergbau und Huettenkunde.
Drawing—Topographical drawing; tinting and grading; problems in graphics. Text book: Honey's Perspective.

SECOND SESSION.

Graphics—Shades and shadows, perspective and isometrical drawing. Text book: Church's Shades and Shadows.
Chemistry—Organic. Lectures, and "Fownes' Manual of Chemistry."
Quantitative Analysis—Lectures, and Cairn's Quantitative Analysis.
Crystallography—Lectures and illustrative diagrams.
Botany—Lectures, and Nicholson's Manual of Zoology.
Zoology—Lectures, and Gray's Botanical Text Book.
French—Text book: same as first session.
German—Text books: same as first session.
Drawing—Problems in graphics.
Summer Vacation.—Memoir.

FIRST SESSION.

THIRD YEAR—*Geology*—Lithological, cosmical, physiographic.
Surveying, with compass, sextant, hand level, and pacing, use of solar compass in land and mineral surveys, adjustments and use of transit and levelling instruments, triangulation and traversing.
Applied Chemistry—Air, water, fuel, artificial illumination.
Quantitative Analysis.
Stoichiometry.
Mineralogy—Determinative.
Metallurgy—General metallurgy, fuels, etc.
Physics—Mechanical theory of heat, electricity.
Drawing—Geological drawings.

SECOND SESSION.

Geology—Historical, including palæontology.
Surveying—Topographical work with plane table, magnetic survey.
Physics—Physical optics and the undulatory theory of light.
Applied Chemistry—Limes, mortars, and cements; building stones; decay and preservation; timber and its preservation: pigments, paints, essential oils, varnishes; glass and ceramics; explosives: gunpowder, guncotton, nitroglycerine, etc.
Quantitative Analysis.
Mineralogy—Determinative.
Metallurgy—Iron and steel.
Drawing—Geological drawings.
Summer Vacation.—Memoir.

WITHOUT DISTINCTION OF SESSIONS.

FOURTH YEAR—*Economic Geology*—Theory of mineral veins, ores, deposits and distribution of iron, copper, lead, gold, silver, mercury, and other metals; graphite, coal, lignite, peat, asphalt, petroleum, salt, clay, limestone, cements, building and ornamental stones, etc.
Surveying—Principles of Geodesy; Railroad surveying: reconnoissance, location of line, calculations of cuttings and embankments.

FIRST SESSION.

V.—COURSE IN ANALYTICAL AND APPLIED CHEMISTRY.—*Second Year.-Graphics*—Descriptive Geometry. Text books: Church's Descriptive Geometry.
Chemistry—The Metals. Lectures, and "Fownes' Manual of Chemistry."
Quantitative Analysis—Lectures, and "Cairn's Quantitative Analysis."
Stoichiometry.
Blowpipe Analysis—Qualitative. Text book: Plattner's Blowpipe Analysis.
Zoology—Lectures, and Nicholson's Manual of Zoology.
Botany—Lectures, and Gray's Botanical Text Book.
French—Text books: Fasquelle's French Grammar; Beudant's Geologie; La bouchee de pain.
German—Text books: Wershoven's Technical Vocabulary; Stoeckhardt's Schule der Chemie; Bernoulli's Vademecum des Mechanikers; Stoehr's Katechismus der Bergbaukunde: Gurlt's Bergbau und Huettenkunde.
Drawing—Topographical drawing; tinting and grading; problems in graphics. Text book: Honey's Perspective.
Metallurgy.—Copper, lead, silver, gold, zinc, tin, mercury, etc.
Drawing.—Dissertation and thesis work.
Supplementary lectures on iron and steel.

SECOND SESSION.

Graphics—Shades and shadows, perspective and isometrical drawing. Text book; Church's Shades and Shadows.
Chemistry—Organic. Lectures, and "Fownes' Manual of Chemistry."
Quantitative Analysis—Lectures, and "Cairn's Quantitative Analysis."
Crystallography—Lectures, and Egleston's Diagrams of Crystals.
Zoology—Lectures, and Nicholson's Manual of Zoology.
Botany—Lectures, and Gray's Botanical Text Book.
French—Text Books: same as first session.
German—Text books: same as first session.
Drawing—Problem in graphics.
Summer Vacation.—Memoir.

FIRST SESSION.

Third Year.—Applied Chemistry—Air, water, fuel, artificial illumination.
Quantitative Analysis.
Mineralogy—Determinative.
Geology—Lithological, cosmical, physiographic.
Metallurgy—General metallurgy, fuel, furnaces, etc.
Physics—Mechanical theory of heat, electricity.

SECOND SESSION.

Applied Chemistry—Limes, mortars, and cements; building stones; decay and preservation; timber and its preservation; pigments, paints, essential oils, varnishes; glass and ceramics; explosives; gunpowder, guncotton nitroglycerine, etc.
Mineralogy—Determinative.
Geology—Historical, including palæontology.
Metallurgy—Iron and steel.
Physics—Physical optics and the undulatory theory of light.
Quantitative Analysis.
Summer Vacation.—Memoir.

WITHOUT DISTINCTION OF SESSION.

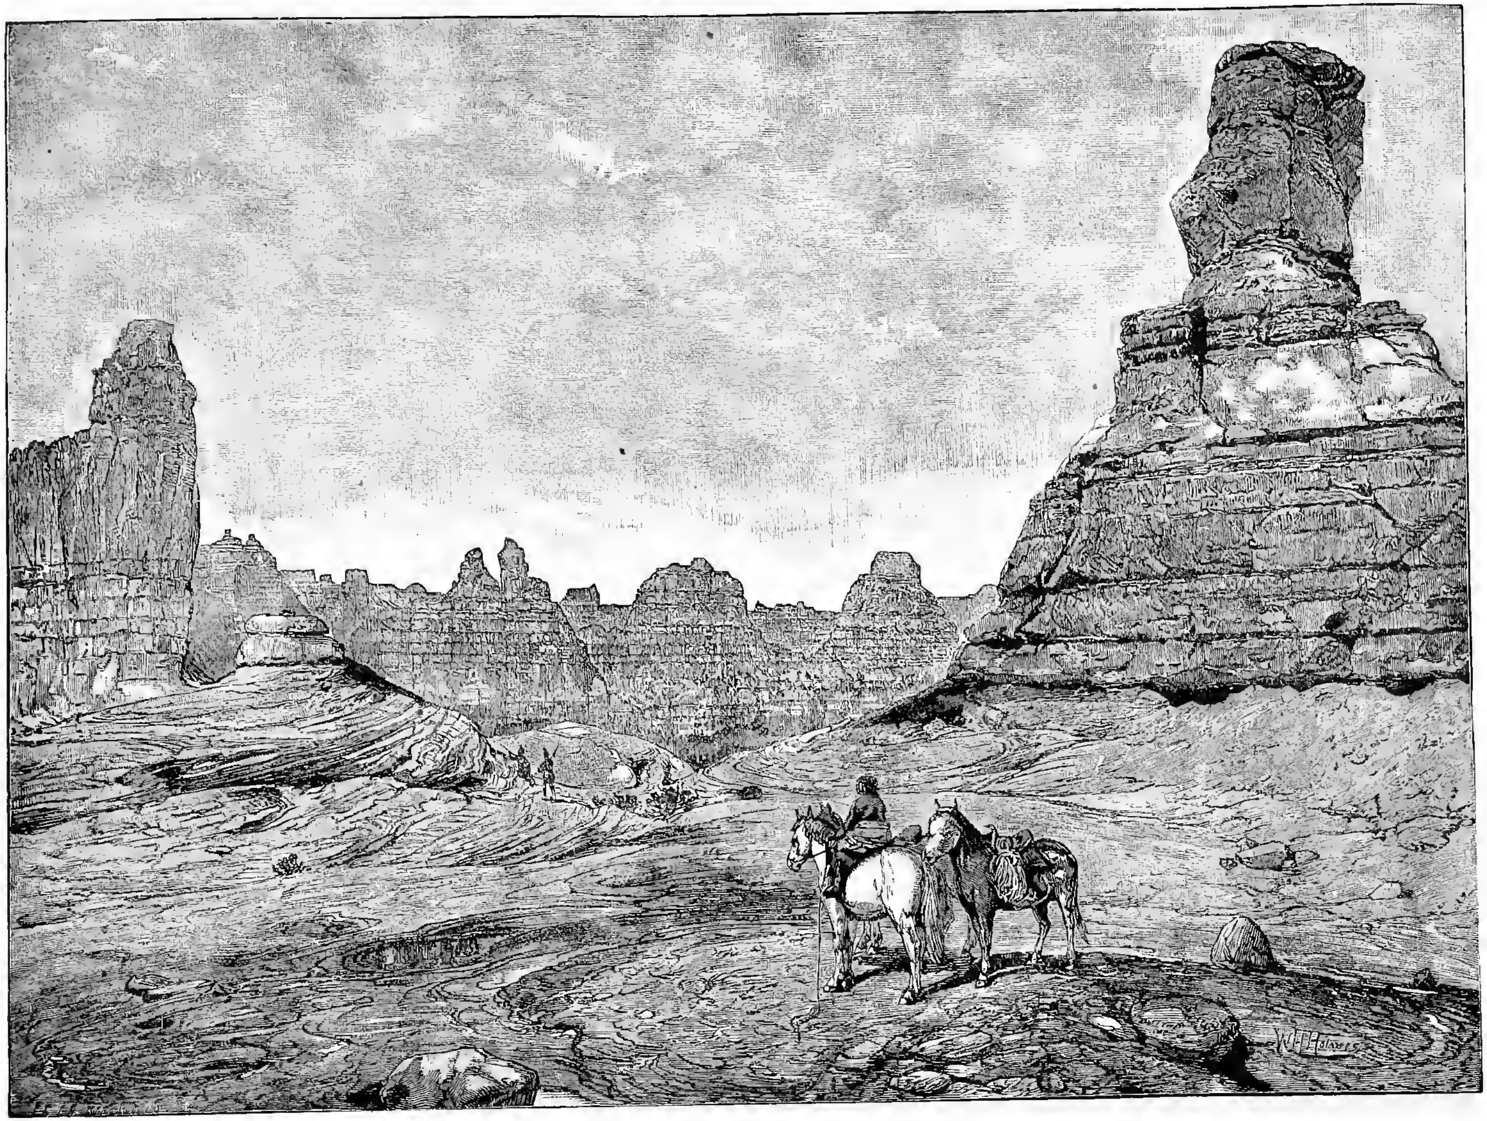
FOURTH YEAR.—*Applied Chemistry.*—I. Chemical manufactures; acid, alkalies and salts. (1) sulphur, sulphurous acid, hyposulphites, sulphuric acid, Bisulphide of carbon, etc. (2) Common salt, soda ash, hydrochloric acid, chlorine, binoxide of manganese, bleaching powder, chlorates, chlorimetry, etc. (3) Carbonate of potash, caustic potash, alkalimetry, acidimetry, etc. (4) Nitric acid and nitrates. (5) Iodine, bromine, etc. (6) Sodium, aluminium, magnesium. (7) Phosphorus, matches, etc. (8) Ammonia salts. (9) Cyanides. (10) Alum, copperas, blue vitriol, salts of magnesia, baryta, strontia, etc. (11) Borates, stannates, tungstates, chromates, etc. (12) Mercury salts, silver salts, photography. (13) Electro-metallurgy. (14) Oils, fats, soaps, glycerine. II. Food and drink: milk, cereals, starch, bread, meat, tea, coffee, sugar, fermentation, wine, beer, spirits, vinegar, preservation of food, tobacco, etc. III. Clothing: textile fabrics, bleaching, dyeing, calico printing, paper tanning, glue, India-rubber, gutta percha, etc. IV. Fertilizers: guano, superphosphates, poudrettes, etc.
Organic Chemistry.—Laboratory practice.
Assaying—Ores of lead, silver, gold, platinum, tin, antimony, bismuth, copper, nickel, cobalt, iron, mercury, and zinc; and gold, silver, and lead bullion, mattees, slags, etc.
Metallurgy—Copper, lead, silver, gold, zinc, tin, mercury, etc. Supplementary lectures on iron and steel.
Economic Geology—Theory of mineral veins, ores, deposits and distribution of iron, copper, lead, gold, silver, mercury, and other metals; graphite, coal, lignite, peat, asphalt, petroleum, salt, clay, limestone, cements, building and ornamental stones, etc.
Drawing—Dissertation and thesis work.

FIRST SESSION.

VI.—COURSE IN ARCHITECTURE.—*Second Year.—Analytical Geometry*—Text book; Peck's Analytical Geometry.
Graphics—Descriptive Geometry. Problems.
Chemistry—The Metals. Lectures, and "Fownes' Manual of Chemistry."
The Elements of Architecture—The forms and proportions of the five orders, and of balustrades, steps, doors, windows, arches, vaults, domes, roofs, spires, etc.
Greek Architectural History—Reber's History of Ancient Art.
French—Text books: Fasquelle's French Grammar; Beudant's Geologie; La bouchee de pain.
German—Text books: Wershoven's Technical Vocabulary; Stoeckhardt's Schule der Chemie; Bernoulli's Vademecum des Mechanikers; Stoehr's Katechismus der Bergbaukunde; Gurlt's Bergbau und Huettenkunde.
Drawing—Tracing; ornament; plans, sections, and elevations. Text book: Honey's Perspective.

SECOND SESSION.

Differential and Integral Calculus—Text book: Peck's Practical Calculus.
Graphics—Shades and shadows; perspective, isometrical drawing. Problems.



WESTERN SCENERY—LAND OF THE STANDING ROCKS—GRAND CAÑON. DISTRICT.

—FROM U. S. GEOLOGICAL SURVEY REPORT.

SEE PART X.

Stone Cutting.
The Elements of Architecture, continued.
Roman Architectural History.
French—Text books, same as first session.
German—Text books: same as first session.
Drawing—Ornaments from casts; details; perspective drawings. Text books: Honey's Perspective.

FIRST SESSION.

THIRD YEAR—*Summer Vacation*—Memoir.
Mechanics of Solids—Including forces, moments, equilibrium, stability etc., and elementary machines.
Engineering.—General principles relating to materials and structures, physically and mechanically considered.

1. *Materials*—Stone, cements, brick, metals, timber, treated in regard to strength, durability, mode of preparation, defects, tests of quality, and fitness for special uses.
2. *Structures*—Foundations and supports, superstructure, joints, stability, strength, and stiffness of parts; special rules of construction for masonry of public buildings, bridges, retaining walls, arches, railroads, common roads, and canals.
3. *Theory of Strains and Strength of Materials*—Elasticity, mechanical laws, application of principles of mechanics to beams, girders, and roof trusses under various conditions of loading and supports.

Applied Chemistry—Air, water, fuel, artificial illumination.
Geology—Descriptive.
* *Mediæval Architectural History.*
* *The History of Ornament*—Lectures and exercises.
* *The Decorative Arts*—Terra cotta, faience, stained glass, enamels, mosaic, fresco, distemper. Lectures and sketching. Excursions.
* *Specifications and Working Drawings*—Excavation, foundations, piling, stone work, brick work, plastering, and stucco work. Lectures and laboratory work. Excursions.
Architectural Design—Design by dictation. Problems.
Modelling.
Drawing from the Cast—Ornament and the human figure.

SECOND SESSION.

Mechanics of Solids—Dynamics, including uniform, varied, rectilineal and curvilinear motion, rotation, vibration, impact, work done, etc.
Engineering—Theory of Strains and Strength of Materials continued—Graphical methods of determining strains, deflection of beams and girders; quantity of material in braced girders under various conditions of loading and supports; angle of economy for bracing; torsion of shafts; crushing and tensile strength of materials; working strains and working load; mode of estimating cost of girder work.
Applied Chemistry—Limes, mortars and cements; building stones; decay and preservation; timber and its preservation; pigments, paints, oils, and varnishes; glass and ceramics; explosives; gunpowder, guncotton, nitro-glycerine, etc.
Geology.—Historical.
**Mediæval Architectural History.*
**The History of Ornament*—Lectures and blackboard exercises.
**The Decorative Arts*—Embroidery, weaving, jewelry, metal work, inlays. Lectures and sketching. Excursions.
* *Specification and Working Drawings*—Carpentry, painting, glazing, plumbing, iron, lead, and copper work; tinning and slating. Lectures and laboratory Work. Excursions.
Architectural Design—Alterations and Restorations—Problems.
Drawing—Water colors.
Summer Vacation—Memoir.

WITHOUT DISTINCTION OF SESSIONS.

FOURTH YEAR.—*Sanitary Engineering.*
Sewerage.
Economic Geology—Clay, limestone, cements, building and ornamental stones.
Graphical Statics.
Book-Keeping—Time books, contracts, pay rolls, analysis of accounts, and cost sheets.
**Business Relations* between architects, clients, mechanics, and draughtsmen: office papers; competitions; legal obligations; superintendence.
**Estimates*—Quantity, weight, time, labor, cost; squaring.
**Modern Architectural History.*
**The History of Painting and Sculpture.*
**The Theory of Architecture*—the theory of form, the theory of color, the theory of composition.
Literature and Criticism—Themes, Reports. Abstracts of book.
Architectural Design—Problems.

DEPARTMENTS OF INSTRUCTION.—*Modern Languages.*—The design in this department is to teach the students to read French and German scientific books with facility. Instruction is given for three hours a week in each of these languages during the first year and two hours a week during the second year. As the text-books employed in the class-room are altogether works on science, the students can acquire a sufficient vocabulary to enable them to use French and German authors in all the departments of the school. No attempt is made to produce accomplished scholars in all branches of German and French literature, but attention is concentrated upon the immediate wants of the young men. In this way no time is lost, and the instruction is made thoroughly practical.

Mathematics.—The students of the First Class attend four hours per week throughout the year. In the first session, they complete the subject of Geometry, plane, volumetric, and spherical; the parabola, ellipse, and hyperbola, geometrically treated; and Algebra, including the general principles and properties of logarithms and the logarithmic series, the general theory of equations, embracing the principal transformations and properties, derived equations and equal roots, Sturm's theorem and the solution of higher equations. In the second session they are taught Trigonometry, plane, analytical, and spherical, with the solution of many practical problems by formulæ and by construction; and the Mensuration of surfaces and of volumes. The students of the Second Class attend four hours per week throughout the year. In the first session, they complete the subject of Analytical Geometry, with applications to lines and surfaces of the second order; and in the second, the Differential and Integral Calculus, with some of its applications to mechanics and astronomy, as centre of gravity, moment of inertia, falling bodies, attraction of homogeneous spheres, orbital motion, law of force, etc.

Mechanics.—This subject is taught during the third year. The course of instruction embraces the following subjects: Representation and measurement of forces: Composition, resolution, and equilibrium of forces; principles of moments and virtual moments; theory of parallel forces; application to centre of gravity; stability. Elementary machines: friction, resistance to rolling, stiffness of cords, atmospheric resistance, General equations of motion: rectilineal, uniform, and uniformly varied motion; curvilinear motion, free and constrained; centrifugal force; application of the Governor; vibratory motion; application to the pendulum; motions of translation and rotation; moment of inertia, principal axes, and ellipsoid of inertia; laws of impact; centre of percussion; general theorem of work; accumulation of work; application to fly-wheel. Mechanics of fluids: pressure due to weight; equal transmission of pressures; application to hydraulic press; buoyancy and flotation; application to specific gravity. Tension and elasticity of gases and vapors: laws of variation; application to pumps and siphons; investigation of the barometer formula; motion of liquids in pipes and open channels; living force of fluids; application to hydraulic ram; mechanics of capillarity.

Practical Astronomy and Geodesy.—Students of the Third and Fourth Classes in the course of Civil Engineering are required to attend the course of Practical Astronomy and Geodesy. This course includes the theory and use of the transit and sextant, and the determination of geographical position; also the theory and use of geodetic instruments.

Physics.—The students of the First Class are occupied during the first term with the subject of heat including the steam engine, and with acoustics; during the second term, in the study of optics, voltaic electricity, magnetism, and electro-magnetism. The courses are fully illustrated by appropriate experiments, and practical problems are occasionally proposed for solution. To the students of the Third Class, courses of lectures are delivered on the laws of electro-statics, on the mechanical theory of heat, on mathematical optics, and on the undulatory theory of light. Portions of these courses are accompanied by experimental demonstrations. The cabinet of physical apparatus will rank with the best on this continent, and extensive additions are made to it each year.

Chemistry.—I. GENERAL CHEMISTRY.—The First Class attends three exercises a week in the general chemistry of the non-metallic elements throughout the year. It is intended to lay the foundation of a thorough knowledge of the theory of the subject preliminary to the practical in-

* For convenience these subjects are given in alternate years, the third and fourth year students taking them together.

struction in the chemical laboratory. For this purpose the students are drilled upon the lectures, with free use of a text-book. They are expected to write out full notes. At the end of the year, they must pass a rigid examination before being admitted to a higher grade. The Second Class also attends three times a week during the year, and receives instruction in theoretical chemistry adapted to the wants of special scientific students. In the first session, the chemistry of the metals; in the second session, organic chemistry.

II. ANALYTICAL CHEMISTRY.—There is a laboratory devoted to qualitative analysis, another to quantitative analysis, and an assay laboratory. These laboratories are provided with all the necessary apparatus and fixtures, and each is under the special charge of a competent instructor with an assistant. Each student is provided with a convenient table, with drawers and cupboards, and is supplied with a complete outfit of apparatus and chemical reagents. During the first year, qualitative analysis is taught by lectures and blackboard exercises, and the student is required to repeat all the experiments at his table in the laboratory. Having acquired a thorough experimental knowledge of the reactions of a group of bases or acids, single members of the group or mixtures are submitted to him for identification. He thus proceeds from simple to complex cases till he is able to determine the composition of the most difficult mixtures. When the student shows, on written and experimental examination, that he is sufficiently familiar with qualitative analysis, he is allowed to enter the quantitative laboratory. During the second and third years, quantitative analysis is taught by lectures, and the student is required to execute in the laboratory in a satisfactory manner a certain number of analyses. He first analyzes substances of known composition, such as crystallized salts, that the accuracy of his work may be tested by a comparison of his results with the true percentages. These analyses are repeated till he has acquired sufficient skill to insure accurate results. He is then required to make analyses of more complex substances, such as coals, limestones, ores of copper, iron, zinc and nickel, pig iron, slags, technical products, etc.—cases in which the accuracy of the work is determined by duplicating the analyses and by comparing the results of different analyses. Volumetric methods are employed whenever they are more accurate or more expeditious than the gravimetric methods. In this way each student acquires practical experience in the chemical analysis of the ores and products which he is most likely to meet in practice.

III. ORGANIC CHEMISTRY.—Organic chemistry is taught by lectures in the second session of the second year. During the fourth year the students in the course of Analytical and Applied Chemistry devote their time in the laboratory to organic chemistry.

IV. STOICHIOMETRY.—Stoichiometry, the arithmetic of chemistry, is taught by lectures and blackboard exercises as a part of the course of instruction in general chemistry in the first and second years; and its practical applications are developed in lectures on quantitative analysis and assaying.

V. ASSAYING.—During the fourth year, the student is admitted to the assay laboratory, where he is provided with a suitable table and a set of assay apparatus, and where he has access to crucible and muffle furnaces, and to volumetric apparatus for the assay of alloys of gold and silver. The general principles as well as the special methods of assaying are explained in the lecture room, and at the same time the ores of the various metals and their appropriate fluxes are exhibited and described. The student is then supplied with the different ores, and is required to assay each one in duplicate under the immediate supervision of the instructor. To facilitate the assay of ores of the precious metals a system of weights has been introduced by which the weight of the silver or gold globule obtained shows at once, without calculation, the number of troy ounces in a ton of ore. Students are also given an opportunity of testing the milling qualities of gold and silver ores, and are required to give special attention to sampling and the mechanical assaying of the ores of the precious metals.

VI. APPLIED CHEMISTRY.—The instruction in applied chemistry extends through the third and fourth years, and consists of lectures illustrated by experiments, diagrams, and specimens.

The subjects discussed are:

IN THE THIRD YEAR.

(*For all Students.*)

I. Air; nature, sources of contamination, sewer gas, plumbing, drainage, disinfection, ventilation.
II. Water; composition of natural waters, pollution, disposal of sewage and house refuse.
III. Fuel and its applications.
IV. Artificial illumination: candles, oils and lamps, petroleum, gas and its products, electric light.
V. Limes, mortars, and cements.
VI. Building stones: decay and preservation.
VII. Timber and its preservation: pigments, paints, essential oils, varnishes.
VIII. Glass and ceramics.
IX. Explosives, gunpowder, guncotton, nitroglycerine, etc.

IN THE FOURTH YEAR.

(*For students in the course of Analytical and Applied Chemistry*).

I. Chemical manufactures: acids, alkalies, and salts.
(1) Sulphur, sulphurous acid, hyposulphites, sulphuric acid, bisulphide of carbon, etc.
(2.) Common salt, soda ash, hydrochloric acid, chlorine, binoxide of manganese, bleaching powder, chlorates, chlorimetry, etc.
(3.) Carbonate of potash, caustic potash, alkalimetry, acidimetry, etc.
(4.) Nitric acid and nitrates.
(5.) Iodine, bromine, etc.
(6.) Sodium, aluminium, magnesium.
(7.) Phosphorus, matches, etc.
(8.) Ammonia salts.
(9.) Cyanides.
(10.) Alum, copperas, blue vitriol, salts of magnesia, baryta, strontia, etc.
(11.) Borates, stannates, tungstates, chromates.
(12.) Mercury salts, silver salts, photography.
(13.) Electro-metallurgy.
(14.) Oils, fats, soaps, glycerine.
II. Food and drink: milk, cereals, starch, bread, meat, tea, coffee, sugar, fermentation, wine, beer, spirits, vinegar, preservation of food, tobacco, etc.
III. Clothing: textile fabrics, bleaching dyeing, calico printing, paper, tanning, glue, India-rubber, gutta percha, etc.
IV. Fertilizers: guano, superphosphates, poudrettes, etc.

Geology and Palæontology.—The course of instruction in this department is as follows:

SECOND YEAR.

Botany and Zoology, as an introduction to Palæontology—lectures throughout the year.

THIRD YEAR.

Lithology: Minerals which form rocks and rock masses of the different classes—lectures and practical exercises.

Geology: Cosmical, physiography, and historical—lectures and conferences throughout the year.

FOURTH YEAR.

Economic Geology: Theory of mineral veins; ores; deposits and distribution of iron, copper, lead, gold, silver, mercury, and other metals; graphite, coal, lignite, peat, asphalt, petroleum, salt, clay, limestone, cements, building and ornamental stones, etc.

MINERALOGY AND METALLURGY.

1. *Mineralogy.*—The studies in mineralogy continue through two years. During the first year the students are instructed in the use of the blowpipe, in crystallography, and in theoretical mineralogy.

The instruction in blowpipe is entirely practical, and lasts through the first half of the year. It consists in instruction how to use the different flames, and in teaching the students how to examine mixtures, alloys, and natural compounds, so that they are able to determine with ease the constituents of a mixture containing a large number of simple substances. In order to do this, substances whose composition they know are given to them, upon which they are required to perform all the characteristic reactions which take place in the different flames with different fluxes. After they are sufficiently familiar with the behaviour of substances the composition of which they know, they are given substances, the composition of which they do not know, to determine. The collection of blowpipe substances consists of four hundred alloys, mixtures, and minerals. Students are taught to examine qualitatively all the different commercial alloys and a large number of the natural combinations which exist in minerals. The blowpipe laboratory is a large, well-ventilated room, to which the students have access at all hours of the day, where each student has a drawer with a lock assigned to him, which he retains until the close of the term.

At the commencement of the second term the lectures on crystallography commence. They embrace the entire subject of crystallography, including the descriptions of both normal and distorted forms, for the study of which the students have access to a collection of over 300 models in wood, embracing all the theoretical forms. Besides this collection they have the use of the collection of 150 models in glass, and have access to the collection of minerals, most of the species of which are illustrated by models in wood, showing the perfect and distorted crystallographic forms. Conferences are held during the term, in which the students are required to determine models of the theoretical forms as well as those found in minerals. They are also taught theoretical mineralogy, including the optical and physical properties of minerals, which lectures are illustrated by the very complete set of apparatus, presented by F. A. Schermerhorn, and a cabinet containing a large number of sections of minerals for lantern and instrumental use. For the study of sections the students are taught the use of Groth's and Soleil's Polariscopes, and of Goniometers. At the commencement of the third year the students begin the study of practical mineralogy. They are required to determine minerals by the eye, or by asking questions with regard to those characteristics which cannot be determined without experiment. They are required to give the name, the composition, the crystalline form, and the prominent blowpipe chemical and physical characteristics of the mineral they determine. To facilitate this work they have unrestricted access to a collection of about 3,000 carefully labeled specimens, on which they are allowed to make any experiments. They have, besides, constant access to the cabinet of minerals, which contains about 30,000 specimens, arranged in table cases to show the different characteristics of minerals, and about three thousand specimens, arranged in wall cases to show their association. The crystals of minerals are arranged upon pedestals in such a way that they can be readily seen and examined by the students. At the commencement of the second term of the third year they are required to determine the minerals without asking questions, by making the chemical and blowpipe tests on specimens given to them for the purpose. Most of the instruments in this department were presented to the School by D. Willis James, C. R. Agnew, and the late Gouverneur Kemble. The collection of minerals was founded by a valuable collection presented as the first donation to the School before it was opened in 1864, by the late George T. Strong, of this city. It was shortly afterwards supplemented by another collection, presented by the late Gouverneur Kemble, containing many autographs and specimens from the cabinet of Hauy. As these collections were both very rich in duplicates, very many valuable additions have been made to the cabinet by exchange. Collections were also made in Europe during several years by the Professor in charge, having the necessities of the collection of the school in view, and were presented to the school through the generosity of Morris K. Jessup, Wm. E. Dodge, Jr., D. S. Egleston, C. Lanier, and J. Crearer, of this city; and the late John H. Caswell, Wm. H. Aspinwall, and R. P. Parrot.

II. Metallurgy.—The lectures in metallurgy continue through two years, and discuss in detail the methods in use in the best establishments in this country and in Europe for working ores. They embrace, in general metallurgy, the subjects of combustion, fire-clays, furnaces, natural fuels—wood, peat, lignite, bituminous and anthracite coals—artificial fuels, charcoal, peat charcoal, and combustible gases manufactured in generators, chimneys, the different kinds of blast engines, regulators, hot-blast ovens, and tuyeres. The metallurgy of iron consists in discussion of the general properties of iron and its ores; theory of the blast furnace process—the causes of variation in the charge produced in the furnace by the blast, by the fuels, by the variations in the charge, and by the form of the furnace; the effects of moisture; the methods of ascertaining the cost; the calculations of the heat developed and lost in the furnace; moulding; melting the iron in crucibles, in cupolas, in reverberatory furnaces; methods of making the moulds; precautions required in casting; and the manufacture of malleable cast iron. In the manufacture of wrought from cast iron, the German process and its modifications are discussed; the English processes, including fining; the dry and boiling process in puddling; stationary and rotary furnaces; shears; hammers; squeezers; saws; rolls; reheating in ordinary and regenerator furnaces; two and three high trains; method of caculating cost of wrought iron. In the manufacture of iron from the ore, the Catalan processes and its derivatives are discussed; in the metallurgy of steel, low furnace processes, puddled steel, cement steel, Bessemer steel, Siemens-Martin steel, crucible steel, the utilization of scrap-iron, manufacture of sheet iron, nails, wire, and rails. The lectures on the metals include the treatment of native copper; the treatment of pure sulphurous ores by the Swedish, German, and mixed methods in Europe and the United States; the treatment of rich pure ores; the treatment of impure ores in the Hartz mountains and in the United States; the treatment of very poor ores by lixiviation; the treatment of rich and pure ores by the English method in the reverberatory furnace in the United States and Europe, and the treatment of impure ores in the same furnace; method of making calculations for works treating a definite number of tons; mixed method treatment in Europe and in the United States; treatment of oxides of copper, wet methods; treatment of ores of lead, roasting and reaction in France, England, and the United States; method of roasting and reduction; method by precipitation in France, Germany, and the West; mixed method in France, Germany, and the West; refining of lead, extraction of silver by the Pattinson method and by zinc; cupellation; condensation of volatile products; treatment of silver ores in furnaces, in Germany and in the United States; separating of silver by amalgamation, Saxon method, Mexican method, pan amalgamation, treatment in the wet way; Augustin's methods, Ziervogel's methods, Von Patera's method; refining silver; treatment of gold ores, washing, sluicing, hydraulic mining, Plattner's process, parting gold and silver; treatment of tin, in shaft furnaces and in reverberatory furnaces; treatment of ores of zinc, Silesian method, Belgian method, English method, wet method; treatment of ores of mercury, method by precipitation, by roasting, in Europe and in California, by the wet way; treatment of ores of antimony; treatment of nickel and cobalt; treatment of ores of bismuth.

It is designed to make these lectures as practical as possible, and for this purpose the economic details of cost are given whenever they can be obtained from authentic sources. Special details are given of the ores of this country which are difficult to treat, to the solution of practical problems which may occur, and to changes which different economic relations are liable to cause in the treatment of the same ore in different localities. Nearly a thousand lecture diagrams and the same number of photographic illustrations for use in the lantern have been prepared to illustrate the furnaces, machines, and appliances used in the different metallurgical works, as well as to illustrate the construction of furnaces, etc. To the Fourth or graduating Class is given a course of twelve supplementary lectures on the metallurgy of Iron and Steel, embracing: (1) Steam engines, boilers and apparatus as adapted to iron manufacture; hydraulic mchinery; lifting and transporting apparatus. (2) Heating and melting furnaces; the gas furnace. (3) Direct processes; the crucible steel processes; refractory materials. (4) Puddling, especially mechanical puddling and refining by oxide of iron. (5) The Bessemer plant and manufacture. (6) Open-hearth plant and manufacture. (7) Casting apparatus; the manufacture of castings in steel and iron. (8 and 9) Rolling mill; roll turning. (10) Forging machinery and rolling mill finishing machinery. (11) General arrangement of iron and steel works. (12) Temper and treatment of steel. The collection illustrating the department of metallurgy includes models of furnaces and a very large collection of drawings and tracings, in most cases copies from the working drawings of establishments in actual operation. This collection embraces several hundred tracings collected from the best types of works in this country and abroad, many of them being sufficiently detailed to be used as construction drawings. The metallurgical collection, properly speaking, embraces about 3,000 specimens, illustrating every stage of all the prominent metallurgical processes. Many of these specimens have been analyzed and assayed. They are constantly open to the inspection of the students. As an application of the lectures the students are required to work out a project, and to present working drawings and estimates for the erection of works to treat a giveu ore under stated conditions. The problems given are those which require solution in some parts of the United States.

ENGINEERING.—Engineering, in its widest sense, involves applications of the sciences of physics, mechanics, and chemistry to a great variety of problems met with in works and enterprises of a public and private nature or of an industrial character, in which the employment of materials, the building of structures, the use of machinery, the utilization of natural resources, or the protection or improvement of the ways of commerce, are essential and important elements and conditions. The educated engineer, whatever may be the branch of the profession to which he devotes himself, should, therefore, have a thorough foundation of knowledge in certain subjects of common application; for example, free-hand and instrumental drawing; mathematics, physics, and mechanics, and the application of these sciences to the resistance of materials to machinery, to structures of iron and wood and masonry; the flow of streams in artificial channels required for water-works, drainage, and for sanitary purposes; the theory of heat, as applicable to air and steam in their various uses in ventilation, etc.

The courses in mining engineering and civil engineering are, therefore, identical in all that pertains to these subjects. It is essential, however, that in each of these branches of engineering the subjects technically appertaining to each should receive as great a share of the attention of the students, in the courses in mining and civil engineering respectively, as possible in the short period devoted to collegiate instruction. The mining engineer encounters in his practice questions which are rarely met with in civil engineering, for example, the results of experience in the searching for, winning, and exploitation of mineral deposits, special problems of ventilation, and drainage; while, on the other hand, he is seldom or never called upon to discuss questions which are common and important in the practice of civil engineering, such as the supply of water to towns and cities, and other sanitary works, on a large scale, the erection of extensive public buildings, the improvement of harbors and rivers, works of irrigation, the building of extended bridges, etc. The arrangement of the two courses in engineering has been made under the above view of the subject, utilizing, as it does, in the best manner, the time of the instructors, and avoiding a repetition of the same instruction to different classes. The collateral branches of study for the engineering courses, chemistry, metallurgy, geology, subjects quite as essential to mining and civil engineers as physics and mechanics, have also been assigned to these two courses, in accordance with the general requirements of the respective professions.

I. DRAWING, DESCRIPTIVE GEOMETRY, ETC. — The course in drawing embraces instrumental drawing, descriptive geometry, shades, shadows and perspective, stone cutting, isometric drawing, topographical and geological drawing, drawings of engineering constructions and machinery. The first year is devoted to the elements of instrumental drawing, the use of instruments, lettering, projections of objects, plans, sections, and elevations, intersection of solids and of surfaces, and the development of surfaces. During the vacation which follows, the execution of sketches from nature and from engineering and architectural constructions is required. During the second year, the first session is occupied in the study of descriptive geometry, in grading and tinting as well as in topographical drawing. The instruction in these subjects requires all the problems and illustrations to be carefully and neatly executed on the drawing board, and the principles of construction explained by the student in oral examinations. During the second session, the subjects of shades and shadows, perspective and isometrical drawing and stone cutting, are taken up in the same manner. Practice is also given in drawing the simple elements of architecture, such as the plans of private and public buildings, showing the details of walls, floors, windows, and door casings, etc. During the vacation which follows, definite architectural plans are required. The drawing of the third year includes elements of machine construction, the drawing of maps from field work executed by the students themselves, parts of engines, geological drawings, etc. During the vacation which follows, the necessary drawings for memoirs and theses are made. The drawing of the fourth year is limited to working drawings of machines and engineering constructions, drawings illustrating the principles of mechanism, and the execution of plane table maps with contour lines, etc. The whole course of drawing is progressive, and embraces nearly 100 sheets, each succeeding sheet being illustrative of a principle of construction or an advance towards more difficult methods or combinations; and it is designed to qualify students for the execution of all kinds of drawing and the most difficult constructions.

II. CIVIL ENGINEERING.—Instruction in civil engineering extends through the third and fourth years. During the third year, the more simple elements of civil engineering and surveying are taught. In civil engineering the various subjects are considered in the following order: First, Materials —building-stones, limes, cements, mortar, concrete, brick, wood, metals; their properties and general qualities, mode of preparation, and their respective uses, and combinations in constructions, their strength and durability. Second, Masonry—construction of masonry, retaining walls, arches, etc. Third, Framing—structures of wood, carpentry. Fourth, Stone and Wooden Bridges—descriptions of various kinds of wood and iron trusses in use, suspension bridges, etc., general principles of roof constructions. Fifth, Common Road Construction—general principle of railway construction; construction of canals, general principles of rivers, slack water navigation, etc. The instruction in surveying embraces a series of lectures on the principles of the subject and the use and description of instruments, and the following order of field work, viz.

1. At the beginning of the third year, the students are divided into small squads of 3 to 6 each, each squad being provided with an instrument. The field work begins with instruction in general methods of ascertaining distances and dimensions without instruments, by pacing and by employing the height of the body, the length of the arm, etc., for obtaining rough measurements when instruments are not available.

2. The use of the compass for topographical surveys and for ascertaining areas; the use of the hand-level for contouring or for determining differences of levels, use of sextant, measurements with chain and tape, in making compass surveys, a map of each survey being made by each student.

3. Use of solar compass for U. S. land and mineral surveys.

4. Use of transit; measurement of angles, closed survey by traversing; calculation of coördinates; city surveying.

5. Use of surveyor's level; running line of level, trigonometrical levelling, by measurements of vertical angles.

Spring work—four or five weeks.

1. Use of plane table for a topographical survey of a portion of Central Park.

2. Magnetic survey with solar compass and dipping needle, with determination of curves of equal deviation and intensity.

Instruction in Practical Astronomy and Geodesy during the third year embraces:

1. A course of general lectures on Astronomy, fully illustrated by lantern views.

2. Lectures on Geodesy; general outlines of Geodesy; description and illustration of the different kinds of triangulation, primary, secondary, and tertiary; description of the United States Coast Survey primary base apparatus; description of the United States Coast Survey secondary base apparatus; measurement of subsidiary base lines; reconnoissance surveys; stations and signals; observing tripods and scaffolds; station marks, underground and surface; observation of angles; instruments, direction and repeating; application of Legendre's Theorem to the solution of spheroidal triangles; records and computations; latitude, longtitude, azimuth, and time observations and computations.

3. Practical use, in the observatory, of the transit instrument for time and zenith telescope, for latitude, and, in the

field, use of the sextant and reflecting circle for time, latitude, and longitude approximations. During six weeks of the summer vacation, at the close of the third year, the students in Civil Engineering are required to make a geodetic survey of some region. In the summer of 1882 a survey was made of Otsego Lake, N. Y., at the request of the Director of the New York State Survey. The results of this survey are to be used by the State Board in constructing a map of that region.

During the fourth year a line of railroad is surveyed, locating the line on the ground, setting grade and slope stakes, levelling, and calculation of cuttings and embankments, drawings, and estimates. In addition, the course in railroad engineering embraces a series of practical lectures on permanent way, rolling stock, motive power, and administration of railroads, with instruction in the economics of location and transportation. The course in civil engineering in the fourth year embraces the principles of mechanics applied to engineering constructions and to machinery, the strength of materials, the theory of retaining walls and arches, and the methods of determining the dimensions of the parts of iron roof and bridge trusses, by means of the stresses to which they are subjected, the theory of such structures and the details of practical construction; the principles of hydraulics applied to the improvements of rivers, the water supply of towns, reservoirs, dams, etc., and the general principles of sanitary engineering, drainage, sewers, house drainage and ventilation. The students in the civil engineering course are also instructed in the principles of mechanisms beginning with the general theory of motion; the principles of transmission of motion, the various modes of mechanical connection, the calculation of relative velocities of moving pieces of machinery, valve gearing, and the mechanism, movements, and construction of machinery in practice; the dynamics of machinery or the determination of the relations between the forces which act upon machines, and the general application of mechanics to machines; the study of prime movers, including steam-engines, hot-air engines, and water-wheels; the theory and construction of steam boilers, and the general principles of heat, as applied to air and vapors. Instructions in Geodesy continued, by lectures and use of instruments—spirit levelling—trigonometric levelling—magnetic determinations—figure of the earth.

III. Mining Engineering.—The course in mining engineering is the same as that in civil engineering, in drawing and surveying, except that the students of mining will have additional instruction in underground surveying and geological reconnoissance. The courses in mining and civil engineering are also identical during the third year in all that relates to materials and general principles of engineering constructions, excepting that the course in mining engineering is intended to be more extended in the principles of mechanism and construction of machinery, and less extended in the detailed principles of roof and bridge construction, hydraulics as applied to river improvements, sanitary engineering, water supply of towns, etc. During the third and fourth years, the course in mining engineering embraces lectures on practical mining, or miners' work, including excavation of clays, peat, bog iron ore, and other easily worked materials; quarrying for extraction of large blocks of stone, marble, etc.; blasting, drilling tools, hand boring, use of explosives; well-boring, by hand for exploration, and machine-boring, sinking of shafts and slopes, timbering and driving of adits and levels, in the use of picks and gads in the mining of coal, salt, fire-clay, and other soft rocks, coal-cutting machines, mining of ores and hard rocks; handling of excavated mineral in working places; underground transportation, tramming by man or animal power, mechanical haulage with chains or wire rope, and by underground locomotives; accidents to men, their cause and prevention; organization and administration; mine book-keeping, accounts with men, time books, pay roll, analysis and dissection of mine accounts and making out of cost sheets. The instruction in mining engineering during the fourth year is the same as for the civil engineers in all that relates to the general dynamics of machinery, and to the application of the principles of mechanics to engineering constructions. It is more extended in the application of machinery to mining purposes, especially in connection with the use of compressed air, pumping and ventilating machinery, and hoisting machinery.

It embraces also the study of mineral deposits, classification and description of veins, beds, and masses, and their geological characteristics, interruptions and intersections, methods of prospecting, of reaching deposits, of prosecuting the underground workings; and methods of making and supporting excavations made for special purposes, junctions of levels, chambers for machines, and of making and supporting excavations in watery strata; proper provisions for pumping and ventilation; general principles to be observed in laying out, opening and working mines, and methods applicable to special deposits, such as narrow and wide veins or lodes, thick and thin seams of coal; hydraulic mining, etc.; also instructions in the proper administration of mining works, exterior transportation, mine regulations, etc. A course of lectures on ore dressing includes the general principles of ore dressing, preliminary hand dressing, and sorting and preliminary cleansing and sizing; crushing by hand and with machinery; cleansing in ditches and troughs, in sieves, trommels, and by special machines; sizing, bar gratings, and other stationary screens, riddles, revolving screens; concentration of coarse and fine material by jigs, buddles, tables, etc.; illustrations from American and foreign practices; mechanical preparation of coal and other minerals, and the concentration and purification of copper, lead, iron, and other ores. A course of lectures on the machinery of the plant for the manufacture of iron and steel includes the engineering of blast engines and hoists, and all the hydraulic machinery of the steel works, overhead-cranes, etc.

Architecture.—During the second year the time which is given in the other courses to laboratory work is in this course given to architectural drawing. This is so laid out as to include exercises in the ordinary processes of draughtsmanship, the making of plans, elevations, sections, and details, both on a large and on a small scale; using pencils and pens, brushes, and colors, with auxiliary exercises in tracing and sketching. The examples are so chosen as to make the student familiar with the common-places of architectural form, and are accompanied by lectures upon the Elements of Architecture, in which the forms and proportions of the Greek and Roman Orders, of doors and windows, arches, staircases and balustrades, domes and vaults, roofs and spires, are set forth, and the best ways of drawing them explained. At the same time a series of illustrated lectures is given upon Egyptian, Assyrian, Greek, and Roman Architectural History. During this year the students of architecture complete their elementary studies in Mathematics and Chemistry, French, and German, following at the same time the work in Descriptive Geometry, Stone Cutting, and Shades, Shadows, and Perspective, given in the Department of Engineering, and a portion of the work in Geology. In the third and fourth years the study of scientific construction is pursued in connection with the classes of Engineering, most of the time, however, being given to strictly professional work. This is for the most part pursued by the two classes in common, one class taking up in their fourth year what the next class takes in the third, and *vice versa*, the whole thus forming a single two years' course. These studies are arranged under four heads:

I. Under the head of History, the architecture of the Middle Ages is taken up in one year, and that of the Renaissance, and its more modern derivatives, in the next. On completing the study of ancient architecture, then, in the second year, one class goes on directly to that of the Middle Ages in the third year, and to that of the Renaissance in the fourth. The next class passes at once from ancient classical architecture to modern, finishing with the Mediæval styles.

II. Under the general head of Ornament, etc., is comprised the study of the decorative details of the different architectural styles, and of the contemporary forms in other branches of art, especially the decorative arts employed in building. The materials and processes employed in these arts, and the theory of æsthetics, in form and color, come under this head.

III. Under the head of Architecural Practice comes the study of specifications and working drawings, so far as they can be profitably studied in such a school, and of the materials and processes employed in building operations. The buildings erected in the neighborhood will here serve as examples, and a special architectural laboratory will afford opportunity for the study of oils and paints, cements, mortars, etc., and for testing their quality. Experiments upon the strength of materials will be made at the same time by classes in Civil Engineering.

IV. Under the head of Drawing and Design is comprised the practice of original composition in the working out of problems, in design, from given data, as well as further exercises in draughtsmanship, both free hand and with the pencil, pen, or brush, illustrating the study of the special topics enumerated above. The laboratory will be provided with facilities for modelling in clay or wax, and for working in plaster. The students of the fourth year will give a certain portion of time to exercises of a critical and literary character, designed to practice them both in reading and in writing. The buildings now in process of erection will afford ample accommodation for this work, and for the necessary collections of drawings, photographs, casts, and books.

Memoirs, Projects, and Dissertations—The following memoirs, projects, and dissertations required from students of the several classes of the year 1881–82, are given simply to illustrate the kind of work required by By-laws 22 and 24, pages 14 and 15. Students of the Second Class in all the courses were required to hand to the Instructor in Drawing, on or before October 3, 1881, six free-hand sketches as follows:

No. 1. Hoisting Machine. No. 2. Stone Doorway. No. 3. Bridge. No. 4. Staircase. No. 5. Steam Pump. No. 6. Railroad Car. These sketches must be drawn from the objects themselves, on sheets 15x22 inches, and location, date, and signature must be given on each.

Course in Mining Engineering—Students of the Third Class are required to hand to the Professor of Engineering, on or before October 3, 1881: For those not attending the Summer School of Mechanical Engineering, six drawings (15x22) as follows; No. 1. Orthographic View. Plan and Elevation of a Building, Dimensions, etc., assigned in class. No. 2. Details—Doors, Windows, Stairs, etc. No. 3. Tracing of No. 2. No. 4. Enlarged Plan and Elevation of principal entrance, with details. No. 5. Perspective view of Exterior. No. 6. Isometric view of exterior. For those attending the Summer School of Mechanical Engineering, descriptive and illustrated memoirs upon shop practice. Students of the Fourth Class were required to hand to the Professor of Engineering, on or before October 3, 1881: A Memoir upon some topic assigned to each member of the class in connection with the Summer School in Practical Mining; and on or before January 13, 1882, to hand in to the Professor of Metallurgy: A Metallurgical Project on a subject assigned by the Professor of Metallurgy.

Course in Civil Engineering.—Students of the Third Class were required to hand to the Professor of Engineering on or before Oct. 3d, 1881.

For those not attending the Summer School of Mechanical Engineering, six drawings, 15x22 inches, as follows:

No. 1. Orthographic View. Plan and Elevation of a Building. Dimensions, etc., assigned in class.

No. 2. Details—Doors, Windows, Stairs, etc.

No. 3. Tracing of No. 2.

No. 4. Enlarged Plan and Elevation of principal entrance, with details.

No. 5. Perspective View of Exterior.

No. 6. Isometric View of Exterior.

For those attending the Summer School of Mechanical Engineering, descriptive and illustrative memoirs upon shop practice.

Students of the Fourth Class were required to hand the Professor of Engineering, on or before October 3, 1881, descriptive memoir upon engineering topics assigned to the member individually, embracing: Reclamation of Tide Lands at Green River Harbor, Mass.; Methods of Laying Out and Constructing Roadways on Pennsylvania Railroad; Improvements of Charleston Harbor, S. C., and Cape Fear River, N. C.; Construction of New Railroad Bridge across the Harlem River at 155th Street.

Course in Metallurgy.—Students of the Third Class were required to hand to the Professor of Metallurgy, on or before October 3, 1881.

A Memoir on one of the following subjects:

(1) The occurrence, preparation and properties of Ozone. (2) The comparative certainty and delicacy of the different qualitative tests for Arsenic. (3) The occurrence and detection of Titanium. (4) Qualitative detection and separation of Nickel and Cobalt.

Students of the Fourth Class were required to hand to the Professor of Metallurgy, on or before October 3, 1881:

A Memoir on one of the following subjects:

(1.) Regenerative Furnaces. (2.) Blair's Direct Process. (3) The Siemens-Martin Process.

And on or before January 13, 1882:

A Metallurgical Project on a subject assigned by the Professor of Metallurgy.

Course in Geology and Palæontology.—Students of the Third Class were required to hand to the Professor of Geology, on or before October 3, 1881:

A Memoir on one of the following subjects:

(1.) Notes on the Fauna or Flora of any geographical district visited. (2.) Observations on the structure, distribution, and habits of any of our Fresh-water Fishes. (3.) Catalogues and collections of Mollusks inhabiting any lakes, rivers, or districts. (4.) Notes on the economy of observed insects. (5.) Notes on the various observed methods by which the Seeds of Plants are distributed.

Students of the Fourth Class were required to hand to the Professor of Geology, on or before October 3, 1881:

A Memoir on one of the following subjects:

(1.) Report on the Geology of any district visited. Embracing: *a.* Topographical features and their causes. *b.* Surface geology. *c.* Sections of strata, with lithological character, thickness, dip, strike, and fossils of each bed. Sketches of rock outcrops. *d.* Suites of specimens of rocks and fossils, rocks 3—4—1 inches.

(2.) Report on any special formation which may be examined. Embracing: *a.* The geographical area of its outcrops. *b.* Its mineral character, and origin of the material composing it. *c.* Sets and collections of its fossils. *d.* Reading of the history of its deposition.

(3.) Report on any examined deposits of ore or other useful minerals: as, *a.* The Magnetic Iron Ores of New York and New Jersey, phenomena and history. *b.* The Limonite Ores of the Alleghany Belt, character of deposits and age. *c.* The Zinc Ores of Franklin and Friedensville. *d.* The Chromic Iron of the Alleghany Belt, where and how it occurs.

And on or before the 15th of April, 1882; A Dissertation on one of the following subjects:

(1.) The Mesozoic Sandstones of New Jersey and the Connecticut Valley; their geological phenomena, history, and relations to the associated trap rocks.

(2.) The Limonite Ores of the Alleghany belt; their phenomena, age, and origin, *i. e.;* Where and how they occur, when and how they are deposited.

(3.) Eozoon Canadense; is it organic?

Course in Analytical and Applied Chemistry.—Students of the Third Class were required to hand to the Professor of Chemistry, on or before November 3, 1881:

A Memoir on one of the following subjects:

(1.) Water Gas. (2.) Petroleum. (3.) Photo-Mechanical Processes. (4.) Gun Cotton.

The Memoir must include a general account of the group; constitution, formation, physical and chemical properties, and decompositions; together with a complete classified list of all the members of the group, with the names of the discoverers, date of discoveries, and references to original publications.

The students of the Fourth Class were required to hand in to the Professor of Chemistry, on or before November 3, 1881; A Memoir on one of the following subjects:

(1.) Artificial Stone. (2.) Artificial Indigo. (3.) Quinine and its allies. (4.) Resins and Varnishes.

The Memoir must contain full references to authorities throughout the text, a table of contents, and an index.

And on or before April 14, 1882.

A Chemical Dissertation on a subject which they may select, subject to the approval of the Professor of Chemistry. All memoirs and Dissertations must be written on paper 8x10 inches, with a margin of one inch, and be illustrated by drawings made to scale, on paper 24x36 inches in size, and accompanied, when possible, by specimens.

Vacation Work.—During the vacations at the close of the first, second, and third years, students are required to prepare memoirs on subjects assigned to them by the Faculty. Specimens illustrative of the kind of work required in the memoirs have just been given. During the vaction, a class in practical mining, composed of students in the course in Mining Engineering who have completed the third year, is required to visit a mine for practical mine work. The class is under the immediate superintendence of the Adjunct Professor in Surveying and Practical Mining, and is occupied in this way from four to six weeks. During the vacation, also, a volunteer class in practical mechanical engineering is formed from among the students of either of the Engineering courses who have completed their second year, for the purpose of visiting foundries and machine shops in the city, and engaging in practical work and study. This class is under the immediate supervision of the Adjunct Professor of Mechanical Engineering, and is occupied in this way four or five weeks of the months of June and July. During the vacation a class in practical geodesy, composed of students in the course of Civil Engineering who have completed the third year, is required to make a geodetic survey of some region. This includes measuring a base line with a United States Coast Survey secondary base apparatus—secondary and tertiary triangulation with eight inch theodolite—trigonometric levelling with eight inch theodolite, with vertical circle. Determinations of time, latitude, and azimuth, using portable transit, zenith telescope, and theodolite. Approximate determinations of time, latitude, and longitude, with sextant and reflecting circle. The class is under the immediate supervision of the Director of the Observatory and Instructor in Geodesy.

Text Books.—The text books required by the first and second classes are named in connection with the subjects in the synopsis of studies. Books preceded by an asterisk (*) are optional—the others are indispensable.

Third Class.—Peck's Mechanics (new edition). Murray's Land Surveying. Newcomb's and Holden's Astronomy. *Publications of the U. S. Coast and Geodetic Survey, relating to the fundamental geodetic operations. *Rankine's Machinery and Mill Work. Mahan's or Wheeler's Civil Engineering. Gillmore's Roads and Pavements. Stoney's Theory of Strains. Searle's Henck's Field-book for Engineers. *Davis's Formulæ for Railroad Earthwork. Ritter's Iron Bridges and Roofs. *Callon's Lectures on Mining. Johnson's Fresenius's Quantitative Analysis. Dana's Manual of Geology. Nicholson's Palæontology. Wagner's Chemical Technology. *Kerl's Metallurgy. Plattner's Blowpipe Analysis. Egleston's Lectures on Mineralogy. Egleston's Tables for Determining Minerals. Egleston's Metallurgical Tables. Egleston's Tables of Weights, Measures, Coins, etc. Von Cotta and Lawrence's Rocks. Cairn's Quantitative Analysis.

Fourth Class.—Burat's Géologie Appliqué. *D'Orbigny's Palæontologie Elémentaire. Rickett's Manual of Practical Assaying. *Whitney's Metallic Wealth of the United States. *Kerl's Probirkunst. Egleston's Metallurgical Tables. *Cotta's Treatise on Ore Deposits, by Prime. Page's Economic Geology. Weisbach's Mechanics of Engineering. Callon's Lectures on Mining. *Burat's Exploitation des Mines. *Rigg on the Steam Engine. Goodeve on the Steam Engine. *Welsh's Designing Valve Gearing. Rankine's Prime Movers. Rankine's Civil Engineering. Rankine's Machinery and Mill Work. *Lottner's Bergbaukunst. Stevenson on Harbors. Stevenson on Canals and Rivers. *Vose's Railroad Engineering. *Clarke's Geodesy. *Publications of the U. S. Coast and Geodetic Survey, relating to the fundamental geodetic operations. *Gaetschsman's Aufbereitung. Fanning's Water Supply Engineering. Diedrich's Theory of Strains. Latham's Sanitary Engineering. *Röntgen's Thermodynamics, Du Bois's Translation. *Planât on Warming and Ventilation. *Joly, Warming and Ventilation. *Colyer's Hydraulic Lifting and Press Machinery. *Rittinger's Die Aufbereitungkunde. Allen's Introduction to the Practice of Commercial Organic Analysis. Berthelot's Leçons sur les Methodes Générales de Synthése en Chimie Organique. Berthelot and Jungfleisch's Traité Elémentaire de Chimie Organique. Roscoe and Schorlemmer's Treatise on Chemistry (Organic Chemistry). Strecker's Short Text Book of Organic Chemistry by Wislicenus.

Library.—The Library of the School of Mines, established when the school was founded, was especially designed to assist the students in the course of studies pursued in the various departments. Having at the time no fund for the purpose, a portion of the college library appropriation was devoted to the purchase of a few books which partially supplied the existing needs. To these were subsequently added about a thousand volumes removed from the library of the School of Arts to another department, and a further increase was soon after made by the addition of books obtained in exchange for duplicate reports of Natural History, Surveys of States and Territories, presented by various authorities. Since then frequent donations, and a gradually increasing annual appropriation, have raised the number of volumes to about eighty-five hundred. The number of volumes upon its shelves, however, affords by no means a just measure of the value of the library, which consists rather in the judicious selection of standard and recent works in the various departments of science which, it embraces, and in their adaptation to the specific wants of the school. The catalogue contains the titles of about three thousand monographs, rather more than one-half of which are in the English language, and the remainder in German and French. But the most important feature of the library, and that which places it in advance of others much larger, is its valuable collection of periodical publications, which now make up about half the number of volumes collected. The present subscription list comprises a hundred and fifty serials devoted to science and the arts, published at the various literary and scientific centres of the world. The early numbers of some of the most important of these have been procured, and form complete series not to be found elsewhere in New York, or, indeed, in the country. Valuable maps and volumes of plates have also been added to the library by purchase and by generous donations to which the School of Mines is frequently indebted for important acquisitions. The appropriations made by the Trustees for the increase of the library have gradually increased from sums of less than five hundred dollars to two thousand dollars per annum. The books are arranged upon the shelves in alphabetical order, and in sections bearing labels which indicate the subject to which each is devoted. A catalogue was published in 1875, giving first, the systematic works and periodical publications, arranged alphabetically, without reference to subjects; and secondly, the same titles repeated and classified according to a logical method. This is supplemented by catalogues printed each session, containing the list of books recently added.

Cabinets and Collections.—Collections of specimens and models, illustrating all the subjects taught in the school, are accessible to the students, including:

Crystal Models.
Natural Crystals, Pseudomorphs.
Ores and Metallurgical Products.
Models of Furnaces.
Collection Illustrating Applied Chemistry.
Fossils.
Economic Minerals.
Rocks.
Olivier's Models of Descriptive Geometry.
Models of Mechanical Movements.
Models of Mining Tools.
Models of Mining Machines.
Casts, Antique Statuary, Animals, etc.

Crystal Models.—The lectures on crystallography are illustrated by a collection of 150 models in glass, which show the axes of the crystals and the relation of the derived to the primitive form. This suit is completed by 400 models in wood, showing most of the actual and theoretical forms.

Minerals.—The cabinet of minerals comprises about 30,000 specimens, arranged in cases. It includes a large suit of pseudomorphs, and a collection illustrating crystallography by natural crystals, showing both their normal and distorted forms. The minerals are accompanied by a large collection of models in wood, showing the crystalline form of each. Arranged in wall cases are large specimens, showing the association of the minerals.

Ores and Metallurgical Products.—A very complete collection of metallurgical products, illustrating the different stages of the type process in use in the extraction of each metal in this country and in Europe, is accessible to the students. This collection is constantly increasing. Most of the specimens have been analyzed and assayed.

Models of Furnaces.—An extensive collection of models of furnaces has been imported. A very large number of working drawings of furnaces and machines used in the different processes is always accessible to the students.

Applied Chemistry is illustrated by several thousand specimens of materials and products, arranged in a cabinet of industrial chemistry, for exhibition at the lectures and for inspection by the students.

The Geological Collection consists of over 80,000 specimens (to which additions are constantly made), forming the following groups:

1st. A systematic series of the rocks and fossils characteristic of each geological epoch, numbering over 50,000 specimens.

2d. A collection of ores, coals, oils, clays, building materials, and other useful minerals, illustrative of the course of lectures on economic geology, and believed to give the fullest representation of our mineral resources of any collection yet made.

3d. A collection of 5,000 specimens of rocks, and the minerals which form rocks, to illustrate the lectures on lithology.

4th. A Palæontological series, which includes collections of recent and fossil vertebrates, articulates, mollusks, radiates, and plants. In this series is to be found the largest collection of fossil plants in the country, including many remarkably large and fine specimens, and over 200 species, of which representatives are not known to exist elsewhere. Also the most extensive series of fossil fishes in America, including, among many new and remarkable forms, the only specimens known of the gigantic *Dinichthys;* a suit of Ward's casts of extinct saurians and mammals: a fine skeleton of the great Irish elk, etc., etc.

DRAWING MODELS. There are, for the use of students, a large collection of flat models and of plaster casts; the Olivier models, forming all mathematical surfaces by silk threads, and admitting of a variety of transformations; also other models, illustrating general and special problems, of descriptive geometry, shades and shadows, and stone cutting; photographs of plaster casts and of parts of machines for use in free hand drawings; drawings of machines and parts of machines for studying and copying; also landscapes in crayon and in water color for instruction in sketching; models of mining machines and mining tools, stationary steam engines, single and double cylinders, sections of steam cylinders, water wheels, turbines; shaking tables, stamps, crushers, blowing machines, pumps, etc.

CIVIL ENGINEERING is illustrated by a collection of models of beams, beam joints, roof and bridge trusses, masonry doorways, arches, walls, culverts, bridges, and canal locks; working models of overshot, breasts, undershot, and different kinds of turbine water wheels, a machine, made by Fairbanks & Co., for testing the strength of materials; a five inch condensing steam engine, with a stroke of six inches; horizontal, vertical, and sectional steam engines and valves, etc. There has recently been added to the department of Engineering for the use of students in Geodesy two four-metre compound bars with Borda's scales, etc., for measuring base lines; one standard four-metre bar; one eight-inch theodolite with horizontal and vertical circles for measuring horizontal angles and double zenith distances.

MINING ENGINEERING is illustrated by models of blowing engines, ventilators, mine shafts, tunnels, galleries, methods of walling, methods of tubbing shafts, methods of measuring shafts, shaft house, hoisting engine, safety cages, man-engines, ladders, shaking tables, washers, stamps, crushers, mining machines, lamps and tools, artesian wellborer, blasting apparatus, etc. Additions to the various collections are constantly made.

ASTRONOMICAL OBSERVATORY.—The Astronomical Observatory contains a set of portable astronomical instruments; a forty-six inch transit, by Troughton & Simms; a combined transit and zenith instrument for time and latitude determinations, an equatorially mounted refractor of five inches aperture, to which is attached a spectroscope with the dispersive power of twelve flint glass prisms of fifty-five degrees, by Alvan Clarke; also a diffraction spectroscope with grating, by L. M. Rutherfurd, Esq. A set of comparison apparatus, with electrodes, Plucker's tubes, coil, etc., accompanies the spectroscope. Instruction in practical astronomy is given in the observatory to students of the Third and Fourth Classes in the course of Civil Engineering.

DEGREES.—Those who complete the required course of studies will receive the degree of Engineer of Mines, Civil Engineer, or Bachelor of Philosophy. Graduates of the school who pursue for not less than one year a course of study prescribed by the Faculty, pass a satisfactory examination thereon, and present an acceptable dissertation embodying the results of special study upon an approved subject, receive the degree of Doctor of Philosophy.

CALENDAR.—Examination for Admission begins, Wednesday, Sept. 27th, 1882.

Oct.	2.—First Session begins, Monday.	
Nov.	14.—Election Day, Holiday.	
	Thanksgiving Day, Holiday.	
Dec.	25.—Christmas Holidays begin, Monday.	
1883—Jan.	8.—Lectures resumed, Monday.	
	29.—Examinations begin, Monday.	
Feb.	7.—Ash Wednesday, Holiday.	
	7.—First Session ends, Wednesday.	
	8.—Second Session begins, Thursday.	
	22.—Washington's Birthday, Holiday.	
March	23.—Good Friday, Holiday.	
	26.—Easter Monday, Holiday.	
May	21.—Annual Examinations begin, Monday.	
	30.—Decoration Day, Holiday.	
June	13.—Commencement, Wednesday	

A SUMMER SCHOOL OF PRACTICAL MINING.

WE get a further insight into the excellent work of Columbia College, in this direction from a paper by Professor Henry S. Munroe of the School of Mines, read before the American Institute of Mining Engineers, which paper Professor Munroe has corrected to date for this work. It is appended:

The plan of organizing a summer class of students of the School of Mines, for practical study of mining and miner's work, received at the outset the following cordial indorsement:

"I have thought over the plan proposed by you of taking the students to the mines during the summer, and of having them actually take part, under the direction of skilled workmen, in all the various kinds of mining work; and of using them as a corps of engineers to make inside and outside surveys, particularly with a view to the detailed study of the geology of the mine. I have no hesitation in saying, that if the students have been previously instructed in the theoretical part of their studies, by lectures and practice during the winter, the plan would be an admirable one. Of course experience will suggest modifications of detail. From the work you have done at our mines this spring, I feel sure that you would be perfectly competent to carry out your plan, and I shall gladly aid you in any way I can.

"Yours, sincerely, E. B. COXE."

The plan of the proposed summer school thus indorsed by Mr. Coxe was adopted by the trustees of Columbia College, and an appropriation of one thousand dollars, or so much thereof as might be necessary, was voted for the experiment. A volunteer class of thirteen students was formed, and the first summer school was held at Drifton, in July and August of that year (1877). The following extract, from an editorial notice in the *Engineering and Mining Journal*, of August 11, 1877, will give an idea of the organization of the school and the work required of the students.

"The students, on reporting to Professor Munroe, were divided into squads of two or three men each, and on Monday, July 2d, were assigned to the care of skilled miners, selected for the purpose by the mine boss, for instruction in gangway work. Half of the students worked in the morning, and the other half in the afternoon, one squad at a time with each miner. The times of going and coming to and from work were so arranged that each student spent four to four and a half hours in the mine each day. While in the mine, they assisted the miner to load his car, thereby learning readily to distinguish 'slate' and 'bony' from good coal, even in the uncertain light afforded by their mine lamps. They were also instructed in the use of the drill and pick, boring themselves the blast-holes, judging the quantity of powder required, making up the cartridge, tamping and firing the shot. On coming out of the mine, each squad was required to make a written report of the work done, with sketches showing the location, direction, depth, etc., of each shot fired, and the effect produced. Four days were thus spent in the gangways learning the rudiments of miners' work, and then the students were transferred to the charge of other miners, selected by the mine-boss, working in breasts of different degrees of pitch, spending one or two days with each. From this time on less importance was attached to manual labor on the part of the students as a necessary part of the scheme of instruction, though most of the students of their own choice still continued to work more or less. The principal advantage gained by this manual work was the breaking of the ice between the student and the miner, placing them in pleasant relations and on common ground, the student for the time becoming, to all intents and purposes, the miner's 'butty,' and to be treated and instructed as such.

"Another advantage gained was the knowledge of the different conditions having influence on the ease or difficulty of working, and thus some idea of the value of that most variable quantity—a day's work. In addition to their work in gangways and breasts, the students also spent some days with other skilled miners in setting props and timbering gangways, building brattice and driving airways, laying tracks and putting in switches on mine roads, in getting coal by robbing, in artesian-well boring for water, boring by hand for exploration, etc.

"After the students had spent in this way about twenty days at different kinds of work underground and in the 'breaker,' subjects for more detailed study and investigation were assigned them. Each student having chosen his theme, spent the remainder of his time in collecting material for a memoir. 'Underground Haulage,' 'Ventilation,' 'Mine Pumps,' 'Hoisting Engines,' 'Winning of Coal in Breasts of Different Degrees of Pitch,' 'Artesian-Well Boring,' 'Breaking and Sizing of Anthracite,' 'Separation of Slate from Anthracite,' 'Water-supply for Boilers and for Household Use, and Washing of Coal,' etc., were among the subjects thus assigned. During the last few days trips were made to several mines in the vicinity, at Hazleton, Ebervale, etc., spending a day underground in each case with the mine-bosses, who explained in detail the characteristics of their mines and their methods of working. Mr. Coxe, also, during their stay, gave the students several informal talks of great practical value on the mining of anthracite, installation of machinery, management of men, necessity for scientific bookkeeping, discussion and analysis of mine accounts, etc.

"The miners and the mine-bosses of the Cross Creek collieries have taken great interest in the experiment, and to their cordial and hearty co-operation in the carrying out of all the details of the plan is due in no small degree the very gratifying success attained. It is, however, to the interest taken by Mr. Eckley B. Coxe in this new departure in mining education that its success is in a large measure due, for he not only encouraged the idea when proposed, but placed his collieries—probably the finest in this country—at the service of the school, and gave such instructions as secured for the student a favorable introduction to the miners. 'One of the most notable and prominent features of this effort to introduce the practical element into the studies of the School of Mines has been the demonstration that the students are not 'a nuisance' about the works, but, on the contrary, are welcomed by the miners, and are found to make no trouble or interference with the work of the colliery."

The experiment having proved successful, the trustees of the college voted to make the summer class a part of the regular course of study for the degree of Mining Engineer. The next summer (1878) the school was held at Mineville, N. Y., at the large magnetite mines of Witherbees, Sherman and Co., and of the Port Henry Iron Ore Company. The session of 1879 was held in the copper regions of Lake Superior, with headquarters at the Atlantic Mine, near Houghton. In 1880 the field of operations was enlarged, and the time devoted to practical work was divided between the Dickerson Mine (magnetite) of the Musconetcong Iron Company, near Dover, N. J., and the mines of the Westmoreland Coal Company, near Pittsburgh. Last Summer (1881) the time was divided between the copper mines of Keweenaw County and the iron mines of Marquette County, Michigan. The present summer (1882) the class spent four weeks at the Cross Creek Collieries of Messrs. Coxe Brothers & Co., and one week at the Hibernian Iron Mines, Morris Co., New Jersey. The plan of Work, as it has developed itself in these five sessions of the school, begins with a detailed study on the part of each student of the plant and methods of working at the mine selected for the summer school. The students for this purpose are divided into squads of two or three men, and each squad is assigned to the care of a skilled miner and given each day some one subject for observation and study. To aid the student in systematizing his work, and to suggest lines of investigation, he is provided with a printed scheme of study, which he is expected to follow in making out his daily reports. The following scheme of study was used (1880) at the Dickerson Iron Mine.

Dickerson Mine, Ferromont, Morris County, N. J.,

June 14th, 1880.

Each student of the summer school will be required to make the following reports:

1. *Hand-drilling and Blasting.*

Description from actual observation, of the method of blasting in driving a cross-cut or drift. The report will include:

1. A description of the tools employed, illustrated by careful sketches, half size, showing form and dimensions of each tool.

2. The time of boring, number and size of drills used, and the position, direction, and depth of each hole. To be illustrated by drawings of the heading of the drift or cross-cut, on a scale of one-twentieth, showing in three projections the position and direction of each hole bored. Holes bored during the night shift, or in the absence of the student, should be drawn in dotted lines, and the order in which the holes were bored should be indicated by numbering them.

3. The kind and amount of powder and of tamping used in each hole, and method of charging, tamping, and firing.

4. The reasons for the location and direction of each hole, and the work intended and actually performed by the blast. The failure of any blast to do the work expected, and holes which for any reason have to be abandoned, should be carefully noted, with the reason for such failure or abandonment, if possible.

5. The number of men employed at the work and duties of each; number and length of shifts; amount driven during previous months, and average progress of drifts; number of drills, hammers, shovels, and other tools required, average number of drills sharpened per day, wear of steel, consumption of powder, oil or candles, etc.

2. *Stoping of Ore.*

Description, from actual observation, of the methods of stoping, including the preparatory sinking or drifting, and the breaking of the ore by machine or hand-drilling and blasting; illustrated by sketches of the stope in horizontal projection, with longitudinal and cross-sections.

Sketches on a scale of one-twentieth, showing the location, direction, and depth of several consecutive blast-holes, with description in detail of the boring, charging, tamping, firing of each hole.

3. *Machine Drills.*

Description of machine drills, size, weight, pressure of air, and size and shape of drilling-bits, etc.

Description of the work of boring one or more blast-holes, including setting of machine, starting of hole, feeding of drill, changing of bits, etc. Give time of each operation, noting delays and their cause. Number of holes and total depth bored per shift. Number of drills blunted per day. Wear of steel.

4. *Timbering.*

Description and sketches of the different forms of timbering used in the mine, stulls and lagging, studdles, etc.

Sketches of details of skip-roads, showing different methods of supporting track-timbers and ladders on stulls, etc.

Sketches of timbering of slope and of shafts. Supports of ladders and pump-rods, details of landing-stage and sollars.

Arrangements for protecting men, machinery, etc., from blasts and falling rock—batteries, pentice, etc.

Description and measurement, illustrated by careful sketches and from actual observation, of the work of putting in one or more stulls; including cutting of hitches in rock, measuring and cutting timber, lowering of timber from surface and handling it in the mine, arrangement of tackle and hoisting of timber to place, and wedging.

Kinds of timber used, whence obtained; seasoned *vs.* green timber; stripping of bark; renewal of timber, etc.

5. *Pumps.*

Details of pumping engines and of pumps, stroke, diameter, speed, valve motion, etc. Sketches of pumps, pump-rods, bobs, and methods of changing direction of rods. Manner of connecting and supporting rods. Use of plunger, and of lift or jack-head pumps. Repair and packing of pumps. Pumps, location and size. Gallons of water pumped per day. Use of steam pumps in the mine, support and covering of steam-pipes, disposal of exhaust steam.

6. *Handling of Ore.*

Description of the method of handling ore in the stopes, including the getting down of ore after a blast with pick or bar, the breaking up of large masses by block-holing or sledging, sorting of ore from rock, loading of cars or barrows, dumping into skips, etc. Sketches of tram-car, loading platform and chute, details of track, turnouts, and switches, etc.

Description of hoisting engines, dimensions, speed, steam pressure, valve motion, gearing, etc. Construction of hoisting drum, diameter, length; number of revolutions per minute, and to hoist from bottom. Description of brake. Size and character of wire rope. Tell-tales and signals. Number of skips of ore hoisted and of timber lowered per day. Speed of buckets, skips, or cars. Sketches of skip, and self-dumping devices. Sketches of sheaves, and of guide rollers for wire rope, on surface and in the mine.

Handling of ore on the surface, loading of cars, breaking, cobbing, and hand-picking. Transportation to market.

Handling and disposal of waste rock underground, and on the surface.

Sketches of whims, poppet-heads, and other surface constructions.

7. *Surface Works.*

Sketch map showing relative position of surface works, shafts, tunnels, engine and boiler-houses, shops, change-house and other buildings; railroad tracks, switches, turnouts, etc., tramways; lines of steam, water, and air-pipes, and of surface drainage. Description of above buildings, roads, etc., and notes on source of water-supply for boilers and for household use. General description of miners' houses, number, internal arrangements, etc. Plans of change-house, shops, and other buildings.

8. *Shops.*

Sketches showing arrangement of blacksmith-shop, machine-shop, carpenter-shop, etc. Description of the method of sharpening and tempering drills, picks, etc. Sharpening and repairs of bits of machine drills. Work of machine-shop, repairs to pumps, rock drills, and other machinery. Carpenter-shop, making of ladders, tram-cars, and miscellaneous repairs. Number of men required, etc.

The following scheme of study was prepared for the use of the students at the mines of the Westmoreland Coal Company after the completion of their work at the Dickerson Mines:

Westmoreland Coal Mines, Irwin's Station,
Westmoreland Co., Pa., July 12th, 1880.

Each student of the summer school will be required to make the following reports:

1. *Shaft Sinking.*

Description, from actual observation, of the method of blasting in sinking a shaft. The report will include:

1. A description of the tools employed, illustrated by careful sketches, half size, showing form and dimensions of each tool.

2. The time of boring, number and size of drills used, and the position, direction, and depth of each hole. To be illustrated by drawings of the bottom of the shaft, on a scale of one-twentieth, showing in three projections the position and direction of each hole bored. Holes bored during the night shift, or in the absence of the student, should be drawn in dotted lines, and the order in which the holes were bored should be indicated by numbering them.

3. The kind and amount of powder and of tamping used in each hole, and method of charging, tamping, and firing.

4. The reasons for the location and direction of each hole, and the work intended and actually performed by the blast. The failure of any blast to do the work expected, and holes which for any reason have to be abandoned, should be carefully noted, with reason for such failure or abandonment, if possible.

5. The number of men employed at the work and duties of each; number and length of shifts; amount sunk during previous months; and average progress of the sinking; number of drills, hammers, shovels, and other tools required, average number of drills sharpened per day, wear of steel, consumption of powder, oil or candles, etc.

2. *Drifting.*

Description of the method of driving entries, "bearing in" or undercutting, "shearing," and wedging. Main entries and cross entries; entries on the "face" and on the "end" or "butt" of the coal; advantages of double entries. Cross-cuts or "cut-throughs." Section, to scale, of the coal seam, showing the "bearing in" seam and the different slate partings. Inventory and sketches of tools used in driving. Description of work, number of men required, length and number of shifts, progress of work per shift and per month. Time required for each operation, undercutting, shearing, breaking down, loading, taking up bottom coal, laying track, etc.

3. *Mining of Coal.*

Description of method of getting coal in the rooms. Sketch, to scale, showing plan of room, with track, posts and slate heap, stump, ribs, etc. Breaking down of coal by wedges or powder, after undercutting and shearing. Precautions necessary for safety. Manner of conducting the work so as to make a minimum of fine coal or dirt. Separation and disposal of slate and fine coal. Number of cars loaded per day, etc.

Getting of coal by robbing. Sketches showing method of attacking ribs, with subsequent robbing of stumps and pillars. Description of the work and precautions used for the safety of the men and to avoid loss of coal. Number of men, length of shifts, and amount of coal obtained and lost.

4. *Ventilation.*

Sketch map showing the course of the air through a section of the mine, location of doors, stoppages, brattice, crossings, etc. Sketches showing construction of fans employed, and the passages by which they are connected with the air-ways of the mine. Arrangement for reversing the ventilating current. Description and sketch of ventilating furnace. Details of doors, stoppings, brattice, air-boxes, etc. Methods of measuring air and regulating and dividing air-currents. Résumé of ventilation law, with object of different requirements.

5. *Drainage.*

Description of the different methods of draining the mines. Ditches in entries; grade required, etc. Special water-courses. Drainage of "swamps" by siphons, pumps, or water cars. Pumping of acid waters and method of protecting water-column and the working parts of the pumps from the action of the acid.

6. *Timbering.*

Timbering in shafts, entries, and rooms. Sketches showing arrangement of timbers, manner of notching and wedging, etc.

7. *Underground Haulage and Shipment of Coal.*

Description and sketches of cars, size, weight, capacity, etc. Description of different kinds of track used, width of gauge, size and weight of strap iron or rails, etc. Switches and crossings. Maximum and minimum grade of track in main and cross entries. Hauling by mules and locomotives, number of cars hauled at once on different grades and on different tracks. Organization of trips.

Description of hoisting engines, dimensions, speed, steam pressure, valve motion, gearing, etc. Construction of hoisting drum, diameter, length, number of revolutions, and time required to hoist from bottom. Speed of cage. Description of brake. Size and character of wire ropes. Tell-tales and signals. Number of cars hoisted per day. Sketch of cage, showing safety catches, hood, means of holding car on platform, etc.

Description and sketches of arrangements for screening and weighing the coal and for the loading of railroad cars. Transportation to market.

8. *Surface Works and Shops.*

Sketch map showing relative position of surface works, entries, shafts, engine and boiler houses, shops, change-house and other buildings; railroad tracks, switches, turnouts, etc., tramways; lines of steam, water, and air pipes, and of surface drainage. Description of above buildings, roads, etc., and notes on source of water-supply for boilers and for household use. General description of miners' houses, number, internal arrangements, etc. Plans of change-house, shops, and other buildings.

Sketches showing arrangement of blacksmith-shop, machine-shop, carpenter-shop, etc. Description of the method of sharpening and tempering drills, picks, etc. Work of machine-shop, repairs to pumps, and other machinery. Carpenter-shop, making of tram-cars and miscellaneous repairs. Number of men required, etc.

About four weeks was required for the detailed study indicated in these schemes. By this time the student is familiar with the ordinary routine of mine work, having spent from two to four days each with the miners engaged in sinking, drifting, stoping, and timbering, making sketches and taking notes under ground, and each afternoon or evening reviewing carefully the work of the day as he makes out the required report. In a similar manner he has examined and studied the plant connected with the mine, pumps, engines, etc., the timbering in the shafts, slopes, and gangways, the shops and other surface work, and has followed the coal or iron ore from the time it is broken down by the miner, till it is finally loaded on the railroad cars. This careful and detailed examination of one mine finished, the student is prepared with the information and insight thus gained to visit other mines in the same district, for the purpose of studying variations in practice, and differences in plant and methods of working, by comparing similar work as carried on in other mines and under different conditions. A week or ten days is, therefore, devoted to excursions to neighboring mines. Finally, each member of the class has assigned him a subject for a memoir, either the description of the plant and workings of some mine, or the machinery and methods of a stamp-mill or dressing works, or some general subject connected with mining. In most cases he is instructed to describe in greater detail some one or more machines or methods peculiar to the place. In collecting the data for this descriptive memoir the student spends about two weeks at one mine, or in visiting different mines, as the subject assigned him may require; the class being divided into small parties, not more than two or three men at a mine. The memoirs are illustrated by sketches, tracings, and working drawings, and have in most cases been compiled with great care. They are often exceedingly interesting and valuable, containing much material descriptive of plant and methods of working at the mines visited. Under this plan of work it will be seen that the student makes a careful and detailed study of at least two mines, at first with the class and under the instruction and superintendence of the professor, and afterwards at another mine by himself, in collecting the data for his memoir. The excursions and visits to other mines supplement this detailed study, and give the student a wider view of the practice of the whole region.

THE STEVENS INSTITUTE OF TECHNOLOGY, HOBOKEN, N. J.

THIS institution was founded in accordance with the will of Mr. Edward A. Stevens, of Hoboken, who bequeathed for the purpose a large block of land in that city, and a large sum amounting, at the discretion of the trustees, to $650,000. The Stevens Institute is especially a school of mechanical engineering; but the fact that chemistry, metallurgy, and mineralogy, as well as the whole science of machinery, so important to mining engineers of the present day, are taught here, and the magnificent completeness of the buildings and apparatus of instruction, justifies us in including it in the present chapter. The building is situated in the pleasantest portion of the city, its windows commanding a beautiful view of the surrounding country, as well as of New York harbor and bay, and the edifice itself presenting a fine appearance when viewed from the deck of the ferryboat as we cross the river to visit it. The building is very substantially built of blue trap-rock, with brown-stone trimmings, from designs by Upjohn. It extends from street to street, and has two wings in the rear. It is three stories in height, and has a dry and roomy basement.

FACULTY.—Henry Morton, Ph. D., President; Alfred M. Mayer, Ph. D., Professor of Physics; Robert H. Thurston, A. M., C. E., Professor of Mechanical Engineering; De Volson Wood, A. M., C. E., Professor of Mathematics and Mechanics; Charles W. MacCord, A. M., Professor of Mechanical Drawing; Albert R. Leeds, Ph. D., Professor of Chemistry; Charles F. Krœh, A. M., Professor of Languages; Rev. Edward Wall, A. M., Professor of Belles-Lettres; James E. Denton, M. E., Instructor in Experimental Machines and Shop-work; Adam Riesenberger, M. E. Instructor in Mechanical Drawing.

PLAN OF THE INSTITUTION.—The plan of instruction which has now been successfully pursued for eleven years, is such as will best fit young men of ability for positions of usefulness in the department of mechanical engineering, and in those scientific pursuits from which this and all sister arts are daily deriving such incalculable benefits. With this view there is afforded:

1. A thorough training in the elementary and advanced branches of Mathematics, and their application to mechanical constructions.

2. The subject of Mechanical Engineering, including theory and practice in the construction of machines, forms a distinct department, under the charge of a professor experienced in the practical relations of his subject, who will devote his entire attention to the branch. A Mechanical Laboratory has been instituted as an adjunct to this department, in which students are permitted to study the materials of construction during the process of testing, which is at nearly all times in progress, and frequently to take part in such work. They are given opportunities to take part in tests of steam engines, boilers, and other commercial operations carried on in this laboratory, and witness and take part in the construction of machinery and other work done in the workshop. Much of this work is made from designs produced by students, and some machines here used are the work of students entirely.

3. The subject of Mechanical Drawing (which may well be called the language of engineering) forms a separate department, to which much time and attention is devoted. The course comprises the Use of Instruments and Colors, Descriptive Geometry, Shades, Shadows and Perspective, and the Analysis of Mechanical Movements—the principles involved being at once and continuously applied in the construction of working drawings from measurements of machines already built, as well as in making original designs.

4. An extensive course of manual exercises in shop practice is combined with a course of experimental mechanics, to form a separate department, which aims to co-operate with the departments of engineering, mechanics, and drawing, so as to bear to them the same relation as the physical and chemical laboratories do to the class-room work in physics and chemistry. Its courses, aside from the introduction of the student to the function of tools, etc., are directly supplemental to the department of mechanical drawing, by familiarizing the student with the use of working drawings in the shop, and by the embodiment of the theoretical principles of mechanism in the form of exercises in gear cutting, etc., and directly supplemental to the departments of engineering and mechanics, by re-enforcing the apprehension of theoretical principles through the performance of exercises in the course of experimental mechanics.

5. Arrangements of an unusually perfect character have been made, to give a thorough, practical course of instruction in Physics, by means of physical laboratories, in which the student is guided by the Professor of Physics, in experimental researches bearing upon the subjects of his special study. Thus the student will experimentally study those methods of making measures of precision which are used in all determinations in Physics; he will measure for himself the tension of steam at various temperatures, and construct the curve showing their relations; he will determine the electrical resistance of several conductors and insulators, and so on through the subjects of Physics. By such means as these not only will facts and laws be impressed in a manner which no other process can approach, but a training will be given in methods of investigation, which will be invaluable for the mastery of the always new and varied problems of actual work.

6. The subject of Chemistry is taught, chiefly by experimental work in the laboratory, with accompanying lectures and classroom instruction. It is believed that in this manner only can students be made thoroughly conversant with the subject.

7. The French and German languages form an essential part of the course of instruction, since they are indispensable to the engineer and man of science as the vehicles of a vast amount of information, and also as affording that kind of mental culture which mathematical and physical science, if followed exclusively would fail to supply.

8. A department of Belles-Lettres furnishes the means of cultivating literary taste and a facility in the graceful use of language, both in speaking and writing, which are as desirable in the engineer and man of science as in the classical student.

THE WORKSHOP.—During the last three years the course of workshop instruction has been greatly extended, and as a result of this, a year since there came to be an urgent need for larger accommodation and an increase in the number of machine and other tools. Fortunately, this need has been supplied by a gift from President Morton, who fitted up the building (formerly used as a lecture hall, and afterward as a gymnasium), and stocked it with an engine of 20 horse power, and numerous machine and other tools, at an aggregate outlay of $10,000, and presented the same to the trustees. The building occupied by the shop is 50 feet wide by 80 feet long, with a high open roof. Galleries have been erected on all sides of it at a height of 12 feet, reaching out 15 feet from the walls, thus leaving a space 20 by 50 open in the centre. The engine being placed about the middle of the building, two lines of main shafting run along the front of the galleries, and from these belts are carried off to the counter shafts of the various machines. A spiral stairway gives access to the west gallery near its centre, where is located the tool room, which is fully stocked with all the small tools, mandrels, gauges, cutters, taps, dies and the like, required for use with the machine tools. These are given out to students on presentation of brass checks, as in all large shops. Platforms run the whole length of the room under the windows, and on these are placed, on the east side, 10 carpenter benches, each with a locker or cupboard above it, containing a set of carpenter's tools. On the west side 10 benches are fitted up for vise work.

Other Appliances for the Workshop Course.—In the basement of the main building is a foundry, provided with a 17″ cupola furnace, a 12″ brass furnace, a number of moulders' benches, moulders' tools, and everything else required for practical work in this direction. A large collection of carefully selected patterns are here provided, and each student is required to make a good mould in sand of each of these, including the making and baking of the requisite cores. Castings in iron are make likewise, by the students, of a selected series of these patterns. Two forges, anvils and sets of blacksmith tools, and a steam hammer are provided for the course of instruction in this subject. Two sets of steam fitter's tools and vises are arranged so that two pair of students at once can work at the exercises required in this subject. The large basement room, formerly occupied as a workshop, is now provided with a small engine and one line of shafting. Extra sets of shafting, hangers, couplings, pulleys, etc., of various styles, are also provided, with which the exercises in this subject are carried out. In one of the small rooms of the basement is a vertical engine of 5-horse power, from the New York Safety Steam Power Company, and the transmitting dynamometer built in the Institute by the Class of 1879. Also absorbing dynamometers, measuring tanks and calorimeters. These, as well as the engine and other appliances of the old shop, are used in the course of Experimental Mechanics.

CALENDAR.—The full course of the Stevens Institute of Technology occupies the period of four years, each year being divided into a Preliminary Term, during which the Sophomore, Junior and Senior Classes devote eight hours per day to the Department of Experimental Mechanics and Shop Work, and three regular terms.

Preliminary Term.

Junior and Senior Classes, from Monday, September 4th, 1882, to Wednesday, September 27th, 1882.

Candidates for admission to the Freshman Class should not present themselves for examination prior to September 20th, 1882.

First Regular Term.

From Wednesday, September 27th, 1882, to the Wednesday before Christmas.

Public examination on the work of the term begins Wednesday, December 13th, 1882.

Second Regular Term.

From Wednesday, January 3d, 1883, to Wednesday, March 21st, 1883.

Public examination on the work of the term begins Wednesday, March 14th, 1883.

Third Regular Term.

From Monday, April 2d, 1883, to Wednesday, June 13th, 1883.

Public examination on the work of the term begins Wednesday, June 6th, 1883.

Commencement, Thursday, June 14th, 1883.

Examinations.—The examination of applicants for admission, and the re-examination of students deficient at the end of the preceding college year, will be held between the hours of 10 A. M. and 2 P. M., on September 20th, 21st, 22d, 23d, 25th, and 26th, 1882. Students will present themselves as early as possible, in order that they may have ample time to prepare answers to the questions assigned them. Examinations in each department will be held in public at the end of each term; and, previous to graduation, a special examination, also in public, will be held, of the graduating class, and from the combined results of all these examinations, the questions of proficiency and qualifications for degrees will be determined. The transfer of a student from a lower to a higher class will depend in each case upon the result of the examination of the year preceding the time of transfer, so that no student can pass from a lower to a higher class until he has given satisfactory evidence of his proficiency in the studies of the former. The following days will be observed as Holidays: Thanksgiving Day (First Term), Washington's Birthday (Second Term), and Decoration Day (Third Term). Thanksgiving Day and Washington's Birthday falling on Thursday, there will be no exercises on the Friday and the Saturday following.

Requirements for Admission.—No applicant under the age of seventeen years will be admitted to the examination, unless the Faculty be satisfied that he is able to bear the burden of the Institute course, without detriment to his health, nor will any applicant under the age of seventeen be allowed to enter his class unless his examination show proof of unusual proficiency. The examinations will be on the following subjects:

Arithmetic.—The preparation should be especially thorough upon the properties of numbers, the operations in common and decimal fractions, the methods of finding the greatest common divisor, and the extraction of the roots of numbers.

Algebra.—Simple equations, theory of radicals, equations of the second degree, arithmetical and geometrical progression, permutations, binomial theorem, indeterminate coefficients, and the summation of series.

Geometry.—All of plane and solid geometry. The examination in this subject will be chiefly upon the definitions and the statements of facts, as contained in the more important propositions; but the ability of the applicant to make a logical demonstration will also be tested.

English Grammar.—The requirements are a practical acquaintance with the parts of speech, their relations, agreement, and government; the proper use of tenses and moods; the construction and arrangement of sentences. On all these points we desire exact knowledge of the principles deduced from copious examples, and we attach no value to a minute knowledge of subtleties and exceptions. The latter properly belong to an advanced college course.

Geography.—The examination will be in the most important countries, cities, rivers, etc., most frequently occurring in the perusal of the daily newspaper and in general history.

Composition.—An Essay upon some topic assigned at the time of examination, and examined with reference to legible hand-writing, correct spelling, punctuation, and proper expression.

Universal History.—In the examination in Universal History but little prominence is given to dates. The questions relate to the great events; their cause and effects. A conspicuous place is given in the questions to the History of the United States.

Rhetoric.—The examination in Rhetoric will embrace all parts of the subject which are contained in the text books on Rhetoric. Candidates for admission to the higher classes must be prepared to pass a satisfactory examination in the studies previously pursued by the class which they enter. Advanced students and men of science desiring to avail themselves of the appliances of the laboratories of the Stevens Institute, to carry on special investigations, may make arrangements to that end with the President.

DEGREES.—The Stevens Institute of Technology, as will be seen from its secondary title, and from the account of its general scope and plan of studies already given, is essentially a School of Mechanical Engineering, and will therefore confer upon its regular graduates the degree of Mechanical Engineer, when due evidence of proficiency has been afforded in the final examinations, and upon the presentation of these, as described further on. Three years after graduation an alumnus, who shall have creditably pursued the practice of the profession, may, upon producing satisfactory evidence of the fact, receive a post-graduate degree—the title and the conditions of the conferring of which have not yet been definitely determined. Five years or more after graduation, a second and higher degree may be conferred, where evidence of good professional standing and of the performance of work of exceptional importance or excellence shall show the candidate to be entitled to such distinction. In certain cases, however, graduates from other institutions, or meritorious students, of at least two years' standing, may pursue a special course, from which they may graduate, upon passing the requisite examinations, with the degree of Bachelor of Science; and such graduates, on presenting a thesis embodying the results of original investigation in the subjects of chemistry and physics, may receive a further degree of Doctor of Philosophy.

EXPENSES.—The fees for each year of the entire Course, for instruction and the use of instruments, are one hundred and fifty dollars, for students at the time residing in the State of New Jersey. Those not so residing—(*i. e.*) coming across the river each day from New York or the like—are charged seventy-five dollars extra. This discrimination is made necessary by a clause in Mr. Stevens' will. In the Chemical Laboratory each student will be supplied with a set of reagent bottles; and an adequate quantity of chemicals, and platinum vessels, agate and steel mortars, etc., will be loaned to him from time to time, as his work may make their use necessary. With reference to other apparatus, he is at liberty to furnish himself from any dealer, or borrow from the supplies of the school. At the end of each session he will be credited with those articles returned in good order, while the cost value of those destroyed will be deducted from his deposit. In the Drawing Department each student will be expected to furnish his own instruments and materials. In the Department of Shop Work the student will be expected to pay for the material used; the total cost for the entire course will not exceed sixty-five dollars. The student is advised not to make his purchases before coming to the Institute, as arrangements have been made by which the best articles can be had on advantageous terms. The fees are payable in advance, at the beginning of each term. Each student will be required on admission to make a deposit of ten dollars to meet incidental expenses, such as those for drawing materials or special chemical supplies. This deposit can only be withdrawn when he graduates or leaves the Institute. Boarding and commons will not be supplied in connection with the Institute; but board, on reasonable terms, may be readily secured in private families in the city, at a cost of from six to ten dollars a week.

SCHOLARSHIPS.—One scholarship each year is given to the graduate of the Stevens High School who passes the best examination at the end of the Spring Term. The candidates for these scholarships must have attended the regular course in the High School for at least one year and be in good standing. Three scholarships each year are given to such graduates from the public schools of Hoboken as are recommended by the officers of the same, provided such candidates pass successfully the regular examinations for admission to the Stevens Institute of Technology. A scholarship confers the privilege of attending the entire course of the Institute for four years, free of all charge for tuition, provided, of course, the student holding the scholarship keeps up in all cases with the standard of proficiency and good conduct required.

PRIZES.—A prize in Chemistry, known as the "Priestley Prize," in honor of the renowned discoverer of oxygen, was instituted in the year 1877, by means of funds contributed by Mr. William W. Shippen, Rev. S. B. Dod, President Henry Morton, and Prof. Leeds. The income, amounting to twenty-five dollars, is annually bestowed as a prize upon the student who has most distinguished himself in the department of chemistry during the current year. Mr. Wm. A. Macy has contributed one hundred dollars, the proceeds of which are to be awarded to that student entering the College from the public schools of Hoboken, who has the best standing at the end of the Freshman year.

The Course of Instruction—*Department of Mathematics and Mechanics.*—It is intended in this course to give the student such a thorough knowledge of the several branches of Mathematics as will enable him to use them advantageously in the investigation of Practical Problems. The Course for 1882-3 is arranged as follows:

First Year.—First Term—Trigonometry (Olney); Theory of Logarithms and Theory of Equations.
Second Term.—Co-ordinate Geometry (Wood).
Third Term.—Differential Calculus.

CLASS OF 1885.

Second Year.—Co-ordinate Geometry (Wood); Differential and Integral Calculus.

CLASS OF 1886.

Differential Calculus (continued), Integral Calculus, and Analytical Mechanics (Wood).

CLASS OF 1885.

Third Year—Analytical Mechanics (Wood), and Resistance of Materials (Wood)

CLASS OF 1886.

Analytical Mechanics (Wood); Resistance of Materials (Wood); and Theory of Bridges and Roofs (Wood).

CLASS OF 1885.

Fourth Year.—First Term.—Theory of Bridges and Roofs (Wood), and use of the Transit and Level.
Second Term—Graphical Statics.

CLASS OF 1886.

First Term.—Theory and use of the Transit and Level. Graphical Statics.

Department of Mechanical Engineering.—At the close of the second year the student will be prepared to enter upon the studies of the Department of Mechanical Engineering, which will occupy the principal portion of his time during the remainder of his course. The course of instruction in Mechanical Engineering will commence with lectures upon the nature of materials used in constructing, locating, and operating machinery; and the methods of obtaining them and preparing them for use, so far as such instruction is not included in the Course of Technical Chemistry. The uses to which each material is specially adapted are stated, the methods of testing their quality and preserving them from decay are described, while the principles and practical considerations involved in the application of tools to the working of each are exhibited in the work-rooms of the institute. A Course of Instruction in the Strength of materials follows, in which the laws determining the forms of greatest strength are deduced from experiment, and applied to the solution of such problems as arise daily in engineering practice. In the illustration of this portion of the Course, samples exhibiting the various qualities of each material are placed before the student for his inspection; models and drawings illustrate the methods of their preparations; and specimens of materials, wrought into their strongest forms, impress upon him the principles already learned of the strength of materials, and their application in design. The mathematical principles, and the theory of the strength of materials are taught in the Department of Mathematics. The course is continued by the study, from the text-book and lecture, of the Theory of Machinery, with detailed instructions in the use of tools and in designing machinery and mill work; care being taken to call the atteution of the student to such modifications in design as are dictated by difficulties in forging, pattern-making, moulding, finishing, and, "fitting-up." Finally, the course is completed by a series of lectures and lessons from text-books, treating of the prime movers, accompanied by exercises in planning and estimating the cost of machinery, mills, and manufactories. While studying heat engines, the steam engine is made a subject of special and extended investigation in its principles, and in the details of design, construction, and management, according to the best and most recent practice. Essays on professional subjects are written by the student at stated intervals during his course, in which he is expected to give concise and accurate statements of knowledge acquired by the course of reading accompanying his regular studies. In some instances, reports and opinions relating to the merits of mechanical devices, or to the economical performance of machinery, are demanded, as an exercise of essential importance.

Problems in design are presented to the student at intervals during the course, which are made, as far as possible, similar in character to those which meet the Mechanical Engineer most frequently in the practice of his profession. The student is informed of the exact result to be attained, and of the conditions necessary, and means available for reaching it. He is then expected to prepare his plans, and submit them to the Head of the Department, together with a report, oral or written, for criticism. A "graduating thesis" is demanded of the student at the close of his studies, in which he is expected to exhibit his proficiency, by designing and describing the construction and management of some machine, or in planning a manufacturing establishment, giving estimates of cost. The originals of these theses are retained at the Institute, and deposited among the manuscripts of its library.

THE MECHANICAL LABORATORY.—The Trustees have established a Mechanical Laboratory in connection with the Department of Mechanical Engineering. It is evident that a Laboratory for Technical Research, or a "Testing Laboratory," if properly organized, well equipped, and effectively operated, must be of exceptional value in the direct advancement of science, as well as in the promotion of purely technical interests. The officers of our important lines of railroad desire frequently to obtain dynamometric determinations of the resistance of trains, and of the efficiency of locomotives; to learn with precision the strength and the various other hardly less important characteristics of materials which it was proposed to use in construction; and to ascertain the value of fuel and of lubricating materials. Iron and steel makers are equally desirous of obtaining reliable and thoroughly accurate knowledge of the chemical constitution of their products, and of their physical structure and properties, and such knowledge of the relations existing between these two sets of qualities as can only be secured by careful comparison of the results of skilful and systematic investigation. Manufacturers of machinery, and constructors generally, are seriously in need of a recognized authority, to which they may send the materials purchased, or proposed to be purchased by them, with confidence that their qualities shall be carefully determined and their value ascertained, and that the deductions from experimental examination shall be intelligently made, uninfluenced by any private interest. Those members of the engineering profession who are engaged in general practice, constitute still another class of business men to whom such an institution would lend valuable aid; and, in fact, every business would derive, directly or indirectly, great advantage from its establishment. This plan gives to the country an institution such as has never before been organized, and one whose value will prove beyond estimation. The accumulation of facts, the valuable application of science, and the directly practical bearing of the work which may be done, will, in a comparatively short time, be productive of rich results. It will do most effectually that work which has hitherto been too much neglected—the application of scientific knowledge to familiar work and matters of business. It will do much to close up the space which so widely separates the man of business from the man of science, and will lead to a far more perfect system of mutual aid than has yet existed; it must also aid in the development of the natural resources of our country, stimulate the growth, in extent and perfection, of its most important industries, and contribute in many ways to the welfare of the people. The Trustees have placed at the disposal of the Director of the Mechanical Laboratory, for use where required, the machine shop and tools of the Institute, and a considerable amount of apparatus, including several testing machines, steam engine indicators, dynamometers, and other instruments, of a total value of about $5,000. They authorize the use of any available space within the buildings or upon the grounds, and set apart a strip of land adjacent to the buildings of the Institute, not exceeding 200 feet in length and 50 feet in breadth, upon which any new buildings required may be erected.

DEPARTMENT OF MECHANICAL DRAWING.—In the organization of the department of mechanical drawing, the object aimed at was to make the course of instruction thorough, practical, of direct utility, and comprehensive. The requirements of many of the industrial arts at the present day are such as to necessitate the delineation, not only of what already exists, but of what is yet to be made. Both demand a knowledge of the science of drawing, and the latter especially involves a certain exercise of the imagination, in order to form clear physical conceptions of the particular design in contemplation, not only in regard to its appearance as a whole, but as to the relations and proportions of its parts. This ability to form a vivid and distinct mental image, as well as to fix it permanently by accurate representations, though useful to all, is more emphatically so to the mechanical engineer, who is daily called on, not to copy what has been done, but to do what has not been. These considerations have been kept distinctly in sight in the conduct of this department; the matter taught and the method of teaching having been selected with the view of giving the student a firm grasp of underlying principles, of developing and strengthening his imaginative power, and of giving him direct practice in the application of both. The course adopted to attain these ends may be briefly outlined as follows: The foundation is laid by practice in the simple drawing of lines, in order to acquire facility in the manipulation of the instruments. The exercises selected are such as will be of subsequent use, arranged in a progressive order; beginning with geometrical constructions involving straight lines and circular arcs only, and ending with the more complex curves, such as the ellipse, helix, epicycloids, etc. Attention to symmetry, proportion and arrangement is enforced from the first, the diagrams not being copied, but constructed, mostly from rough sketches. Elementary studies of projection are then taken up, the method adopted being that of beginning by making the drawings of a solid object bounded by plane surfaces, such as a prism, in various positions, and proceeding by degrees to the similar treatment of more complex forms. The relation between the drawing and the thing drawn is more easily grasped at first, when the latter is not a mere abstraction, like a line or plane in space, but a definite and tangible object; and when the subject is presented in this manner, no difficulty is experienced with the simpler problems of intersection and development, which not only brings the imaginative faculty into play, but affords practical exercises of great utility. The next step is to the drawing of parts of machines from actual measurements. The student is at once set to work as a draughtsman; a part or the whole of some piece of mechanism is assigned to him, which he is to study, to measure, to sketch, and finally to draw; the requirement being, exactly as if he were employed in the drawing office of an engineering establishment, that he shall produce complete working plans, from which the original could be replaced were it destroyed. He thus acquires some knowledge of details, and is taught to observe closely, while at the same time his previously acquired skill and information are practically applied. Simultaneously with this, descriptive geometry is taken up as an abstract science, not as an ultimate object, but its practical applications being kept always in view, it is made a means to an end, and that end is the acquirement of such a mastery of the principles of drawing, that the student shall be able to cope with any problem when it arises in the course of his practice. The identity of the operations with those of Mechanical Drawing is never lost sight of, and the problems are frequently put in a practical form. This is not done exclusively, however, because they afford, in the abstract, the best possible exercise of the imaginative power. The study is continued in application to shades and shadows and to linear perspective; in connection with which the principles of aerial perspective, as applied to the shading of mechanical objects, are explained, and a little time is given to practice in the execution of finished drawings. But the ability to make elaborately shaded pictures is regarded as the least valuable of the qualifications of a mechanical draughtsman. However great his skill in this way may be, the accomplishment will serve him but little in his professional career if it be acquired at the expense of accuracy, or facility in the construction of working plans. Therefore, while it is designed to impart a thorough understanding of the principles involved in making such drawings, comparatively little time is devoted to their practical execution. The mechanical engineer plans machines, and these move; consequently the study of the laws of their motions is an important branch of his education; and it is properly given a place in this department, since to make the drawings of a piece of mechanism implies the making of them so that each part shall move in harmony with the rest, and the depth of engineering disgrace is reached when, through any oversight, one part interferes with another. This study might also, especially when the more complicated mechanical movements are considered, be regarded as a branch of applied mathematics of the higher order. But, however these laws may be investigated, this fact remains: that for the purposes of the draughtsman the results must be translated into his language and expressed in a graphic form—the ways of the analyst are not his ways, and the algebraic formula must be replaced by a diagram. Fortunately, however, the investigations may be made, at least as applied to by far the larger and more important part of the motions with which he has to deal, in his own language and by his own methods. In this part of the course, therefore, the geometry of mechanism is taught by graphical construction alone, practical exercises in the platting of mechanical movements, the drawing of the various forms of gearing, the construction of curves representing varied motion and the like, being introduced from time to time.

Further, the course includes some practice in actual planning. A subject being assigned or selected, the student proceeds to work it up as though already engaged in the active pursuit of his profession; making first a skeleton diagram of the movement, and sketching in the proposed arrangement of parts, he calculates the strength and proportion of these, thus making the design an exercise in the Departments of Engineering and Mathematics, modifying the original plan when it is found necessary to do so by the results of these calculations, then making drawings of each part in detail, and finally a general plan of the completed designs; a general supervision being exercised over the work while in progress, and hints and suggestions as to details and arrangement being made as occasion arises. It should be stated, also, that much care is taken throughout the course to form the habit of correct judgment in determining what drawings to make of any subject in hand, and how to arrange them most advantageously. Written instructions in regard to this are exceedingly meagre, and yet it is a very important matter. The object is to show the workman what to make and how to make it; and experience proves that it is very easy to produce drawings which are perfectly correct, and yet do not clearly illustrate the objects represented. Nothing facilitates the operations of the mechanic more than to have a set of working plans which are clear, easily read, and connectedly arranged, and it is almost as important that the draughtsman should know just what to draw, as that he should be able to draw it well. From the first to the last, therefore, the student is taught the necessity of exercising his judgment in this direction, as well as care and forethought in all that he does; in a word, he is led to put his brains into his fingers, and every precaution is taken to guard against the common and offensive heresy that Mechanical Drawing is a simple matter of rote and routine, and the draughtsman a mere animated machine, to which a mind is superfluous. Summarily, then, the object of the course is not merely to teach the student to read and write certain set phrases of the graphic language with ease and fluency, but to enable him to wield it with power and for a purpose. He is taught not so much to memorize as to compose; he is encouraged to think for himself, and to acquire vigor and facility by giving expression to new ideas; his practice during the course being made as nearly as possible to resemble that upon which he will enter at its close. It would be impossible to state in detail all that has been done in carrying out the design sketched above; but it is proper to mention some of the more meritorious pieces of practical work in this Department, executed by the students since its organization in 1871. The fact that some, coming well prepared from other institutions to complete their studies here, were able to undertake work of this description from the outset, gave at once an opportunity to test the working of the system proposed, which has been such, we think, as to entitle it to be considered fairly successful.

Department of Experimental Mechanics and Shop Work.—The "work shop" course of the Institute is intended to supply the student with a knowledge, as complete as possible, of the best existing appliances, methods, and processes necessary to the construction of such mechanical designs as the theoretical part of the Institute's course will enable him to originate. In accordance with this plan, the Institute is provided with a machine and carpenter shop, an iron and brass foundry, and a blacksmith's shop, in which the student is first sufficiently familiarized with the working of wood and metal, to enable him to recognize and appreciate differences in machines, tools, and methods of manipulation in founding and blacksmithing, after which he is taken to certain large manufacturing establishments, so selected as to enable him to see and examine, on a large scale, that with which the Institute's shops have afforded him familiarity in an elementary and limited degree. In accordance with this plan, a regularly organized inspection tour is undertaken with each class. The following are the outlines of the tours of the classes of 1882:

Inspection Tours of Class of 1882.—After a day spent at Iron Mines in observing the use of the Dipping Needle, Pumping, Hoisting and Rock Drilling Machinery, the Timbering and Blasting Processes, a day at the Bethlehem Iron and Steel and Zinc Works, Bethlehem, Pa., a day at the Wire Rolling Mills of the Trenton Iron Co., at Trenton, and visits to typical machine shops, an extended tour was made as follows: Left New York on New Haven boat from Peck Slip at 11.30 P. M., Wednesday, April 5th. Every one took his own means to be on board boat, where instructor had engaged sleeping quarters. Arrived at New Haven, 6 A. M., April 6th. Took train immediately for Hartford and breakfasted at Allyn House. Visited Pratt and Whitney Co. and Billings & Spencer Drop Forging Works, before dinner. After dinner at Allyn House, visited Hartford Engineering Company's Works, Colt's Armory and Machine Works, and Heating and Ventilating Plant in Hartford State House. Remained at Allyn House over night, took train to Willimantic where the Mills of the Willimantic Linen Company were visited in order to inspect two pair of Porter-Allen Engines running at very high speed, and also to observe the processes of spinning and weaving linen fabrics. Returned to Hartford at 11.30 A. M. Dinner at Allyn House. Left Hartford for Springfield at 2.12 P. M. Immediately upon arriving at Springfield, took train for Holyoke, where the Holyoke Water Power Constructions were inspected and a return was made to Springfield, where the night was spent at the Massasoit House. On the morning of April 8th, the Springfield Arsenal was visited. Left Springfield at 12.28 P. M., for Worcester. Visited Pond Tool Works and Worcester Free Institute. Left for Boston at 5 P. M. Arrived in Boston at 6 P. M., and put up at United States Hotel until Monday April 10th.

On the morning of April 10th, Boston & Albany R. R. for Watertown Arsenal to inspect large U. S. testing machine. Took dinner at arsenal, and took Fitchburg R. R. to Waltham Watch Works. Returned by Fitchburg road to Boston to United States Hotel. Tuesday, April 11th, visited Boston sewage engines and South Boston Iron Foundry at South Boston, and also the Massachusetts Institute of Technology. Left same day at 5.30 P. M., from Boston and Providence depot for Providence, arriving at Narragansett House to supper. Wednesday, April 12th, visited Brown Manufacturing Co. and Nicholson File Works in the forenoon, and the Cornish and Corliss five-cylinder pumping engines in the afternoon. Thursday, April 13th, visited Corliss Steam Engine Works in forenoon. Took dinner at Pawtucket and visited Pawtucket pumping engine in afternoon, returning by horse-cars to Providence to take steamboat train for New York at 7 P. M. Total Expense $40 per head. Following this a trip was made to Philadelphia, Chester, Edge Moor and Wilmington, to the Southwark Foundry, Cramp's and Roach's Ship Yard, Sellers & Co., Baldwin Locomotive Works, Ferris & Niles' Works, Bement's Works, Betts Machine Co.'s Works, Morris, Tasker & Co.'s Tube Mill, Edge Moor Iron Works, the Otto & Lange Gas Engine Works, and the Works of I. P. Morris & Co.

The course, as a whole, is divided into two main sections, viz.:

I. Carpenter work and wood turning, millwrighting and steam fitting, which are pursued by the Freshman Class during the three regular terms of the college year, and during the Preliminary Term.

II. Machinist work, blacksmithing, moulding and founding, and pattern making, which are pursued by the Sophomore Class during the Preliminary Term and three regular terms, and by the Junior Class during a portion of the regular terms. The student finishes the course in machinist work by being sent: 1. To two of the leading machine tool manufacturing establishments of the country, where he is required to prepare himself for examination upon a set of questions with which he is provided, regarding the various sizes, and the reasons for such variety of lathes, planers, and shapers, boring and drilling machines, and also regarding any general differences in the angles and rates of cutting of such tools as he has used here.

2. To a locomotive works, a rolling mill, three of our large iron works, and two marine engine works, where he will be required to acquire material for an examination upon a set of questions regarding the kind and size of tools and the methods used in the manufacture of certain large machinery.

Course of Experimental Mechanics.—This is a course given to the Senior Class during the Preliminary Term, and during a portion of the regular terms, which is intended to be supplementary to the work of the third year in Analytical and Applied Mechanics, Resistance of Materials and Heat, as well as preparatory to the study of the Steam Engine pursued during the regular term of the fourth year. It involves the following experimental tasks, at each of which a group of three or more members of a class are simultaneously engaged:

1. Dynamometrical Measurement of Power of Machine Tools.
2. Experimental determination of effects of different Fly Wheels upon steadiness of engine.
3. Determinations of Coefficients of Friction of Leather Belts and of Lubricants.
4. Comparison of Huntoon, Porter, Pickering and common Fly Ball Governors.
5. Test of Transverse Strength and Elasticity of Cast Iron, Wrought Iron, Wood and Brass.
6. Test of Tensile Strength and Elasticity of Cast Iron, Wrought and Steel.
7. Test of Compressive Strength of Cast Iron, Wrought Iron, and Stone.
8. Test of Shearing Strength of Wrought Iron.
9. Test of Torsional Strength of Cast Iron, Wrought Iron and Steel.
10. Test of Evaporative Power of Boilers, including Calorimetrical test of Quality of Steam, measurement of Temperature of Furnace and Chimney, and Pressure and Velocity of Draught.
11. Experimental determination of Total Heat of Combustion of Coal used in Boiler Test, and comparison of this heat with that computed from the analysis of the coal.
12. Measurement of effect of boiler covering in preventing radiation.
13. Measurement of Friction of Steam flowing through pipes.
14. Comparison of Velocity of flow of Steam experimentally determined, with velocity as computed from formulæ.
15. Comparison of Efficiency of Steam Pump and Injector.
16. Setting of Engine Valves with Link Motion and Independent Cut-off.

The Department of Physics.—This department offers the students every facility for the acquisition of a thorough knowledge of physics. During the *first year* the first term is given to the study of the general properties of matter and to inductive mechanics; the second term, to pneumatics and to the laws of vibratory motions and acoustics; the third term to light. In the *second year* the first term is occupied in the study of heat and meteorology; the second and third terms are spent in the study of magnetism and electricity. During the *third year* the Professor of Physics delivers lectures on the modes of making precise measures. He shows the application of these measures in the various departments of physics, and explains the construction, the methods of adjustment, and the manner of using instruments of precision. The *fourth year* the student spends in the physical laboratories, pursuing experimental investigations, schedules of which are prepared for him by the Professor of Physics. In the organization of the Department of Physics, two objects were sought: *First*, to give thorough instruction to the students by means of lectures and recitations on general physics, aided by the most perfect illustrations, followed by practical experimental work in the physical laboratory; and *secondly*, to advance knowledge in this department of science by original researches, conducted by the Professor of Physics. This mode of work has been of eminent service to the student, by causing a lively interest in his studies, as he verifies and extends, by his laboratory experiments, the knowledge which he had previously derived from lecturers and text-books. The extensive cabinet of instruments which the Institute possesses affords the student advantages which are nowhere excelled. It would be proper to state in this connection, that the facilities of the laboratories and cabinets of the Institute will be extended to advanced students who may wish to avail themselves of such means in carrying out their investigations, on such conditions as may be determined by arrangement in each special case.

Department of Chemistry.—The material employed for purposes of instruction in this department, while embracing too great a variety of substances and apparatus to be particularly described, may be conveniently summarized under its most important heads:

First.—Apparatus for purposes of demonstration and for teaching, by means of lecture illustration, the principal topics of general and applied chemistry. This includes the various forms of apparatus, designed by Hofmann and others, for elucidating the doctrines of modern chemistry.

Second.—Materials for qualitative, volumetric, and quantitative analysis, including standard solutions and apparatus for the determination of weight and volume, which have been carefully calibrated and adjusted. As part of this material, should be mentioned, a cabinet of somewhat more than 5,000 specimens of the principal ores, minerals and rocks.

Third.—Instruments of precision, employed in the graduation of eudiometers, the measurement of crystals, in the operations of gas analysis, etc. The study of chemistry is begun by instruction in the subject of chemical physics, in the laws of chemical combination, and in the principles involved in the determination of atomic and molecular weights. This is followed by the study of chemical notation and nomenclature, with practice in stoichiometry. Afterward, the subject of chemical structure is taken up, along with an examination of the chemical and physical properties of bodies, as far as is involved in their identification and chemical classification. Instruction in these general principles is accompanied by a course of lectures, the chief object of which is to supply the experimental demonstrations required. In the third year, the student enters upon a course of laboratory practice. He begins by acquainting himself with the properties and reactions of the elements, and their most generally occurring compounds. Then he proceeds to the examination of more or less complex minerals and artificial mixtures. This course of qualitative analysis is continued, until it is believed that the student should have no difficulty in ascertaining the composition of any ordinary mineral substance. Practice is likewise given in the examination of ores, with instruction in the chemistry of metallurgical processes. Finally, it is required to understand the methods involved in quantitative analysis, both gravimetric and volumetric, and to determine the percentage composition of certain salts and common minerals.

The course laid down above is to be pursued by students proposing to obtain the degree of Mechanical Engineer. For those desirous of fitting themselves for the profession of chemistry, the time devoted to work and instruction in the laboratory is greatly extended at the beginning of the third year. The number and variety of the substances which are required to be analyzed are much increased, and it is expected that a student shall become qualified to analyze all the ordinary minerals and chemicals, and the most important technical products. In addition, some acquaintance with the methods employed in organic analysis is imparted. A reasonable amount of proficiency in the various lines of work indicated will be required in order to obtain the degree of Bachelor of Philosophy. If, after this has been conferred, a research be undertaken, with the result of discovering new and important chemical compounds, or of adding materially to the store of precise information concerning the properties of bodies previously known, or of originating or perfecting some important chemical method, and a thesis, embodying these results, be prepared and submitted to the Faculty, the student will be eligible to the further degree of Doctor of Philosophy. Special arrangements will be made for these advanced courses of study, which, however, in all cases, must be prosecuted with the approbation and under the direction of the head of the department.

SHEFFIELD SCIENTIFIC SCHOOL, YALE COLLEGE, NEW HAVEN.

THE Sheffield Scientific School is devoted to instruction and researches in the mathematical, physical, and natural sciences, with reference to the promotion and diffusion of science, also to the preparation of young men for such pursuits as require especial proficiency in these departments of learning. It is one of the Departments of Yale College, like the law, medical, theological, and art schools, having its separate funds, buildings, teachers, and regulations, but governed by the Corporation of Yale College, which appoints the professors and confers the degrees. It is, in part, analogous to the academic department, or classical college, and, in part, to the professional schools. The instruction is intended for two classes of students:—

I. Graduates of this or of other Colleges, and other persons qualified for advanced or special scientific study.

II. Undergraduates who desire a training chiefly mathematical and scientific, in less part linguistic and literary, for higher scientific studies, or for various other occupations to which such training is suited.

The School was commenced in 1847. In 1860, a convenient building and a considerable endowment were given by Joseph E. Sheffield, Esq., of New Haven, whose name at the repeated request of the Corporation of Yale College, was afterward attached to the foundation. Mr. Sheffield has since frequently and munificently increased his original gifts. In 1863, by an act of the Connecticut Legislature, the national grant for the promotion of scientific education (under the congressional enactment of July, 1862) was given to this department of Yale College. Since that time, and especially since the autumn of 1869, numerous liberal gifts have been received from the citizens of New Haven, and from other gentlemen in Connecticut, New York, and St. Louis, for the endowment of the School, and the increase of its collections. The action of the State led to the designation by law of a State Board of Visitors, consisting of the Governor, Lieutenant-Governor, three senior Senators, and the Secretary of the State Board of Education; and this Board, with the Secretary of the Scientific School, is also the Board for the appointment of students to hold the State scholarships. At the request of the Governing Board, the Corporation of Yale College has also appointed a Board of Councillors for the School, consisting of a number of gentlemen who have taken a deep interest in its welfare. The Governing Board consists of the President of Yale College and the Professors who are permanently attached to the School. There are several other instructors associated with them, a part of whom are connected with other departments of the College.

Buildings and Apparatus.—The two buildings in which the work of instruction in the Scientific School is mainly carried on are called Sheffield Hall and North Sheffield Hall; but instruction in Mineralogy, Geology, and Biology, including Zoölogy and Comparative Anatomy, is now given entirely in the Peabody Museum. These halls contain a large number of recitation and lecture rooms, a hall for public assemblies and lectures, chemical and metallurgical laboratories, a photographical room, an astronomical observatory, museums, a library and reading room, besides studies for some of the professors, where their private technical libraries are kept. The following is a summary statement of the collections belonging to the School.

1. Laboratories and Apparatus in Chemistry, Metallurgy, Physics, Photography and Zoology.

2. Metallurgical Museum of Ores, Furnace Products, etc.
3. Agricultural Museum of Soils, Fertilizers, useful and injurious insects, etc.
4. Collections in Zoology.
5. Astronomical Observatory, with an equatorial telescope by Clark and Sons of Cambridge, a meridian circle, etc.
6. A Collection of Mechanical Apparatus, constituting the "Collier Cabinet."
7. Models in Architecture, Geometrical Drawing, Civil Engineering, Topographical Engineering, and Mechanics; diagrams adapted to public lectures; instruments for field practice.
8. Maps and Charts, topographical, hydrographical, geological, etc.

The herbarium of Professor Brewer, and the astronomical instruments of Professor Dyman, are deposited in the buildings. Professor Eaton's herbarium, near at hand, is freely accessible. Students also have access to the various laboratories and collections in Natural Science in the Peabody Museum.

Students are also admitted, under varying conditions, to the College and Society Libraries, the College Reading Room, the School of the Fine Arts, and the Gymnasium.

Library.—The special technical library of the Scientific School consists of about five thousand volumes. Included in this is the "Hillhouse Mathematical Library" of twenty-four hundred volumes, collected during a long series of years by Dr. William Hillhouse, and in 1870 purchased and presented to the Institution by Mr. Sheffield. A catalogue of this collection forms a supplement to the Annual Report of the Governing Board for 1870. All the prominent scientific journals of this country and of Europe, together with the proceedings of foreign academies, and of scientific societies, can be found either in this library or in the College Library, to which students have access.

Instruction for Graduates and Special Students.—Persons who have gone through undergraduate courses of study, here or elsewhere, may avail themselves of the facilities of the School for more special professional training in the physical sciences and their applications, gaining in one, two, or three years the degree of Bachelor of Philosophy, or, in two additional years of Engineering study, that of Civil Engineer, or of Dynamic Engineer. Or, engaging in studies of a less exclusively technical character, they may become candidates for the degree of Doctor of Philosophy. The instruction in such cases will be adapted to the particular needs and capacities of each student, and may be combined with that given by the graduate instructors in other departments of the University. This degree is conferred upon those who, having already taken a Bachelor's degree, engage as students in the Department of Philosophy and the Arts for not less than two years in assiduous and successful study. It is not given upon examination to those whose studies are pursued elsewhere. The requirements for it will in some cases exact of the student more than two years of post-graduate labor; so, especially, wherever the course of undergraduate study has been, as in the Scientific School, of less than four years. The candidate must pass a satisfactory final examination, and present a thesis giving evidence of high attainment in the branches of knowledge to which he has attended. A good knowledge of Latin, German and French will be required in all cases, unless, for some exceptional reason, the candidate be excused by the Faculty. The graduation fee is ten dollars.

Subjects likely to receive special attention are suggested as follows:—Professor Norton will instruct in applied mechanics and in spherical astronomy. Professor Lyman, in the use of meridional and other astronomical instruments. Professor DuBois, in the principles of thermodynamics, and utilization of heat as a source of power. Professor Brush, in the analysis and determination of mineral species, and in descriptive mineralogy. Professor Johnson, in theoretical, analytical, and agricultural chemistry. Professor Brewer, in agriculture and forest culture, in the use of the microscope, and in physical geography. Professor Clark, in definite integrals, differential equations, analytical mechanics, the theory of numerical approximation, and the method of least squares. Professor Eaton, in structural and systematic botany, with reference to both flowering and cryptogamous plants. Professor Allen, in analytical chemistry, and in metallurgy. Prof. Verrill, and Prof. Smith, in zoology and geology. The same courses of study are open, for a longer or shorter time, to graduate students who do not desire to become candidates for a degree.

Students who have taken the degree of Bachelor of Philosophy, may obtain the degree of CIVIL or of DYNAMIC ENGINEER at the end of two academical years, by pursuing the following higher course of study and professional training.

The course of study for the degree of CIVIL ENGINEER will comprise—

1. Higher Calculus. Higher Geometry. Theory of Numerical Operations.
2. Analytical Mechanics. Mechanics applied to Engineering.
3. A Course of Construction and Design. Projects.
4. Practical Astronomy, with use of instruments, computations, etc.

This course will occupy one year.

To secure the requisite amount of professional knowledge and practice, the candidate will be required to furnish a comprehensive report of the results of an examination into the existing condition of some special line of constructive art; or to present proper evidence that he has had actual charge in the field, for several months, of construction or surveying parties, or held some responsible position deemed equivalent to this. An elaborate design must also be submitted of some projected work of construction, based upon exact data obtained from careful surveys made by the candidate, and comprising all the requisite calculations, and the necessary detailed drawings, and accompanied by full specifications of the work to be done, and the requirements to be met by the contractor. The fee for this degree is five dollars. The course of study for the degree of DYNAMIC ENGINEER will comprise—

1. Higher Calculus. Higher Geometry. Theory of Numerical Operations.
2. General Principles of Dynamics (Analytical Mechanics), including special application of these Principles to Dynamical problems.
3. Construction of Machines. Designs.
4. Preparation of theses on special subjects in Dynamic Engineering.

During the second year candidates will be permitted to employ such a portion of their time as may be deemed advisable or necessary in the examination of engineering works and manufacturing establishments, and may also have the privilege of entering upon professional practice, provided it is done with the knowledge and consent of the Professor of Dynamic Engineering, and under such circumstances as shall appear to him to be favorable to professional progress. An elaborate thesis on some professional subject, with an original design, or project, accompanied by proper working drawings, will be required at the end of the second year. The fee for this degree is five dollars.

SPECIAL STUDENTS.—For the benefit of those who, being fully qualified, desire to pursue particular studies without reference to the obtaining of a degree, special or irregular students are received in most of the departments of the School; not, however, in the Select Course or in the Freshman Class. It should be distinctly understood that these opportunities are not offered to persons who are incompetent to go on with regular courses, but are designed to aid those who, having received a sufficient preliminary education elsewhere, desire to increase their proficiency in special branches.

Requirements for Admission.—TERMS OF ADMISSION.—Candidates must be not less than fifteen years of age, and must bring satisfactory testimonials of moral character from their former instructors or other responsible persons. For admission to the Freshman Class the student must pass a thorough examination in the following subjects:

English.—Including grammar, spelling, and composition. In grammar, Whitney's Essentials of English Grammar, or an equivalent.

History of the United States.

Geography.

Latin.—(1.) Simple exercises in translating English into Latin. (Smith's "*Principia Latina,*" Part I, or the First and Second Latin Books of the Ahn-Henn Latin Series, are named as indicating the nature and extent of this requirement, and an acquaintance with one of these works will be required unless some satisfactory substitute is offered. In the last-named course one-third of each exercise may, if desired, be omitted.) (2) Cæsar—six books of the Gallic War, or their equivalent. (As advantageous substitutes for the last three books of Cæsar may be suggested three books of Virgil's Æneid, or a similar quantity of Ovid.)

Arithmetic.—Fundamental Operations, Least Common Multiple, Greatest Common Divisor, Common and Decimal Fractions, Denominate Numbers, including the Metric System of Weights and Measures; Percentages, including Interest, Discount, and Commission; Proportion, Extraction of the Square and Cube Roots.

Algebra—Fundamental Operations, Fractions, Equations of the First Degree, with one or several unknown quantities; Inequalities, Ratio and Proportion, Involution, including the Binomial Formula for an entire and positive Exponent; Evolution, the Reduction of Radicals, Equations of the Second Degree, Progressions, Permutations and Combinations, the Method of Indeterminate Coefficients, Fundamental Properties of Logarithms, Compound Interest.

Geometry—Plane, Solid, and Spherical; including fundamental notions of Symmetry, and examples of Loci and Maxima and Minima of Plane Figures.

Trigonometry—Including the Analytical Theory of the Trigonometrical Functions, and the usual formulæ; the Construction and Use of Trigonometrical Tables; and the Solution of Plane Triangles; so much, for example, as is contained in Wheeler's Plane Trigonometry (Boston, 1877), or Richards's Plane Trigonometry (New York, 1878). While no entrance examination is held in the *History of England*, candidates for admission are urgently advised to make themselves as familiar as possible with that subject; as a knowledge of it is essential to the most successful prosecution of some of the studies of the course. Candidates will be allowed the option of passing on the above-named subjects in two successive years. In such a case they must present themselves for examination at the June examination of the first year in the following subjects or parts of subjects: *History of the United States, Geography, Arithmetic, Plane Geometry, Algebra to Quadratic Equations.* In order to have this preliminary examination counted, candidates must pass satisfactorily on *all* the subjects; and notice must be given of the intention to divide the examination to Professor G. J. Bush, Executive Officer of the School, on or before June 15.

For preparation in Algebra and Geometry the recently published text-books of Professor Newcomb on these subjects, may, without indicating undue preference, be especially recommended. And to the candidate who prepares in other works, they may serve to indicate the extent and kind of attainments expected in the prescribed topics. Candidates who prepare in the Geometry of this author, may for the present omit the short chapters on the Ellipse, Hyperbola, and Parabola; though they will find it advantageous to study them. In his preparation in GEOMETRY the candidate should, as far as practicable, have suitable exercises in proving simple theorems and solving simple problems for himself. It is important, too, that he should be accustomed to the numerical application of geometric principles, and especially to the prompt recollection and use of the elementary formulæ of mensuration. In TRIGONOMETRY he should be exercised in applying the usual formulæ to a variety of simple reductions and transformations, including the solution of trigonometrical equations. Readiness and accuracy in trigonometrical calculations are also of prime importance to the candidate. If the use of logarithms is postponed in his preparation till Trigonometry is taken up (which is by no means necessary or advisable), he should then have abundant applications of them to all forms of calculation occurring in ordinary practice, as well as those appearing in the solution of triangles. Finally, in all of his calculations, he should study the art of neat and orderly arrangement. In LATIN the student should have such continued training in parsing as shall make him thoroughly familiar with declensions and conjugations, and with the leading principles of Syntax. To secure these results more effectually, the requirement has been adopted of simple exercises in translating English into Latin. As this course of exercises is designed solely as a preparation for reading, it should be begun at the earliest stage of Latin study. A very large proportion of the deficiencies in the Latin examination for several years past has been due to the neglect of the suggestions of this paragraph, and to attempt to read a Latin author with totally inadequate grammatical preparation. The examination for admission takes place at North Sheffield Hall, on Tuesday and Wednesday, September 12, 13, 1882. Opportunities for private examinations, may, in exceptional cases, be given at other times. Candidates for advanced standing in the undergraduate classes are examined, in addition to the preparatory studies, in those already pursued in the class they wish to enter. No one can be admitted as a candidate for a degree, later than at the beginning of the Senior year.

THE COURSES OF INSTRUCTION, occupying three years, are arranged to suit the requirements of the various classes of students. The first year's work is the same for all; for the last two years the instruction is chiefly arranged in special courses. The special courses most distinctly marked out are the following:

(*a.*) In Chemistry; (*b.*) In Civil Engineering.
(*c.*) In Dynamical (or Mechanical) Engineering;
(*d.*) In Agriculture; (*c.*) In Natural History:
(*f.*) In Biology preparatory to Medical Studies;
(*g.*) In Studies preparatory to Mining and Metallurgy;
(*h.*) In Select studies preparatory to other higher studies.

The arrangement of the studies is indicated in the annexed scheme.

FRESHMAN YEAR.—Introductory to all the Courses:—First Term—*German*—Whitney's Grammar and Reader. *English*—Lounsbury's History of the English Language; Exercises in composition. *Mathematics*—Plane Analytical Geometry. *Physics*—Atkinson's Ganot, with experimental lectures. *Chemistry*—Recitations and Laboratory practice. *Elementary Drawing*—Practical Lessons in the Art School.

Second Term—*Language, Physics, and Chemistry*—as stated above. *Mathematics*—Spherical Trigonometry (Wheeler's); Elements of Mechanics. *Physical Geography*—Lectures. *Botany*—Elementary, with Lectures. *Drawing*—Isometric drawing, with application to drawing from models and structures by measurement. Shading and tinting. Principles of orthographic projection. Reading of working drawings and isometric construction of objects from their orthographic projections. Sections.

For the Junior and Senior years the students select for themselves one of the following courses:

(a.) IN CHEMISTRY—*Junior Year*—First Term—*Theoretical Chemistry*—Lectures and Recitations. *Qualitative Analysis*—Fresenius's. *Laboratory Practice. Blowpipe Analysis. German. French.*

Second Term—*Laboratory Practice*—Qualitative Analysis, and experimental work in Organic Chemistry. *Mineralogy*—Blowpipe Analysis and determination of species. Lectures. *French. German.*

SENIOR YEAR—First Term—*Organic Chemistry*—Lectures and Recitations. *Agricultural Chemistry*—Recitations (optional). *Laboratory Practice*—Volumetric and Mineral Analysis. *Geology*—Dana's. *Zoology*—Lectures. *French.*

Second Term—*Laboratory Practice*—Analysis of Minerals and Technical Products. *Assaying* (optional). *Geology*—Dana's Manual. *Metallurgy* (optional) *Mineralogy* (optional). *French.*

(b.) IN CIVIL ENGINEERING—*Junior Year*—First Term—*Mathematics*—Analytical Geometry of Three Dimensions; Elements of the Theory of Functions; Numerical Equations; Differential Calculus. *Surveying*—Field Operations. *Drawing*—Descriptive Geometry, begun. *German. French.*

Second Term—*Mathematics*—Integral Calculus. Rational Mechanics. *Drawing*—Descriptive Geometry, concluded. Topographical. *Surveying*—Topographical. *German. French.*

SENIOR YEAR—First Term—*Field Engineering*—Laying out Curves. Location of Line of Railroad, with calculations of Excavation and Embankment. Henck's Field Book for Railroad Engineers. *Civil Engineering*—Resistance of Materials. Bridges and Roofs, begun. Stone Cutting, with Graphical problems. *Geology*—Dana's. *Mineralogy*—Blowpipe Analysis and Determinative Mineralogy. *French.*

Second Term—*Civil Engineering*—Bridges and Roofs. Building Materials. Stability of Arches and Walls. Mahan's Civil Engineering. *Dynamics*—Principles of Mechanism. Steam Engine. *Hydraulics*—Hydraulics and Hydraulic Motors. *Drawing*—Graphical Statics. *Astronomy*—Loomis's Astronomy with practical problems. *Mineralogy.*—Continued. *Geology*—Dynamic. *French.*

(c.) IN DYNAMIC ENGINEERING—*Junior Year*—First Term—*Mathematics*—Analytical Geometry of Three Dimensions; Elements of the Theory of Functions; Numerical Equations; Differential Calculus. *Surveying*—Field Practice. *Drawing*—Descriptive Geometry, begun. *German. French.*

Second Term—*Mathematics*—Integral Calculus. Rational Mechanics. *Kinematics*—General Theory of Motion and Principles of Mechanism; Elementary Combinations of Pure Mechanism; Pulleys and Belts; Gearing and forms of teeth for Wheels; Parallel Motions. *Drawing*—Descriptive Geometry, concluded. *German. French.*

Senior Year—First Term—*Statics*—Application of the Principles of Statics to Rigid Bodies; Elasticity and Strength of Materials; Forms of Uniform Strength; Stability of Structure; Construction of Roof Trusses, Girders, and Iron Bridges. *Machine Drawing*—Bolts and Nuts; Riveting; Journals, Axles, Shafts, Couplings, Pillow Blocks; Shaft-hangers, Pulleys; Connecting Rods and Cranks; Cross-Heads; Pipe connections; Valves; Steam Cylinders; Stuffing Boxes, Glands, etc. Shop Visits. *Blowpipe Analysis. French.*

Second Term—*Hydrostatics and Hydrodynamics*—Equilibrium and Pressure of fluids: Hydrometers, Manometers, Gauges, etc.; Water Pressure Engines and Water Wheels; Construction of Water Reservoirs and Conduits; Measurement of Water Supply; Discharge of Pipes. *Thermodynamics*—General principles of Heat employed as a source of power; Theory of the Steam Engine; Hot Air Engines; Gas Engines. *Machine Designing*—Proportioning of Machine Parts, continued. Designing of Hoisting Engines; Shearing and Pumping Engines; Complete working drawings for a high speed Steam Engine. Shop Visits and Reports. *Metallurgy.*

IN STUDIES PREPARATORY TO MINING AND METALLURGY:—Young men desiring to become Mining Engineers, can pursue the regular course in Civil or Mechanical Engineering, and at its close can spend a fourth year in the study of Metallurgical chemistry, mineralogy, etc.

(b) IN THE SELECT STUDIES PREPARATORY TO OTHER HIGHER STUDIES:—*Junior Year.*—FIRST TERM—*Mineralogy* — Blowpipe Analysis and Determinative Mineralogy. *Astronomy. English*—Early English. *History*—Green's Short History of the English People. *French. German.*

SECOND TERM—*Mineralogy*—Lectures. *Physical Geography*—Guyot; Lectures. *Botany*—Lectures; Excursions; Laboratory Practice. *English*—Chaucer, Bacon, Shakspere. *History*—Green's History, continued; History of the United States. *German. French.*

Senior Year.—FIRST TERM.— *Geology*—Recitations and Excursions. *Zoology*—Lectures and Excursions. *Linguistics*—Whitney's Life and Growth of Language. *English*—Shakspere. *Constitutional Law of the United States. French.*

SECOND TERM—*Geology*—continued. *Meteorology*—Lectures. *Political Economy*—Recitations and Lectures. *English*—Shakspeare, Milton, Dryden, Pope, Gray, and later authors. *French.*

Exercises in English Composition are required during the entire course from all the students. The preparation of graduating theses is among the duties of the Senior Year. Lectures on Military Science and Tactics are annually given by General Abbot, and other officers of the Engineer Corps of the United States Army.

Drawing.—The course in Drawing extends through the three years. During the first term of the Freshman year, the students practice free-hand drawing at the Art School building, under the direction of Professor Niemeyer, of the Yale School of the Fine Arts. After the Completion of the course in free-hand drawing, instruction is given by Mr. F. R. Honey, during the second term in the elementary principles of instrumental drawing, embracing Elementary projection drawing, Isometric drawing, and Descriptive Geometry as far as Warped Surfaces. This course is obligatory upon all. During the Junior and Senior years, instruction in drawing is obligatory only on the students in Civil and Mechanical Engineering. In the former year the system of instruction embraces shades and shadows, tinting, perspective, and warped surfaces. By this method all the problems in Descriptive Geometry are required to be worked out on the drawing-board instead of the black-board. The course extends through the entire year, and is under the direction of Mr. Honey. In Senior year, students are required to apply the principles of drawing already obtained to works of construction, under the general supervision of the Professors of Civil and of Dynamic Engineering.

METHODS OF INSTRUCTION.—The instruction of this institution is given chiefly in small class rooms, in connection with recitations and by familiar lectures, illustrated by the apparatus at the command of the various teachers. In many studies weekly excursions are made for the purpose of collecting specimens and examining natural phenomena. In Chemistry and Metallurgy the students work several hours daily in well-appointed laboratories, under the direct superintendence of the instructors, and are guided through systematic courses of quantitative and qualitative analysis, assaying, and the blow-pipe determination of minerals and ores.

In Geology excursions are made for the purpose of examining geological phenomena and making special collections of rocks and minerals. Each student is required to pass a satisfactory examination on his collections at the end of the first term of Senior year. In Civil Engineering the students, besides attending on Class recitations and lectures, pursue a systematic course of exercises in the different branches of Geometrical Drawing and Graphical Statics, and in the application of the principles of drawing to works of construction; and have good practice in the operations of Surveying and Field Engineering—acquiring facility in the use and adjustment of Surveying and Engineering Instruments. In Topographical Surveying they are instructed in the use of the Plane Table for topographical work, and are required to prepare a detailed chart of the ground surveyed—exhibiting the contour lines and all its topographical features. Numerous problems of computation, and graphical exercises, are included in the Course of Construction pursued in the Senior year. A course of Blowpipe Analysis is also taken by the Senior Class, that a more thorough knowledge may be gained of minerals and building stones.

In Dynamic Engineering the method of instruction is by recitation and lectures, supplemented by work in the drawing room, by shop visits, and visits of inspection in and out of the city, and by tests with the indicator and dynamometer. The lectures are illustrated by models, by large cartoons adapted for the purpose, and by the complete collection of working drawings of the Novelty Iron Works, owned by the School. In the drawing room, detailed working drawings of various machines are made. A general sketch of the proposed machine is given and complete detailed drawings are required, in proper shape for the pattern-maker or machinist. The student is taught the best practice, and his judgment is trained in choosing relative proportions. The student is required to describe the steps to be followed in building the machine, and to make as nearly as possible an estimate of its cost. Pattern, foundry, blacksmithing and machine work are studied in detail. In the visits, machinery and processes are critically examined in detail, and sketches of important machines with written descriptions are required. In addition to the above, a course of lectures is given every winter by the professors of the schools and others, on topics of popular interest.

Tuition Charges.—The charge for tuition for undergraduate students is $150 per year, payable, $55 at the beginning of the first and of the second term, and $40 at the middle of the second term. The student in the Chemical course has an additional charge of $70 per annum for chemicals and use of apparatus. He also supplies himself at his own expense with gas, flasks, crucibles, etc., the cost of which should not exceed $10 per term. A fee of $5 is charged members of the Freshman Class for chemicals and materials used in their laboratory practice, and the same fee is required from all (except Chemical students) who take the practical exercises in Blow-pipe Analysis and Determinative Mineralogy. A fee of $5 a term will also be charged to the students in the Zoological laboratory, for materials and use of instruments. An additional charge of $5 is annually made to each student for the use of the College Reading Room and Gymnasium. For graduate students the charge for tuition is $100 per year.

Church Sittings.—Free sittings for students in this department of Yale College are provided as follows: in the Central Church (Congr.); in the Trinity (Episc.); and in the First Methodist Church. Those who prefer to pay a sitting for a year, more or less, in the churches above mentioned, or in any other church of any denomination, will be aided on application to the Secretary of the School. Sittings in the Gallery of the College Chapel are free as heretofore to the students of this department.

Faculty and Assistants.—*President:* Rev. Noah Porter, D.D., LL.D. *Chairman and Executive Officer:* George J. Brush. *Professors:* (arranged in the order of their graduation) William A. Norton, Civil Engineering. Chester S. Lyman, Physics and Astronomy, Theoretical and Practical. William D. Whitney, Linguistics and French. George J. Brush, Mineralogy. Samuel W. Johnson, Theoretical and Agricultural Chemistry. William H. Brewer, Agricultural (Norton Professor). John E Clark, Mathematics. Daniel C. Eaton, Botany. Thomas R. Lounsbury, English. Oscar D. Allen, Analytical Chemistry and Metallurgy. Addison E. Verrill, Zoology and Geology. Sidney I. Smith, Comparative Anatomy. William G. Mixter, Chemistry. A. Jay Dubois, Dynamical Engineering (Higgin Professor). Henry W. Farnam, Political Economy and History. Albert S. Wheeler, German. Mark Bailey, Elocution. John H. Niemeyer, Professor in Yale School of Fine Arts, Free Hand Drawing. Frederick R. Honey, Descriptive Geometry and Projection Drawing. Herbert Miller, French. Thomas W. Mather, Kinematics and Machine Design. Allen B. Howe, Analytical Chemistry. Russell H. Chittenden, Physiological Chemistry. Charles Hildebrand, Mathematics. Samuel L. Penfield, Mineralogy. Marcus D. Munn, Analytical Chemistry.

Degrees.—Students of this department, on the recommendation of the Governing Board, are admitted by the Corporation of Yale College to the following degrees. They are thus conferred: 2. *Civil Engineer and Dynamical Engineer.*

Calendar.—September 12, 13, 1882, Tuesday, Wednesday, Examination for admission; September 14, 1882, Thursday, first term begins; December 21, 1882, first term ends.

LAWRENCE SCIENTIFIC SCHOOL, HARVARD UNIVERSITY, CAMBRIDGE, MASSACHUSETTS.

THE Lawrence Scientific School of Harvard College offers a complete course of instruction in various departments of science training. The faculty is as follows: Charles W. Eliot, LL. D., President; Henry L. Eustis, A. M., Dean and Professor of Engineering; Joseph Lovering, LL. D., Professor of Mathematics and National Philosophy; Josiah D. Whitney, LL. D., Professor of Geology; Wolcott Gibbs, M. D., LL. D., Professor of Physics; Josiah P. Cooke, A. M., Professor of Chemistry and Mineralogy, and Director of the Chemical Laboratory; James M. Pierce, A. M., Professor of Mathematics; George L. Gondale, A. M., M. D., Professor of Botany, and Director of the Botanic Garden; Charles H. Moore, Instructor in Drawing and Principles of Design; Nathaniel S. Shaler, S. D., Professor of Palæontology; John Trowbridge, S. D., Professor of Physics; William G. Farlow, A. M., M. D., Professor of Botany; William James, M. D., Assistant Professor of Philosophy; Charles L. Jackson, A. M., Professor of Chemistry; William M. Davis, M. E., Instructor in Geology; Henry B. Hill, A. M., Assistant Professor of Chemistry; Walter Faxon, A. B., S. D., Assistant Professor of Zoölogy; Edward L. Mark, Ph. D., Instructor in Zoölogy; Harry B. Hodges, Instructor in German; Francis W. Dean, S. B., Tutor in Engineering. Assistants, Leonard P. Kinnicutt, S. B., Assistant in Chemistry; William H. Melville, Ph. D., Assistant in Mineralogy; Charles F. Mabery, S. D., Assistant in Chemistry; Harold Whiting, A. M., Assistant in Physics; John Eliot Wolff, A. B., Assistant in Geology; Henry Champion Jones, A. M., Assistant in Botany; Charles Henry Morss, A. B., Assistant in Biology; Charles Robert Sanger, A. B., Assistant in Organic Chemistry.

Courses of Instruction—*I. Civil and Topographical Engineering—Spherical Trigonometry and Analytic Geometry*—Wheeler's and Howison's.—Lectures. Additional examples. Five times a week. Mr. Dean.

Descriptive Geometry and Perspective—Church's. Three times a week. Prof. Eustis.

Elementary Physics—One lecture a week. Prof. Lovering.

Surveying, Plotting, and Topographical Drawing—Gillespie's Land Surveying.—Gillespie's Higher Surveying.—Field-work. Seven hours a week. Mr. Dean.

Mechanical Drawing—Six hours a week. Mr. Dean.

SECOND YEAR—*Differential and Integral Calculus* - Church's, with numerous additional examples. Five times a week. Prof. Eustis.

Elementary Physics—One lecture a week. Prof. Lovering.

Elementary Chemistry—(Twenty lectures). Once a week. Prof. Jackson.

German—Sheldon's Grammar.—Translation from German into English, and Elementary Exercises in translating into German. Three times a week. Messrs. Sheldon and Lutz.

(Required of students who did *not* offer German at their examination for admission.)

French—Brachet (Grammaire francaise).—Bocher's Reader.—French Prose. Three times a week. Asst. Prof. Jacquinot.

(Required of students who did *not* offer French at their examination for admission.)

Mechanical Drawing—Six hours a week. Mr. Dean.

Levelling, Topographical Drawing—Searle's Field Engineering—Wellington's Economic Theory of the Location of Railways. Six hours a week. Mr. Dean.

THIRD YEAR.—*Mechanics.*—Weisbach's Mechanics.—Wood's Bridges and Roofs. Five times a week. Prof. Eustis.

French—French Novels and Plays.—Exercises in Conversation and Composition. Three times a week. Asst. Prof. Jacquinot.

German—German Plays, Stories, and Essays.—Advanced Grammar. Three times a week. Asst. Prof. Cook.

Mechanical Drawing—Four hours a week. Mr. Dean.

Free-hand and Water-color Drawing—Four hours a week. Mr. Moore.

FOURTH YEAR—*Applied Mechanics and Constructive Engineering.* Building Materials, and their applications in Railroads, Canals, Bridges, etc.—Graphical Statics.—Hydraulics.—Discussions of existing structures and working out of projects.—Rankine's Applied Mechanics and Rankine's Civil Engineering. Five times a week. Prof. Eustis.

Applications of Descriptive Geometry to Masonry and Stone-Cutting. Lectures and Drawing. Prof. Eustis.

Determinative Mineralogy and Lithology (with study in the Mineral Cabinet). Three times a week. Dr. Melville.

Preparation of Thesis.

Students who complete this course, pass the required examinations, and present a satisfactory thesis, receive the degree of Civil Engineer, and are prepared to enter on the practice of their profession.

CHEMISTRY.

FIRST YEAR—*Descriptive Chemistry (with laboratory work).* Three times a week. Prof. Jackson and Dr. Mabery.

Elementary Physics. One lecture a week. Prof. Lovering.

German. Sheldon's Grammar.—Translation from German into English, and Elementary Exercises in translating into German. Three times a week. Messrs. Sheldon and Lutz.

(Required of Students who did *not* offer German at their examination for admission.)

French. Brachet (Grammaire francaise).—Bocher's Reader.—French Prose. Three times a week. Asst. Prof. Jacquinot.

(Required of students who did *not* offer French at their examination for admission.)

Quantitative Analysis, as the regular laboratory work of the first half year. Eighteen hours a week. Asst. Prof. H. B. Hill and Dr. Mabery.

Quantitative Analysis, as the regular laboratory work of the second half year. Eighteen hours a week. Mr. Kinnicutt.

SECOND YEAR.—*Technological Chemistry*, including the manufacture of chemical products, organic as well as inorganic, dyeing, calico printing, etc. Recitations and Excursions. Three times a week.

Elementary Physics. One lecture a week. Prof. Lovering.

German. German Plays, Stories, and Essays.—Advanced Grammar. Three times a week. Asst. Prof. Cook.

Quantitative Analysis, as the regular laboratory work for the year. Twenty hours a week. This includes assaying, water and gas analysis, and the more important commercial tests. Mr. Kinnicutt.

THIRD YEAR.—*Physics.* **Practical exercises in the Laboratory, including the use of instruments of precision in testing the laws of Mechanics, Acoustics, Optics, Magnetism, and Electricity; and an extended course in Electrical Measurements.* Three times a week. Prof. Trowbridge.

French. French Novels and plays.—Exercises in conversation and composition. Three times a week. Asst. Prof. Jacquinot.

Determinative Mineralogy and Lithology (with work in the Mineral Cabinet). Three times a week. Dr. Melville.

Organic Chemistry, as the regular laboratory work for the year. Eighteen hours a week. Asst. Prof. H. B. Hall.

FOURTH YEAR.—*Crystallography and the Physics of Crystals (with work in the Mineral Cabinet).* Three times a week. Prof. Cooke.

Mechanical Drawing. Four hours a week. Mr. Dean.

Laboratory Work. Twenty-three hours a week in preparation of thesis.

This course is intended for students preparing to become practical chemists or teachers of the science; and a student who completes the four years course, passes the required examinations, and presents a satisfactory thesis, receives the degree of Bachelor of Science.

The course is also open to "special students," not candidates for a degree. It has been so arranged that the studies of the first two years constitute a special course in practical chemistry, including all the details of chemical analysis. To those who finish satisfactorily this partial course, and prove their competency by laboratory work and by examination, certificates will be given stating the length of time they have been members of the school, and the extent of their preparation in Practical Chemistry.

Natural History.—These courses are designed to furnish a special training in the departments of Geology and Biology. The studies of the first year are common to both departments. Students are required to designate at the beginning of the second year the departments in which they intend to take their degrees.

FIRST YEAR.—*Physical Geography and Meteorology.* Three times a week. Mr. Davis.

Descriptive Chemistry (with laboratory work). Three times a week. Prof. Jackson.

Physics. Ganot's Physics—Lectures. Twice a week. Dr. Hall.

Botany. Three times a week. Prof. Farlow.

Zoology. Twice a week. Dr. Mark.

German. Sheldon's Grammar—Translation from German into English, and Elementary Exercises in translating into German. Three times a week. Messrs. Sheldon and Lutz.

(Required of students who did not offer German at their examination for admission.)

French.—Brachet (Grammaire francaise)—Bocher's Reader.—French Prose. Three times a week. Asst. Prof. Jacquinot.

(Required of students who did not offer French at their examination for admission.)

SECOND YEAR.—*German.* German Plays, Stories, and Essays.—Advanced Grammar. Three times a week. Asst. Prof. Cook.

French. French Prose.—Exercises in Conversation and Composition. Three times a week. Asst. Prof. Jacquinot.

Geology. Three times a week. Prof. Shaler.

Biology. Three times a week. Prof. Farlow and Asst. Prof. Faxon.

Free-hand and Water-color Drawing. Four hours a week. Mr. Moore.

GEOLOGY.—*Determinative Mineralogy and Lithology (with work in the Mineral Cabinet.)* Three times a week. Dr. Melville.

BIOLOGY.—*Logic.* Three times a week. Asst. Prof. James.

THIRD YEAR.—*Qualitative Analysis (with laboratory work).* Three times a week. Asst. Prof. H. B. Hill and Dr. Mabery.

Palæontology (with laboratory work). Twice a week. Prof. Shaler.

Free-hand and Water-color Drawing. Four hours a week. Mr. Moore.

GEOLOGY.—*Advanced Geology.* Three times a week. Prof. Shaler and Mr. Davis.

Topographical Surveying. Seven hours a week. Mr. Dean.

BIOLOGY.—*Advanced Zoology.* Three times a week. Asst. Prof. Faxon.

Advanced Botany. Lectures and laboratory work. Three times a week. Prof. Farlow.

FOURTH YEAR.—During the fourth year the student will be expected to devote a considerable part of his time to some special investigation, the results of which will be embodied in his thesis: in the selection of a subject he will be advised by the Professors whose courses he has followed in previous years. Students of geology will be encouraged to give as much time as possible to work in the field, and a report of such work will form the best thesis that can be presented.

The following courses, selected from those offered in the University during the present year, will serve to indicate the character of the instruction of which the student may avail himself during the last year of the Natural History course.

GEOLOGY.—*Historical Geology (with laboratory work).* Twice a week. Prof. Shaler.

Geological Field-work; for training in the principles of Geological Surveying, with work in the field and in the preparation of reports. Nine hours a week. Mr. Davis.

Economical Geology. Twice a week. Prof. Whitney.

Lithology. Lectures (with practical instruction in the Laboratory). Once a week. Prof. Whitney.

Quantitative Analysis (in the Laboratory). Three times a week. Mr. Kinnicutt.

BIOLOGY.

Advanced Morphology and Histology of Phanerogams. Three times a week. Prof. Goodale.

Anatomy and Development of Higher Cryptogams. Three times a week. Prof. Farlow.

Embryology (with laboratory work). Once a week. Dr. Mark.

Agricultural Chemistry. Twice a week at the Bussey Institution. Prof. Storer.

General Entomology (with laboratory work). Twice a week. Prof. Hagen.

*Students who are not qualified for this course will take in place of it the course in Physics prescribed for the first year's students in Natural History.

Applied Zoology (Anatomy and Physiology of Domestic Animals). Twice a week at the Bussey Institution. Prof. Slade.

Human Anatomy and Physiology. At the Medical School. Professors Holmes and Bowditch and Doctors Beach and J. W. Warren. Students are advised to attend Asst. Prof. James's lectures on Physiology and Hygiene during some part of their residence in Cambridge. Students who make good use of the opportunities afforded by the summer schools or who, during the long vacation, pursue studies under the direction of the professors in their departments, may shorten this course of study to three years. Students who complete either of the above courses, pass the required examinations, and present a satisfactory thesis, will receive the degree of Bachelor of Science.

Admission.—Candidates for admission to any one of the regular courses in Engineering, Chemistry, Natural History, *or* Mathematics, Physics, and Astronomy, will be examined in the following subjects:—

Modern Geography.—Miss Hall's Our World, No. 2.

English Composition.—Every candidate will be required to write a short English composition, correct in spelling,* punctuation, grammar, division by paragraphs, and expression, upon a subject announced at the the time of examination. In 1882, the subject will be drawn from one of the following works:—

Shakspeare's Othello, and King John; Goldsmith's Vicar of Wakefield, and Deserted Village; Carlyle's Essay on Scott; Scott's Bride of Lammermoor; George Eliot's Mill on the Floss.

Every candidate is expected to be familiar with *all* the books in this list.

Every candidate will also be required to *correct specimens of bad English* given him at the time of the examination.

In 1883, the subject will be drawn from one of the following works:—Shakspeare's Julius Cæsar, and As You Like It; the Sir Roger de Coverley Papers in the Spectator; Macaulay's Essay on Addison; Thackeray's Henry Esmond; and Scott's Marmion.

In 1884, the subject will be drawn from one of the following works:—Shakspeare's Julius Cæsar, and Merchant of Venice; Thackeray's Henry Esmond; Irving's Sketch Book; Scott's Lady of the Lake; Carlyle's Essay on Burns; Burns's Cotter's Saturday Night.

French or German.—Translation at sight of easy French prose, or of easy German prose, if the candidate prefer to offer German. It is expected that a knowledge of the language itself will be shown in examination, rather than a knowledge of the grammar; but proficiency in elementary grammar, a good pronunciation, or facility in speaking, will be accepted as an offset for some deficiency in translation. There will be no required examination in pronunciation, but it is recommended that attention be given to pronunciation from the outset. Candidates who offer German will be required to study French, and those who offer French will be required to study German, during the Freshman year.

Latin.—Four books of Cæsar's Commentaries, and four books of the Aeneid of Virgil, or their equivalents; Latin Grammar, as much as is contained in either Allen and Greenough's or Harkness's Elementary Latin Grammar.

Arithmetic (including the metric system of weights and measures, and the use and rudiments of the theory of logarithms).—The examples requiring the use of logarithms at the examinations will be adapted to a four-place table.

Elementary Algebra.—Through quadratic equations.

Elementary Geometry.—The first five books of Chauvenet's Geometry.

Plane and Analytic Trigonometry.—As much as is contained in the first eight chapters of Chauvenet's Trigonometry, or Wheeler's Elements of Plane Trigonometry.

Elementary Descriptive Chemistry.—As much as is contained in Nichols's abridgement of Eliot and Storer's Manual.

Elementary Physics.—As much as is contained in Balfour Stewart's Lessons in Elementary Physics.

For the Course in Engineering or *in Mathematics, Physics, and Astronomy.*—In addition to the above requisitions, candidates who propose to take either of these courses will be examined in—

Advanced Algebra.—As much as is contained in the larger works of Olney, Robinson, Todhunter, or Greenleaf.

* Worcester's Dictionary is the Standard.

Solid Geometry.—The last four books of Chauvenet's Geometry.

Every candidate for admission to advanced standing will be further examined in all the studies already pursued by the class for which he offers himself. Graduates of Harvard College who have passed a satisfactory examination while in College on the subjects of the first and second years of the Engineering course, except Drawing and Surveying, will be admitted to the third year of that course. Undergraduates who intend to study Engineering are recommended by the Scientific Faculty to take, as extras, the courses in Drawing and Surveying in the Scientific School; but these subjects may be made up in the third and fourth years. The successful study of any subject in College will be taken as an equivalent for the same subject in the Scientific School. Two regular examinations for admission are held each year, —one at the beginning of the summer vacation, and the other at the beginning of the academic year in the autumn.

In 1882 the first examination will be held at the following places on Thursday, Friday, and Saturday, June 29, 30, July 1: in *Cambridge*, in Lawrence Hall; in *Exeter*, in rooms of the Phillips Exeter Academy; in *New York*, in the lecture-room of the Young Men's Christian Association, Twenty-third Street, corner of Fourth Avenue; in *Philadelphia*, in the library hall of the Academy of Natural Sciences, S. W. corner of Nineteenth and Race Streets; in *Cincinnati*, in the rooms of the Literary Club, 24 West Fourth Street, second floor; in *Chicago*, in the rooms of the Chicago Athenæum, 50 Dearborn Street; in *San Francisco*, in rooms of the Boys' High School, on Luther Street, between Gough and Octavia Streets: the second examination will be held in Cambridge only, on Wednesday, Thursday, and Friday, September 27, 28, and 29. For each examination attendance on the three days is required. Candidates will assemble punctually at 8 o'clock, A. M.

Degrees.—The Degrees of Civil Engineer and Bachelor of Science.—As already stated, the degree of CIVIL ENGINEER may be conferred upon any student who has completed the prescribed course of study in Civil Engineering, passed the required examinations, and presented a satisfactory thesis; and the degree of BACHELOR OF SCIENCE may be conferred upon any student who has fulfilled the above requirements in Chemistry, Natural History, *or* Mathematics, Physics, and Astronomy. The grades of the degree of Bachelor of Science are *cum laude*, *magna cum laude*, and *summa cum laude*. The grade of the degree and the course of study for which the degree is given will be specified in the Diploma. The degree of DOCTOR OF SCIENCE is open to Bachelors of Science of Harvard University, and to Bachelors of Science and Bachelors of Philosophy of other institutions who shall have satisfied the Faculty of the Lawrence Scientific School, by examination, that the course of study for which they received the Bachelor's degree is equivalent to that for which the degree is given in Harvard University, or shall have passed such additional examinations as that Faculty may prescribe. The Academic Council will recommend for the degree of Doctor of Science candidates otherwise properly qualified, who, after taking their Bachelor's degree, shall reside at least two years at the University, and pursue during three years a course of scientific study, embracing at least two subjects, and approved by the Council, and shall pass a thorough examination upon that course, showing in one of the subjects special attainments, and shall also make some contribution to science or some special investigation, to be embodied in a thesis; provided, however, that a course of study of two years only shall suffice for candidates who are both Bachelors of Arts and Bachelors of Science of Harvard University. In special cases the Academic Council is authorized to remit the requisition of residence at the University to Bachelors of Arts or of Science of Harvard University. For the standing rules of the Academic Council, relating to the higher degrees, see Harvard University Catalogue, or application may be made to Professor C. J. White, Registrar, Cambridge, Mass.

INSTRUCTION FOR TEACHERS.—1. The school also offers facilities to teachers and to persons preparing to be teachers, who desire to qualify themselves in the modern methods of teaching science by observation and experiment. A one-year's course of study, adapted to this purpose, may be selected from the elements of Natural History, Chemistry, and Physics, including any of the following subjects: Physical Geography and Elementary Geology; General Chemistry and Qualitative Analysis; Mineralogy; Physics; Botany; Comparative Anatomy and Physiology; Zoölogy. This course is flexible and comprehensive, the instruction is mainly given in the laboratories and museums of the University, and is of the most practical character, every student being taught to make experiments and study specimens. Botanical instruction is given at the botanical laboratory. Dissecting microscopes are provided for students, and the garden and greenhouses afford ample material for the practical study of the science. All work is under the special supervision of Professors Goodale and Farlow. Similar facilities are afforded for the study of Zoölogy, Comparative Anatomy and Physiology, Geology, and Paleontology, at the laboratories of the Museum of Comparative Zoölogy, and of Mineralogy, at the Mineral Cabinet. The instruction in Experimental Chemistry and Physics is given in the laboratories, and the students are shown the best methods of illustrating experimentally the principles of these sciences.

2. Special courses in Botany, Chemistry, and Geology are given during the vacation to teachers and others who are unable to attend during term time.

3. There is no examination for admission to the Teachers' Course.

Special Students.—Persons who are not candidates for a degree, may enter the School as Special Students at any time, without examination, and pursue any of the courses of instruction, given in the school for which they are found competent. Such students, who have been members of this School for at least one year, shall be entitled to a certificate, specifying the subjects in which they have proved themselves proficient either by examination or laboratory work.

Instruction in Other Departments of the University.—All students of the Scientific School may, if found competent, pursue any of the courses of instruction given in the other departments of the University, except exercises carried on in the special laboratories, without additional charge.

Scholarships.—Four University Scholarships, of the annual value of one hundred and fifty dollars each, have been established in the Scientific School. They are assigned at the beginning of each academic year to meritorious students standing in need of such assistance, who have been in the School the whole of the preceding year, and propose to remain in it the whole of the ensuing year. The award is made by the Corporation on the recommendation of the Faculty. One-third of the annual value of the Scholarships is paid at the time of the award, one-third on January 12, and one-third on April 12, following. Applications for these scholarships must be addressed in writing, to the Dean, by the first of June. There are also scholarships in the Scientific School, not exceeding eight at any one time, of the annual value of one hundred and fifty dollars each, for the benefit of graduates of the State Normal Schools. The manner in which these scholarships are divided among the Normal Schools is determined by the State Board of Education. The incumbents are originally appointed for one year on the recommendation of the principals of the schools from which they have been severally graduated; these appointments may be annually renewed on the recommendation of the Faculty of the Scientific School.

Fees and Expenses.—The tuition fee for the academic year in any of the above departments or courses is $150. The tuition fees for candidates for the degree of Doctor of Science are stated in the Harvard University Catalogue, and in the Circular relating to the Graduate Department. The other expenses of a student for an academic year may be estimated as follows:—

Room	from $30 to $100
Board for thirty-eight weeks	from 133 to 304
Books	from 20 to 25
Fuel and lights	from 15 to 35
Washing	from 19 to 38
Total	$217 to $502

Scientific School bills are payable in each year on January 12, April 12, and October 10; but the third bill of all candidates for degrees must be paid at least one day before Commencement. Each bill will contain one third of the annual charges. When a student severs his connection with the School, his whole bill becomes payable at once. Deductions from the full year's tuition fee will be made as follows: If a student joins or leaves the School between January 1 and April 1, one third will be deducted. If a student joins the School between April 1 and Commencement, or leaves the School before January 1, two thirds will be deducted. But no deduction will be made in case of a student leaving the School, unless he gives immediate notice thereof, in writing, to the Dean and to the Bursar. Students in the Scientific School may obtain rooms in the College buildings by applying to the Bursar, either by mail or in person. They may also join the Harvard Dining Association, and board at cost at Memorial Hall. Students in Chemistry are supplied with all needed apparatus, but are required to restore it in as good condition as when received. They are charged for all damage or breakage, and also from ten to thirty dollars per annum for chemicals and use of apparatus. Students in Engineering provide their own drawing materials. The Hemenway Gymnasium, the Scientific School Library, and the College Library are open to members of this School without extra charge.

Testimonials and Bonds.—All students admitted to the Lawrence Scientific School must furnish satisfactory evidence of good moral character; give bonds in the sum of $200, signed by two bondsmen, one of whom must be a citizen of Massachusetts, for the payment of all dues to the University; and register their names with the Dean of the Faculty of the School. Instead of filing a bond, a student may deposit with the Bursar such a sum of money as may be deemed sufficient to secure the payment of all dues to the University. Students engaging College rooms, or boarding at Memorial Hall, will be required to file the same bond as undergraduates of the College ($400), or to pay rent for the year in advance, and deposit the sum of $200 as security for the payment of their board; and they hold the rooms subject to the regulations of the Parental Committee, in the same manner as if they were undergraduates. No officer or student of the University will be accepted as bondsmen.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY, BOSTON.

THE Massachusetts Institute of Technology provides a series of scientific and literary studies and practical exercises, embracing pure and applied mathematics, the physical and natural sciences, with their applications, drawing, the English language, history, political economy, international and business law, French and German, with other modern languages, if desired. These studies and exercises are so arranged as to offer a liberal and practical education in preparation for active pursuits, as well as a thorough training for most of the scientific professions. The following regular courses have been established:

1. A Course in Civil and Topographical Engineering. 2. A Course in Mechanical Engineering. 3. A Course in Mining Engineering, or Geology and Mining. 4. A Course in Building and Architecture. 5. A Course in Chemistry 6. A Course in Metallurgy. 7. A Course in Natural History. 8. A Course in Physics. 9. General Courses (A, B, and C).

The first five of these courses are of a distinctly professional character, the one in Metallurgy is similar to that in Chemistry, but has more particular reference to the production and working of the metals. The course in Natural History affords an appropriate general training for those whose ulterior object is the special pursuit of geology, mineralogy, botany, zoology, pharmacy, or rural economy. It is specially suitable for those who intend subsequently to enter the medical profession. The course in physics is based on the mathematical and physical sciences, and offers a suitable preparation for persons desirous of fitting themselves to teach physical science, as well as for those desiring to enter upon the pursuit of the various practical applications of Physics, as in electrical engineering, or in making physical tests of materials. In addition to the foregoing, certain general courses have been established for such as may not intend to adopt a distinctly scientific profession, yet desire to obtain an education through studies of a predominantly scientific character. These courses are especially recommended in the case of young men whose purpose it is to become merchants, manufacturers, or bankers, and who desire a preparation for active life, which shall be liberalizing in its tendencies, but without any influence to alienate them from the ideas, tastes, and habits which are appropriate to practical business pursuits.

Each of these courses contains a solid body of scientific study, and of scientific field or laboratory work. In the first, Physics, with the requisite Mathematics, predominates among the scientific studies; in the second, Chemistry, with the closely related sciences of Botany and Physiology; in the third, Geology, with Botany and Zoölogy, forming a thorough course in Biology, with field work and laboratory practice, especially with the microscope. While, in all the courses, it is intended to secure to the student a liberal culture, as well as the more strictly techical education which may be his chief object, in the courses under consideration, far more time will be devoted to the study of language, literature, history, and political, social, and industrial science than is found compatible with the requirements of the professional courses. The time which, in the latter, is given to the special technical study and work essential to the architect, the engineer, the naturalist, or the chemist will, in the courses under consideration, be given to more general studies which are of a nature to enlarge the views and enrich the life of the man of businesss. All the regular courses of the Institute, whether professional or general, extend through four years, and for proficiency in any one of them the degree of S. B., Bachelor of Science, is conferred. Students who find it advantageous to take fewer studies in any year than are prescribed in a single course may continue in the school a fifth year to make up the studies required for a degree. Advanced courses of study may be pursued, and the granting of the degree of Doctor of Science has been authorized by a vote of the Corporation. Provision is also made for persons who desire to pursue special portions only of any of the regular courses. At the request of the Woman's Education Association of Boston, and with their generous co-operation, special laboratories have been provided for the instruction of women. The design is to afford them facilities for the study of Chemical Analysis, Industrial Chemistry, Mineralogy, and Biology. The instruction is arranged for such students as may be able to devote their whole time to the work, as well as for those who, by reason of other engagements, can spend only a few hours a week in the exercises. Instruction will also be given to women in other subjects so far as suitable arrangements can be made for them. The Institute also provides afternoon and evening courses of instruction, scientific and literary, open to both sexes. At present the courses are free, being supported by the Trustees of the Lowell Institute. Fuller details are given under "Free Courses of Instruction.

FIRST TERM.

REGULAR COURSES.—*All Courses—First Year.*—Algebra continued; Solid Geometry; General Chemistry; Chemical Laboratory; Rhetoric; English Composition; French; Mechanical Drawing. Free Hand Drawing; Military on drill.

SECOND TERM.

Plane and Spherical Trigonometry; General Chemistry; Qualitative Analysis; Chemical Laboratory; English History; English Literature; French; Mechanical Drawing; Free Hand Drawing; Military Drill.

CIVIL ENGINEERING.

SECOND YEAR.—*First Term.*—Elementary Surveying. Field Practice. Plotting from Notes. Topography. Analytic Geometry. Descriptive Geometry. Physics. Descriptive Astronomy. English History and Literature. German.

Second Term.—Advanced Surveying. Leveling. Field Practice. Plans and Profiles. Differential Calculus. Physics. Physical Geography. English History and Literature. German.

THIRD YEAR.—*First Term.*—Roads and Railroads. Field Practice. Engineering Drawing. Integral Calculus. General Statics. Physics; Lectures and Laboratory work. Structural Geology. Constitutional History. German.

Second Term.—Graphic Statics. General Hydraulics. Rivers and Harbors. Locks, Dams, and Canals. Field Practice. Engineering Drawing. Strength of Materials. Kinematics and Dynamics. Physics; Laboratory Work. Historical Geology. Political Economy. German.

FOURTH YEAR.—*First Term.*—Framed Structures. Water Supply. Sewerage of Cities and Towns. Drainage and Irrigation. Details of Construction. Study of actual works. Practice in Design. Strength of Materials. Metallurgy.

Second Term.—Details of Construction. Study of actual works. Specifications and Contracts. Practice in Design. Theory of Elasticity. Dynamics completed. Building Materials. History of Engineering, Thesis Work.

MECHANICAL ENGINEERING.

SECOND YEAR.—*First Term.*—Setting of Machines. Transmission and Production of Power. Machine Drawing. Carpentry (shopwork). Analytic Geometry. Descriptive Geometry. Physics. Descriptive Astronomy. English History and Literature. German.

Second Term.—Kinematics of Machines. Graphical Kinematics of Machines. Machine Drawing. Pattern and Foundry Work (shopwork). Differential Calculus. Physics. Physical Geography. English History and Literature. German.

THIRD YEAR.—*First Term.*—Combustion of Fuel. Steam Generators and Steam Engines. Machine Drawing. Steam Engineering Laboratory. Blacksmithing (shopwork). Integral Calculus. General Statics. Physics; Lectures and Laboratory Work. Constitutional History. German.

Second Term.—Machine Design. Elements of Thermodynamics. Machine Drawing. Steam Engineering Laboratory. Chipping Filing (shopwork). Perspective. Strength of Materials. Kinematics and Dynamics. Physical Laboratory. Political Economy. German.

FOURTH YEAR.—*First Term.*—Machine Design. Measurement and Regulation of Power. Machine Drawing. Abstracts from Memoirs. Steam Engineering Laboratory. Blacksmithing (shopwork). Strength of Materials. Hydraulics. Metallurgy.

Second Term.—Thermodynamics of Steam and other Heat Engines. Pumping Engines, Hydraulic Motors, Machines, and Regulators. Steam Engineering Laboratory. Machine Design. Machine Drawing. Engine Lathe work (shopwork). Hydraulics. Theory of Elasticity. Dynamics completed. Building Materials. Thesis Work.

MINING ENGINEERING.—A.

SECOND YEAR.—*First Term.*—Blowpipe Analysis, Crystallography, and Determinative Mineralogy. Qualitative Chemical Analysis. Use of Surveying Instruments. Surveying. Field Practice. Drawing. Analytic Geometry. Physics. German.

THIRD YEAR.—*Second Term.*—Quantitative Chemical Analysis, Lectures and Laboratory work. Differential Calculus. Physics. Physical Geography. English History and Literature. German.

First Term.—Quantitative Chemical Analysis. Mining Engineering, Sinking, Timbering, Hoisting, Pumping, Ventilating, etc. Integral Calculus. General Statics. Physics; Lectures and Laboratory work. Structural and Chemical Geology. Constitutional History. German.

Second Term.—Mining Engineering continued. Assaying by Fire and by Wet Methods. Quantitative Chemical Anaylsis. Strength of Materials. Kinematics and Dynamics. Physical Laboratory. Historical Geology. Political Economy. German.

FOURTH YEAR.—*First Term.*—Quantitative Chemical Analysis. Mining Laboratory:—work upon Gold, Silver, Copper and Lead Ores in Quantity. Metallurgy, Lectures. Drawing. Strength of Materials. Dynamics completed. Memoirs.

Second Term.—Quantitative Chemical Analysis. Mining Laboratory as in 1st term. Metallurgy, Lectures. Ore dressing, Lectures. Welding and Tempering (shop-work).

GEOLOGY AND MINING.—B.

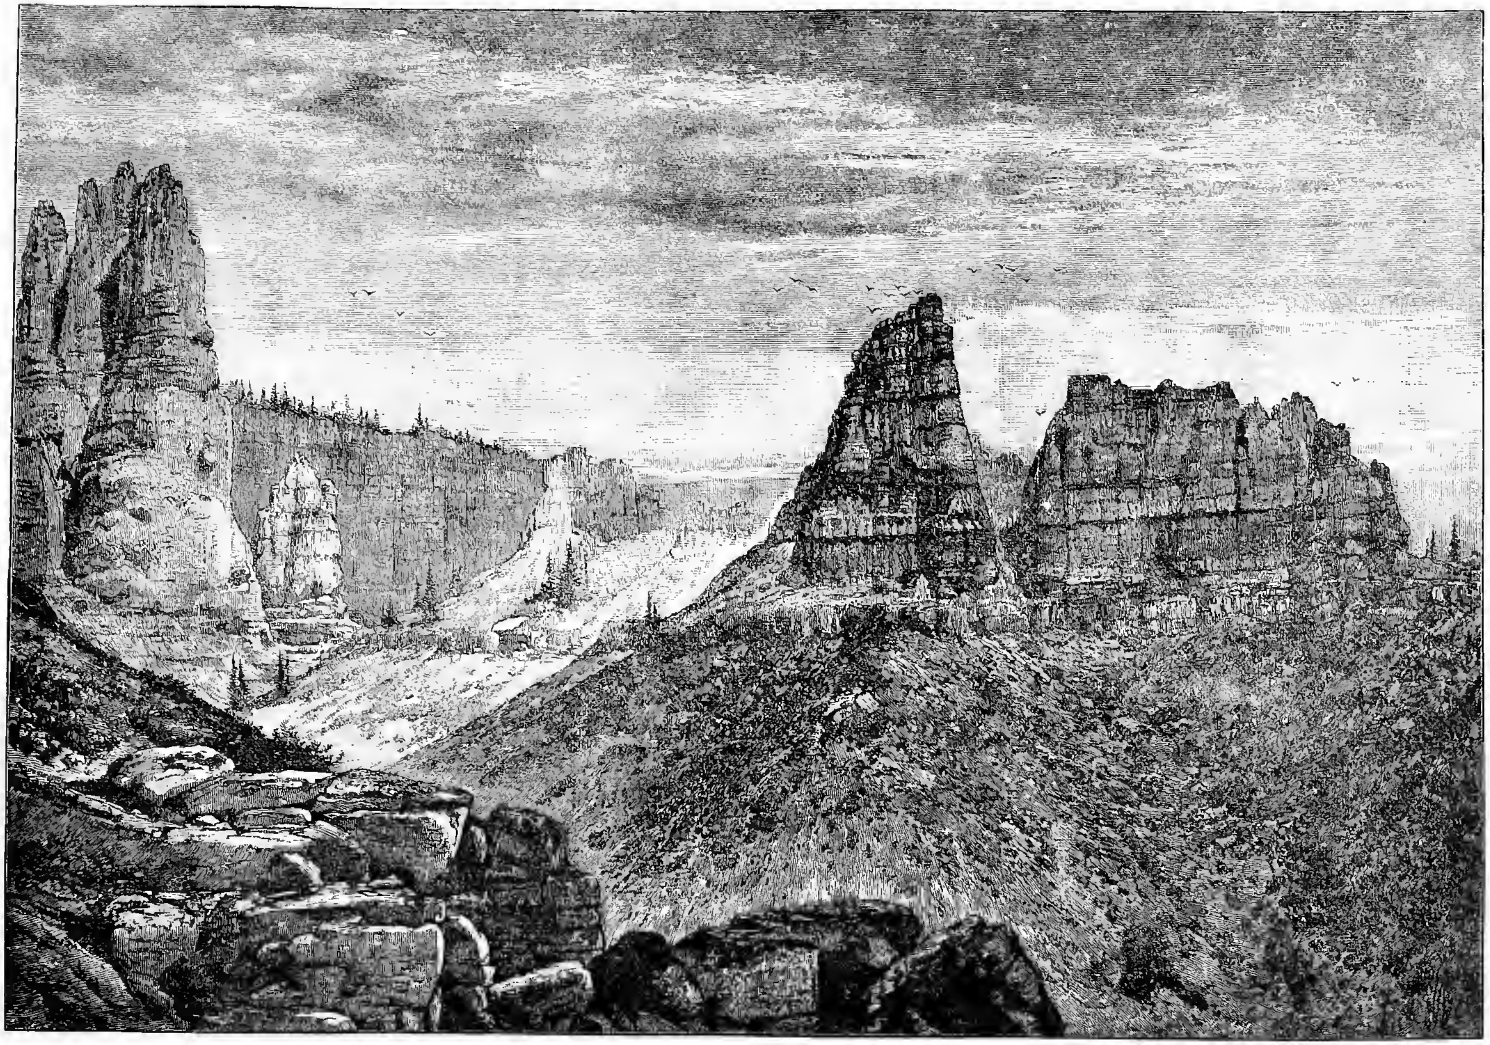
SECOND YEAR.—*First Term.*—Blowpipe Analysis, Crystallography, and Determinative Mineralogy. Qualitative Chemical Analysis. Use of Surveying Instruments. Surveying. Field Practice. Drawing. English History and Literature. Physics. German.

Second Term.—Quantitative Chemical Analysis, Lectures and Laboratory work. Physics. Physical Geography. Zoology. Palæontology. Botany. English History and Literature. German.

THIRD YEAR.—*First Term.*—Mining Engineering. Sinking Timbering, Hoisting, Pumping, Ventilating, etc. Quantitative Chemical Analysis. Zoology. Palæontology. Physics. Lectures, and Laboratory work, Structural and Chemical Geology. Constitutional History. German.

Second Term.—Mining Engineering continued. Assaying by Fire and Wet Methods. Quantitative Chemical Analysis. Industrial Chemistry. Physical Laboratory. Historical Geology. Political Economy. German.

FOURTH YEAR—*First Term*—Quantitative Chemical Analysis. Mining Laboratory:—work upon Gold, Silver, Copper, and Lead Ores in quantity. Metallurgy, Lectures. Drawing. Applied Physics. Memoirs.



WESTERN SCENERY—FINK CLIFFS—EOCENE—PAUNSAGUNT—GRAND CAÑON DISTRICT.

SEE PART X.

—FROM U. S. GEOLOGICAL SURVEY REPORT.

Second Term—Quantitative Chemical Analysis. Mining Laboratory as in 1st term. Metallurgy, Lectures. Ore Dressing, Lectures. Welding and Tempering (shopwork). Building Materials. Thesis work.

CHEMISTRY.—A.

SECOND YEAR—*First Term*—Qualitative Analysis, Blowpipe Analysis, Crystallography and Determinative Mineralogy, Analytic Geometry, Physics, English History and Literature, German.

Second Term—Quantitative Analysis, Lectures, and Laboratory work, Chemical Philosophy, Differential Calculus, Physics, English History and Literature. German.

THIRD YEAR—*First Term*—Quantitative Analysis, Laboratory work, Quantitative Analysis, Special Methods, Work with the Microscope, Physics; Lectures and Laboratory work. Constitutional History, German.

Second Term—Quantitative Analysis, Laboratory work, Industrial Chemistry, Lectures, Drawing, Assaying, Physical Geography, Physical Laboratory, Political Economy, German.

FOURTH YEAR—*First Term*—Organic Chemistry, Lectures, Organic Chemistry, Laboratory work, Metallurgy, Lectures, Abstracts of Memoirs, Applied Physics, Optional Studies.

Second Term—Studies for this term, including Thesis work, will be specially assigned to each student.

CHEMISTRY.—B and C.—Second Year—*First Term*—Qualitative Analysis. Blowpipe Analysis. Crystallography, and Determinative Mineralogy. Descriptive Astronomy. Physics. English History and Literature. German.

Second Term—Quantitative Analysis, Lectures, and Laboratory work. Chemical Philosophy. Botany, Systematic and Structural. Physical Geography. Physics. English History and Literature, German.

THIRD YEAR.—*First Term.*—Quantitative Analysis, Laboratory work. Quantitative Analysis. Special Methods. Biology, Physics; Lecture and Laboratory work. Structural and Chemical Geology. Constitutional History, German.

Second Term.—Quantitative Analysis, Laboratory work. Industrial Chemistry, Lectures. Drawing. Assaying. Physical Laboratory. Historical Geology. Political Economy. German.

FOURTH YEAR—FIRST TERM.—*Course B.*—Organic Chemistry, Lectures. Chemistry. Laboratory work. Metallurgy, Laboratory work. Metallurgy, Lectures, Abstracts of Memoirs, Applied Physics, Optional studies.

Course C.—Organic Chemistry, Lectures. Chemistry, Laboratory work. Industrial Chemistry, Laboratory work. Metallurgy, Lectures. Abstracts of Memoirs. Applied Physics. Optional Studies.

FOURTH YEAR—*Second Term*—Studies for this term, including Thesis work, will be specially assigned to each student.

Candidates for the degree in Chemistry may elect either of the courses A, B, or C. Course A is for those who wish to continue the study of mathematics beyond the first year. Course B is for those who prefer a larger amount of the natural science; and course C for those whose aim is the pursuit of Industrial Chemistry.

METALLURGY.—Second Year.—*First Term*—Blowpipe Analysis, Crystallography, and Determinative Mineralogy. Qualitative Chemical Analysis. Descriptive Astronomy. Physics. English History and Literature. German. Drawing.

Second Term—Quantitative Analysis; Lectures, and Laboratory work. Chemical Philosophy. Botany. Zoology and Palæontology. Physical Geography. Physics. English History and Literature. German.

THIRD YEAR—*First Term*—Quantitative Analysis, Lectures. Quantitative Analysis, Laboratory work. Biology. Physics; Lectures, and Laboratory work. Structural and Chemical Geology. Drawing. Constitutional History. Zoology. Palæontology. German.

Second Term—Quantitative Analysis, Laboratory work. Industrial Chemistry, Lectures. Physical Laboratory. Historical Geology. Political Economy. German. Assaying.

FOURTH YEAR.—*First Term.*—Quantitative Analysis, Laboratory work. Metallurgy. Metallurgical Laboratory:—Work upon Gold, Silver, Copper, and Lead Ores in quantity. Drawing. Applied Physics. Blacksmithing (shopwork), Abstracts of Memoirs.

Second Term.—Quantitative Analysis. Laboratory work. Metallurgy and Ore-dressing. Mining Laboratory as in 1st term. Thesis Work. Building Materials. Drawing.

Advanced Courses.—The particular course of study which a candidate for the degree of Doctor of Science wishes to pursue must be submitted to the Faculty in writing, and must meet their approval. The minimum term of residence of candidates for this degree will be two years; but occasional short absences, when the time is spent upon professional work by advice of the Faculty, will not be considered as interruptions of the student's residence. Final examinations will be held, and the candidate will be required to present at least one printed thesis on some subject embraced in his course.

Conditions of Admission.—Regular Courses.—To be admitted as a regular student of the first year's class, the applicant must have attained the age of sixteen years, and must pass a satisfactory examination in:—

Arithmetic—(Including the metric system of weights and measures);

Algebra—Through equations of the second degree;

Plane Geometry.

French—Grammar through irregular verbs*; and the first two books of Voltaire's "Charles XII.," or an equivalent;

English grammar and composition;

Geography.

In general, the training given in the best high schools and academies will be a suitable preparation for this school; but applicants must be thoroughly prepared in the three Mathematical subjects above named.

Students will find their progress in Physics and Chemistry facilitated by making themselves thoroughly familiar with so much of Physics as is contained in Balfour Stewart's Primer of Physics.

A knowledge of the Latin language is not required for admission; but the study of Latin is strongly recommended to persons who purpose to enter this school, as it gives a better understanding of the various terms used in sciences, and greatly facilitates the acquisition of the modern languages. Those who intend to take a course in Natural History will find it advantageous to acquire also the elements of Greek.

In June, 1883, the requirements adopted by the New England Association of Colleges in Algebra; viz.: Algebra through Quadratics, including Arithmetical and Geometrical Progressions, the Binomial theorem with positive integral exponents and proportion; will be adopted as requirements for admission to the Institute. To be admitted as a regular student of the second year's class, the applicant must be at least seventeen years of age, and, besides passing the examination for admission to the first year's class, must pass a satisfactory examination in the first year's studies; and a like rule applies to the case of applicants for admission into the classes of the succeeding years. Graduates of Colleges will, in general, be presumed to have the requisite attainments for entering the third year as regular students, and may do so on satisfying the Faculty that they are prepared to pursue the proposed studies to advantage. Such students, if deficient in any of the scientific studies of the first two years, will have opportunities for making them up without extra charge, and will be required to pass an examination in them before entering upon the studies of the fourth year. Should they be already proficient in any of the general studies of the third and fourth year, they may be excused from attendance on the exercises in these subjects.

Special Students will be allowed to enter special divisions of either of the courses—as, for example, the classes of mathematics, chemistry, physics, drawing, engineering, metallurgy, architecture, natural history, etc.—on giving satisfactory evidence to the Faculty that they are prepared to pursue with advantage the studies selected. Information respecting the requirements for admission to each special course of study may be obtained on application to the Secretary. Examinations for the above-mentioned class of students will be held at the times of the regular entrance examinations as stated below. An examination for admission to the first year's class will begin at 9 A. M., on the Tuesday preceding the last Monday in September, and continue two days. Attendance on both days is required. Applicants for advanced standing must present themselves for further examination at 9 A.M., on the Thursday following the entrance examination. Applications for admission to the regular or special courses at other times than the above will be received only when sickness or some other equally good cause has prevented attendance on the days prescribed.

Advanced Courses.—Graduates of the Institute may enter on these courses without examination. Bachelors of Arts, Science, or Philosophy, of any other Institution, may enter on giving satisfactory evidence, by examination or otherwise, that they are qualified to pursue the course selected.

Methods and Apparatus of Instruction—*Ordinary Exercises.*—Instruction is given by lectures and recitations, and by practical exercise in the field, the laboratories, and the drawing-rooms. Text-books are used in many, but not in all departments. A high value is set upon the educational effect of laboratory practice, drawing, and field work.

Written Examinations.—Besides oral examinations in connection with the ordinary exercises, written examinations are held from time to time. Near the close of the months of

*Part 1 of Otto's French Grammar represents what is required.

January and May general examinations are held. After the examinations, the standing of the student in each distinct subject is reported to his parent or guardian. The examinations of January and May form the basis of admonition or advice from the Faculty in the cases of students who are not profiting by their connection with the school.

The Instruction in Mathematics.—Great importance is attached to the study of mathematics both as a means of mental discipline and as affording a necessary basis for farther instruction in the professional courses. In the first year all regular students continue Algebra, and also study Solid Geometry, Plane and Spherical Trigonometry. In the following years, students in most of the courses receive instruction in Analytic Geometry, and in the Differential Integral Calculus.

The Instruction in Drawing.—During the first year, instruction is given to all regular students in the principles of Free-Hand and Mechanical Drawing and a large amount of time is devoted to practice in the drawing room, to enable the student to acquire the necessary skill and to prepare him for his future work. In subsequent years, Drawing is continued in connection with the professional studies.

The Instruction in Descriptive Geometry and Stereotomy.—The exercises in Descriptive Geometry are of two kinds. In the lecture room instruction with models and diagrams is combined with testing the student's knowledge as gained from the text book. In the drawing room the student aims to construct such problems, each week, from the lessons for that week, as shall, during the course, give him practice in all the usual operations belonging to the subject. The instruction in Stereotomy is given by means of lectures, and drawing exercises, illustrating a variety of problems in Stone Cutting, on plane, double-curved, and warped surfaces. The application of Descriptive Geometry is extended to the construction of the oblique arch, and winding staircases of various forms, so as to include a large number of useful and practical problems.

The Instruction in Chemistry,—In the laboratories provision is made for teaching General Chemistry, Qualitative Analysis, Quantitative Analysis, Organic Chemistry, Assaying, Determinative Mineralogy, Metallurgy, and Industrial Chemistry, the use of the blowpipe, as well as the use of the microscope, spectroscope, and other optical apparatus. Instruction in General Chemistry is given to all regular students by recitations and lectures, and by practical exercises in the laboratory, where every one is provided with a desk and the necessary apparatus, and is required to perform, under the supervision of the professor, a large number of experiments, selected to illustrate the laws of chemical action and the properties and relations of all the more important chemical elements. This is followed by a systematic course of instruction in Qualitative Analysis, with laboratory practice. In the second year those who require a fuller knowledge of chemistry continue Qualitative Analysis, and take up Chemical Philosophy, and Mineralogy with the use of the blowpipe. The principal subjects of study in the third and fourth years are Volumetric and Gravimetric Analysis, Organic Chemistry, Gas Analysis, Assaying, the Preparation of Chemical Products, Metallurgy, and Industrial Chemistry. A large portion of the time is alloted to work in the laboratories. In the third year, lectures are given on Quantitative Analysis, and on Physiological and Industrial Chemistry. In the fourth year the lecture room exercises are devoted to Organic Chemistry and Metallurgy. During the last two years the student is required to make reference to standard works and original memoirs in English, French, and German. Both regular and special students are encouraged to undertake experimental researches, and assist in bringing them to useful results. Arrangements will be made, as far as practicable, for the accommodation of students who wish to devote themselves to special subjects, such as Toxicology, Food and Water Analysis, Gas Analysis, Dyeing, Tanning, and other chemical arts. Special provision has been made for giving women ample opportunities for laboratory work in Chemistry, Mineralogy, and Biology. Each study may be pursued by itself, or in connection with studies in other departments of the Institute.

The Instruction in Theoretical and Applied Mechanics.—This instruction, which is given to all regular students of the courses of Engineering and Architecture, is begun about December 1st of the third year. During the third year the subjects studied are the composition and resolution of forces, the general laws of Kinematics and Dynamics mathematically discussed, the principles governing the determination of the stresses in the different members of trusses, centre of gravity, moment of inertia, and the ordinary principles of the strength of materials, this latter subject occupying fully half the time devoted to Applied Mechanics in the third year, and being subsequently completed in the fourth year. In this course the methods of the differential and integral calculus are freely used whenever they are the most convenient. In the fourth year's classes the subjects pursued by the students of each professional course are arranged with reference to the special wants of that course, and then two or more classes are taught together whenever the instruction to be given covers the same ground. This instruction embraces the completion of the study of Strength of Materials; Theory of Elasticity; main principles of the stability of arches and domes; Hydraulics, Thermodynamics, and special study of Dynamics. Through the kindness of certain friends of the Institute, a testing machine of 50,000 pounds capacity has been provided, capable of testing the tensile strength of specimens not more than 20 inches long, as well as the compression of small cubes, and it is now being arranged to test the transverse strength of beams 25 feet long. The classes are divided into small sections for the purpose of making, by the use of this machine, investigations on the strength and elastic properties of the materials used in construction.

The Instruction in Civil Engineering is given by means of lectures and recitations, and by practice in the field and in the drawing rooms. The use of the various instruments for measuring lines and angles, and of the level, plane-table, etc., is taught mainly by actual work in the field. The field-work embraces the various kinds of land surveying, Topography, Hydrography, and the several operations with the level and transit involved in Railroad, Hydraulic and Sanitary engineering. The work in the drawing room consists in representing upon paper the surveys made in the field, and in making both working drawings and finished plans from direct measurements of actual engineering structures, a large number of which are found in the immediate neighborhood of the Institute. The regular course in Civil Engineering embraces Roads, Railroads, Bridges, Rivers, Harbors, Canals, Water Supply and Sewerage, Drainage and Irrigation. In the lower classes, the student is held closely to the best text-books, but, as he advances, he works more and more without these aids; and during the last part of his course, while he makes constant reference to the best engineering books of this and other countries, he is, at the same time, brought into continual and direct contact with actual works in process of construction, and is made to see the exact connection between his theoretical acquirements and the real engineering practice of the day. In this manner he not only becomes familiar with the practical details of construction, but a new interest is given to the purely theoretical part of his studies.

The Instruction in Mechanical Engineering is given by means of lectures and recitations, and by practice in the drawing rooms, and in the Laboratory of Steam Engineering. Occasional excursions are made to enable students to witness running machinery, and manufacturing processes. The instruction in Mill-work treats of placing machinery in the manufactory, and of the distribution, measurement, and regulation of force and power. The instruction in the Kinematics of Machines treats of the motions and changes of motions which occur in machines, of those problems in machine design which relate to motions that machines are to produce, and of the comparative examination of equivalent mechanisms. The first term instruction in Machine Design treats of those dimensions of elements of machines that depend upon the force which a pair of elements may transmit, or upon the work-shop processes by which the elementary parts are produced. It also involves the application of principles of kinematics and dynamics of machines, in determining stresses and their fluctuations in machines and motors, and the applications of the principles of strength of materials, and of work-shop practice to the proper proportioning of the various parts. The instruction in Steam Engineering treats of the fundamental laws of thermodynamics, and their application to steam and other heat engines, of the combustion of fuel, of steam generators and their construction, of the mechanism of the steam engine, and of the characteristic features of typical steam, and other heat engines. The instruction in designing the parts of the steam engine is given under the head of Machine Design. The instruction in Hydraulic Motors and Machines treats of water-wheels, and of water pressure engines and machines. The practice in Drawing is carried on in conjunction with the lectures, and text-book study. It comprises tracing, copying, sketching from the structure, machine or motor, scale drawing from sketches, and the representation by curves of the results of experiments or of mathematical investigations; to which is added the reproduction of drawings by the "Blue Process." The Laboratory of Steam Engineering affords an opportunity of becoming acquainted, by experiment, with fundamental laws which underlie the practice of Steam Engineering. It also provides practice in adjusting, testing, and managing steam machinery and apparatus.

The Instruction in Mining is given to students of the third year by a course of eighty lectures on the general character of the various deposits of useful minerals, and on the theory and practice of mining operations, such as prospecting, boring, sinking of shafts, driving of levels, different methods of working, hoisting, pumping, ventilation, etc. These lectures are illustrated by drawings, and by a set of models from Freiberg, Saxony, which show in detail the methods of working underground, by underhand and overhand stoping, the timbering and walling of shafts and levels, the arrangement of pumps, man engines, ladder ways, hoisting ways, the sinking of shafts, etc. In the fourth year ore-dressing and metallurgy are taken up in a course of sixty lectures. This is accompanied by a series of continuous practical exercises in the concentration and smelting of ores in the Mining and Metallurgical laboratories. The professors in this department hope to give each student of Mining and Metallurgy at least one chance during his course of study to join a party organized for visiting some of the more interesting mining regions. The valuable scientific library of the late Prof. Henry D. Rogers, of the University of Glasgow, presented to the Institute by Mrs. Rogers, is accessible to the students in Geology and Mining.

The Mining and Metallurgical Laboratories.—These laboratories furnish to students in Mining and Metallurgy the means for studying experimentally the various processes of ore-dressing and smelting. Ores of different kinds may be here subjected, on a small scale, to the same modes of treatment as have been adopted at the best mining and metallurgical establishments. The experimental work of the laboratory is carried on by the students, under the immediate charge of an instructor. A sufficiently large quantity of ore is assigned to each student, who first examines it for its component minerals, sorts and samples it, and determines its character and value by analysis and assays, and makes such other preliminary examinations as serve to indicate the proper method of treatment. He then treats the given quantity, makes a careful examination of the products at each step of the process, ascertains the amount of power, water, chemicals, fuel, and labor expended, wherever practicable, and thus learns approximately the effectiveness and economy of the method adopted. Each student is assisted in working his ore by his classmates, who have an opportunity in this way to run the boiler, engine, machines, and furnaces. The Institute is from time to time receiving ores of gold, silver, lead, copper, antimony, zinc, iron, etc., from various localities. These ores are worked, and reports sent to those who contribute them; and it is hoped that, by the co-operation of those who wish to have examinations made, the laboratory will continue to receive the necessary amount and variety of ores.

Models etc., relating to the Engineering courses.—The collections under this head consist of models in wood, in metal, and in plaster, besides lithographs, photographs, and drawings collected in the United States and in Europe. They illustrate the following subjects:—General descriptive Geometry, Linear Perspective, Shades, Shadows and Reflections, Masonry and Stone Cutting, Joints, Girders and Trusses for wood and Iron Structures, Furnaces and Boilers, Steam and Water Motors, Machines and their details.

The Instruction in Mineralogy.—Determinative Mineralogy is taught by the study of crystalline forms and the physical properties of minerals, and use of the blowpipe, and by the handling of specimens. The collection of minerals in use for instruction is placed in the study room of the Mining department, and is thus ready for reference at any time.

The Instruction in Geology and Physical Geography.—The instruction in these branches has been so arranged that the topics to be taught may be presented in the order of their logical succession.

I. Forty-five lessons in Physical, including Dynamical Geology, are given during the second term of the second year. It is the aim of these lessons to lead the student to a scientific knowledge of the principal features of the earth's surface, their characteristics, classification, geographical relation, and the changes which they have experienced within the historic period. Frosts, glaciers, rains, streams, tides, volcanoes, earthquakes, plants, animals, etc., are considered as geological agencies, and also in their bearing upon navigation, the construction and maintenance of roads, and various works of improvement. The instructions of this term are likewise an important preparation for the studies in Structural and Historical Geology of the next year.

II. Thirty exercises in Structural Geology, including a systematic course in Lithology, are next given during the first term of the third year. Oral instruction and laboratory work are combined, the aim being to place in the hands of each student a specimen of each type to be considered. The principal structural features characterizing large masses of rocks, embracing stratification, joint structure, faults, folds, slaty cleavage, veins, dikes, etc., are taught as practically as circumstances will allow. This instruction is supplemented by frequent excursions to localities of geological interest in the vicinity of Boston. Fifteen lessons in Chemical Geology and the history of crystalline formations are then given, which comprise the formation, alteration, and decay of rocks, the origin of vein-stones and ore deposits, of rock-salt and mineral waters, and of coal and petroleum, also a general sketch of the chemical forces which co-operated with physical agencies in the formation of the earth.

III. Forty-five lessons in Historical Geology are then given during the second term of the third year. In these the outlines of the physical history of the earth are taught, and special attention is given to American geological history. The geological positions of ores and other economic products, and the modes of their occurrence, are taught in connection with the geological formations in which they are found. The instruction is made as practical as its limits will admit. A collection of specimens and a series of pictorial representations are employed in the illustration of this branch. During the summer vacations excursions of a few weeks are often made to regions where the fossiliferous formations are well developed. The instruction in Meteorology and Industrial Geography provides for an advanced course of study in the fourth year. It includes the outlines and industrial applications of Meteorological science, also the influences of geographical positions, physical features, climates, etc., upon the resources of countries, and upon the character and prosperity of nations.

The Instruction in Shop Work.—Shops or laboratories have been provided, and furnished with the more important hand and machine tools, so that the student may acquire a direct knowledge of the nature of metals, and woods, and some manual skill in the use of tools. Practical instruction in the nature of the materials of construction, and in the typical operations concerned in the arts, is considered a very valuable adjunct to the theoretical treatment of professsional subjects. Students in the course of Mechanical Engineering are required to devote a considerable amount of time to work in Carpentry, Wood Turning, Pattern Making, Moulding and Casting, Forging, Chipping and Filing, and Planing and Turning the metals, the design being to learn the principles, and not to manufacture articles for sale or use. Students in other departments will be allowed to take shop work when the time can be arranged so as not to interfere with their regular studies.

Excursions.—In aid of the practical studies of the school, and as a means of familiarizing students with the actual details of work, they are required, in term time, to make visits of inspection to machine-shops, engines, mills, furnaces, and chemical works, and to important buildings and engineering constructions within convenient reach. In the vacations more extended excursions are made for the survey of mines and geological features, and for the study of metallurgical works and noted specimens of engineering. In past years parties of students have in this way visited mines, furnaces, and engineering works in Nova Scotia, Vermont, New York, Western Massachusetts, Pennsylvania, Colorado, Missouri, and the Lake Superior copper and iron regions. During the past summer the students of Mining Engineering and Metallurgy, accompanied by two of the professors, made an excursion to the zinc mines of Franklin, N. J., the zinc and iron works at Bethlehem, Pa., the zinc mines at Friedensville, the burning coal mine at Summit, the coal mines and washers at Drifton, Pa., the coal mines and breakers at Wilkesbarre, the wire-cable works at Wilkesbarre, the Ashley Planes, the iron and steel works at Steelton, the extensive works of the Cambria Iron Co. at Johnstown, iron, steel, and glass-works at Pittsburg, the great iron-ore banks at Lebanon, the extensive bridge-works, the pottery, and the copper-works at Phœnixville, Pa., the copper, zinc, and chemical works at Bergenpoint, N. J.

Occasional Lectures.—In addition to the instruction given by the permanent corps of teachers, gentlemen in active life who are eminent in their respective professions will, from time to time, be invited to give courses of lectures on subjects of practical importance.

Scholarships.—A scholarship for regular students has been founded by the English High School Association, in memory of the late Thomas Sherwin, who, for more than thirty years, was the distinguished Master of the English High School in the City of Boston. Mr. Sherwin was also an active and influential member of the Corporation of the Institute. The pupil, to receive the benefit of this scholarship, is to be a graduate of the English High School in the city of Boston. Two scholarships were founded by the late James Savage, LL.D., the benefit of which is given to meritorious students on recommendation of the Faculty. Five advanced scholarships have been established, and will be awarded to such applicants as are recommended by the Faculty.

Degrees and Diplomas.—The degrees corresponding to the regular courses are as follows:—I. A Degree in Civil and Topographical Engineering. II. A Degree in Mechanical Engineering. III. A Degree in Mining Engineering, or in Geology and Mining. IV. A Degree in Building and Architecture. V. A Degree in Chemistry. VI. A Degree in Metallurgy. VII. A Degree in Natural History. VIII. A Degree in Physics. IX. A Degree in the General Course. To be entitled to any one of these degrees, the student must have passed satisfactory examinations in all the prescribed studies and exercises; and, in addition, a final or degree examination, embracing all the subjects which particularly relate to his course. He must, moreover, prepare a dissertation on some subject included in his course of study; or an account of some research made by himself; or an original report upon some machine, work of engineering, industrial works, mine, or mineral survey; or an original architectural design accompanied by an explanatory memoir. This thesis or design must be approved by the Faculty. Persons who have been admitted to departments of instruction in the school may, should they so desire, be examined for a degree, and, if found qualified to pass, under the prescribed conditions, they will be entitled to the appropriate diploma. The examinations for Degrees are held in the month of May. The title of the degree in each of the courses is S. B., or Bachelor of Science. The degree of S. D., or Doctor of Science, is awarded for proficiency in complete Advances of study. Besides the diplomas of the Regular and Advanced Courses, certificates of attainment in special subjects are given to such students as, on examination, are found to have the required proficiency in them.

Regulations of the School.—*School-year.*—The first term begins on the last Monday in September. There is a recess of one week after the semi-annual examinations, and the second term begins on the first Tuesday in February. On legal holidays, and on the Friday and Saturday following Thanksgiving day, the exercises of the school are suspended.

Bond or Deposit.—Every student is required, on entering the school, either to give a bond for two hundred dollars to pay all charges accruing under the regulations of the school, or to deposit, if he prefer so to do, the sum of two hundred dollars with the Bursar, to be accounted for at the end of the school-year, or whenever the depositor leaves the school, in case he leaves it before the end of the year. This deposit must be renewed at the beginning of each year. The bond must be executed by two bondsmen, satisfactory to the Bursar, one of them being a citizen of Massachusetts; and it must be filed within ten days after the date at which the student joins the school.

Fees.—The fee for regular students is $200 per year, $125 at the beginning, and $75 at the middle (First Tuesday in February) of the school-year. For one-half, or any less fraction, of the school-year, the fee is $125. Payment is also required of the cost of apparatus broken, or used up in the laboratories. Special students pay, in general, the full fee; but when a few branches only are pursued, and the time required for instruction is limited, some deduction may be made. The fee for students in the advanced courses is the same as that for regular students.

Attendance.—Regular students are expected to attend all the exercises of their several courses. Special students are expected to attend all the exercises in the subjects they have selected, unless excused by special vote of the Faculty. Students entering a lecture room, drawing room, or laboratory more than five minutes after the hour designated for the beginning of the exercise will be marked tardy. Students are, in general, expected to devote themselves to the work of the school between the hours of 9 A. M. and 4.30 P. M., except during the interval for dinner. There are no exercises on Saturday afternoon, and the rooms are closed.

Discipline.—While within the limits of the Institute, students are expected to behave with decorum, to obey the regulations of the school, and to pay a due respect to its officers. Every student will be held responsible for the furniture which he uses, and the cost of repairing any damage thereto will be charged to him. In case of injury to the building, or to any of the furniture, apparatus, or other property of the Institute, the damage will be charged to the student or students known to be immediately concerned; but if the persons who caused the damage are unknown, the cost of repairing the same will be assessed equally upon all the students of the school. Conduct inconsistent with the general good order of the school, if repeated after admonition, will be followed by suspension or dismissal. It is the aim of the Faculty so to administer the discipline of the school as to maintain a high standard of integrity, and a scrupulous regard for truth; and the attempt of any student to present as his own the work of another, or to pass any examination by improper means, is regarded as a most serious offence, and renders the offender liable to immediate expulsion.

Residence and Expenses.—As the exercises of the school begin at nine o'clock in the morning, and end at half-past four or five o'clock in the afternoon, students may conveniently live in any of the neighboring cities or towns on the lines of the various railroads, if they prefer to do so. The cost of board and rooms in Boston, and the neighboring cities and towns need not exceed from six to eight dollars a week. The cost of board at the Institute restaurant is three dollars and fifty cents per week, and conveniently located rooms may be found at a cost of two dollars and upwards additional per week. The cost of books, drawing instruments, paper, exclusive of chemical breakage, is from twenty-five to thirty-five dollars a year.

School of Mechanic Arts.—A School of Mechanic Arts, in which special prominence is given to *manual* instruction, has been established for those who wish to enter upon industrial pursuits rather than to become scientific engineers. This school is designed to afford such students as have completed the ordinary grammar-school course an opportunity to continue the elementry scientific and literary studies, together with mechanical drawing, while receiving instruction in the use of the typical tools for working iron and wood. The shop is conducted upon a plan designed at the Imperial Technical School of Moscow, Russia, and carried out there with satisfactory results. Its exact and systematic method affords the direct advantages of training the hand and eye for accurate and efficient service with the greatest economy of time; and the instruction in the use of tools and materials has also proved a valuable aid in intellectual development. The shop courses of the school are as follows:—

First year:—I, Carpentry and Joinery; II, Wood Turning; III, Pattern making; IV, Foundry Work.

Second year:—I, Iron Forging; II, Vise Work; III, Machine Tool Work.

The full course includes two years of theoretical and practical studies combined, and students who successfully complete it will receive a certificate, Students will be received for shorter times, and for special portions of the course. When it is desired, such provision will be made for advanced and specific shop work as is consistent with due attention to the regular classes. Students in this school are recommended to attend the exercises in Military Drill, and hours will be so arranged as to allow them to do so without detriment to their studies.

Applicants for the regular course must be at least fifteen years of age, and must pass a satisfactory examination in arithmetic, geography, and English composition. The tuition is $150 a year, with no extra charge for the use of tools, or materials, used in regular exercises. Special students, taking the same amount of shop work only as the regular class shop work, will be charged less. The student is entitled to the products of his work. Students while on the premises of the Institute, are expected to remain in the study room, except when at recitations or in the work shops. A monthly return of absences is made to the parent or guardian.

FIRST YEAR.—*First Term.*—Shop Work. Carpentry. Algebra commenced. English composition. Mechanical and Free hand Drawing.

Second Term.—Shop Work. Wood Turning, Pattern Making, Foundry Work. Plane Geometry. English Composition. Mechanical and Free hand Drawing.

SECOND YEAR.—*First Term.*—Shop Work.—Forging. Algebra completed. Elementary Physics. English Composition. Mechanical Drawing.

Second Term.—Shop Work.—Vise Work, Machine Tool Work. Geometry. Physics. English Composition. Mechanical Drawing.

The beginning and ending of the school-year and the days of entrance examinations are the same as in the School of Industrial Science. The two scholarships, founded by this Association, are awarded to sons of present or past members of the Association, on recommendation by the President and Secretary of the Association. The scholarship entitles the student to free tuition in the School of Mechanic Arts.

Free Courses of Instruction.—The Trustee of the Lowell Institute has established, under the supervision of the Institute of Technology, courses of instruction, generally given in the evening, and open to students of either sex, free of charge. These courses are more or less varied from year to year by the omission or interchange of particular subjects, but include in their entire scope instruction in mathematics, mechanics, physics, drawing, chemistry, geology, natural history, biology, English, French, German, history, navigation, and nautical astronomy, architecture, and engineering. The subjects, and the extent of the several courses, will be made known in October of each year. As it is the object of these courses to provide substantial teaching rather than merely popular illustrations of the subjects treated, it is expected that all persons attending these courses will come with a serious purpose of improvement, and that they will cheerfully comply with such rules as may be prescribed in regard to attendance and to order in the class or lecture-room. The conditions of attendance on these gratuitous courses are as follows:—

1. Candidates must have attained the age of eighteen years.
2. Their applications must be made in writing, addressed to the Secretary of the Faculty, specifying the course or courses they desire to attend; mentioning their present or prospective occupations; and, when the course is of a nature demanding preparation, stating the extent of their preliminary training.

The number of students in each class is necessarily limited.

CALENDAR.—Entrance Examinations, Tuesday, Sept. 19, 1882, and Wednesday, Sept. 20, 1882. Examinations for Advanced Standing, Thursday, Sept, 21, 1882. The next School year will begin Monday, Sept. 25, 1882.

Officers of Instruction.—Francis A. Walker, Ph. D., LL. D., President. William B. Rogers, LL. D., Professor Emeritus of Physics and Geology. John D. Runkle, Ph. LL. D., Walker Professor of Mathematics. William P. Atkinson, A. M., Professor of English and History. George A. Osborne, S. B., Professor of Mathematics. John M. Ordway, A. M., Professor of Metallurgy and Industrial Chemistry. Robert H. Richards, S. B., Professor of Mining Engineering, and Director of the Mining and Metallurgical Laboratories. William Ripley Nichols, S. B., Professor of General Chemistry. Charles P. Otis, A. M., Ph. D., Professor of Modern Languages. Charles H. Wing, S. B.. Professor of Analytical and of Organic Chemistry. Alpheus Hyatt, S. B., Custodian of Boston Society of Natural History, Professor of Zoölogy and Palæontology. William H. Niles, Ph. B., A. M., Professor of Geology and Geography. Channing Whitaker, S. B., Professor of Mechanical Engineering. Charles R. Cross, S. B., Thayer Professor of Physics. Gaetano Lanza, S. B., C. E., Professor of Theoretical and Applied Mechanics. George L. Vose, A. M., C. E., Hayward Professor of Civil and Topographical Engineering. Theodore M. Clark, A. B., Professor of Architecture. Eugene Letang, Assistant Professor of Architecture. Jules Luquiens, Ph. D., Assistant Professor of Modern Languages. William P. P. Longfellow, Adjunct Professor of Architectural Design. Charles Kastner, Lowell Instructor in Practical Design. Henry K. Burrison, S. B., Instructor in Mechanical and Free-Hand Drawing. Clarence W. Fearing, A. M., Instructor in the School of Mechanic Arts. Ellen H. Richards, A. M., S. B., Instructor in Chemistry and Mineralogy in the Woman's Laboratory. Silas W. Holman, S. B., Instructor in Physics. William O. Crosby, S. B., Instructor in Geology, Palæontology, and Mineralogy. Colonel John C. Chadwick, Instructor in Military Tactics. George F. Swain, S. B., Instructor in Civil Engineering. Wm. Henry Beeching, S. B., Assistant in Mechanical Engineering. W. Keltner Robbins, M. S., Assistant in Quantitative Analysis. Wm. H. Pickering, S. B., Assistant in Physics. Charles L. Adams, Instructor in Drawing in the School of Mechanic Arts. John Duff, Jr., S. B., Assistant in the Mining and Metallurgical Laboratory. William B. Lindsay, S. B., Assistant in General Chemistry and Qualitative Analysis. James Lund, S. B., Assistant in Quantitative Analysis. Evelyn M. Walton, S. B., Assistant in Chemistry and Biology. Frank W. Whitney, A. B., Assistant in General Chemistry and Qualitative Analysis. Artemas L. Tyler, Assistant in General Chemistry and Qualitative Analysis. George L. Perry, S. B., Assistant in Drawing. Charles M. Wilkes, S. B., Assistant in Applied Mechanics. Thomas Foley, Instructor in Iron Working. George Smith, Instructor in Wood Working. Arthur W. Sanborn, Assistant in Iron Working. William C. Fisher, Assistant in the Weaving Department of the Lowell School of Practical Design.

The instruction in Political Economy and in International Law is given by the President; that in Descriptive Geometry and Stereotomy by Professor Osborne; that in Descriptive Astronomy by Prof. Cross; and that in Botany and Biology by Prof. Ordway. The instruction in Quantitative Analysis in the Woman's Laboratory is also in charge of Prof. Ordway.

FACULTY.—Francis A. Walker, President, William B. Rogers, John D. Runkle, Willian P. Atkinson, George A. Osborne, John M. Ordway, Chairman, Robert H. Richards, Secretary, William Ripley Nichols, Charles P. Otis, Charles H. Wing, Alpheus Hyatt, William H. Niles, Channing Whitaker, Charles R. Cross, Gaetano Lanza, Jules Luquiens, George L. Vose, Theodore M. Clark.

A MINING LABORATORY.

A CLEARER insight into the work being accomplished at the Massachusetts Institute of Technology is afforded by the following paper on the Mining Laboratory connected with the Institute, read before the American Institute of Mining Engineers, by R. H. Richards, Professor of Mining, at the Institute.

Whether it was wise or not to establish a mining school so far from the principal mining centres, does not now enter into the question. Given, a mining school already begun, how shall it be made most efficient in developing engineers who are trained to think for themselves as well as versed in the works of others? This is the question with which we have had to deal. In considering the bearing of this laboratory work upon the students' preparation, it will be convenient to take it up under five different heads:

1. The methods and aims of the laboratory.
2. The advantage to students of having a part, at least, of their practical work in the curriculum of their school.
3. The advantage to be derived by mines and works.
4. Degree of accuracy which may be attained in working ores on a small scale.
5. Results of work in the laboratory.

1. *The Methods and Aims of the Laboratory.*—Perhaps the aims of the laboratory can be most clearly shown by illustration. Many young engineers leave school thinking that they know everything. They go to the works, and expect to teach the superintendent something and the men a good deal, regardless of the fact that it is this spirit that has prejudiced workmen against schoolmen. They are often more trouble than they are worth for a considerable period of time. They have simply learned metallurgical processes from books, but they have not derived from them a realizing sense of the meaning of the word economy, nor do they understand how to carry it out in actual practice. They are too apt not to perceive that the profit of works lies in the little savings in material, in labor, in time and power, etc., and that the difference between making these little savings and in not making them is almost always the difference between profit and loss, or between success and failure. In fact, our young engineers are not, as a rule, fully enough aware of the fact that failures in mines and works are quite as often the resnlt of errors in judgment as they are from poverty of the deposit or process. The aim of this laboratory is to correct this state of things, and to turn out men who have learned somewhat of the value of economy; who have found out by *their own* experience that little losses, taking place here and there and everywhere in their work, mount up enormously in their final account of stock.

For the sake of example, we will suppose that a silver-lead ore is given to a student who is entirely inexperienced in such matters, and who is inclined to be self-sufficient. On reading up, he finds that such ores, when worked on the large scale, are subject to a loss, which we will say is 15 per cent. of the silver, and which takes place largely in the smelting. He is surprised at this, and thinks it is a large loss, and expects to do as well or better. On taking account of stock, however, we will suppose he finds his losses are: silver in dust while crushing and handling, 2 per cent.; roasting, 15 per cent.; agglomerating, 3 per cent.; smelting, 15 per cent.; fume in refining, 2 per cent.; handling in refining, 6 per cent.; fume in cupelling, 4 per cent.; parting and recovering, 3 per cent.; total, 50 per cent. He is astonished to find that his total loss amounts to 50 per cent. and that by carelessness in handling alone, he has lost 11 per cent., the whole of which might have been obviated as well as not; that in roasting he used too high a heat, and in cupelling the same; that by having large condensing flues, he might have saved a large portion of the loss in smelting and refining. In fact, this man has either learned a lesson in the economy of metal working that will last him his life, or he has failed to learn it. In either case, whatever may be the risk incurred by a works in taking an untried man from a school, the risk is in some degree lessened by this test of the man. We believe that ability to offer to works a selection of men is all the incentive we need for developing this laboratory. We hold that the school owes a duty to the works as well as to the student, and that the supplying of works with good men is fully as important a duty of the school as the finding of places for the student.

The methods of working the laboratory will best be given by a brief description of the last year's work. The course began in February with a class of thirteen students. The work was allotted so that each student had the entire responsibility of a whole process or of a part of a process. A quantity of low grade ore from the Merrimac Mine, weighing $4\frac{1}{2}$ tons, was treated first. Two students, A and B, took charge of the mineral examination, and of the crushing and washing. They were assisted in the washing by their whole class, who had this opportunity to operate the washers, and to make themselves familiar with the principles on which they work. The class came on, five men at a shift, and they worked ten shifts of four hours each; in this way every man had an opportunity to work and to study every machine. The captains, A. and B., meantime took charge on the alternate shifts, so that one of them was always on hand to keep watch, and to see that waste did not take place, that samples were taken at the proper intervals, and that everything went on as it should. When the work was through, they dried, weighed, sampled, and assayed all the final products. They found out then whether the refuse was poor enough to throw away. They found out which machine did the greatest work, and which the least. In fact, they were in condition to report upon the economy of the process from beginning to end. They afterward made numerous tests on sands falling into water, and speculated on possible alterations which would be desirable if the washers were to be used exclusively for the ore in question. These tests were rendered possible by means of a series of samples which had been taken at every stage of the process. A, reported especially upon the crushing machines and the washing jigs, while B, reported upon the spitzkasten and on the tables which were used in washing. Three products were the result of this treatment:

1. Smelting ore. 2. Middle-grade ore. 3. Refuse.

C. and D. took charge of the smelting ore; this was first roasted in reverberatory furnaces. The whole class came on by shifts of four hours each, and the operation went on night and day continuously until finished. The total time required was 52 hours. C. and D. then agglomerated the ore, sampled it, analyzed it, and also their fluxes (limestone, tap cinder, magnetic iron ore, etc). They planned their smelting to obtain a given slag, matte, and metal. When it was smelted in the shaft furnace all the class came on by shifts, and by means of this run, and several others during the term, every man was able to serve in every place, and thus to learn the principles which underlie the whole operation, as well the details by which it is carried on in the laboratory. This smelting yielded—

1. Lead. 2. Matte. 3. Slag.

C. followed up the metal, and turned out silver, lead, and gold. D. followed up the matte, and turned out copper, lead, and silver. Their reports consist of a detail of the operations, results of analyses, and tables showing where, when, and how the losses took place, with suggestions as to how they would mitigate them another time. E. and F. undertook to work the middle-grade ore, and they tried the Ziervogle, Augustin, Von Patera, as well as roast, chlorination with amalgamation, and a number of other methods. They divided the processes, one taking the responsibility of a part, the other of the rest. They report moderate success in some and dead failures in others. A sulphuretted ore was allotted to G. and H. This ore, as a matter of course, required to be first roasted. We have two methods of roasting, by reverberatory furnace and by kiln. But as a kiln had never been tried in the laboratory, and as it was to a certain extent doubtful whether it could be made to work, a division was made. G. took the kiln roasting followed by the subsequent smelting, roasting and smelting, etc., while H took the method by reverberatory furnace, followed by the subsequent processes. This work was carried on in the same spirit as before indicated.

K. took up nickel, looked up the published methods, and experimented upon its extraction

L. worked a gold ore by Atwood's amalgamators, concentration, and gas chlorination. This method is still in its experimental condition with us.

M. had a barrel of quartz galena assigned to him.

N. had a barrel of silver ore assigned him, which was to be treated by pan amalgamation.

O. worked out a problem on a copper ore from a mine at Santa Fe. The question to be settled was whether it would pay best to turn out a slag lean in copper, and at the same time a pure copper pig, or to turn out a pure copper pig, and at the same time allow some metal to enter the slag. His results are very interesting.

Thus it will be seen that every student who has worked in the laboratory during the last year has not only had a definite work of his own to do, but has also had the opportunity to watch or to assist in a very considerable variety of other work.

2. *Advantage to the Student of having a part of his Practical Work in the curriculum of his School.*—We learn by our mistakes. Men can try, and fail; can find out usually why they failed; can repeat the work with the failure in part or in whole corrected. They can learn economy by their own lack of it. Large works cannot afford to spoil a charge to show a student what happens from a little carelessness. A well-regulated establishment may go on a long time without such a slip, and unless the superintendent is used to giving instruction, and takes pleasure in it, the student may be months at a works without finding out what the key to the success of the establishment is. Again, a student learns the value of chemistry as a check upon metallurgical work. Who would attempt to run a blast furnace on lead ores or on iron ores without knowing something about the composition of slags and of the fluxes at hand? The students here plan the proportion of the fluxes to be used from their own analyses of the same. And if they find from their reading that a slag of 30 per cent. SiO_2, 45 per cent. FeO, 15 per cent. CaO, 10 per cent. Al_2O_3, should give a good fusion and a slag clear of lead, they put in fluxes containing these elements in the above proportions, and when they get through they analyze their slag, to see if they got what they tried for and to see if it was as lean in lead as they wished it to be. But perhaps the greatest advantage of all to the student, and the one which will stay with him through his whole life long, is the spirit of investigation which is awakened by his work, and which is made evident by the questions he asks, and by the zest and intelligence with which he carries on his work. This we consider has been proved beyond all question. We wish to disclaim any pretensions which we may be supposed to have that this laboratory is in any sense of the word a substitute for the works. What we do claim is that it prepares students to go into works and profit by them.

3. *Advantage to Works.*—We have already noticed one advantage, viz., that the men have had a chance to test themselves and find out where they are weak. There is, however, another advantage which may grow out of their experience in the laboratory. These men are used to testing processes on a small scale, and if they are, when older, called upon to erect costly works and to devise new and expensive processes, they will naturally spend a thousand or two dollars in trying the process practically. Most of us are familiar with large and costly failures which might have been prevented if the process had been studied in this way. For while work on the small scale does not pretend to deal with the relation between the cost of production, of transportation, and the market value, it does test most thoroughly the chemical and mechanical principles on which the process must depend. Again, this practical work enables us to make a far more just division of hand-men from head-men than could possibly be made from recitations and examinations alone. And if we have an application for a man who may by-and-by be needed to superintend, we recommend a very different man from what we do when we were asked for an analyst or a surveyor.

Advantage to Mines of having their own Ores treated in the Laboratory.—We will cite one example. The Merrimac Mine of Newburyport has recently called an engineer from a distance to systematize their smelting works. He informs me that the figures furnished by the students were of very great value to him in planning his ore charge. And again, as soon as the mine is prepared to establish washing-works, and the matter is under consideration at the present time, the results of our washers will be at their service. To sum up what has been said: We believe that such a course of instructions will bring out latent originality if a student has anything of it in his composition, and that, if he is nothing but a copyist, his instructors, as well as the man himself, will be convinced of the fact before he leaves his school; and again, that such instruction will enable him to profit far more by his visits to works, or studies in them, than he otherwise would. The testimony of graduates of the school and of their employers bear us out in the above statements.

4. *Degree of Accuracy of working Ores on the Small Scale as compared with the Large Scale.*—On the large scale the operations are continuous. If a little is left by one charge, it is taken up by the next one, and does not affect the total. On the small scale, however, what is lost in one charge by carelessness is not picked up by the next, because there is no next charge to follow it. In large works men are chosen to fill places by their skill or aptness for those places. On the same scale the students spend a part of the time of doing the work in learning how to do it. To be sure they learn vastly quicker than the ordinary hands who are usually employed for such work; but still this does not wholly make up for their lack of skill in the first instance, nor does it make the small works quite on a par with the large ones in this respect.

5. *Results of Work in the Laboratory.*—The following examples will serve to show the kind of work that is done by the students, as well as the scale of it and the degree of accuracy attained. A lot of poor ore from the dump heap of the Merrimac Mine of Newburyport, weighing 8485 pounds, was crushed and washed to separate the argentiferous materials from the gangue rock, and yielded these proportions:

1. A smelting ore . .	weighing	624¼	pounds.
2. A middle-grade ore .	"	1823½	"
3. Refuse . . .	"	6016⅛	"

Referring this yield to one ton of crude ore, the intrinsic value of the metals in the products obtained from it would be:

1. Smelting ore, 147.14 lb., containing					
	39.4	per cent. lead, or	57.92	lb., or	$3 47
	0.7	" silver, or	.103	"	1 73
	.0024	" gold, or	.00353	"	1 06
					$6 26
2. Middle-grade ore, 429.8 lb., containing					
	9.11	per cent. lead, or	39.15	lb., or	$2 35
	.031	" silver, or	.133	"	2 13
	.00114	" gold, or	.0049	"	1 47
					$5 95
3. Refuse, 1418.06 lb. containing					
	1.25	per cent. lead, or	17.72	lb. or	$1 06
	.0116	" silver, or	.1645	"	2 63
					$3 69
				Total	$13 37

The ore itself was valued for lead and silver, but not for gold, with this result:

1 ton contained	5.23 per cent. lead,	104.6 lb.	$6 28	
	.02 per cent. silver,	.4 "	6 42	
				$12 70

The values of the above products would be:

1 ton smelting ore,	39.4	per cent. lead,	788 lb.	$47 28	
	.07	" silver,	20.41 oz.	23 47	
	.0024	" gold,	.6998 oz.	14 42	
					$85 17
1 ton middle-grade ore,	9.11	per cent. lead,	182 lbs.	$10 92	
	.031	" silver,	9.039 oz.	9 94	
	.00114	" gold,	.3324 "	6 85	
					$26 49
1 ton refuse .	1.25	per cent. lead,	25 lb.	$1 50	
	.0116	" silver,	3.382 oz.	3 72	
					$5 22

A lot of lead ore, composed chiefly of galena with a little pyrite, blende, quartz, and feldspar, from ore of the veins crossed by the Burleigh tunnel of Georgetown, Colorado, was roasted, agglomerated, smelted, refined, and cupelled. It gave the following results:

Ore, ...	1100 lb. at 67.37 per cent. lead, 675-07 lb.	.095 " silver, 15.24 oz.
After roasting and agglomerating . . .	996¼ lb. at 60.68 per cent. lead, 604.52 lb.	.086 " silver, 12.48 oz.
After smelting and refining to soft lead . .	429.75 lb. at 98.95 per cent. lead 425.24 lb.	1.97 " silver, 12.33 oz.

From which it appears that the loss in roasting and agglomerating was 70.55 pounds lead and 2.76 ounces silver; smelting and refining was 179.28 pounds lead, and .15 ounce silver. This loss in silver is too little to represent the truth, as 12.33 ounces is known to be too high, the sample was taken from the tops of the pigs. The zincing was accomplished by stirring in one per cent. of zinc with melted lead and then casting it in ingots and sweating it. This operation was repeated three times, and each time yielded a rich argentiferous zinc dross and a poorer zinciferous lead; the actual weight of silver in each of these six products is here given:

429.75 pounds refined lead, at .197 per cent. contains 12.33 oz. silver.
1st. Argentiferous dross, 9.73 oz. silver (a little high), sample poor.
1st. Sweated lead, - 3.09 " by assay.
2d. Argentiferous dross, 2.895 " (by difference).
2d. Sweated lead, - .195 " by assay.
3d. Argentiferous dross, .145 " (by difference).
3d. Sweated lead, - .059 " by assay.

This last sweated lead contained but .001 per cent. of silver. The distilling and final cupelling were not as successful as the rest, as from breaking of the cupel and other mishaps only 9.73 ounces of pure silver were obtained. A copper ore from Santa Fe was worked by a student who was preparing himself to go to the mine. His main object was to experiment on slag, to find out a suitable composition that would yield soft, clean copper in the blast furnace. The ore was composed of malachite, chrysocolla, cuprite, atacamite, with a very large quantity of grossularite (lime garnet), and also quartz, calcite, and a little pyrolusite. Its chemical composition is given in the table below. The run was divided into halves; after the first was through, the furnace was run out and then charged up again with a new mixture. During the first run the slag was planned to carry a high per cent. of iron, during the second run it was planned for a high per cent. of lime. The results are as follows:

		First-run Slags.		Second-run Slags.	
	Ore.	As planned.	As obtained.	As planned.	As obtained
SiO_2, . . .	38.40	40	46.07	46.	49.90
Al_2O_3, . . .	14.95	16	20.92	17.5	10.53
Fe_2O_3, . . .	13.11	..	....	....	.....
FeO,		34	16 65	15.	14.17
Cao, . . .	10.63	10	7.01	21.05	20.61
MgO . . .	trace	..	trace	....	.20
MnO, . . .	.80	..	2.35	....	.43
Cu, ...	12.32	..	1.23	....	1.55
H_2O & CO_2, etc. undetermined.					

It will be noticed at once in the first-run slag as obtained a monstrous deficiency in FeO. This will be accounted for by the pig copper from this run, which contained 18 per cent. iron. The second run was much more nearly adjusted to suit the furnace reactions, as is shown by the slag, which is not very far from the plan, and also by the copper, which was soft and malleable, and contained but .3 per cent. iron.

CORNELL UNIVERSITY, ITHACA, N. Y.

THE existence of Cornell University is due to the bounty of the United States and of Ezra Cornell. On the second of July, 1862, Congress passed an act granting public lands to the several states which should "provide at least one college where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts." Thirty thousand acres for each of its senators and representatives in Congress were appropriated to every state; and the share of the State of New York was nine hundred and ninety thousand acres in land scrip. On the twenty-seventh of April, 1865, the legislature of New York incorporated "The Cornell University," appropriating to it the income arising from the sale of this land scrip. The most important conditions were, that Ezra Cornell should give to the University five hundred thousand dollars; that it should give instruction in branches relating to agriculture, mechanic arts, and military tactics; and that it should receive, without charge for tuition, one student annually from each assembly district. Mr. Cornell fulfilled the first requirement of the charter, and made an additional gift of more than two hundred acres of land, with buildings, to be used as a farm in connection with the department of agriculture. The act of incorporation satisfies the condition of the congressional grant by providing for instruction in such branches of learning as are related to agriculture and the mechanic arts, and in military tactics, "in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life." And it further declares that "such other branches of science and knowledge may be embraced in the plan of instruction and investigation pertaining to the University, as the trustees may deem useful and proper." The University, organized in accordance with the requirements of its charter, was opened on the seventh of October, 1868.

FACULTY.—(Arranged, with the exception of the Officers of the Faculty, in the order of seniority of appointment), Hon. Andrew Dickson White, LL.D., President, Professor of History. Rev. William Dexter Wilson, DD., LL.D., L.H.D., Registrar, Professor of Moral and Intellectual Philosophy. Daniel Willard Fiske, A.M., Ph.D., Librarian, Professor of North European Languages. George Chapman Caldwell, B.S., Ph.D., Professor of Agricultural and Analytical Chemistry, and Secretary of the Faculty. Burt Green Wilder, B.S., M.D., Professor of Physiology, Comparative Anatomy, and Zoölogy. James Law, F.R.C.V.S., Professor of Veterinary Medicine and Surgery. Albert Nelson Prentiss, M.S., Professor of Botany, Horticulture, and Arboriculture. John Lewis Morris, A.M., C.E., Sibley Professor of Practical Mechanics and Machine Construction. Thomas Frederick Crane, A.M., Professor of Spanish and Italian, and Acting Professor of French. Ziba Hazard Potter, A.M., M.D., LL.B., Assistant Professor of Mathematics, and Medical Examiner. Charles Ashmead Schaeffer, A.M., Ph.D., Professor of General and Analytical Chemistry, and of Mineralogy. Frederick Otto Louis Rœhrig, Ph.D., M.D., Professor of Sanskrit and Living Asiatic Languages, and Assistant Professor of French. Hiram Corson, A.M., LL.D., Professor of Anglo-Saxon and English Literature. Waterman Thomas Hewett, A.M., Ph.D., Assistant Professor of German. Bela Phillips Mackoon, A.M., Associate Professor of German. Alfred Stebbins, A.M., Assistant Professor of South European Languages. Lucien Augustus Wait, A.B., Associate Professor of Mathematics. Isaac Flagg, Ph. D., Professor of the Greek Language and Literature. Charles Chauncy Shackford, A.M., Professor of Rhetoric and General Literature. Rev. Charles Babcock, A.M., Professor of Architecture. James Edward Oliver, A.M., Professor of Mathematics. William Arnold Anthony, Ph.B., Professor of Physics and Experimental Mechanics. Estevan Antoni Fuertes, Ph.B., C.E., Professor of Civil Engineering. Edwin Chase Cleaves, B.S., Associate Professor of Freehand Drawing and Mechanical Drawing. Isaac Phillips Roberts, M.Agr., Professor of Agriculture. Abram Adam Breneman, B.S., Professor of Industrial Chemistry, and Assistant Professor of Analytical Chemistry. Charles Lee Crandall, C.E., Assistant Professor of Engineering. Irving Porter Church, C.E., Assistant Professor of Engineering. Horatio Stevens White, A.B., Professor of the German Language and Literature. John Henry Comstock, B.S., Assistant Professor of Entomology, and Lecturer on the Zoölogy of Invertebrates. William Russell Dudley, M.S., Assistant Professor of Botany. James Brattle Burbank, Brevet Maj. 3d Art., U.S.A., Professor of Military Science and Tactics. George William Jones, A.M., Assistant Professor of Mathematics. Samuel

Gardner Williams, A.M., Ph.D., Professor of General and Economic Geology. Henry Shaler Williams, Ph.D., Assistant Professor of Palæontology. William Rufus Perkins, A.B., Assistant Professor of Latin and Greek. George Sylvanus Moler, B.M.E., Assistant Professor of Physics William Gardner Hale, A.B., Professor of the Latin Language and Literature. Walter Craig Kerr, B.M.E., Assistant Professor of Mechanics. John Burkitt Webb, C.E., Professor of Applied Mathematics and Theoretical Mechanics. Simon Henry Gage, B.S., Assistant Professor of Physiology, and Lecturer on Microscopical Technology. William Edward Lucas, Ph.B., Assistant Professor of Rhetoric and Composition. Charles Francis Osborne, Assistant Professor of Architecture. Moses Coit Tyler, LL.D., Professor of American History and Literature.

Lecturers and Non-Resident Professors.—Goldwin Smith, LL.D., L.H.D., Lecturer on English Constitutional History. Charles Hallet Wing, B.S., Non-Resident Professor of Organic Chemistry. Herbert Tuttle, A.M., Non-Resident Professor of International Law. Henry Carter Adams, Ph.D., Non-Resident Professor of Political Economy. Charles Kendall Adams, LL.D., Non-Resident Professor of English Constitutional History. Edward Augustus Freeman, D.C.L., Oxon., Lecturer (for the current year) on General European History.

Instructors.—Madison Monroe Garver, B.S., Instructor in Chemistry and Mineralogy. Stephen Moulton Babcock, Ph.D., Instructor in Chemistry. George Lincoln Burr, A.B., Instructor and Examiner in Modern History.

Other Officers.—Wesley Newcomb, M.D., Curator of the Newcomb Collection of Shells. George William Harris, Ph.D., Assistant Librarian. Spencer Baird Newbury, E.M., Ph.D., Chemical Analyst to the Agricultural Station. Benjamin Hermon Smith, Director of the University Press. George W. Tailby, Foreman of the Farm. Miles Lorin Clinton, Foreman of the Machine Shop. Albert Franklin Matthews, Master of the Chimes. William Ogden Kerr, Meteorological Observer. Ernest Emmery Russell, Janitor.

Chemistry and Physics.—The President, Professor Schaeffer, Professors Anthony, Caldwell, Breneman, and Moler.

Civil Engineering.—The President, Professor Fuertes, Professors Anthony, Babcock, Morais, Oliver, Schaeffer, Church, and Crandall.

Mathematics.—The President, Professor Oliver, Professors Anthony, Babcock, Fuertes, Morris, Webb, Wait, Jones, and Potter.

The Sibley College of Mechanic Arts.—The President, Professor Morris, Professors Anthony, Babcock, Fuertes, Webb, Oliver, Kerr, and Cleaves.

ADMISSION.—All candidates for admission, except those provided with certificates or diplomas as specified below, are examined as follows:

1. In *English Grammar;* Whitney's Essentials of the English Grammar is the standard. A short composition is required as a test of the candidate's knowledge of spelling, punctuation, the use of capitals, and elementary English construction.

2. In *Geography,* political and physical; as much as is contained in Harper's School Geography, or in Warren's Common School Geography.

3. In *Physiology;* as presented in the smaller text-books upon the subject, exclusive of the nervous system and the names of bones and muscles.

4. In *Arithmetic,* including the metric system of weights and measures; as much as is contained in the larger text-books.

5. In *Plane Geometry;* as much as is contained in the first five books of Chauvenet's Treatise on Elementary Geometry, or in the first five books of Wentworth's Elements of Plane and Solid Geometry, or in the first five books of Newcomb's Elements of Geometry.

6. In *Elementary Algebra,* through quadratic equations, and including radicals and the theory of exponents; as much as is contained in the first twelve sections of Loomis's Treatise on Algebra, or in Olney's Elementary Course in Algebra, or in the first five sections of Robinson's University Algebra.

In place of these examinations certain certificates or diplomas are received as follows:

1. *Certificates* issued by the *Regents* of the State of New York are accepted instead of the examinations in English Grammar, Geography, and Arithmetic.

2. *Certificates* issued by the *Superintendent of Public Instruction* of the State of New York, and *Diplomas* issued by the state normal schools, and by those academies and high schools of the State of New York whose requirements for graduation have been approved by the Faculty, and whose course of study requires Physiology and Plane Geometry, are accepted instead of the examinations in all the subjects named above *except Algebra.*

3. *Diplomas* issued by the *Regents* to graduates from the high schools and academies of the State of New York are accepted instead of the examinations in all the subjects named.

Candidates must be of good moral character and at least *sixteen* years of age, or, if women, *seventeen.*

The requirements for admission to the courses in *Agriculture, Architecture, Civil Engineering* and *Mechanic Arts,* are the same as those for admission to the University; but for admission to any of the other regular courses of study, the examinations, *in addition to the Primary Examinations* are as follows:

To the Courses in Science, Science and Letters, Mathematics, and Chemistry and Physics.

In addition to the primary Examination, an examination in *any one* of the following sets of subjects;

1. In *French,* the principles of French Grammar, the translation of English into French, and three books of Voltaire's Charles XII or its equivalent; *or,*

2. In *German,* the whole of Whitney's German Grammar, translation of German at sight, the translation of English into German, and one hundred pages of Whitney's Reader, including two of the longer prose extracts or an equivalent, *or*

3. In *Mathematics,* Solid Geometry and Conic Sections, as much as is contained in Newcomb's Elements of Geometry; Advanced Algebra, as much as is contained in Olney's University Algebra, or in Newcomb's Algebra; and Trigonometry, Plane and Spherical, as much as is contained in Wheeler's Elements of Trigonometry, or in the unstarred portions of Oliver, Wait, and Jones's Treatise on Trigonometry.

Admission to Special Departments.—Any person at least twenty-one years of age, and having satisfactory attainments, may be admitted without examination, by a vote of the Faculty, to any of the Departments in which either laboratory work or drafting is required, on the recommendation of the professor in charge of the department. Such special students are required to devote at least fifteen hours a week to the work of the department which they have entered, and to renew their application for admission at the end of each year.

Admission to Advanced Studies.—Candidates for admission to advanced studies in any course are required to pass, *in addition to the entrance examinations* for that course, examinations in the work already performed by the classes which they design to enter.

Candidates from Other Colleges.—Certificates of honorable dismissal from other colleges are received in place of the *Primary Examination* only, and when offered by those who *have passed at least one term's examinations* at the institution granting such dismissal. No person, whether from another college or not, is admitted to *advanced* studies except after examination as above stated.

Admission to Graduate Study.—Students are admitted to graduate study after having taken a baccalaureate degree in this University, or on presenting the diploma of any equivalent degree conferred elsewhere; they are at liberty to attend lectures, recitations, or other exercises of undergraduates, and to use the library, museums, etc. They are expected to pursue some study of advanced character under the direction of a professor or a special faculty.

MECHANIC ARTS.—In 1870, Hon. Hiram Sibley, of Rochester, N. Y., provided for the erection of a suitable building for the Department of Mechanic Arts. He also gave ten thousand dollars for increasing its equipment of tools, machines, etc., and has since made a further gift of thirty thousand dollars for the endowment of the professorship of the Practical Mechanics and Machine Construction. Still later, he provided the means for erecting and fitting up a brass and iron foundry, and a blacksmith shop. Closely connected with the lecture-rooms are the rooms for freehand and mechanical drawing, the designing of machinery, and pattern-making, and the machine shop. The shop practice embraces work requiring the use of all hand-tools and the machines employed in the ordinary machine shops. Each student in the department is required to devote two hours a day to work in the shop; but such students as have, before entering, acquired sufficient practical knowledge, are admitted to advanced standing. Attendance is required upon ten lectures or recitations a week, or their equivalent, in addition to two hours daily drawing, two hours daily shop-work, and the passing of the examinations at the close of each term.

The machine shop is used for the sole purpose of giving instruction in practical work. It is supplied with lathes of various kinds, planers, grinding machinery, drilling machines, shaping machines, a universal milling machine fitted for cutting plane, bevel, and spiral gears, spiral cutters, twist drills, with additional tools and attachments for graduating scales and circles, and for working various forms and shapes. In addition to the hand and lathe tools of the usual kinds there are tools of the greatest accuracy, consisting of standard surface-plates, straight-edges, and squares of various sizes, a standard measuring machine, measuring from zero to twelve inches by the ten-thousandth of an inch, a universal grinding machine for producing true cylindrical and conical forms, and a set of Betts's standard gauges. In the iron and brass foundry and the blacksmith shop, instruction is given in molding, casting, and forging. The cupola used is one of Colliau's improved, with a capacity of melting one ton of iron per hour. For the purpose of instruction in experimental work there is a twenty-ton Riehle testing machine, arranged for testing the strength of materials by tension, compression, and transverse strain; Richards's and Thompson's steam-engine indicators, and Amsler's planometer; Schaeffer & Budenberg's revolution counter, steam-gauges, injector, inspirator, pop-valve, steam pump; Baldwin's link and valve motion, experimental valve motion, together with a large collection of brass, iron, and wooden models illustrative of mechanical principles. The course of instruction in mechanical drawing is progressive, from geometrical drawing to the designing of machines and the making of complete working drawings. The appliances for instruction consist of several hundred drawings selected from those of technical schools abroad, and from representative American steam-engine makers and others; of photographs, models, and machines; and of apparatus used in copying by the "blue print process."

THE COURSE IN MECHANIC ARTS.—Leading to the Degree of Bachelor of Mechanical Engineering.

FIRST YEAR—*First Term*—German, 5; geometry and conic sections, 5; freehand drawing, 3; shop-work, 3.

Second Term—German, 5; algebra, 5; freehand drawing, 3; shop-work, 3.

Third Term—German, 5; trigonometry, 5; geometrical drawing, 3; shop-work, 3.

SECOND YEAR.—*First Term*—German, 3; rhetoric, 2; analytical geometry, 5; experimental mechanics and heat, 3; shop-work, 3.

Second Term—German, 3; rhetoric, 2; calculus, 5; electricity and magnetism, 3; shop-work, 3.

Third Term—Calculus, 5, descriptive geometry, text and drawing, 4; mechanical drawing, 2; building materials, 3; shop-work, 3.

THIRD YEAR—*First Term*—Calculus and analytical geometry, 5; descriptive geometry, text and drawing, 6; mechanism, 3; shop-work, 3.

Second Term—Mechanics of engineering, 5; mechanism, 3; physics, laboratory work, 3; chemistry, 3; shop-work, 3.

Third Term—Mechanics of engineering, 5; mechanical drawing, with shades, tinting, and perspective, 3; physics, laboratory work, 3; chemistry, 3; shop-work, 3.

FOURTH YEAR.—*First Term*—Mechanics of engineering, 5; mechanical and working drawings, 3; physics, laboratory work, 3; steam-engine, 3; shop-work, 3.

Second Term—Mechanical drawing, 4; steam-engine, 3; metallurgy, 2; experimental work with indicators, governors, pumps, and injectors, 3; shop-work, 3.

Third Term—Graphical statics, 3; field practice and the use of instruments, 3; industrial chemistry, 3; technical reading and preparation of thesis, 3; shop-work, 3.

GRADUATE COURSE.—*First Term* — Machines for regulating, counting, etc., 3; mechanical or physical experiments, or chemistry, 3; riparian laws, contracts, patent office laws, etc., 2. *Elective*, 7.

Second Term—Machines for change of form, 3; mechanical or physical experiments, or chemistry, 3; technical reading, 2. *Elective* 7.

Third Term—Locomotive machines, hoists, cranes, etc., 3; mechanical or physical experiments, or chemistry, 3; shop systems and accounts, 2. *Elective*, 7.

The elective studies are hydraulics, assaying, mineralogy and blow-pipe analysis, chemical laboratory practice, physics (acoustics and optics), motors other than steam, architecture, civil engineering, shop-work, mathematics, botany, French, rhetoric, history, literature.

The White Architectural Library contains over one thousand volumes, and the photographic gallery nearly two thousand prints, all accessible to the student. Seven hundred drawings, and about two hundred models in wood and stone have been prepared to illustrate the constructive forms and peculiarities of the different styles.

CIVIL ENGINEERING.—The instruction is given by means of lectures and recitations, with drafting and field laboratory practice. The field work embraces the usual operations and the more recent methods of land, railroad, and subterranean surveying, together with hydrography and geodetic practice; and since 1874 the Department of Civil Engineering has been engaged in the surveys of the hydrographic basin of central New York, as a contribution to the goedetic surveys of the United States Government. Laboratory practice is provided in chemistry, mineralogy, metallurgy, geology, physics, and civil engineering. The students of this department receive instruction in an extended course of mechanics, as applied to engineering, and their professional preparation comprises the following subjects: The location and constructions of railroads, canals, and water-works; the construction of foundations, in water and on land, and of superstructures and tunnels; the surveys, improvements, and defenses of coasts, harbors, rivers, and lakes; the determination of astronomical co-ordinates; the application of mechanics, graphical statics, and descriptive geometry to the constructions of the various kinds of right and oblique arch bridges, roofs, trusses, and suspension bridges; the design, construction and application of wind and hydraulic motors; air, electric, and heat engines, and pneumatic works; the drainage of towns and the reclaiming of lands; the preparation of plans and specifications, and the proper selection and tests of the materials used in constructions. As a part of their instruction, students have frequent practice in the preparation of papers on subjects of professional importance. An elementary course of lectures is given in engineering and mining economy, finance and jurisprudence. To meet the growing demand for special training, the five-year course has been arranged, allowing considerable option and diversity of studies to students wishing to pursue special lines of study in bridge architecture, or in railroad, mining, topographical, sanitary, geographical, electrical, or industrial engineering. The five year course also offers lines of continuous study of a historical, literary, or scientific character, which may alternate with the prescribed studies, and with architecture, general science and technology. The special library of the department possesses many valuable works, among them the extensive publications recently presented to it by the French government; and in addition, the resources of the general library are available for the purposes of the department. The engineering laboratories contain various machines, models, and appliances for engineering investigations. The engineering museum contains the following collections, which receive regular additions from yearly appropriations:

1. The Muret collection of models in descriptive geometry and stone-cutting.
2. The De Lagrave general and special models in topography, geognosy, and engineering.
3. A nearly complete collection of the Schroeder models in descriptive geometry and stone-cutting, with some of the Oliver models, and others made at the University.
4. The Grund and Sohn collections of bridge and track details, roofs, and trusses, supplemented by similar models by Schroeder and other makers.
5. A complete railroad bridge of one-hundred feet span, the model being one-fourth of the natural scale.
6. The Digeon collection of working models in hydraulic engineering.
7. Several collections of European photographs of engineering works during the process of construction; and many other photographs, diagrams, and models.

8. The following instruments of precision for astronomical purposes: a Troughton & Simms' transit, a universal instrument by the same makers reading to single seconds, three sextants, two astronomical clocks, chronographs, chronometers, two small equatorials, the larger of four and a half inch aperture, made by Alvan Clark, and other instruments necessary to the equipment of a training laboratory.

9. For geodetic work, a secondary base-line apparatus, made under the direction of the Geodetic and Coast Survey Office, and all the portable astronomical and field instruments needed, including sounding machines, deep-water thermometers, heliotropes, etc.

10. Among the coarser field instruments there is nearly every variety of engineers transits, theodolites, levels and compasses; such modern instruments as omnimeters, tacheometers, and tachometers, with a large number of special instruments, such as planimeters, pantographs, eliptographs, arithmometers, pocket altazimuths and sextants, hypsometers, and meteorological instruments of all descriptions.

THE COURSES IN CIVIL ENGINEERING.

I. A Four-Year Course.—Leading to the Degree of Bachlelor of Civil Engineering.

FIRST YEAR.

First Term.—French or German, 5; rhetoric, 2; geometry and conic Sections, 5; freehand drawing, 3; hygiene, six lectures.

Second Term.—French or German, 5; rhetoric, 2; algebra, 5; freehand drawing, 3; linear drawing, 2.

Third Term.—French or German, 5; trigonometry, 5; descriptive geometry, text and drawing, 4; botany, 3; experimental mechanics and heat, 3.

SECOND YEAR.

First Term.—French or German, 3; analytical geometry, 5; descriptive geometry, text and drawing, 6; experimental mechanics and heat, 3.

Second Term. French or German, 3; calculus, 5; pen topography, 2; tinting and shading, 2; electricity and magnetism, 3; chemistry, 2.

Third Term. Calculus, 5; land surveying, 4; acoustics and optics, 3; Chemistry, 3; technical essays, 1.

THIRD YEAR.—*First Term.* Calculus, 5; shades, shadows and perspective. 3; topographical, mapping and sketching, 2; lettering, 1; kinematics, or physics, laboratory work, 3; technical essays, 1.

Second Term. Mechanics of engineering, 5; detail drawing and graining, 2; physics, laboratory work, 3; mineralogy or metallurgy, 2; geology, 3.

Third Term. Mechanics of engineering, 5; railroad surveying, 5; colored topography, 3; lettering, 2.

FOURTH YEAR.—*First Term.* Mechanics of engineering 5; spherical astronomy, 5; practical astronomy, night observations, 2; Egyptian, Greek and Roman architecture, or physics, laboratory work, 3; stereotomy and original problems, 3; civil engineering, 2; technical essays, 1.

Second Term. Hydraulics, 5; higher geodesy, 5; mineralogy or metallurgy, 2; stone-cutting and original problems and practice, 5.

Third Term. Hydraulic motors, 2; civil engineering, 3; engineering economy, 2; bridge stresses, 5; hydrographic surveying, chart-making and geodesy, field-work, 3; preparation of thesis.

Students in the courses in civil engineering are required to write memoirs upon professional subjects of their own selection before the close of the spring term, and these memoirs are presented on the first Friday of the following term. The memoir of the last two years must contain original investigations. On the satisfactory completion of the above four-year course, students take the degree of Bachelor of Civil Engineering, and become entitled to all the privileges of resident graduates.

II. A FIVE-YEAR COURSE.—Leading to the degree of Civil Engineer.—The first four years are the same as in the four-year course. The choice of electives in the fifth year is subject to the approval of the dean of the department. Students in the fifth year pay no tuition fees and have all the privileges of resident graduates.

FIFTH YEAR.—*First Term.* Riparian rights and law of contracts, 3; bridge construction and details, 3; projects, designs and specifications, 3.

Elective, 9; Greek history, 2; modern history, 3; psychology, 2; American history, 2 or 3; physiology and zoology, 5; languages, 2; technical reading, 2; renaissance architecture, 3; chemistry, laboratory work, 3; engineering, laboratory work, 3; physics, laboratory work, 3; rock drills and air compressors, 3; the steam-engine, 3; mining projects, 3; geology, 3; industrial chemistry, 3; mathematics, 3.

Second Term. River and harbor improvements, 3; advanced astronomy and geodesy, 3; technical reading, 2; projects, designs and specifications, 2.

Elective, 8; Roman history, 2; American history 2 or 3; political economy 2; languages, 2; pure or applied mathematics, 5; zoology, 3; metallurgy, or mineralogy, 3; chemistry, laboratory work, 3; Engineering, laboratory work, 3; Physics, laboratory work, 3; Romanesque architecture, 3; the steam-engine, 3; mining projects, 2; industrial chemistry, 3; geology, 3.

Third Term. Sanitary engineering, 3; locomotive machines, etc., 3; projects, designs and specifications, 2.

Elective, 6; Roman history, 3; American history, 2 or 3; languages, 3; pure or applied mathematics, 4; historical or technical reading, 3; geology, 3; chemistry, laboratory work, 3; Engineering, laboratory work, 3; Physics, laboratory work, 3; Gothic architecture, 3; pumps and small machinery, 2; industrial chemistry, 3; mining projects, 4; arch ribs, 3; geodesy, field-work.

MINING ENGINEERING.—Although no department of Mining Engineering has yet been formally established, all the main instruction required by a mining engineer is now given, as follows: The professor of civil engineering and his associates pay special attention to the needs of those intending to connect themselves with the mining industries, giving lectures on tunneling and on the theory and practice of such constructions as are common to the professions of the civil and mining engineer; the professor of mechanical engineering and his associates pursue a like course, giving instruction in mining machinery; the professors of general chemistry and mineralogy, of analytical chemistry, and of industrial chemistry, give instruction in metallurgy, assaying, chemical analysis, and cognate subjects; the professors of geology and palæontology give instruction in the theory and classification of ores, and in those branches relating to chemical geology. It is intended, at an early day, to supplement the existing force by the appointment of such additional professors and lecturers as are necessary to the establishment of a mining school for the most advanced work, both as regards theory and practice. As it is, the University, by its existing provision in the departments named above, is enabled to give such instruction that a student graduating in them can, in a very short time, make himself acquainted with the practical processes; and, in all probability, by the time any student now entering the existing departments shall be sufficiently advanced to need instruction in the more elaborate special processes connected with mining, provision will have been fully made to give it.

THE COURSE OF MATHEMATICS—Leading to the Degree of Bachelor of Science—*First Term*—French, 5, and German, 3, or German, 5, and French, 3; rhetoric, 2; geometry and conic sections, 5; hygiene, six lectures.

Second Term—French, 5, and German, 3, or German, 5, and French, 3; rhetoric, 2; algebra, 5; linear drawing, 2.

Third Term—French, 5, and German, 3, or German, 5, and French, 3; rhetoric, 2; trigonometry, 5.

SECOND YEAR—*First Term*—Analytical geometry, 5; mathematical essays, 1; freehand drawing, 3; experimental mechanics and heat, 3; physiology, 3; composition and elocution, 1.

Second Term—Calculus, 5; mathematical essays, 1; freehand drawing, 3; electricity and magnetism, 3; chemistry, 3; composition and elocution, 1.

Third Term—Calculus, 5; mathematical essays, 1; descriptive geometry, text and drawing, 4; acoustics and optics, 3; chemistry, 3; composition and elocution, 1.

THIRD YEAR—*First Term*—Calculus and analytical geometry, 5; determinants, 2; descriptive geometry, text and drawing, 6; physics, laboratory work, 3; essays, 1.

Second Term—Differential equation, 5; projective geometry, 3; descriptive astronomy, 3; mathematical essays, 1; physics, laboratory work, 3; essays and orations, 1.

Third Term—Differential equations and finite differences, 5; physical astronomy, 3; mathematical essays, 1; physics, laboratory work, 3; botany, 3; essays and orations, 1.

FOURTH YEAR—*First Term*—Imaginaries and elliptic functions, 3; mecanique analytique, 2; mathematical essays, 1; shades, shadows, and perspective, 3; geology, 1; modern history, 3; English literature, 2.

Second Term—Imaginaries and elliptic functions, 3; mecanique analytique, 2; quaternions, or modern methods in analytical geometry, or applied mathematics, 5; mathematical essays, 1; philosophy of history, 3; English literature, 2.

Third Term—Imaginaries and elliptic functions, 3; mecanique analytique, 2; quaternions, modern or methods in analytical geometry, or applied mathematics, 3; mathematical essays, 1; logic, 3; Constitution of the United States, twelve lectures; English literature, 2.

For most of the studies not closely connected with the Mathematics substitutes are allowed.

To graduates and special students, instruction is offered in theory of numbers, quantities, and celestial mechanics.

I. DESCRIPTIVE AND THEORETICAL CHEMISTRY.

Chemistry and Mineralogy.—The instruction begins with lectures on inorganic chemistry in the second year, and continues through two terms. Three lectures a week are given on the theoretical principles and the general study of the chemistry of inorganic bodies. During the first term of the third year, a course of lectures is given on the chemistry of organic bodies. In addition to the final examination at the end of the term, occasional examinations are held during the term, of which no previous notice is given, the students being expected to hold themselves in readiness for such an examination at all times. For laboratory instruction in this branch of the subject a course of introductory practice is given in the third term of the second year. This course is required of students in the course in Science, and of students in the course in Chemistry and Physics, and in Agriculture; it is required, further, of all students in other courses who take chemical practice as an optional study, in the beginning of their practice, except those who can give only the minimum amount of the time (seven and a half hours a week) for two or three terms, and who for sufficient reasons desire to devote all that time to chemical analysis. This introductory practice consists in the performance by the student of a series of experiments illustrating the more important general principles of the science. The details of the manipulation of each experiment are carefully described, but the results to be obtained are not given. For the better cultivation of the student's powers of observation he is required to observe and describe these results for himself, and trace their connection with the principles which they are intended to illustrate. The instruction in theoretical chemistry is continued in the course in Chemistry and Physics by recitations in chemical philosophy, and by lectures on organic chemistry.

Metallurgy and Mineralogy.—During the second term two lectures a week are devoted to each of these subjects in alternate years. The course in Metallurgy is intended to give the students in the technical courses a general idea of fuels, ores, and the most important methods of extracting the various metals which are especially used in construction, the metallurgy of iron claiming naturally the most attention. A certain amount of laboratory work in blowpipe analysis, with practice in the identification of crystalline forms, is required in connection with the lectures on mineralogy. In the course in Civil Engineering a course of practice in blowpipe analysis is provided, which is intended to give to engineers such facility in the use of the blowpipe in determinative mineralogy as will enable them to avail themselves of this useful instrument in their field work, for the determination of the character of rocks and minerals.

Chemical Laboratory.—A new building for the department of Chemistry and Physics has recently been begun, and will be ready for occupation about January, 1883. This building will contain all the necessary space for a museum, a library, laboratories, lecture-rooms, and other rooms, and will be thoroughly equipped with the most recent and approved appliances for the proper prosecution of the work of the department. The chemical laboratory now in use contains, besides two lecture-rooms and the private laboratories of the professors, laboratories for students, with accommodations for two hundred. It is provided with gas and a full supply of apparatus for wet analysis, dry assaying, blowpipe, spectroscopic, and all other branches of chemical analysis. Its reading-room contains the best English, French, and German works of reference, and the current numbers of the chemical journals.

THE COURSE IN CHEMISTRY AND PHYSICS.—Leading to the Degree of Bachelor of Science.

FIRST YEAR.—*First Term*—French, 5, and German, 3, or German, 5, and French, 3; rhetoric, 2; geometry and conic sections, 5; hygiene, six lectures.

Second Term—French, 5; and German 3, or German, 5, and French, 3; rhetoric, 2; algebra, 5.

Third Term—French, 5, and German, 3, or German, 5, and French, 3; rhetoric, 2; trigonometry, 5.

SECOND YEAR.—*First Term*—French or German, 3; composition and elocution, 1; analytical geometry, 5; experimental mechanics and heat, 3; chemistry, laboratory work, 3.

Second Term—French or German, 3; electricity and magnetism, 3; chemistry, lectures, 3; laboratory work, 8.

Third Term—French or German, 3; acoustics and optics, 3; chemistry, lectures, 3, laboratory work, 5; botany, 3.

THIRD YEAR.—*First Term*—Physics, laboratory work, 3; chemical philosophy, 3; chemistry, laboratory work, 7; geology, 3.

Second Term—Physics, laboratory work, 3; chemical philosophy, 3; organic chemistry, 1; chemistry, laboratory work, 5; mineralogy or metallurgy, 2; economic geology, 3.

Third Term—Physics, laboratory work, 3; chemical philosophy, 3; industrial chemistry, 2; chemistry, laboratory work, 7.

FOURTH YEAR.—*First Term*—Physics, laboratory work, 4; organic chemistry, 1; chemistry, laboratory work, 8; history of philosophy, 3.

Second Term—Physics, laboratory work, 4; organic chemistry, 2; chemistry, laboratory work, 8; metallurgy *or* mineralogy, 2.

Third Term—Industrial chemistry, 2; chemistry, processes, 2, laboratory work, 8; organic chemistry, 1.

Instruction is given in general and economic Geology and Lithology by means of lectures, laboratory practice, and field work. The lectures consist of a course on general Geology in the first term, a course on economic Geology in the second term; and, in the third term, a course on physical geography, designed to show the action of geological agencies in fitting the earth for human habitation. The laboratory work consists of a progressive series of exercises in determinative mineralogy and lithology; and of exercises in the preparation of geological sections and maps from the data furnished by government reports. During the first and third terms there are frequent excursions and lessons in field work. To advanced students, opportunities are offered for the microscopic investigation of minerals and rocks, and for the extended study of important mineral districts, with the preparations of reports thereon, and discussions of the metallurgical methods and appliances adapted to their products. The rocks of Ithaca and its neighborhood afford ample material for study and original research.

LABORATORY.—The laboratory is furnished with the appliances needful for successful study, and these appliances have been greatly increased during the past year. Among other things, it has numerous maps, wall tablets, engravings of geological objects, and magic-lantern slides. Large and important additions have also been made to the lithological collections.

THE LIBRARY.—The Library contains about forty thousand volumes, besides fifteen thousand pamphlets. It is made up chiefly of the following collections: A selection of about five thousand volumes purchased in Europe in 1868, embracing works illustrative of agriculture, the mechanic arts, chemistry, engineering, the natural sciences, physiology, and veterinary surgery, The Anthon Library, of nearly seven thousand volumes, consisting of the collection made by the late Professor Charles Anthon, of Columbia College in the ancient classical languages and literature, besides works in history and general literature; the Bopp Library, of about twenty-five hundred volumes, being the collection of the late Professor Franz Bopp, of the University of Berlin, relating to oriental languages, oriental literature, and comparative philology; the Goldwin Smith Library, of thirty-five hundred volumes, presented in 1869 to the University by Professor Goldwin Smith, comprising chiefly historical works, and editions of the English and ancient classics—increased during later years by the continued liberality of the donor; the publications of the Patent Office of Great Britain, about three thousand volumes, of great importance to the student in technology and to scientific investigators; the White Architectural Library, a collection of over a thousand volumes relating to architecture and kindred branches of science, given by President White; the Kelly Mathematical Library, comprising eighteen hundred volumes and seven hundred tracts, presented by the late Hon. William Kelly, of Rhinebeck; the Cornell Agricultural Library, bought by the Hon. Ezra Cornell, chiefly in 1868; the Sparks Library, being the library of the late Jared Sparks, President of Harvard University, consisting of upwards of five thousand volumes and four thousand pamphlets, relating chiefly to the history of America; the May Collection, relating to the history of slavery and anti-slavery, the nucleus of which was formed by the gift of the library of the late Rev. Samuel J. May, of Syracuse. By the establishment of the McGraw Library Fund, the income of which will be available after the present year, and which is to be applied to the support and increase of the University Library, the efficiency of the Library, both as regards the number of books and the facilities for their use, will be greatly enlarged. Beginning this year, it is proposed to issue a serial containing classified lists of recent accessions and of books in various departments, as well as other bibliographical matter intended to assist students in their use of the Library. The Library is a circulating one, so far as the members of the Faculty are concerned, and a library of reference for students. Undergraduates have free access to a collection of cyclopædias, dictionaries, and works of reference in the various departments of study, but they apply to the librarians for other works desired. Graduate students are admitted to the alcoves.

GRADUATION.—No person may receive a baccalaureate degree who has not spent four entire years in the University, unless he has pursued elsewhere part of the studies of his course Students admitted to advanced studies must, before the close of their first year, pass examination on the previous work of the classes they enter. Each student is required, before taking a degree, to submit to the Faculty a satisfactory oration, poem or essay on some subject in science or literature, and to deposit a copy in the Library. The degree of Bachelor of Science is conferred after the satisfactory completion of any one of the following courses: Science, Science and Letters, Chemistry and Physics, Mathematics, and Natural History. The particular course is specified in the diploma. The degrees of Bachelor of Arts, of Literature, of Philosophy, of Agriculture, of Architecture, of Civil Engineering, and of Mechanical Engineering are conferred after the satisfactory completion of the corresponding courses. The degree of Bachelor of Philosophy is also conferred after the satisfactory completion of the course in History and Political Science. The degree of Bachelor of Veterinary Science is conferred only after the completion of a full course of four years in that department. No person is allowed to receive more than one degree at the same Commencement.

ADVANCED DEGREES.—Graduate courses of study leading to advanced degrees are provided for in the following general departments: Chemistry and Physics, Mathematics, Natural History; History and Political Science; Comparative Philology, Ancient Classical Languages and Literature, Modern European Languages and Literature, Oriental Languages and Literature; Philosophy and Letters. A graduate who desires to take an advanced degree should apply to the Faculty to be admitted as a candidate for that degree and in his application should state in what departments he wishes to work. The degree of Master of Arts or Master of Science is conferred on those who have taken the corresponding baccalaureate degree here, or elsewhere where the requirements for that degree are equal to those of this University, on the following conditions:

1. The candidate must spend at least one year at the University in a course of study marked out for him by the Faculty, must present a satisfactory thesis, and pass an examination.

2. The same degrees are conferred without residence on graduates of this University only, on conditions the same in all respects as above, except that the degree is not given until three years after the baccalaureate degree has been conferred

3. Any person who has taken a baccalaureate degree in this University may become a candidate for either of the above second degrees by passing such additional examination as may be required for the corresponding first degree.

The degree of Master of Science is conferred on graduates in the course in Philosophy on the same conditions as if they had been graduated in the course of Science. The degree of Civil Engineer is conferred (1) on bachelors of Civil Engineering, after two years of study and practice, on passing the requisite examination and presenting a satisfactory thesis; (2) on those who have completed the five-year course, at their graduation. The degree of Doctor of Veterinary Medicine is conferred on bachelors of Veterinary Science after two years of additional study, on passing the requisite examination. The degree of Doctor of Physiology is conferred on graduates of this University, and of other universities and colleges whose requirements for the baccalaureate degree are equal to those of this University, on the following conditions:

1. In order to become a candidate the applicant must have, over and above what is required for graduation in the course in Philosophy, a knowledge of Greek equal to that required for admission to the course in Arts.

2. The candidate must spend at least two years at the University pursuing a course of study marked out by the Faculty as leading to this degree.

3. He must, at least six weeks before Commencement, present a meritorious thesis upon some subject included in the course, and pass the requisite examination.

The degree of Doctor of Science is conferred on graduates of this University, and of other universities and colleges whose requirements for the baccalaureate degree are equal to those of this University, on the following conditions:

1. In order to become a candidate the applicant must have a knowledge of Latin and Greek at least equal to that required for admission to the course in Natural History; a knowledge of French and German equal to that required for graduation in the course in Science; a knowledge of science, of literature, and of philosophy equal to that required for graduation in the course in Philosophy.

2. The candidate must spend at least three years, two of them at this University, in the study of not less than two scientific subjects, approved by the Faculty, in one or more of the departments of Chemistry and Physics, Mathematics, and Natural History.

3. He must pass an examination upon these subjects, showing in one of them special attainments, and must present a meritorious thesis based on special investigations, or make some other contribution to science.

Candidates for the degree of Doctor are required to print their thesis and deposit ten copies in the Library. Other candidates for advanced degrees are required to deposit one copy. No student in a graduate course is allowed to take two degrees for the same course, to take any inferior degree for any part of the study that leads to a higher one, or to be a candidate for more than one degree at the same time. Candidates for a second degree are required to make application to the Registrar and present their thesis at least twenty days before Commencement. The examinations for advanced degrees are held during the second week before Commencement.

Miscellaneous Information.—The academic year is divided into three terms, and there are three vacations. Commencement day is the third Thursday in June. The first term begins, after a vacation of thirteen weeks, on the Tuesday following the eleventh day of September, and ends on the Friday after the fourteenth day of December. The second term begins on the Tuesday after the second day of January; except when, in leap-year, that Tuesday is the third day of January, in which case it begins on the Tuesday after the third day. It ends on the Friday after the twenty-third day of March. The third term begins on the second Saturday after the end of the second term, the instruction begins on the Monday following, and continues until Commencement. For the terms and vacations of the present academic year, see the calendar. Persons wishing more detailed information than is given here as to courses of study, methods of instruction, and the like, may address the professor in charge of the department concerned. Candidates for admission will obtain permits for examination at the Registrar's office (in the south University building), and the results of examinations may be ascertained from the Registrar. Each person, upon admission, receives a copy of the "Rules for the Guidance of Students," and is thereafter supposed to be acquainted with its contents. The registration day for each term is indicated in the calendar. On that day each student qualified for admission, whether previously a member of the University or not, is required to give notice of his studies for the term to the Registrar in person and obtain a ticket of registration. No person is allowed to register at any other time, except by permission of the Faculty. In order to join any class, the student must show his registration ticket to the instructor in charge. A printed schedule of the University exercises is issued at the beginning of each term. Most of the lectures and recitations occur between the hours of 8 A. M. and 1 P. M., from Monday to Friday inclusive. Every student is required to take the equivalent of fifteen hours of recitations a week, exclusive of military drill. Two and a-half hours of laboratory practice, or three hours of drafting or shop-work, are regarded as the equivalent of one recitation. The regular examinations in all studies are held at the end of each term. Failure at examination entails forfeiture of position in the class, or exclusion from the course, or, in some cases, from the University. The *course-book* affords the student an opportunity of preserving a record of his examination; it is procurable at the bookstores, and the entries in it are made by the Registrar, or by the heads of departments. The fee for tuition is $25 a term, payable within ten days after registration. Tuition is free to *state students*, to *resident graduates*, and to students pursuing either of the prescribed courses in *Agriculture*, and *intending to complete* that course. Every person taking laboratory practice in Chemistry, Physics, Zoölogy, or Entomology, must deposit with the Treasurer security for the materials to be used in the laboratory. Students residing in the University buildings are required to pay their room-bills one term in advance. All members of the University are held responsible for any injury done by them to its property. A fee of $5, to cover expenses of graduation, degrees, etc., is charged to each person taking the baccalaureate degree; a fee of $10, to each person taking an advanced degree. These fees must be paid at least three days before Commencement.

Expenses of Residence—The following is a fair estimate of the yearly expenses: Tuition, $25 a term, $75; Room, board, lights, fuel, and laundry, about $200; Text-books, etc., about $25; Total, $300.

The cost for board, rent of furnished room, fuel and lights at the Sage College, varies from $5 to $6.50 a week. A student occupying alone one of the most desirable rooms, pays $6 50 a week. If two occupy such a room together, the price is $5.75. Those occupying less desirable rooms, with two in a room, pay $5 a week each. The entire building is warmed by steam, and, in most cases, the sleeping apartment is separate from the study-room. The expense of living in Ithaca varies, for board, room, fuel, and lights, from $4 to $7 a week. In many cases students, by the formation of clubs, reduce their expenses to sums ranging from $2.50 to $3.50 a week for board. In the year 1881, the sum of forty-five thousand dollars was bequeathed by Mrs. Jenny McGraw Fiske as a provision for the care of students who may fall ill during their attendance at the University. It is proposed that a portion of this sum be devoted to the erection of a cottage hospital, made comfortable and attractive, and thoroughly equipped in all respects; and that a trained nurse be attached to it, who shall be ready to give attention the moment it is needed.

State Scholarships.—The laws of the State of New York [chap. 585, §9, chap. 654, §1] provide that the University "shall annually receive students, one from each assembly district in the State, to be selected as hereinafter provided, and shall give them instruction in any or in all the prescribed branches of study in any department of said institution, free of any tuition fee, or of any incidental charges, to be paid to said university, unless such incidental charges shall have been made to compensate for damages needlessly or purposely done by the students to the property of said university." There are one hundred twenty-eight assembly districts, and therefore one hundred twenty-eight free scholarships, each good for four years. The law provides that "the candidates in each county or city shall meet at such place and time in the year as the school commissioner or commissioners of the county and the boards of education of the cities in those counties which contain cities, shall appoint; and the said commissioner or commissioners, and the said board of education, or such of them as shall attend and act, shall proceed to examine said candidates and determine which of them are the best scholars. The law is mandatory and imposes upon school commissioners of counties and boards of education of cities the duty, which they cannot avoid, of holding such competitive examinations once each year. It is understood to confer a right upon every person who is qualified to enter the examination, and who desires to obtain the scholarship, to have such an examination held; and it is believed that any such candidate for the scholarship can enforce his right, if need be, by an appeal to the proper state authorities. The law which requires the examination to be held, requires also, by implication, that due public notice shall be given of the time and place. When it shall be held and where it shall be held, is left to the discretion of the commissioners and the boards of education; but doubtless it ought to be held in the summer after the close of the public schools for the season, and before the beginning of the fall term of the University. Only one examination can be held during the year in any one county, and, except to fill vacancies as below, appointments can be made but once a year. The law does not designate the studies upon which candidates shall be examined, nor have the trustees of the University expressed any opinion on the subject.

The law provides that "the said free instruction shall moreover be accorded to said students in consideration of their superior ability, and as a reward for superior scholarship in the academies and public schools of this state. . . . In making these selections preference shall be given (where other qualifications are equal) to the sons of those who have died in the military or naval service of the United States; consideration shall be had also to the physical ability of the candidate. . . . But in no case shall any person having already entered the said university be admitted as one of such candidates." The trustees of the University understand the law to mean that candidates must have been educated in the academies or public schools of the state, and in the county in which they offer themselves for the competition. Not that they must necessarily be residents of the county in which they seek the scholarship, but only that they have attended an academy or public school long enough to be entitled to be regarded as having obtained their education, or at least a large part of it, in the county. The length of time is not fixed by law. They do not understand that a person otherwise qualified to be a candidate, can be debarred from entering the examination, in consequence of having finished his studies and been out of school for one or two years; especially if during this time he has been occupied in providing the means of defraying his expenses while attending the University. Nor do they think that the fact of his having been engaged out of the county during this time and for the purpose above mentioned ought to work to his disadvantage.

If, however, a person has been attending school, whether a public or a private school, out of the county, for the period which intervenes between his attendance upon the schools in the county and his application to be received as a candidate, this, they think, ought to exclude him from the examination in that county.

The law provides that the school commissioners of counties and boards of education of cities shall determine by the competive examination above noted which of the duly qualified candidates "are the best scholars." It says: "And they shall then select therefrom to the number of one from each assembly district in said county or city, and furnish the candidates thus selected with a certificate of such election, which certificate shall entitle said student to admission to said university, subject to the examination and approval of the faculty of said university." In deciding upon the merits of the competitors and awarding the certificates, no regard need be paid to the assembly district in which the candidate has his residence, or has attended school, but the certificate must name the district for which the appointment is made. The certificate of scholarship must in all cases be awarded on the basis of the competitive examination, and not on any examination held otherwise or elsewhere, or on any testimonials obtained from any other source. In all cases of contested or duplicate certificates, the trustees have decided, and instructed their treasurer, to accept the first certificate that is regular on its face and granted by the proper authorities. The University proposes to leave all questions as to the regularity of the proceedings and the rights of the respective claimants to be adjusted in the county from which the student comes. No allowance is made for absence or non-attendance upon the University by a student holding a state scholarship. His certificate secures him free tuition for only that part of the four years during which he is in attendance upon his University duties. Whenever any student selected as above described shall have been from any cause removed from the University before the expiration of the time for which he was selected, then one of the competitors to his place may be selected to succeed him therein, as the school commissioner or commissioners of the county or the board of education of the city may direct. Preference is rightly given to competitors in the order of the superiority of their scholarship. A certificate is good for four years from the time when the examination is held, and in case of a new certificate to fill a vacancy, that certificate will be accepted for only that portion of the four years which remains unexpired. No appointment can be made from one county to fill a vacancy in another county. Neglect to appoint does not create a vacancy which can be legally filled.

CALENDAR.—Sept. 19–21, Tuesday–Thursday, Entrance Examinations. Sept. 21, Thursday, Registration Day, Sept. 22, Friday, Instruction begins.

UNIVERSITY OF MICHIGAN, ANN ARBOR.

IN 1875 the State Legislature took the first step towards organizing at the University a school to be called "The School of Mines," but subsequently a different arrangement was effected and the instruction designed for those students who intend to become mining engineers is now given in connection with that given to other students of engineering.

Members of the Faculties.—James B. Angell, LL. D., President. Henry S. Frieze, LL. D., Acting President, and Professor of the Latin Language and Literature. Alonzo B. Palmer, M. D., LL. D., Professor of Pathology and the Practice of Medicine and Clinical Medicine. Corydon L Ford, M. D., LL. D., Professor of Anatomy and Physiology. Hon. James V. Campbell, LL. D., Marshall Professor of Law. Hon. Thomas M. Cooley, LL. D., Jay Professor of Law, and Professor of Constitutional and Administrative Law in the School of Political Science. Edward Olney, LL. D., Professor of Mathematics. Charles K. Adams, LL. D., Professor of History. Charles A. Kent, A. M., Fletcher Professor of Law. Rev. Benjamin F. Cocker, D. D., LL. D., Professor of Psychology, Speculative Philosophy, and Philosophy of Religion. Albert B. Prescott, M. D., Professor of Organic and Applied Chemistry and Pharmacy. Rev. Martin L. D'Ooge, Ph. D., Professor of the Greek Language and Literature. Charles E. Greene, A. M., C. E., Professor of Civil Engineering. George E. Frothingham, M. D., Professor of Materia Medica, Ophthalmic and Aural Surgery, and Clinical Ophthalmology. Donald Maclean, A. M. M. D., Professor of Surgery and Clinical Surgery. Edward S. Dunster, A. M. M. D., Professor of Obstetrics and Diseases of Women and Children, and Clinical Gynæcology. William H. Pettee, A. M., Professor of Mineralogy, Economic Geology, and Mining Engineering. Jonathan Taft, M. D., D. D. S., Professor of the Principles and Practice of Operative Dentistry. John A. Walting, D. D. S., Professor of Clinical and Mechanical Dentistry. John W. Langley, S. B., M. D., Professor of General Chemistry. William P. Wells, A. M., Kent Professor of Law. Charles I. Walker, LL. D., Filling the Chair of Kent Professor of Law in the absence of Professor Wells. Edward C. Franklin, M. D., Professor of Surgery and Clinical Surgery in the Homœopathic Medical College. Mark W. Harrington, A. M., Professor of Astronomy, and Director of the Observatory. Joseph B. Steere, Ph. D., Professor of Zoölogy, and Curator of the Museum. Edward L. Walter, Ph. D., Professor of Modern Languages and Literatures. Alexander Winchell, LL. D., Professor of Geology and Palæontology. William H. Payne, A. M., Professor of the Science and the Art of Teaching. Hon. Alpheus Felch, LL. D., Tappan Professor of Law. Thomas P. Wilson, M. D., Professor of the Principles and Practice of Medicine, Ophthalmology, and Otology in the Homœopathic Medical College. Isaac N. Demmon, A. M., Professor of English and Rhetoric. George S. Morris, Ph. D., Professor of Ethics, History of Philosophy, and Logic. William H. Dorrance, D. D. S. Professor of Prosthetic Dentistry and Dental Metallurgy. Elisha Jones, A. M., Associate Professor of Latin. Albert H. Pattengill, A. M., Associate Professor of Greek. Mortimer E. Cooley, Assistant Engineer, U. S. N., Professor of Mechanical Engineering. Charles K. Wead, A. M., Acting Professor of Physics. Byron W. Cheever, A. M., M. D., Acting Professor of Metallurgy. Volney M. Spalding, A. B., Acting Professor of Botany. Joseph B. Davis, C. E., Assistant Professor of Civil Engineering. Wooster W. Beman, A. M., Assistant Professor of Mathematics. Charles N. Jones, A. B., Assistant Professor of Mathematics. Richard Hudson, A. M., Assistant Professor of History. Otis C. Johnson, A. M., Assistant Professor of Applied Chemistry. William J. Herdman, Ph. B., M. D., Assistant Professor of Pathological Anatomy, and Demonstrator of Anatomy. Victor C. Vaughan. Ph. D., M. D., Assistant Professor of Physiological Chemistry. Charles H. Stowell, M. D.. Assistant Professor of Histology and Microscopy. Benjamin C. Burt, A. M., Assistant Professor of English and Rhetoric. Calvin Thomas, A. M., Assistant Professor of German and Sanskrit. Charles S. Denison, M. S., C. E., Acting Assistant Professor of Mechanical and Free Hand Drawing. Raymond C. Davis, A. M., Librarian. Henry C. Adams, Ph. D., Lecturer on Political Economy. Henry C. Allen, M. D., Lecturer on Materia Medica, Pharmacology, and Clinical Medicine in the Homœopathic Medical College. Henry Sewall, M. D., Lecturer on Physiology. P. R. B. de Pont, A. B.. B. S., Instructor in French. Alfred Hennequin, A. M., Instructor in French and German. Calvin B. Cady, Instructor in Music. Charles M. Gayley, A. B., Instructor in Latin. Theodore John Wrampelmeier, A. B., Instructor in Analytical Chemistry. Louis Reed Stowell, M. S., Assistant in Microscopical Botany. Elizabeth M. Farrand, Assistant Librarian. Dennie J. Higley, A. M., Assistant in Museum. Douglas A. Joy, E. M., M. D., Asssistant in General Chemistry. John M. Schaeberle, C. E., Assistant in the Observatory. George A. Hendrics, M. D., Assistant Demonstrator of Anatomy, and Curator of the Medical Museum of the Department of Medicine and Surgery. Aaron R. Wheeler, M. D., Resident Physician and Surgeon in the Homœopathic Hospital. Uriah D. Billmeyer, D. D. S., Assistant to the Professor of Clinical Dentistry, George F. Heath, M. D., Resident Physician and Surgeon in the University Hospital. Arthur W. Potter, Assistant in Mathematics. Geordie Z. Whitney, A. B., Assistant in Mathematics. Joseph F. Geisler, Ph. C., Assistant in Qualitative Chemistry. George L. Field, D. D. S., Demonstrator of Continuous Gum Dentures. Lorin Hall, M. D. Assistant to the Professor of Obstetrics and the Diseases of Women and Children. Thomas J. Sullivan, M. D., Assistant to the Professor of Surgery. John G. Kennan, M. D., Assistant to the Professor of Materia Medica and Ophthalmic and Aural Surgery. Calvin S. Case, D. D. S., Assistant in Prosthetic Dentistry. Lucius L. Van Slyke, A. M., Assistant in Chemical Laboratory. Seward W. Williams Ph. C., Asssistant in Chemical Laboratory. Oscar Textor, Ph. C., Assistant in Quantitative Analysis. Richard Gay De Puy, A. B. M. D., Asssistant to the Professor of Surgery in the Homœopathic Medical College. Charles P. Pengra, M. D., Assistant in the Chemical Laboratory. Albert R. Halsted, M. D., Assistant to the Professor of the Principles and Practice of Medicine in the Homœopathic Medical College. Willis P. Polhemus, M. D., Assistant to the Lecturer on Materia Medica in the Homœopathic Medical College. Kate Crane Johnson, Ph. C., Dispensing Clerk in the Chemical Laboratory. Charles F. Dight, M. D., Assistant to the Professor of Pathology, and the Practice of Medicine. Schuyler C. Graves, M. D., Assistant Demonstrator of Anatomy. Lena C. Leland, M. D., Assistant Demonstrator of Anatomy.

The University of Michigan is a part of the public educational system of the State. The governing body of the Institution is a Board of Regents, elected by popular vote for terms of eight years, as provided in the constitution of the State. In accordance with the law of the State, the University aims to complete and crown the work that is begun in the public schools, by furnishing ample facilities for liberal education in Literature, Science, and the Arts, and for thorough professional study of Medicine, Pharmacy, Law, and Dentistry. Through the aid that has been received from the United States and from the State it is enabled to offer its privileges, without charge for tuition, to all persons, of either sex, who are qualified for admission. Its relation to the public schools of the State has been, since the year 1871, when students were for the first time admitted on diploma from approved high schools, even closer and more vital than ever before. While Michigan has endowed her University primarily for the higher education of her own sons and daughters, it must be understood that she also opens the doors of the Institution to all students, wherever their homes. It is in this broad, generous, and hospitable spirit, that the University has been founded, and that it endeavors to do its work. The University comprises the Department of Literature, Science, and the Arts (including the School of Political Science), the Department of Medicine and Surgery, the Department of Law, the School of Pharmacy, the Homœopathic Medical College, and the College of Dental Surgery. Each of these Departments and Colleges has its Faculty of Instruction, who are charged with the special management of it. The University Senate is composed of all the Faculties, and considers questions of common interest and importance to them all. In the Department of Literature, Science and the Arts, different lines of study lead to the attainment of the degrees of Bachelor of Arts, Bachelor of Science, Bachelor of Letters, the corresponding Masters' degree, the degree of Doctor of Philosophy, and the degree of Civil Engineer, Mechanical Engineer, and Mining Engineer. When the same degree is given for different lines of study, this fact is indicated in the diploma. Students that do not wish to become candidates for a degree may, if they are prepared to enter the University, pursue selected studies for such time, not less than one semester, as they may choose. In the Professional Schools the instruction is given largely by lectures.* Degrees are given to graduates as follows: In the Department of Medicine and Surgery, the degree of Doctor of Medicine; in the Department of Law, the degree of Bachelor of Laws; in the School of Pharmacy, the degree of Pharmaceutical Chemist and of Master of Pharmacy; in the Homœopathic Medical College, the degree of Doctor of Medicine; in the College of Dental Surgery, the degree of Doctor of Dental Surgery. Students in any Department of the University may enter the classes in any other, upon obtaining permission from the Faculties of the respective Departments.

The Libraries.—The Libraries of the University accessible to the students contain in the aggregate about 39,150 volumes, and 10,000 pamphlets. The General Library contains about 32,250 volumes, and 9,000 pamphlets. In 1871 it was enlarged by the addition of the library of the late Professor Rau, of the University of Heidelberg, Germany. The Rau library was purchased and presented to the University by Mr. Philo Parsons, of Detroit. It contains, with the recent additions made by Mr. Parsons, about 4,325 volumes and over 5,000 pamphlets. It is especially rich in European works on the Science of Government, Statistics, Political Economy, and the cognate subjects. An appropriation of five thousand dollars for the increase of the University Library was made by the Legislature at its last session. The catalogue consists of two parts, a catalogue of titles on slips arranged in the alphabetical order of the names of the authors, and a catalogue of the subjects treated in all the books, reviews, and magazines in the Library. The catalogue is accessible to readers. One hundred and forty-three American and European periodicals are taken; and sixty magazines and newspapers, representing nearly every part of the country, are kept upon the tables by the Students' Lecture Association. The Library is open every day except Sundays and holidays, from 9 o'clock A. M. to 5 P. M., and from 7 P. M. to 9½ P. M., during the academic year, and for a large part of the day during the summer vacation. It is free to all persons.

The Museums.—The collections in the University Museums are illustrative of Natural History, Agriculture, Archæology, Ethnology, The Fine Arts, History, Anatomy, and Materia Medica, and are constantly increasing. The whole of the valuable collection made by Professor Steere during his five years' exploration in South America, Formosa, and the East Indies, has become the property of the University. A considerable addition to this collection was made by Professor Steere, as a result of his visit to the mouth of the Amazon in the summer of 1879. The collections are arranged in such a way as to render them accessible both to students and to visitors. The University affords a secure depository for objects of value and curiosity, and it is therefore hoped that frequent gifts will be made to its several Museums. The new Museum building, erected in 1879-80, by means of a special legislative appropriation, now contains the collections in Mineralogy, Geology, and Zoölogy. The following description will indicate the character of the several collections belonging to the University: I. The Mineralogical Collection comprises about 6,000 specimens. It embraces about 2,500 specimens (principally European) purchased of the late Baron Lederer, and known as the Lederer Collection; and, besides others, a rich collection of the Mineral Species of Michigan, including all varieties of copper ore and associated minerals from the different localities of the Lake Superior mining district

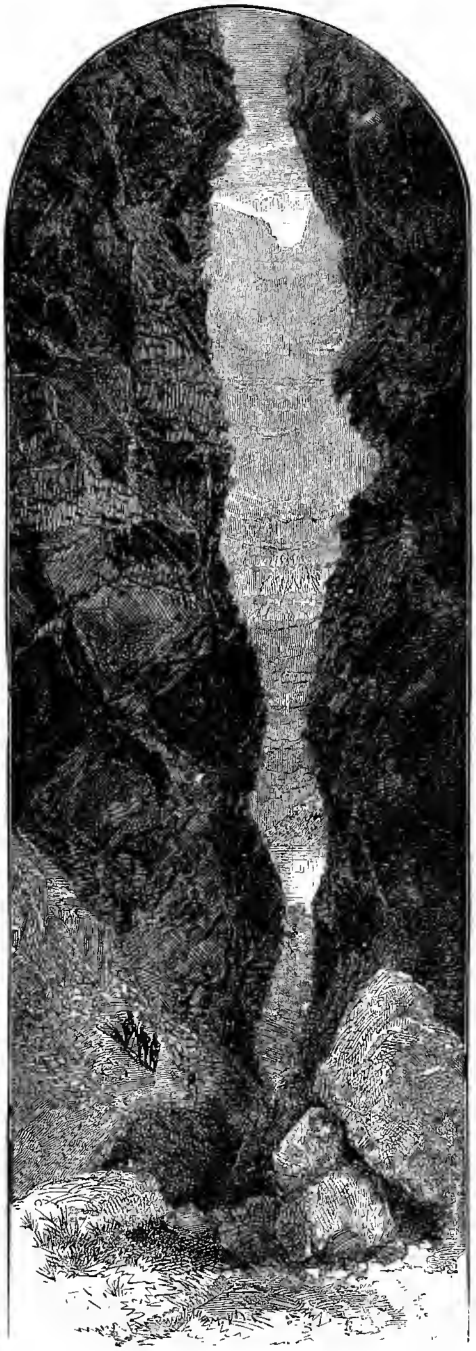
The Geological Collection consists of: 1. The large and complete series of lithological and palæontological specimens, brought together by the State Geological Surveys, of which over a hundred fossil species have already become the types of original descriptions. 2. The White Collection, consisting of 1,018 distinct entries, 6,000 specimens. 3. The Rominger Collection, embracing about 2,500 entries, 6,000 specimens, mostly from the mesozoic formations of central Europe. This collection embraces about 500 specimens of mesozoic ammonites. 4. Smithsonian Deposits, consisting, for the present, of a collection of specimens of foreign and domestic building stones, and twenty-three specimens of fossils from the Upper Missouri. 5. Miscellaneous Donations and Collections, including a series illustrative of the metalliferous regions of the Upper Peninsula, collected by Professor Winchell, and an interesting collection of fossils, chiefly cretaceous, from the Yellowstone Valley, presented by the late General Custer, U. S. A. The entire Geological Cabinet is estimated to contain about 14,000 distinct entries, 41,000 specimens.

The Laboratories.—In the several Laboratories of the University opportunities are provided for practical instruction in Physics, Chemistry, Geology, Zoölogy, Botany, Physiology and Histology, Mechanical Engineering, and Dentistry.

I. The Physical Laboratory.—This Laboratory was established in the year 1877 with the aid of a special appropriation of the Legislature. It is in charge of the Acting Professor of Physics, and is now used principally by students of the Department of Literature, Science, and the Arts. Apparatus has already been provided for the accurate determination of weights and measures, specific gravity, elasticity, strength and stiffness of beams and simple structures, such as trusses and bridges; for determining the laws regulating the flow of liquids and gases; for measuring rates of vibration in sounding bodies, for measuring indices of refraction, length of waves of light, intensity of light, strength of galvanic batteries, electricity resistance, and specific and latent heat; and for the investigation of other physical problems. The course of instruction is designed to give the student familiarity with the manipulation of physical apparatus, and a clear understanding of the methods used in the construction of physical tables. Provision is made to meet the wants of advanced students, as well as of undergraduates.

II. The Chemical Laboratory.—In this Laboratory, which was enlarged in the summer of 1880 by the addition of a second story, better facilities than ever before are now provided for systematic instructions in laboratory methods of study, general chemistry, analytical and applied chemistry, physiological chemistry, pharmacy, metallurgy, and assaying, and for original investigations in nearly all of these branches. Earnest encouragement and coöperation are promised to all those, who, with due preparation, will enter upon original work. In addition to the lecture-rooms and balance-rooms, there are eleven distinct working-rooms, independent of those used by the officers, or required for the storage of material and apparatus. Two hundred and sixty-nine students can be provided with tables for work at the same time. The Laboratory is open to all students of the University, and is regularly used by all Departments excepting the Department of Law. The Laboratory is also open to any person who wishes to pursue special studies therein, provided he comply with the requirements for admission, and with the regulations of that Department of the Univer-

*A knowledge of stenography, though not indispensable, and not insisted on as a condition for admission, will be of great advantage to students of these schools. Students of the Department of Literature, Science and the Arts, will also find such knowledge useful.



WESTERN SCENERY—A SIDE CAÑON—CAÑONS OF THE COLORADO.

—FROM REPORT OF J. W. POWELL.

sity to which the desired special studies properly belong. In all these courses of instruction there are recitations and lectures in the class-room, giving direction daily to the student at his table, and demanding constant study of the work undertaken. This method of teaching makes it indispensable that the student begin with a class. The Laboratory is open to students through the college year in the afternoon from one to five o'clock, and, after the first of April, from one to six o'clock.

THE GEOLOGICAL AND ZOÖLOGICAL LABORATORIES.—Opportunity for practical work in Geology and Zoölogy is provided in rooms set apart for this purpose in the new Museum. The rooms are furnished with microscopes, photographic instruments, cutting and polishing lathes, and other apparatus for the preparation of specimens. Special encouragement and assistance are given to students wishing to carry on original investigations.

THE MECHANICAL LABORATORY.—With the aid of a special appropriation of the Legislature, a building has been erected and furnished for the accommodation of students desiring instruction in the use of tools for working in wood and in metal, as well as on the nature of the most common materials used for manufacturing purposes. Complete sets of hand tools have been provided for pattern-making, machinists' and blacksmiths' work, and moulding. Steam-power and a few of the most essential machine tools have also been provided. A cupola and brass furnace have been added, so that students may have the actual charge of both during operations of casting in iron and in composition. The instruction is made thoroughly practical.

The Hospitals.—During the past few years the facilities for clinical instruction in the two Medical Schools connected with the University have been largely increased. By the liberality of successive Legislatures, aided by contributions from the city of Ann Arbor, ample hospital accommodations have been provided. The University Hospital is under the direction of the Faculty of the Department of Medicine and Surgery; the Homœopathic Hospital is connected with the Homœopathic Medical College. Further information in regard to the Hospitals is given in connection with the descriptions of the Medical Schools.

Fees and Expenses.—Every student, before entering any Department of the University, is required to pay a matriculation fee. This fee, which, for residents of Michigan, is ten dollars, and, for those who come from any other state or country, twenty-five dollars, is paid but once and entitles the student to the privileges of permanent membership in the University. In addition to the matriculation fee, every student has to pay an annual fee for incidental expenses. This fee is paid the first year of residence at the University, and every year of residence thereafter. Resident graduates are required to pay the same annual fee as under-graduates. Beginning with the academic year, 1882-83, the annual fee in the several departments of the University will be, in accordance with action taken by the Board of Regents since the publication of the last annual calendar, as follows: Department of Literature, Science, and the Arts: for residents of Michigan, twenty dollars; for non-residents, thirty dollars. The matriculation fee and the annual fee must be paid at the beginning of the college year. A By-Law of the Board of Regents provides that no student or graduate shall be allowed to enjoy the privileges of the University until he has paid all fees that are due. The fee for the diploma given on graduation is ten dollars, and the By-Laws of the Board of Regents prescribe that no person shall be recommended for a degree until he has paid all dues, including the fee for diploma. Students who pursue laboratory courses of study are also required to pay for the materials and apparatus actually consumed by them. The deposits required in advance are different for the different courses, ranging from one dollar to twenty dollars. The laboratory expenses of students will vary with their produce and economy. Experience has shown that in the Chemical Laboratory the average expense is about one dollar and twenty cents a week for all courses. Students obtain board and lodging in private families for from three to five dollars a week. Clubs are also formed, in which the cost of board is from one dollar and a half to two dollars and a half a week. Room-rent varies from seventy-five cents to two dollars a week for each student. There are no dormitories and no commons connected with the University. Students on arriving at Ann Arbor can obtain information in regard to rooms and board by calling at the Steward's office. The annual expenses of students in the Literary Department and in the Medical Schools, including clothing and incidentals, has been, for the last few years, on the average, about three hundred and seventy dollars. The expenses of the Law students and the Dental students are from one hundred and fifty to two hundred dollars for a term of six months. It is proper to say, in answer to numerous inquiries, that the University does not undertake to furnish manual labor to students; yet a small number find opportunities in the city for remunerative labor.

Relation of Students to the City Government.—Students are temporary residents of the city, and, like all other residents, are amenable to the laws. Whenever guilty of disorder or crime, they are liable to arrest, fine, and imprisonment, and can claim no peculiar exemption from public disgrace and legal penalties.

ADMISSION.—Candidates for admission must be at least sixteen years of age, and must present satisfactory evidence of good moral character. They must be provided with credentials from their last instructor, or from the last institution with which they have been connected. These credentials must be presented to the President, at his office, before the candidate can enter upon the examination. Students who desire to pursue studies in this Department, and do not desire to become candidates for a degree, will be admitted on the following conditions:

1. All persons under twenty-one years of age must pass the entrance examinations required of candidates for some degree.

2. Persons over twenty-one years of age must pass the entrance examination in English required of candidates for the degree of A. B. Students thus admitted may then enter any of the classes upon first giving satisfactory evidence to the Professor in charge that they are prepared to pursue profitably the study they may desire to take up.

ADMISSION OF CANDIDATES FOR A DEGREE.

Students who desire to become candidates for a degree must, unless admitted on diploma, pass examinations * as follows:

Candidates for the Degree of Bachelor of Science.—The University provides different lines of study leading to this degree: 1. A Course in General Science. 2. Courses in Engineering, Civil, Mechanical, and Mining. The diplomas given in the latter courses indicate the line of study pursued.

1. THE COURSE IN GENERAL SCIENCE.

Candidates will be examined in the following subjects:

1. ENGLISH LANGUAGE, GEOGRAPHY, AND MATHEMATICS.—In all, the same as for the degree of Bachelor of Arts.

2. HISTORY.—An outline of General History; an Outline of the History of the United States, to the close of the Revolutionary War. A year's study ought to be given to preparation in History.

3. FRENCH, GERMAN, AND LATIN.—Candidates may offer either French or German; French and Latin; or German and Latin;—two of these three languages being required. The requirements in each are as follows:

French.—The whole subject of French Grammar. The candidate will be expected to be thoroughly familiar with the formation and use of French verbs, to read at sight easy French, and to translate correctly into French simple English sentences. Two years ought to be given to this purpose, the first year being spent on the grammar, and the second devoted to reading good modern French, accompanied by grammatical analysis and exercises in writing. Hennequin's French text-books are especially recommended; preparation in Fasquelle or Otto will be accepted.

German.—The whole subject of German Grammar. The candidate will be expected to read easy German at sight and to translate simple sentences from English into German. To this end he should have devoted two years to the study; one year to the grammar, reader, and the writing of exercises, and a second year to the reading of complete works of literary art. As a text for the second year's study works in dramatic form, and especially the classical plays of Schiller, are recommended.

* Requests for specimen copies of examination papers are often made to the University authorities. As the examinations for admission are chiefly oral, it is not practicable to comply with these requests.

Latin.—Jones' First Latin Book, or Harkness's Latin Reader, or an equivalent amount in any other text-book; four books of Cæsar's Commentaries, and one of Cicero's Orations. It is expected that about two years will be given to preparation in Latin.

4. NATURAL PHILOSOPHY.—An amount represented by one year of study, with experimental illustrations. Avery's Natural Philosophy is recommended as a text-book.

5. BOTANY.—The elements of Vegetable Anatomy and Physiology, as given in the first twenty-seven chapters of Gray's Lessons, or the First and Second Parts of Wood's Class Book of Botany; also an analysis and written descriptions of fifty species of Phanerogams.

6. CHEMISTRY, GEOLOGY, ZOOLOGY, AND PHYSIOLOGY.—The candidate may offer any one of these subjects. The requirements, intended to cover a half year's work in each subject are as follows:

Chemistry.—Nichols's Abridgment of Elliot and Storer's Manual, or an equivalent.

Geology.—Candidates who offer themselves in Geology must have a good acquaintance with the subjects treated in at least the first three parts of Dana's Text-book of Geology.

Zoology.—Packard's Zoology, or Nicholson's Manual of Zoology

Physiology.—Martin's The Human Body.

COURSES OF INSTRUCTION.—The University provides a large number of courses of study in the various branches of learning, from which the student may choose his studies. The studies chosen may be pursued in any order, subject only to certain regulations prescribed by the faculty. The courses offered are subject to change from year to year. Those offered for the year 1882–83 are as follows:

MATHEMATICS.—*First Semester.*—1 Advanced Algebra. Monday, Tuesday, Wednesday, and Thursday, Sec. I., 5; Sec. II., 4–5. Assistant Professor Beman.

2. General Geometry and Calculus. Monday, Tuesday, Wednesday, and Thursday. Sec. I. 3–4; Section II. 4–5. Professor Olney.

3. Advanced General Geometry and Calculus. Five times a week, 5-6. Professor Olney.

4. Determinants. Tuesday and Thursday, 11½–12½. Assistant Professor C. N. Jones. 10. Plane and Spherical Trigonometry- Monday and Wednesday, Sec. I,, 9½–10½; Sec. III,, 10½–11½; Sec. V., 11½–12½; Tuesday and Thursday, Sec. II;, 9½–10½; Sec. IV.; 10½–11½. Assistant Professor C. N. Jones.

12 *Loci of Equations*—Friday, Sec. I., 9½–10½; Sec. II., 10½–11½; Sec. III., 11½–12½. Assistant Professor C. N. Jones.

13 *General Geometry and Calculus*—Five times a week, 3–4. Assistant Professor Beman.

17 *Mathematical Reading*—Five times a week, 2–3.

SECOND SEMESTER.

5 *Advanced Geometry;* Plane and Spherical Trigonometry. Monday, Tuesday, Wednesday and Thursday, Sec. I., 4–5; Sec. II., 5–6. Assistant Professor Beman.

6 *General Geometry and Calculus*—continuation of Course 2. Monday, Tuesday, Wednesday and Thursday, Sec. I., 3–4; Sec. II., 4–5. Professor Olney.

7 *Modern Geometry and Trilinear Co-ordinates*—Tuesday and Thursday, 2–3. Assistant Professor Beman.

8 *Calculus of Variations*—Not given this year. Professor Olney.

9 *Quaternions*—Tuesday, Wednesday and Thursday, 5-6. Professor Olney.

11 *Analytical Mechanics*—Five times a week, 9½–10½. Assistant Professor C. N. Jones.

14 *Advanced Algebra*—Monday, Wednesday, Sec. I., 10½–11½; Sec. II., 11½–12½; Sec. III., 2–3. Assistant Professor C. N. Jones.

15 *Geometry*—Tuesday and Thursday, Sec. I., 10½–11½; Sec. II., 11½–12½; Sec. III., 2–3. Assistant Professor C. N. Jones.

16 *General Geometry and Calculus*—continuation of Course 13. Five times a week, 3–4. Assistant Professor Beman.

17 *Mathematical Reading*—Five times a week, 2–3.

Courses, 2, 4, and 13 cannot be taken till after Courses 10, 12, 14 and 15, or Courses 1 and 5 have been completed. Course 3 cannot be taken till after Course 6 or Course 16 has been completed. Course 7 cannot be taken till after Course 4 and either Course 6 or Course 16 have been completed. Course 8 cannot be taken till after Course 3 has been completed. Course 9 cannot be taken till after Course 6 or Course 16 has been completed. Course 11 requires a knowledge of Integral Calculus; it will be given hereafter in the first semester, and will be followed in the second semester by a more extended Course in Dynamics. Course 17 is designed to give advanced students an opportunity to read with members of the Mathematical Faculty such standard Mathematical works as Salmon's Higher Algebra, Frost's Solid Geometry, Scott's Determinants, Price's Integral Calculus, Tait's Quaternions, and Routh's Rigid Dynamics.

MINERALOGY AND GEOLOGY.

FIRST SEMESTER.

1 *Short Course*—Tuesday and Thursday, 10½–12½. Professor Pettee.

2 *Mineralogy and Lithology*—Five times a week, 2–4. Professor Pettee.

SECOND SEMESTER.

2 *Mineralogy and Lithology*—Five times a week, 8½–10½. Professor Pettee.

For Course 1 an elementary knowledge of Chemistry is desirable. Course 2 can be taken only by those who are taking or have taken, a Course in Analytical Chemistry; it will not be given in the first semester hereafter.

II. GEOLOGY—FIRST SEMESTER.

1 *Succession of Geological Events*—Embracing in their relations, the elements of geological dynamics, continent-building and sculpturing, rock-classification, geographical geology, time divisions, and palæontology. Part I, Facts and Doctrines. Monday and Wednesday, 3–4. Professor Winchell.

2 *Oral Exercises*—Supplementary to Course 1, and parallel with it; being a review, with exercises on the geological map, and in various specific geological problems. Friday, 3–4. Professor Winchell.

3 *Advanced Geology and Palæontology*—Lectures, reading, and museum study. Tuesday and Thursday, 3-4. Professor Winchell.

4 *Palæontological Investigations*—Laboratory work, with reading, and such instruction as the student may require. Five times a week, 2–4. Professor Winchell.

[8 *Economic Geology*—Twice a week. Not given this year. Professor Pettee.]

9 *Geology of the United States*—Tuesday and Thursday, 4-5. Professor Pettee.

SECOND SEMESTER.

5 *General Geology*—Part II. Theories. Monday, 3–4. Professor Winchell.

6 *Oral Exercises*—Parallel with Course 5. Friday, 3–4. Professor Winchell.

7. *Palæontological Investigations,* as in course 4. Professor Winchell.

Course 2 is intended to accompany Course 1; it may be taken, however, by any person somewhat acquainted with the elements of Geology. Course 3 is intended for students who have taken Course 1, or who enter the University with thorough preparation in the elements of Geology. Course 5 can be taken only by those who have had Course 1, or an equivalent. Course 6 is intended to accompany Course 5; it may be taken, however, by any person somewhat acquainted with the elements of Geology. Course 7 is intended for students aspiring to proficiency in Geology; it must follow Course 1, and also Courses 1 to 5 in Zoology. Course 8 must be preceded by Course 2 in Mineralogy. Course 9 requires some previous knowledge of General Geology. Course 3 or 5 may be taken as an advanced Course by students who have passed an entrance examination in Geology.

SURVEYING.

FIRST SEMESTER.

1 *Surveying*—Use of Transit and Level. Monday, Wednesday, Friday, 8½–12½. Assistant Professor Davis.

2 *Surveying with Compass*—Solar Compass; U. S. Surveys. Tuesday and Thursday, 8½–12½. Assistant Professor Davis.

SECOND SEMESTER.

3 *Higher Surveying*—Plane Table; Sextant; Earth-work. Five times a week, 2–6. Assistant Professor Davis.

4 *Field Work*—Four weeks entire, 8–12 and 1–5. Assistant Professor Davis.

Courses 1 and 2 presuppose a knowledge of Plane Trigonometry. Course 3 must be preceded by Courses 1 and 2.

ENGINEERING.

I. CIVIL ENGINEERING—FIRST SEMESTER.

1 *Strength and Resistance of Materials*—Monday and Wednesday, 9½–10½. Professor Greene.

2 *Engineering*—Theory of Construction. Friday, 9½–10½ Professor Greene.

3 *Graphical Analysis of Structures*—Tuesday and Thursday 9½–10½. Professor Greene.

4 *Engineering Design*—Daily, three hours a day; to count as one full course. Professor Greene.

5 *Mechanism and Machine Drawing*—Tuesday and Thursday, 8½–10½. Assistant Professor Denison.

6 *Machinery and Prime Movers*—Water Wheels and Steam Engines. Monday, Wednesday, and Friday, 10½–11½. Professor M. E. Cooley.

SECOND SEMESTER.

3 *Graphical Analysis of Structures*—Tuesday and Thursday, 10½–11½. Professor Greene.

8 *Engineering*—Theory of Construction. Monday, Tuesday, Thursday, and Friday, 9½–10½. Professor Greene.

9 *Hydraulics*—Water Supply and Sewerage. Wednesday, 9½–10½. Professor Greene.

10 *Stereotomy.*—Tuesday and Thursday, 8½–10½. Assistant Professor Denison.

Course 4 accompanies 1, 2, and 8. Course 10 must be preceded by Course 5 in Drawing.

II. MECHANICAL ENGINEERING—FIRST SEMESTER.

1 *Workshop Appliances and Processes, Pattern Making, Moulding, and Founding.* Monday and Friday, 11½–12½. Professor M. E. Cooley.

[2 *Mechanical Laboratory work*—Tuesday and Thursday, 2–4. Not given this year. Professor M. E. Cooley.]

5 The same as Course 5 in Civil Engineering.

6 The same as Course 6 in Civil Engineering.

7 *Machine Design*—Monday, Wednesday, and Friday, 8½–11½. Professor M. E. Cooley, and Assistant Professor Denison.

[10 *Naval Architecture*—Tuesday and Thursday, 4–5. Not given this year. Professor M. E Cooley.]

SECOND SEMESTER.

8 *Mechanical Laboratory work*—Tuesday and Thursday, 2–4. Professor M. E. Cooley.

4 *Machinery, Machine Construction, and Drawing*—Monday, Wednesday, and Friday, 8½–11½. Professor M. E. Cooley, and Assistant Professor Denison.

[8 *Thermodynamics*—Monday, Wednesday, and Friday, 11½–12½. Not given this year. Professor M. E. Cooley.]

9 *Original Design, Estimates, Specification, and Contracts.* Tuesday and Thursday, 8½–10½. Professor M. E. Cooley.

11 *Naval Architecture*—Tuesday and Thursday, 4–5. Professor M. E. Cooley.

Course 5 precedes Course 6. Course 6 and 10 must be preceded by Course 11 in Mathematics. Course 7 must be preceded by Courses 4 and 5, and must precede Course 9. Course 10 precedes Course 11.

III. MINING ENGINEERING—SECOND SEMESTER.

1 *Mining.*—Five times a week. Professor Pettee.

METALLURGY.

FIRST SEMESTER.

1 *Fuel and Refractory Material, Iron, Steel, Copper, and Zinc.* —Tuesday and Thursday, 10½–11½; Wednesday, 11½–12½; Friday, 4–5. Professor Cheever.

SECOND SEMESTER.

2 *Lead, Silver, Gold, Mercury, and other metals.*—Twice a week Hours to be arranged with the instructor. Professor Cheever.

Requirements for Graduation.—Five exercises a week during a semester, whether in recitations, Laboratory work, or lectures, constitute a *Full Course of Study.* The completion of *Twenty-four Full Courses* is necessary to obtain the recommendation of the Faculty for the degree of Bachelor of Arts, or of Bachelor of Science (for the courses in Civil, Mechanical, or Mining Engineering). The completion of *Twenty-six Full Courses* is necessary to obtain the recommendation for the degree of Bachelor of Science (for the course in General Science), or of Bachelor of Letters. It is not essential that the exercises constituting a *Full Course* shall be in one and the same branch of study. Thus, a part (two for instance) may be in Mathematics, a part (say two) in Greek, and a part (say one) in Latin, making a total of five.

THE DEGREE OF BACHELOR OF SCIENCE.—Of the *twenty-six Full Courses* that the student is required to complete before he will be recommended by the Faculty for the degree of Bachelor of Science for the course in General Science *thirteen and four-fifths Full Courses* are prescribed as follows:

Courses 10, 12, 14, 15, in Mathematics, Courses 2, 6, in French, Course 1, 3, in German, Courses 1 or 7, and 2 or 8, in English, Course 3, in Philosophy, One Full Course in Physics, One Full Course in General Chemistry, One Full Course in Zoology, or in Botany, Five Full Courses in Organic Sciences, or Five Full Courses in Inorganic Sciences.

In addition to these the student must choose and complete from the other Courses offered enough to make in all *Twenty-Six Full Courses.*

Some of the Courses in Professional Studies.—It is thought desirable to add fuller statements than are given on the preceding pages concerning certain branches of study that lead to the professions of Engineer, Chemist, and Teacher.

I. *Engineering.*—The University is now better prepared than ever before to give complete courses of instruction in all branches of engineering, civil, mechanical, and mining. In *Civil Engineering* the University offers to persons that wish to become professional engineers a thorough course of study extending over about four years. The aim in this course of study is to lay a foundation of sound theory, sufficiently broad and deep to enable its graduates to enter understandingly on the further investigation of the several specialties of the profession; and at the same time to impart such a knowledge of the usual practice of an office, and of an engineering party, as shall make its students useful in any position to which they may be called. While the adaptation of theory to practice can be thoroughly learned only by experience, there are many matters in which the routine work of an engineering field party, office, or drafting room can be carried out on a greater or less scale in a training school. In all such particulars the civil engineering course of the University will embody as close an imitation of the requirements of active labor as the instructors who have the several branches in charge can devise. All the technical branches are under the direct care of those who have had professional experience as well as a full scientific training. In *Mechanical Engineering* the course of study though to some extent parallel with that in civil engineering, includes such a range of special studies as will enable the graduate to enter understandingly on the practice of his profession. Theory and practice are combined as far as possible, and no efforts are spared to make the relation between them plainly evident. The special work will be mainly under the direction of Professor Mortimer E. Cooley, assistant engineer in the United States navy, who has been recently detailed by the Navy Department for this purpose. In *Mining Engineering and Metallurgy* the course of instruction, which is intended to cover about four years of study, includes a part of that provided for students in civil and in mechanical engineering, though more especial attention is paid in the latter part of the course to mineralogy, geology, and Chemistry. The instruction in the technical branches is arranged so as to meet the wants, both of those whose purpose it is to confine their professional work more closely to metallurgy, and of those who intend to engage in the practice of mining and metallurgy combined.

Requirements for Admission.—Candidates for a degree in any of the courses in engineering must pass examinations for admission as follows:

1. *English Language, Geography, and Mathematics.*—In all, the same as for the degree of Bachelor of Arts.

2. *History and Natural Philosophy.*—In both, the same as for the degree of Bachelor of Science.

3. *English Literature.*—The same as for the degree of Bachelor of Letters.

4. *Chemistry, Geology, Zoölogy, or Physiology.*—In any *two* of these subjects, the same as for the degree of Bachelor of Science.

5. *French or German.*—The same as for the degree of Bachelor of Science. A candidate who has had no opportunity for preparation in French or German will not be rejected for lack of knowledge of those subjects. If satisfactory examinations are passed in the other subjects, the candidate may be admitted, but will be required to make up the deficiency in French or German.

Students not candidates for a degree may be admitted to pursue such studies as they prefer, provided they are found prepared to join the classes in those studies. They will be expected to attend all the lectures, recitations and examinations in the branches prescribed for the regular students, and will be required to take enough work to occupy them profitably.

Courses of Instruction.—The studies pursued in the earlier parts of the course, common to all students in engineering, will comprise, *in Mathematics*, algebra, geometry, plane and spherical trigonometry, general geometry, and the elements of differential and integral calculus; *in French and German*, an amount covering in all about two years of study, the choice depending upon the language presented at the examination for admission; *in English*, a course in higher English grammar and composition; *in Physics* and *in General Chemistry*, the study of the elementary principles; and, *in Drawing*, practice in geometrical and in mechanical drawing, and the study of descriptive geometry. The more technical subjects are taken up in the latter part of the course. Some of these subjects are of equal value to all classes of engineering students, such as analytical and applied mechanics, the strength and resistance of materials, and the metallurgy of the useful metals, especially iron and steel; others are adapted more particularly to the wants of the special students in the several courses. Their general scope may be seen from the following descriptive outline:

1. *Drawing.*—A very complete course in mechanical drawing is given, embracing plane projection drawing, isometric drawing, descriptive geometry, and the elementary principles of coloring and shading, with original problems executed in the drawing room. Students of mechanical engineering are required to sketch pieces of machinery, and afterwards to make working drawings suitable for use in the shop. Problems peculiar to mining practice are also given. Examples from numerical data are always given in all branches, and copying from the flat is avoided. Instruction is also given in free-hand drawing, topographical drawing, ornamentation and lettering, shades and shadows, linear perspective, and drawing for stone-cutting. The plans of surveys, plane-table work, maps, designs in engineering construction, and the thesis drawings naturally come under this head. The work in drawing occupies the student a part of almost every day throughout the course.

2. *Surveying.*—The work in surveying combines theory and practice. A course of lectures and text book work, in daily exercises, covers so much of one year as is not given to field work: the theory of instruments, and all the operations of surveying, laying out work, and computing are explained in detail. Every student is afforded abundant opportunity for becoming familiar, by actual use, with the excellent and full assortment of instruments owned by the University, embracing those usually employed in actual work, and numbering enough to well equip the parties. The classes in surveying are drilled in all the field work that pertains to that branch of engineering; they make surveys, traverse them, calculate contents, divide areas, and solve problems in heights and distances from data taken by themselves. They also determine the meridian, and take observations for latitude. This work is done during the fall months; the finished plans of the surveys are made during the winter. The classes in railroad engineering have practice in running levels and curves of different kinds, and in the measurement of earthwork. In the month of June they are taken into the field as a railroad party, for a space of four weeks continuously, where, under competent supervision, they go through all the field-work for a projected line; doing all the work up to the point of actual construction, such as reconnoissance, preliminary and location surveys, cross-sectioning, staking out, contouring, and topography. A plan and profile, carefully made in the field by each student from the notes of the party, completes this portion of the subject, and serves to fix the practical application of the principles obtained from the text-books and lectures. In the above work are usually included a plane-table survey, triangulation, and some hydrography when the selected locality is favorable. The principal text-books used in this work are Henck's Field-Book for Engineers, and Rankine's Civil Engineering.

3. *Civil Engineering: Theory of Structures.*—The study of the strength of materials and the theory of construction covers a course of recitations and lectures for an entire year. The text-book used is Rankine's Manual of Civil Engineering, supplemented with full explanations, additional lectures, examples, and problems. A complete course of instruction is also given in the graphical analysis of roof and bridge trusses and arches, as recently developed and applied. The student is made familiar with both the analytical and graphical methods of treatment, and thus possesses ready proof of the accuracy of his calculations.

4. *Machinery and Prime Movers.*—A course of instruction is given in mechanism, or the general principles of machinery, involving the study of gearing, cams, screws, cranks and levers, the dynamics of machinery, the strength and construction of machinery, and the materials used in construction. Careful attention is given to the principles of mechanics as applied in the construction of various kinds of machinery, and in the erection of blast-furnaces, foundries, rolling mills, and steel-works. In the study of the prime movers special attention is given to turbines and other water-wheels, and to the steam engine. Lectures are given on the different types of engines and boilers, links and valve motions, condensers, pumps, and propelling instruments, the theory and practice of the use of steam, combustion and fuel, and the efficiency of furnace, boiler, and engine. The care and management of engines and boilers, both in use and out of use, are also discussed. Additional lectures are given on the designing of the different parts of both the simple and the compound engine and boiler, and their various attachments.

5. *Designs in Engineering and in Machine Construction.*—Contemporaneously with the study of theory, students are required to work out problems in design. They are furnished with the usual data for a design, and the kind or type of structure or machine will be indicated. They are then expected to make the necessary calculations, paying particular attention to proportioning the different parts, so as to secure strength, simplicity, and effect, and to present, at a specified date, complete working drawings, giving full details, accompanied by bills of materials, estimates, and specifications.

6. A course in *Thermodynamics* embraces the study of the principles governing the action of heat engines in general.

7. *Mechanical Engineering and Laboratory work.*—The elementary courses in mechanical engineering embrace the explanation of the principles governing the action of cutting tools, and a description of the principal machine and hand tools used in the work-shop. They also treat of the usual and more important processes employed in the shop. Lectures are given on pattern making, moulding, and founding, covering the principal features of each. The *Laboratory work* is intended to cover the application of principles previously studied. It comprises the actual manipulation of the tools used in working metal and wood, and in moulding. The student is required to do work in pattern making, and moulding in green sand, in dry sand, and in loam, and will charge and have the management of the cupola and brass furnace during the operations of casting. Careful attention is given to the selection of sands for different purposes, and to making composition metals for specific purposes. The student is also required to put in practice, at the blacksmith's forge, his knowledge of the elementary principles of forging, and to forge and temper his own cutting tools. By working with iron and steel of different qualities, the student becomes familiar with all grades of those materials. Practice is also afforded in soldering, brazing, and steam-fitting. The principal text-books and books of reference used in the work in mechanical engineering are Rose's Practical Machinist and Pattern Maker's Assistant, Shelley's Workshop Appliances, Spretson's Casting and Founding, Rankine's Machinery and Mill-work, Rankine's Steam Engine, Sonnet's Dictionnaire des Mathematiques Appliquées, Unwin's Elements of Machine Design, Marks's Proportions of the Steam Engine.

9. *Economic Geology.*—Particular attention is paid to the geology of mines and mineral districts, and to the modes of occurrence and distribution of mineral substances that have an economic or commercial importance.

10. *Mining.*—In this branch the instruction is given mainly by lectures. The machines in use at the best mines are described, and the mutual relations of parts explained and illustrated with the aid of plates and diagrams. The different operations connected with the discovery, opening, development, and working of mines are all studied in their proper order.

11. *Metallurgy.*—A complete course of instruction by lectures and recitations is given upon the subjects of fuel, refractory material, iron and steel, copper, zinc, lead, gold, silver, and other metals, extending over an entire year. The lectures are illustrated by charts and drawings of the furnaces and appliances used, and by samples of furnace products. In connection with this course of study, the student is required to work out problems in heat, furnace construction, ore mixtures, blast furnace slags, and blast engines, and to write out the chemical reactions that take place in the different metallurgical operations. Certain days are devoted to laboratory work, and the student is required to determine by actual tests the heating value of different fuels, to make tests of fire-proof material, and, from data and material

furnished, to produce slags whose composition shall correspond to a given formula.

12. *Visits of Inspection.*—As often as may be practicable, visits will be paid to the neighboring manufacturing establishments for the purpose of acquiring a knowledge of the methods employed in building, and in the construction of machinery and ships. It is hoped, also, that provision will soon be made for a regular course of study, during the summer vacation, among the mines and furnaces of the Upper Peninsula.

Facilities for Instruction.—The collections for illustrating the instruction given comprise models, drawings, photographs, and lithographs, representing trusses, arches, and details of construction in iron, wood, and stone; also shapes of iron, working models of turbines and engines, and working drawings of a number of bridges. These collections are receiving additions from year to year, by gift and purchase, and are invaluable to the student. The mechanical laboratory, for the erection and equipment of which the sum of twenty-five hundred dollars was appropriated by the last Legislature, has been built and is now ready for occupancy. There is also a large and convenient metallurgical laboratory connected with the chemical laboratory, amply supplied with assay furnaces and other appliances such as are usually found in laboratories of this description. The latest and best books on professional subjects are added yearly to the library, where they are accessible to all; and frequent references are made to them in the class-room as the various subjects are brought forward.

Examinations.—Examinations, usually in writing, are held at the end of each semester; but the classes are liable to be examined at any time, without notice, on any portion of their previous work.

REQUIREMENTS FOR GRADUATION.—Upon the completion of a prescribed course of study, amounting to twenty-four Full Courses, as given below, and the presentation of a satisfactory thesis, the student receives the degree of Bachelor of Science. The diploma given indicates the line of study pursued. Bachelor of Arts, of Science, and of Letters, of this University, and graduates of any other reputable University or College, will be recommended for the same degree with the regular students, after attendance on, and a satisfactory examination in, the technical subjects alone of the several courses. These studies can be completed in two years. The culture imparted by classical or other liberal training will be found to have its uses for one engaged in engineering work, and the previous discipline of the faculties in exact research will enable the professional student to master more easily the requirements of the course. All the time the student can devote to general studies before taking up specialties will be well spent. The requirements for the several degrees as follows:

1. *Civil Engineering.*—To obtain the recommendation of the Faculty for the degree of Bachelor of Science, for a course in Civil Engineering, the student must complete

Courses 1, 3, 5, 11, 13, 16, in Mathematics.
Courses 2, 6, in French.
Courses 1, 3, in German.
Course 1 or 7, in English.
Course 10, in Physics.
Course 2, in General Chemistry.
Course 1, in Mineralogy.
Course 3, in Astronomy.
Courses 1, 2, 4, 5, 6, in Drawing.
Courses 1, 2, 3, 4, in Surveying.
Courses 1, 2, 3, 4, 5, 6, 8, 9, 10, in Civil Engineering.

These make *twenty and four fifths Full Courses.* From the other Courses offered he must choose and complete *three and one fifth Full Courses*, making *twenty-four Full Courses* in all. He must also prepare a satisfactory thesis.

2. *Mechanical Engineering.*—To obtain the recommendation of the Faculty for the degree of Bachelor of Science, for a course in Mechanical Engineering, the student must complete

Courses 1, 3, 5, 11, 13, 16, in Mathematics.
Courses 2, 6, in French.*
Courses 1, 3, in German.*

*For students who passed an admission examination in German instead of French the prescribed Courses are 1 and 5 in French, and 2 and 6 in German

Course 1 or 7, in English.
Course 10, in Physics.
Course 2, in General Chemistry.
Course 1, in Mineralogy.
Courses 1, 2, 4, 5, 6, in Drawing.
Courses 1, 3, 10, in Civil Engineering.
Courses 1 to 9 inclusive, in Mechanical Engineering.
Course 1, in Metallurgy.

These make *twenty and two-fifths Full Courses.* From the other Courses offered he must choose and complete *three and three-fifths Full Courses*, making *twenty-four Full Courses* in all. He must also prepare a satisfactory thesis.

3. *Mining Engineering.*—To obtain the recommendation of the Faculty for the degree of Bachelor of Science, for a course in Mining Engineering, the student must complete one of the two following sets of requirements:

I.

Courses 1, 3, 5, 11, 13. 16, in Mathematics
Courses, 2, 6, in French.*
Courses 1, 3, in German.*
Course 1 or 7, in English.
Course 10, in Physics.
Course 2, in General Chemistry.
Courses 1, 5*a*, 9, 10, in Analytical Chemistry.
Course 2, in Mineralogy.
Courses 8, 9, in Geology.
Courses 1, 5, in Drawing.
Courses 1, 2, in Surveying.
Courses 1, 3, 5, 6, in Civil Engineering.
Course 1, in Mining.
Course 1, in Metallurgy.

These make *twenty-three Full Courses.* From the other Courses offered he must choose and complete *one Full Course*, making *twenty-four Full Courses* in all. He must also prepare a satisfactory thesis.

II.

Courses 10, 12, 14, 15, in Mathematics.*
Courses 2, 6, in French.†
Course 1, in German.†
Course 1 or 7, in English.
Course 10, in Physics.
Course 2, in General Chemistry.
Courses 1, 5*a*, 5*a′*, 9, 10, in Analytical Chemistry.
Course 2, in Mineralogy.
Courses 8, 9, in Geology.
Courses 1, 3, 5, in Drawing.
Courses 1, 2, 3, in Mechanical Engineering.
Course 1, in Mining.
Courses 1, 2, in Metallurgy.

These make *nineteen and three fifths Full Courses.* From the other Courses offered he must choose and complete *four and two-fifths Full Courses* making *twenty-four Full Courses* in all. He must also prepare a satisfactory thesis.

REQUIREMENTS FOR THE DEGREES OF CIVIL ENGINEER, MECHANICAL ENGINEER, AND MINING ENGINEER.—The conditions on which the degree of Civil Engineer, as a second degree, is conferred, are as follows: The degree of Civil Engineer may be conferred upon Bachelors of Science of this University who have taken the degree for a course in Civil Engineering, if they furnish satisfactory evidence that they have pursued further technical studies for at least one year, and, in addition, have been engaged in professional work, in positions of responsibility, for another year. The first of the above requirements may be satisfied by pursuing at the University, under the direction of the Faculty, a prescribed course of study for an amount of time, not necessarily consecutive, equivalent to a college year. If the candidate does not reside at the University, his course of study must be approved in advance by the Professor of Civil Engineering, and he must prepare a satisfactory thesis on some engineering topic, to be presented, together with a detailed account of his professional work, one month, at least, before the date of the Annual Commencement at which he expects to receive the degree. The conditions on which the degrees of

* Instead of these Courses the student may take Courses 1 and 5.

† For students who passed an admission examination in German instead of French, the prescribed Courses are 1 and 5 in French, and 2 and 6 in German.

Mechanical Engineer and Mining Engineer, as second degrees, will be conferred are not yet fully determined, though they will probably be similar to those required for the degree of Civil Engineer.

ANALYTICAL AND APPLIED CHEMISTRY.—Students desiring to qualify themselves for research and educational service in chemical science, or for the profession of an analytical and consulting chemist, can, by making a judicious choice of elective studies, accomplish this object, and at the same time satisfy the requirements for the degree of Bachelor of Science. The prescribed *general studies*, those namely, in Mathematics, French, German, English, Philosophy, Physics, and Zoölogy or Botany, amount to *seven and four-fifths Full Courses*, and leave *eighteen and one-fifth Full Courses* to be completed by the student, of which *one Full Course* must be taken in General Chemistry, and *five Full Courses* either in Organic or in Inorganic Sciences.

Students wishing to complete a professional course in Chemistry are recommended to take the following Courses, which amount in all to *twelve and four-fifths Full Courses*:

Course 3, in Physics.
Courses 3, 6, in General Chemistry.
Courses 1, 2, 4, 5a, 5a′, 7, 9, 10, 11, 14, in Analytical [Chemistry.
One Full Course, in Drawing.

To those students who wish to pursue special subjects, the following Courses, in addition to the above, are recommended:

I. For Mineralogical and Metallurgical Chemistry:
Course 2, in Mineralogy.
One Full Course, in Geology.
One Full Course, in Metallurgy.
These make *three Full Courses.*

For Manufacturing Applications:—Course 13, in Analytical Chemistry. Course 2, in Mineralogy. One Full Course, in Metallurgy. These make *two-and four-fifths Full Courses.*

3. *For Medical Chemistry and Biology*: - Course 8, in Analytical Chemistry. One Full Course in Zoology. Course 1, 2 in Physiology. These make *two and three-fifths Full Courses.*

4. *For Sanitary Chemistry*, the examination of foods, and the detection of adulterations:—Courses 4, 5a″ in Analytical Chemistry. Course 2 in Botany. These make *Three Full Courses.*

CALENDAR.—September 21-25. Examination of Candidates for admission to the department of Literature, Science and the Arts.

September 25, 26. Examination for admission to the School of Pharmacy. First year's work begins.

September 25-30. Examination for admissions to the Department of Law.

September 27. First Semester begins.

September 28-30. Examination for admission to the Department of Medicine and Surgery, the Homœopathic Medical College, and the College of Dental Surgery.

October 2. Professional school opens.

November —. Thanksgiving Recess of three days, beginning Tuesday evening, in the Department of Literature. Science and the Arts, the department of Medicine and Surgery, the School of Pharmacy, and the Homœopathic Medical College; recess of one day, Thursday, in the department of Law, and in the College of Dental Surgery.

December 22. (Evening.) Holiday Vacation begins for all departments.

1883.

January 9. Exercises resumed.

February 16. (Evening.) First Semester closes.

February 18. Second Semester begins.

March 28. Commencement in the department of Law, and in the College of Dental Surgery.

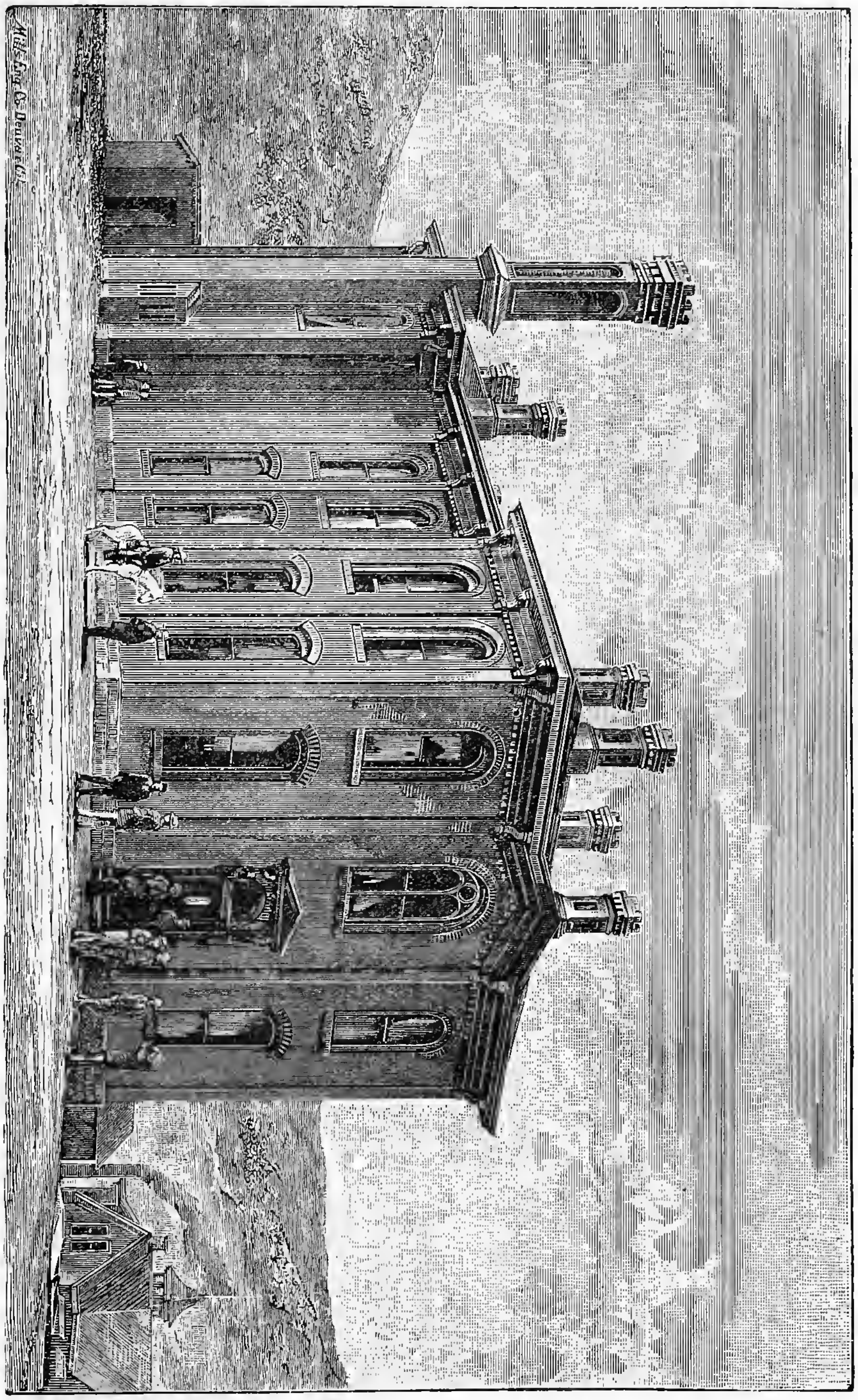
COLORADO STATE SCHOOL OF MINES, GOLDEN, COLORADO.

THE State School of Mines of Colorado was established by act of the Legislative Assembly, approved February 9th, 1874. The General Assembly of 1879 recognizing that the highest interests of the State were best subserved by enabling the School of Mines to occupy a position and accomplish a work worthy of its object and aims, wisely granted a decided increase to the former appropriation for the Institution, thus putting it into the power of the Board of Trustees to re-organize and equip the School on a basis which would insure a competent preparation of its students to fill any department of practical work in Mining and Metallurgy. In harmony with this action the Board of Trustees during the summer of 1880, erected a new and commodious building in Golden, within three minutes' walk of the centre of business, in a convenient location, and supplied it with every facility requisite for the most successful prosecution of work in the various departments of study The faculty was at the same time re-organized and greatly increased. Large additions were made to the library and chemical apparatus and the Assay and Chemical Laboratory were fitted up according to the most approved plans, and a scale sufficient to meet the increased demands made upon the Institution. The School re-opened in the new building, which is illustrated on the next page, on Wednesday, October 13th, 1880, and has already met with the most unqualified success under its present organization. An additional building is now in process of erection to be connected with the present one, making the capacity of the whole *three* times that of the building represented in the cut. This has been necessitated by the rapid increase in the number of students during the past two years, and by the present enlarged sphere of work of the institution.

The building represented in our cut is of brick manufactured from the excellent clay of the neighborhood. Its location, style and proportions give it a very pleasing effect: while its windows command views in every direction of surpassing beauty. The plan of its interior was the result of careful study on the part of the Board of Trustees, under the advice of the Faculty, and, in points of convenience and adaptation to the purposes in view, is well-nigh perfect. Two stories in height, the front, on each floor, is devoted to halls, offices and recitation rooms. The main part below affords a spacious chemical laboratory, besides three rooms in the rear occupied by the Assay department. The corresponding space upon the upper floor constitutes a large lecture room, the center being furnished with seats, sides and one end occupied by cases containing the various cabinets, while the remaining end furnishes room for the lecture-stand, fitted with pneumatic cisterns and every modern convenience. The advantages of location at Golden are threefold, viz.: 1st, it is easily accessible by rail from all parts of the State; 2d, Golden is situated at the very foot of the mountains, at a point affording most remarkable opportunities for illustrating studies in geology, nearly all the formations known to the geology of Colorado being well represented in the neighborhood. Mines, also of coal, fireclay lead, silver and gold are either immediately at hand or to be reached within a few miles by rail. 3d. The establishment here of various reduction works for treating ores—access to which is freely accorded the students—furnishes invaluable aid in acquiring a knowledge of metallurgy that shall not be merely theoretical but eminently practical.

FACULTY.—Albert C. Hale, A. M., E. M., Ph. D., President, Professor of Chemistry and Assaying. Milton Ross, Ph. D., Professor of Mineralogy and Metallurgy. Arthur Lakes, Professor of Geology and Drawing. Gregory Board, E. M. Treatment of Colorado Ores. Magnus C. Ihlseng, E. M., C. E., Ph. D., Professor of Engineering, Mathematics and Physics. Eri P. Rice, Secretary, and Assistant in Chemistry. Carlton H. Hand, Assistant in Assaying.

Admission.—Candidates for admission to any of the regular courses are expected to be at least seventeen years of age, to have had a liberal education in the English branches, and to sustain a thorough examination on the first five chapters of Peck's Manual of Algebra and on the first four books of Wentworth's Geometry or an equivalent of Davies' Legendre. Candidates for advanced standing will be examined upon all the studies of the course below the class they purpose to enter, as well as upon the subjects required for admission. A certificate from other institutions bearing satisfactory evidence that the candidate has completed any or all of the required subjects, will be accepted in lieu of an examination upon the same. Special students are received at any time during the regular sessions, provided their age and attainments are sufficient for the studies they wish to pursue.



COLORADO STATE SCHOOL OF MINES, GOLDEN, COLORADO.

Courses of Study.—There are three regular courses of study, viz: Mining Engineering, Civil Engineering and Metallurgy—each covering a period of four years. Students who complete any of the courses and pass the required examination in all the studies of the same will be entitled to receive a State Diploma in recognition of their attainments. Those in the course of Mining Engineering receive the degree Engineer of Mines (E. M.) in Civil Engineering, that of Civil Engineer (C. E.), and those in Metallurgy the degree Bachelor of Philosophy (Ph. B.)

Special Courses of Study.—It being the aim of the Institution to adapt itself to the Mining and Metallurgical interests of the State, students who wish to pursue special courses of study in Assaying, Chemical Analysis, Geology, Mineralogy or Surveying, will find *superior* advantages for doing so under the advice and direction of the Faculty, and every opportunity for study and practice will be afforded those who wish to prepare themselves thoroughly to do successful work as prospectors, assayers or surveyors. Special students attend lectures with the regular classes so far as possible, and *all receive individual instruction* in the laboratories.

Expenses.—The charges are twenty dollars ($20 00) per term for the regular courses of study, and the same for special courses in which the student is engaged in laboratory work. As *tuition is free* the fee is simply to defray the cost of chemicals, apparatus, fuel, etc. Students can obtain board and suitable accommodations in Golden at a cost averaging from six to seven dollars per week.

Course in Mining Engineering.—First Year.—*First Term.* Algebra, Physics, Chemistry, Drawing, free hand, French.

Second Term.—Algebra, Physics, Chemistry, Drawing, free hand, French.

Third Term.—Algebra, Geometry, Physics, Chemistry, Drawing free hand, Botany (optional), French.

Vacation.—Memoir on subject assigned by the Faculty.

Second Year—*First Term*—Geometry, Qualitative Analysis, Assaying, Drawing, Crystallography, German.

Second Term—Trigonometry, Mensuration, Conic Sections, Qualitative Analysis, Drawing, Assaying, Mineralogy, Blowpipe Analysis, German.

Third Term—Descriptive Geometry, Surveying, Stoichiometry, Qualitative Analysis, Drawing, Determinative Mineralogy, Zoology, (optional) German. Vacation Memoir.

Third Year—*First Term*—Analytical Geometry, Surveying, Quantitative Analysis, Applied Chemistry, Drawing, Shades, Shadows and Perspective, Geology.

Second Term—Calculus, Geodesy, Quantitative Analysis, Applied Chemistry, Drawing, Civil Engineering, Stone Cutting, Geology.

Third Term—Calculus, Mechanics, Metallurgy, Applied Chemistry, Drawing, Civil Engineering, Economic Geology, Spanish (Optional). Vacation Memoir.

Fourth Year—*First Term*—Kinematics, Mechanics, Metallurgy, Practical Mining, Drawing, Mining Law, Theory of Strains and strength of materials, Spanish, (optional.)

Second Term—Dynamics, Hydraulic Engineering, Metallurgy, Practical Mining, Drawing, Mining Engineering, Plans, Constructions, and Estimates.

Third Term—Mechanical Engineering, Ore Dressing, Mining Engineering, Thesis Work, including Plans, Estimates and Drawings.

Course in Civil Engineering—First Year—*First Term*—Algebra, Physics, Chemistry, Drawing, free hand, French.

Second Term—Algebra, Physics, Chemistry, Drawing, free hand, French.

Third Term—Algebra, Geometry, Physics, Chemistry, Drawing, free hand, Botany, (optional,) French.

Vacation—Memoir on subject assigned by the Faculty.

Second Year—*First Term*—Geometry, Qualitative Analysis, Assaying, Drawing, Crystallography, German.

Second Term—Trigonometry, Mensuration, Conic Sections, Qualitative Analysis, Drawing, Assaying, Mineralogy, Blowpipe Analysis, German.

Third Term—Descriptive Geometry, Surveying, Stoichiometry, Qualitative Analysis, Drawing, Lithology, Zoology, (optional), German.

Vacation Memoir.

Third Year—*First Term*—Analytical Geometry, Surveying, Quantitative Analysis, Quarrying, etc., Drawing, Shades, Shadows and Perspective, Geology.

Second Term—Calculus, Geodesy, Excavation and Tunneling, Applied Chemistry, Drawing, Civil Engineering, Stone Cutting, Geology.

Third Term—Calculus, Mechanics, Metallurgy, Architecture, Drawing, Civil Engineering, Economic Geology, Spanish, (optional.)

Vacation Memoir.

Fourth Year.—*First Term.* Kinematics, Mechanics, Railroad Equipment, Architecture, Spanish, (optional), Drawing, Lectures on Laws pertaining to railroads and their management. Theory of Strains and Strength of Materials.

Second Term. Dynamics, Hydraulic Engineering, Problem in Graphics, Drawing, Mining Engineering, Plans, Constructions and Estimates.

Third Term. Mechanical Engineering, Sewage and Sanitary Engineering, Thesis Work, including Plans, Estimates and Drawings, Bridges, Aqueducts, etc.

Course in Metallurgy.—First Year.—*First Term.* Algebra, Physics, Chemistry, Drawing, free hand, French.

Second Term. Algebra, Physics, Chemistry, Drawing, free hand, French.

Third Term. Algebra, Geometry, Physics, Chemistry, Drawing, free hand, Botany, (optional), French.

Vacation. Memoir on subject assigned by the Faculty.

Second Year—*First Term*—Geometry, Qualitative Analysis, Assaying, Drawing, Crystallography, German.

Second Term—Trigonometry, Mensuration, Conic Sections, Qualitative Analysis, Drawing, Assaying, Mineralogy, Blowpipe Analysis, Analysis, German.

Third Term—Descriptive Geometry, Metallurgy, Stoichiometry, Quantitative Analysis, Drawing, Determinative Mineralogy, Zoology (optional), German. Vacation Memoir.

Third Year—*First Term*—Analytical Geometry, Metallurgy, Quantitative Analysis, Applied Chemistry, Drawing, Determinative Mineralogy, Shades, Shadows and Perspective, Geology.

Second Term—Calculus, Metallurgy, Quantitative Analysis, Drawing, Stoichiometry, Geology, Applied Chemistry.

Third Term—Calculus, Mechanics, Metallurgy, Applied Chemistry, Drawing, Quantitative Analysis, Economic Geology, Spanish (optional). Vacation Memoir.

Fourth Year—*First Term*—Kinematics, Mechanics, Furnace Products, Practical Mining, Drawing, Mining Law. Theory of Strains and Strength of Material, Spanish (optional).

Second Term—Dynamics, Hydraulic Engineering, Problems in Graphics, Drawing, Constructions and Estimates, Practical Mining.

Third Term—Mechanical Engineering, Ore Dressing, Thesis Work, including Plans, Estimates and Drawings.

Mathematics and Mechanics.—In this department the student is given such an accurate knowledge of mathematics, pure and applied, as will enable him readily to solve difficult practical problems. The subjects are pursued in the following order, viz.: Review and completion of Algebra and Geometry; Trigonometry and Mensuration; Conic Sections; Analytical Geometry; Calculus and Analytical Mechanics.

Drawing.—Both Free Hand and Mechanical Drawing are taught. The object of Free Hand Drawing is to furnish that skill of the hand and eye which will enable the student promptly and effectively to illustrate any object with suitable sketches. In Mechanical Drawing the aim is to render the student a reliable and efficient draughtsman. The various methods of graphical expression are carefully investigated, and the principles therein embodied are put into practice in the formation of plans and in the execution of detailed drawings both from copies and original designs.

After devoting one year to Free Hand Drawing, the student is taught lettering, coloring, and the use of instruments. This is succeeded by a thorough course in Mechanical Drawing. Descriptive Geometry; Shades, Shadows and Perspective; Masonry and Stone-Cutting are taken up in their proper order. The students are also instructed in Topographical and Architectural Drawing and in the reproduction of drawings by the "Blue Process." The last year will be employed in making plans and designs for furnaces, mills, engines, machinery, etc., which are executed upon paper in the most careful and detailed manner in connection with Thesis work. These drawings are required to be presented upon paper 19 x 27 inches, to be preserved in the Institution for subsequent reference and inspection. The public will be allowed to examine and make copies of these, subject to such conditions as will insure their careful preservation.

Physics.—The students of the first year will be occupied for three hours per week with this subject. During this time the class will have, by lectures and recitations, amply illustrated by experiments, a complete course, embracing the following: The Principles of Mechanics; Elementary Machines; Optics, Acoustics, Heat, and Electricity, and also the application of the same to practical questions of every day life.

Surveying.—Surveying is taught in the most practical manner, the student becoming thoroughly familiar with the use of compass, transit, aneroid and hypsometer. Instruction is given in railroad and canal surveying, in sewage and street extension, in chain and underground surveying, and in Geodesy. The student learns to anticipate the various problems which he is likely to encounter in subsequent experience, and is carefully prepared by the selection of such as will be of special importance in his work as mining or civil engineer. His field and underground work are plotted under the personal supervision of the Professor.

Engineering.—This subject is systematically pursued through three years under the following heads: Strength of Materials; Civil Engineering; Hydraulic Engineering; Kinematics; Dynamics of Machinery, and Mining Engineering. Strength of Materials will occupy a term in the determination of dimensions of parts of roof, bridge, trusses, etc., by means of the stresses to which they are subjected. Civil Engineering will embrace the nature, elasticity and tests of materials; construction of retaining walls; trestles, bridges, canals, etc., estimation of quantities of materials required for the same; sewage and Sanitary Engineering. Hydraulic Engineering includes mechanics of fluids, gauging of streams, and the calculation for water supply, reservoirs, conduits, pipes, etc. In the study of *Kinematics* and *Dynamics* the student investigates the theory and construction of boilers, machinery, motors, pumps, teeth, cams, and also the transmission of power. The distinction between Mining Engineering and Civil Engineering being only in the difference of application, *Mining Engineering* proper will embrace, apart from the general subjects of engineering, the following branches, viz.: Practical Mining, which will consist of lectures and recitations upon prospecting, excavations, blasting, tunneling, shafting and timbering, hydraulic and placer mining, with details of construction and economy of pipes; also riffles, sluices, ditches, dams, etc; and Mine Engineering, which treats of the modes of exploitation, drainage and ventilation of mines; machinery for hoisting and pumping, ground plant and ore dressing in principle and detail, which is treated according to both the American and European methods and plans. The class accompanied by the Professor will visit prominent mines and mining regions after which each student is required to hand in a written report of his observations.

Chemistry.—A large amount of time is devoted to Chemistry, general, analytical and applied. A knowledge of the principles of the science, the nature of the most important elements and their compounds, their behavior with re-agents, and their deportment in Assaying and Metallurgical processes is regarded as indispensable to the successful metallurgist, and of great value to the engineer, prospector, and practical miner. It also affords a solid foundation upon which to build the sciences of Mineralogy and Geology. The Chemical Laboratory is capable of accommodating forty-five students at a time. Each student is provided with a convenient desk with shelves of re-agents and drawers and cupboards for apparatus. The more rare and costly chemicals are kept in special cases in the Laboratory rooms, and are accessible to students as they need them. The Laboratory is well lighted and ventilated, and is furnished with hoods to carry off poisonous and offensive gases. The building is furnished throughout with gas and water. Theoretical and Experimental Chemistry are taught during the whole of the first year, the students repeating in the Laboratory so far as possible the experiments shown in the Lecture room, and also testing the behavior of the most important elements and compounds towards the ordinary re-agents, thus preparing the way for the strictly analytical work which follows, and which, with Applied Chemistry is continued until the fourth year—students in Civil Engineering, however, do not pursue the subject so far. In Qualitative Analysis the most reliable and direct methods are adopted. The student is required to write out accurately the formula expressing the reaction and also to give a full explanation of the same. In Quantitative Analysis the student first analyzes salts of known composition, thus being able to test the accuracy of his work by comparing his results with the *true* percentages calculated from the chemical formula. When sufficient skill is acquired in this way, more complex substances are investigated, the accuracy of work being determined by comparing the results of duplicate analyses. The substances analyzed are principally ores, metallurgical products, comprising slag, matte, etc., products of economical geology, such as building stone, cement, clays, mineral waters, and other substances of commercial importance.

Assaying.—A course in assaying following the most approved and practical methods for the determination of gold, silver, lead, copper, zinc and iron, may be completed in two months. During the same time instruction is given in the assay of coals and in Blowpipe Analysis sufficient to enable the student to determine the presence of valuable metals contained in minerals and approximately the quantity of silver. Those pursuing the regular courses of Mining Engineering and Metallurgy are expected to acquire a more extended knowledge of the subject. The instruction is principally oral in connection with Laboratory work. The furnace can be used any time from 8:30 A.M. until 5 P.M.

Mineralogy, Crystallography and Blowpiping.—This course embraces instruction in Crystallography, in Descriptive Mineralogy and in the determination of minerals by actual examination of the physical properties of individual specimens and by Blowpipe tests. In Blowpiping the student first becomes familiar with the oxidizing and reducing flames and their effects. He is then given simple substances of known composition and, after he has studied their deportment under the Blowpipe, unknown mixtures of the same compounds, and finally, alloys and minerals—the latter comprising all the important ores of the various metals. A certain amount of time is also devoted to the determination of minerals by sight, aided only by such tests as can be made without the use of special apparatus and re-agents. A carefully selected collection of mineral is kept on hand for the use of the students who are allowed to make upon them such tests as are necessary in studying the nature and properties of the specimens. The School possesses also a good collection of models to illustrate the forms and systems in which the different minerals crystallize. These models are at all times accessible to the students.

Metallurgy.—Metallurgy is taught by class-room lectures and conferences, also by frequent visits to the smelting works under the guidance of the Professor. The various processes for the reduction of gold, silver, lead, and copper ores are in this way learned by observation as well as theoretically, and samples of the products are collected for examination. The course of metallurgy begins with the study of fuels and refractory materials. Then follows the discussion of furnaces, engines, and the various other constructions and appliances of metallurgical establishments When the student is familiar with these, the treatment of the ores of the different metals is taken up successively in detail, all the well-known and important processes being thoroughly studied, and their relation and applications to the reduction of the ores of the western states and territories are particularly considered. Students in Civil Engineering attend the lectures on fuel, refractory materials, furnace constructions, etc., devoting one term to the work. Those in Mining Engineering pursue a more complete course, becoming familiar with the most important processes used in the reduction of the principal ores; while those in the Metallurgical course devote four terms to an exhaustive study of the whole subject, and after acquiring a comprehensive knowledge of Metallurgy and having considerable experience in Chemical work, one term is spent in the examination of the nature of the different furnace products, and in making quantitative analyses of the same.

Geology.—The advantage of a thorough knowledge of Geology can hardly be over-estimated. It is important for the prospector and the practical miner to be able to distinguish properly the different rocks in which the minerals lie. Mining is not wholly of a haphazard nature. Every district has its own special character and certain formations in which the ore principally occurs, and in which it is distributed according to certain laws. The knowledge of this local character can be more readily acquired when the general principles of Geology are understood. Few regions present greater advantages for the study of this science than the Rocky Mountains. The appreciation of this fact and of the mineral importance of this region is evinced by the many expeditions sent out here by the United States Government and by Eastern Colleges. The State School of

Mines of Colorado is particularly favored by being located in one of the most remarkable Geological sections of this region. Nearly the whole series of the Rocky Mountains is represented in this vicinity. It abounds in fossils, and amongst them the enormous Dinosaurs discovered by Professor Arthur Lakes and brought into world-wide celebrity through his labors in connection with Professor Marsh and others. Our Table Mountains, capped with basaltic lava, abounding in zeolites and other volcanic minerals, beneath which lie the finest typical fossil impressions of leaves of the Lignitic group that have been discovered, afford rare opportunities for the geologist and the mineralogist. Economic Geology is also well represented by beds of coal, fire-clay, and quarries of freestone and limestone. The course pursued at the School of Mines comprehends Theoretical Geology supplemented by a study of specimens characteristic of the different rock formations, also field work to verify the instruction of the class-room, and to encourage original research. Connected with this is the collecting of specimens, and making geological sections and maps of the surrounding country. The weekly excursions, which have proven an unfailing source of healthful and instructive enjoyment, will be continued every Saturday as heretofore. During the past year the most important points of the "Foot Hills" and adjacent formations from Morrison to Fort Collins, a distance of eighty miles, were carefully studied by students who took part in these excursions. The Geology of Colorado thus receives special attention, and frequent reference is made to materials gathered by the Professor and students.

Botany and Zoology.—These two subjects are studied mainly as aids to the better understanding of the fossils found in the various rock formations described in Geology. Each is pursued but one term, and the lectures have constant reference to the practical end to be attained.

Meteorology.—There is, connected with the department of Physics, a recording observatory in communication with the U. S. Signal Service, to which monthly reports are sent.

Modern Languages.—No separate professorships have as yet been established in this department. French and German are taught, however, by members of the Faculty in other departments, who have enjoyed special facilities for perfecting themselves in these languages by many years of study and travel in the respective countries. The object of instruction in French and German is to teach the students to read works on science in these languages, and to this end elementary scientific works in French and German will be read in the class-room as soon as sufficient knowledge of the grammar is acquired. The study of Spanish is made optional in all the regular courses for the purpose of enabling those students who desire it to acquire the means of ready communication with the Spanish speaking population of Colorado and adjacent territories.

Museum.—Large additions have been made to the Museum during the past year. A choice collection of the most important minerals and ores, arranged according to Dana, has been procured lately, and is displayed in suitable cases. The geological collection, which includes many of the best fossil specimens found in the formations along the base of the "Foot Hills," is exhibited in a suitable manner, and there are separate cases for the ores from the different mining sections of the State. It is proposed that this department of the Museum shall represent the typical fossils and rocks of Colorado. Owners of mines and others are invited to contribute to this collection. Specimens of both the average and richest yields of the mines are desired, also of crystals and associated minerals. Contributions of the gangue and of the ore with inclosing contact rock are likewise solicited. These should be plainly labeled with the name of the mine, its location, and the name of the donor, that the various mining interests of the State may be fairly represented. Such a collection would be of great interest and importance both to the scientist and to the capitalist desirous of investment. Quite a good beginning has already been made in this direction, but it is specially desired that all the prominent mining properties of the State be well represented. Fossils, characteristic rock from any portion of the State, specimens of coal, clay, etc., are desired for the Geological section; and all specimens should be clearly and fully labeled and of uniform size, preferably 4 by 5 inches.

Library and Apparatus—The Institution possesses a good library of standard scientific works, and is liberally provided with apparatus. Among the most important pieces of apparatus may be enumerated the following, viz.: A full set of surveying instruments, including an aneroid barometer and two very superior mining transits; a fine projection apparatus, consisting of lantern with triple condenser and vertical attachment for use either with the oxy-hydrogen lime light or with the electric arc, for which a battery of fifty Grove cells has been purchased; 21 inch Toepler Holtz machine; a large Ruhmkorff coil, length of wire forty-four miles; hydraulic ram; air pump; dipping battery; full set of meteorological apparatus; Crooke's tubes; Geissler's tubes; large gasometers for oxygen and hydrogen; several very accurate chemical and bullion balances; ore balances; Blake's laboratory crusher; and a full equipment of muffle and wind furnaces provided with all necessary appliances.

Lectures.—Prominent members of the legal profession will be engaged to deliver a series of lectures upon mining and railroad law, with special reference to the wants of the students. During the school year a course of scientific lectures is delivered upon subjects of popular interest by the members of the Faculty and others. These lectures, to which the public are invited, are given in the evening and are illustrated by experiments, drawings and lantern pictures.

Memoirs and Thesis—Each student in the regular course is required, during the summer vacation, to execute a Memoir on some subject assigned by the Faculty. The subject is chosen so far as possible, with direct reference to the practical end the student has in view in his course of study. A minimum of actual work, adequately described and illustrated by drawings, is insisted upon. Careful inspection of mines, metallurgical works, etc., furnishes the student material from which to make his estimates and calculations. Early in the fourth year the student is assigned a subject for a graduating thesis. Such data are given as would be met with in practical experience. The student after careful consideration, selects what he regards as the best method of treatment, giving his reasons for the same with estimates and drawings. When finally completed, the thesis is presented to the Faculty for approval.

Scientific and Literary Society.—A Society known as the School of Mines Athenæum has been organized for the purpose of scientific and literary culture. This society, which is composed of students, members of the Faculty and prominent persons in the city, holds its regular meetings in the lecture hall of the School of Mines every Friday evening. Special entertainments, both literary and social, are occasionally given.

1882–83.

Calendar. Fall Term begins September 27th, 1882; ends December 15th, 1882. Winter Term begins January 3d, 1883; ends March 21st, 1883. Spring Term begins March 26th, 1883; ends June 1st, 1883.

UNIVERSITY OF CALIFORNIA, BERKELEY, CALIFORNIA.

THE University of California is an integral part of the public educational system of the State. As such it aims to complete the work begun in the public schools. It offers the best opportunities in the State for a higher education. Through aid from the State and the United States, and by private munificence, it furnishes ample facilities for instruction in Science, Literature, and the professions of Law, Medicine, Dentistry, and Pharmacy. In the undergraduate courses, *i. e.*, in the Colleges of Letters, Agriculture, Mining, Mechanics, Civil Engineering, and Chemistry, in the Literary Course, and in the Course in Letters and Science, these privileges are offered without charge for tuition, and to all persons residents of the State, who are qualified for admission. Persons from other States are admitted to equal privileges upon the payment of a small matriculation and tuition fee. The professional courses, being self-sustaining, require as reasonable tuition fees as possible. All courses are open to all persons without distinction of sex. The Constitution of the State provides for the perpetuation of the University under its present form of government. With this guarantee of security from change, it looks forward to an era of ampler development and greater usefulness. The departments of instruction comprise the following:

(1.) *Letters and Science*, including the College of Letters or Classical Course, and Colleges of Agriculture, Mechanics, Mining, Civil Engineering, and Chemistry, the Literary Course, the Course in Letters and Science, and certain irregular courses.

(2.) *Law.*—The Hastings College of the Law.

(3.) *Medicine.*—The Toland College of Medicine.

(4.) *Dentistry.*—The College of Dentistry.

(5.) *Pharmacy.*—The College of Pharmacy.

The general funds of the University are devoted to the Colleges of Letters and of Science. The Colleges of Medicine, Dentistry, and Pharmacy are self-supporting. The College of Law has a separate endowment. The distinctive characteristics of the various Colleges are given, both in general statements and in detail, upon subsequent pages of the Register.

The University was instituted by a law which received the approval of the Governor, March 23, 1868. Instructions were commenced in Oakland in the Autumn of 1869. The commencement exercises of 1873 were held at Berkeley, July 16th, when the University was formally transferred to its permanent home. Instructions began at Berkeley in the Autumn of 1873. The College of California, which had been organized several years before the University, transferred its property and students upon terms which were mutually agreed upon, and closed its work of instruction in 1869. This College was incorporated in 1855, and through its agency a part of the Oakland property of the University, and the Berkeley site, now owned and occupied by the University of California, were secured. The site of the University, at Berkeley, is a domain of about two hundred acres, situated on the slope of the Contra Costa hills, about five miles from Oakland, facing the Golden Gate. It is traversed by two water-courses, is much diversified in aspect, and is adapted to a great variety of culture. A part of the site is reserved to illustrate the work of agriculture and horticulture, and is now under cultivation. The undergraduate colleges were the only ones included in the original organization; the professional colleges were added from time to time. These latter are all located in San Francisco.

The University of California is a State institution, established by the Legislature in accordance with the Constitution, and intrusted to the care of a Board of Regents, which includes the Governor, the Lieutenant-Governor, the Speaker of the Assembly, the State Superintendent of Public Instruction, the President of the State Agricultural Society, the President of the Mechanics' Institute of San Francisco, the President of the University, and sixteen other Regents appointed by the Governor and approved by the Senate. To this body of Regents the State has committed the administration of the University, including the finances, care of the property, appointment of teachers, and determination of the interior organizations in all particulars not already determined by law. The Provisions of the Constitution, of the laws of the State, and of the Congressional enactment of July 2, 1862, which pertain to the government of the University, together with the terms of affiliation of the professional colleges, and other regulations, are published in a separate pamphlet. The instruction and Government of the students at Berkeley are intrusted to two Faculties, which have hitherto acted as one body—the Faculty of Science and the Letters. The Faculties of Law, Medicine, Pharmacy, and Dentistry, in San Francisco, are distinct bodies. All the Professors and Instructors of the University constitute what is termed by law the Academic Senate, the meetings of which are expected to be infrequent, and restricted to matters of general concern.

Funds.—The resources from which the University is maintained are derived from various sources, and include the following endowments: 1. The Seminary Fund and Public Building Fund, granted to the State by Congress. 2. The property received from the College of California, including the site at Berkeley. 3. The fund derived from the Congressional land grant of July 2, 1862. 4. The Tide Land Fund, appropriated by the State. 5. Specific appropriations by the Legislature, for buildings, current expenses, etc. 6. The gifts of individuals.

Faculties of Colleges of Science and of Letters.—William T. Reid, A. M., President of the University; William Ashburner, Honorary Professor of Mining; Geo. Woodbury Bunnell, A. M., Professor of the Greek Language and Literature; George Davidson, A. M., Honorary Professor of Geodesy and Astronomy; Stephen J. Field, LL. D., Honorary Professor of Law; Frederick G. Hesse, Professor of Industrial Mechanics; Eugene W. Hilgard, Ph. D., Professor of Agriculture, Agricultural Chemistry, General and Economic Botany; Martin Kellogg, A. M., Dean, and Professor of the Latin Language and Literature; John LeConte, M. D., LL. D., Professor of Physics; Joseph LeConte, M. D., LL. D., Professor of Geology and Natural History; Bernard Moses, Ph. D., Professor of History and Political Economy. Willard B. Rising, Ph. D., Professor of Chemistry; Edward R. Sill, A. M., Professor of the English Language and Literature; Frank Soulé Jr., (U. S. Military Academy), Professor of Civil Engineering and Astronomy; ——— ———, Agassiz Professor of Oriental Languages and Literatures; ——— ———, Mills Professor of Mental and Moral Philosophy and Civil Polity; John W. Bice, Ph. B., Instructor in Engineering; Ross E. Browne, Instructor in Mechanical and other Branches of Instrumental Drawing; Samuel B. Christy, Ph. B., Instructor in Mining and Metallurgy; John B. Clarke, Ph. B., Assistant Instructor in Mathematics; George C. Edwards, Ph. B., Instructor in Mathematics and Colonel Commanding University Corps of Cadets; A Wendell Jackson, Jr., Ph. B., Instructor in Mineralogy, Petrography, and Economic Geology; Henry B. Jones, Instructor in French; Wm. Carey Jones, A. M., Recorder of the Faculties and Instructor in Latin; Edmund C. O'Neil, Ph. B., Assistant Instructor in Chemistry; Albin Putzker, Instructor in German; Joseph C. Rowell, A. B., Librarian; Josiah Royce, Jr., Ph. D., Instructor in the English Language and Literature; E. H. Sears, A. B., Instructor in Latin and Greek; F. Slate, Jr., Superintendent of the Physical Laboratory, and Instructor in Physics and Mechanics; John M. Stillman, Ph. B., Instructor in Chemistry; George B. Willcutt, Ph. B., Assistant Instructor in Chemistry; Charles H. Dwinelle, Ph. B., Lecturer on Practical Agriculture; Myer E. Jaffa, Ph. B., Assistant in Agricultural Chemistry; Frederick W. Morse, Ph. B., Assistant in Viticultural Laboratory; J. J. Rivers, Curator of the Museum; Abel Whitton, Manager of University Press.

Library.—The General Library, a very valuable collection, particularly for reference, contains nineteen thousand five hundred volumes. It receives a large number of periodical publications—literary, scientific, and general. It is being constantly augmented, by gift and purchase, especially from the income of the Reese Fund of $50,000. The private collection presented by Mr. H. D. Bacon has been shelved, and is now ready for use. It comprises twelve hundred volumes, bound, with few exceptions, in full yellow calf, hand-tooled, with fine examples of tree and grained calf, full gilt, bound by Bedford, Riviere, and others. The Library is placed in the new Bacon Library and Art building.

The Collections of the University.—The collections belonging to the University, though still incomplete, are both large and valuable. Those at Berkeley are made up from material derived mainly from the following sources: The *State Geological Collection*, the entire material of which has been placed at the disposal of the University; the *Voy Collection*, consisting of a large number of California fossils, minerals, rocks, etc., collected by Mr. C. D. Voy, and presented to the University by D. O. Mills, Esq.; the *Pioche Collection*, an extensive miscellaneous collection of minerals, rocks, ores, shells, etc., from all parts of the world, and especially from South America, presented to the University by the late F. L. A. Pioche; the *Hank's Collection*, consisting of miscellaneous minerals and rocks, presented by James R. Keene, Esq., of San Francisco; selections from the *Ward Series of Casts*, purchased by the University; and current donations. The following description will show the general character of the collections at Berkeley:

The Museum of Historical Geology is in process of formation. The Museum of Palæontology contains a full suite of the fossils of California, both animal and vegetable. Most of these have been already described and figured; the animals in the State Geological Reports of Professor J. D. Whitney, and the plants, recently, by Mr. Lesquereux, in the Memoirs of the Museum of Comparative Anatomy of Harvard. The palæontological material from the Voy Collection has, however, never been worked up, and offers, consequently, to the student an excellent field for original work. There are, also, selections from the series of *Ward Casts.* The Museum of Petrography contains many foreign rocks, but is especially rich in California material, collected by the corps of the State Geological Survey and by Mr. C. D. Voy. Plenty of case room is at disposal, and the rocks are being arranged as fast as determined. The rocks are arranged systematically and geographically, so that, as the collection becomes more complete, the geographical distribution of the rocks of the Pacific Coast will be known with great accuracy and detail. It is designed to issue, as soon as possible, a descriptive catalogue of the rocks of California. The Museum of Economic Geology, although so recently founded, is already assuming proportions, and is in frequent receipt of valuable acquisitions from all parts of the Pacific Coast. The importance and value of this collection can scarcely be overestimated. It will subserve two purposes; on the one hand, it renders possible a course of instruction in ore deposits, which is of essential importance to those who intend to pursue the profession of mining engineer; and on the other hand, the ore deposits of this coast will be collected together, for the first time in one institution, where they can be subjected to careful and critical comparative investigation, to the end that the laws of their occurrence may, as far as possible, be determined. To this end an elaborate blank book has been devised, in which are carefully tabulated the name, locality, form, thickness, dip, strike, wall rocks, etc., of every ore deposit on the coast, as soon as accurate information upon these points can be obtained. The mass of statistics thus obtained will be made the basis of the above mentioned investigations. The Museum of Mineralogy is very large and fully arranged, and is supplied with ample case room. It fully illustrates the instruction in Mineralogy and offers inexhaustible material for investigation, facilities for which are freely placed at the disposal of the student. All of the foregoing museums are open at all times to the public, Mr. Rivers being in constant attendance to show visitors through the various collections.

Chemical Laboratories.—The chemical Laboratories were planned after the most careful study of the newest and best arranged laboratories of this country and of Europe, with the aid and advice of many experienced teachers of analytical chemistry. They are commodious, convenient, well lighted, well ventilated, and adapted to the study of analytical chemistry in all its branches, and to the carrying on of original research. There are two principal laboratory rooms, one for qualitative analysis, the other for quantitative analysis, each having accommodations for thirty-two students. They contain a number of evaporating niches, sand and steam baths, drying ovens, filter apparatus, etc.; there are rooms all well equipped for fusions, organic analysis, gas analysis, etc.; also, a balance room supplied with balances from the best makers. Such apparatus as is needed for the study of analytical chemistry is loaned to the students without charge, if returned in good order. There is a good supply of apparatus for carrying on original investigations.

Metallurgical Laboratories.—These laboratories are designed to offer every facility for the assays of ores, bullion, slags, mattes, etc., and for experiments in treating ores. They contain rooms devoted to special work, as will appear from the following enumeration: A crushing and sampling room, provided with large iron mortars, rubbers, sieves, and a sampling table; a furnace room, containing four iron-clad crucible furnaces built into the wall, three muffle furnaces constructed in a similar manner, together with all the necessary work benches and tools; besides these permanent furnaces there is a full assortment of movable French clay, muffle tubs, and crucible furnaces; a weighing room, containing ore scales for weighing out charges, also hoods and sand bath for parting gold and silver; two separate balance rooms for the finer assay balances; one room specially arranged with yellow glass windows for the humid or mint assay of silver bullion; two rooms devoted to volumetric work and special investigations. All the appliances are of the most improved pattern, and the laboratories offer excellent facilities for instruction and original research.

Mineralogical Laboratory.—This laboratory is provided with a large collection of unlabeled minerals, which students determine by their physical properties. A separate course on blowpipe analysis is offered by the Chemical Department.

Petrographical Laboratory.—Every facility is furnished for the study of rocks, both by the ordinary processes of mineralogical investigations and by the preparation of thin rock sections and examination under the microscope. The laboratory possesses six first class microscopes. The student has access at all times to the facilities provided for this work, and the material to be investigated is practically inexhaustible.

Courses of Instruction.—The Colleges of Letters and of Science comprise the College of Letters, embracing a classical course; the College of Science, embracing Agriculture, Mechanics, Mining, Engineering, and Chemistry; a Literary Course; a Course in Letters and Science; and certain irregular courses not leading to a degree. The completion of any of the following named courses requires four years.

The *Courses in Science:* Agricultural, Mechanics, Mining, Engineering and Chemistry lead to the degree of Bachelor of Science, and are founded for training those who wish to prepare themselves for the industrial professions. Each College gives to the student a good English education, such instruction in either French or German as will insure a reading power of one of the modern languages, and an introduction to the principles of modern science, together with special instruction preparatory to a fuller course of professional study in the particular department he may choose. Neither Latin nor Greek is required for these courses, but a preparatory course in Latin is recommended.

The *Course in Mechanics* is designed for students who wish to become mechanical engineers or machinists (so far as they are constructors of machinery), or to devote their energies to such technical and industrial pursuits as involve a knowledge of machinery.

The *Course in Mining* is designed for students who wish to become mining or metallurgical engineers, or to engage in one of the many pursuits connected with the mining industries, such as the surveying and mapping of mines, the assaying and working of ores, the designing and use of mining machinery, or the exploitation of mines.

The *Course in Engineering* is designed for students who wish to adopt civil engineering as a profession, and to engage in such work as the survey of lands, leveling, topographical engineering, triangular or geodetic surveying, the location and construction of roads, railways, and canals, the designing and construction of bridges of wood, iron, or stone, the building of dams, reservoirs, and systems of water supply, drainage, and sewerage, and the improvement of rivers, harbors, and sea coasts.

The *Course in Chemistry* is designed for students who wish to become professional chemists, either as teachers or investigators, or manufacturers in chemical industries, and also for those who wish to become expert chemists preparatory to the pursuits of medicine, pharmacy, etc.

IRREGULAR COURSES NOT LEADING TO A DEGREE.

N. B.—Written application to be allowed to take either of the three following named courses must, in all cases, and from year to year, be made at the Recorder's office. In this application the reasons for wishing to take the course must be given, and no student will be admitted to either of these courses without a certificate from the President. Students pursuing either of these courses are not enrolled in either of the college classes. Students who wish a thorough and systematic education are advised to take one of the eight regular courses.

The *Student at large Course* does not lead to any degree; but students in this course may, by vote of the Faculty, be recommended to a degree upon the satisfactory completion of studies equivalent to those pursued in one of the regular courses. It is designed for students who wish to take a full, but a purely elective course. They may select studies from any of the courses, provided they satisfy the Faculty that they are fitted to take the studies selected. Candidates for this course are required to pass one of the regular admission examinations, and, upon admission, to take studies enough to make up the full number of exercises required of students pursuing a regular course. Students who fail to maintain their standing as regular students will not be admitted to this course.

The *Special Course* does not lead to a degree, but students in this course may, upon leaving the University, receive a certificate of proficiency in the studies which they have pursued and in which they have attained marked scholarship. It is designed for students who are mature, and who wish to pursue some one line of *special* study and correlated branches. Students under age will not ordinarily be admitted to this course. Applicants who fail on the admission examinations, or students who fail to maintain their standing as regular students, will not be admitted to this course. The *Partial Course* does not lead to a degree, but students in this course may, upon leaving the University, receive a certificate of proficiency in the studies which they have pursued and in which they have attained marked scholarship. It is designed for students who, because of ill health or other disability, are able to pursue only a limited number of studies, or to remain at the University only a short time. Applicants will not be admitted to this course until they have passed a satisfactory examination on such preparatory subjects as may be thought necessary to fit them for the studies they wish to pursue. Certificates of proficiency must be presented to the President before he will issue permission to be enrolled in this course. Applicants who fail on the admission examinations, and students who fail to maintain their standing as regular students, will not be admitted to this course, and the privileges of the course will be summarily withdrawn from students whose attainments or conduct indicate a want of earnestness.

NOTE.—Before entering upon the examinations for admission, candidates will be asked to make known the course they wish to take. It is very desirable that the choice should be made as early in their preparation as possible, and under the best advice attainable. After entering upon their University Course students will not be allowed to change their course except for the most urgent reasons; and students will not under any circumstances, be allowed to change until all deficiencies in the course previously taken are made up.

Admission.—N. B.—All examinations are conducted in writing, except such as must of necessity be oral, such as reading and the pronunciation of a foreign language. Candidates must be at least sixteen years of age, and must present certificates of good moral character. All candidates for courses leading to a degree, and candidates for the Student at Large Course, must pass a satisfactory examination in the five following named subjects:

1. *English.*—Candidates will be required to write a composition of about two pages (foolscap), correct in spelling, punctuation, grammar, and division into paragraphs, upon a subject announced at the time of the examination. It is suggested that the candidate write such a composition or essay as he would write to a friend who knows nothing of the subject, and to whom he wishes to give as clear and as enjoyable an idea of it as possible. The candidate should have acquired the elements of grammar, so as to distinguish the parts of speech and explain the relations of words and phrases in ordinary sentences, and the elements of prose composition, as found in such a book as Kellogg's Text Book on Rhetoric. Much composition writing is indispensable. The subjects for 1882 will be taken from one of the following works: Tom Brown's School Days at Rugby, Scott's Marmion, Charles and Mary Lamb's Tales from Shakspeare, Shakspeare's Merchant of Venice. As the examination will be given upon subjects taken from but one of the books, candidates must be familiar with all the books in the list. In 1883 the subjects will be taken from one of the following works: Tom Brown's School Days at Rugby; Charles and Mary Lamb's Tales from Shakspeare; Irving's Sketch Book; Dickens' Christmas Stories and David Copperfield; Scott's Marmion and Quentin Durward; Shakspeare's Merchant of Venice and Julius Cæsar. 2, 3, 4. *Mathematics.* (2) *Arithmetic.* Higher Arithmetic, including the metric system, but omitting the technical parts of commercial arithmetic. (3) *Algebra*, through quadratic equations, except for applicants for the Classical and the Literary Courses, who will be examined to quadratics. (4) *Plane Geometry*, as much as is contained in Wentworth's Plane Geometry, omitting Isoperimetrical Polygons and Symmetry, except for applicants for the Classical and the Literary Courses, who will be examined in the equivalent of four books of Wentworth's Geometry. 5. *History and Geography.* History of the United States, the general facts of Physical and Political Geography. Barnes's Brief History of the United States, and the geographies used in first grade grammar schools, will serve to indicate the amount of knowledge expected.

(6) MINERALOGY.—The elements of Mineralogy. A good knowledge of the physical properties of minerals in general. Ability to determine, by their physical properties alone, twenty-five of the commonest minerals, and to give reasons for determination: First seventy-two pages of Nicol's Manual of Mineralogy, or first seventy-five pages of Dana's third edition. Applicants who pass with honors in Chemistry will be put in an advanced division.

Course in Letters and Science and the Courses in Science.—Candidates for the Course in Letters and Science, and for either of the Courses in Science, viz.: Agriculture, Mechanics, Mining, Engineering, and Chemistry, must pass a satisfactory examination on subjects 1, 2, 3, 4, 5, 11, and 12, as above, and subjects 13 and 14, as follows:

13. HISTORY.—History of England; Anderson's, Lancaster's or Dickens' will indicate the amount.

14. ENGLISH.—The examination in English will be of a more critical character than that given under Subject 1, and will include whatever geographical, biographical, historical, grammatical, or other questions (including derivation and definition) may be necessary to a full understanding of the selection. The candidate must, in addition, be prepared to write in good English such an essay on any one of the selections, including biographical sketches, as would convey to one not acquainted with the selection named a clear idea of its character and scope. A bad failure in this examination alone will be considered sufficient to reject a candidate for admission to the course in Letters and Science. The examination will be given upon the following named selections: American Prose, American Poems, Shakspeare's King Lear, Hawthorne's Our Old Home, Milton's L'Allegro and Il Penseroso, Byron's Prisoner of Chillon, Goldsmith's Deserted Village and Traveller, Burns' Cotter's Saturday Night, To a Mouse, and To a Mountain Daisy, Scott's Lay of the Last Minstrel, Bacon's Essay of Truth, of Revenge, of Envy, of Boldness, of Travel, of Riches, and of Studies, and Macaulay's Essay on The Pilgrim's Progress. In 1882, American Prose, American Poems, and King Lear will be accepted.

[American prose, and American poetry published, by Houghton, Mifflin & Co., Boston; any well annotated edition of Shakspeare, such as the single play editions of the Clarendon Press, Rolfe, etc. The selections are found in a series entitled "English Classics," at ten cents a copy, published by Clark & Maynard, New York; most of the selections may be found in the text-books on English literature used in most High Schools.]

In 1884, readings from English history, by J. R. Green, will also be required. Candidates who pass without conditions will be credited with honors on subjects on which they pass with special excellence; but honors will not be given to a student who enters with a condition.

PRELIMINARY EXAMINATIONS.—Any candidate for admission to the University may, at his option, pass the entire examination at one time as heretofore, or he may pass a preliminary examination on a part of the requirements and be examined on the remaining subjects the following year; but neither the preliminary examination nor the final completion of the examination may be divided between the June and the August examinations. Candidates will not be admitted to the preliminary examinations without certificates from their teachers that they are prepared. These certificates should be sent to Recorder Wm. Carey Jones, Berkeley, at least two weeks before the examination. No certificate of proficiency will be given by the University unless the candidate passes upon at least six of the eight subjects prescribed for the preliminary examinations.

Expenses.—Tuition in the Colleges of Sciences and of Letters is free to residents of California. Students from other States pay a matriculation fee of twenty-five dollars, and a tuition fee of fifty dollars a year. A small charge is made for chemicals in the chemical laboratory. This is often met by rendering services. Upon graduating, a fee of ten dollars is charged for a diploma. Board and lodging may be obtained in private families at Berkeley and Oakland, at from eighteen dollars to thirty dollars a month. The hours of recitation are such that many students reside in Oakland and San Francisco. Steam connection brings San Francisco within fifty minutes of the University. The gymnasium, erected by Mr. A. K. P. Harmon, at his own expense, and presented to the University, is well equipped and provides all the students with opportunities for exercise. Students in the College of Agriculture can frequently find work in connection with the instruction in Agriculture and Horticulture. Some students are employed in the University printing office at a fair compensation. It is expected that students may earn something by work upon the grounds. Work is often obtained on Saturdays and in vacations away from the University.

Examinations.—Examinations are held at the close of each term and of each year. For students taking the complete course the four annual examinations constitute the examinations for degrees. Students from other colleges, academies, or schools may present themselves for a general examination for degrees. The degree for the classical course is A. B., Bachelor of Arts. For all the scientific courses it is B. S., Bachelor of Science. For the Literary Course, and for the Course of Letters and Science it is L. B., Bachelor of Letters. The higher professional degree of Ph. D., C. E., M. E., Mech. E., etc., will be given only on the completion of prescribed courses of higher study. The University Medal, by direction of its founders, is bestowed upon the most distinguished scholar of the graduation class of each year.

THE EARLY ENGLISH TEXT SOCIETY and the NEW SHAKSPEARE SOCIETY, through the courtesy of Mr. A. G. Snelgrove, Honorary Secretary of the two societies, offer an annual prize of certain of their publications, for the encouragement of studies in those lines. The prize is open to all regular students, and is awarded upon written examination under the direction of the Professor of English Literature.

THE MATHEMATICAL PRIZE OF FIFTY DOLLARS is offered by Mr. John B. Clark, Instructor in Mathematics, for the best essay on any subject connected with the advanced courses in Modern Higher Algebra and the Calculus of Quaternions.

College of Mechanics.— *Objects of the Course.*—This College will educate mechanical engineers, and others who wish to devote their energies to such professional pursuits as involve a knowledge of machinery. If such is not the aim of the student, he will receive the advantage of such instruction as will enable him to follow any vocation based on the applied or pure exact sciences.

Course of Study.—The course of instruction directly related to the College during the junior and senior years, will be as follows:

Junior Year.—1. Kinematics of a point, plane, system, and rigid system in space; that is, motion considered in the abstract, without reference to its cause. 2. Dynamics of a material point, and of a system of masses, considering the actual causes which produce motion. 3. Statics of a material point, and of a rigid body or system of bodies. The subject is treated as a special application of Dynamics. 4. Application of number three to the determination of strains in structures. 5. Graphostatics, applications in the determination of centers of gravity, moment of inertia, and stresses on structures.

Senior Year.—1. Strength of materials, entering in detail upon the analysis of inner strains. 2. Hydrostatics and Hydrodynamics. Theory of hydraulic motors and their construction. 3. Regulators and accumulators of motion. 4. Kinematics and applications in the construction of machines.

Post-Graduate Year.—1. Thermo-Dynamics. Theory and construction of steam and heat engines. Heat engines in general. 2. Theory and construction of machines for transmission. Mining machines, etc.

Department of Drawing.—The instruction in this department is a direct application of the course, especially in Graphostatics as applied to the analysis of stresses in roof and bridge structures, and in the designing of simple machines, water-wheels, etc.

College of Mining.—*Object of the College.*—This College is designed for students who wish to become Mining or Metallurgical engineers, or to engage in one of the many pursuits connected with the mining industry, such as the surveying and mapping of mines, the assaying and working of ores, the designing and use of mining machinery, or the exploitation of mines.

Undergraduate Course.—This course includes a thorough preparation in the modern physical sciences, training in English, and in a reading power of German. It may be completed by the average student in four years. It leads to the degree of Bachelor of Science. Instruction is given according to the nature of the subject, either by lectures and recitations, or by practical exercises. The lectures are illustrated by numerous experiments, apparatus, tables, collections, drawings and sketches, whenever required by the nature of the subject. The practical exercises consist of laboratory and field work with instruments, apparatus and collections, in which each student does the work for himself, under proper guidance. The following is an outline of the course in addition to English and German:

Mathematics, including Algebra, Geometry, Trigonometry, Analytical and Descriptive Geometry, Differential and Integral Calculus. The whole course is illustrated by numerous practical problems and applications.

Physics.—A general course which will be supplemented during the coming year, as soon as the physical laboratory is established, by a special course in heat and electricity.

Chemistry.—Lectures and recitations on Inorganic Chemistry, particular attention being paid to the chemistry of the metals as introductory to metallurgy. Both this course and the one on Physics are illustrated by experiments. Also, laboratory practice in Qualitative and Quantitative Analysis of rocks, ores and metallurgical products. Blowpipe Analysis is taught in connection with this work.

Mineralogy.—Lectures on Crystallography and the Physical Properties and uses of the most important ore, gangue, and rock-forming minerals. The course is illustrated by numerous crystal models and a collection of over ten thousand minerals. Considerable time is devoted to practice in the Determination of Minerals by the use of the knife, lens, and streak plate. The working collection for this purpose alone contains over two thousand specimens.

Geology.—A course of lectures on Dynamical, Structural, and Historical Geology. The course is illustrated by numerous drawings, casts, and models of fossils.

Mechanics.—Lectures on Analytic Mechanics, Strength of Materials with applications to framing, timbering, and machine construction. Hydraulics, pressure of water in dams and reservoirs, flow of water in pipes and ditches, hydraulic motors. The course is illustrated by numerous problems and applications.

Mechanical Drawing and Construction.—These are made, as far as possible, an application of the course in Mechanics to Mining Engineering. Instruction is given in Designing Machinery and Fixed Structures for mining and metallurgical work.

Surveying.—This course includes: Land and Topographical Surveying and Leveling; Laying out roads, tramways, ditches, pipe lines, mining claims; Underground work; extensive Practice in the Field with compass, transit, level, and plane table, and the Plotting of Field Notes and Construction of Maps and Sections. The instruments and grounds of the University furnish excellent facilities for this work.

Mining.—Nature and mode of occurrence of Ores; Prospecting and Exploring Ore Deposits; United States laws, governing location of claims; Open Cut and Quarry Work; Hand and Machine Drilling; Explosives; Blasting; Tunneling, with methods of Excavation and Timbering; Shaft-sinking, Timbering, and Walling; Stoping; Tramming; Hoisting; Pumping, and Drainage; Lighting; Hydraulic Mining; General Organization and Administration. The course is illustrated by drawings, sketches, data, and reference to typical mines in operation on the coast.

Metallurgy.—General Part: Classification of ores and processes; Crushing and sampling ores; Fuels; Fluxes; Refractory Materials; Furnaces; Accessory Machinery; Metallurgical Products. Special Part: The metals selected are the ones at present most important on this coast—Gold, Silver, Lead, and Quicksilver. Both wet and dry methods of reduction are taken up and discussed in detail. The illustrations and data are drawn, as far as possible, from actual work on the coast.

Assaying.—The fire assays accompany each metal in the course in Metallurgy, and the instruction is made, as far as possible, to illustrate the methods used on the large scale. Each student has sufficient practice to become skilled in the assays of the above metals. The Metallurgical Laboratory is well equipped for such work, and contains four crucible furnaces, three muffle furnaces, and all the necessary apparatus.

Thesis.—The undergraduate course concludes with the preparation of an original Thesis on some subject connected with Mining or Metallurgy.

Excursions.—Students are urged to use their holidays and shorter vacations throughout the course to visit and study the many large machine shops, foundries, rolling mills, powder, smelting, and other technical works in the vicinity of Berkeley, Oakland, and San Francisco. They are also urged to use their Summer vacation of two months, and their Winter vacation of three weeks, to visit and study various typical mines and reduction works at a greater distance. The importance of the above is insisted upon. Students who earnestly and systematically pursue the above plan not only do better and more intelligent work at college, but make acquaintances and acquire a fund of information that is afterwards of great practical use to them.

Post-Graduate Course.—This course is intended for those students who have completed the previous course. It comprises such special technical studies as are necessary for the professional degrees. Information concerning this course will be furnished in the next Register.

College of Civil Engineering —*Object of the College.*—The object of this College is to give thorough instruction in those studies which pertain to the profession of the Civil Engineer. To a very considerable extent, these studies are likewise preliminary to the profession of an Architect. They are also serviceable to all who wish proficiency in the application of Mathematics and Physics.

Special instruction in Engineering begins with the Surveying Course in the Junior year, and includes Land Surveying, Levelling, Topographical Surveying, Use of the Plane Table, Road and Railroad Surveying and Construction, and computations of earth-work required by excavations, tunnels, and embankments. A large amount of time is allotted to practice in the field, and to the use of instruments, such as the compass, level, field transit, plane table. etc., and to the working up and plotting of field notes. Topographical drawing and map-making are taught in connection with this part of the course. During the present year an accurate topographical survey has been made, by the class, of the ground immediately surrounding the University buildings. This will be mapped by them, and the work continued by successive classes till the entire tract shall have been accurately plotted. The use of the Aneroid and Mercurial Barometers is taught, and practice given in the determination of heights, etc. Journeys over the adjacent roads are made for the purpose of constructing itineraries, and of measuring and estimating distances by the eye alone, or by ordinary available means. Sketches will be made of the surrounding country, and directions of hill ranges, streams, etc., will be taken as the bases of reconnoissance maps. Students proficient in this course will be well fitted to undertake the work of the field Engineer. In the Senior year the characteristics and properties of the various building materials, wood, stone, iron, steel, mortar, mastic, etc., their strengths, uses, and different methods of employment in structures, are discussed. The rules governing the construction of works of masonry, including foundations in dry and wet soils, and under water, of stone bridges, dams, sewers, culverts, and retaining walls, are acquired. Problems relating to the more difficult constructions of masonry, such as groined, cloistered, askew and rampant arches, domes, and walls bounded by warped surfaces, etc., are solved in the engineering draughting room. The principles and practice of framing, bridge and truss building, and of the construction of estimates and working plans, are investigated; and the solution of a problem in engineering, selected or approved by the Professor of Engineering, terminates the undergraduate course, leading to the Degree of Bachelor of Science (B. S.) A practical bearing is given to the instruction of this year by the solution of interesting problems, connected with the subjects taught; and by visits to important accessible structures, completed or in process of construction. A post-graduate course of three years' length, embracing the higher subjects of engineering study, leads to the degree of Civil Engineer (C. E.) A valuable collection of surveying instruments, including rods, steels, tapes, chains, hand and Y levels, theodolites, transits, solar and surveyor's compasses, plane tables, etc., is in the possession of this department. There is an excellent assortment of models in wood of the various bonds of masonry, and of different walls, arches, gate ways; of joints and fastenings in carpentry, and framework, and of bridge and roof trusses. Diagrams of various European and American engineering structures and the hypsometrical and surveying apparatus formerly belonging to the California Geological Survey, are in the collection. Advantage is taken of the beautifully varied nature of the grounds at and about the University, for practice in the various kinds of surveying.

College of Chemistry.—*Objects of this College.*—The course of instruction in the College of Chemistry is designed for those who wish to become professional Chemists, either as teachers and investigators, or as analytical chemists and manufacturers in chemical industries; and also for those who wish to become expert chemists preparatory to the pursuits of medicine, pharmacy, mining, etc. The special teaching in Chemistry may be thus described: Instruction will be given in General and Theoretical Chemistry, by lectnres, recitations, and laboratory practice. This elementary course will extend through a whole year. An advanced course of lectures will be given to the members of the Sophomore Class on General and Theoretical Inorganic Chemistry, embracing a discussion of the general principles of the science, and their application to Analytical and Metallurgical Chemistry, and to Mineralogy. A like advanced course will be given to the Senior Class on Organic Chemistry. Each course will extend through the whole year, and will be given with the expectation of presenting to students, in a comprehensive form, the fundamental principles of the science.

Analytical Chemistry.—The chemical laboratories will be open daily to students. The course of instruction in qualitative analysis will include the analysis of simple and complex substances in the wet way, their analysis by the use of the blow-pipe and flame reactions. Students will be required to keep a careful record of their work, and to submit the same to the inspection of the Professor. Upon passing a satisfactory examination in qualitative analysis, students may pass to the quantitative laboratory. In the quantitative laboratory instruction will be given in the quantative gravimetric analysis of simple and complex salts, minerals, ashes of plants, mineral waters, etc.; in volumetric analysis, including acidimetry, alkalimetry, chlorimetry, etc.; in organic analysis; in gas analysis; in the preparation of inorganic and organic compounds, and in the carrying out of original investigations. Practical instruction in electro-metallurgy will be given to such students as desire it. Students in agriculture will receive special instruction in the analysis of manures, including the determination of phosphoric acid and nitrogen, etc. So far as practicable, students will be employed in the preparation of chemicals used in the laboratories, the object being to give them as much practice in Manufacturing Chemistry as is possible. Special training in the analysis of mineral waters will be given to such of the advanced students in Chemistry as may desire it. Careful lists of waste products, minerals, etc., which may be utilized, will be kept, and students instructed in methods of saving them.

Organic Chemistry.—This course is by lecture—about seventy lectures in the course. It comprises the Chemistry of the Compounds of Carbon; Organic Analysis; Principles of Chemical Structure; General Properties, Methods of Preparation, and characteristic reactions of the principal classes of Organic Compounds; Relations of Chemical Structure to Physical and Chemical Properties; and the more important technical processes connected with the manufacture or use of organic compounds.

Visits to Chemical Establishments.—It is the intention of the Professor of Chemistry to encourage the students to visit the various chemical and metallurgical works in the vicinity, so far as this is practicable. Among the special advantages which such students may avail themselves of at the University may be mentioned a special course of lectures on Physiological Chemistry; also one on Toxicology and Urine Analysis. Opportunities for laboratory practice in the last named subjects will be given.

Special Students in Chemistry.—The advantages of the laboratory and lectures are open not only to those who pursue a full course of instruction, but to those who wish for a short period to pursue some special course, or carry on some special iuvestigation. For admission to the Chemical Department they will be required to pass an examination in the elements of chemistry, and to show that they have sufficient general culture to profit by the opportunities here afforded.

Advanced Instruction.—Courses of lectures on Inorganic Chemistry; Organic Chemistry; Physiological Chemistry; Agricultural Chemistry; Toxicology; Urine Analysis; Thermo-Chemistry; Fundamental Principles in Analytical Chemistry. Laboratory Instruction and Assistance.

Laboratory Facilities.—Convenient Rooms, with suitable equipment and apparatus for carrying on quantitative analysis and special experiments of various kinds. A very complete supply of *pure reagents,* including many rare ones. A good supply of apparatus, balances, glassware, etc. The equipment is ample for the investigation of minerals, mineral waters, and organic products.

PETROGRAPHY.—The instruction covers the following ground: (1) The different methods of rock investigation, viz., physical and chemical; (2) rock texture and rock structure; (3) the different forms in which rock masses occur; (4) classification and nomenclature of the leading systems proposed; (5) descriptive petrography, special attention being given to the rocks of California; (6) petrogenesis, or the origin of rocks; (7), changes and decompositions which rocks undergo. The laboratory is well equipped, and the student has every opportunity for practice in the determination of minerals by the microscope and ordinary mineralogical methods. A large field for original research is open to the student in the museum of Petrography. The course is open to all students who have completed the university course in mineralogy, or an equivalent course elsewhere. A course of lectures is in preparation. It will consist, (1) of a consideration of the geological nature of ore deposits; (2) a special description of the ore deposits of this country, with references to the most instructive examples of foreign ore deposits. The first part will be delivered during the first term of 1882-3.

CALENDAR.—August 9, 10, 11—Examinations for admission to Colleges of Science and of Letters, in Berkeley; to College of Law, in San Francisco.
August 10—First Term in Colleges of Science, of Letters, and of Law begins.
August 11—Assignment of exercises to upper classes in Colleges of Science and of Letters.
August 15—Assignment of exercises to Freshman class in Colleges of Science and of Letters.
October 9-16.—Fall Recess of one week in Colleges of Science, of Letters, and of Law.
October 21.—Semi-annual Field Day.
October 27.—Junior Day in Colleges of Science and of Letters.
October 30—Regular term in Colleges of Medicine, Dentistry, and Pharmacy ends.
November —Commencement in College of Medicine.
November —Commencement in College of Pharmacy.
November 23, 24, 25—Thanksgiving Recess of three days.
December 20—End of First Term in Colleges of Science, of Letters, and of Law. Vacation of three weeks.

AMERICAN STUDENTS OF MINING IN GERMANY.

AS AMERICAN students of mining, philosophy, philology, music, history, or art have found it necessary or highly advantageous to supplement their course of study at home by a residence of some years at a foreign university, so, ever since mining has been practiced in this country in any other than a rude and wasteful manner, many American students of mining have sought in London or Paris, but chiefly in the Academy of Freiberg, Clausthal, or Berlin, such information and experience as would give them confidence in themselves, and make them worthy of the confidence of those wishing the services of mining engineers. But a broad distinction must be observed. Medicine, philosophy, philology, history, and art are universal sciences; their theories and applications are much the same throughout the civilized world; moreover, the principles of justice which underlie law, and the principles of mathematics, mechanics, chemistry, and geology, upon which the sciences of civil, mechanical, and mining engineering are founded, are also universal, but their practical application depends upon local conditions. The economy of mining is a function of such variables as government, labor, wages, distance, quantity and kind of ore, timber, water, and transportation, and to many it seems as absurd to attempt to obtain in any other country the knowledge to fit one to practice mining in America, as it would be to attempt, by studying law in a German university, to fit one's self for practice in the New York courts.

A young man who has decided to fit himself as a mining engineer is at a loss how to begin. On the one hand, he is told that our schools are not practical enough, that practical miners do not find the graduates capable of doing what they profess, and that he should study abroad, where theory and practice are united. On the other hand, he is informed that American methods differ from the foreign so fundamentally that, if he studies abroad, he must afterwards unlearn, everything, and to learn mining he is advised to "go West,' which now celebrated advice is somewhat indefinite. Truer but hardly less sweeping and discouraging is the opinion of the Commissioner of Mining Statistics, who said of the graduates of foreign schools, "Every such graduate has to reconstruct, alone and for himself, the whole art which he has learned—a work requiring genius as well as intelligent perseverance." It is, nevertheless, a fact that a large part of the prominent mining and metallurgical engineers and professors of our country have been students abroad, mostly in Germany, and it is fair to assume that their training was an important element or cause of their success; and since the annual exodus still continues, the belief is evidently widespread that our schools do not yet furnish all that is necessary, nor even the most important part. In view of the immense mineral wealth of the country, in view of the present enormous production and the more enormous waste, in view of the fact that mining industries will always remain among the most important sources of our national wealth and prosperity, the subject of the education of miners and mining engineers demands of this society earnest thought, thorough discussion, and, what is not to be forgotten, subsequent action. Moreover, the subject should be considered by itself, and not in connection with mechanical and civil engineering. In discussing education in general, we may come to general conclusions; in discussing technical education, to more definite conclusions, and in discussing mining technical education, we may reach still more definite and directly applicable results.

If civil, mechanical, and mining engineering are distinct enough to form three independant professions, the proper preparatory courses for each have points of distinction enough to warrant an independent discussion. We have had the general discussion—what we need is the special. How, then, do our schools correspond to our mineral resources and existing appliances? Are American methods of mining and metallurgy, or foreign methods, or any definite methods taught in them? Are the attractive courses of the various catalogues and prospectuses given to students in reality? Are the requirements for the degree of mining engineer sufficiently exacting in theories and practice? These questions are asked in no spirit of criticism, but for information, with the hope of obtaining it for the benefit of present and future students, on the one hand from engineers of the Institute who are in practical life, and on the other hand from the professors in our schools. These questions are suggested to promote discussion, that the students may learn what is desired and will be expected of them as young engineers; that they may be told where and from whom they may learn what they lack; that the faculties of our schools may know what changes to introduce to make the courses more efficient, and that out of this discussion may be devised some means of establishing some connection between the schools and the mines and metallurgical works, so that our students may enjoy some such advantages as they are favored with abroad. It may be well to consider some of the advantages and disadvantages of the German instruction, and to give some of the actual experiences of the American student in Germany. For this purpose the academy at Freiberg will be considered, because it is there that the greater number of our past students have studied; the greater number of those now abroad are there, and it is the school with which the writer is best acquainted.

Admission to the academy is very easily obtained. If the applicant from a foreign country can understand what the director says to him when he makes personal application, and can speak a very moderate amount of German, and can produce a diploma awarded to him by any college or technical school, that is sufficient. Not having a diploma, he may, instead, pass an easy examination, much similar to that required by our own technical schools for admission. In the statutes we read, "In suitable cases, especially in the case of applicants from foreign countries, the director may dispense with the admission examination." We also read "Older and independent persons, and such as have already completed higher technical studies elsewhere, may be permitted by the Director to attend lectures and practical exercises, upon the payment of the regular fees," etc. Such students are called Hospitanten, and correspond to our special students. Under these liberal regulations, there is no difficulty in entering. I have heard of one American, some years ago, who could not gain admission, but he was so totally deficient that he has not learned anything to this day. It seems to be the desire to make the entrance easy, not for the sake of securing students, but to avoid throwing hindrances in the way of those wishing to learn; and, in general, the kindness of the director and of the professors to all foreign students is very marked and gratefully acknowledged. This leniency, often a desirable accommodation for the mature student, is often a serious disadvantage to the young student not familiar with the German language. Not being able to understand much of the lectures, and his previous education not having been such as to enable him to pursue intelligently the mathematical studies of the course, he quickly becomes discouraged and lazy, and often yields to the manifold temptations of Freiberg life. At all events the foundation being poorly laid, the superstructure is insecure. Too easy entrance examinations are not a peculiarity of foreign schools.

The theoretical instruction is mainly imparted by lectures, a system which is perhaps the best for highest instruction of the universities, but which in a technical school, where hardly more than the elements can be given, is very wasteful of time and unsatisfactory. If a professor has something original or new to offer, or if his subject is one on which good books are rare or expensive, then lectures are justifiable and necessary; but to give entirely by lectures a course on ordinary mathematics, mechanics, surveying, mining, theoretical chemistry, or any subject on which there are scores of good and inexpensive books, is a wicked waste of the time of professor and students. To illustrate, let us suppose the subject is mining, and the particular subject for the day is power drills. The lecturer gives, perhaps, a short history of the invention of the steam or compressed-air drill, and then proceeds to discuss the various systems; he makes elaborate freehand drawing of a steam drill, and lectures while he draws. Now the student may take his choice; either he may copy the drawing as well as he may, being, perhaps, a poor draughtsman, or he may write the description and criticism; but, recognizing the uselessness of having one without the other, he generally tries to get both, and if he writes an intelligible description he may have time to copy half the drawing itself before the figure is rubbed out to make room for something else. Or perhaps the student devotes his main energy to the drawing and keeps pace with the professor, when suddenly the latter discovers that he is making his drawing out of proportion, and with a stroke he erases a third of his work. The student, who is working with ink or pencil, cannot introduce changes so easily and neatly. He scratches or rubs out or begins again, and perhaps gets a passable drawing and a fair description. Meanwhile the professor has drawn and described another drill, and closes his lecture with the remark: this last drill is in general use; the one before it has long since gone entirely out of use. Let us suppose the student hears lectures on some mathematical study. At his room he conscientiously rewrites and studies his notes, and finds that he has omitted important steps in the reasoning; be misses a lecture perhaps, and not being able to make good the deficiency without copying the probably imperfect notes of some friend, he loses his enthusiasm, goes to lectures less frequently, or finally not at all. These are not fanciful examples, but such as are occurring constantly. It requires much more determination and perseverance than can reasonably be expected of a young student, though he starts with resolution and enthusiasm, to write, rewrite, and annotate a whole treatise on each of the studies he pursues. And when he has it all done, he may find nine-tenths of it more fully given and better expressed in any of the excellent text-books. Add to these objections, which apply in the case of all students, the fact that the art of writing German rapidly, of paraphrasing a lecture, is not easy for a foreigner to acquire, and we may imagine how little good our students would acquire if the main benefit of a residence at Freiberg were to be gained from the lectures.

Connected with some of the courses of lectures there are weekly recitations which are very thinly attended, sometimes as few as two or three or even none out of a lecture division of thirty or forty being present. This non-attendance proceeds from various causes; some students may have been irregular at lectures, many do not take the trouble to read their notes, at least for months or till just before the final examinations; some are not willing to make an exhibition of bad German, and some have not been able to get enough out of the lectures to be questioned on.

As regards discipline, the school is conducted on the most liberal principles, the student being allowed to select such lectures and practical exercises as he wishes, and to attend or not as he may choose. The only exception to voluntary attendance which appears in the statutes is contained in the following extract, "Students who receive scholarships, or from whom the fees have been entirely or in part remitted, are required (*verpflichtet*) to attend the recitations," which significant clause implies that recitations are important, and so important that mild coercion is justifiable. As foreign students receive no pecuniary assistance, but are charged $25 a year more than other students, this restriction does not apply to them. Moreover, students are not required to give any proof of progress unless they are candidates for a degree, and then only at the end of their course. In consequence of this freedom, many who are registered as students scarcely ever attend any lectures or other exercises. Sometimes an example is made and a young man is sent away, ostensibly for neglect, but in such cases it will be found that he was otherwise a bad character, and had made himself notorious in the town. This *laissez faire* principle may be allowable for the oldest and best students, but for the greater number, especially for those away from the supervision of home and the more exacting social restraints of our country, it is certainly pernicious. It is seeking for itself a foothold here, but it is to be hoped we shall stand by our practice of requiring proof of progress, regularly and frequently. It is said that a student who is required to prepare a certain number of pages for a recitation, or a certain subject for an examination, does not have the proper object of study placed before him; that he ought to be encouraged to study for the love of knowledge. This is perhaps the kind of suasion to apply to those who are destined to become ardent lovers and devotees of abstract science; but becoming a successful engineer is probably as lofty an object as the ordinary student of mining will appreciate, and the advisability of showing him from time to time just how far advanced he ought to be, and whether he is actually up to the mark, is a sufficient reason for recitations and examinations. Habits of industry, as well as facts and theories of science, are to be inculcated and maintained. The German school acts on the assumption that such habits have already been inculcated in the preparatory school, an assumption not justified by experience. We cannot afford to allow a promising but lazy fellow to go to ruin through neglect, and we ought, for the interest of all concerned, to weed out, long before the end of the course, such as nature plainly intended to shine in some other sphere of usefulness. It is also said that our young men are too old and manly to be treated longer as schoolboys, and, now that it has been suggested to them, the young men themselves feel that their dignity as gentlemen is wounded. But at West Point or at the Naval School, where honor is generally assiduously cultivated and carefully guarded, the young men still continue to bear up under the degradation of being obliged to turn out early and make their own beds, or stand up stiff and straight before a blackboard and demonstrate a proposition in military style. A certain amount of discipline is necessary for efficiency in any body of men, be they men or really boys, and especially is strict discipline necessary for those who expect afterwards to exercise authority.

In what, then, does the superiority of the German mining schools consist? Why do our young men pass by our magnificently endowed and appointed schools without entering, or pass from them to spend two or three years at considerable expense and discomfort at Freiberg? It is mainly because the Freiberg Academy gives its students the union of science and art; because it furnishes them with ample facilities for learning, either within its walls or in the neighboring works, or somewhere in Saxony, or somewhere in Germany, the *practice* of the various processes of mining, concentration and smelting. Moreover, it is distinctly a school for mining and metallurgy, untrammelled by any connection with mechanical or civil engineering; its professors are specialists, generally of the highest ability; there are no fancy courses in its instruction, and no more than two or three courses which might perhaps be considered superfluous. The following is a list of the professors, the subjects of instruction, the number of hours of lecture given weekly in each subject, and the practical exercises:

Gretschel.—Higher Mathematics (Trigonometry, Analytic Geometry, and Calculus), 6; Selections from the Higher Mathematics, 2; Descriptive Geometry, 4; Introduction to the Theory of Determinants, 1; Graphic Calculation, 1.

Undeutsch.—Mechanics, 6; Mining Machinery, 4; Machine Drawing, part first, 4; Machine drawing, part second, 4.

Viertel.—Geodesy and Mine Surveying, 3; Practical Exercises in the field (Summer term), ½ day; Practice in Surveying, including Mine Surveying, ½ day.

Winkler.—Inorganic Chemistry, 4; Organic Chemistry (Summer term), 2; Chemical Technology, 2; Quantitative Analysis, 1; Practice in Qualitative and Quantitative Analysis, from 9 to 6 daily except Saturday; Volumetric Analysis, 1.

Richter.—General Metallurgy, 4; Assaying, 1; Practice in Assaying, ½ day; Blowpipe Analysis, 2; Practice in Blowpipe Analysis, 2.

Ledebur.—Metallurgy of Iron, 4; Metallurgical Technology, 4; Salt Works (Summer term), 1; Assaying of Iron (Winter term), 1; Practice in Iron Assaying (Summer term), ½ day.

Weisbach.—Mineralogy, with one hour recitation, 5; Practice in Determining Minerals, 4; Mathematical Crystallography (Winter term), 1; Practice in Determining Crystals (Summer term), 1; Pseudo-morphology (Summer term,) 1.

Stelzner—Geology, with one hour recitation, 5; Ore Deposits, 2; Petrifaction, 2; Microscopic Examination of Minerals and Stones, 1; Practice in the same, 1; Practice in Determining Rocks (Summer term), 1.

Erhard.—Experimental Physics, 5; Practice in Physical Manipulations, 2; Fuels and Furnaces, 2; Meteorology (Winter term), 2; Mathematical Examination of the Physical Properties of Gases, 2.

Kreischer.—Mining, part first, with one hour recitation, 5; Mining, part second, with one hour recitation, 5.

Muller.—Construction of Buildings (Winter term), 3; Estimates for Mining and Smelting Buildings (Summer term), 3; Designing and Drawing of Mining and Smelting Buildings, 4.

Freiesleben.—General Law (Winter term), 4; Mining Law (Summer term), 4.

Schober.—Political Economy, 2.

Walther.—Hygiene of Miners and Smelters, 2.

Ostuckenberg.—Freehand Drawing, 4.

Great satisfaction is universally expressed with the lectures and practical exercises under Richter, Gretschel, Winkler, Weisbach, Stelzner, Viertel, and Ledebur. These departments are the strong attractions of the school, and better instruction than is given in the practice of wet and dry assaying, blowpipe analysis, chemical analysis, mineralogy, geology, surveying, and survey plotting, could not be asked. Moreover, the large and valuable collections of minerals, geological specimens, and models of machinery are accessible for inspection or study. With the professor of mining, or machinery, or geology, or iron, the students occasionally perhaps two or three times in a year with each, have the opportunity of visiting works or making geological tours in and out of Saxony.

These trips are sometimes of profit professionally, but a crowd of twenty students spending several hours only in large and complicated works, passing rapidly from one thing to another, cannot be expected to carry away much definite information or many lasting impressions. The geological trips are perhaps the most useful and enjoyable; the study of Quadersandstein of Saxon Switzerland is not so engrossing that the beauties of this charming region pass unadmired; the wonderful formation of the Prebisthor does not preclude an appreciation of its beer, and the tramp over its wooded hills or through its cultivated valleys is enlivened by those glorious German student songs.

But thus far our schools offer as much, and there is no reason why they may not actually give as much, as the Freiberg Academy. We have larger, more convenient, and better appointed buildings; we have more money; we have equal facilities for laboratory and field practice, except in mine surveying; we have visits to works, geological trips, and summer excursions. Nay even, our schools ought, for the American student, to be very superior to any German school. American methods and machinery are hardly mentioned at Freiberg, and certainly do not receive the attention and discussion which their importance and the presence of a large number of American students might justify. American pumps, drills, engines, waterwheels, amalgamating machinery, and metallurgical processes are quite ignored, and American hydraulic mining is disposed of in about five minutes, with some apparently fabulous accounts of hundreds of miles of ditches and the washing away of whole hills. In fact, the student gets nothing peculiarly American from his course, and hence what he learns outside of general principles he must unlearn, or at least reconstruct. But the one great advantage overtopping all others and outweighing all deficiencies is the intimate connection of the academy with the works of the vicinity and the permission to visit and study similar works, which is granted throughout Germany, and also in Austria, to the holder of the Freiberg student's card. Almost no limits or restrictions are placed upon the student; he may, on proper application, either before his theoretical course or during it, make what is called a practical course. In this case he is placed under the direction of a mining captain, who puts him through all the different operations of mining, giving him information on each operation, answering cheerfully all questions, and assigning him a place to work in this or that gang of miners, who are also invariably very kind and willing to assist by information or example. Or he may make an independent course, and visit any of the mines in the vicinity every day, or as often as he likes. In the same way he has perfect liberty to visit and work in the ore-dressing establishments about Freiberg, or in the excellently managed coal mine and washer at Zaukeroda, near Dresden. He may study in similar manner at the Muldner and Halsbrückner smelting works, and as a good foundation for such study a practical smelting course is given during the first two weeks in August at the works by the professor of metallurgy or his assistant, which any student upon application may attend. Nor are less advantageous facilities granted outside of Saxony. It was the privilege of the writer, with one or two companions, to spend some two or three weeks in the summer of 1875 in the ore-dressing works of the Harz, at Clausthal and the neighboring towns, Grund, Lautenthal, and St. Andreasberg, and in the summer of 1876 some two weeks in the mines and ore-dressing works at Pzibram, in Bohemia; again two weeks in the Harz, and about the same length of time in works near the Rhine, at Laurenburg, Ems, Mechernich, and Cologne. At no place was permission to examine the works refused. On the contrary, the directors and overseers were everywhere willing to impart any information in regard to their works, and spent much time and pains in so doing. Permission was given to make sketches, take notes and dimensions, copy working drawings of machines, and statistics as regards cost of working and working capacity. The Germans and Austrians are particularly kind to foreigners, and they ask and expect nothing in return except the appreciation on the part of the student. Other young men, who were studying coal and iron in other places, were equally well received; the testimony from all sources is the same. Herein lies the great advantage of studying in Germany, and in spite of discomforts and expense, and objections such as have been mentioned, our students will continue to go thither till some definite, sure, and permanent connection is established between our schools and the mines and metallurgical works.

In 1876 there were at Freiberg Academy 139 students, as follows: from Germany 64, including 42 Saxons; from Wallachia, Spain, Portugal, Holland, Asiatic Turkey, 1 each; from Switzerland and Japan, 2 each; from Italy and Norway, 3 each; from Greece, 5; from England, 9; from Russia and Poland together, 11; from Austria-Hungary, 11; from America, 24. Of the 24 from America, 1 was from Canada, 2 were from Chili, 3 from Mexico, and 18 from the United States. Of these 18, 1 came from each of the States of Alabama, Connecticut, Iowa, Louisiana, Maryland, Massachusetts, Michigan, and Ohio; 2 came from California, 3 from Pennsylvania, and 5 from New York. Of the 18, one was pursuing especially the study of mineralogy, one the study of iron, two of coal, four general metallurgy, and ten mining and concentration, or were not pronounced. Of the 18 perhaps a half were hard workers, a part of the remainder worked easily, the rest made no pretensions, but were going to begin. In general, the reputation of the students from the United States is good among the professors, at the works, and in the town. Together with the English and Canadian students, with whom they stand on terms of intimacy and friendship, they form the largest distinct foreign element, being about one-fifth of the whole number—a very creditable element, exhibiting the robustness and energy which characterize the English-speaking people everywhere. Thither, also, they carry their fondness for, and proficiency in, outdoor athletic sports, which are not cultivated by the other students. In skating they have no rivals or competitors, and in other games, such as base-ball and foot-ball, they have the field alone. Although this muscular development is not mental training, it is nevertheless conducive to mental activity, and the vigor and originality of the English race are largely due, perhaps, to physical health and freshness caused by the active outdoor sports practiced from boyhood up to and into manhood.

The principal subjective drawbacks to the progress of the American student in Germany are youth, an insufficient previous training in habits of study, and want of a working knowledge of the language. The first two generally go together, and often all three are combined; in which case the young man easily falls into ways of idleness and dissipation, which make his stay in Germany worse than useless, if they do not prove his utter ruin. To obviate these objections, it may be allowable to suggest as a course of study a collegiate course followed by two years in a mining school at home, and then one or two years abroad; or, what would be a saving of time and obviate the course abroad, a college course followed by two years in one of our mining schools, the time from the first of May or June till October in each of these years being spent at mines or works. It is now generally acknowledged that a liberal education is the best foundation for a professional training, and certainly, if the profession of mining engineering is to rank with the other liberal professions and be acknowledged by them, such a foundation is necessary, even if it does require as much time as is required by the other professions. Under the first plan a young man would be ready to reconstruct his art at the age of 25 or 26, and in the second case to begin work at 23 or 24, or one year later if it should be considered expedient to require another year of steady work after the two summer courses already indicated. The preparatory schools for our best colleges are the best training schools for boys, for the one reason, if no others, that they not only have a definite and not insignificant amount of instruction to impart, but that this instruction is to be tested by the broad and strict examination for admission to college, and it is a fact, unpalatable indeed, that those who, by reason of physical or mental weakness or indolence, are not capable of being brought up to this standard, deviate to a technical school, where they are nursed for a year or two till they are strong enough to leave and go into business. While in college the student may, besides attending faithfully to his literary subjects, anticipate the mathematics, chemistry, physics, modern languages, a part of the geology and mechanics, and some other studies, so that in two years at most he may finish the course in one of our mining schools. Then, if he wishes to study in Germany, he has a character all formed, a liberal and technical drill, and a good knowledge of the language.

The devising of a plan for the union of the schools and works is full of difficulties. The conditions are so widely different here from what they are in Germany that the introduction of the German system without important modification is practically impossible. There both schools and mines are, to a great extent, directly under the control of the government. It grants to the student the right to assume the responsibility of an engineer only after he has served as "practicant," and requires the mines to receive its students in such capacity. As our schools and works are all private enterprises no other than a voluntary arrangement can be made here. There competition is not so sharp and speculation is not so wild as here; the richness of good mines does not have to be concealed to freeze out undesirable owners, poor mines do not have to be puffed to effect a sale, and patent machines and secret processes are not so common, consequently permission to visit works is more readily obtained. Moreover, our schools are more numerous, and are already established far distant from the important works, which are scattered far and wide, separated by many hundreds or thousands of miles, and often difficult of access. Very strong arguments were presented, as you remember, by the United States Commissioner of Mining Statistics, in 1868, and again in 1869, in favor of a national school of mines. As yet the government has not seen fit to act according to the suggestions, and I am not aware that the subject is likely to receive the attention of Congress. It would be impossible to locate such a school anywhere in this country as advantageously as the German institutions are situated, from which in a few hours, or in a day or two at most, any of the large mines or works may be reached. In consideration of this fact, and the possibility that, on account of State or local jealousy or interests, or political jobbing, or for other reasons, the foundation of a national school west or east of the Rocky Mountains may be delayed indefinitely, and of the fact that we already have millions of dollars invested in magnificently equipped mining schools, is it not advisable, instead of seeking other millions, to endeavor to increase the usefulness of those already invested? We certainly have schools enough, more perhaps than we have teaching ability to supply. One great and just criticism on American education is that we have so many institutions that the instruction is too dilute. Two or three good professors in a mining school cannot of themselves make that school satisfactory, and drawing away a good professor from this school and that to found another weakens those drawn upon, and generally adds another to the long list of moderately efficient attempts.

The works generally consider that they only grant favors and receive no good in return, and perhaps from their previous experience they have reason to consider the students nuisances. But it is not so abroad, and there is no reason why it should be so here. The labor of the study would not be worthless, and, indeed, to secure the owners against imposition or loss, and to insure diligence on the part of the student, the power of discharging an unfaithful young man would, of course, be one of the rights reserved by the works. Moreover, the works, always having several young men making a practical course, would have an excellent opportunity to select from the number some who would be valuable men to employ permanently, first as assistants and eventually as engineers. Moreover, as part of the compact, the schools might agree, as some return for the kindness of the owners, to furnish essays, or analyses, or geological opinions, or surveys, or plans, or drawings, or render some other assistance to the engineer of the works. It is by no means a case in which the favors are of necessity all on one side. To begin on something definite, the circular might contain a preliminary plan of operations, and might ask each mine on industrial work and each school whether, on the proposed basis or on any basis, it would co-operate; it might invite criticism and suggestions for improvements on the plan, and from the discussions before the Institute, and from the answers to the circulars, a final arrangement might be made and put into operation.

Compiled from a paper by J. C. Bartlett, A.M., Transactions American Institute of Mining Engineers.

THE AMERICAN INSTITUTE OF MINING ENGINEERS.

THIS now famous Institute that has done so much for the mines and miners of this country had its origin in the following:

WILKES-BARRE, PA., April, 1871.

The great development of the mines and metallurgical works of this country during the last few years, accompanied as it has been by the investment of enormous sums of money in purchasing lands, and in the erection of improvements, requires that advantage should be taken of the accumulated knowledge of engineers, superintendents, and others, in mastering the problems which are constantly presenting themselves for our action. Among those may be mentioned the consideration of more economical systems of mining in our coal and metalliferous mines, improved methods of transportation above and below ground, unwatering and ventilating mines, the mechanical preparation of coal and other minerals, the various metallurgical processes, and, in fact, every question tending to the attainment of two great objects:

1st. The more economical production of the useful minerals and metals.

2nd. The greater safety and welfare of those employed in these industries.

In European countries, where the arts of mining and metallurgy have long been the subject of the most careful study, no means have been found so effectual in attaining the end above proposed as the free interchange of experience among those actually engaged in these industries, and this object has been accomplished, mainly, through the medium of institutes, associations or societies, composed of those engaged in these occupations, and by the periodical publication of essays or papers communicated to such societies by their members. It must be evident to all practical men that the interchange of the varied experience of those engaged in such occupations in this country could not fail to advance very materially the desired objects; it is, therefore, proposed to establish an *American Institute of Mining Engineers*, which will hold its meetings periodically in the great mining and metallurgical centres, where works of interest, such as mines, machine shops, furnaces, and other metallurgical works, can be inspected, and the members exchange their views, and consult for mutual advantage upon the difficulties encountered by each; these transactions or proceedings, when published, would form a most valuable and greatly-needed addition to our professional literature. It is proposed that a meeting of those sympathizing with the object above mentioned shall be called for the purpose of organizing such an association, the place and time of meeting being Wilkes-Barre, Pa., and the month of April or May.

Communications indicating the opinion and wishes of all, both as to these points, and also as to the organization and objects of the Institute, will be gladly received by any of the undersigned, and a notice of the date of meeting, which will be arranged to suit the greater number, will be duly communicated. Any one who may have devoted himself to a particular subject connected either with mining or metallurgy, and who may be possessed of new facts in reference to it, would greatly aid in furthering the object of the proposed association by preparing a paper giving the result of his experience, to be communicated at the first meeting. It is expected that the desire for the advancement of professional knowledge, combined with the attractions of a visit to the most beautiful of our coal fields, the Wyoming Valley, will insure a large attendance from all parts of the country.

Signed,

ECKLEY B. COXE, Drifton, Pa.
R. P. ROTHWELL, Wilkes-Barre, Pa.
MARTIN CORYELL, Wilkes-Barre, Pa.

The foregoing circular having been extensively circulated by mail, and also by publication in the leading engineering papers, the following named gentlemen assembled in Wilkes-Barre, Pa., May 16th, 1871, and organized the American Institute of Mining Engineers:

Bramwell, J. H.,	Fairchance, Fayette Co., Pa,
Daddow, S. Harries,	St. Clair, Pa.
Drinker, H. S.,	Philadelphia, Pa.
Drown, Thomas M.,	Philadelphia, Pa.
Gaujot, E.,	Pottsville, Pa.
Haight, Ogden,	New York.
Hick, W. B.,	Wilkes-Barre, Pa.
Hoffman, Daniel,	Pottsville, Pa.
Jones, Lewis S.	Wilkes-Barre, Pa.
McNair, Thomas S.,	Hazleton, Pa.
Mercur, Fred.,	Wilkes-Barre, Pa.
Neal, R. C.,	Bloomsburg, Pa.
Petherick, Thomas,	Pottsville, Pa.
Raymond, R. W.,	New York.
Rothwell, R. P.	Wilkes-Barre, Pa.
Silliman, Prof. J. M.,	Easton, Pa.
Sturdevant, W. H.,	Wilkes-Barre, Pa.
Symons, W. R.,	Pottsville, Pa.
Thomas, James,	Wilkes-Barre, Pa.
Timpson, James, A.,	Wilkes-Barre, Pa.
Ward, Willard P.,	New York.
Williams, T. M.,	Wilkes-Barre, Pa.

Mr. R. P. Rothwell was elected temporary Chairman, and Mr. R. W. Raymond temporary Secretary.

A Committee appointed to prepare rules for the Institute reported a series of rules, which, after some discussion, were adopted in the following form:

RULES.

Adopted May 16th, 1871.

1. The objects of the American Institute of Mining Engineers are to enable its members, comprising Mining Engineers and other persons interested in mining and metallurgy, to meet together at fixed periods for the purpose of reading papers upon and discussing subjects which have for their aim the economical production of the useful minerals and metals, and the safety and welfare of those employed in these industries, and to circulate among its members, by means of its publications, the information thus obtained.

2. The Institute shall consist of Members, Honorary Members, and Associates. Members and Honorary Members shall be mining Engineers. Associates includes other persons interested in mining and Metallurgy. All these classes shall be equally entitled to the privileges of Membership except as herein provided.

3. The annual subscription of each member and associate shall be ten dollars, which shall be payable in advance at each annual meeting or immediately after his election.

4. Any member who shall make a donation of one hundred dollars, or upwards, shall become a Life Member, and any associate who shall make a like donation shall become a Life Associate, and shall not be liable for any further annual subscription.

5. Honorary members shall not be called upon to pay any annual subscription. The number of honorary members shall not exceed twenty.

6. Persons desirous of becoming members or associates of the Institute shall be proposed by at least three members or associates, approved by the Council, and elected by ballot at a regular meeting upon receiving at least three-fourths of the votes cast.

7. Every person proposed as an honorary member shall be recommended by at least ten members of the Institute, approved by the Council, and be elected by ballot on receiving nine-tenths of the votes cast.

8. The officers who shall constitute a Council for the direction of the affairs of the Institute, shall consist of a President, who shall be a Mining Engineer, six Vice-Presidents, at least four of whom shall be mining Engineers (the word "Mining Engineers" in these rules comprehend Engineers connected either with mining or metallurgy), nine Managers, at least six of whom shall be Mining Engineers, a Secretary and Treasurer. All these officers shall be members or associates of the Institute, and shall be elected at the annual meeting (except in cases of vacancies), and shall be eligible for re-election, with the exception of any President or Vice-President who may have held office for the three immediate preceding years, and such two Managers of the Mining Engineers and one other Manager who shall attend the fewest Council meetings during the past year, but such members shall be eligible for re-election after being one year out of office; and such election shall be made in the manner following: A.—Any member of the Institute shall be at liberty to nominate in writing, and send to the Secretary, not less than thirty days prior to the annual meeting, a signed list of such persons as are considered suitable to fill the various offices; which list, having been duly stamped, with the Institute seal, together with the list of such officers as shall be eligible for re-election, and a copy of this Rule, shall be posted, at least ten days previous to the annual meeting, to all members of the Institute, who must strike out or add to such list so as to leave a record of their votes for Officers, not exceeding the number to be elected; but nothing shall prevent any member nominating in writing subsequently (specifying the classes as aforesaid), and up to, and on the day of, and prior to the election taking place, any other member or members to fill the various offices, nor shall anything prevent the members, whether present or absent, from having power to vote for any other member or members, although he may not be nominated as before provided for. The voting papers, being so filled up, must be returned through the post, addressed to the Secretary, or be handed to him or to the Chairman, in all cases so as to be received before the hour fixed for the election of officers. B.—The Chairman shall, in all cases of voting, appoint scrutineers of the lists, and the scrutiny shall commence on the conclusion of the other business of the meeting, or at such other time as the Chairman may appoint. On the conclusion of the scrutiny the voting papers shall be destroyed, and the List, prepared and verified by the scrutineers, shall be kept until the next annual meeting. C.—In the event of any vacancies occurring in the number of officers subsequent to the annual meeting, such vacancy or vacancies shall be filled by the Council. D.—At meetings of the Council five shall be a quorum.

9. General meetings of the Institute shall take place on the third Tuesday of February, May, August and November, and the May meeting shall be considered the annual meeting, at which a report of the proceedings of the Institute and an abstract of the accounts shall be furnished by the Council. Special meetings may be called whenever the Council see fit; and the Secretary shall call a special meeting on a requisition signed by fifteen or more members. The notices for special meetings shall state the business to be transacted, and no other shall be entertained.

10. Every question which shall come before any meeting of the Institute shall be decided by the votes of the majority of the members then present.

11. The funds of the Institute shall be deposited in the hands of

the Treasurer, and shall be disbursed by him according to the directions of the Council.

12. All Papers sent for the approval of the Council shall be accompanied by a short abstract of their contents.

13. The Council shall have power to decide on the propriety of communicating to the Institute any papers which may be received, and they shall be at liberty, when they think it desirable, to direct that any paper read before the Institute, shall be printed in the Transactions. Intimation, when practicable, shall be given at each general meeting of the subject of the paper or papers to be read and of the questions for discussion at the next meeting, and notice thereof shall be posted to all members. The reading of papers shall not be delayed beyond such hour as the President shall think proper, and if the election of members or other business shall not be despatched soon enough, the President may adjourn such business until after the discussion of the subject for the day.

14. Members elected at any meeting between the annual meetings shall be entitled to all papers issued that year.

15. The copyright of all papers communicated to and accepted by the Institute shall be vested in it, unless otherwise agreed upon between the Council and the author; and such communications shall not be published for sale or otherwise without the permission of the Council.

16. All proofs of discussion forwarded to members for correction must be returned to the Secretary not later than seven days from the date of their receipt, otherwise they will be considered correct and printed.

17. The Institute is not, as a body, responsible for the facts and opinions advanced in the papers which may be read, nor in the abstracts of the conversations which may take place at the meetings of the Institute.

18. The author of each paper read before the Institute shall be allowed twelve copies of such paper (if ordered to be printed) for his own use, and shall have the right to order any number of copies at the cost of printing and paper, provided they are not intended for sale.

19. Any member of the Institute shall have power to introduce a stranger to any meeting, but the latter shall not take part in any discussion without the consent of the meeting.

20. Any member who has not paid his subscription for the space of one year after it is due, shall not be entitled to vote at elections, or to receive a copy of the Transactions of the Institute.

21. The place of holding the general meetings for the ensuing year shall be fixed at each annual meeting, by a vote of the Institute; or, in default of such determination, by the Council; the place for special meetings shall be fixed by the Council; and notice of all such meetings shall be given by mail or otherwise to all members and associates, at least twenty days before the time appointed for said meeting.

22. No alteration shall be made in any of the Laws, Rules, or Regulations of the Institute except at the annual meeting.

The following resolution was then offered and passed:

Resolved, That the Chairman appoint a committee of five, to whom all applications from persons not present at this meeting, desiring to be connected with the Institute, shall be presented, and the said committee shall report at the meeting to-morrow a list of suitable names so nominated; and that all persons who have recorded their names at this meeting, and all persons who shall be so reported by the said committee, and all persons elected at the present series of sessions, constituting the May meeting of the Institute, shall be considered as Associates of the Institute; and the Council to be hereafter elected under the rules shall report at the August meeting the said persons in two lists, as Members and Associates, for adoption by the Associates then present; and that all persons to be permanently classed as Members or Associates shall signify the same to the Council before the August meeting.

The committee appointed, as provided by this resolution, reported at the subsequent sessions, May 17th and 18th, the following names with approval:

Robert Allison, Pottsville, Pa.; Jesse Beadle, Shickshinny, Pa.; W. P. Blake, New Haven, Conn.; John F. Blandy, Philadelphia, Pa.; David Coghlan, Scranton, Pa.; Martin Coryell, Wilkesbarre, Pa.; W. S. Coulter, Ashley, Pa.; W. M. Courtis, Wyandotte, Mich.; Eckley B. Coxe, Drifton, Pa.; A. B. De Saules, Orange, N. J.; Prof. T. Egleston, New York; Anton Eilers, New York; E. B. Ely, New York; Prof P. Frazer, Jr., Philadelphia, Pa.; N. Friedrich, Drifton, Pa; J. H. Harden, Wilkes-Barre, Pa.; C. E. Hawley, Wilkes-Barre, Pa.; J. R. Hoffman, Pottsville, Pa.; John Hoise, Tamaqua, Pa.; Theo. P. Jenkins, New York; George Johnson, Pittston, Pa.; W. W. Kenrich, Wilkes-Barre, Pa.; Prof. G. W. Maynard, Troy, N. Y.; Arthur McClellan, Drifton, Pa.; Paul A. Oliver, Wilkes-Barre, Pa.; Chas. Parrish, Wilkes-Barre, Pa.; C. W. Parsons, Wilkes-Barre, Pa.; Edmund C. Pechin, Dumbar, Pa.; Prof. W. B. Potter, St. Louis. Mo.; Prof. F. Prime, Jr., Easton, Pa.; Prof. Raphael Pumpelly, Cambridge, Mass.; C. E. Richter, Philadelphia, Pa.; R. Bruce Ricketts, Wilkes-Barre, Pa.; W. H. Roberts, Mauch Chunk, Pa.; I. H. Stearns, Wilkes-Barre, P.; W. S. Stewart, Wilkes-Barre, Pa.; J. H. Swoyer, Wilkes-Barre, Pa.; David Thomas, Catasauqua, Pa.; Samuel Thomas, Catasauqua, Pa.; H. Wentz, Wilkes-Barre, Pa.; John White, New York, S. B. Whiting, Pottsville, Pa.; Pryor J. Williams, Wilkes-Barre, Pa.; Morgan B. Williams, Wilkes-Barre, Pa.; W. D. Zehner, Summit Hill, Pa.

An election for permanent officers of the Institute resulted in the choice of the following:

President:—David Thomas, Catasauqua, Pa.

Vice-Presidents:—R. W. Raymond, New York; E. B. Coxe, Drifton, Pa.; W. R. Symons, Pottsville, Pa.; W. P. Blake, New Haven, Conn.; J. F. Blandy, Philadelphia, Pa.; J. H. Swoyer, Wilkes-Barre, Pa.

Managers:—R. P. Rothwell, Wilkes-Barre, Pa.; T. S. McNair, Hazleton, Pa.; G. W. Maynard, Troy, N. Y.; Raphael Pumpelly, Cambridge, Mass.; Thomas Petherick, Scranton, Pa.; T. M. Williams, Wilkes-Barre, Pa.; Thomas Egleston, Jr., New York; E. Ganjot, Pottsville, Pa.; Frederick Prime, Jr., Easton, Pa.

Secretary:—Martin Coryell, Wilkes-Barre, Pa.

Treasurer:—J. Pryor Williamson, Wilkes-Barre, Pa.

Since that time, the Institute has prospered exceedingly. It numbered on July 1st 1882, six honorary members, 914 members, 121 associates, 51 foreign members. The officers in July 1st, were as follows:

President.—R. P. Rothwell. Vice-Presidents.—J. P. Kimball, W. H. Pettee, C. O. Thompson, (Term expires February, 1883.) T. N. Ely, Charles Macdonald, J. W. Powell, (Term expires February, 1884.) Managers.—James C. Bayles, W. S. Keyes, Percival Roberts, Jr., (Term expires February, 1883.) J. S. Alexander, H. S. Munroe, J. C. F. Randolph, (Term expires February, 1884.) William Burnham, Anton Eilers, A. S. McCreath, (Term expires February, 1885.) Secretary.—Thomas M. Drown, Easton, Pa. Treasurer.—Theodore D. Rand, Philadelphia.

The following are the rules as amended to July 1, this year:

I. OBJECTS.—The objects of the "American Institute of Mining Engineers" are to promote the Arts and Sciences connected with the economical production of the useful minerals and metals, and the welfare of those employed in these industries, by means of meetings for social intercourse, and reading and discussion of professional papers, and to circulate, by means of publications among its members and associates, the information thus obtained.

II. MEMBERSHIP.—The Institute shall consist of Members, Honorary Members, and Associates. Members and Honorary Members shall be professional mining engineers, geologists, metallurgists, or chemists, or persons practically engaged in mining, metallurgy, or metallurgical engineering. Associates shall include all suitable persons desirous of being connected with the Institute and duly elected as hereinafter provided. Each person desirous of becoming a member or associate shall be proposed by at least three members or associates, approved by the Council, and elected by ballot at a regular meeting upon receiving three-fourths of the votes cast, and shall become a member or associate on the payment of his first dues. Each person proposed as an honorary member shall be recommended by at least ten members or associates, approved by the Council and elected by ballot at a regular meeting on receiving nine-tenths of the votes cast; *Provided*, that the number of honorary members shall not exceed twenty. The Council may at any time change the classification of a person elected as associate, so as to make him a member, or *vice versa*, subject to the approval of the Institute. All members and associates shall be equally entitled to the privileges of membership; *Provided*, that honorary members shall not be entitled to vote or to be members of the Council.

Any member or associate may be stricken from the list on recommendation of the Council, by the vote of three-fourths of the members and associates present at any annual meeting, due notice having been mailed in writing by the Secretary to the said member or associate.

III. DUES.—The dues of members and associates shall be ten dollars per annum, payable in advance at the annual meeting; *Provided*, that persons elected at the meeting following the annual meeting shall pay eight dollars, and persons elected at the meeting preceding the annual meeting shall pay four dollars as dues for the current year. Honorary members shall not be liable to dues. Any member or associate may become, by the payment of one hundred dollars at any one time, a life member or associate, and shall not be liable thereafter to annual dues. Any member or associate in arrears may at the discretion of the Council be deprived of the receipt of publications, or stricken from the list of members when in arrears for one year; *Provided*, that he may be restored to membership by the Council on payment of all arrears, or by reelection after an interval of three years.

IV. OFFICERS.—The affairs of the institute shall be managed by a Council, consisting of a President, six Vice-Presidents, nine Managers, a Secretary and a Treasurer, who shall be elected from among the members and associates of the Institute at the annual meetings, to hold office as follows:

The President, the Secretary, and a Treasurer for one year (and no person shall be eligible for immediate re-election as President who shall have held that office subsequent to the adoption of these rules, for two consecutive years), the Vice-Presidents for two years, and the managers for three years; and no Vice-President or Manager shall be eligible for immediate re-election to the same office at the expiration of the term for which he was elected. At each annual meeting a President, three Vice-Presidents, three Managers, a Secretary and a Treasurer shall be elected, and the term of office shall continue until the adjournment of the meeting at which their successors are elected.

The duties of all officers shall be such as usually pertain to their offices, or may be delegated to them by the Council or the Institute; and the Council may in its discretion require bonds to be given by the Treasurer. At each annual meeting the Council shall make a report of proceedings of the Institute together with a financial statement.

Vacancies in the Council may occur by death or resignation; or the Council may by vote of a majority of all its members declare the place of any officer vacant, on his failure for one year, from inability or otherwise, to attend the Council meetings or perform the duties of his office. All vacancies shall be filled by the appointment of the Council, and any person so appointed shall hold office for the remainder of the term for which his predecessor was elected or appointed; *Provided*, that the said appointment shall not render him ineligible at the next annual meeting.

Five members of the Council shall constitute a quorum, but the Council may appoint an Executive Committee, or business may be transacted at a regularly called meeting of the Council, at which less than a quorum is present, subject to the approval of a majority of the Council, subsequently given in writing to the Secretary, and recorded by him with the minutes.

V—ELECTIONS.—The annual election shall be conducted as follows: Nominations may be sent in writing to the Secretary, accompanied with the names of the proposers, at any time not less than thirty days before the annual meeting; and the Secretary shall, not less than two weeks before the said meeting, mail to every member or associate (except honorary members), a list of all the nominations for each office so received, stamped with the seal of the Institute, together with a copy of this rule, and the names of the persons ineligible for election to each office. And each member or associate qualified to vote, may vote, either by striking from or adding to the names of the said list, leaving names not exceeding in number the officers to be elected, or by preparing a new list, signing said altered or prepared ballot with his name, and either mailing it to the Secretary, or presenting it in person at the annual meeting *Provided*, that no member or associate, in arrears since the last annual meeting, shall be allowed to vote until the said arrears shall have been paid. The ballots shall be received and examined by three Scrutineers, appointed at the annual meeting by the presiding officer; and the persons who shall have received the greatest number of votes for the several offices, shall be declared elected, and the Scrutineers shall so report to the presiding officer. The ballots shall be destroyed, and a list of the elected officers, certified by the Scrutineers, shall be preserved by the Secretary.

VI—MEETINGS.—The annual meeting of the Institute shall take place on the third Tuesday of February, at which a report of the proceedings of the Institute, and an abstract of the accounts, shall be furnished by the Council. Two other regular meetings of the Institute shall be held in each year, at such times and places as the Council shall select. Special meetings may be called whenever the Council sees fit, and the Secretary shall call a special meeting on a requisition signed by fifteen or more members. The notices for special meetings shall state the business to be transacted, and no other shall be entertained.

Every question which shall come before any meeting of the Institute, shall be decided, unless otherwise provided by these Rules, by the votes of the majority of the members then present. The place of meeting shall be fixed in advance by the Institute, or, in default of such determination, by the Council, and notice of all meetings shall be given by mail, or otherwise, to all members and associates, at least twenty days in advance. Any member or associate may introduce a stranger to any meeting, but the latter shall not take part in the proceedings without the consent of the meeting.

VII—PAPERS.—The Council shall have power to decide on the propriety of communicating to the Institute any papers which may be received, and they shall be at liberty, when they think it desirable, to direct that any paper read before the Institute shall be printed in the Transactions. Intimation, when practicable, shall be given at each General Meeting, of the subject of the paper or papers to be read, and of the questions for discussion at the next meeting. The reading of papers shall not be delayed beyond such hour as the presiding officer shall think proper; and the election of members or other business may be adjourned by the presiding officer, to permit the reading and discussion of papers.

The copyright of all papers communicated to, and accepted by the Institute, shall be vested in it, unless otherwise agreed between the Council and the author. The author of each paper read before the Institute shall be entitled to twelve copies, if printed, for his own use, and shall have the right to order any number of copies at the cost of paper and printing, provided said copies are not intended for sale. The Institute is not, as a body, responsible for the statements of fact or opinion, advanced in papers or discussions, at its meetings, and it is understood that papers and discussions should not include matters relating to politics, or purely to trade.

VIII—AMENDMENTS.—These rules may be amended, at an annual meeting, by a two-thirds vote of the members present, provided that written notice of the proposed amendment shall have been given at a previous meeting.

THE NATIONAL MINING EXHIBITION AT DENVER, COLORADO.

THE National Mining and Industrial Exhibition, which opened at Denver on Tuesday, August 1, 1882, with an address by the Hon. William D. Kelley, of Pennsylvania, was first suggested by Mr. J. W Ryckman in the Chicago *Industrial World*. The suggestion was adopted readily and the work of organizing began. The reason for this is found in the National ignorance upon mining matters. Denver was particularly interested. It was felt that the necessity existed for removing the many erroneous impressions prevalent, and showing in the most convincing and satisfactory manner that Colorado instead of being in one portion a barren desert, and in another a mass of snow-clad mountains, really contains a soil encouraging to the agriculturist, and a marvelous diversity of native minerals. only awaiting the introduction of manufacturing facilities to find an active market. It was believed too that in mining, inventors would be stimulated by the demand for new processes that will make low grade ores more profitable; in manufactures, capitalists and skilled labor would find every inducement for the establishment of new industries. The remoteness from Eastern sources of supply acts as a protective tariff to the producer in Colorado, where crude material exists in profusion, and it is comparatively neglected. To bring capital face to face with these opportunities for investment, and with skilled labor, to more rapidly develop the country, is the aim and purpose of the Exposition, and the display now shown is designed especially to hasten the establishment of extensive and flourishing industrial communities.

The principal events in the history of the Great West—more particularly those events which induce exploration and settlements—are of comparatively recent date. California, as described by Mr. Dana in "Two Years Before the Mast," treats of no commerce save that in hides, and suggests no idea of auriferous wealth. When the results of the Mexican war changed the boundary line between the United States and Mexico, and the discovery of placer gold in California became known, the bright visions of sudden wealth drew thousands towards the Pacific slope by the tedious sea voyages "around the Horn" or through the pestilential and deadly marshes of the Isthmus route. Those who feared the one or dreaded the other sought the overland routes and found ample opportunities to test their skill and endurance. Many perished by the way, but the movement did not cease. In 1858 news reached the East of gold discoveries in what was known as the Pike's Peak region, and a fresh impetus was given to immigration. The most important advance was made when railway facilities were inaugurated and the country became easily accessible to all who chose to visit it. With these facilities available the tide has continued year after year. Explorers have been and are still seeking new fields and announcing fresh discoveries The country west of the Missouri river is now easy of access, and in its striking contrasts and glorious scenery, furnishes fresh sensations to the pleasure seeker; while its great natural resources and remarkable climate are a strong inducement to those seeking new homes. It can be visited easier and more comfortably than Europe, even from the Atlantic seaboard, and every citizen of America should be conversant with the attractions of his own land before seeking recreation abroad. The population, as a class, combine all that is energetic and effective in pushing to satisfactory results whatever it undertakes. Intelligence is the rule, and public schools, equal to any in the country, exist in profusion. These remarks apply to the entire region covered by the great mineral belt. In natural resources the Rocky Mountains contain a varied and practically inexhaustible supply. The number is only limited by the incomplete examinations which have been made from time to time. Each year brings to light new deposits, not only of precious metals but of other mineral substances of great commercial value. There is no portion of the world that possesses equal advantages or surer highways to fortune than these mountain States, and many of these paths are to-day awaiting their particular pioneers. There is a reason for this, and an honest reason, too. It is because everything has been made subordinate to mining for precious metals. That prompted the early settlement and induced the following immigration to a great extent. All miners are not successful, and necessity has driven those who failed in mining into other pursuits. Horace Greeley declared the country capable of great things in agriculture, and received only jeers in return, until the harvests of Weld, Larimer, Boulder and other Counties in Colorado, portions of Utah, New Mexico and otherTerritories, to say nothing of the vast crops of cereals annually produced in California, justified his opinion in the most positive manner. Farmers in the great valleys of the Mississippi and its tributaries contend with frosts, drought, floods and hurricanes; all prominent factors in his annual calculations, but entirely unknown to the husbandman here. The dry atmosphere prevents killing frosts, and removes the danger from floods; the lofty mountain ranges send the hurricanes high overhead, and the extensive systems of irrigation that are constantly increasing, enable him to feed his growing crops as regularly as he feeds himself. When his grain is ready for the harvest he fears no danger from soaking rains. His wheat is always of high grade, his barley clean and bright, and his root crops swell to enormous proportions in the rich virgin soil. His market is at home—because, in spite of the annual increase in acreage, the rapid increase in population keeps in the lead and absorbs more than has been produced. There are thousands of acres yet laying idle, capable of splendid crops. The value of the cereals annually produced in the Pacific Seaboard States is far in excess of that of the precious metals, and other portions of the mountain region have equal advantage. Within this wide region there are many native products, besides precious metals, all with more or less commercial value, that are now wholly or partially neglected. With a view to bringing these hidden treasures to light, and to learn their full value is one of the great purposes of the Mining and Industrial Exposition. With their worth ascertained, it is confidently believed that new industries will be established convenient to the sources of supply and a market. Practical men will be encouraged to embark in these new enterprises wherever they may choose to locate them in our midst, and will have the benefit of the distance and cost of transportation from other sources of supply to protect their wares from competition.

In the selection of Denver as the place for the Exposition, many weighty reasons justify the choice. It is the largest city between the Mississippi Valley and the Pacific Coast. It has railway facilities radiating in every direction, affording easy communication with Wyoming, Utah, Idaho, Montana, New Mexico, Arizona, Nevada, California, Kansas and Nebraska. It is the objective point of summer travel from the Eastern States, and is visited by thousands of Americans and Europeans annually. It thus possesses superior opportunities for displaying our undeveloped means where they can be critically examined by capitalists and their values carefully tested. These considerations should prompt every one resident in the west to strive earnestly for a complete representation from his own locality, and thus make a fitting exhibit for the benefit of investors.

That an idea may be obtained of the size of these mining States and territories, a few comparative figures may be given. The area of the great western territory interested in mining, aggregates 1,196,084 square miles, or nearly one third of the whole area of the United States, Alaska included. Colorado, New Mexico, Arizona, Utah and Wyoming together have an area of 521,976 square miles, or over one seventh of the entire nation. With the Exposition replete with exhibits of crude material, accompanied by the necessary statements of locality and quantity, many neglected deposits will be brought into prominence, and lay the foundations for industrial advancement. As the Exposition is repeated year after year, it will become a vivid record of progress not only of the general prosperity of the great west, but it will also show that the people are constantly being taught to know new uses for crude material existing in Colorado, and are adding to their prosperity by all the rapid methods of manufacture, that spring from the inventive brain of an intelligent people.

As soon as the matter was actively pushed, Congress (on April 7th, 1882) passed the following law:—"That all articles which shall be imported for the sole purpose of exhibition at the National Mining and Industrial Exposition to be held in the city of Denver, in the year 1882, shall be admitted without the payment of duty or custom fees, or charges, under such regulations as the Secretary of the Treasury shall prescribe. Provided, that all such articles as shall be sold in the United States, or withdrawn for consumption therein, at any time after such importation, shall be subject to the duties, if any, imposed upon like articles by the revenue laws in force at the date of importation. And provided further, that in case any articles imported under provisions of this act shall be withdrawn for consumption, or shall be sold without payment of duty as required by law, all the penalties prescribed by the revenue laws shall be applied and enforced against such articles, and against the persons who may be guilty of such withdrawal or sale."

Officers for 1882.—H. A. W. Tabor, President; Herman Silver, Vice-President; W. A. H. Loveland, Treaserer; S. T. Armstrong, Secretary; H. D. Perky, General Manager; Hon. F. W. Pitkin, Governor of Colorado, and State and Territorial Governors, Honorary Vice-Presidents. *Directors.*—W. A. H. Loveland, H. A. W. Tabor, H. D. Perky, H. S. Wicks, John W. Knox, S. T. Armstrong, O. L. Haskell, Herman Silver, J. T. Cornforth, A. C. Hunt. *Executive Committee.*—O. L. Haskell, S. T. Armstrong, H. D. Perky. Geo. A. Crofutt, Sole Agent for the Bureau of Tourists and Excursions.

The exposition building, of which the accompanying engraving is a literal *fac-simile*, is a superb edifice of brick and stone, in the shape of a Maltese cross, having about two hundred thousand square feet of exhibition space. It is a permanent structure of 500 feet in length and 316 feet wide, designed particularly for the purpose. It will be furnished with the proper refreshment and retiring rooms necessary to the comfort of visitors and exhibitors. It is a great ornament to Denver and occupies an elevated position in the picturesque suburbs of the city, overlooking a stretch of three hundred miles of the Rocky Mountains. The Mineral exhibit will be a permanent feature; increased from time to time as new discoveries will demand, and is intended to present a faithful object lesson of the mineral deposits, not only of the Western States, but of the whole Union. It is under the immediate supervision of Prof. J. Alden Smith, State Geologist of Colorado. The following were the rules adopted at the outset:

1. The building will be open for the reception of articles on and after July 15th, and all exhibits must be in position, and machinery ready for operation on the opening day.

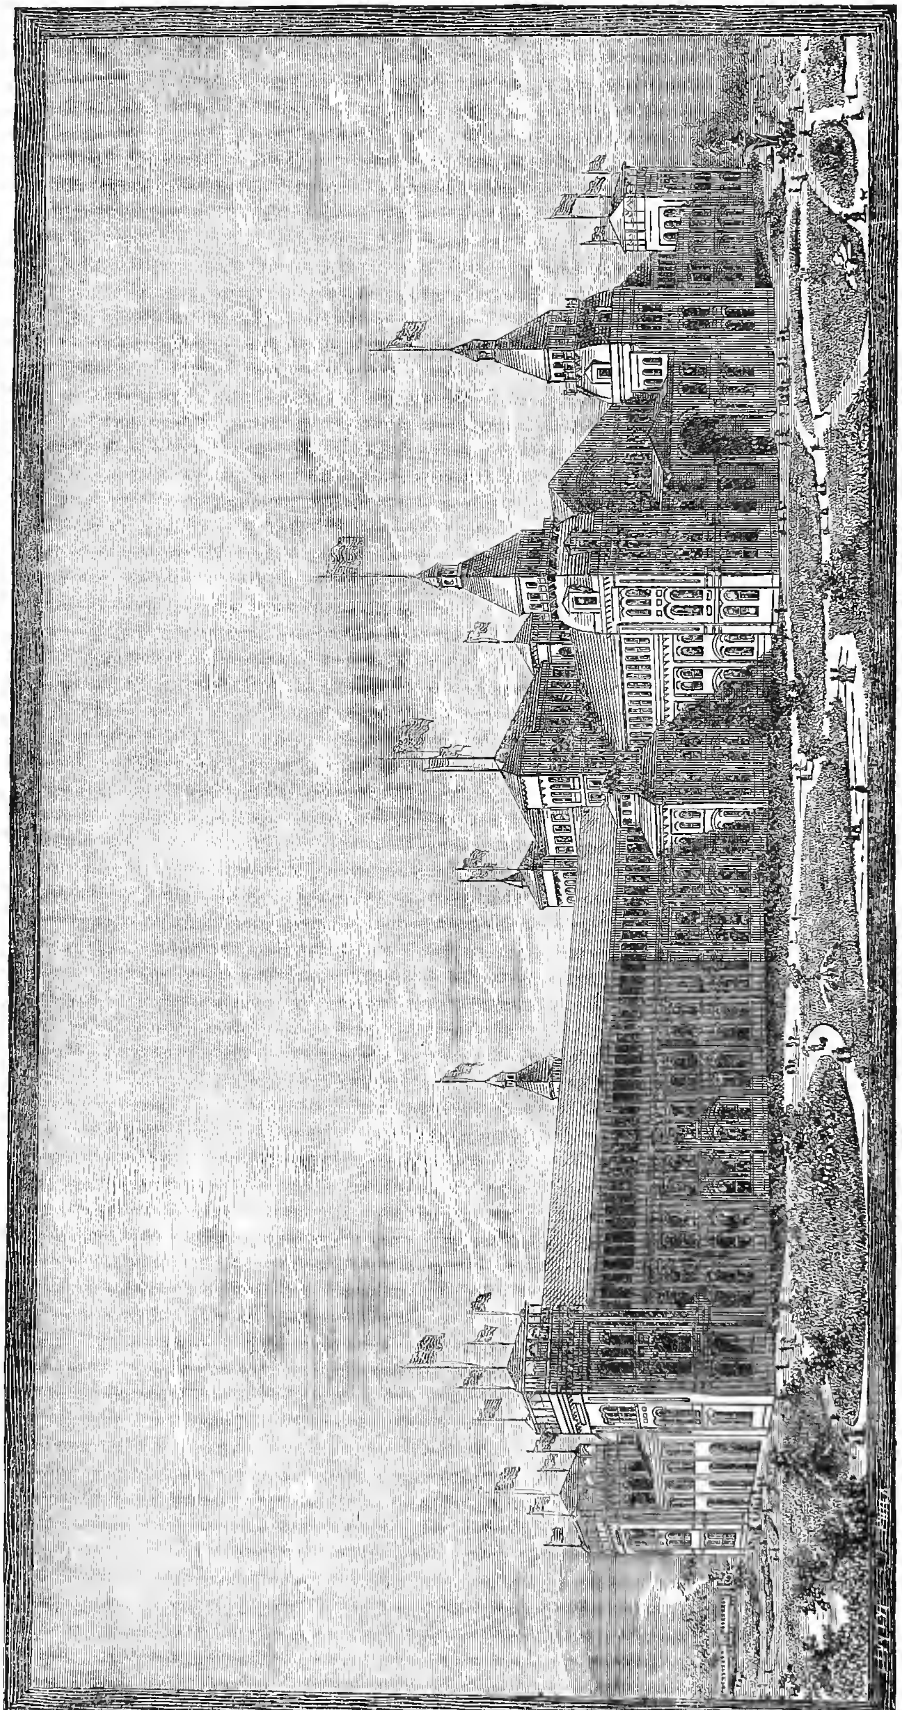
2. Machinery and manufactured articles must be entered in the name of the manufacturer. Entries will be permitted by manufacturers' agents. Mineral specimens may be entered by mine owners and through their accredited representatives.

3. The driving engines will be ready to furnish power to the main shafts ten days before the opening free of charge; but exhibitors must make their own attachments.

4. The entry clerk will furnish each exhibitor with an original and duplicate tag, the duplicate to be securely attached to the article exhibited when it is placed in position, the original will be kept by the exhibitor during the Exposition, and be surrendered to the entry clerk when the articles are removed from the building.

5. All articles on exhibition must remain until the Exposition closes. Removal will not be permitted except upon the written consent of the Board of Directors. Every facility for making sales of articles to be delivered at the close of the Exposition will be extended.

6. An efficient police will be provided for the care of arti-



THE NATIONAL MINING AND INDUSTRIAL EXPOSITION BUILDING, DENVER, COLORADO.

cles both day and night, but exhibits will be entirely at the owner's risk. Insurance against loss by fire will be effected when desired at the cost of the exhibitor.

7. To preserve harmony in the general effect of the display the Board reserves the right to regulate the position of all articles and the size of signs.

8. Space will be allotted in the order of application, and exhibitors notified as early as practicable. But space not occupied, either by the arrival of the goods or otherwise, one week before the opening day will be reassigned by the board.

9. As there will be no charge made to exhibitors, for entries or space, admission tickets will only be furnished to such exhibitor or to one employé, or both, when it is shown that the attendance of the exhibitor or employé is actually necessary. For these tickets five dollars each will be charged. These tickets will be registered, and forfeited if used by any other person than the one to whom they are issued.

10. The Board of Directors will take charge of all articles upon which the freight is prepaid, and remove them to the Exposition building at the expense of the exhibitor.

11. All unclaimed articles left by exhibitors fifteen days after the close of the Exposition will be stored and disposed of according to law.

12. All platforms and other temporary structures erected by exhibitors must be removed from the building by them within fifteen days after the close of the Exposition. No attachments to the floor by nails, screws, or otherwise, will be permitted. This does not include permanent exhibits.

13. There will be three lines of shafting in Power Hall, one $2\frac{7}{16}$ inches in diameter, for light machinery, will be driven at a speed of 150 revolutions per minute. The others will be $2\frac{1}{1}\frac{5}{6}$ inches in diameter, with a speed of 200 revolutions per minute. Driving pulleys as required, also counter-shafts and pulleys, belts and hangers, will be furnished for exhibitors at cost, if timely notice is given. They should be ready to be placed on the shafts before the 25th July.

The custom of awarding premiums has been so freely condemned that it has been omitted here. The action of ignorant or biased jurors will thus be avoided. Exhibitors will appreciate this feature, as it leaves them free to win success among the people, who will prove the claims of inventors by actual tests.

CLASSIFICATION.

DEPARTMENT A—*Mineralogy*—Gold ores, class 1; Silver ores, class 2; Iron ores, class 3; Lead ores, class 4; Copper ores, class 5; Fire, potters', and other clays, class 6; Bituminous coals, class 7; Anthracite coals, class 8; Cannel coal, class 9; Lignite, class 10; Other metalliferous specimens not enumerated above, class 11.

DEPARTMENT B—*Geology*—Marbles, class 1; Lithographic stone, class 2; Limestone, class 3; Miscellaneous building stone, class 4; Fossils, class 5; Gypsum, class 6; Precious stones and crystals, class 7; Native chemicals, class 8.

DEPARTMENT C—Hardware, edge tools, cutlery, and all cast and wrought iron goods, including stoves, safes, and metallic household utensils. Foundry productions, including all heavy castings, stoves, ranges, etc., class 1; All the light cast products, builders' hardware, plumbers' goods, brass goods, iron fencing, etc., class 2; House furnishing goods, edge tools, cutlery, iron safes, and other wrought iron goods, class 3; Grates and mantels, lamps and gas fixtures, class 4.

DEPARTMENT D—*Metallurgical Machinery*—Reverberatory roasting furnaces, blast and reverberatory smelting furnace, cupel, retort and other furnaces for separating base and precious metals, class 1; Stamp mills for free gold ores, stamp mills for free silver ores, stamp mills for dry crushing, and furnaces for roasting refractory gold or silver ores, class 2; Pans and settlers for amalgamation, leaching vats for leaching process, concentrators for crude ore or tailings, class 3; Other devices not included in the above classification, class 4.

DEPARTMENT E—*Agricultural and Horticultural Products and Floral Displays*—Cereals in half bushel samples, class 1; Fruits and roots, class 2; Plants and shrubbery, class 3; Cut flowers and transient exhibits, for which special arrangements will be made, class 4; Dairy products, class 5; Miscellaneous, class 6.

DEPARTMENT F—*General Machinery including Steam Engines and Machine Tools*—Stationary and portable engines and locomotives, class 1; Metal and wood working machinery, tools and appliances, class 2; Printing machinery, leather working machinery, pneumatic machinery, class 3; Miscellaneous machinery and machines tool, class 4; Laundry Machinery, class 5.

DEPARTMENT G—*Agricultural and Horticultural Implements and Machinery, Carriages, Wagons, and other vehicles*—Threshing machines, mowers, reapers, harvesters, ditching machines, hay rakes, feed cutters, etc., class 1; Plows, drills, planters, and other implements used in seeding, class 2; Farm vehicles of all descriptions, carriages, etc., class 3; Miscellaneous agricultural tools, class 4.

DEPARTMENT H—*Textile Fabrics, Leather and their products*—Wools (in fleeces) and other crude textile materials, class 1; Cotton, linen and woolen goods, bagging, rope and twine, class 2; Manufactured articles, clothing, hats, caps, etc., class 3; Leather, boots, shoes, harness, belting, furs and their manufactured products, class 4.

DEPARTMENT I—*Household Goods, Watches, Jewelry, Ornamental Articles, Optical and Scientific Instruments, Ceramics, etc*—Furniture and bedding, etc., class 1; Watches, jewelry, ceramics, bronze ornaments, etc., class 2; Optical and scientific instruments, class 3; China, glass and stone table ware, class 4; Wooden, willow, and wire goods, class 5; Paper hanging, etc, class 6.

DEPARTMENT K—*Liberal Arts, Natural Science, and Education*—Typography and bookbinders' work, class 1; Musical instruments, class 2; Photography, lithography, etc., class 3; Stationers' goods, class 4; Books and miscellaneous prints, educational devices, etc., class 5.

DEPARTMENT L—*Food Preparations and Miscellaneous Articles used in Domestic Economy, Miners' Supplies, etc.*—Flour, meal, etc., in sacks, class 1; Canned goods, class 2; Special food preparations not otherwise classified, class 3.

DEPARTMENT M—*Chemical and Medicinal Preparations (Patent Medicines excepted) Illuminating and Lubricating Oils*—Chemical preparations, class 1; Medicinal articles, class 2; Illuminating and lubricating oils, class 3; Miscellaneous articles in chemistry, not enumerated above, class 4.

DEPARTMENT M—*Miscellaneous Unclassified Articles.*

THE U. S. GEOLOGICAL SURVEY AND ITS WORK.

THE literature of geology has grown to large proportions. To obtain a detailed and comprehensive knowledge of the reported facts and the discussions based thereon is a task of magnitude. In territories governed by civilized nations geologic research is actively prosecuted, and geologists are penetrating the lands inhabited by savage and barbaric tribes; and thus a large body of men are engaged in geologic investigations. From year to year more refined methods of study are introduced, and new classes of facts are discovered; and the old fields are ever becoming new fields for examination. So the literature, already great, is rapidly increasing, and its prospective magnitude is such as to demand of geologists the adoption of all methods and devices that will secure economy of time and thought to scholars and students. The U. S. Geological Survey is working exactly within the limits and ambitions of this spirit. The last published report by the able director of the survey, Mr. John W. Powell, of Illinois, is for the fiscal year ending June 30th, 1881, and forms the second annual report. From its pages we learn that the following reports exhaustively made were printed or about to be printed.

TERTIARY HISTORY OF THE GRAND CANON DISTRICT OF COLORADO by Captain C. E Dutton. In his report he does not undertake to give an exhaustive account of the entire range of the geology of the district, but limits himself to the discussion of its Tertiary history and of the problems of physical geology involved therein. This work is illustrated by Mr. W. H. Holmes.

THE HISTORY OF LAKE BONNEVILLE by Mr. G. K. Gilbert. Mr. Gilbert's study of Lake Bonneville, the lake which during Quaternary time occupied the desert basin of western Utah, was begun ten years ago, at which time he was attached to the geographic corps of Capt. George M. Wheeler, of the United States Engineers. Since that time his duties as a member of the Survey of the Rocky Mountain Region have carried him repeatedly to the same district and permitted him to continue his study of the ancient lake. He had thus accumulated before the organization of the present Survey a considerable body of facts, and had already published an outline of the subject. As a member of the new organization he has devoted his time almost exclusively to this research, complementing the material previously gathered and setting at rest the greater number of the questions that had been raised. His field investigation was completed in 1880, and he has now finished a monograph on the subject.

GEOLOGY OF THE EUREKA DISTRICT by Mr. Arnold Hague. The field of Mr. Hague's researches, known as the "Eureka District," is in Central Nevada, and embraces a tract about twenty miles square. Mr. Hague's report will constitute an important contribution to structural geology and will contain valuable information in economic geology.

GEOLOGY OF LEADVILLE by Mr. S. F. Emmons. From the date of its organization the Geological Survey has been engaged in prosecuting investigations in economic geology; that is, in researches having in view questions of immediate and direct importance to the mining industries of the country. All wisely conducted geologic investigations ultimately result in a practical benefit to mining and correlated industries. The influence of general geology—that is, structural geology, with the aid of paleontology—is indirect, while that of mining geology is direct. But mining geology is superficial and almost valueless unless it has a solid foundation in structural geology. The occurrence, magnitude, and value of all ore deposits are primarily related to geologic structure. The laws of this relation are but partly known, as the science of mineral deposits is but imperfectly developed, but every year adds new facts, and many of these which will be contributed during 1882 will be from the admirable researches of Mr. Emmons. An abstract of his work can be found in another part of this volume.

GEOLOGY OF THE COMSTOCK LODE by Mr. G. F. Becker. The Comstock Lode is in every respect a remarkable occurrence. The fact of its enormous production is familiar, but it is not equally well known that its vertical workings are carried to a greater depth than any in the world except those of Przibram, in Bohemia. It also presents scientific problems of equal obscurity and interest, which have attracted great attention. It would be a reproach to American geology to leave the character of so prominent a mining district unsettled, and the present investigation was undertaken in the hope that the additional facilities presented by the great extension of the mine workings during late years and by recent advances in science would permit a more satisfactory solution than has yet been reached.

NEW METHOD OF HYPSOMETRY by Mr. G. K. Gilbert. Not only the present Geological Survey but its predecessors in the same field have been compelled to make maps for their own use, and in this way have come to perform an amount of geographic work which has proved even more expensive than the geologic investigations to which it is accessory. Although a geologist by profession, Mr. Gilbert has been called upon from time to time, and especially as a member of the Survey of the Rocky Mountain Region, to conduct geographic work, and this paper is the embodiment of the results of a series of investigations initiated in connection with those duties.

The adoption of a nomenclature is to an important extent an attempt to establish the categories of classification; but every stage in the progress of knowledge is marked by a stage in the progress of classification, and any attempt to fix permanently the categories for a nascent science must be futile. In so far, then, as proposed uniform methods of nomenclature and representation are designed to establish the fundamental categories, no good can be accomplished. On the other hand, useful results can be obtained by the employment of a uniform nomenclature and system of representation in the presentation of like facts. From time to time new classifications will be advanced, and new terms for more refined distinctions must be multiplied *pari passu* with the growth of the science, but diverse terms for the same classes and distinctions should be eradicated. A multiplication of means for like purposes in the presentation of scientific subjects is a characteristic of low development, in the same manner as is the multiplication of organs for like purposes in a living being. Economy of time and thought is the goal to be attained. As of interest, in this connection, we present here the General Scheme adopted in all of its work and publications:

ERA OR SYSTEM.	*Period or Group.*	Epoch or Formation.
Era of Man	Quaternary	To be formulated in various districts as the facts demand.
Cenozoic or Tertiary	Pliocene	
	Minocene	
	Eocene	
Mesozoic	Cretaceous	
	Jurassic	
	Triassic	
Paleozoic	Permian	
	Carboniferous	
	Devonian	
	Silurian	
	Cambrian	
Archæan	Huronian?	
	Laurentian?	

The cost of the work prosecuted by the Survey was given as follows during the fiscal year, June 30, 1880, to June 30, 1881.

Amount appropriated by Congress for the use of the Geological Survey for the fiscal year ending June 30, 1881	$156,000 00
Expended during the fiscal year	150,948 47
Remaining on hand June 30, 1881 (required to meet outstanding liabilities)	5,051 53

The following is a classification of the expenditures:

	Amount.
Salary of Director	$6000 00
Services of assistants and employes	101,392 43
Rent of offices	3,760 93
Repair of offices	101 35
Office furniture	2,495 52
Fuel	1,034 04
Gas	217 80
Ice	53 47
Telegrams	858 14
Rent of telephones	82 00
Rent of post-office boxes	50 00
Stationery	1,695 62
Drawing material	277 45
Books	171 35
Instruments purchased	1,171 03
Instruments repaired	285 30
Laboratory supplies	1,998 63
Photographic material	256 03
Publication of maps	175 00
Illustrations for reports	727 00
Job printing	36 00

Transportation of assistants and properties	7,825 40
Traveling expenses	6,768 94
Purchase of horses	240 00
Purchase of mules	930 00
Camp and field equipage	1,190 51
Subsistence	6,626 90
Forage	2,338 83
Pasturage	597 94
Tollage	32 47
Storage	331 93
Apprehension and delivery of lost public property	95 00
Miscellaneous	1,131 46
Total	150,948 47

THE MINING AND SCIENTIFIC PRESS OF THE UNITED STATES.

SOME of our readers will doubtless want to know just where to lay their hands on the publications that pertain strictly to mining interests and matters of science. We therefore furnish here some facts concerning the mining and mechanical press of the United States, which is not, perhaps, as full as it could be made. We also add some notes upon publications that can hardly be said to belong to the mining press and yet are of great importance. The publications of the Government are very elaborate works abounding in exact scientific information, but the volumes are often exceedingly difficult of attainment, and their size prevents any general circulation. Some documents are to be had for the asking, in cases where the applicant is the least bit interested. Prominent among these are the

ANNUAL REPORT UPON THE PRODUCTION of PRECIOUS METALS IN THE UNITED STATES, by Horatio C. Burchard, Director of the Mint. This volume is full of information gathered by Government officials. It will be published in September, 1882, and covers the production of precious metals between Jan. 1, 1881 and Jan. 1, 1882. To be had free at Washington.

THE ANNUAL REPORT OF THE DIRECTOR OF THE MINT. Covering the coinage of the country, and various reports on the coinage of other countries. This is issued in November of each year for the fiscal year, ending on the previous 30th of June. To be had free at Washington.

ANNUAL REPORT OF THE AMERICAN IRON AND STEEL ASSOCIATION. Prepared by James M. Swank, Secretary, and published annually in June. This is always able and reliable. To be had at 261 south Fourth street, Philadelphia, price, $2.00. Tenth annual issue this year.

THE COAL TRADE—By Frederick E. Saward. A handy compilation containing facts and figures regarding the Coal Trade. Issued annually in April. This year is the ninth year of publication. Price 50 cents. Published at 111 Broadway, New York.

ANNUAL REVIEW OF THE COPPER AND IRON PRODUCTION OF LAKE SUPERIOR.—Issued annually in July by A. P. Swineford & Co., Marquette, Michigan. Price 50 cents.

TRANSACTIONS OF THE AMERICAN INSTITUTE OF MINING ENGINEERS.—These very valuable publications are issued yearly by the Institute. Now in the tenth year of publication. Contains the papers read by the Members of the Institute at the different meetings. To be had from the Secretary, Easton, Pa. Price $5.00 per volume.

THE IRON AGE.—A Review of the Hardware, Iron and Metal Trades. Published every Thursday by David Williams, 83 Reade Street, New York City. Now in its 29th volume. This in the Iron Trade is the leading paper. Price $4.50 a year.

THE ENGINEERING AND MINING JOURNAL.—Published every Saturday by the Scientific Publishing Company, 27 Park Place, New York City, Richard P. Rothwell, C. E. M. E., Rossiter W. Raymond, Ph. D., Charles Kirchoff, J. M. E., editors. In the 34th volume. The leading paper in its line. $4.00 a year.

THE MINING RECORD.—Published every Saturday by A. R. Chisolm, at 61 Broadway, Mr. Thomas Jordan, editor. Publishes a good deal of news and is an ardent advocate of Bi-Metalism. Now in its 12th volume. $4.00 a year.

VAN NOSTRAND'S ENGINEERING MAGAZINE.—Published monthly. Now in its 26th volume. Established in 1869. Published by D. Van Nostrand, 23 Murray and 27 Warren Streets, New York City. $5.00 a year.

BULLION.—Published monthly at 42 Broad Street, New York City. A Monthly Statistical Review of labor, trade and money. In its 7th volume. $3.00 a year.

MAINE MINING JOURNAL.—Published every Friday at 28 West Market Square, Bangor, Maine. $2.00 a year. A paper representing the Mining Interests of Maine, New England and Nova Scotia.

THE ECONOMIST.—Published every Saturday at Boston and New York. A financial, political, railway, trade and mining weekly. In its 7th volume. $3.00 a year. R. E. Straine Proprietor, 31 Milk Street, Boston.

THE BULLION MINER.—Published every Saturday by The Bullion Miner Publishing Co., 123 S. 3d street, Philadelphia. In its 5th volume. $3.00 a year.

THE MINING JOURNAL.—Published every Saturday by The Mining Journal Co., 330 Walnut street, Philadelphia. In its 3d volume. $2.50 a year.

CHICAGO MINING JOURNAL.—Published monthly by the Western Mining Bureau, 78 Dearborn street Chicago. In its 2d volume. $1.00 a year.

THE MINING REVIEW.—Published every Saturday by the Mining Review Co., Times Building, Chicago. In its 7th volume. $3.00 a year.

THE MINING JOURNAL.—Published every Saturday by A. P. Swineford & Co., Marquette, Michigan. Devoted to the Iron and Industrial Industries of the County of Marquette. Established in 1846. $3.00 a year.

MINING INDEX.—Published every Saturday by A. F. Wuensch, No. 300 Harrison Avenue, Leadville, Colorado. In its 2d volume. $4.00 a year.

ROCKY MOUNTAIN MINING REVIEW.—Published every Thursday by James R. Ives, 422 Curtis Street, Denver, Colorado. In its 6th volume. $4.00 a year.

MINING AND SCIENTIFIC PRESS.—An illustrated Journal of mining, popular science and general news. Published every Saturday by Dewey and Co., 202 Sansom street, San Francisco. In its 40th volume. $4.00 a year.

COAL.—A weekly Journal of the coal trade. Published every Wednesday by the Scientific Publishing Co., 27 Park Place, New York City. In its 1st volume. $2 a year.

THE COAL TRADE JOURNAL.—Published every Wednesday by Frederick E. Saward, at 111 Broadway, New York City. A valuable organ of the coal trade. Established in 1869. Now in its 21st volume. $3.00 a year.

THE SCIENTIFIC AMERICAN AND SCIENTIFIC AMERICAN SUPPLEMENT.—Published every Saturday by Munn & Co., 261 Broadway, New York City. Now in its 47th volume. Scientific American $3.20 a year. Supplement $5.00 a year.

THE VIRGINIAS.—Published monthly by Jed Hotchkiss at 346 E. Main street, Staunton. Virginia. A Mining Industrial and Scientific Journal. In its 4th volume. $2.00 a year.

In addition to these all of the daily papers of the extreme Western States, furnish Mining News and most of the Eastern dailies do the same. A further list of somewhat similar publications to the above is furnished here:

American Journal of Science and Arts (monthly), Scien., New Haven. Forest, Forge and Farm (monthly), Mech., Ilion, N.Y. American Gaslight Journal (semi-mo.), Scien., New York. Engineering News, Mech., New York; Illustrated Scientific News (monthly), Sci. and Mech., New York. Mechanical Engineer (bi-weekly), Mech., New York. Mechanical News (semi-mo.), New York. Mechanics, Mech., New York. Metal Worker, Mech., New York. Science, Scien., New York. Scientific Man, Scien., New York. Transactions of the American Society of Civil Engineers (monthly), Eng., New York. Young Scientist (mo.), Scien., New York. Journal of the Franklin Institute (monthly), Scien., Philadelphia. North American Manufacturer, Mech., Philadelphia. American Manufacturer and Iron World, Mech., Pittsburg. Brick, Tile, and Metal Review (monthly), Pittsburg. Mechanic, Mech., Smithville. Mechanical Journal (mo.), Mech., Indianapolis.

American Engineer (monthly), Mech., Chicago. Journal of Science (mo.), Scien., Chicago. Northwestern Mining Journal, Mech., Hancock. Portage Lake Mining Gazette, Mech., Houghton. Miner, Mech., Ontonagon. Review of Science and Industry (monthly), Scien., Kansas City. Age of Steel, St. Louis. Wood and Iron (mo.), Mech., Minneapolis. Scientific Canadian, Mech., Montreal.

THE CALIFORNIA MINING BUREAU.

THE California State Mining Bureau is the creation of the twenty-third Legislature of the State of California. The bill—which is given in full below—originated in the Assembly. It was introduced by Honorable Joseph Wasson, representing the counties of Mono and Inyo:

AN ACT TO PROVIDE FOR THE ESTABLISHMENT AND MAINTENANCE OF A MINING BUREAU.—Approved April 16, 1880.

The People of the State of California, represented in Senate and Assembly do enact as follows:—

SECTION 1. There shall be and is hereby established in this State, a Mining Bureau, the principal office of which shall be maintained in the City of San Francisco, at which place there shall be collected by the State Mineralogist, and preserved for study and reference, specimens of all the geological and mineralogical substances, including mineral waters, found in this State, especially those possessing economic or commercial value, which specimens shall be marked, arranged, classified, and described, and a record thereof preserved, showing the character thereof, and the place from whence obtained. The State Mineralogist shall also, as he has opportunity and means, collect, and in like manner preserve at said office, minerals, rocks, and fossils of other States, Territories, and countries, and the collections so made shall at all reasonable hours be open to public inspection, examination and study.

SEC. 2. It shall be the duty of the Governor to appoint a citizen of this State having a practical and scientific knowledge of mining and mineralogy, to the office of State Mineralogist, to hold his said office for the term of four years, or until the appointment and qualification of his successor, who shall take and subscribe the oath of office prescribed by the Constitution, and who shall receive for his services a salary of three thousand dollars per annum, to be paid as other officers of the State are paid, and shall also receive his necessary travelling expenses, when travelling on the business of his office, to be allowed and audited by the State Board of Examiners, the whole to be paid out of the Mining Bureau Fund hereinafter provided for, and not otherwise.

SEC. 3. In addition to the collection, classification, arranging, and preservation of specimens, as provided in the first section of this Act, it shall be the duty of the State Mineralogist to make analytical assays as required; and when the funds in the Mining Bureau Fund are sufficient therefore, to provide and maintain a library of works on mineralogy, geology, and mining; to arrange in cases such specimens as he may collect; to procure and preserve models and drawings of mining machinery, and of milling machinery used in the production of ores; to correspond with established schools of mining and metallurgy, and obtain and preserve for public inspection and use, such information respecting improvements in mining and mining machinery as will be of practical value to the people of this State; to visit the several mining districts of each county of the State, from time to time, ascertain and record their history, describe their geological formation and altitudes, the character of the mines and ores, and the general development of the district. At the close of each year he shall make a report in detail to the Governor, showing the amount of disbursements of the Bureau under his charge, the number of specimens collected, and giving such statistical information in reference to mines and mining as shall be deemed important.

SEC. 4. The State Mineralogist may, from time to time, and as the funds in the Mining Bureau Fund will permit, appoint such assistants as he may deem necessary and proper for the carrying out of the objects of this Act, and the efficient provision and maintenance of a Bureau of mining information and statistics, and may procure and maintain the necessary rooms and furniture for the office and uses of the Bureau in San Francisco; but the entire expenses of the Bureau for salaries, assistance, rents, furniture, fuel and all other things pertaining to the Bureau, must not, in any one year, be greater than can be paid out of the mining Bureau Fund herein provided for.

SEC. 5. For the purpose of establishing a fund for the maintenance of the said Mining Bureau, it shall be the duty of the Tax Collectors in the several counties in this State, and of the License Collector of the City and County of San Francisco, on the second Monday in January, April, July and October, in each year, to transmit by express to the State Treasurer all money collected by them from mining corporations, or from corporations formed for milling ores, or for supplying water for mining purposes, under or by virtue of the Act entitled "An Act imposing a tax on the issue of certificates of stock corporations," approved April first, eighteen hundred and seventy-eight, and to forward to the State Controller by mail a certificate showing the amount of money so forwarded to the State Treasurer, and the date when the same was transmitted, and also showing the names of the several corporations from which the same was received, and the amount received from each. The State Treasurer shall receive the amounts so transmitted, and give duplicate receipts therefor, one of which shall be filed with the State Controller, and the other shall be returned by mail, or return express, to the Collector from whom the money was received; and after paying out of the money so received the charges for the transmission thereof, the amount of which shall be noted on the receipt filed with the State Controller, he shall retain the remainder in his hands as a separate fund, to be known as the Mining Bureau Fund, to be used only in payment of drafts made for the expenses of the Mining Bureau established under the Act, and out of which all the expenses of said Bureau shall be paid.

SEC. 6. Such Tax Collectors and License Collectors shall hereafter be required to pay into the county treasuries of their respective counties only that portion of the moneys collected by them under the Act of the Legislature mentioned in the last preceding section, which is collected from corporations other than those mentioned in section five of this Act.

SEC. 7. This Act shall take effect and be in force from and after its passage.

The present State Mineralogist, Henry G. Hanks, was appointed by the Governor in May following the passage of the bill, his commission bearing the date of May fifteenth, eighteen hundred and eighty. The first step taken toward the establishment of the Bureau was the temporary occupation of a small room, in the building number six hundred and nineteen Montgomery street. It was found difficult to obtain rooms suitable for the use of the Bureau. After examining many, a suite was finally selected which, although falling far below the requirements of a Museum worthy of the great State of California, is perhaps the best available at the present time for the purpose. The rooms at present occupied by the Bureau are on Pine street, number three hundred and thirteen, south side, between Sansome and Montgomery. They consist of a large main hall, lighted from above by a skylight, a spacious office and reception room for the State Mineralogist, an adjoining room, containing the nucleus of the reference library, a large storeroom, and one serving the double purpose of a chemical laboratory and for the preparation of specimens for the Museum. As it is expressly understood that the building is soon to be torn down and rebuilt, the occupation is considered as temporary, and no cases or fixtures have been or will be constructed which cannot be readily removed. Immediately on taking possession of the Pine street rooms, the following circular was prepared and extensively distributed, not only in California but also in the adjoining States and Territories. Another setting forth briefly the objects and plans of the State Mining Bureau, and containing the full text of the bill, was sent to scientific institutions and individuals, both in the United States and in foreign countries:

CALIFORNIA STATE MINING BUREAU,
Office of State Mineralogist, San Francisco.

DEAR SIR: By an Act of the Twenty-third Legislature there has been established in the City of San Francisco a State Mining Bureau, and a State Mineralogist appointed by the Governor, authorized to carry out the provisions of the law. As it is an institution new to the people, this circular is prepared to set forth the objects and aims of the Bureau, and at the same time to request the co-operation of all who are interested in the development of the mining interests of the State. The law would on first thought seem exclusive, yet its scope is liberal as to the mining interests of "other States, Territories, and countries," as the tax for the support of the institution comes from the stock of the companies operating in the world at large, but who have their transfer and chief offices in the mining metropolis and cosmopolitan city of California. It is proposed to make the State Bureau of Mining a depository of useful and interesting information in every department.

Heretofore, mining in California, and throughout the country generally, has been chiefly confined to the precious metals, while the State and coast at large are rich in many other minerals possessing great economic value in connection with the arts and manufactures. Now that railroads are being built which offer increased facilities for transportation, the utilization of mineral substances hitherto considered worthless, is no longer a problem. Old mines and mining districts that were abandoned because inaccessible, and for want of cheap and rapid transportation, are again attracting attention. As speedily as possible everything bearing on these subjects in the way of practical and reliable information will be gathered into the State Bureau, to which the public will have free access at reasonable hours during every legal day of the year. The State Mineralogist is empowered to employ scientific and practical assistants, as the funds will permit, to operate in the field, and there will be new and interesting matter constantly added, such as maps, statistics, reports, surveys, etc., besides a collection of all the ores, minerals, fossils, rocks, metallurgical products, building stones, etc., of the Pacific Coast, with models of mining machinery in use and newly invented, and a general collection of ores and minerals of other countries for reference. It is intended to include everything that pertains to practical and legitimate mining.

The Bureau will constitute an historical repository, and all maps, reports, volumes of newspapers, copies of district laws and records, however old and seemingly out of date, will be sought for and preserved; many, if not all such documents, will be found to possess value outside of their rarity, involving as they may, questions of title to valuable property, neglected or idle. The Museum of Practical Geology will be made a special feature of the Bureau, and all contributions will be duly accredited, displayed, and preserved. A feature of leading interest will be the procuring and exhibiting of models of mining machinery; all that is interesting, whether old or new, will be carefully preserved and shown. Inventors are specially requested to exhibit models in the rooms of the Bureau, which will also include a reading-room, where the press will be represented, and a reference library of works on mineralogy, geology, metallurgy, and kindred subjects will be collected. The State Mineralogist has secured for an indefinite period the central, commodious, and well appointed rooms formerly occupied by the San Francisco Art Association, No. 313 Pine street, near Sansome, which he will occupy on the first of June. Satisfactory arrangements with the principal transportation and express companies have been made, whereby persons contributing articles of value and interest can forward such without expense to themselves. The law requires that all mineral waters or springs throughout the State be examined, their value and characteristics ascertained, and the information duly published. This will materially increase the interest of the world at large in California as a health resort.

It is desired to make the ethnology of the Pacific Coast a feature of the Museum. All Indian relics, recent or prehistoric, will find a place, and their collection will no doubt throw much light on the ancient history of the State. It is the intention of the Bureau to make sooner or later, a thorough industrial survey of the State. As every county is, to a certain extent, a mining county, all should be represented, and the prominent men of each are requested to see that the State Museum is provided with a full representation of the mineral resources of the county in which they reside. As every article of value sent to the Bureau will become the property of the State for the use and benefit of the public, and will be carefully preserved in the State Museum, and as it is desirable to make it as instructive and attractive as may be, donations of other articles of interest, such as views, pictures, paintings, curiosities, and works of art—in short, anything which would add to the general interest of the Bureau and tend to make the Museum a popular resort for information and study, are solicited. The Bureau commences with a large and valuable donation of ores, rocks, fossils, reports, books, etc., the entire collection and property of the State Geological Society. Miners and prospectors are requested, when new finds are made, for better determination as to value and character, to always accompany ores with samples of the wall and country rocks, with written descriptions of the same. It is desirable that every mine in the State and adjoining States and Territories, which has a name, should be represented in the Bureau.

When anything occurs in the working of the Bureau that is of special or immediate interest, it will be given to the public through the medium of the press. Annual reports to the Governor will be printed for general distribution. These reports should be valuable for permanent reference.

The California State Geological Society was organized in January, 1877, and incorporated under the laws of the State. The following is an extract from the By-Laws of the Society:

Article I—Name. The Society shall be known as the "California State Geological Society."

Article II—Objects. The objects of the Society are:

1. To make a Pacific Coast geological collection, to be offered to the State of California gratis, upon such terms and conditions as the Society may determine, and as may be agreed upon.

2. To encourage the study of geology in all its branches.

Article III—Conditions. Among the conditions which shall be required by the Society before such collection mentioned in the preceding article shall be presented to the State of California, are the following:

The State of California shall provide suitable rooms where the collection may be kept, and shall provide cases to contain the same.

The collection shall remain in the City and County of San Francisco, and shall not be removed therefrom.

It shall always be open to the inspection of the public free of charge, during seasonable hours.

It becoming possible for the State to accept the collection upon these terms by the institution of the State Museum the whole property, including the collection aforesaid and the valuable library, were turned over to the State by the Society. The collection embraces one thousand three hundred and twenty-seven specimens from all parts of the Pacific Coast; many of them are of special value. The library numbers seventy-eight volumes and twenty-five pamphlets, including testimony, arguments, and decisions in the case of the Eureka Consolidated Mining Company vs. Richmond Mining Company, of Nevada, a large volume, of which there were but twelve copies published. The identical specimens used in Court in this important suit are included in the mineral collection, and have been placed in a separate case for ready reference. The collection represents a large amount of labor and money expended in acquisition and preparation of the specimens. The donation is therefore very valuable, and it is to be hoped will be followed by others. The Geological Society retains its organization, but all specimens, publications, and other collections made in the future will revert to the State Museum. The mineral interests of the State were represented at the Paris Exposition of eighteen hundred and seventy-eight. The collections attracted much attention, and won for the State a gold medal. The greater portion was donated to the French Government, in the name of the State of California, and is now in the Museum of the Ecole des Mines, in Paris. The specimens returned to the State after the Exposition naturally came into the possession of the Bureau. Both collections above referred to were delivered to the Mining Bureau packed in boxes. Although partially arranged, it required considerable labor to prepare them for the new Museum. This work was immediately commenced by the State Mineralogist and Lewis G. Larsen, who had been appointed Janitor.

The following is a correct showing of the contents of the cases: Four cases California minerals, two cases California gold ores, one case California silver ores, one case California lead ores and products of lead manufacture, one case California quicksilver ores, one case California chromic iron and products, one case California fossils, five cases California rocks, one case California copper ores and products, two cases Nevada minerals, one case Nevada rocks, one case Nevada ores, one case Nevada ores, Comstock mines; one case Nevada ores, illustrating suit between Eureka Con. and Richmond; one case Oregon and Washington Territory ores, minerals, and fossils; two cases Arizona ores and minerals, two cases ethnological, including Egyptian and other antiquities; two cases foreign minerals, three cases Eastern States minerals and ores, one case foreign paleontology, one case casts of rare fossils, two cases corals and shells, three cases not classified, owing to lack of case room.

On the tenth of June, Mr. Joseph Perkins was appointed Secretary and Accountant. From the commencement specimens of minerals began to come in and a general interest on the part of the citizens became manifest. Correspondence has also gradually increased, and questions on matters within the province of the Bureau are asked and answered daily. On the first of August, Mr. Edward Booth was appointed chemist, and the foundation of a chemical laboratory laid, which should be made in the future the best possible, as this department is of the highest importance. It has been the policy of the Bureau to collect maps of the counties of the State, and geological and mining maps generally, which has resulted in the acquisition of a large number. Some of them are now placed on the walls of the Museum, Library, and Office, for reference. While the work of the Bureau has been in progress several scientific gentlemen have been employed to prepare manuscript for publication on various subjects, all within the requirements of the Mining Bureau bill. The science of geology, to which all others are tributary, is so vast in its scope that no one human mind can fully grasp it in detail. It has been found necessary to divide the science into departments, and in many cases to subdivide into specialties. There are, in California, gentlemen who have devoted their lives to these departments, and to them the special work of the Bureau should be intrusted. Owing to the great amount of time and labor required to institute the Bureau, and to set the

Museum in operation, but little field work has been attempted. The State Mineralogist has, however, found time to visit the locality of "*roscoelite,*" near Coloma, Eldorado County, (a new mineral, of which but little is known), and to commence the study of the valuable iron deposits near Clipper Gap, in Placer County. He also visited a number of limestone quarries in the same county, the granite quarries at Penryn, and at Rocklin, the Thermal Springs, at Calistoga, in Napa County, and a number of mines in the counties of Placer and Eldorado, reports of which will appear in future publications.

In obtaining information relating to mines and mineral deposits in California, care has been taken to obtain the exact locality—section, township and range—with a view to place them eventually on a sectional map of the State. When any new discovery is announced in the columns of the press, or any information obtained otherwise by the Bureau, it has been the custom to write for specimens and more accurate information. Experience has shown that while many are willing to send desired specimens, but few are competent to do so. Many important things are overlooked that would attract the attention of a person of experience. Still the Museum has received many valuable additions by carrying out this plan. When any feature of special interest is thus developed, a memorandum has been made with a view to a thorough personal examination when time and the condition of the funds will permit. There have been many visitors to the Museum, but there is no way of estimating the number. Visitors do not register unless specially requested to do so. When the Museum becomes more important and extensive, there will be an attendant in charge, whose duty it will be to receive visitors, give information, and to keep a general supervision. When this is the case, no person will enter without registering name and residence. There seems to have been an impression that the Museum is a place suited only for mining men, while it is specially desirable that ladies and children, students of both sexes, strangers in the city, and the public generally, should make free use of it.

PART V.

STATISTICS OF AMERICAN COINAGE—HOW MONEY IS MADE —THE MONEY QUESTION—MONEY AND BI-METALISM —GOLD PRODUCTION—RELATIVE VALUES OF GOLD AND SILVER.

PERHAPS that thing among the vital necessities of our daily life about which we know the least is money. That is, for an object so precious and so striven after, it is singular how little is known concerning what it is and how it is made, and what effect it has upon the course of progress from an economic standpoint. The high-sounding platitudes that are constantly being uttered in daily papers upon the question of "remonetization," "double standard," "single standard," "bi-metalism" and "monometalism," are seldom understood by the writers of them, to say nothing of the readers.

In Part V. of the MINES, MINERS AND MINING INTERESTS OF THE UNITED STATES we present our readers with the last annual report of the Director of the Mint, the Hon. Horatio C. Burchard, which furnishes a good deal of information concerning coinage, both here and abroad. From Mr. Burchard's report we pass naturally to the silver question, which we endeavor to present clearly. The proceedings of the Assay Commission are also given, and the laws authorizing it. A number of important tables from various sources which supplement the coinage question conclude the part.

THE REPORT OF THE DIRECTOR OF THE MINT.

THE annual report of Horatio C. Burchard, Director of the Mint for the year ending June 30, 1881, contains the following: The bullion and coin received and operated upon during the year, at all the mints and assay offices, including redeposits, contained $193,371,101.01 of gold and $32,854,421.45 of silver, a total $226,225,522.46, exceeding in value the receipts of any previous year by more than $50,000,000. The reports and accounts submitted to this bureau show, during the year, deposits of gold of domestic production, $35,815,036.55; of plate jewelry, and worn coin, $1,784,207.90; and of foreign coin and bullion, $93,233,858; being a total of $130,833,102.45, and thirty-two millions in excess of the gold deposits of last year. The silver bullion deposits and purchases, including partings from gold, amounted at the coining value to $30,791,146.66, of which $28,477,059.21 consisted of domestic bullion, $2,046,576.80 of foreign coin and bullion, and $267,510.65 of plate, jewelry, and American coin. The following table shows the amount and character of the deposits:

	Gold.	Silver.	Total.
Domestic production	$35,815,036 55	$28,477,059 21	$64,292,095 76
United States coin . .	440,776 97	7,307 40	448,084 37
Foreign bullion	37,771,472 26	1,312,144 58	39,083,616 84
Foreign coin	55,462,385 74	734,432 22	56,196,817 96
Old jewelry, plate, &c.	1,343,430 93	260,203 25	1,603,634 18
Total . . .	$130,833,102 45	$ 30,791,146 66	$161,624,249 11

A portion of these deposits were manufactured at the institutions receiving them into bars, which were again deposited or transferred to other institutions for treatment or coinage. The redeposits for this purpose amounted to $62,537,998.56 in gold, and to $2,063,274.79 in silver. At the commencement of the fiscal year the coinage mints and assay offices held $40,724,337.91 of uncoined gold bullion. The deposits of the year, amounting to $130,833,102.45, increased the stock of bullion available for coinage to $171,557,440.36. The value of the total gold coinage of the year was $78,733,864, and of the gold bullion uncoined at its close, $86,548,696.96, a portion of the deposits having been paid in fine bars. The silver coinage amounted to $27,649,966.75, of which $27,637,955 were silver dollars, and 12,011.75 proof silver coins of other denominations. The coinage of gold into smaller denominations than heretofore executed was continued, only $15,345,520 in double eagles having been struck, while the eagles and half eagles amounted to $63,371,230. Nearly all the gold produced on the Pacific coast was deposited and coined at the San Francisco Mint, while the principal part of the gold coined at the Philadelphia Mint consisted of New York Assay Office bars manufactured from imported bullion and coin. The number of pieces and the value of the total coinage were as follows:

	Pieces.	Value.
Gold . .	10,111,115	$78,733,864 00
Silver	27,698,820	27,649,966 75
Minor . .	38,335,665	405,109 95
Total . .	76,145,600	$106,788,940 70

The comparative values of the coinage of gold, silver, and minor coins executed during the fiscal year and the calendar year 1880 are as follows:

	Calendar Year 1880.	Fiscal Year 1881.
Gold	$62,308,279 00	$78,733,864 00
Silver	27,409,706 75	27,649,966 75
Total . .	$89,717,985 75	$106,383,830 75
Minor	391,395 95	405,109 95
Total coinage	$90,109,381 70	$106,788,940 70

The gold coinage of the mints prior to the year 1873 has been grouped and tabulated into three divisions. The first embracing the forty years from the commencement of coinage at the Philadelphia Mint in 1834 to the time of the change in the ratio of gold and silver and the reduced valuation of the gold dollar to correspond therewith, during which period $11,915,890 of gold were coined. The second from 1834 to 1849, when gold from California first began to arrive at the mints, adding $64,425,550 to the gold coinage. The third from 1849 to 1873, during which time $740,564,438.50 were coined. The coinage of silver before 1873 is separated into two periods: The first containing the coinage prior to 1853, during which time all the silver coins amounting in value to $79,213,371.90, were full weight and unlimited legal tender. The second from 1853 to 1873, when fractional silver of reduced weight and limited tender to the amount of $60,389,564.70 was coined on government account; but, although the mints were open to individuals for the coinage of full-weight silver dollars, only $5,538,948 of the latter were coined. Fine, standard, sterling, and unparted bars were manufactured during the year to the value of $100,750,649.94 in gold and $6,542,232.35 in silver. At the New York Assay Office $89,643,135.29 of gold deposits were made into bars for conversion into coin at the mint at Philadelphia. The value of fine gold bars manufactured at the mints and assay offices was $10,041,482.78 and of the unparted bars $1,066,031.87. Of the silver bars $5,857,276.98 were fine, $77,611.39 were standard and sterling, $88,296.45 unparted and $519,047.53 made at the New York Assay Office and transmitted to Philadelphia for coinage. During the year, 11,449,704.19 gross ounces of bullion, containing both gold and silver or base metals, were sent to the acid refineries of the coinage mints and assay office at New York for parting or refining, from which were separated or refined 1,295,443.259 ounces of standard gold and 9,774,730.86 ounces of standard silver. The following table exhibits in detail the gross ounces of bullion sent to the respective refineries and the ounces of standard gold and silver received therefrom:

Ounces.

Mint or assay office.	Gross.	Standard gold.	Standard silver.
Philadelphia	535,770 27	125,700 460	389,617 83
San Francisco . . .	6,507,762 50	612,429 779	5,591,629 12
Carson	525,785 05	27,819 475	607,723 00
New Orleans . . .	13,886 37	2,793 545	11.860 91
New York	3,866,500 00	526,700 000	3,273,900 00
Total	11,449,704 19	1,295,443 259	9,774,730 86

Value.

Mint or assay office.	Gold.	Silver.	Total.
Philadelphia	$ 2,338,613 21	$ 453 373 47	$2,791,986 68
San Francisco . .	11,394,042 40	6,506,622 98	17,900,665 38
Carson	517,571 62	590,804 94	1,108,376 56
New Orleans	51,972 93	13,801 78	65,774 71
New York	9,799,069 76	3,809,629 09	13,608,698 85
Total . .	$24,101,269 92	$11,374,232 26	$35,475,502 18

At the commencement of the last fiscal year there were on hand in the coinage mints and New York Assay Office 5,403,980 ounces of standard silver bullion, worth at its coining value, $6,283,613. This bullion in part consisted of 1,750,000 standard ounces procured prior to the passage of the resumption act, under the provisions of section 3545 of the Revised Statutes, and held as part of the bullion fund for the immediate payment of silver deposits in Silver bars. A further portion, amounting to 2,500,000 standard ounces, had been purchased subsequent to January 14, 1875, the date of the resumption act, for the coinage of subsidiary silver, under the provisions of that act, or had been parted from gold or received in payment of charges on silver bullion, under sections 3520 and 3506. The remainder, about 1,400,000 standard ounces, was obtained by direct purchase for the coinage of the standard dollar, or in the settlement for silver parted from gold, and in payment of charges on silver deposits. Notwithstanding the regular monthly coinage of 2,300,000 and upwards of silver dollars, the purchases and deposits had increased the silver bullion on hand January 1, 1881, to 6,553,350 standard ounces, the cost of which was $7,145,487, and its coinage value $7,625,717. Of this amount, 2,928,752.49 standard ounces were at the Philadelphia Mint. The limit of subsidiary coinage having been reached, no necessity existed for keeping on hand any silver for such coinage. It was, therefore, considered advisable by the Secretary of the Treasury to use in the silver-dollar coinage the balance of silver that had been procured for the subsidiary coinage, and to reduce the amount of monthly purchases, especially at the Philadelphia Mint, where, in view of the heavy amount of gold coinage required, it was thought that sufficient silver bullion had already been accumulated for the probable silver coinage of that mint during the remainder of the fiscal year. By including the 2,250,000 ounces of standard silver as belonging to the account of purchased silver, to be used in the coinage of the standard dollar, it became necessary to reduce the amount on hand, so that not more than $5,000,000 above the resulting coinage should be invested in such purchases. The weekly purchases of the department were, therefore much lighter during February and the succeeding months of the year. In the month of May, owing to the higher prices asked and the small amounts offered for delivery at the Pacific coast mints, the weekly purchases of silver bullion were reduced for San Francisco and resumed at the Philadelphia Mint. To enable the Philadelphia Mint to employ as much of its force as possible in the coinage of gold, the monthly allotment of silver coinage for the New Orleans Mint was increased and that for the Philadelphia Mint lessened, and to procure sufficient bullion to execute the required coinage at the New Orleans Mint, the owners of silver bullion were solicited to bid and send their bullion for delivery at that mint.

The prices for delivery in lots of less than ten thousand ounces at the New Orleans Mint were also fixed from time to time by the Director of the Mint, slightly below the equivalent of the London price, and notices of the rates and changes were given to the smelting and refining works in the Western States nearest to the mint, with the hope of inducing them to deliver their silver bullion at New Orleans. Two of these refineries have availed themselves of the advantages of direct shipment, saving the previous expense of double transportation to and from the Atlantic sea-board and benefiting the Government as well as themselves. The purchases during the year, of silver bullion, were 21,904,351.54 standard ounces, at a cost of $22,339,728.67. The silver received for charges and parted from gold and paid for as provided by sections 3520 and 3506 of the Revised Statutes, costing $239,183.05, was 232,568.85 standard ounces, making the total amount purchased 22,136,920.39 standard ounces, at the cost of $22,578,911.72. From the silver purchases of the year and the 2,250,000 standard ounces, directed to be used and carried into the silver purchase account, 23,751,368 standard ounces, exclusive of silver bullion wasted and sold in sweeps, were consumed in the coinage of 27,633,955 standard dollars, being an average monthly coinage of $2,303,166. The London price of silver, during the year, averaged 51$\frac{15}{16}$ pence, which with exchange at par ($4.8665) equals $1.13852 per ounce, and at the New York average monthly price of sight exchange on London (4.847) equals $1.13508 per ounce fine. The New York average price of silver during the year was $1.12957 per ounce fine. The following statement shows the purchases at the coining mints and the New York Assay Office.

Mint or assay office at which delivered.	Purchases.		Partings and received for charges.		Total purchased.	
	Standard ounces	Cost.	Standard ounces.	Cost.	Standard ounces.	Cost.
Philadelphia .	6,322,103 90	$ 6,458,604 34	21,726 01	$ 21,726 01	6,343,829 91	$ 6,480,330 35
San Francisco	10,236,685 17	10,412,523 54	73,373 57	73,629 04	10,309.968 74	10,486,152 58

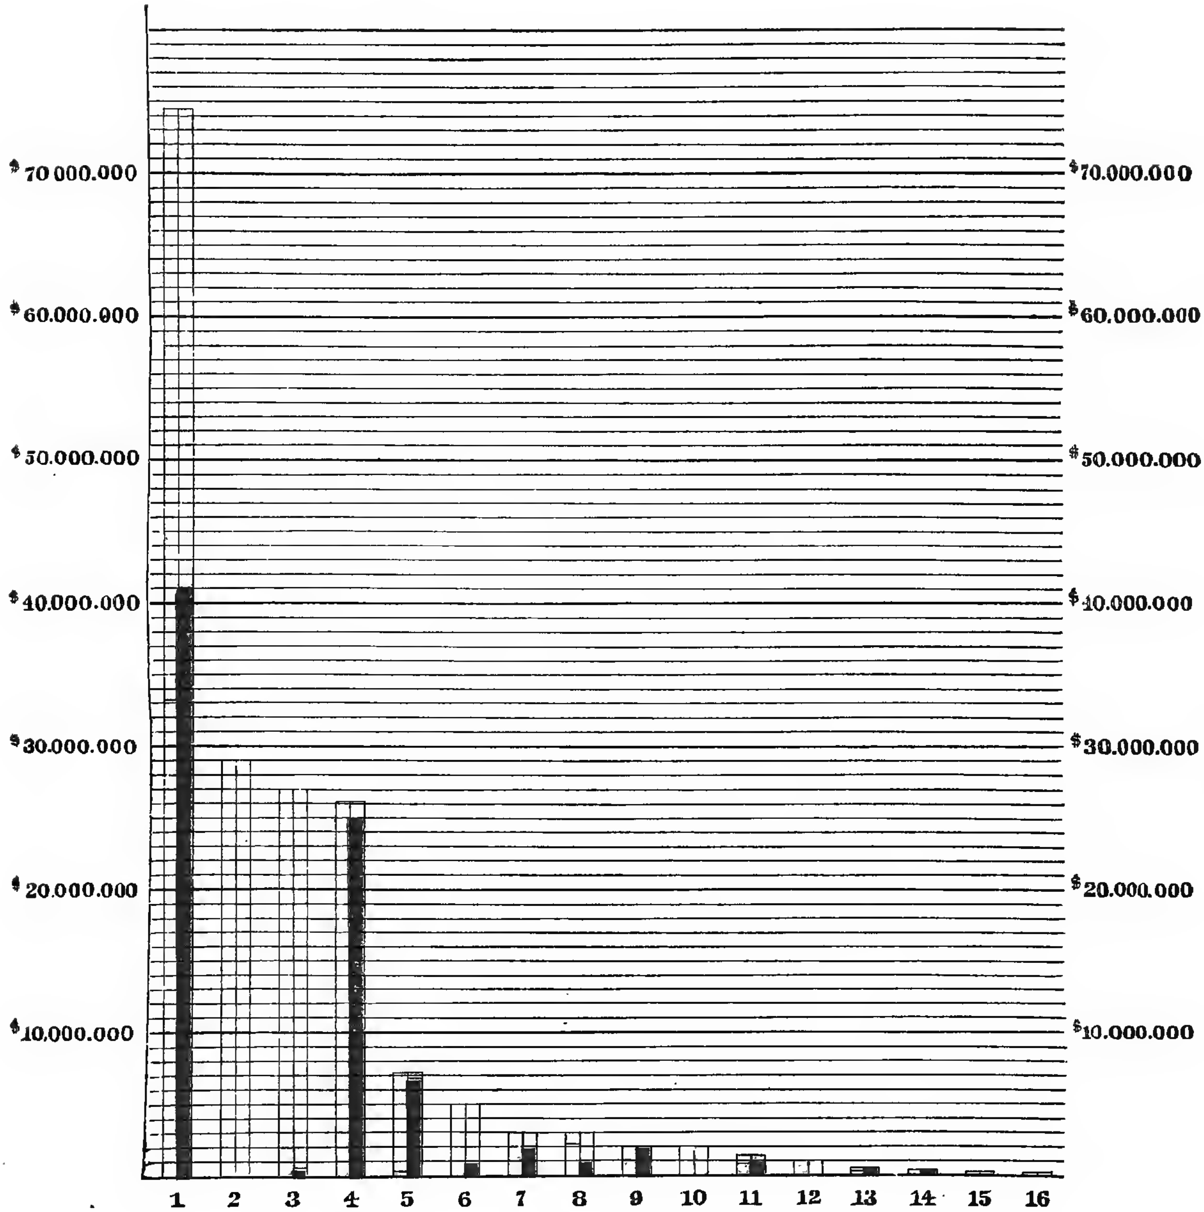
ANNUAL PRODUCT of the WORLD.

(POLITICAL DISTRIBUTION.)



1. UNITED STATES. 2. AUSTRALIA. 3. RUSSIA. 4. MEXICO. 5. GERMANY. 6. COLOMBIA. 7. AUSTRIA. 8. SOUTH AMERICA, EXCEPTING COLOMBIA AND THE ARGENTINE REPUBLIC. 9. EUROPE, EXCEPTING RUSSIA, GERMANY, AUSTRIA, NORWAY, ITALY AND SWEDEN. 10. AFRICA. 11. JAPAN. 12. BRITISH COLUMBIA. 13. ARGENTINE REPUBLIC. 14. NORWAY. 15. ITALY. 16. SWEDEN.

The areas in old gold indicate gold, those in light blue, silver; the relative totals being shown by the extreme height of each column.

Including the amounts paid out at the mints and exchanged for gold as provided by law, $17,706,924 of the 27,637,955 silver dollar coinage of the year, have been transmitted and distributed. The amount of standard dollars in the mints at the close of the fiscal year, including $2,000,000 received at the New Orleans Mint, and $1,000,000 at the Philadelphia Mint from assistant treasurers, was $23,341,000.60, of which nearly $16,000,000 was in the San Francisco Mint. The coinage and distribution at each mint, as shown by their statements to this bureau, appear in the following table:

	Philadelphia.	*San Francisco.*	*Carson.*	*New Orleans.*	*Total.*
On hand June 30, 1880	$ 875,942	$ 5,469,769	$1,119,700	$2,944,618	$10,410,629
Coinage of year	9,113,955	11,460,000	539,000	6,525,000	27,637,955
Total	$9,989,897	16,929,769	$1,658,700	$9,469,618	$38,047,984
In mints June 30, 1881	* 1,250,802	15,941,135	1,060,991	†5,088,132	23,341,060
Distributed	$9,739,095	$ 988,634	$ 597,709	$ 6,381,486	$17,706,924

* Includes $1,000,000 transferred from the Treasury. † Includes $2,000,000 transferred from the Treasury.

Besides the standard dollars remaining in the mints at the close of the year, considerable amounts had been deposited in the Treasury for the payment of outstanding silver certificates. The following table, compiled from the Treasurer's monthly statements of assets and liabilities, shows in six months' periods from the commencement until the close of the last fiscal year and up to November 1st, 1881, the amount (including that in the mints) in the Treasury, held for the payment of silver certificates and for other purposes and the amount in general circulation:

Period.	*Total coinage.*	*In the Treasury.*			*In circulation.*
		Held for payment of certificates outstanding.	*For distribution.*	*Total.*	
July 1, 1880	$63,734,750	$5,789,569	$38,635,746	$44,425,315	$19,309,435
January 1, 1881	77,453,005	36,127,711	12,062,807	48,190,518	29,262,487
July 1, 1881	91,372,705	39,110,729	23,433,993	62,544,722	28,827,983
November 1, 1881	100,672,705	58,838,770	7,737,608	66,576,378	34,096,327

The total appropriations for the support of the mints and assay offices during the fiscal year ending June 30th, 1881, amounted to $1,178,250, out of which the sum of $1,160,347.71 was expended. In addition $97,311.60 was expended on account of the mints and $7,440.14 at the Treasury Department, a total of $104,751.74 from the appropriation contained in the act of February 28th, 1878, authorizing the coinage of the standard silver dollar.

During the year $255,939.78 was collected from depositors, and $274,784.64 paid on account of parting and refining bullion. The following statement shows the amount collected for parting and refining, and the payments for expenditures in those operations, including that portion of the operative officers' wastages and the loss on sale of sweeps properly chargeable to that fund. A much larger amount, consisting of undeposited refinery earnings of previous years, was deposited in the Treasury to the credit of the appropriation. Included in the payments are expenses for railroad freight incurred in prior years, the bills for which were not rendered until the last fiscal year.

Institution.	*Charges collected.*	*Expenditures.*
Philadelphia Mint	$5,399 89	$9,753 05
San Francisco Mint	161,441 22	170,276 94
Carson Mint	9,008 33	10,397 79
New York Assay Office	80,090 34	84,356 86
Total	255,939 78	274,784 64

The net excess of the earnings of the refineries over the expenses, from the 1st of July, 1876, to June 30, 1881, as shown by the books of the Treasury Department, amounted to $121,238.90.

The commission appointed by the President to test the weight and fineness of the coins reserved for the annual assay, performed the duty at the time designated by law, and the records of their proceedings show that all the coins tested by them were found to be within the limits of exactness required by law, as to weight, and that very few varied from the standard by one-half the tolerance.

As to fineness, the record states that in all cases, both in mass and single pieces, the coins from Philadelphia, San Francisco, and New Orleans were found to be correct, and safely within the limits of tolerance. But the committee on assaying reported that, in the case of the Carson Mint, they found the assay of mass melt of silver to be very low, but within tolerance, and that one single piece showed a fineness below the limits of tolerance. This fact was reported to the President, as required by law.

The assayer of the Mint Bureau, in October, 1880, in his assay of the coins required monthly to be forwarded to the Director for test, had discovered that a silver coin of the Carson Mint, from the coiner's July delivery of that year, was below the legal limit of tolerance. The superintendent of that mint was immediately directed not to pay out, but to retain in his possession all of the coins of that delivery, and to seal up, until further orders, all packages which might contain any of such coins, after selecting and forwarding to the Director sample coins from each package for further test. Ninety-six packages, each containing one thousand dollars, were thus sealed up and reserved for further assays at the bureau, and a special examination made by Andrew Mason, melter and refiner of the New York Assay Office, in conformity with the order of the President to investigate the matter, confirmed the previous assays, and demonstrated that the fineness of a certain bar of bullion, about to be melted for coinage, had been incorrectly stated to the melter and refiner of the Carson Mint, and that ingots of defective fineness made therefrom had afterward passed the assay department of that mint without detection. It did not appear that the error had occurred through the neglect of the assayer's subordinates, and as the assayer himself had died shortly after the first discovery of the defective coinage, it became unnecessary to take any further action, except to order all the coins contained in the 96 packages to be remelted for coinage, which was done.

Estimation of the Values of Foreign Coins.—The values of foreign coins were estimated by the Director of the Mint, and proclaimed by the Secretary of the Treasury on the first of January of the current year, as required by law. The computation of their values was made in the same manner as that of the previous year. No change in the value of the gold coins will be found, excepting that resulting from more accurate information or recent modifications of the law prescribing their weight and fineness. The commercial value of silver bullion for the time the estimation was made having fallen about 1.56 per cent. from its value for a like period of the preceding year, the value of silver coins based on the market rate of silver were correspondingly reduced. The usual examinations and settlements were made at the close of the fiscal year at all the mints and at the New York Assay Office. The magnitude and importance of these settlements are evident when it is known that they covered for the last year transactions and actual transfers between the superintendent and operative officers of gold and silver bullion to the value of $603,230,121, and that bullion and funds amounting at the time of settlement to $128,318,274 were examined, counted, or weighed, and their value ascertained. At each institution the superintendent, after the delivery to him of the bullion in the hands of the operative officers, was, upon taking account of the coin, bullion, and other moneys in his possession, found to hold the amount required by his accounts with the Treasury. The wastage of each of the operative officers was found to be within the legal limit, and the total wastage during the year was, considering the amount received and worked, much less than that of the preceding year. The total amount operated upon in the melter and refiner's department of the mints and the New York Assay Office was, of gold bullion, 16,319,460 standard ounces, on which the legal limit of wastage was 16,319 standard ounces and the actual wastage 1,608 standard ounces, and, of silver bullion, 54,798,707 standard ounces, on which the legal limit of wastage was 82,198, and the actual wastage only 4,453 standard ounces. The amount operated upon in the coining department of the mints was, of gold bullion, 10,514,159 standard ounces, upon which the legal limit of wastage was 5,257 standard ounces, and the actual wastage 367 standard ounces; and of silver bullion, 48,182,982, upon which the legal limit of wastage was 48,183 standard ounces, while the actual wastage was only 4,021 standard ounces, being heavier in gold and less in silver than that of last year. The total wastage during the year was $36,767.14 gold and $8,576.83 silver, a total of $45,343.97, which was no greater than that of the previous year, although three times as much gold was melted. Bullion, however, of the value of $8,406.12 was recovered during the year, from the deposit melting-rooms, and the melter and refiner of the New York Assay Office returned, on settlement, surplus bullion of the value of $24,733.24, making a total of $33,139.36 bullion gained. The net actual loss to the government on the immense amount received, redeposited, and reworked during the year, was only $12,204.16. Loss and wastage in the handling, melting, separating, refining, and coinage of the precious metals is unavoidable. It is contemplated and provided for by law, which limits and authorizes an allowance to be made in favor of the melter and refiner's accounts, to the extent of one thousandth of gold and one and a half thousandths of the silver, and, of the coiner's accounts, one-half thousandth of the gold and one thousandth of the silver delivered to them, respectively, during the year, if the superintendent is satisfied there has been *bona fide* waste of the precious metals. At the last, as well as the preceding settlement, the melter and refiner's gold wastages at the Philadelphia and San Francisco Mints, although far within the legal limits, were heavier than the usual loss of those officers. During the last two years large amounts, aggregating $90,000,000 of foreign coin and bullion, received and melted at the New York Assay Office, were transmitted to the Philadelphia Mint in the form of gold mint-bars alloyed with copper. The melter and refiner of that mint attributed his wastage, in part, to insufficient deductions on these bars for oxide of copper and other adhering impurities, the weight of which would occasion a loss in his accounts, but increase, to a corresponding extent, the surplus at the New York Assay Office, and, therefore, cause no real loss to the government. The melter and refiner's wastage at the San Francisco Mint can, in part, be accounted for by greater deposits during the year of brittle, fine gold bars and unrefined gold bullion, containing refractory and volatile base metals, in the elimination of which loss of gold is a frequent, if not a necessary consequence. How far this cause has operated to produce the wastage of that mint is under consideration; but, as yet, sufficient examination and analysis have not been made of the records and transcripts obtained for a comparison of the character of the deposits and the methods of weighing, assaying, and reporting the fineness of gold bullion, with those of previous years and of other mints and assay offices.

Philadelphia Mint.—On account of the continued heavy import of foreign gold coin and the payment of its value immediately upon assay in American coin, it became necessary to increase the monthly gold coinage at the Philadelphia Mint to supply the Treasury with coin thus paid out. Its gold coinage had averaged previous to the heavy gold import of 1880 less than $10,000,000, but in 1881, besides coining $9,125,966.75 silver and $405,109.95 minor coins, its gold coinage amounted to $49,809,274, and at the close of the fiscal year the mint held $23,023,206.62 of uncoined gold bullion. This increased coinage necessitated the employment of a larger working force and extra hours of labor, and also much heavier purchases of copper and other supplies. By reason of these greater expenditures and in order to execute the monthly silver coinage required by law, it became necessary to make advances to the mint and use during the year $78,712.48 from the appropriation contained in the act authorizing the coinage of the standard silver dollar. The following presents a comparison of the operations of the last and preceding fiscal year:

	1880.	1881.
	Value.	*Value.*
Deposits	$53,309,250 60	$70,651,442 91
	Pieces.	*Pieces.*
Gold coinage	3,789,820	7,275,928
Silver coinage	15,223,400	9,174,820

Gold wastage of coiner	....	197
Silver wastage of coiner	3,047	1,869

On the large amount operated upon during the last year the wastage of the melter and refiner was, on gold, 4.5 per cent. of the legal limit of the allowance and 4.2 per cent. on silver, and of the coiner on gold 5.4 per cent., and on silver 11.4 per cent.

San Francisco Mint.—A much larger amount of work was executed at this mint, both in coinage and in the refinery, during the past fiscal year than in 1880, the number of pieces of gold coined being nearly half a million more, and of silver about three and a half millions more. The comparative values of the deposits, number of pieces coined, and bullion operated on in the refinery during the last and preceding years are:

Silver operated upon by melter and refiner	15,733,815	22,471,852
Gold operated upon by the coiner	2,918,714	3,230,718
Silver operated upon by the coiner	13,497,415	20,969,005
Gold wastage of the melter and refiner	283	1,228
Silver wastage of the melter and refiner	18,654	2,498
Gold wastage of the coiner	118	168
Silver wastage of the coiner	102	942

At the annual settlement, the melter and refiner's wastage in gold was 40 per cent. of the legal limit of allowance, and his silver wastage was 7 per cent. His silver wastage was much less, but the gold wastage heavier than that of the preceding year. The coiner's gold wastage was 13¾ per cent., and his silver wastage 4½ per cent. of the amount allowed by law. Improvements have been made at this mint in refining bullion by the use of the sulphuric acid process. The charges for parting and refining the higher grades of bullion were, near the beginning of the year, reduced, yet, as a greater amount of bullion requiring to be parted or refined was deposited during the year, the charges collected for these operations exceed those of the preceding year. The expenses of the refinery, however, owing to the large amount of work performed, were slightly increased. Besides this heavier expenditure, the sum of $6,000 was expended in procuring apparatus and fixtures and making the necessary arrangements for operating the sulphuric acid refinery, and nearly $4,000 was paid on account of freight bills of the previous year. These necessary but unusual expenditures made the payments during the year for expenses on account of parting and refining some $8,000 more than the charges collected.

Carson Mint.—Coinage at the Carson Mint, which had been suspended in May, 1880, was resumed July 1, 1880, and was continued from that date until April 1, 1881, during which period $883,590 were coined, when, from lack of sufficient bullion, it was again discontinued, and so remained until the close of the year. The mint, however, was kept open for the reception and purchase of bullion, and payment was made, as usual, on deposits and purchases as soon as the value could be ascertained. No inconvenience or delay was therefore occasioned to depositors or to the mining interests of that portion of the country. The work at this mint during the year compares with that of the previous year, as follows:

	1880.	1881.
	Value.	*Value.*

Silver wastage of melter and refiner	135	249
Gold wastage of coiner	2	3
Silver wastage of coiner	138	148

At the annual settlement the wastages of the operative offices were as follows: of the melter and refiner, on gold, 49.3 per cent. of the legal limit. and on silver, 14.7 per cent.; of the coiner, 15.7 per cent. on gold and 14.7 per cent. on silver. The assayer of the mint, William P. Prescott, died December 5th, 1880, and Josiah M. Hetrich was appointed to the position December 21, 1880 and entered upon duty January 4, 1881.

New Orleans Mint.—The work of this mint has been principally confined to the manufacture of standard silver dollars, for which the demand through the South continued heavy during the year and nearly equalled the coinage. The monthly allotment of silver coinage was raised to 500,000, and occasionally to 600,000 standard dollars, and executed with dispatch and little additional expense under the efficient management of the officers of the mint. The following table exhibits the deposits and purchases of bullion and coinage of the year compared with the fiscal year of 1880:

	1880.	1881.
	Value.	*Value.*
Deposits	$4,599,895 64	$6,439,652 39

Silver wastage of melter and refiner	. . . .	656
Gold wastage of coiner	. . . . .	. . . . .
Silver wastage of coiner	807	1,062

The wastage during the year of the melter and refiner was, on gold, 31.5 per cent. of the legal limit, and on silver 4.3; and of the coiner, nothing on gold, and on silver 10.6 of the legal limit. Notwithstanding the amount of work performed at this mint during the year many necessary repairs were made in the rolling and coining rooms, and to the machinery; and it is expected that other repairs will be completed during the present fiscal year.

New York Assay Office.—The business of the New York Assay Office assumed immense proportions during the year, owing to the continued and increased importation of foreign gold. The gold deposits were the largest in the history of the institution, $91,497,168.61 of the amount being foreign coin and bullion The following table exhibits the value of deposits and bars manufactured at the New York Assay Office during the fiscal year ended June 30, 1880, and June 30, 1881:

Deposits and bars.	1880.	1881.
Gold deposits	68,273,628	$99,635,644 46
Silver deposits	4,491,416	5,285,715 57

Gold, fine bars, manufactured	11,378,980	9,805.028 07
Gold, mint bars, manufactured	57,368,761	89,643,135 29
Silver, fine bars, manufactured	4,372,705	4,763,189 08
Silver, sterling bars, manufactured	24,347	1,418 03
Silver, mint bars, manufactured	. . . .	619,047 53
Total bars manufactured	73,144,795	104,731,818 00

There were paid during the year to depositors $99,603,-605.42 in gold coin and bars, and $4,976,641.10 in silver coin and bars, making the aggregate payments $104,580,246,52, and gold bullion of the value of $61,560,816.10 was transferred to the mint at Philadelphia, for conversion into coin. On the annual settlement of his accounts the melter and refiner returned 1,329,100 standard ounces of gold bullion of the value of $24,727,44, and 498 standard ounces of silver bullion, valued at $5.80, in excess of the amounts with which he was charged, having recovered the same in his operations. The aggregate of these sums, $24,733.24, has been deposited in the Treasury of the United States. But, although the amount appears as an earning of the assay office, it is not available for payment of expenses, and was not credited to the appropriation for parting and refining, as, by law, only the charges collected from depositors for parting and refining bullion are authorized to be used for defraying the expenses of those operations.

Denver Mint and Assay Offices at Charlotte, Helena, Boise City and St. Louis.—The assay offices were established for the local convenience and development of the mining interests in their vicinity and to afford miners and those owning, operating and prospecting for mines facilities for ascertaing the value of ores and bullion, and for the exchange of their gold bullion for coin. The work done by each during the year, including the Denver Mint (which, by law, can only be operated as an assay office) was;

	Denver.	*Charlotte.*	*Helena.*	*Boise.*	*Total.*

The St. Louis Assay Office was established so near the close of the fiscal year that nothing could be done except to have suitable rooms set apart in the United States building at St. Louis, and to commence fitting them up and procuring the necessary fixtures and apparatus for the use of the office. Mr. E. C. Jewett was appointed assayer July 1, 1881, and has been placed in charge. The appointment of melter was delayed until his services should be required, and the office ready for the reception of bullion.

Coin Circulation of the United States.—In the last annual report of the United States coin was estimated from the amount previously on hand, and the annual coinage and import of United States coin to have been on the 30th of June, 1880, $358,958,691 of gold and $142, 597,020 of Silver. The net gain during last year from coinage and import was, in gold coin, $84,118,062, and in silver coin, $28,937,746. This would make the total circulation of United States coin on the 30th of June, 1881, $443,077,023 gold, and $171,534,766 silver. Heretofore no reduction has been made for coin used in manufactures and the arts, as it was believed that it should be offset by the excess of United States coin brought by immigrants upon their persons above the sums in like manner taken out of the country by travelers; but the circulation of United States gold coin, and its consequent abrasion and use in the arts, have largely increased, while the amount held abroad has, as shown by its diminished import, become depleted, so that much less American coin than heretofore is obtained and brought into the country by immigrants. It seems proper, therefore, that allowance should be made for use in the arts to the extent of the sum reported to this bureau to have been used by manufacturers, which was, for the last fiscal year, in round numbers, $3,300,000 gold, and $75,000 silver. This would reduce the circulation of United States gold coin at the close of the fiscal year to about $440,000,000, and of silver coin to $175,500,000. During the first four months of the current fiscal year there has been a further coinage of $26,544,000 and a net import of $2,172,474 gold, and a coinage of $9,300,000 and net import of $310,858 United States silver coin, making a total gain to the first of November, 1881, in the circulation, of $28,609, 000 gold and $9,600,000 silver. This, added to the amount estimated to be in circulation June 30, 1881, makes the coin circulation of the country, November 1, about $469,000,000 gold and $181,000,000 silver, a total of $650,000,000. At the latter dates the mints and assay office at New York held of bullion $94,075,744 gold and $4,966, 741 silver, swelling the stock of coin and bullion available for coinage to $563,000, 000 gold and $186,000,000 silver, a total of $749,000,000, being a *per capita* of $14.93.

The following table shows the gain in the coin circulation of the United States from June 30, 1880, to June 30, 1881, and to October 31, 1881:

United States coin.	*Gold.*	*Silver.*	*Total.*
Circulation June 30, 1880.	$358,958,691	$142,597,020	$501,555,711

Estimate of Values of Foreign Coins.

Country.	*Monetary unit.*	*Standard.*	*Value in U. States money.*	*Standard coin.*
Austria	Florin	Silver	$0 40.7	
Belgium	Franc	Gold and silver	19.3	5, 10 and 20 francs.
Bolivia	Boliviano	Silver	82.3	Boliviano.
Brazil	Milreis of 1,000 reis	Gold	54.6	
British Possessions in North America	Dollar	do	1 00	
Chili	Peso	Gold and silver	91.2	Condor, doubloon, and escudo.
Cuba	do	do	93.2	1/16, 1/8, 1/4, 1/2, and 1 doubloon.
Denmark	Crown	Gold	26.8	10 and 20 crowns.
Ecuador	Peso	Silver	82.3	Peso.
Egypt	Piaster	Gold	04.9	5, 10, 25, 50, and 100 piasters.
France	Franc	Gold and silver	19.3	5, 10, and 20 francs.
Great Britain	Pound sterling	Gold	4 86.6½	½ sovereign and sovereign.
Greece	Drachma	Gold and silver	19.3	5, 10, 20, 50, and 100 drachmas.
German Empire	Mark	Gold	23.8	5, 10, and 20 marks.
India	Rupee of 16 annas	Silver	39	
Italy	Lira	Gold and silver	19.3	5, 10, 20, 50, and 100 lire.
Japan	Yen	Silver	88.8	1, 2, 5, 10, and 20 yen; gold and silver yen.
Liberia	Dollar	Gold	1 00	
Mexico	do	Silver	89.4	Peso or dollar, 5, 10, 25, and 50 centavo.
Netherlands	Florin	Gold and silver	40.2	
Norway	Crown	Gold	26.8	10 and 20 crowns.
Peru	Sol	Silver	82.3	Sol.
Portugal	Milreis of 1,000 reis	Gold	1 08	2, 5, and 10 milreis.
Russia	Rouble of 100 copecks	Silver	65.8	¼, ½, and 1 rouble.
Sandwich Islands	Dollar	Gold	1 00	
Spain	Peseta of 100 centimes	Gold and silver	19.3	5, 10, 20, 50, and 100 pesetas.
Sweden	Crown	Gold	26.8	10 and 20 crowns.
Switzerland	Franc	Gold and silver	19.3	5, 10, and 20 francs.
Tripoli	Mahbub of 20 piasters	Silver	74.3	
Turkey	Piaster	Gold	04.3	25, 50, 100, 250, and 500 piasters.
United States of Colombia	Peso	Silver	82.3	Peso.
Venezuela	Bolivar	Gold and silver	19.3	5, 10, 20, 50, and 100 Bolivar.

Average Monthly Price of Fine Silver Bars at London, &c.

Date.	*Price per ounce British standard, 925 thousandths fine.*	*Equivalent in United States money per ounce fine with exchange at par, $4.86.65.*	*Average monthly price at New York of exchange on London.*	*Equivalent in United States money of fine bar silver, 1,000 fine, based on average monthly London quotations with exchange at average monthly rate.*	*Average monthly New York price of fine bar silver.*

Of foreign bullion	1,380,416 00	250,207 00
Of domestic bullion	3,653,136 00	4,579,994 00
Of plate, &c	522,918 00	177,940 00
Total	5,723,838 00	5,128,932 00

Very respectfully,

THOS. C. ACTON, *Superintendent.*

HOROLOGICAL PRODUCTIONS OF VARIOUS COUNTRIES.—Watches to the value of $2,135,000 were imported into Great Britain in 1880. From a Swiss journal we learn that in 1880 there were produced at Besançon, France, 146,047 gold and 267,783 silver watches, being 3,860 gold and 26,618 silver watches less than during the preceding year. The total value of this trade for 1880 is estimated at 19,108,170 francs. The falling off in the product is attributed to increased importations of watches from Switzerland into France, the Swiss having been able to reduce the wages of mechanics considerably, owing to the falling off of the American demand for Swiss watches. In 1872 there were imported into the United States 366,000 watches; in 1876 only 75,000. In these four years the industry had been so developed, and its products so cheapened, that we had become large exporters of watches, and could beat the Swiss watchmakers on their own ground. This led the Swiss manufacturers to change their tactics. As the Americans could surpass them in the finer grades of watches, they began to cheapen their productions, and were thus able again to bring up their export trade quite largely, until in 1880 that country excelled her best previous record, her exportations of watches having reached a total value of $2,000,000. There were imported into France in 1880, 32,082 gold and 51,592 silver watches, exceeding by 20 per cent. the importations of 1879. The total number of watches represented in the Geneva trade of 1880 was:

Watches from Besançon	413,832
Watches from other French towns	800
Foreign	83,674
Total	498,306

Formerly, Switzerland sent to France watches to the value of over 4,000,000 francs; but France now sends a large number of watches into Switzerland. The value of the entire clock and watch trade of France in 1880 is estimated at 57,000,000 francs, and something like 60,000 workmen are engaged in this industry, of which the greater part are employed at Besançon. In Paris there are 6,000 watchmakers.

* * * * * * *

According to M. Saûnier, England contributes to this art in money value about one-fifteenth of the production of the world. The following table, showing the total annual manufacture of horological instruments in the various nations, does not give the year covered by the estimate:

France, clocks and watches	$13,000,000
Switzerland, watches	12,000,000
America, clocks and watches	6,400,000
Germany, clocks	5,000,000
England, chronometers and watches	3,200,000
Austria, clocks	2,000,000
Total	41,700,000

†Reduced to gold valuation.

GREAT BRITAIN—GOLD IN THE ARTS.

Professor Suess, in his book, "Die Zukunft des Goldes," says: "In order to get some reliable information on the consumption of gold in the arts in Great Britain, I wrote to the chamber of commerce in Birmingham, a principal seat of that industry. Its secretary, Mr. H. J. Harding, has been kind enough to procure an answer from Mr. John Bragg, a very competent expert, who writes, under date of January 10, 1877, as follows: "The amount of bullion, including sovereigns, which are melted every day in large quanties, is from 250,000 to 300,000 ounces annually. In the year 1874 120,000 ounces passed the Birmingham assay office. This amount has risen for several years 20,000 ounces annually, and may be now from 150,000 to 160,000 ounces. As we know for certain that not one-half passes this office, it is reasonable to conclude that the amount is to-day near 300,000 ounces, to which figure an eminent bullion dealer consents. This single place consumes therefore about

Table comparing the Ratio of Circulation to Population and Wealth with the Currency and Gold Prices of Staple Articles in the New York Market for years named, taking the Ratios and Prices of 1850 as 100.

30,000,000 of francs annually, with an increase of 2,000,000 per year. It seems to follow from this that the opinion of an annual consumption of gold in England of from 4,000,000 to 5,000,000 sterling for use in the arts, for abrasion and for recoining, is probably far below the truth."

Some information on this subject may be gathered from the hall marks, which are registered according to law, and from the amounts of duty on manufactures from gold and silver, which is 17s. for the ounce of gold. Manufactures of a low degree of fineness (of 15, 12, and 9 karats) are not subject to that duty, and not also gold used for the production of foil and thread, and that used in gilding porcelain, etc. It follows from this that the information cannot be exact, and is only apt to show the proportional increase in the course of years. There was subject to this duty on gold manufactures:

Years.	Total ounces.	Average ounces.
1807–1814	50,750	6,344
1815–1823	51,321	6,415
1831–1835	27,991	5,590

Other civilized countries	53,000		40,000
Total	600,000		471,000

To an inquiry of the Chamber of Commerce, the following sums are given as representing the value of the industries named in Paris alone for 1860: Manufactures of gold and silver thread, 3,469,190 francs; gold and silver foil, 13,607,300 francs; fine jewelry, 69,213,700 francs; chains, 14,837,760 francs. In the official statistics for 1879, the following statements occur: Export of gold jewelry, 4,694 kilograms, value 25,798,000 francs; gold foil, 1,185 kilograms, value 3,793,000 francs; gold thread 3,882 kilograms, value 3,885,000 francs.

A note from an expert, in my possession, states that from 60,000,000 to 80,000,000 of francs, fine gold, is used in the arts annually in Paris.

The last figure may be too high, but it is clear that the consumption of gold has increased very much in France, which is in this respect much above almost every other country. This circumstance goes far to explain the great difference between import and export of gold in France. The following are the figures for it:

	1847-1856.	1857-1866.	1867-1876.
	Kilos.	*Kilos.*	*Kilos.*
Import	66,405	171,511	131,498
Export	17,086	83,888	66,752
Import greater by	49,319	87,623	64,746

[*Extract from Verwendung des Goldes und Silbers. Statistische Untersuchung von Dr. Adolf Soetbeer.*]

The French gold coinage from 1851 to 1875 reached the enormous sum of 5,464 millions of francs, for which were required 1,762,600 kilograms gold, on the average 70,000 kilograms annually. It is evident that for industrial uses coin was melted to a large extent. All these circumstances duly considered, it will come near the truth if we assume the use of gold in the arts at 21,000 kilograms for France.

Decrease of amount of precious metals in the civilized world by the absorption of Asia.

*War with Russia. † Comparison made on basis of 100 in 1862.
‡ Mr. Ernest Seyd, in his testimony before the Select Committee of Parliament on Depreciation of Silver, estimated the quantity of gold money present before 1871 at £260,000,000; full legal-tender silver £70,000,000, and subsidiary change £14,000,000. (Report of Committee, p. 56.)
§ Journal of the Statistical Society, December, 1879, p. 853.

The following seems to be a fair estimate of the use of gold in the arts in Germany:

	Kilograms.
Manufacture of gold wares in Southwestern Germany	10,000
In rest of Germany	2,000
Gold foil	1,400
Other gilding material	1,300
Total	14,700

As to export of gold manufactures, Germany is almost the first country in the world; the reason why it uses less gold in the arts than England and France is to be sought in the fact that it makes only few gold watch-cases, for which large quantities of gold are needed in the other countries.

[*Extract from Verwendung des Goldes und Silbers. Statistische Untersuchung von Dr. Adolf Soetbeer.*]

Germany.—Production of the precious metals in the years from 1876 to 1879. From official sources it appears that the production of gold and silver in Germany was as follows:

Years.	Gold.		Silver.		
	Weight.	Value.	Weight.	Value.	Price per kilogram.
	Kilog'ms.	Marks.	Kilograms.	Marks.	Marks.
1871–'75, average	284.4	778,921	143,080	24,929,200	174.19
1876, average	281.3	784,658	139,779	21,969,415	157.17
1877, average	307.9	857,845	147,612	23,812,056	161.32
1878, average	378.5	1,056,338	167,660	25,390,332	151.44
1879, average	466.7	1,302,398	177,507	26,518,123	149.39

Part of this production is from ores mainly imported from the west coast of South America. For the year 1879 there were produced from such ores 1,000 kilograms in Mansfeld, 19,500 in Stolberg, 12,000 kilograms in the Hartz, 10,000 kilograms in Freiberg, and in other places 1,000 kilograms. The proportion of reduction of silver from the two sources (native and foreign ores) is the following:

Years.	From native ores.		From foreign ores.	
	Kilograms.	Per cent.	Kilograms.	Per cent.
1871	90,886	92.7	7,216	7.3
1872	100,742	79.3	26,265	20.7
1873	92,253	52.1	84,958	47.9
1874	109.820	70.5	46,032	29.5
1875	134,066	86.3	23,152	14.7
1876	123,146	88.1	16,633	11.9
1879	134,000	75.5	43,500	24.5

NOTE.—Throughout the kilogram of gold is valued at 2,790 marks, and the kilogram of silver at 180 marks.

AUSTRIA. Statement of the Precious Metals used in Austria, from 1867-1880, inclusive, for the manufacture of different objects, and of gold and silver thread.

Designation.	Precious Metals. Sum total from 1867 to 1880.		Average Yearly.

Manufactured Gold.—An imperial order of May 26, 1866, prescribes that every newly manufactured article of gold or silver is to be registered. The legal degrees of fineness are .920, .840, .750, and .580. No article is permitted to be made of less fineness than .580; the fineness of Austrian articles is on the average between .620 and .660. Foreign articles are likewise inspected as to their fineness. The following are the official figures:

Years.	Gold.	
	Home-made articles.	Imported articles.
	Kilograms.	Kilograms.
1870	2,041	630
1871	2,486	822
1872	3,618	1,489
1873	3,617	1,493
1874	2,490	1.001
1875	2,354	1,104
1876	1,805	812
1877	1,714	856
1878	1,913	1,046
1879	2,008	1,316

Gilded silver thread was declared at the main registering office to the amount of 4,183 kilograms in 1870, and 2,269 kilograms in 1879. Eight large establishments in Vienna and Prague, melted in 1870, 35,050 ducats (121 kilograms) for making gold foil. Gold for gilding may be used to the amount of 250 to 350 kilograms, annually. Schwicker estimates the value of gold and silver wares manufactured annually in Hungary, at 1,000,000 florins.

Norway and Sweden.—In answer to the question presented by the honorable delegate of Switzerland Monsieur Lardy, (International Monetary Conference, held in Paris in 1881) at the meeting of the 10th of May, 1881: "What is the importance of the use, for industrial purposes, of the precious metals, especially of gold?" I, Dr. O. J. Broch, have the honor to present to the Conference the following table, upon the employment of silver and of gold, except their consumption by photography. The silver used always consists of bars; articles of silver, melted and remade into utensils or jewels, are not included. Gold usually consists of the coinage of the country, or of foreign coins. Neither imported silver nor gold jewelry is included.

Statement of the monetary situation of the Kingdom of Norway, before and after the change from the standard of silver to the standard of gold.—The ancient monetary system of Norway was regulated by the law of the 14th of June, 1816. This system was based on the single standard of silver. The unit was the "speciesdaler," thirty-seven pieces of which, 875 thousandths fine, were made from four marks of Cologne of fine silver. The value of the mark of Cologne was fixed in Norway, by the law of weights and measures, of July 28, 1824, as follows: 1 pound=2 marks of Cologne, being equal to 123,144.5 gram, Norwegian weights of commerce, which gives for the mark of Cologne the value of 233.99335 grammes. In Denmark and in Hamburg the mark of Cologne was valued at a little less, that is 233.85489 grammes. In Prussia it is valued at 233.8555 grammes. The ancient ounce of Charlemagne was equivalent to 30.9504 grammes, and the mark of eight ounces was then originally equivalent to 244.752 grammes. The Norwegian "speciesdaler" thus would weigh 28.9104 grammes, 875 thousandths fine, and contain 25.2966 grammes fine silver. In comparison with the piece of five francs, silver, the "speciesdaler" is valued at 5 francs 62 centimes. As current moneys, having full circulating power, they still coin moneys of the same fineness, equivalent to $\frac{1}{2}$, $\frac{1}{5}$, $\frac{1}{10}$, and $\frac{1}{15}$. speciesdaler. The speciesdaler was divided into 120 skillings.

—*Extract from Verwenduug des Goldes und Silbers Statische Untersuchung, von Dr. Adolph Soetbeer.*

In Sweden and in Denmark they coin money similar to the Norwegian speciesdaler and of the same fineness; but the weight, and consequently the amount, of fine silver contained differ somewhat.

The Swedish species contain	25.5045 grammes fine silver.
The Danish species	25.2816 grammes fine silver.
The Norwegian species	25.2966 grammes fine silver.

The Danish species coincides with the reichsthaler Hamburger-banco, or 3 marks-banco, the unit of account, not coined; then $59\frac{1}{3}$ marks-banko represents 500 grams of fine silver. In Sweden the monetary unit being the "riksdaler" $=\frac{1}{4}$ Swedish speciesdaler, which they divide into 100 "ore." In Denmark the monetary unit is the "rigsdaler" $=\frac{1}{2}$ Danish "speciesdaler" that they divide into 6 "mark," and the mark into 16 "skilling," and the rigsdaler into 96 Danish skillings. In current moneys having full circulating power there was coined in Norway, in conformity with the law of 1816, until the end of the year 1873 a sum of 3,934,355 speciesdaler 16 skilling, as follows:

	Spd.	Sk.
In 1 speciesdaler for	2,518,155	
In $\frac{1}{2}$ speciesdaler for	439,462	50
In $\frac{1}{5}$ speciesdaler for	462,102	96
In $\frac{1}{10}$ speciesdaler for	462,860	60
In $\frac{1}{15}$ speciesdaler for	54,774	40
Total sum	3,934,355	16

This coinage was almost exclusively done on account of the Bank of Norway. The seignorage paid for the coinage of moneys at Konigsberg was 2 per cent. for the 1 and the $\frac{1}{2}$ "speciesdaler," and $2\frac{1}{2}$ per cent. for the $\frac{1}{5}$, $\frac{1}{10}$, and $\frac{1}{15}$ "speciesdaler." A part of the "speciesdaler" had from time to time been exported into Hamburg and transformed into bullion at the Bank of Hamburg. The current Swedish and Danish moneys circulate side by side. The real circulation, outside of the national bank, was almost exclusively on trust, with bank notes, reimbursable at sight, in 5, 10, 50, and 100 speciesdaler. The current coins of $\frac{1}{2}$, $\frac{1}{5}$, $\frac{1}{10}$ and $\frac{1}{15}$ speciesdaler are the only real circulation. Even the pieces of the $\frac{1}{2}$ "speciesdaler" are rare. In small transactions they often calculate in $\frac{1}{5}$ speciesdaler called "ort," which may thus be called the popular unit. In Sweden and Norway the real circulation was also, by preference, on trust. The smallest bank note then in Sweden was the note of the rigsdaler, and in Denmark the note of 5 rigsdaler. The cash in hand of the Bank of Norway was in a great part in Danish speciesdalers and in silver ingots. The bank is allowed to place even a third of its cash in circulation with its agents. The bank buys drafts upon a foreign bank, and then sends them at once to its correspondents to be cashed. At the same time the bank sells drafts, always short dated, upon its agents. The bank maintains by these operations an exchange of drafts upon the principal places with which Norway has trade, within certain restricted limits. When the payment of the commercial balance of the country demands exportations of silver, the bank itself often sends to its agents upon whom it sells time drafts. The paper circulation of the Bank of Norway the only bank of issue, was, toward the end of the year 1873, 11,794,633 speciesdaler. The monetary circulation outside of the bank, in current silver money, and in money of silver with copper, at the same time, can be valued at 1,000,000 speciesdaler, comprising Swedish and Danish moneys which circulate in Norway. The total circulation, outside of the cash in hand of the bank, was then 12,800,000 speciesdaler. The population of Norway was estimated at the same time at 1,780,000 inhabitants. The paper and coin circulation was therefore 7.2 speciesdaler, or 40 francs 40 centimes per each inhabitant. The cash in hand of the Bank of Norway at the same time was 8,593,435 speciesdaler, comprising the amount invested abroad. The change from the single standard of silver to the single standard of gold took place in Norway January 1, 1874, in accordance with a law of June 4, 1873. A law of June 17, 1869, the result of the international monetary conference at Paris in 1867, had already authorized the Bank of Norway to change a part of its cash in hand into gold. The administration of the bank profited by this to sell, from time to time, silver and buy gold. This change took place principally in sending silver money to Hamburg, where it was recoined into the "Hamburger-banco-mark" in the proportion of $118\frac{3}{5}$ mark to a kilogram of fine silver. By the monetary reform of Germany the "Hamburger-banco-mark" was afterward changed to gold in the proportion of 2 mark-banco=3 reichsmark, or in the proportion of 15.674 to 1. The cash of the bank, including the capital in the hands of the agents of the bank at Copenhagen, Hamburg and London, was, near the close of the years—

	1871.	1872.	1873.
	Spd.	*Spd.*	*Spd.*
Silver	6,483,136	6,839,308	1,535,448
Gold	105,827	722,002	7,057,987
Total cash	6,588,963	7,561,310	8,593,435

The transition to the single standard of gold took place simultaneously in the three Scandinavian kingdoms. Without discussion and without mention in the Scandinavian monetary convention of December 18, 1872, it was recognized as a right, also an unquestionable international duty, that each state was responsible for the money that was coined at its mint and that was stamped with its coat of arms, and that in case of demonetization and change from silver to gold, it should withdraw these current moneys, also the fractional money of silver or copper, and change them for gold. Thus already in the autumn of 1873 the Government of Denmark received from the Bank of Norway 2,200,000 speciesdaler of Danish silver that it redeemed in gold. By the law of June 4, 1873, the former silver moneys were, from January 1, 1874, reduced to fractional moneys with circulating power limited to 5 speciesdaler or 20 crowns. The Government is obliged, not only to receive them in unlimited payment, but also to change them for gold money.

The demonetization of the former circulation of silver and copper, and the coinage of new fractional currency appropriate to the new system of crowns, took place April 17, 1875. The "speciesdaler" was converted into 4 kroner, or crowns, according to the new monetary system. Pieces of gold of 10 or 20 crowns were struck according to the law of June 4th, 1873, and of April 17th, 1875, of the fineness of .900; there were, therefore, struck from a kilogram of fine gold 248 pieces of 10 crowns and 124 pieces of 20 crowns. Eight of these pieces of gold were then exactly equivalent to 9 German pieces of gold of designation similar to the mark. A Scandinavian crown is, then, exactly equivalent to 1⅛ mark of Germany. In comparison with the French gold pieces the Scandinavian crown is equivalent to $\frac{100}{72}$ francs. They thus have in gold: 100 francs=81 German marks=72 Scandinavian crowns. The conversion of silver into gold then took place according to the following proportion:

In Norway	25.2966×5×0.124=15.684
In Denmark	25·2816×5×0.124=15.675
In Sweden	25.5045×5×0.124=15.813

The difference between the former silver coinage of the three Scandinavian kingdoms disappeared by the conversion into gold according to these different proportions. At the time of the simultaneous proposition for the transition from the silver to the gold standard in the three kingdoms, in the month of December, 1872, that proportion was according to the London market, 15.79 to 1. In Norway they have successively withdrawn from circulation the following old coinage:

	Spd.	Sk.		Crowns.	Ore.
1 spd. for	765,986	00	converted into	3,063,944	00
½ spd. for	109,543	00	converted into	438,172	00
⅕ spd. for	322,422	24	converted into	1,289,688	00
$\frac{1}{10}$ spd. for	327,900	60	converted into	1,311,602	00
$\frac{1}{15}$ spd. for	17,469	00	converted into	69,876	00
Total in coined money	1,543,320	84	converted into	6,173,282	00
Amount in silver bars	148,075	76	converted into	592,302	54
Copper money	47,129	44	converted into	188,517	47
Total of old coinage	1,738,525	84	changed into	6,954,102	81

Current silver moneys were melted into ingots and sold at London—

In 1874 . . . . 2,636,000 crowns in proportion of *59d.* to 59¼*d* per st. oz.
In 1879 . . . 1,000,000 crowns in proportion of 52*d.* per st. oz.
In 1880 . . . 400,000 crowns in proportion of 52⅛*d.* per st. oz.

Total sum 4,036,000 crowns, or 1,009,000 speciesdaler sold in the form of ingots.

There has also been melted and sold the sum of 65,533 crowns 08 öre in ancient copper coinage. Finally, there has been used in the manufacture of new fractional money debased coin of silver and copper—

2,413,045 crowns 34 öre in ancient silver moneys.
38,983 crowns 67 öre in ancient copper moneys.

Sum realized, 6,553,562 81

The loss in weight of the current moneys produced by the circulation has been found to be as follows:

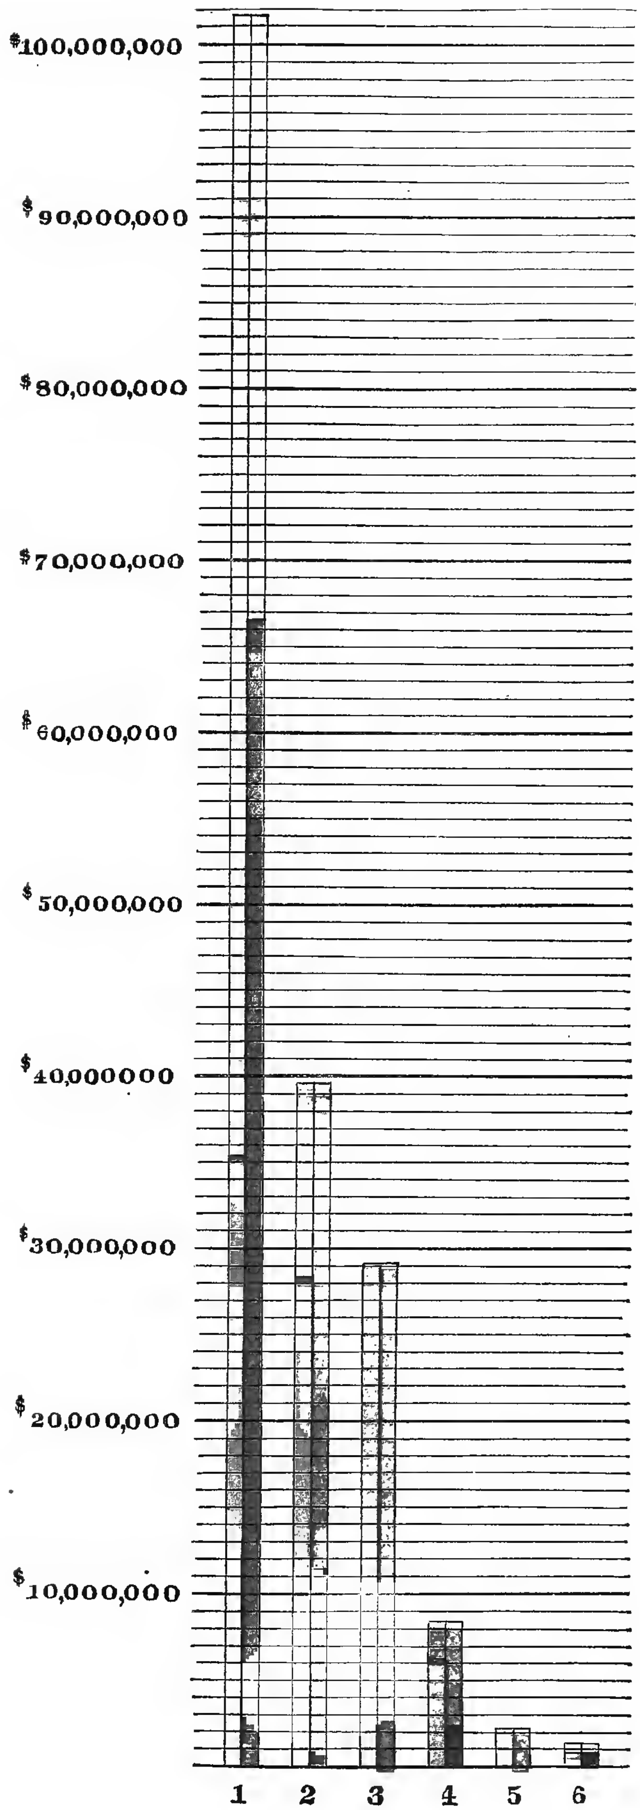
	Per cent.
For the 1 speciesdaler	0.188
For the ½ speciesdaler	0.416
For the ⅕ speciesdaler	1.749
For the $\frac{1}{10}$ speciesdaler	2.279

On the other hand, the standard has been found to average a little higher than it was according to the former legislation. The scale of 4,036.000 crowns in the old currency gave place to a loss of 319,179 crowns 05 öre, including commissions, expense of transportation, &c., The sale of copper accruing from 65,533 crowns 80 öre, in old copper money, caused a loss of 41,677,72. The sum of 2,413,045 crowns 34 öre, former circulation of silver, and 38,983 crowns 67 öre of debased copper coin, converted into change at the mint to be used as the basis of the new fractional money, was valued upon the basis of the price of silver at London, and of copper in trade, at the time of the different changes, caused a loss of 322,664,48. The usual expenses of collection of the former coinage, and transportation, were 3,376,72. Thus the total loss from the conversion of 6,553,562 crowns 81 öre of old system of coinage was estimated at 686,897,97. On the other hand, the profit of the manufacture during the years 1874–1879, of 5,040,000 crowns in new money of silver and copper, resulting from that monetary reform has been estimated upon the same bases at 774,172,84; therefore the excess of profit was 87,274 crowns 87 öre. The 400,540 crowns of the old coinage of silver and copper which still remained in the state treasury served for the coinage of the debased money of the new monetary system, and consequently gave place only to an insignificant profit or loss. The 1,009,000 speciesdaler, or 4,033,000 crowns, contain 25,000 kilograms of fine silver that the monetary reform in Norway during the years 1874–'79 threw upon the London market. The former current silver money contained 25,2966 grammes of fine silver to the speciesdaler, or 6.32415 grammes fine silver to the crown, while the new fractional silver money contains only 6 grams of fine silver to the crown. The exchange at the mint of the old silver coinage for the new fractional silver coinage thus gave place to a profit of 5⅛ per cent. The redemption took place according to the proportion of 15,684 to 1 for gold to silver, while the coinage of new fractional money was in the proportion of 14.880 to 1. The greatest paper circulation took place near the end of June, 1874: it was then 50,111,925 crowns. There were coined in Norway, previous to the end of the year 1880, in gold—

12,686,480 crowns in pieces of 20 crowns.
141,130 crowns in pieces of 10 crowns.

Total sum, 13,127,610 crowns in gold equivalent to 18,232,792 francs.

As material for coinage, ingots of gold purchased at London were exclusively used. The exchange of each coin was done at the mint. The paper circulation of the bank of Norway was, toward the end of the year 1880, 38,713,675 crowns in notes of 5, 10, 50, 100, 500, and 1,000 crowns. The metallic reserve of the bank in money and in gold ingots was at the same time 33,721,357 crowns of which 10,330,572 crowns were with the agents of the bank abroad. The monetary circulation outside of the bank might at the same time have been estimated at 7,000,000 crowns, the greatest part in fractional money. Thus the whole sum outside of the bank was 45,700,000 crowns. The population of the kingdom of Norway at that time was estimated at 1,890,000 inhabitants. Thus the paper and coin circulation was 24 crowns 18 öre, or 33 francs 58 centimes, per each inhabitant.



ANNUAL BULLION PRODUCT of the WORLD.

(CONTINENTAL DISTRIBUTION.)

1. North America.
2. Europe, including Russia in Asia.
3. Australia.
4. South America.
5. Africa.
6. Japan.

The areas in old gold indicate gold, those in light blue, silver, the relative totals being shown by the extreme height of each column.

Articles of gold manufactured in or imported into Sweden from 1848 to 1880, according to the rolls of the office of the comptroller.

Years.	Exported, in coin.	Exported, in ingots.	Amount in treasury and banks.
	Kilos.	Kilos.	Kilos.
1869	5,966	10,814	56,208
1870	5,899	627	56,340
1871	12,324	157	72,144
1872	528	43	97,290
1873	12,599	6,204	86,616
1874	15,150	23,888	53,432
1875	862	8	59,430
1876	5,400	8,536	23,652
1877	....	34	23,546
1878	90	255	31,224

As nearly as can be calculated, the amount of silver coin in circulation in the country at the beginning of 1878 was 11,000,000 crowns.

Amount of circulating Bank Notes.

	Crowns.		Crowns.
1869	61,868,000	1874	104,488,000
1870	69,400,000	1875	96,004,000
1871	79,000,000	1876	91,321,000
1872	102,600,000	1877	77,718,000
1873	111,938,000	1878	72,785,000

Gold, Silver and paper money in Norway.—The Bank of Norway had at the end of each year from 1872 to 1878, in balance of coined gold or gold in bars:

	Crowns.		Crowns.
1872	2,121,200	1876	22,286,800
1873	17,498,000	1877	14,652,000
1874	19,461,600	1878	12,064,800
1875	14,520,000		

Before 1872, coined gold or gold in ingots was not used in Norway. The treasury had no gold balance. The amount of gold then in the Bank of Norway, and in other banks of circulation, cannot be stated, but may be regarded as inconsiderable.

The Bank of Norway's balance of coined silver or silver in ingots at the end of each year from 1858 to 1878 was as follows:

	Crowns.		Crowns.
1858	11,950,000	1869	11,861,200
1859	9,987,200	1870	12,405,600
1860	9,921,600	1871	17,993,400
1861	8,755,600	1872	18,529,600
1862	10,178,400	1873	1,969,600
1863	11,844,800	1874	1,419,600
1864	12,300,400	1875	240,000
1865	16,575,600	1876	196,000
1866	12,720,400	1877	161,600
1867	14,827,600	1878	1,154,900
1868	11,885,200		

The treasury's balance of coined silver at the end of each year from 1875 to 1878 (before that time the treasury's metal balance was inconsiderable):

	Crowns.		Crowns.
1875	1,166,400	1877	1,499,300
1876	1,617,500	1878	770,500

The amount of silver in other banks and in the Norwegian Bank, or the amount of coined silver in circulation, which cannot with accurracy be given, may be said to be, approximately at the end of each year from 1874 to 1878, as follows:

	Crowns.		Crowns.
1874	4,600,000	1877	4,900,000
1875	4,450,000	1878	4,500,000
1876	4,600,000		

The amount of bank notes in circulation at the end of each year from 1858 to 1878, as follows:

	Crowns.		Crowns.
1858	26,323,300	1869	27,162,600
1859	24,207,000	1870	28,388,000
1860	25,847,000	1871	33,982,200
1861	24,648,800	1872	38,515,900
1862	27,819,200	1873	47,178,500
1863	26,643,300	1874	45,869,700
1864	25,596,600	1875	37,229,500
1865	28,524,200	1876	39,668,800
1866	27,944,800	1877	36,309,000
1867	29,094,600	1878	30,967,700
1868	26,436,900		

No gold is produced in Norway. The quantity of silver from Konigsberg silver mine—the only silver mine in Norway—was from 1858 to 1878 as follows:

	Kilograms.		Kilograms.
1858	4,970	1868	3,835
1859	4,818	1869	3,680
1860	4,259	1870	3,585
1861	3,469	1871	3 457
1862	3,091	1872	3,703
1863	3,216	1873	3,558
1864	3,053	1874	3,348
1865	3,682	1875	4,057
1866	3,498	1876	4,067
1867	3,487	1877	4,524

The coinage of gold commenced in 1874. There has been coined in—

	Kilograms.		Kilograms.
1874	1,696	1877	391
1875	847	1878	1,120
1876	882		

The amount of gold used in arts and industry from 1870 to 1878, as follows:

	Kilograms.		Kilograms.
1870	20	1875	29
1871	18	1876	24
1872	21	1877	22
1873	20	1878	21
1874	28		

It may be remarked here that a considerable portion of the gold articles sold in Norway are imported ready made, and are not included in the above estimate. The amount of silver coined from 1862 to 1878 is as follows:

	Kilograms.		Kilograms.
1862	2,242	1872	648
1864	3,063	1873	1,584
1865	2,765	1874	1,200
1867	1,696	1875	6,600
1868	2,126	1876	6,280
1869	1,703	1877	8,572
1870	360	1878	4,147
1871	1,282		

In the above coinage estimate were included about 14,700 kilograms manufactured from old coins remelted. The amount of silver used in art and industry from 1870 to 1878, is as follows:

	Kilograms.		Kilograms.
1870	1,400	1875	2,200
1871	1,340	1876	1,700
1872	1,680	1877	1,680
1873	1,940	1878	1,400
1874	2,440		

The information in regard to the importation and exportation of gold and silver which we are able to give is far from satisfactory, partly because we cannot distinguish between gold and silver, partly because the custom-house report of this question of foreign trade has shown itself to be unreliable. The following estimates are taken from the official table of commercial statistics, which gives our exportation and importation of gold and silver in the form of coin and ingots. It must therefore be used with care.

Imported Silver.

	Crowns.		Crowns.
1866	630,000	1869	2,432,000
1867	1,344,000	1870	1,425,000
1868	1,193,000	1871	4,947,000

Exported Silver.

1866	402,000	1870	34,000
1867	181,000	1871	30,000
1868	1,142,000	1872	284,000
1869	506.000	1873	14,997,000

Imported Gold.

1872	3,202,000	1876	768,000
1873	15,346,000	1877	1,306,000
1874	3,238,000	1878	3,646,000
1875	118,000		

Exported Gold.

1874	27,000	1877	5,000
1875	2,807,000	1878	568,000
1876	788,000		

Any reliable information as to the importation and exportation of gold and silver in other forms than as coins and ingots cannot be given.

Quantity of Gold in Sweden

Description		1878.	1879.
Received from the mines	kilograms	9	3
Imported:			
Coined	do.	1,253	4,175
In ingots	do.	1,777	1,075
Used for the arts, &c.	do.	264	217
Coined	do.	1,976	606

Quantity of Silver in Sweden.

Received from the mines	kilograms	1,268	1,502
Imported:			
Coined	do.	234	600
In ingots	do.	1,044	486
Used for the arts, &c.	do.	2,199	1,565
Coined	do.	4,539	464

Amount of gold in 1879 *exported.*—Coined in 1879, 443 kilograms; 1878, 302 kilograms; coin in state treasury and banks at end of 1879, 8,552 kilograms; in 1878, 6,072 kilograms. In circulation probably no particular change has taken place since the end of 1878, when it was estimated at 5,500,000 kronors.

Amount of silver in 1879 *exported.*—Coined in 1879, 447 kilograms; in 1878, 90 kilograms; 1879, in ingots, 15 kilograms; 1878, 255 kilograms; silver coin in the State treasury and banks at the end of 1879, 35,275 kilograms; in 1878, 31,224 kilograms. In circulation probably no particular change has taken place since the estimate at the close of 1878, when the total amount was 11,000,000 kronors. Amount of bank notes in circulation at the end of 1879, 80,811,090 kronors; at the end of 1878, 72,785,000 kronors.

NOTE 1.—In the above tables only banco silver of 83⅓ proof is taken into account.

NOTE 2.—Besides the silver shown in the above tables, there is other silver on hand, 48 proof, as follows:

	Roubles.
1874	1,186,624
1875	2,299,325
1876	3,434,283
1877	4,823,006
1878	4,421,466

Amount of coin in the Russian State Bank, which forms its circulation from the time of its establishment.

Years.	Amount.	Years.	Amount.
	Roubles.		Roubles.
1861	84,300,000	1871	141,800,000
1862	81,100,000	1872	156,300,000
1863	80,600,000	1873	196,000,000
1864	66,300,000	1874	217,300,000
1865	55,400,000	1875	229,400,000
1866	57,800,000	1876	229,400,000
1867	57,700,000	1877	149,000,000
1868	165,000,000	1878	147,800,000
1869	132,400,000	1879	147,000,000
1870	141,800,000	1880	173,200,000

The proportion in 1879 was: Gold, 137,200,000 roubles, or 92.8 per cent.; silver, 10,600,000 roubles, or 7.2 per cent. The quantity of paper money of the State Bank in circulation and in the bank was as follows:

Years.	Amount.	Years.	Amount.
	Roubles.		Roubles.
1871	715,800,000	1876	797,300,000
1872	724,200,000	1877	790,000,000
1873	774,700,000	1878	1,041,000,000
1874	792,300,000	1879	1,189,300,000
1875	797,300,000	1880	1,163,700,000

In the last two years the amounts in bank and in circulation were as follows:

Years.	Bank.	Circulation.	Bank.	Circulation.
	Roubles.	Roubles.	Per cent.	Per cent.
1879	35,600,000	1,153,700,000	3	97
1880	33,800,000	1,129,900,000	3	97

Gold has been the principal metal mined since 1825. Systematic mining of gold commenced in 1751. Since then the production has been 80,000 puds. During the ten years from 1868 to 1877 amounts have been—

Years.	Puds.	Years.	Puds.
1868	1,710	1873	2,020
1869	2,010	1874	2,030
1870	2,160	1875	2,000
1871	2,400	1876	2,050
1872	2,330	1877	2,520

Production of silver during the ten years from 1868 to 1877 as follows:

Years.	Puds.	Years.	Puds.
1868	1,120	1873	610
1869	1,770	1874	720
1870	870	1875	600
1871	830	1876	680
1872	750	1877	680

Imports and exports of gold and silver (not shown separately) as follows:

Years.	Imports.	Exports.
	Roubles.	Roubles.
1869	2,600,000	15,700,000
1870	2,700,000	23,900,000
1871	7,400,000	17,700,000
1872	13,000,000	7,900,000
1873	20,600,000	14,700,000
1874	16,600,000	17,500,000
1875	6,400,000	28,000,000
1876	5,400,000	103,300,000
1877	10,900,000	19,300,000
1878	16,500,000	14,200,000

The quantity of the precious metals consumed in the arts and manufactures cannot be ascertained.

Coinage of gold since 1800.

Period.	Roubles.	Period.	Roubles.
1800–1809	4,300,000	1840–1849	137,300,000

[Copy of a note of the Minister of Agriculture, Industry, and Commerce, dated October 29, 1879. No. 13.030 gives information as to the amount of gold and silver in Italy, as reported by the Minister of Finance, in reply to letter of July 31, 1879.]

It is impossible to reply with entire certainty to all the inquiries of the Ministry as to the quantity of gold and silver, or ingots, supposed to be in circulation in the Kingdom of Italy, the production of the mines, and the annual consumption in the arts and manufactures. The reserve in gold and silver in the treasury, with which is included that of analogous institutions, amounts to a sum total of about 120,000,000 of lire. As to the reserve of gold and silver existing outside of the treasury, it would be impossible to furnish any positive information; even an estimate would have a purely hypothetical character.

If an amount should be required (taking into consideration all the researches made as to the approximate issue) of the reserve held by individuals, and of bank issues, it may be placed at something more than 100,000,000 of lire, making the total of gold and silver coin existing in Italy to be about 300,000,000 lire. As regards the production of the gold and silver from our mines, it may be stated that for the three years from 1875-'77 the production of gold and silver has been as follows;

1875.	£ 80,000
1876	286,000
1877.	375,000

The production of silver in Tuscany has been for—

1875.	£131,000
1876.	92,000
1877.	93,000

It would be impossible to furnish any approximate estimate of the annual consumption of gold and silver in the arts and manufactures.

Italian Coinage from 1862 till 1878.

Years.	Gold— Of $\frac{900}{1000}$. Pieces of 100, 50, 20, 10, 5 lire.	Silver— Of $\frac{900}{1000}$. Pieces of 5 lire.	Silver— Of $\frac{835}{1000}$. Pieces of 2 and 1 lire—50 and 20 cents.	Remarks.
1862	£28,608,760	£964,435	£330,960.50	From 1874 the circulation of 5-lire pieces was annually limited.
1863	76,514,100		31,751,913.20

The German consular reports from Sydney contain the following remarks, 1877: "During 1876 were received in the mint of Sydney, from the colony of New South Wales, 126,788 ounces = £479,133." This sum decreases with every year; the highest amount was delivered in 1872, viz: £1,513,186. 1878: "During 1877 were received only 97,582 ounces = £366,329." 1879: "The amount received in 1878 was 75,492 ounces = £279,166, all produced by the colony," the whole amount delivered in the mint of Sydney for coinage during 1878 was 107,347 ounces, of a value of £382,741.

The gold production of 1879 is given in the report of the department of mines as follows: "Delivered in the mint of Sydney, from the various mining districts, 106,900 ounces gold; there were exported 2,750 ounces gold, together 109,650 ounces, valued at £407,219, while the production of the previous year had been 119,655 ounces. Of the production of 1879, three-fourths came from the gravel mines, one-fourth from quartz veins. Up to the year 1878 there were produced 434,379 ounces of silver in New South Wales (mostly from copper ores). The production of 1878 was 60,563 ounces; that of 1879 already 83,164 ounces, and for 1880 more than 100,000 ounces have been produced in all probability; it is to be concluded with great certainty that many new gold-fields may still be found." The report for 1878 says: "Mining industry in Queensland is still in its infancy; nevertheless, the export of gold alone is nearly equal to that of wool, our staple article of export, viz: about £1,000,000." According to this, the expectations of a few years ago were not realized.

—*Extract from "Zur Statistik der Edelmetalle in den Jahren 1876-80," von Dr. Adolf Soetbeer.*

New Zealand.

	1876.	1877.	1878.
Export of gold . .	£1,268,599	£1,476,312	£1,244,192
Import of gold coin	104,802	425,059	333,135

Some gold still found in Tasmania.

On the total export of gold by the Australian colonies, and the net export after deduction of inter-colonial import, we find the following figures in the "Statistical Abstract:"

	1876.	1877.	1878.
Total gold export	£8,212,368	£10,248,024	£8,877,171
Gold export after deductions of colonial import . .	5,793,236	7,599,887	5,828,951

The direct import of gold into England from Australia was—

		Kilograms.
1871–1875, on the average,	£7,097,800	=52,000
1876, on the average,	4,956,800	=35,500
1877, on the average,	6,655,438	=48,700
1878, on the average,	5,680,600	=41,000
1879, on the average,	3,184,600	=23,300
1880, on the average,	3,614,200	=26,400

As the annual report of gold alone is no sure indication of the production of the corresponding year, I paid attention to other reports in making the following table of gold production in the Australian colonies:

	1876.	1877.	1878.	1879.
	Kilos.	*Kilos.*	*Kilos.*	*Kilos.*
Victoria	34,100	25,200	23,580	23,600
New South Wales	4,000	3,100	3,720	3,400
Queensland	11,700	13,200	8,900	?
New Zealand	9,300	10,800	9,100	?
Total	59,100	52,300	45,300	39,000

The following table shows the Australian gold production for twenty-four years:

	Kilograms.
1856–1860 . . .	86,700
1861–1865 . . .	77,700
1866–1870 . . .	70,400
1871–1875 . . .	59,900
1876 . . .	59,100
1877 . . .	52,300
1878 . . .	45,300
1879 (incomplete) . . .	39,000

The above table shows an extraordinary diminution of the Australian gold production during the last twenty years, which fact contributed a great deal to raise doubts respecting a full supply of gold in the future, as they found expression in the book of Professor Süss, "Die Zukunft des Goldes." It will be of interest to learn the views of a mineralogist on the future production of gold in Australia, which are in no way influenced by views on the question of standard. Mr. Ulrich writes from Dunedin, New Zealand, November, 1878, to the News Jahrbuch für Mineralogie, &c., 1879: "I cannot agree with Professor Süss when he speaks despondingly of the Australian gold production. It cannot be denied that the yield in Victoria has decreased since a number of years, and that it will continue to decrease. But it is just equally probable that the yield of New South Wales, South Australia, Tasmania, and above all of Queensland, will not only make up for the deficit of Victoria, but will swell the total amount of Australian gold production. In *Victoria* the alluvial gold deposits are nearly exhausted, and the quartz reefs are already worked. There are in all probability large deposits of gold under a thick layer of basalt, the working of which will be costly and can only take place slowly, not influencing much the annual yield of gold in Victoria. It has been proved that the richness of the strata diminishes with their depth. All things considered it seems probable that the yield of gold in Victoria will decrease down to 600,000 to 700,000 ounces; but at that point it will remain stationary for a longer time. All depends on the number of miners, which was diminished by 20,000 to 30,000, as new land laws made them take up land. This thirst for land being stilled, we may count upon a greater stability in the number of miners. As to New Zealand, I can state that the discovery of many new alluvial diggings may be foreseen with great certainty, and a large immigration is, of course, a good source for miners. For Queensland the prospects are all excellent. The veins of Gympie and Gilbert and other old mines still yield well, and promise well for the future, and every mail brings news of discovered alluvial and quartz mines. There seems to exist a broad gold-containing zone, of various breadth, through the whole of Queensland, up to the gulf of Carpentaria, where it meets the gold fields of Port Darwin, in the northern territory of South Australia. There is certainly a great improvement for vigorous working of these mines; the climate is unfavorable for white persons. The Chinese prosper there, but recent legislation has put obstacles in the way of a large Chinese immigration. Besides this the natives are troublesome.

In South Australia are the just mentioned mines of Port Darwin, remarkable for their rich quartz veins and for numerous alluvial mines, but the climate is even more unfavorable to white miners than that of Queensland. As the veins occur in primary rocks they may be considered of a stable nature. *Tasmania* is beyond doubt a colony rich in metals. Its richness in gold, doubted a few years ago, is now proved by new discoveries and great yields. The gold occurs mainly in rich quartz veins, yet alluvial diggings are by no means rare; they only wait for legislation, as they mostly occur on private lands. As to New Zealand, the reports of the State geologist promise an increase of gold production for the northern island. I know the province of Otago well, and am sure of an increased production of gold there. The older alluvial diggings are certainly well-nigh exhausted, but there are other deposits in conglomerates, so-called cements, which promise a good yield for a long time to come. The main cause of the decrease of the gold production in New Zealand is the fertile soil and climate favorable to agriculture which allured the miners to the easy task of the husbandman. Increased immigration, however, will bring new miners to the gold deposits. The report of the mining department in Sydney quoted above and dated September, 1880, goes far toward corroborating the views of Mr. Ulrich. It says that the decrease in the Australian yield is mainly caused by the preference for agriculture and industrial pursuits evinced by the miners. "The production would rise immediately if capital was applied to the mines in larger proportion, bringing with it new miners and more rational methods of mining. Old mines deserted for their unproductiveness could be restored in this way to new life, as we see it indeed not very rarely." Thus it will be seen that testimony is not wanting which may be opposed to the theory of an unavertable decline of the Australian gold fields.

Victoria.	1876.	1877.	1878

Average annual earnings in alluvial mines	51 10 7	47 8 0¾	47 3 6¾	48 10 ⅛
New mining companies . .	94	60	81	167
Nominal capital	£1,349,696	£667,316	£791,960	£1,286,674
Estimated value of steam engines and other inventory in the gold mines . .	1.989,500	2,029,962	1,903,494	1,899,788

The quantity of gold exported from Victoria in a form other than coin and that coined in the colony from the discovery of gold to December 31, 1879, is officially given as 48,719,930 ounces, valued at £194,879,722. In 1879 mines of more than 2,270 feet depth were successfully worked. The production of gold during 1880 is estimated at 800,000 ounces, about 40,000 ounces more than in the two preceding years. The production of silver up to the end of 1879 was 151,267 ounces.

Queensland.	1876.	1877.
Export of gold dust	£1,284,165	£1,452,396
Export of gold bars	143,764	158,707
Total	1,427,929	1,611,103
Import of gold coin	181,550	

The German Consular Report for 1876 says: "Gold is the main metal exported from Queensland. The gold export amounted to 374,776 ounces, valued at £1,427,929. Gympie, on the Mary River, is here the oldest gold field. The shafts are now sunk deeper, and very rich strata have been found in this way. In the north, on the rivers Normanby, Laura, and Palmer, gold washing is prosecuted with good success, and some deep shafts have been sunk, which meet numerous gold veins in quartz. On the rivers are still found, besides dust, large chunks of gold of several pounds weight. Almost every day brings new gold discoveries, and since we have many hundreds of square miles in the mountains that have never been prospected, we may conclude that new gold fields will still be found.

Total	3,089,306,364 48

MINES.

Value of the gold yielded by the mines of the republic, approximately $989,161
Value of the silver produced by the mines, approximately . . 25.167,763
Value of the gold coined at the various mints of the republic 589,161
Value of the silver coined at the same mints 23,667,763

The standard value of pure gold is $675.41 per kilogram. The standard value of pure silver is $40.91 per kilogram. These values have been deduced from the quantity of pure metal, which according to law, must be contained in a piece of gold of the value of $20 and the weight of silver.

Table showing the amount of gold and silver coined by the mints of the Republic during the year 1879.

* Official estimate "L'Economiste Français," July, 1881, p. 112.
† Estimated.
‡ Victoria and New South Wales official; the other colonies estimated as producing the same amounts reported officially for 1877.
§ Dr. A. Soetbeer.
‖ Estimated as the same as 1879.
a From total production 17 per cent. of gold and 25 per cent. of silver deducted for foreign ores.

Coinage of Various Countries.

[Calendar years, with the exception of Japan, India, and Portugal. Foreign coins converted into United States money at the values estimated by the Director of the Mint, January 1, 1881.]

HISTORICAL MEMORANDA CONCERNING GOLD AND SILVER.

FOR the following we are indebted to the valuable "History of the Precious Metals," by Alexander Delmar. Nothing more forcibly illustrates the almost purely accidental character of supplies of the precious metals than the discovery of the gold placers; indeed, the whole settlement and working of California as a great mining country. The Spaniards, solely intent upon obtaining the precious metals, had discovered and partly explored this country so early as the sixteenth century. They colonized and held possession of it for three centuries, established missions, pacified and converted the Indians, whom they used as domestic servants and workmen, and cultivated many of its arable valleys. They introduced into it all of the cereal grains known in Spain, and even transplanted the grape, the fig, the pomegranate and the artichoke. Persuaded from the outset that it was a country rich in the precious metals they never ceased to look for them. Occasionally they found some particles of gold, but not enough to warrant further search. The few adventurers who were attracted thither from time to time by stories of its mineral wealth, generally found their way back, disappointed and impoverished, to Mexico, whence, for the most part, they had come. A few remained to turn rancheros, and settle down with the mission fathers and the semi-Christianized Indians into a sort of pastoral community, which eventually became a race of half-breeds, given to apathetic habits and the pursuit of pleasure

Such were the economical and social conditions of California when the adventitious "success of the Democratic party (of the United States) in the close presidential election of 1844"[1] led to the independence of Texas, the war with Mexico, the annexation of California, and to its settlement by Americans. But for these events, which have no necessary connection with mining or the search for the precious metals, Alta California might have remained as Lower California has to this day, a province of Mexico, and might still have been the remote and undeveloped country that it was under the Spanish mission fathers. The existence of Gold in Lower California was known to Cortes, who fitted out an expedition from Mexico in 1537, and returned with some small quantities of the precious metal. Its existence in Alta California was discovered in 1577–79 by Drake's expedition, and noticed in Hakluyt's account of the region.[2] The finding of gold was mentioned in 1690 in a work published in Spain by Loyola Cavello, a priest at the mission of San José, in the bay of San Francisco. Captain Shelvocke in 1721 noticed signs of gold in the soil. The historico-geographical dictionary of Antonio de Alcedo, 1786–89, positively affirms the abundance of gold, and speaks of lumps weighing from five to eight pounds. In 1837 a priest from California went to Guatemala, and induced a Mr. Young Anderson, a Scotch gentleman, to endeavor to obtain English capital for the purpose of mining gold, which, he averred, was to be found not far from San Francisco. The favorable geological appearance of the country for gold was noticed by Prof. J. D. Dana, and recorded in his report on California. In April, 1847, a Mr. Sloat made a very decided statement of this kind in Hunt's "New York Merchants' Magazine." At this time the Mormons connected with the army, together with some Mexicans and Indians, were engaged in searching for gold upon the banks of the streams. In January, 1848, some of these men gathered a quantity of gold on Mormon Island, near Sacramento, and within a few miles of the rich placers afterwards discovered.

And yet none of these observations or operations led to the great discovery, which was made by a child, the daughter of one Marshall, the overseer of Captain Sutter's mill. While a race was being dug for this mill on the American fork of the Sacramento, the child found a lump of gold which she showed to her father as a pretty stone. That lump was the

[1] "Report of the U. S. Monetary Commission," p. 43.

[2] The report of the U. S. Mining Commissioner, Nov. 24, 1866, p. 268, contains other references to early discoveries of gold in California.

beginning of over two hundred and twenty million pounds sterling, ($1,100,000,000) which the California placers have yielded to the world.

During the first few years after the discovery of the placers the entire precious metal product of the coast was derived from this source, and consequently consisted entirely of gold. Hydraulic mining was commenced in a small way so early as 1854, but it did not assume material proportions until after the close of the American Civil War. Vein mining was begun in California at about the year 1860. It has not even yet become important. It has, however, assumed enormous dimensions in the adjoining State of Nevada, where it was commenced at about the same time, and where the chief part of the product, in quantity though not in value, is silver. The principal, but by no means the only locality of this industry has been the Comstock lode, upon which Virginia city is built, many of the mines being directly beneath the town. The principal ones are thirty in number, and at the present time are being worked at an average depth of 2,000 feet, though some few of them are down nearly half a mile. From the following table it will be seen that the placers reached their maximum productiveness almost immediately after their discovery, the greatest yield having been in the year 1853, when sluicing and hydraulic mining had already been commenced. Since the year 1853 the production has steadily fallen off, until at the present time it certainly does not equal £4,000,000, and may not exceed £3,000,000 a year.

Production of Gold in the State of California Proper.

Sums in Millions of Pounds Sterling and Decimals.

Year.	Production.	Year.	Production	Year.	Production.
1848	£2·0	1859	£10·0	1870	£5·0
1849	8·0	1860	9·0	1871	4·0
1850	10·0	1861	8·16	1872	3·8

1853	13·0	1864	7·0	1875	3·52
1854	12·0	1865	7·0	1876	3·72
1855	11·0	1866	5·0	1877	3·0
1856	11·0	1867	5·0	1878	3·4
1857	11·0	1868	4·4		
1858	10·0	1869	4·5		

Turning from the statistics of the State of California proper to those of the Pacific coast generally—and this means substantially all of the United States, for the production of the precious metals on the Atlantic coast is too insignificant to merit consideration in this connection—we have the following results:—

Production of the Precious Metals in all the United States.

The production of gold from 1776 up to and including 1847 is estimated at £4.000,000. From 1848 to 1860 inclusive the productions of California shown in the preceding table will answer as well for that of all the United States.

The production of silver from 1776 up to and including 1858 is estimated at £200,000. For 1859 it is estimated at £20,000, and for 1860 at £30,000.[1] The annual production of gold and silver, respectively, from 1861 to 1878 inclusive is shown in the following table:

Annual Production in the United States of Gold and Silver, respectively, from 1861 to 1878 inclusive.

Year.	Gold.	Silver.	Year.	Gold.	Silver.
1861	[2]£8,600,000	[2]£400,000	1870	[3]£6,750,000	[4]£3,200,000

[1] R. W. Raymond, formerly Mining Commissioner, in Hewitt's "Century of Mining," pamphlet, Philadelphia, 1876, p. 31.

[2] R. W. Raymond in Hewitt's "Century of Mining."

[3] John J. Valentine's Amended Estimates, published in "Report of U. S. Monetary Commission," vol. i. app. 22.

[4] Returns from the mines to the present writer on behalf of U. S. Monetary Commission; "Report," vol. i. app. pp. 13, *et seq.*

All the above estimates, except those based upon the returns from mines, are excessive. Both Mr. Valentine's estimates and Mr. Raymond's, which are based upon them, contain many duplications, which were, perhaps, unavoidable from the method employed to obtain returns. They also contain (except those marked "[3]") the precious metals produced on the west coast of Mexico and in British Columbia, which are shipped to San Francisco for market. The estimates marked "[4]" are free from these objections. The details of the returns from the mines are given at length in the Appendix to Report of the United States Monetary Commission, vol. i., pp., 1 to 60 inclusive. The following table showing the estimated annual production of gold and silver together, by States, is derived from Mr. Valentine's original estimates, which, although excessive in its total sums by about one-fifth, or at least one-sixth, [1] is given here in order that a rough view may be had of the quantities produced in the various districts mentioned. The sums are in millions of pounds sterling and decimals.

The annual production of gold in British Columbia, nearly all of which finds its way to San Francisco, and is included in Mr. Valentine's original estimates, and therefore also in Mr. Raymond's, is given by the Colonial Minister of Mines in his report dated Victoria, February 1, 1878, as follows. (Sums in pounds sterling):—

Year.	*Production.*	*Year.*	*Production.*	*Year.*	*Production.*
	£		£		£
1864	740.000	1869	360,000	1874	360,000
1865	700,000	1870	260,000	1875	500,000
1866	540,000	1871	360,000	1876	360,000
1867	500,000	1872	320,000	1877	320,000
1868	480,000	1873	260,000		

From these statements and figures it will be observed that the production of the precious metals in the United States reached its climax as to gold in 1853, and as to silver in 1876, and that it has since declined. At the present time the great Mines of the Comstock lode, which of late years have yielded the principal supplies of both gold and silver, have recently almost ceased to be productive, and the outlook for the future, unless it is changed by the new mining developments, points to a still further reduction in the crops of both metals.

Australia.—Gold was discovered on the Macquarie River, New South Wales, in February, 1851, and by the 1st of June following there were upwards of 1,000 men in the diggins. On the 10th of June it was discovered on a tributary of the river Loddon, Victoria;[1] on the 20th of July at Mount Alexander, Victoria; and on the 8th of August at Mount Buninyong, Victoria; and on the 8th of September at Ballarat, Victoria. In the month of October upwards of 7,000 miners were at work. By the end of the year the number of persons in all the placers of Australia was from 15,000 to 17,000, and some £900,000 worth of gold (mint value) had been taken out.[2] In 1852 the number of miners had swollen to something like 150,000 (including about 9,000 ticket-of-leave convicts[3]), when, notwithstanding the extraordinary and unequalled production of that year, it was found that on the average gold-digging was unprofitable, and many persons left the workings to engage in other pursuits. Although gold-fields were subsequently discovered in several other of the Australian colonies,[4] both the total production and the number of miners employed declined after the year 1852 with little interruption,[5] until, at the present time, the former scarcely exceeds £4,000,000 a year, and the latter 50,000 men.

The following table shows the estimated annual production of gold in all the Australian Colonies from the discovery of the first placers in 1851 to the present time, and is chiefly from the tables, presented to the British Parliamentary Commission on Silver in 1876, by Sir Hector Hay. The estimates for the years 1851, 1876, 1877, and 1878 are by the present writer.

Annual Production of Gold in all Australia, 1851 to 1878 inclusive, chiefly after Sir Hector Hay. Sums in pounds sterling.

Year.	*Production.*	*Year.*	*Production.*	*Year.*	*Production.*
	£		£		£
1851[6]	900,000	1854	9,540,000	1857	11,400,000
1852[7]	20,600,000	1855[8]	12,000,000	1858	10,680,000
1853	14,140,000	1856	14,280,000	1859	10,820,000

Year.	*Production.*	*Year.*	*Production.*	*Year.*	*Production.*
	£		£		£
1860	10,500,000	1867	5,920,000	1874	6,000,000
1861	9,760,000	1868	7,640,000	1875	5,760,000
1862	9,360,000	1869	6,320,000	1878	6,200,000
1863	8,880,000	1870	5,840,000	1877	4,800,000
1864	9,140 000	1871[9]	6,660,000	1878	4,000,000
1865	8,820,000	1872	5,800,000		
1866	8,840,000	1873	6,300,000		

The total production from the discovery to the present time has amounted to upwards of £240,000,000, a greater sum than that obtained from either of the previous notable gold-fields, of which the following table affords a rough comparison:—

[1] See Mr. Valentine's evidence given before the writer, in "Rep. U. S. Mon. Com.," vol. i. App. pp. 32–48. Mr. Valentine's tables include nearly a million pounds sterling worth of lead, contained each year in silver (base) bullion. See Ibid., Question 107, and Mr. Valentine's report for 1878, where the value of this lead is placed at £700,000 to £1,000,000 a year, since 1873.

[2] "U. S. Monetary Com. Rep.," i. App. 22; and Valentine's Report, 1878.

[3] As nearly as can be ascertained at present. Probably excessive as gold portion.

[1] New South Wales and Victoria were made separate colonies in 1856.

[2] "App. Cyc.," viii. 346, and "Progress of Victoria," by Wm. Henry Archer Melbourne, 1867, p. 50.

[3] "App. Cyc.," ii. 383.

[4] New Zealand, 1852; South Australia and Tasmania about 1852; Queensland, 1857.

[5] "Report of Mr. Consul James F. McGuire," "U. S. Commercial Relations," 1860, p. 53.

[6] This estimate for 1851 is based on the statement in the "Progress of Victoria," p. 50, that 145,137 oz. of gold were exported in that year from Melbourne alone. "App. Cyc.," viii. 351, gives a nearly equal amount for the production in that year of New South Wales.

[7] This figure seems excessive; but it has been retained only after a careful comparison of several authorities. The Melbourne gold-brokers, who had every opportunity of being well informed on the subject, state that, in the earlier years, large amounts of gold were carried away in private hands without being reported in the exports at the Custom House. See "Progress of Victoria," p. 50; also Appleton, viii. 346, where it is stated that "the product of both colonies decreased annually from 1852."

[8] Vein mining, now successfully established in Victoria, produced in this year one-eighth of the entire yield of the colony. "App. Cyc.," viii. 347.

[9] Vein mining began in New South Wales in 1871. "Progress and Resources of New South Wales," Sydney, 1871, p. 21.

Comparative Yield of the Great Gold Fields of the Modern World.

Country.	Period during which the product was not generally less than £1,000,000 a year.	Total Product of gold from beginning to end.
Japan	1580 to 1639—60 years	£40,000,000
Brazil	1710 to 1789—80 years	180,000,000
Russia[1]	1840 to 1878—39 years	160,000,000
California Proper[1]	1848 to 1878—31 years	220,000,000
Australia[1]	1851 to 1878—28 years	240,000,000
Totals	238 years	£840,000,000

It has been frequently claimed that it was owing to the observations of Sir Roderick Murchison, in 1844, concerning the similarity between the geological formation of the Australian and the Ural mountains, that gold was discovered in Australia.[2] But this was no more the fact than that it was owing to either of the following observations:—

A despatch of the Lieutenant-Governor of the Colony to the Secretary of State dated September 2, 1840, enclosed a report from Count Strzelecki stating that he had discovered auriferous pyrites in the vale of Clwydd in 1839;[3] and the Rev. Mr. Clark, a geologist, announced his discovery of the metal in the same colony in 1841. The Indians knew of it; and made their arrow-heads of gold. The white shepherds found some; but wisely refrained from searching for more.[4] The fact is, that the discoveries of 1851 were not owing to any of these observations, but to the chance prospecting of a California miner named Hargreaves. Australia was not a solitude when Hargreaves visited it. The aborigines had roamed its mountains and encamped upon its auriferous river banks from time immemorial, without troubling themselves about its gold. It had been a penal colony of Great Britain since 1788, and at the period of the discovery of gold contained a permanent population of nearly 400,000 white persons, a large portion of whom were free colonists engaged in agriculture and sheep farming, whose settlements stretched in every direction: who, before the gold discoveries, had been engaged among other industries, in mining copper; and who, therefore, had a motive for prospecting the country for metals. Yet more than sixty years had passed after the colony was established before its auriferous deposits came to light.[5]

The Western World's Production.—The following statistics of the production of gold and silver in the Western world relate to America, Europe, and those portions of Africa open to European commerce. With the exception of the £100,000,000 obtained from Japan by the Portuguese and Dutch they comprise nearly all the precious metals acquired by the European world since the discovery of America to the beginning of the present century.[6]

I. Showing, chiefly by decades, the estimated average annual Production of Gold and Silver by the mines of America from the Discovery to the beginning of the nineteenth century. From the works of Baron von Humboldt, the Abbe Raynal; Mr. Ward, and the Compiler of Executive Document, No. 117, 1st Session, 21st Congress, U. S. A.

Sums in Pounds Sterling.

Average Annual Production.

Period.	Gold.	Silver.
1493 to 1545 (53 years)	£ 340,000	£ 120,000
[7]1546 to 1555	600,000	[2]3,400,000
1556 to 1570 (15 years)	540,000	1,460,000
1571 to 1580	400,000	1,400,000
[1]1581 to 1590	600,000	[1]2,800,000
1591 to 1600	600,000	2,800,000
1601 to 1610	500,000	2,300,000
1611 to 1620	500,000	2,300,000
1621 to 1630	560,000	2,440,000
1631 to 1640	600,000	2,600,000
1641 to 1650	600,000	2,600,000
1651 to 1660	560,000	2,440,000
1661 to 1670	560,000	2,440,000
1671 to 1680	560,000	2,440,000
1681 to 1690	560,000	2,440,000
1691 to 1700	1,500,000	2,300,000
[2]1701 to 1710	[2]2,400,000	2,000,000
1711 to 1720	2,400,000	2,200,000
1721 to 1730	3,000,000	2,400,000
1731 to 1740	6,000,000	2,600,000
1741 to 1750	4,000,000	3,200,000
[3]1751 to 1760	2,000,000	[3]3,800,000
1761 to 1770	2,000,000	3,800,000
[4]1771 to 1780	2,000,000	[4]5,000,000
1781 to 1790	2,000,000	5,600,000
1791 to 1800	[5]2,000,000	[6]6,490,000
Totals, 308 years	£393,120,000	£745,260,000

[1] These gold-fields are still yielding "over £1,000,000," to wit, about £4,000,000 a year each.

[2] Report of the Commissioners of the International Congress of Australian statistics in 1861, published in Phillips on "Mining," p. 102.

[3] The Count afterwards stated that he was urged by the Governor to keep the discovery secret, for fear it would impair the discipline of the 45,000 convicts on the island. "Thirty Years in New South Wales and Victoria," quoted by Phillips.

[4] Some of the shepherds had picked up pieces of gold in Victoria, but they wisely paid no further attention to the matter. Phillips, 103.

[5] Porter's "Progress," ed. 1851, p. 770.

[6] These data were originally compiled by the author for the U. S. Monetary Commission, and published in its report, vol. i. App. p. 61, *et seq.*

[7] Discovery of Potosi.

According to Mr. William Jacob, the gold and silver produced in America, Europe, and Africa, and supplied to the commercial world from 1492 to 1809 was £1,360,600,000. Of this amount he credits Europe and Africa with £137,-000,000, leaving £1,223,600,000 for the production of America alone. Deducting £83,200,000 for the production of the nine years 1801-1809 inclusive, would leave £1,140,400,000 for the production of America during the period 1492-1800 inclusive. The £1,360,600,000 he disposes of as follows:

Exported to Asia	£399,000,000
Converted into articles of use and ornament	440,000,000
Lost by abrasion, casualties, &c.	175,000,000
Left for coin in Europe and America	346,600,000

The last-named sum, added to the estimated stock of coin on hand in Europe in 1492, viz., £33,400,000, amounts to £380,000,000, which is his estimate of the stock of coin in the Western world in the year 1809. Mr. Danson's estimate of the production of the precious metals in America during the period 1492-1803 is £1,122,000,000. Deducting £25,600,000 for the production of the three years 1801-1803, would leave £1,096,400,000 for the production of America during the period 1492-1800 inclusive. The quotient of Table I. given above is £1,138,380,000. It is, therefore, 2,-020,000 less than Mr. Jacob's estimate, and £41,980,000 in excess of Mr. Danson's. While Mr. Danson's estimate for this period is probably nearest the truth, the figures given above are preferred, because they show the production by details of gold and silver separately, and by decades of years, which is not the case with either Jacob's or Danson's tables.

II. *Showing the estimated Production of* SILVER *in the Western World (America, Europe, and Africa) annually, since the commencement of the nineteenth century.*

The figures for the year 1800 to 1829 inclusive are constructed on the following basis:—The amounts coined at all the legal mints of Mexico, brought to the royal mint of Potosi, and raised in and exported from Coquimbo, are put together, and to the quotient £2,-000,000 are added each year for the conjectured production of all other countries in Europe and America. This conjecture is warranted by Sir Hector Hay and employed in his tables of production.

The figures for the year 1830 to 1851 inclusive are from various compilations indicated in the foot-notes. When not otherwise indicated, they are from Danson's compilation, "London Statistical Journal," xiv. 23.

The figures for the years 1852 to 1874 inclusive are from Sir Hector Hay.

The figures for 1875 and 1876 are compiled by the present writer, and for 1877 estimated.

[1] Amalgamation process first employed in America by Medina in 1567. Consult Tooke, vi. 358. This process, however, was well known to the ancients.

[2] Brazilian gold-washings begin to be productive.

1858	8.14	1867	10.84	1876	15.20
1859	8.16	1868	10.04	1877	14.00
1860	8.16	1869	9.46		
				Total, 26 years.	268.36

According to the preceding table the production of silver throughout the Western world during the period 1800–1829 was £159,820,000, and during the period 1830–1851, inclusive £120,080,000. Deducting £24,480,000 for the three years 1849–1851 would leave £255,420,000 for the period 1800–1848 inclusive. For the period 1803-1848 inclusive Mr. Danson estimates the American production of silver at £249,000,000, and Tooke the European and African production at £30,000,000. If to these sums there be added £20,-000,000 for the production of the three years 1801–1803, the total sum of production, 1800–1848 inclusive, according to Danson and Tooke, would be £299,000,000; but for reasons similar to those adverted to in a subsequent part of this chapter, relating to the gold production since 1800, Mr. Danson's estimates of the American production of silver are regarded as excessive, and the figures of the foregoing table are preferred.

III. Showing the estimated production of GOLD *in the Western World (America, Europe, and Africa), annually since the commencement of the nineteenth century.*

[The figures for the years 1800 to 1847, inclusive, are derived from estimates by the following authorities:—Humboldt, Raynal, Duport, Brogniart, Ward, Jacob, Danson's compilation, Price's and Tooke's "History," vol. vi. For this period the statistics are unsatisfactory, and are more reliable by groups of ten years than for any single year taken by itself. The figures for the years 1848 to 1876, inclusive, are from the authorities quoted in the foot-notes.]

1857	[3]26·66	1867	[4]22·80		
				Total, 29 years	676·30

It should be stated in reference to the period of forty-eight years, 1800 to 1847 inclusive, which foots up £120,240,000, that this sum is considerably less than that assigned by Danson to America alone. His figure for the period of forty-five years, 1804-1848, is £142,179,411. If the production for the years 1800-1803, namely, £8,000,000, be deducted from, and the figures for the year 1848, namely, £13,500,000, be added to, the total shown in the above table, so as to make it agree with the period shown in Danson's, the total will only amount to £125,740,000, or to £16,439,411 less than Danson's estimates. An analysis of the latter, however, will hardly stand the test of criticism, and the figures are evidently excessive. For example, on the strength of five years' custom-house returns of exports of gold from Buenos Ayres during the period 1822-1826, Mr. Danson assumes the same average, namely, £71,836 per annum, for the entire period, 1809 to 1848 inclusive, and adds—quite gratuitously—266⅔ per cent. to this for smuggling to make a total from Buenos Ayres of £10,535,976. On the strength of an incidental remark by the British consul, in 1831, to the effect that the exports of specie from Montevideo in 1803 and 1804 may be taken as the ordinary shipments, he makes out a total export from that port during the period 1809-1848 of £40,000,000, of which he arbitrarily assumes 47 per cent., or £18,800,000, to have been in gold. These two results, together with £4,802,282 determined, upon a little better basis, to have been otherwise produced, in Buenos Ayres, give a grand total of £34,138,258 as the production of gold in that country during the period 1809-1848, whereas *one-tenth* of the amount would probably be much nearer the truth. In a similar manner, on the sole basis of returns of £8,825,149 of gold coined at the mints of Bogota and Popayan, in Columbia, during the period 1804-1829, which gold is believed to have consisted entirely of old coin and plate, he makes out a production of gold for that country during the period 1804-1848 of £40,851,066. Not to pursue these palpable exaggerations any further, it need only be stated that while the statistics for this period are very unsatisfactory, the figures of Humboldt, Ward, and Jacob are a sufficient warrant for keeping the average production of the period under £2,000,000 a year until the opening of the Russian gold-washings, and then at very little over £2,000,000 a year until these washings began to make a comparatively important addition to the then very limited supplies of gold to the world; and this did not occur until after the year 1840, when for the first time the Russian product amounted to so much as £1,000,000 a year.

Jacob's estimate of the average production of gold during the period 1809–1829 is £1,598,000 per annum, and this includes £720,000 per annum for Europe and Asia, leaving but £878,000 per annum for all America. A compilation published in U. S. Ex. Doc. 117, 1st Session, 21st Congress, 1830, estimates the annual production of gold in the world from 1801 to 1810 at £2,000,000 a year, and from 1811 to 1825 at £1,540,000 a year. From these evidences and the details contained in Humboldt, Jacob, Ward, Tooke, &c., it is believed that the figures of the above table are approximately correct, at least for any group of ten years, and, if at all wrong, that they are excessive. It will be observed that the lowest point of production is assigned to about the year 1816. MacCulloch differs from this in ascribing the lowest point to about the year 1829; but there is reason to believe that in this respect, and because he judged rather from the receipts of new metal in Europe than from the production at the mines, that eminent author placed the date of the min-

[1] "Westminster Review," January, 1876. [2] MacCulloch.
[3] "Journal des Economistes." [4] Sir Hector Hay. [5] Blake.

imum production a few years behind the true time. The general results of the foregoing tables are as follows:—

Sums in Millions of Pounds Sterling.

	Silver.	Gold.
Production of America during the period 1493—1800	745·26	393·12
Production of America, Europe, and Africa supplied to the Western World during the period of 1801—1876	527·70	794·54
Totals	1272·96	1187·66

or twelve hundred and seventy-two million nine hundred and sixty thousand pounds in silver, and eleven hundred and eighty-seven million six hundred and sixty thousand pounds in gold.

The following table shows the estimated production of gold and silver, respectively, throughout the world, by countries during the years 1877 and 1878.

Sums in Millions of Pounds Sterling.

Countries.	1877.		1878.	
	Gold.	Silver.	Gold.	Silver.
United States	8·3	7·6	7·5	7·0

Other countries	0·5	2·0	0·4	2·0
Total	19·3	14·7	16·7	13·1

With reference to the probable future supplies of the precious metals and their relation to the population and commerce of the world, the former must be expected to decline both relatively and absolutely. The population and commerce of the Western World are both increasing. At the same time the mines of all the principal producing countries, the United States, Mexico, South America, Australia, and Russia, are all declining in productiveness; and unless new and unforeseen discoveries—and it is difficult to conjecture in what quarter of the world such discoveries can be made—should put a different face upon the matter, the production of both gold and silver will continue to diminish. This conclusion should, however, furnish no ground for alarm. Since the beginning of the eighteenth century the precious metals have become less and less the general Measure of Value that they once were throughout the Occidental world, and more and more the measure of the Measure of Value; which latter is now the whole sum of intrinsic coin, plus the sum of token or subsidiary coin, plus the sum of bank and government and other paper employed as money. The precious metals are merely the foundation of this edifice, and for a very considerable portion of the superstructure, to wit, the irredeemable or unredeemed paper currencies of many countries, the precious metals afford no basis whatever. Whether the partially numerary systems in vogue in these countries (Brazil is the only one among them whose monetary system appears to be entirely numerary) will last, and so permanently reduce the requirement for the precious metals or not, is a problem for which it is no part of the design of this article to offer a solution.

There unfortunately exists no means of determining with any reasonable precision the amount of the consumption of the precious metals for other purposes or in other ways than for the purpose of money. Efforts of this sort have been made by Mr. Jacob and other writers, but they are not only too rude to be depended upon: those which, like Mr. Jacob's, have been made with any care, are antiquated, and would not afford any guide to the present disposition of these metals. The only satisfactory view which can be had of the subject is the limited one obtained by deducting from the total supplies since the discovery of America, the stock on hand as money at the present time. The remaining sum will necessarily be that of the meanwhile total consumption of the precious metals in the arts, shipments to Asia, loss by accident, and wear and tear by the abrasion of coin. The total sum of the supplies to Europe up to 1878 inclusive were about £2,627,800,000.[1] To this must be added £33,-400,000 for the amount of specie estimated to have been in use as coin in Europe at the period of the discovery of America. The total of these two sums is £2,661,200,000. The amount of coin estimated to have been in the Western World in 1876 was £700,000,000, and at the present time it is from £600,000,000 to £700,000,000. It follows that of the total supplies nearly £2,000 000,000, or over seventy per cent. has been lost, consumed in the arts, or exported to Asia.[2]

Similar calculations, made up to previous dates, determine the proportion of consumption to production to have been as shown in the following table:—

Sums in millions of pounds sterling.

Date.	Cumulative supplies to date.	Stock at date.	Cumulative consumption	Per cent. of consumption to supplies since last date.
1675	[3]509	250	259	50
1700	592	297	295	50
1775	1,054	275	779	74
1808	1,314	380	935	71
1828	1,441	313	1,128	78
1838	1,510	270	1,240	82
1850	1,675	400	1,275	76
1860	2,040	560	1.480	72
1870	2,365	720	1,645	70
1876	2.564	740	1,824	71

From this calculation it appears that, within the past century, the consumption in the arts, &c., and for exportation to Asia has never fallen below 70 nor risen above 82 per cent. of the total supplies, and this only at one period of unusual metallic dearth. These results appear to afford ground for the opinion that, hereafter as heretofore, this consumption will amount to about three-fourths of the supplies; but such an opinion, though possibly correct, should not be adopted without further examination. The first influence that would seem to govern the distribution of the precious metals is the requirement for coin, for upon the quantity coined appears to hang the most important consequences, to wit, the general level of prices, and therefore the relations of exchange, which means most of those of society. But this is by no means the case. Coin has been superseded to so great an extent in the transaction of exchanges, that although it continues to form the basis of them in several of the leading countries of the world,[4] its actual use has been dispensed with to a very considerable degree. Hence whether more or less of it is used as money, or it is allowed to be superseded by acceptable forms of paper, are facts that do not appear to be essential to the maintenance of prices, or the existing relations of exchange and society. Thus, some £40,000,000 of metal are said to have been accumulated in the United States within the past few years with the view to resumption this year (1879). If this be true it would seem that £40,000,000 which would otherwise have been consumed in the arts, &c., have been reserved for coin; but the fact, if it is one, does not seem to have influenced prices one way or another. These continue generally to be the same as before. The employment of bank cheques, bank and government notes, and other forms of paper is so extensive, that the monetary circulation of the commercial world has become highly elastic; and it is only when the specie basis is dangerously low, as in the years previous to 1838, or needlessly and superfluously high, as in those previous to

[1] This includes £103,400,000 from Japan.

[2] The flow of specie to Asia since the discovery of America is difficult to determine, the principal obstacle lying in the uncertainty which attended this movement during the eighteenth century. According to Jacob, supplemented by other estimates which include the flow before and since the period treated by him, the total flow to date has been upwards of £700,000,000. Allowance for the £103,000,000 obtained from Japan, would reduce the net flow to Asia to £600,000,000. It has therefore absorbed about one-third of the whole amount not reserved for coin in the European world.

[3] Including the £103,000,000 from Japan.

[4] It will be born in mind that, except Great Britain and Germany, no leading country of the world was, until quite recently, paying specie. The United States suspended in 1862; Austria in 1865; Italy in 1866; and France in 1870. Spain, Turkey, Russia and Japan have also, in fact, suspended.

1870 (*vide* the above table) that the value or purchasing power of the precious metals is affected enough to change the usual course of their distribution. For it must be considered that the enormous stock on hand, say £600,000,000 to £700,000,000 at the present time, acts as a powerful conservator of prices. Substantially not an ounce of this metal can change its purchasing power until that of the whole mass is changed, and the mass is so magnified by the use of paper substitutes that such change is slow and gradual. The miner can no more afford to wait until specie goes up, before he sells, than the silver and goldsmith can afford to wait until it goes down before he buys; consequently the one sells and the other buys, from time to time, without the least reference to the world's stock of coin, and without being at all affected (except at periods of extremity) by its fluctuations.

It would therefore seem to follow, that the distribution of the supplies of the precious metals is not primarily governed by the requirement for coin, but, owing to the elasticity of the demand for coin, rather by the requirement for the arts. Another consideration is involved in the fact that, turned into coin, metal affords no profit, while as used in the arts it does. Hence the prime tendency of the consumption of the precious metals should be, and indeed is, towards the latter. In selling his metal to the mint the miner has to compete with the spoliations and servile labor of past ages, for he can obtain no more for his product than the current value of an equal amount of gold or silver, the bulk of which was stolen from conquered races, or forced from the labor of slaves. But in devoting it to the arts, or what is the same thing, shipping it to Asia, he, or rather the silversmith, gold-beater, or merchant, who now acts for him, can dispose of it to better advantage, and this fact is enough to turn the scale in favor of its general flow towards the arts. Still another matter for thought lies in the fact that while there may be no loss in melting coin, there is a very serious one in melting plate, or reducing other works of art to crude gold and silver. Hence, while it is quite a common thing to do the former, it is a very rare one to do the latter.[1] In many forms of art, as in gilding, dentistry, photography, &c., the precious metals cannot be reduced to crude forms, and are, indeed, practically irrecoverable. This is much the case, also, with reference to the shipments of specie to Asia. This specie goes into circulation there at a much lower level of prices than that in Europe, or else it is melted down and used in the arts, for bangles and other jewelry, for gilding crockery, lacquer-ware, &c., or in the manufacture of those beautiful bronzes for which the Orient is famous, and nearly all of which contain some alloy of silver. The general result is that what metal goes into the arts in Europe, or is shipped to Asia, remains there,[2] and as it goes there in the first place without reference to the scarcity or plentifulness of coin in the European world, it remains there with equal indifference to that important consideration. Upon a general review of the subject it would appear that now, at least, not coin, but the arts, are the first and principal attraction that determines the distribution of the precious metals, and that it is only after the demand for the arts has been satisfied that the supplies of specie are permitted to accumulate as coin.

World's Stock of the Precious Metals.—The main purpose of Mr. William Jacob's history of the precious metals, and that one in the pursuit of which he was led into those many interesting digressions which contribute to greatly enhance the value of the work, was to examine "the source of those large accumulations of gold and silver which are represented to have existed in the early ages of the world, of their gradual increase in quantity, and the causes of the disappearance of a large portion of them." Unaware, or careless of the fact, that in many of the States of antiquity, notably Greece, Carthage, and Rome, numerary moneys were employed as currency in certain periods of their progress, the gifted author was led to assume that gold and silver alone, or at least principally, were used as measures of value, and in consequence he was induced to estimate the accumulated stocks of these metals in ancient times at sums which, in the light of this and other considerations, seem far too excessive. Avoiding any precise estimate of these sums until the Augustan age, he begins for that period with the assumption that the stock of the precious metals in the Roman Empire, which he regards as tantamount to all the European world, amounted to about £358,000,000. Having made this assumption he next proceeds to calculate, from the conditions of supply and consumption, particularly from the ascertained loss in the weight of coin from abrasion,[1] the vicissitude of this stock of metal, from time to time, that is to say, every thirty-six years until the year A.D. 806, and afterwards every one hundred years until the beginning of the present century; and arrives at conclusions which, ever since they were published, have commanded the respect of the learned world.[2] It is not proposed to question these calculations for any period subsequent to the discovery of America, because for these periods such abundance of evidence is advanced by Mr. Jacob and others concerning the supplies and accumulations of the precious metals as to leave no room for doubt concerning their reasonable accuracy. With regard to the previous periods the considerations above advanced, together with some others presently to be set forth, render it quite evident that Mr. Jacob's hypothetical calculations are untenable. The basis of these will now be given in the author's own words. Says Mr. Jacob: "We find in Suetonius that Vespasian, when he succeeded to the imperial dignity, asserted that a sum equivalent to £322,916,600[3] was necessary to support the commonwealth. This amount could not have reference either to the annual revenue or to the accumulation in the public treasury; for the produce of neither of those departments at any period could have yielded so large a sum. It is not, however, unreasonable to suppose that it bore reference to the whole mass of coined money at that time known, or believed, or supposed to be in circulation, within the boundaries of the republic. Assuming then that this sum was nearly the amount of the whole stock of current money, we may, without relying on its precise accuracy, venture to make use of it as the foundation of an estimate of the loss created by abrasion in the course of the period we have brought under consideration. Vespasian began his reign, and uttered the opinion we have stated, about two years after the death of Nero. In the time of Nero the aureus had declined in value, from the reign of Augustus, at the rate of somewhat more than ten per cent., and we now assume that the coined money, in this period, had decreased in nearly the same proportion. With these views we should calculate the quantity of money in the time of Augustus to have been about £358,000,000."[4] It is to be objected to this hypothesis—1st, that the sum mentioned by Suetonius refers quite plainly to the revenues which were required to support the State, and these may have included a requirement for the payment of debts during an understood term. This term may have been of one, two, five, or ten years, according to the custom of the period. Estimates of this character are often made in modern States for a period of several years together, and it is therefore not at all necessary to suppose, as Mr. Jacob has done in this case, that, if to the revenue at all, it referred to the "annual" revenue of Rome.

2d. Although long previous to the period of Vespasian, A.D. 70-79, the copper numerary system of the Roman Com-

1 "Not one-hundredth part of what passes through their (the bullion dealers') scales, consists of gold and silver that had before been manufactured." Jacob, vol. ii. p. 316.

2 The only notable exceptions to this rule were the melting of plate during the Spanish and Spanish-American revolutions, and the return of silver from India to England during the years 1832 and 1833.

1 Upon the basis of numerous experiments, made in the British Mint, the details of which are published in the appendix to Mr. Jacob's work, he determined this to be equal to about one three-hundred-and-sixtieth part annually, or a thirty-sixth part in ten years. Jacob, vol. i. p. 224.

2 Humboldt, "Fluctuations of Gold," says that Mr. Jacob's work deserves the highest consideration. Tooke (Newmarch) vi. 359, considers it "the highest authority to which we can appeal."

3 "Quadrigenties millies (scilicet H. S. Vespasianus) statim initio sui principatus opus esse professus est, ut republica stare posset."—Suetonius in Vespasiano, cap. xvi. This passage reads: "*He* (*Vespasian*, understood) *said, at the outset of his reign that, in order that the State should be able to stand, there was need of four hundred thousand*" (*hundreds of thousands of sesterces*, understood). Four hundred thousand hundreds of thousands equal forty thousand million; and this is the sum of numerary sesterces which Arbuthnot, Adam, and Jacob have converted into sterling gold.

4 Jacob, vol. 1, p. 224.

monwealth had perished and given way to a silver, and afterwards, in Cæsar's time, to a gold intrinsic currency, yet there are not wanting evidences that during the Dictator's reign coppers had again become numeraries—at least that they were highly overvalued. There is no other explanation for the fact that Caligula, A.D. 37-41, hastened to coin enormous quantities of them, and without consent of the Senate.[1] It is probable that during the period when they were wholly or nearly intrinsic (from B.C. 207 to B.C 46 or thereabouts) the copper coins of Rome were exported in large quantities to Spain and the other provinces, and that the resulting scarcity at Rome had converted them once more into numeraries, or at least rendered or left them highly overvalued As the sum mentioned by Suetonius is named in (understood) sesterces, and as the sesterce of this period was of copper,[2] and therefore highly overvalued, the rate at which it has been converted by Jacob into intrinsic pounds sterling of gold is erroneous; for this conversion (after Adam and by him Arbuthnot)[3] is made upon the basis that the sesterce was always a silver coin, or at least a sum of intrinsic silver, that is to say, silver coined at its bullion value. Dr. Adam says that the sesterce was a silver coin, the value of which was two asses and a half, "and often called absolutely nummus, because it was in most frequent use."[4] The fact that it was called "nummus," a numerary, should have guarded this learned author against the view that it was an intrinsic coin; but unfortunately it did not. Pliny, who must be regarded as better authority on the subject, informs us not only that the sesterce was of copper, but also that it was made of "aurichalcum," a peculiar sort of copper (probably to guard against counterfeiting), while the as was made of the common copper of Cyprus.[5] Mr. Noel Humphreys published fac-similes of the copper sesterces, vast numbers of which are still extant in the cabinets of numismatists.

At the period of Vespasian there were also sesterces of silver (chiefly from previous reigns[6]): just as at the present time the Americans have three-cent pieces of nickel and silver. But this fact does not help Mr. Jacob, for at this period all the silver coins of Rome were of limited and qualified legal tender, and overvalued. In other words, a given sum of sesterces, whether they were of copper or silver, would purchase more gold before than after being melted; just as at the present time a given sum in either the nickel or base-silver three-cent pieces of the United States will purchase more gold before than after being reduced to crude metal. These three-cent pieces are token coins, and so were the Roman sesterces, their value being due not to the metal they contained, but to the stamp of the government, and the law which made them limited legal tenders. On the general subject of the modern misapprehension of sums in ancient Roman money, the Marquis Garnier, who devoted a life of study to Roman antiquities, says that the translations of these sums are simply preposterous.

3d. The Roman method of notation was extremely liable to error. In the sum mentioned by Jacob, not only is "sesterces" inferred or understood, but so also is "hundreds of thousands of;" the only portion of the supposed sum actually written in the original being "four hundred thousand."

4th. The sum which Jacob assumes to have represented the stock of money in Europe at the Vespasian period of the Roman Empire, when viewed as such, is inadmissible. The population of Europe at this period, according to Merivale, did not exceed 60,000,000, and this number, when divided into the sum assumed by Jacob, gives for result an intrinsic gold or silver currency equal in amount to six pounds sterling per head of population. As even after the opening of Potosi Europe never possessed a stock of the precious metals amounting per capita to much more than one-half of this, the result arrived at by Mr. Jacob must be regarded as excessive.[1] There is no doubt that Mr. Jacob's general conclusion that the European stock of specie gradually diminished from whatever it was in the days of the Empire to about the sum he estimates it to have amounted to at the period of the discovery of America, is correct; it is only his estimate of the stock in the ancient times that is doubted. As to the stock at the period of the discovery, we have, in addition to Mr. Jacob's estimate, a statement made by Mr. Gregory King in 1696, which, although it was published at the time that Jacob wrote, is not alluded to by that writer, and probably escaped his researches. This statement affords support to and confirms the substantial accuracy of Mr. Jacob's view with regard to the stock at the period mentioned. Mr. King estimated the European stock of coin, bullion and plate, at the time of the discovery of America at £45,000,000. Mr. Jacob estimated the coin alone at £34,000,000. This is regarded as a substantial agreement.[2]

Following Mr. Jacob for the various periods between A. D. 1492 and 1828, and the most credible authorities for subsequent dates, and following other credible authorities for estimates of the population of the Western World, we have the following comparative view of the progress of gold and silver money and population at the periods named.

Table showing the estimated stock of Gold and Silver Coin, and the Population of the European world from time to time since the Discovery of America.

Period. A. D.	Authority for Population.	Population.	Authority for Stock of Coin.	Stock of Coin.	Stock per Capita.
				£	£ s. d.
1492	Estimate	40,000,000	Jacob	34,000,000	0 16 0
1636	Estimate	80,000,000	Estimate	240,000,000	3 0 0
1690	Petty-Jacob	85,000,000	Jacob	250,000,000	3 0 0
1700	Voltaire	90,000,000	Jacob	297,000,000	3 6 0
1776	Voltaire	110,000,000	Jacob	275,000,000	2 8 0
1808	Humboldt	200,000,000	Jacob	380,000 000	1 18 0
1828	Balbi	240,000,000	Jacob	313,000,000	1 6 0
1838	Humboldt.	260,000,000	Estimate	270,000,000	1 0 0
1839	MacCulloch	265,000,000	Storch	284,000,900	1 0 0
1850	Putnam	300,000,000	MacCulloch	400,000,000	1 7 0
1860	Stat. Journal	330,000,000	Estimate	560,000,000	1 14 0
1870	Behm & Wagner	370,000,000	Seyd	720,000,000	1 18 0
1877	Behm & Wagner	400,000,000	Estimate	700,000,000	1 15 0
1879	Estimate	410,000,000	Estimate	650,000,000	1 12 0

The bases for many of the foregoing figures will be found set forth in the Minute on the Population and Specie of the Western World, published in the Report of the Monetary Commission, and the authorities therein quoted.[3] They are omitted from this work from considerations of space. The basis for the last line will be found in Appendix B to this chapter. In order to make the dates in the population estimates tally with those in the estimates of coined money, proper allowances have been calculated, and the estimate as thus amended has been credited to the author who furnished its foundation. In a similar way additions have been made for the European population of America, &c., to estimate of

[2] "Though the sestertius was originally a silver coin, its value was estimated in copper." Adam Smith, bk. i. ch. 5. The copper sesterce was first issued in the time of Augustus, and almost immediately became nearly the only monetary unit used in calculation." Humphreys' "Manual of Coins," i. 301.

[3] "The statements of Arbuthnot are not much to be depended upon." J. R. MacCulloch, "Com. Dic.," ed. 1856, p. 1063.

[4] "Roman Antiq.," p. 427.

[5] Pliny's "Nat. Hist.," bk. xxxiv. ch. 2; Bohn's ed. vol. vi. p. 149.

[6] The silver sesterce had almost disappeared during the reign of Augustus. Humphreys' "Manual," pp. 302-3.

[1] In A. D. 1700 the stock per capita was £3 6s., and since that period it has never been so great. It is now about £1 16s. per capita.

[2] Concerning subsequent dates these writers disagree. The following table affords a comparison of their estimates:—

Year.	Year.	King.	King.	Jacob.
King.	Jacob.	Coin, bullion and plate.	Coin and bullion only.	Coin only.
1488	1492	£45,000,000	—	£34,000,000
1588	1599	100,000,000	—	130,000,000
1688	1699	225,000,000	£146,000,000	297,000,000

Mr. Jacob having devoted much greater consideration to the subject, and having had before him the very elaborate data of Baron von Humboldt, has been preferred as an authority in these pages. Mr. King's statement was first reprinted by Mr. Chalmers in 1801, and has since been republished by Mr. Newmarch in Tooke's "History of Prices," vol. vi., p. 667.

[3] Some clerical errors which crept into the original publication ("Report," App. p. 71) are herein corrected. Some alterations are also introduced.

the population of Europe proper. The fact that the stock of coin in 1776 is put at less than that in 1700 may lead to a doubt of its correctness; but it seems to be well authenticated that until the development of the great silver lodes of Biscaina, Sombrerete, and Valenciana, in Mexico, towards the end of the last century, the supplies of the precious metals were not only inadequate to the demands of commerce, but that the stock of coin in Europe and America absolutely declined. The falling-off of the stock from 1808 to 1839 has been admitted by Humboldt, Jacob, MacCulloch, Tooke, and other writers on the subject. Referring now to the general and comparative aspects of the foregoing table, it will be observed that at the period of the discovery of America the Western World started with a stock of coin amounting to about 16*s.* per head of population, and that this proportion continued to increase until the opening of the eighteenth century, when it amounted to £3 6*s.* per capita. During this period plundering, discovery, and commercial adventure were stimulated to the extremest limits. The seas and bays of the entire world were explored, commerce was extended into the Americas, Africa, India, China, Japan, and the islands of the South Sea, and colonies were founded all over the world. The social organism was stimulated into the greatest activity. This was the period of the Revolution, Habeas Corpus Act, and Bill of Rights, in England; of the numerous risings of the peasantry, the Edict of Nantes, and the Fronde in France; of the Republic in the Netherlands; of the Protest and Thirty Years' War in Germany; and of the Reformations throughout Western Europe generally. After this period the stock of coin diminished from £3 6*s.* per capita in 1700 to £2 8*s.* per capita in 1776, £1 18*s.* per capita in 1808, £1 6*s.* per capita in 1828, and £1 per capita in 1838. It is noticeable that coincidently with this fall of the stock of coin the Western World exhibited all the marks of arrested development and social perturbation.

This was the period during which all the great national debts arose; when France, England, Russia, Germany, the Papal States, the American Colonies, the United States, Brazil, and many other countries, suspended specie payments, and when Europe and America were almost constantly shaken with insurrection and wars. It was the period of the American and French revolutions; of the separation of Mexico and the South American colonies from Spain; of the Chartist agitation and riots in England; and of popular commotion in all the countries of the Occident. Assignats, wild-cat banks, ruinous paper experiments, and the open repudiation of their debts by great corporations and States were the financial characteristics of the period. Before the eighteenth century the stock of coin and of money was the same, for there was little circulating paper in Europe beyond the confines of the Italian republics. After the beginning of the eighteenth century the stock of coin was not the same as the stock of money, but only the basis of it. At that time the Bank of England began to issue circulating notes, and this example was soon followed by other institutions. In 1716 circulating notes were issued by the Royal Bank of France; but between 1720, when this institution failed, and the issue of assignats by the French revolutionary government in 1789, no paper issues of any considerable amount were made in Europe proper; though, since the beginning of the century, they had become quite common in the American colonies. Substantially, therefore, the stock of coin and of money were much the same from the beginning of the eighteenth up to nearly the beginning of the present century. After that period they began to differ very considerably.

Of the stock of coin estimated to have been in existence in 1870 about one-third consisted of silver. The demonetizations of this metal which since that date have been effected in several of the leading countries of the world, have resulted in reducing the general stock of coin, which, at the present time, is something below its amount in 1877. The progress of the demonetization of silver threatens to reduce this stock still further, and the present tendency is therefore towards a smaller stock of specie in the European world. With regard to the stock of coin in particular countries the author has examined a great number of authorities, and from these has compiled the data on the subject to be found elsewhere in this book. From these it will be seen that at the present time the stock of coin in the Western World amounts to over £600,000,000, and that two-thirds of this amount are held in France, Great Britain, and the North German Empire. Estimates of the stock of coin existing in given countries are usually founded upon statistics of coinage and foreign commerce, and as a rule are excessive. For example, it is considered very doubtful that either France, Great Britain or Germany contains at the present time any such stocks of coin as are usually credited to them, and as quite probable that, could the truth be ascertained, these would exhibit a considerable reduction.

The Ratio of Ancient Times.—If our view is extended over the entire range of history—both ancient and modern—it will be found that the relation of value, or ratio between gold and silver has varied from 1 silver = 10 gold, to 1 gold =20 silver. An instance of the first-named ratio belongs to the Orient, and carries us back more than fifteen centuries before our era. The second belongs to the London market during the silver panic of July, 1876.[1] In a fragment of the works of Agatharchides—a Greek geographer who lived at the time of Ptolemy VI., Philometer, King of Egypt (B. C. 181—145)—we are informed that at one time the value of silver in ancient Arabia was tenfold that of gold.[2] No date accompanies this statement, but since we are assured by other evidences that so early at least as the eighth century before Christ, gold in the valley of the Tigris was thirteen times the value of silver, we may, without fear, assume that Agatharchides writes of a period long previous to this. If we may trust to the deduction of a German savant, silver was cheaper than gold during the seventeenth century before Christ. But, although this may yet prove to have been the fact, it is deemed hardly safe to infer it from the evidence advanced.[3] The superior value of silver must have disappeared when the silver mines of Greece were opened, and the Phœnician traders exchanged their exuberant metallic produce for the freights of the Orient. This occurrence must be assigned to a very high antiquity, and with the greatest probability to the era of Cadmus, some fifteen centuries before Christ. Xenophon, who lived 443—355 B. C., says of the antiquity of these mines: "No one ever pretended from tradition or the earliest accounts of time, to determine when these mines first began to be wrought, which is a proof of their antiquity."[4] And with reference to their bearing upon the value of silver he says:—

"The divine bounty has bestowed upon us inexhaustible mines of silver, an advantage which we enjoy above all our neighboring cities, by sea and land, who never yet could discover one vein of silver ore in all their dominions."[4] From these evidences there seems to be some warrant for concluding that the superior value of silver to gold, vouched for by Agatharchides, existed at some period previous to the fifteenth century before Christ. It was doubtless confined to the East. Some explanation of the high value of silver in the Orient, and particularly in Arabia, at this remote period, is found in the following named facts. 1st. In the absence of accounts of any important siver mines, or the knowledge of reducing silver ores in the Orient, coupled with the working of the gold sands of the Indian rivers, and the placer and quartz mines of ancient Arabia,[5] we are justified in inferring that previous to the discovery of the Greek silver mines there had accumulated in the Oriental

[1] The writer was informed by one of the parties to the transactions, that shortly after the discovery of gold in California, it was often sold by the miners for its weight in silver coins, or at the ratio of about 1-1. This, however, was quite an exceptional circumstance, and local to California.

[2] Jacob, vol. i. p. 97. The superior value of silver to gold in very ancient times is asserted by Boeckh, "Polit. Econ. Athen.," book i. chap. 6.

[3] Brandis, on the tribute lists of Thutmosis, sculptured upon the monuments of Thebes (Karnak). The date, however, appears to be inferred from a passage in Herodotus relating to a period "eleven centuries later. Consult Brandis as quoted by Raymond, U. S. Mining Com. Rep.," 1874, p. 473, and Herodotus, book iii. and Boeckh, p. 12.

[5] According to Captain Burton's recent work, "The Gold Mines of the Land of Midian," Arabia, in remote times, was devasted in the search for gold as thoroughly as the Roman provinces were in later ones.

world—and of this Arabia formed an important part[1]—a considerable mass of gold with comparatively little silver. Without any reference whatever to cost of production, the presence of a considerable quantity of one metal, and of a very limited quantity of the other, may have rendered the latter the more valuable. This we know to have been somewhat the case in Peru, where, previous to the landing of the Spaniards, gold was less valuable than copper.[2] The narrowness of the ratio in Japan, *i. e.*, 6 to 7, before the Portuguese opened it to the influence of the Western ratio, and *the relapse* of the ratio from 12 or 14, during the era of Portuguese commerce, to 6 or 7 after the ports of Japan were closed in 1639, affords other confirmation of the correctness of this view.

In the Occidental world gold seems to have been the more valuable metal from the remotest historical period. We are informed that, by the laws of Menes the value of gold was fixed in Egypt at two and a half times that of silver.[3] The era of Menes has been placed at the thirty-seventh to the thirty-ninth century before Christ; and if credit be accorded to these statements and dates, it would seem that between the eras of Menes and of Cadmus, either very little commercial intercourse existed between Egypt and Arabia, or else that for some reason, perhaps the use of numerary money, very little commerce in the precious metals took place between them; or else that the Oriental ratio, not differing materially from the Occidental in the time of Menes, had gradually accorded a higher value to silver, until this movement was reversed again through the influence of the Greek mines. It is, however, very much more easy to believe that the ratio quoted from the code of Menes belongs to a later date than Menes himself. Like other great codes of law, this one was doubtless greatly modified in time; and, though always passing by the name of Menes, contained provisions that were incorporated into it centuries subsequent to the epoch of its author. This is the case with the Roman codes, and many others. In turning from these remote eras and insecure hypotheses to the more satisfactory accounts of the classical historians, it becomes desirable to ascertain beforehand, so far as we may, what are the principal influences that govern the relation of value between the precious metals. By this means it is hoped that a more satisfactory connection may be traced between the scattered fragments of antiquity.[4]

The common view of this matter is that the ratio is governed by the relative cost of the production of these metals; but after what is elsewhere advanced by the present writer concerning the fallacy of this view, so far as it relates to the value of each metal compared with other commodities, it need scarcely be repeated that it is equally fallacious in its application to the value of one metal compared with the other. The suddenness and rapidity of many of the changes of ratio —for example, those which followed the conquests of Alexander the Great, Julius Cæsar, Cortez, and Pizarro,[5] and even the late change from the long time ratio of 15½ to the present one of 18—also prove that it cannot be due to cost of production; for these changes, and many others, took place without any corresponding changes in the conditions of production. Referring to the conclusions elsewhere reached with respect to the influences which control the value of the precious metals, it is only necessary to say in this place that quantity is the primal element that determines the value of money, whether it consists of the precious metals or any other substances, or these combined with other substances; and as to the value of one metal in the other, it depends on quantity as effected by legal regulations.

I. Quantity is related to the stock of each metal on hand in the world, monetized, or physically and legally susceptible of being monetized, plus all numeraries, tokens, bank notes, or other money, whether of paper or other substances. Quantity also involves consideration of the current and prospective supplies of metal or other moneys, either from conquest, mining, or legal monetization, and the proportion of such supplies to the combined stock of monetized metals, and other substances or tokens used as money. Taking this to be the meaning of quantity as related to money, it may be accepted as an entirely safe doctrine that it is this, and this alone, which primarily regulates its value. When this quantity is subordinate to the will of man, and that will subject without restraint to individual self-interest, then, indeed is the value of the thing thus produced due to cost of production; but not otherwise. For example, the quantity of cotton cloths which may be produced this year throughout the world is subordinate to the will of man. The exercises of this will is subject, without practical restraint, to the influence of individual self-interest. Any man who has the means may produce as many cotton cloths as he pleases; nor, as things stand, can the combined will of society stop him. There is no interdict upon the production of cotton cloths. Cotton cloth may, therefore, be produced in practically illimitable quantities, or its production may be abandoned altogether. Cost of production alone determines what quantity of it shall be produced. But this is not the case with the precious metals. Their production cannot be indefinitely increased; mines cannot always be found; nor, when found, worked; nor, when worked, made to yield metal. The vast quantity of the precious metals accumulated and on hand in the world cannot be disposed of; and this quantity is so vast compared with the utmost current production, that a long period must elapse before the latter could sensibly affect the value of the former. Nor are the precious metals alone in these respects. Improved land stands in the same category of commodities which are not amenable to the law of cost of production. Its quantity cannot be increased indefinitely; and the vast areas already in the possession of man must necessarily have a powerful conservative influence upon its price. Therefore, although the cost of taming wild lands were to fall to-day to a mere fraction of its previous cost, the fact would have no appreciable influence upon the value of land. Indeed, it may be said, broadly, that no commodity whose production is not amenable to the influence of individual interest derives its value from the cost of production.

For example, though to artificially produce water—a commodity for which there is no substitute, and with the acquisition of which society does not interfere—by the chemical union of hydrogen and oxygen, might make it worth a thousand dollars per cubic inch; yet so long as the earth is as full of it as it is to-day, that liquid will remain not without the highest worth, but without the slightest value. Were it conceivable that the springs and rivers were dried, and man were compelled to resort to the laboratory for his supplies of water, then, and not until then, would the cost of its production determine its value. And so, in a similar way, it may be said, that when there are no substitutes for gold and silver, when their production is entirely amenable to the will of man, not only socially, but individually, and every man may produce as much or little of them as he chooses, then, and not till then, will their value be determined by the cost of their production.

II. Legal regulations, first, concerning the ratio itself, and second, concerning money at all, are, next to quantity, the most potent of all the influences that determine the ratio of value between the precious metals. So potent are they that, under certain circumstances—as those of universal specie money and tolerably equal quantitative stocks and supplies, the regulation of a single important nation, or of several nations combined, might be sufficient to render the market ratio of the world whatever may be desired—for example, 1 gold = 1 silver—and to keep it there for ever, entirely irrespective of cost or of quantity. With regard to the influence of legal regulations upon the relative value of gold and silver, it is to be observed that it was exerted in three ways—firstly, through the effect of such legal regulations upon quantity; secondly, through discriminating taxes or mint charges upon the metals, after they shall have been extracted from the earth, or obtained from conquered nations (no matter what the cost of original production), and introduced into the markets at their cur-

[4] See Buckle's "Essay on Liberty," as to the higher value conferred upon facts by the discovery of their relations.

[5] See table of the ratio appended to this chapter.

rent value; thirdly, by the mere force of law, irrespective of quantity or of discriminating charges. These operations of law will be treated in their turn.

A. The effect of law upon quantity, and of quantity upon ratio.

The monetization or demonetization of either metal, or a change of standard, as it is called, will diminish the supply compared with the demand of the monetized metal. Such an act will enhance the demand, without increasing the supply, and thus render the monetized metal dearer, and contrariwise the demonetized metal cheaper. The most recent notable instance of this kind is that afforded by the German Imperial mint laws of 1871. The limitation or extension of coinage facilities will produce similar results—as witness the effects of the recent closing of the French mints to the coinage of ecus.[1] Like results will follow the suspension or resumption of specie payments by any important country, or the substitution of numeraries, tokens, or bank notes for specie, or of specie for numeraries, tokens, or bank notes. Such legal regulations will cause the supply of the precious metals to change its proportion to the demand for them, and will thus alter their value relative to other commodities. Several instances of this sort have occurred within late years, as when the United States suspended specie payments in 1862, Italy in 1866, and France in 1870.[2]

B. Effect of mint charges upon ratio.

The imposition of discriminating mint charges has an important influence upon the ratio. If the latter stood at 1 gold = 1 silver, and the same rate were levied upon one metal as the other, it would make no difference how mine charges were imposed, whether by weight or value. But when the ratio is unequal, an *ad valorem* mint charge, as though apparently similar for both, becomes in reality a discriminating charge in favor of one metal, and against the other. Thus, suppose the ratio to be, as it was in the days of Herodotus, 1 : 13, a mint charge of, say five, or any other per cent. *ad valorem* upon both metals would amount to thirteen times as much in weight upon silver as gold. The charge upon gold would be ·05 of gold, and upon silver ·65 of silver, which is thirteen times as much. If, instead of this, the mint charge were five per cent. of the weight of the metal coined, it would be equally the same for both. Thus it would amount to .05 pound of gold upon each pound of gold, and .05 pound of silver upon each pound of silver. Hence it makes an important difference whether mint charges are imposed *ad valorem*, or by weight. The tendency of *ad valorem* charges is to widen the ratio; that of weight charges, as far as the ratio is concerned, is *nil*. Whenever debts have to be paid abroad, commercial competition obliges the shipper of metal to select the one upon which the lighter mint charges are levied, in order that, upon being recoined in the country of its destination (history knows nothing of universal coinage or uniform coinage), it should yield him the greater net result in coined metal. One of the metals would thus become more desirable than the other. Since the opening of the Greek and Spanish silver mines, this metal has been gold; and the tendency of discriminating mint charges has been to continually widen the ratio. Every time the metals passed from one country to another—that is to say, every time they had to be recoined—more mint charges had to be paid upon silver than gold (for the charge, so far as we know, has always been *ad valorem*), and but for the almost entire failure, at certain times, of the supplies of both metals, and their relatively limited stock at all times, it is believed that this influence alone would have so greatly widened the ratio as to have rendered silver, ere this, almost worthless for the purposes of specie or "intrinsic" money. Previous to the era of the silver mines alluded to, the tendency of the mint charges was doubtless the other way, namely, to render gold less and less valuable. At the present time, the substitution of Government and bank notes for coins in the various mixed currencies of the world deprives silver of the protection which the limitation of new supplies has afforded to its value, against the encroachments of the mint charge; and the ratio, which now stands at 1 : 18, must be expected to widen to 1 : 20, and further. Nothing seems likely to avert this result, short of one or two measures. Either the mint charges of all the principal countries employing the precious metals for money must be levied upon weight instead of value, or else a number of powerful nations must combine together to sustain the value of silver by arbitrary decree.

C. Arbitrary decree.

Theoretically, arbitrary decree can make the ratio whatever may be desired, irrespective of either quantity or mint charges; practically, arbitrary decree is unattainable. To render such decree effective, it must be that of several important nations combined. It is easy enough for nations to resolve; but what motive beyond their own interest is there to induce them to execute? None but their own sense of right; and among nations—but few of which have as yet clearly passed beyond the feudal stage, and thrown off the influences of Church and caste—this can hardly be relied upon too implicitly. Supposing, however, that such cooperations were attainable, and, for example, the combined nations of Europe and America decree, and remained steadfast to the decree, that the ratio of gold and silver should henceforth be as 1 : 1, it is difficult to conceive how this ratio could ever be changed, either by the operation of quantity, mint charges, or any other influence. Relative demands of the precious metals for the arts could not change it, for even supposing everybody preferred gold plate to silver—a preference which under such circumstances cannot be admitted—this would not change the ratio. As no atom of gold could become money again, except at a par with silver, it is impossible to imagine that any scarcity of the one metal, or plentifulness of the other, could impair their equal value. It would not matter if, other things aside, gold were preferable to silver for use in the arts, or not. The law of nations, making them, when coined, equal as money, and all contracts dischargeable, all debts payable in the same weight of one as the other; and the conversion of both, from coin to bullion, and from bullion to coin, being unlimited, and subject to the same terms of seignorage, it necessarily follows that their value would be the the same.

Nor could the vicissitudes of production effect a change in the ratio. Though but a pound of gold a year were produced against millions of pounds of silver, still would the ratio remain unchanged. Nobody would pay more than a pound of silver for a pound of gold, when the former could discharge the same amount of indebtedness, past, present, and future. Nor would the demands of commerce change it. If debts were due from one country to another, the shipment of one metal would answer all the purposes which could be subserved by a shipment of the other, seeing that both metals, when coined, would be equally legal tender in all countries, and that coinage everywhere would be unlimited, and subject to the same charges for both metals. Nor would the condition of the stock on hand alter the ratio. Although this stock consisted nearly entirely of silver, and very little of gold, still would a pound of silver always buy a pound of gold, so long as the universal law rendered the one equally as effective as the other in the payment of debts, the market and the legal price would always be the same.[1]

Some familiar examples of the operations of law upon the value of the precious metals may seem desirable in this place. Until the passage of the recent law of the United States, remonetizing the silver dollar, that coin, always weighing the same, viz., 371¼ grains pure, was sold to the exchange brokers of San Francisco for about 90 cents in gold—*i. e.*, nine-tenths of 23.22 grains of pure gold.

[1] "Report U. S. Silver Com." [2] Ibid. pp. 21, 22.

[1] On a previous occasion the writer reached the same conclusion from even a narrower basis, *i. e.* upon the assumption of a fixed ratio, and unlimited coinage, by a single important commercial country, instead of, as herein, from the point of view afforded by the supposition of a common law on the subject between all nations. He said:—

"A legal ratio between the precious metals adopted in an important country, if coupled with full legal tender, and unrestricted coinage, at brassage, or a moderate seignorage, constitutes in effect, a standing offer to purchase all the current supplies of one metal at a fixed price in the other . . . It follows that the free mint prices, when the mints are competent to deal with the supplies, make the market ratio." "U. S. Silver Report," Appendix, 66.

Upon the enactment of the law the silver dollar rose to par. The law simply enlarged the legal tender function of the coin from $5 to an unlimited amount. At the present time, while this dollar is at par in gold, the metal it contains can be purchased in the market for 90 cents or less. Again, the trade dollar, which contains 378 grains pure, is not worth as much in the market as the silver dollar of 371¼ grains; because the law makes the latter an unlimited legal tender, and the former not. Finally, two half-dollars—weighing, if coined between 1853 and 1873, only 345·6 grains, and if coined since 1873, only 347.22 grains—are worth in the market more than a trade dollar of 378 grains, the former being legal tender for $10, and the latter not.[1] The operation of law shown by these examples is of a purely local character, and is probably not susceptible of further extension, without incurring the risk of being defeated by counterfeiting. Indeed, it is believed to be already beyond this limit.[2] It is useless to discuss the probability of the adoption by international convention of any general and radical reform, concerning the legal ratio between the metals. Such an event seems too remote; and, before it happens, it is probable that attempts will be made to solve the monetary problem, through the adoption of purely numerary systems.

Reviewing what has been adduced concerning the influences which practically determine the ratio of value between gold and silver, it may be said, briefly, that among these influences, cost of production finds no place at all; that the principal ones are the stock of the precious metals, and the laws concerning money; and that among the latter is one (the discriminating mint charge against the cheaper metal) which has always had the tendency to render the dear metal dearer and the cheap metal cheaper. Resuming our history which may now be read by the light afforded by these conclusions, it is to be observed that a considerable portion of Western Asia, which in the earliest times belonged, by political relations and commercial intercourse, to the Oriental world, had afterwards, through the influence of Phœnician commerce, become attached to the Occidental. Thus, while at the period alluded to by Agatharchides, Arabia belonged to the Eastern world; at the date next to be mentioned, it was fully within the Western, which now also embraced the empires of Assyria and Persia. The earliest instance of the western ratio is derived from the cuneiform inscription at Nineveh (Korsabad) on the Tigris, and is attributed to the year B.C. 708. This ratio is 1 gold = 13·33 silver. A more satisfactory instance is found in Herodotus, and relates to Persia, about the year B.C. 500. This ratio is derived from the payment of the Egyptian tribute to Darius, and is given at 1 gold = 13 silver.[3]

From this period to the fourth century B.C. silver fell in value, and the western ratio widened until it stood in Greece at 1 gold=15 silver; and this was probably also something near the ratio in all Levantine Europe and Asia Minor. From the fourth century B.C. to the discovery of America, gold fell in value, and the western ratio gradually narrowed until, in A.D. 1492, it stood at about 11 throughout Europe. The ratio in England was fixed by the Act of 22 Edw. IV. (1483), at 11·158;[4] North Germany by the Lubeck mint rule of 1463 at 11·60;[5] France, by the law of 1388, at 10·75;[6] Spain, by the law of 1483, at 11·575; in Italy it stood about 10½;[7] in South Germany, Russia and the Levant the ratio cannot be determined from the authorities at command. Spain and France were at that time among the most important commercial countries in Europe, and the legal ratios adopted by those countries went farthest to determine the general market rate throughout Europe. With a tendency of the western ratio, both from the continual accumulation of the stock of silver, and the influence of *ad valorem* mint charges, to always widen—in other words, with a tendency of silver always to fall in value, as compared with gold—the narrowing of the western ratio, or rise of silver, from the time of Alexander the Great to that of Columbus, must have been due to some exceptional cause, having no connection with the principles already adduced. This cause will be found in the influence of the eastern ratio. Next in antiquity to the instance related by Agatharchides is probably that one mentioned by Strabo, who states in his sixteenth book that in a country bordering on that of the Sabæans, gold has two-fold value of silver, and three-fold that of bronze.[1] No date is connected with this circumstance, but it may fairly be inferred to have related to a period long previous to the era of the great geographer.[2] In the fifth century B.C., as we are assured by another authority, gold in the East stood as 1 to 5, or 6 of silver.[3]

From the fifth century B.C. to the seventeenth century of our era, no satisfactory accounts have been met with of the ratio in the Orient, but the direction of the flow of silver furnishes an assurance that the ratio must always have been narrower than in the Occident. Said Sir Isaac Newton in 1717, "In China and Japan one pound weight of fine gold is worth but nine or ten pounds weight of fine silver, and in the East Indies it may be worth twelve." The closer intercourse with the Orient which followed the Portuguese and Dutch maritime discoveries of the sixteenth century, doubtless contributed to widen the eastern ratio from its position at the period of the discovery of America; and at this period it may be conjectured to have stood generally at about 1:6 in Japan to 1:7 in China and India, though probably the difference in localities was very great. It may be noticed here, in parenthesis, that the ratio both in Japan and China has undergone great perturbations. In Japan it probably stood at 1:6 to 1:7 at the period when intercourse was opened by the Portuguese. A century later it stood, according to Newton, at 1:9 or 1:10. In 1860, shortly after the second opening of commerce with Europe, it stood 1:6 (Griffis, "Mikado's Empire," p. 602). According to Alcock, ii. 348, and Williams' "Commercial Guide," which follows Alcock in this particular, the ratio in 1854 was 1.4; and this conclusion, which is said to have been derived from "the face value of their gold and silver coins," has been repeated in many works of reference. But no confirmation has been found of it, and it conflicts with the special report on the subject by the pursers of Perry's expedition. In China the ratio in A.D. 1285 was 1:10. In 1375 it is said to have been 1:4, but this statement lacks confirmation, and is improbable. Lecompte, a Jesuit, who wrote in 1690 (London, 1697) gave the ratio in China at 1:10, whereas, says he, "among us (in Europe), it is as 1:15." Newton (in 1717) gave it at 1:9 to 1:10. Turgot, in 1776, gave it at 1:12.[4]

In 1779 the ratio at Peking is said to have been 1:17½; but this, if true—for it lacks confirmation—was probably merely temporary and local. In 1810 it was 1:10 at Canton. In 1821 it was 1:18 in Peking; in 1844, 1:17 at Canton; and in 1845, 1:16 at Canton; these three ratios, lacking authority, and, if true, probably merely local or temporary. From 1849 to 1860 the ratios at Shanghai compared with the annual average rates at London are given herewith from Rondot's article on Chinese weights and moneys in the "Dictionary of Commerce and Navigation," published by Guillaumin at Paris, in 1861, quoted by United States Minister George F. Seward, from whose valuable communication to the Monetary Commission[5] many of the above ratios in mediæval and modern China are also obtained.

[1] Section 3,586 of the revised statutes, which for a time made the trade dollar legal tender for $5, has been repealed.

[2] The writer publicly expressed this view, upon the day after the passage of the silver bill; and in less than a week afterwards counterfeit dollars, which could not be distinguished from the genuine, were found to be in circulation.

Returning now to the consideration of the general subject of the ratio in ancient times, it is to be observed that while during the twenty centuries previous to the discovery of America the western ratio was narrowing from about 1:14 to 1:11, it widened in the east from about 1:5½ to 1:6 or 1:7.

Apart from any other consideration it seems probable that as commerce progressed, and intercourse between Europe and Asia grew more intimate, each ratio was modified by the other, until they both came to the same level, which they did in the early part of the present century.[2] The influence exercised by the eastern upon the western ratio was, however, not merely to attract the latter from a stationary condition towards the former, but to modify a tendency of the western ratio to widen from 1:14 to a lower value of silver and confine it to 1:11. In other words there existed a tendency of the western ratio to *continually widen.* This tendency had widened it from 1:13⅓ in 708 B. C. to 1:14 or 15 in the fourth century B. C. It was at this period that active intercourse and commerce was open between Europe and farther Asia. The Persian expeditions into Europe occurred during the fifth century B. C. The expedition of Alexander into India during the fourth century; afterwards the Greeks, Carthaginians, and Romans maintained regular commercial intercourse with the Orient. One of the results of this intercourse was that the tendency of the western ratio to widen was counteracted by the eastern ratio; and thenceforth the former, instead of continuing to widen, slowly narrowed. That the western ratio had by itself a tendency to widen, will hardly be disputed, when it is remembered that during the period under review, viz., from the fourth century B. C. to the discovery of America, the principal one of the two precious metals produced in the Western World was silver, and that the stock, though it declined after the exhaustion of the Spanish mines by the Romans, became more and more argentiferous, and less and less auriferous. During this period the Greek silver mines of Laurion, the Spanish silver mines, and the German and Hungarian silver mines, exhibited their highest productiveness; while the little gold acquired by Europe was derived from a remote commerce with the East. Aside from all other reasons—for there was another—here was an insurmountable one for silver to fall in value, compared with gold; and that it did not fall, but on the contrary rose, is solely attributable to the influence of the Oriental trade. The moment that the supplies of the precious metals to Europe from America became so ample that, instead of seeking for gold in the Orient, the former could afford to export silver to Asia, the modifying influence of the eastern ratio was destroyed; and the tendency of the western ratio to widen was left without restraint. This widening has gone on until from 1:11 at the period of the discovery, the rate has now reached 1:18. So long as silver continued to be the principal metal supplied to Europe this movement is easily accounted for. It is attributed to the continual increase of the stock of silver in Europe, and the continual relative diminution of the stock of gold. But when Brazil, and afterwards Japan, Russia, California, and Australia were opened, these conditions were reversed. It was now gold that became more plentiful, and silver relatively scarcer. Why, then, did silver still continue to fall in value? This question has already been answered. The constant tendency of silver to fall in value is found in the laws of money: in the long-time custom of levying mint charges by value. This alone has furnished a constant pressure, which has been upon silver, and promoted its decadence ever since man first learnt to extract it from its ores, and which, without radical reform in the mint laws of leading nations, must ultimately unfit that metal for money.

[1] These ratios (at London) differ slightly from those given farther on, but not enough to warrant farther attention.

[2] Except in Japan which had been almost closed to Western commerce since 1639.

The Ratio in Modern Times.—Above it was shown that in very ancient times silver was more valuable than gold; that afterwards gold became more valuable than silver, first in the Western World, and afterwards in the Eastern; and that the western and eastern ratios remained distinct up to a very recent date, silver having been always more valuable in the East than the West. The time when gold became more valuable than silver was assigned to the period of the opening of the Greek and Spanish silver mines by the Phœnicians; the equalization and unity of the eastern and western ratios was stated to have taken place during the present century. It was also shown that the ratio was produced by two influences, the first of which was the quantity of money in existence (irrespective of the material of which it was formed, but provided that some portions of it were of silver and gold) and the second the prevailing legal regulations respecting money; and that the relative cost of producing the precious metals had no bearing whatever upon their value. So long as there were two ratios in the commercial world, a third influence was added to the two above mentioned. This was that of each ratio upon the other.

Although for the sake of perspicuity and convenience the relation of value between gold and silver has been classified into two great divisions, the eastern and western ratios, it should be stated that in point of law and fact there has been no such thing as either an eastern or a western ratio; the ratio in every locality being different and each country being a law to itself in this respect. Nevertheless, although thus independent, it does not escape the influence of surrounding countries; and with the intimate commercial intercourse that now exists between the various countries of the Occident, it results, as a matter of fact, that the ratio in London, the most important market in the world for the precious metals, is a pretty faithful representative of the result of all conflict on the subject, both economical and legislative, and is therefore a substantial indication of the average ratio of the Western world. At the period of the discovery of America, the (average) ratio throughout Europe stood at about 1:11. The first important act of legislation upon the subject after this date was the Edict of Medina, issued by Ferdinand and Isabella in 1497, and fixing the ratio in the coins of Spain at 1:10·755. As at one period previous to the discovery of America, viz., in 1483, the ratio in Spain had been fixed at 1:11·675, it has been imagined by some[1] that the Edict of Medina was occasioned by uncommonly large supplies of gold, which are assumed to have been obtained from America during the years which first followed the discovery. A glance at the statistics of these supplies should be sufficient to dispel this assumption. Up to 1497, and indeed for many years after, the amount of gold obtained in America did not exceed an annual average of £340,000, and everywhere throughout the correspondence between Columbus and the Court we find intimations of the disappointment of the latter at the trifling amount of metal obtained. It now remains to be shown that the Edict of Medina has been entirely misunderstood, and that instead of according a new ratio to the precious metals, it merely re-affirmed an old one. The following table shows the mint ratios of Spain for upwards of three centuries:

Mint Ratios of Spain.

16—[1]	16 00	Sir Isaac Newton. Silver undervalued.
1730	16·00	Kelly's "Combist." Relation of gold in the doubloon to silver.
1772	16 00	
1786	16.38	

From this table it appears that the ratio affirmed in 1497 was one that had been previously affirmed in 1475, seventeen years before the discovery of America or the new supplies of gold; and that therefore it probably had nothing to do with either event, but, instead, had flowed from the mint ratios of the Italian commercial cities of the Middle Ages, and found its support in the average ratio which prevailed in the principal countries of Europe at the time of its adoption. This ratio, as stated in a previous chapter, was about 1:11, or, omitting Spain, about 1:10¾.

Starting from this point, viz. the period of the discovery of America with the European or western ratio at 1:11, there is no difficulty in perceiving the cause why silver has since almost continually fallen in value, so that now the ratio is little better than 1:18. The mint charges in all countries have invariably been in favor of gold and against silver, varying at first from about 1 to 2½ per cent. on the former, and from about 2½ to 5 per cent. on the latter; to, latterly, nothing, or at most ½ to 1 per cent. on the former, and 1 to 2½ per cent. on the latter. There is no room whatever to doubt that this discrimination against silver, exercised for centuries in the mints of every country of Europe and operating upon enormous sums of coin, has been fully competent to produce the result observed. Every time specie had to be shipped to complete the exchanges between European countries, gold was always preferred for the purpose on account of the lower mint charges upon it, and the inferior loss sustained by the shippers upon its reduction to the coin of the country of its destination. To this rule there has been an occasional exception. In the shipments of silver from America, to Germany, Holland, Russia, India, and such other countries as at various times adopted and sustained the single standard of silver, the metal was conveyed, directly, or indirectly, from the countries that produced it, to those that consumed it; it was coined or recoined but once, and therefore was not subject to discriminating mint charges. But the mass of international exchanges in Europe and America have been effected with gold; not because the carriage of gold costs less than that of silver—it does not, freight charges upon the precious metals being predicated upon their value and not their bulk or weight;[1] but because the seignorage exacted upon gold coins being less than that upon silver ones, the loss sustained by the shipper upon melting the former, either previous to or after shipment, was less than his loss would have been to melt the latter. As to obtaining his supplies from the uncoined bullion, there is seldom enough of this to be had: the demand for coin always tending to attract all disposable metal to the mints.

Within a comparatively recent period the influence of quantity upon the relative value of the precious metals has been exercised through two comparatively new and very powerful agencies, the extensive substitution of bank paper, and afterwards of government paper for coins; and alterations of the metallic basis, or "changes of standard." These agencies came into play at about the same period—the beginning of the eighteenth century. The first circulating bank notes in Europe (except a few by the Bank of Stockholm, established in 1668) were issued by the Bank of England, which was established in 1694. The first governmental circulating notes in Europe since those of the Mediæval Italian republics were those (if governmental they may be called) of the Royal Bank of France, under the administration of John Law. The first formal change of the metallic standard in modern times took place in Portugal in 1688, and nominally in England in 1717.[2] It has already been shown that (owing to the practice of enacting mint charges which discriminate against silver), when a nation, at least when a modern nation, parts with its metallic stock, gold is the metal preferred by exporters, and this metal is therefore always the first to be exported. This gold being recoined in the country to which it has flowed, it there enters into the circulation and assists to raise the level of prices therein. As its subsequent withdrawal would, other things aside, occasion a fall of prices to their

[1] Humboldt, "Fluctuations of Gold," p. 11.

[2] Mr. Rice Vaughan in a work published in 1675 says that "Spain, to raise a tribute on the people, hath extremely falsified the intrinsic value" of her coins; but it does not appear whether gold or silver was over-valued. Consult Harris on "Coins," ii. p. 122.

[1] This is strictly correct as to ocean freights, and generally as to land freights. Consult Cernuschi. As to express freights west of the Rocky Mountains of the United States, it seems that the *ad valorem* freight charge upon silver is about half as much again as upon gold. See examination before the present writer of Mr. John J. Valentine, questions 126 and 127. "Report of U. S. Monetary Commission," vol. i. App, p. 47.

[2] See "History of Money," by the writer.

previous level, this withdrawal is usually resisted by every influence of law or commerce which the spirit of the times or the institutions of the country permit. Some authors maintain that the ancients never forbade the exportation of the precious metals,[1] but this is incorrect.[2] At all events such restrictions were universal during the mediæval ages; formed the basis of the mercantile system of two centuries ago; were maintained in most countries down to a late period; and, in some countries, are in force to-day. When the agency of export restriction cannot be employed to prevent the outflow of gold, recourse is had to arbitrarily raising the rate of interest in government banks, and so of increasing the difficulty of obtaining gold to export. This is the method employed at present in Great Britain, France, Germany, and other countries.

The country which has parted with its gold now has but a single means of getting it back. This is to widen the ratio, to cheapen silver, to enhance the value of gold, to pay more for this last-named metal, and thus to buy it back at a value higher than that at which it was parted with. It was doubtless the perception of this great principle (aided by the product of Brazil, and the Methuen treaty which enabled England to obtain the benefit of and handle this product) that led that country, after Portugal, to adopt Sir Isaac Newton's advice, and effect such a disposition of its mint laws as practically to render gold coin its only money; an arrangement which was ratified by subsequent legislation, particularly and finally by the Act of 1816, and the resumption of specie payments in 1823. Newton's sagacity enabled him, perhaps, to foresee that so long as England continued to remain, as she had already become, the banking centre of the world, she would profit by every exchange of bullion that passed between other countries; because by their own mint laws these exchanges would naturally and inevitably always be effected in gold. Thus, other things aside, gold will continually rise in value; and England, by adopting it for money, keeping a large stock of it always on hand, and making her contracts payable in the same metal, would continually profit by the operation. But what has benefited England has injured the world at large.[3]

Take the United States, for example. Between the termination of the American Revolutionary war in 1783, and the resumption of specie payments in England in 1823, there had accumulated in the States some £3,600,000 or £4,000,000 in gold.[4] These had been purchased at the ratio of 15; for this was the ratio which had been adopted by the United States government in 1790. Between the peace of February, 1815, and the year 1820 all this gold must have been exported to England; for we are informed that from 1820 to 1834 the only coins circulating in the United States were of silver.[5] In order to introduce gold into the currency the Americans raised its price. This they did by widening the ratio in 1834 to 16, and at this price was purchased the whole of the 50 millions which are estimated to have been in the country upon the breaking out of the Civil War of 1861, to say nothing of a sum of gold, probably equally great, which was meanwhile used up in the arts. Between 1862 and 1863 they sold the bulk of this gold at the equivalent in merchandise of 16 in silver, and were recently purchasing some of it back by giving for it eighteen or nineteen times its weight in silver, until this absurd policy was temporarily arrested by the passage of the so-called Silver Bill. If this bill, however, is held not to permit the government to pay its debts in silver dollars, they will have to be paid in gold, and this gold will have to be purchased at a ratio, which, notwithstanding the supposed tendencies of the Silver bill, will be sure to continually widen in future as it has widened in the past. If it be asked why the ratio took nineteen centuries to narrow from 14 or 15 to 11, while it has only taken three centuries to widen from 11 to 18, the answer is, that after the Roman Empire had passed the meridian of its power, until the discovery of America, that is to say from the third century to the fifteenth but comparatively few coins of gold and silver were minted in Europe; and whatever were the mint rules or other laws, or conflict of laws, that, as it is assumed, occasioned the general narrowing of the ratio from the period of the Peloponnesian war to the discovery of America, their practical operation was limited to a comparatively small amount of coin. Moreover, as except between the coasts of the Mediterranean, there was little or no commerce between nations during this period, and no exchanges to effect in specie, unless with India, the consequence of changing the standard was not understood or had been forgotten after Julius Cæsar made gold the standard in Rome; for even Pliny, who wrote but a few years after him, though for other reasons he anathematizes the author of the change, does not perceive in it any bearing upon the future history of money or of the world. It should also be remembered that up to 1873 the ratio stood at 15½, a point to which it was held by the mint laws and the vast coinages of France, and still more by the rules of the Latin Monetary Union of 1867, which provided a means of obviating the necessity of melting any gold coins that might thereafter be paid between the countries which were parties to that Convention.

Long previous to this date, however, many of the legal supports that had contributed to uphold the existing ratio of Europe had been one by one knocked away, so that at this date it depended chiefly on the mint ratio and open mints of the Latin Union. Its other legal supports had perished with the suspension of specie payments in Russia, Austria, the United States, Italy, Spain, etc., and the practical closure of the mints of those countries to silver. Consequently, when the important events next to be mentioned took place, the European ratio fell in a few years as far as, otherwise, it would probably have fallen only during the course of a century. These events grew out of the Franco-German war. Germany in 1870 announced her intention to change from silver to the gold standard. This act by itself could have made no impression on the ratio; which, next to quantity, is chiefly affected by discriminating seignorages between the metals and the international movement of gold occasioned by such discriminations. But it induced France and the Latin Union to paralyze the operation of their mint laws (of 15½) upon the general ratio of the world, by suspending the free coinage of full legal tender silver. This was doubtless done to compel Germany to pay a higher price for the gold she would require, for it is creditable to French statesmen to say that, among all Europeans, they appear best to understand the technism of this intricate matter. The closure of the mints of the Latin Union removed the remaining barrier opposed to the fall of silver, deprived it of the most active means it possessed of being coined into money, and left it to the depressing tendencies of heavy seignorages in the few countries that continued to employ it for subsidiary coins. As for the influence upon the ratio which has been attributed to the extraordinary production of the Nevada mines, and the diminished flow of silver to India—occurrences alleged to have occurred during this period—these arguments were answered so fully in the course of the investigation upon the subject undertaken by the author in connection with the U. S. Monetary Commission, that it is hardly worth while to devote any space in this work to it. The substance of this answer was that the world's normal product of silver had not increased, nor had the normal flow of silver to India diminished.[1] The existing conditions of the accumulated stock, the current production and the commercial demand for the precious metals, for the present preclude quantity from exercising any noticeable influence upon their value. That value

[2] "Exportari aurum non oportere, cum sæpe antea senatus, tum me consule, gravissime judicavit." Cicero, Orat. pro L. Flacco. cap. 28.

[3] As a general rule of statesmanship—to which there are, of course, exceptions—measures of fiscal policy which fit the affairs of England, are ill suited to other countries, because, being the possessor of the greatest reserves of coal (mechanical power) and wealth (capital), she has become the creditor of all the world. In order to counteract Sir Isaac Newton's system of money, the best policy for other nations would have been to adopt the single silver standard; and, so long as England retains the single gold standard, this will continue to be their best policy.

[4] Gallatin's "Reports on the Finances."

[5] Report of Mr. White, Ho. Rep. 21st Cong. 2nd Sess., No. 95. Indeed, Mr. White says there was no gold in circulation so early as 1817; that it had been shipped to England.

[1] See examination of this question in "Report U.S. Monetary Commission," i. app. 81-89.

therefore, both as it exists and evidently tends in the future, has its basis, substantially, in the conflict of the mint laws of nations, and in the operations of domestic mintage and international exchange.

TABLES OF THE RATIO IN MODERN TIMES.—The time covered by this Minute is limited to the year 1760, for the reason that no annual average quotations at one place are attainable for anterior dates, and also because of the want of any comprehensive summary of the mint codes of leading commercial countries for an earlier period. A legal ratio between the precious metals adopted in an important country, if coupled with full legal tender and unrestricted coinage at brassage or a moderate seignorage, constitutes, in effect, a standing offer to purchase all the current supplies of one metal at a fixed price in the other. Hence the free-mint prices of important countries—that is to say, of countries whose practical ability to purchase metal is equal to, and whose mints are capable of coining all that may be offered—control the market ratio, and, except so far as modified by discriminating seignorages, by demand for the arts, for token coinage, and for export to Asia, they control it almost exclusively. It is, therefore, essential to the understanding of a table of fluctuations between the metals to know what were the legal ratios in, or standing prices for, the metals offered by leading countries; and the capacity of their mints during the period covered by such fluctuations. The following is a rough summary of these details relating to France, England, and the United States, the two former countries, with Spain and her colonies, having been the principal double-standard countries during the period under review. Reliable details relating to the Spanish and German coinage systems of the last century are not within reach.

France.—The optional standard[1] at 14½ prevailed up to the year 1785, when it was changed to 15½. This ratio was ratified in 1803, and is the one now nominally existing. The conditions of coinage up to 1803 are not set forth in any of the papers submitted to the writer. In 1803 the mints were thrown open unreservedly to both metals at the charge of brassage. In 1873 they were closed to silver. The capacity of the French mints, as indicated by the greatest coinage of any single year, was as follows: Gold, year 1859, 702,697,690 fr.; silver, year 1811, 256,399,040 fr.

England.—The optional standard at 15.2 prevailed nominally from 1717 to 1816, when it was changed to gold, which is the standard now existing. The coinage throughout this period has always been called "free," but in point of fact it costs a trifle more than the French charges of brassage.[2] In 1797 the mint was closed to free silver. The capacity of the British mint, as indicated by the greatest coinage of any single year, was as follows: Gold, year 1853, £11,952,391; silver, year 1817, £2,436,298.

United States.—From and before 1760 to 1792 the silver standard prevailed in the American States, but no silver was coined by the Government until 1794. From 1792 to 1874 the optional standard prevailed—from 1792 to 1837 at 15, and from 1837 to 1874 at 16; coinage unrestricted for both metals at charge of brassage up to 1873, when the mints were closed to silver. In 1878 the Government commenced a limited coinage of unlimited tender silver dollars at the ratio of 16, and for its own account. The capacity of the American mints, as indicated by the greatest coinage of any single year up to 1876, was as follows: Gold, year 1851, £12,522,898; silver, year 1876, £3,825,300. It may be added that the American mints can easily be rendered capable of coining the entire current production of the world, and as much may be said, perhaps, of the French and British mints. The following tables exhibit the average annual market ratio between gold and silver from 1760 to 1878 inclusive, and the average monthly ratio from 1873 to the present time.

[1] Commonly called the double standard, that is when coins of either gold or silver are legal tenders to an unlimited amount.

[2] See vol. i. app. p. 230 of the "Report of the U. S. Monetary Commission."

Table *showing the average annual Ratio of Value between Gold and Silver—expressed, as is customary, in quantities of pure silver to one of gold—in the London market from 1760 to 1878 inclusive. Up to 1829, from Ex. Doc. 117, First Session, Twenty-first Congress; from 1833 to 1875, from Pixley and Abell's circulars; since 1876, from the weekly gold quotations of standard silver in the London "Economist."*

THE HISTORY OF THE RELATIVE VALUES OF GOLD AND SILVER.

THE topic is one of peculiar interest, because of the general use of these two metals as standards of value in the exchange of commodities. Neither of them is suitable to be, for the political economist, a real standard of value. That standard is rather to be sought in some more universal product of labor, such as wheat—the relation of which to the rate of wages is said, on high authority,[2] to have been substantially unaltered through centuries, one bushel of wheat representing one day's labor. But the most convenient measure of exchange has been furnished by the precious metals, and hence these have been employed as standards of value. Unfortunately the use of both of them as standards has involved a new element of complexity—the fluctuation in the relative value. It is this element, which I wish to trace here, quite independently of the general relation between money and labor and other commodities. Not the purchasing power of the precious metals measured in terms of wages or supplies, but the purchasing power of each of them measured in terms of the other, is the question to be considered; and the use of these metals as currency gives to the inquiry more

[1] "Report of the Director of the United States Mint, 1876," p. 47. No other authority has been found for the ratios given for the years 1830, 1831, and 1832.

[2] I owe the suggestion to a conversation with Mr. Abram S. Hewitt.

than a merely speculative interest. For the attempt to maintain a double standard involves the perpetual readjustment of the relation by law, and the alteration of coinage accordingly. Hence the civilized nations have gradually come, with few exceptions, to the adoption of gold as the standard, and the employment of silver as the material for subsidiary or token coinage. The illustration of this principle is scarcely required; yet a simple statement may not be out of place. If the law says that I may offer in all payments requiring dollars, either gold dollars or silver dollars, as I choose, then both coins are legal tender, and there is a double standard. At the same time the law must have fixed, for the protection of my creditors, the exact amount of fine gold in the gold dollar and of fine silver in the silver dollar; in other words it must fix, for the purpose of coinage, the relative value of these metals. Now so long as this is also the market value, or nearly so, it is a matter of indifference to me whether I give and take silver or gold. But there may be a change in the market value. For instance, a great deal of silver may be wanted by manufacturers, or for shipment in commerce to countries like India, where gold is not available for the purpose; and the parties desiring silver may be willing to pay more than a gold dollar for the silver dollar, in order that they may melt or export the latter. In that case I would prefer, of course, to sell my silver dollar, pay to my creditor the gold dollar, and keep the surplus. Everybody feeling the same impulse the silver coinage disappears, and is melted or exported. If the silver coins smaller than a dollar are also of the same fineness and relative value, this disappearance of silver causes great inconvenience, because people can no longer "make change;" and the natural result is the general use of tokens, dinner tickets, shinplasters, etc., a fractional currency, in short, which is not legal tender at all, and which, when it proceeds from individuals or private corporations, has but a local circulation. Recognizing this evil all governments provide for a regular token currency for small units of money, which shall be legal tender for small amounts only; but is redeemable by the mints in larger amounts. There is not a cent's worth of nickel or copper in the cent, or a dime's worth of paper in the ten-cent note of postal currency. The same principle is extended to the smaller silver coins of most nations, and constitutes, in fact, a recognition of the law of political economy that there should be but one standard of value in coinage. What is universally done with regard to small coins should be done for all silver coins. They should be subsidiary or token coins, legal tender only in small amounts, and redeemable in gold at the mint.

But whether the token coinage is confined to the smallest denominations or includes all silver coinage, the question remains, How shall it be maintained? How shall its value be fixed? In this country, we have seen how the copper cent disappeared, because the price of copper rose until a hundred copper cents could be sold in the market for more than a dollar. The same fate will inevitably overtake any coinage which is undervalued by law. Hence, to prevent the evils resulting from this source, it is necessary to fix upon the subsidiary coinage a value which shall be permanently in excess of its market value as metal. Yet, on the other hand, it is, for reasons which I will not fully discuss here, not advisible to debase a silver coinage or reduce its weight so far as to ignore entirely its real value. This may be done with the smallest coins; but it should not be done, for instance, with dollars and half dollars. A very important reason for this is the increased temptation and facility thus afforded to counterfeiting. The imitation of a die is not a difficult matter; and the security of the public against counterfeit coins is not so much in the design upon the coin, the workmanship of which may be, when genuiue, much defaced by wear, as in the easily ascertainable weight and fineness of the metal, and in the fact that it would not pay individuals to manufacture coins of the same weight and composition. For any coin of higher denomination than five cents, a considerable overvaluation would lead to extensive and dangerous counterfeiting by the use of the genuine metallic alloy, or one nearly approaching to it in fineness.

We have then our two limits for the legal valuation of coins; and the problem is to get as near as possible to the relative market value of gold and silver, and yet keep always on the safe side, which is, as we have seen, the side of the overvaluation of the silver or subsidiary coinage. These considerations render the history of the relative values of gold and silver an important study.

I am indebted, in the investigation of this subject, to various financial and economical authorities, including the Parliamentary Blue Books and Reports, from the days of Sir Isaac Newton, and Congressional documents, from the famous report of John Quincy Adams down to our own day. With these preliminary remarks, I present several tables, and remarks upon them, illustrating the history of the relative value of gold and silver.

ANCIENT PERIOD.

Date B. C.	*Ratio.*	*Authority.*	
1600	13.33	Inscriptions at Karnak, Tribute lists of Thutmosis (Brandis).	
708	13.33	Cuneiform inscriptions on plates found in foundation of Khorsobad.	
.	13,33	Ancient Persian coins Gold Darics at 8.3 grams =20 silver siglos, a 5.5 grams.	
440	13.	Herodotus'account of Indian tributes, 360 gold talents =4680 silver.	
400	13.33	Standard in Asia, according to Xenophon.	
400	12.	Standard in Greece according to Hipparchus," an alleged essay by Plato	
404	12.	Values in Greece, from the Peloponnesian war to the time of Alexander, according to hints in Greek writers. There were variations under special contracts. Unit, the silver drachma.	
to	13.		
336	13.33		
338–326	11.50	Special contracts in Greece.	
323–43	12.50	Standard in Egypt, under the Ptolemies.	
218	17.14	Rate at Rome, fixed for coinage of gold scruples. Violent and temporary	
100	11.91	General rate of gold pound to silver sesterces at Rome to date.	
100	8.00	About this time, sudden influx of gold from Aquileja, temporarily reducing the relative value of the metal.	
58–49	8.93	Great sums of gold brought by Cæsar from Gaul.	
29	12 00	Normal rate in the last days of the Republic.	
A. D.			
1–37	11.97	Rate under Augustus and Tiberius.	During the reigns of these emperors, however, the silver coinage was debased Hence the value of the precious metals, pure, was 1:11, and less.
37–41	12 17	Rate under Caligula.	
54–68	11.80	Rate under Nero.	
69–79	11.54	Rate under Vespasian.	
81–96	11 30	Rate under Domitian.	
138–161	11.98	Rate under Antoninus	
312–	14.40	Rate according tc coinage of Constantine and his successors. Temporary (?)	

NOTE.—In all these tables the figures in the second column show how many times as valuable as a given weight of fine silver would be an equal weight of fine gold.

REMARKS.—It appears from a study of this table that the ancient and long-established relation between silver and gold in the Orient was 1: 13.33. The stability of this relation must be referred probably to the limited nature of commerce, and its control by the sovereigns. Gold, by reason of its specific gravity, and non-liability to oxidation is found, as silver is not, in alluvial deposits; and would naturally be first brought into use among barbarous nations. But the production of silver by rude metallurgical processes (requiring much lower temperature than the metallurgy of iron) would not be a difficult discovery: and we find that at a very early period this metal also was in general use. The greater scarcity of gold and its superior qualities, especially at a time when the chief uses of both metals were for jewelry and ornament, naturally established for it a higher value; and in the absence of sudden demands or fluctuations in supply, such as active industry and free commerce would produce, the relative value of the two metals might remain, for the purposes of trade or tribute, where it was once fixed by arbitrary authority. We see, however, that in Greece, Egypt and Italy, the value referred to did not vary, as a rule, very far from the ancient ratio; and this may justify us in supposing that the relation of 1: 12 or 1: 13 approximately represented the cost of producing silver, as compared with gold. The variations from this ratio, notes, in the table, are generally due either to the sudden influx of gold from new quarters, or to the arbitrary action of governments for purposes of profit in coinage. In those days the laws of political economy were not so well understood as now; and, indeed, until a very recent period, tampering with coinage has been a favorite method of replenishing the treasury of the sovereign.

The Middle Ages.

Date.	*Ratio.*	*Authority.*
A. D.		
864	12	Probable ratio, as shown by the *Edictum Pistense*, under the Carlovingian dynasty.
1104—1494	9–12	Variable and apparently arbitary British mint-edicts.
1260	10.5	Average ratio in the commercial cities of Italy.
1351	12.3	Ratio in North Germany, as shown by very accurate rules of the Lübeck mint, corroborated in the main by the accounts of the Teutonic Order of Knights, averaged in periods of forty years.
1375	12.4	
1403	12.8	
1411	12.0	
1451	11.7	
1463	11.6	
1455—1494	10.5	Ratio according to the accounts of the Teutonic Order of Knights.
1469—1508	9.2	
1497	10.7	Ratio established by Isabella, in Spain. (Edict of Medina.)
1500	10.5	Ratio in Germany, according to Adam Riese's Arithmetic.

Remarks.—The data on which this table is cons+ructed are not all of equal authority. Particularly in England, there appears to have been a considerable undervaluation of gold for purposes of coinage. This would tend to keep the silver coinage at home, and to repay to the government the cost of obtainining silver for that purpose. But it is not necessary here to discuss the special meaning of the British figures. It is safe to say that, down to the fifteenth century, the general market ratio of silver to gold was not far from 1 : 12. The serious variation shown in the thirteenth century, when, according to Italian economists, the average ratio in Milan, Florence, Lucca, Rome, and Naples, was as low as 1 : 10.5, indicates a much greater supply of gold in that region, at that time, than was available in the more warlike and less commercial parts of Europe. Indeed, at the period referred to, these Italian cities were notably prosperous in trade and manufactures; and we may well believe that gold flowed in abundance to them, as to points where it could be safely and profitably invested. There is no doubt, however, that during the fifteenth century the relative value of gold declined from about 12 to the neighborhood of 10, probably by reason of the scanty supply of silver, and the growing demand for that metal in manufactures (especially by the silversmiths) and in Oriental commerce. The ancient source of silver in Thessaly and Spain had been to a great extent exhausted; the New World had not begun to yield its argent treasure; and the mines of Saxony and Bohemia had not reached their maximum productiveness. It will be seen in the following period, as at others in this history, that the development of new fields and new methods of industry checked the tendency created by the currents of commerce and restored the balance of value so seriously disturbed.

From the Discovery of America to the Opening of the Mines in California and Australia.

Date.	*Ratio.*	*Authority.*
A. D.		
1526	11.30	Apparent relation of market value, as deduced from the British mint regulations, some absurd and unsuccessful experiments in coinage being disregarded.
1543	11.10	
1561	11.70	French mint regulations.
1575	11.68	
1551	11.17	German Imperial mint regulations.
1559	11.44	
1604	12.10	British mint regulations—experiments disregarded.
1612	13.30	
1619	13.35	
1623	11.74	Upper German regulations.
1640	13.51	French mint regulations.
1665	15.10	
1667	14.15	Upper German regulations.
1669	15.11	
1670	14.50	British regulations.
1679	15.00	French regulations.
1680	15.40	
1687—1700	14.97	Ratios calculated from the bi-weekly quotations of the Hamburg prices current, giving the value of the gold ducats of Holland in silver thalers, down to 1771, and, after that, in fine silver bars. The nominal par of exchange during this period was 1 : 14.80; and the quotations show the variations of the market rate in percentage above or below this. At par, 6 silver marks banco were equivalent to one ducat—68$\frac{32}{47}$ ducats containing one mark (weight) of fine gold, and 23$\frac{3}{4}$ silver marks banco containing one mark (weight) of fine silver. Hence, $6 \times 68\frac{32}{47} \div 27\frac{3}{4} = 14.80$, the par ratio.
1701—1720	15.21	
1721—1740	15.08	
1741—1790	14.74	
1791—1800	15.42	
1801—1810	15.61	
1811—1820	15.51	
1821—1830	15.80	
1831—1840	15.67	
1841—1850	15.83	

Remarks.—The first part of this table, like those which precede it, is compiled from imperfect data, in the absence of such direct evidence of ruling market values as is furnished from 1687 to 1840 by the Hamburg quotations, the appearance of which is a significant indication of the extension of commerce and manufactures. All conclusions drawn from the mint regulations of countries maintaining a double standard are affected with a double uncertainty. In the first place, the frequent practice of enforcing, for reasons of state, arbitrary relations of value in coinage may mask the real market ratio; and, in the second place, the lack of free commerce and swift intercommunication among the nations may retard the evils resulting from such arbitrary action, and postpone the necessity of legislative remedy. Hence the change, as shown by the mint regulations, may apparently occur some time after the real change in the relative value of the metals. Certain wild experiments with the coinage, particularly in England, have been omitted from the table, as having no real connection with the actual relative value. But if we do not scan the dates too closely, nor lay too much significance upon the maintenance of a certain rate in one country after it had been abandoned in another, the figures above given, down to 1680, may furnish us an instructive picture of the effect of the discovery, conquest, and plunder of South America upon the commercial relations of Europe.

The earliest effect of this discovery was the shipment of gold to Spain during the first quarter of the sixteenth century. At the beginning of that century, as shown in Table II, the ratio of silver to gold was about 1 : 10.7, or 1 : 10.5. The average annual influx of gold to Spain, down to 1527, probably did not exceed $400,000. But this supply, though it seems small to us now, would doubtless have depressed still further the value of gold, but for the remarkable productiveness of the Bohemian and Saxon silver mines. The joint result of both causes was a notable increase of the amount of precious metals in circulation, and hence a rise in general prices, with which we have here nothing to do. The effect on the ratio between gold and silver was a gradual increase in the value of gold. About 1550, the annual supply of gold may be roughly estimated to have been $400,000, and that of silver $2,600,000. By 1600, the production had become about $1,200,000 gold and $10,000,000 silver; in 1650, about $2,300,000 gold and $15,000,000 silver. This increase in the supply of gold is largely due to the development of the Guinea Coast, and the productiveness of the Hungarian gold mines. The increase in the supply of silver is due to the introduction of amalgamation, and its use, principally in the form of the patio process, for the cheap production of silver in Peru and Mexico. It is scarcely necessary to point out that the relative value of the two metals is not in the simple inverse ratio of their supply. The question of cost of production and of superiority in qualities adapting them for different purposes of currency, exportation, ornament, and manufacture, must always play an important part; and, even after all these elements have been calculated, it would be difficult to fix or foretell the relative price of the metals, since the local, temporary, and fluctuating demands, and so-called "movements of specie," come in as disturbing phenomena of that incalculable element, the human will.

Thus we find that in the latter half of the sixteenth, and the first half of the seventeenth, century the production of silver was about seven times as great as that of gold. The drain of silver to the East Indies had already begun, and a large part of the product of South America found its way thither, returning in varied forms of wealth and luxury to enrich and enervate the Mediterranean nations. Yet the remainder of the silver product was great enough to cause an increasing surplus of that metal, and a consequent fall in its relative price. It was, moreover, in many countries a period of war, and the large expenditure incurred led to a general increase in the gold coinage. The sudden and violent changes shown by some of the continental mint regulations are indicative rather of financial and legislative necessities than of commercial changes. The English regulations seem to have been, on the whole, more stable, and represent probably with greater accuracy the steady enhancement of gold, the value of which, as compared with silver, advanced during the seventeenth century about 30 per cent., and during the sixteenth and seventeenth centuries together, about 45 per cent. A general tendency in the same direction is visible in the eighteenth century; but here there is much greater stability, and the rise of gold is frequently checked.

Aided by the exact data drawn from the Hamburg quotations, we can trace the causes of fluctuation more accurately than in former years. I repeat that we are not here concerned with the general rise in prices produced by the greater volume of metallic currency, and the multiplication of its efficiency through banking and credit. Our object is to study simply the agencies at work upon the relative value of the metals, and we find in this period, as in former ones, counteracting causes with a general resultant effect. The influx of silver from South America to Europe was continued and increased down to the beginning of the nineteenth century; but the export to Asia of piastres, coined from American silver, assumed colossal proportions, averaging, as Prof. Soetbeer estimates, from 1690 to 1800, about $6,000,000 annually. Moreover, there was a considerable importation of gold from Asia, in return, to Spain and England. In China and Japan, according to the celebrated report of Sir Isaac Newton, Master of the British Mint in 1717, the pound of fine gold was worth but nine to ten pounds of fine silver, while the ratio in Europe was about 1 : 15. A merchant buying his goods in India with silver, and selling them in Europe for silver or for gold, with which he purchased silver again for a new venture, would gain 50 per cent. in exchange alone, besides the fair profit of the trade; and, of course, it would be worth while for him, after completing in the East his cargo of bulkier products, to lay out the remainder of his cash capital in the purchase of gold, which could be easily stowed and transported. This explains why, in the piracy and naval warfare of those times, the East Indiamen, going or coming, were considered so desirable as prizes. In either case, they were tolerably certain to carry rich booty of silver or of gold.

But besides the exports of silver to India, and the imports of gold from India, there was, for a short period, a notable influx of gold from America, principally from New Granada and Brazil. The Brazilian supply was greatest from 1749 to 1761, and at that period occurred the unusual phenomenon of a rise of more than 4 per cent. in the relative value of silver, due to this cause. From 1701 to 1748 the average ratio was 1 : 15.19; from 1751 to 1755 it was but 1 : 14.53. This reaction, on the other hand, was checked by the demand for gold in the United Kingdom for the purpose of coinage, and for the payment of heavy war subsidies to the continental nation during the struggle with Napoleon. The Bank of England, it is true, suspended specie payments from 1797 to 1819, and during this period the circulation of gold in Great Britain was reduced, but the subsidies and hoarding kept up its price, and the resumption of specie payments caused a sharp rise, so that the average ratio for 1821 was 1 : 15.95. The contemporaneous falling off in the supply from America, Africa, and India, would doubtless have carried this movement still further, but for the unexpected development of a new source of production in Siberia and the Ural. In the absence of the political and commercial causes already enumerated as operating to enhance gold, this sudden influx of it would have mightily diminished its price. In fact, however, the ratio of value was not essentially changed, though the proportion of production was for the time being revolutionized. At the end of the eighteenth century, the whole annual product was estimated at about $15,000,000 gold and $40,000,000 silver. In 1846, on the other hand, by reason of the supply from Russia, the gold product was estimated at about $43,000,000 while the silver had not increased—had, in fact, slightly fallen off. At the beginning of the nineteenth century, in other words, the production of the precious metals was about 27.8 per cent. gold, and 72.2 per cent. silver. By 1846 it had become about 52.3 per cent. of gold to 47.7 of silver. Yet the relations of value had not greatly changed. The average of 1846 shows a ratio of 1 : 15.66. From 1851 to the present time the relative values are calculated from the London quotations, as explained fully below. To this table I invite attention, as the ratio of modern times and its economic effect is something we can more readily appreciate than in foregone centuries.

From 1851 to 1874 Inclusive.

Date	*Ratio.*	*Authority.*
1851	15.46	The London quotations. These give the price of a given weight of standard silver in shillings and pence sterling. Bearing in mind that there is in Great Britain no charge for coinage, and, hence, that the price referred to varies exactly as the market value of the metals, we can calculate ratio as follows: The standard gold is $\frac{11}{12}$ fine, and its value is fixed at 77*s.* 10½*d.*, or 934.5 pence per ounce Troy. Hence the value of an ounce of fine gold is $\frac{12}{11}$ of this sum, or 1019.45 pence. The standard silver on the other hand, is $\frac{37}{40}$ fine; hence an ounce of fine silver is worth 1.081 times as much as an ounce of standard silver. If the fixed value of an ounce of fine gold be divided by 1.081 times the quoted price of an ounce of standard silver, the quotient is the ratio desired; Thus, if x be the quoted price per ounce in pence, $\frac{1019.45}{1.081}=\frac{943}{x}$ (very nearly) is the ratio, Briefly, dividing 943 by the price in pence of an ounce of standard silver gives the ratio correctly to the second decimal place. London being the acknowledged centre of the commercial world, this ratio determines the relative value of the metals among civilized nations. The table shows annual averages only. The lowest *monthly* value of gold was 15.12 in May, 1859, and the highest, 16.35, in Oct., 1874. The annual average for 1874, here given is calculated upon the prices of eleven months, ending Nov. 30.
1852	15.57

1870	15.60	
1871	15.59	
1872	15.63	
1873	15.90	
1874	15.15	

Remarks.—The discovery of gold in California in 1847, and in Australia in 1851, threw an unexampled quantity of this metal into circulation. While the annual product at the beginning of the century had been only about $15,000,000, and in 1846 had been swelled by the Russian placers to the then astonishing amount of $43,000,000, it had reached in 1853, according to Prof. Soetbeer, a value of more than $165,000,000, while the annual silver product was scarcely more than $40,000,000. This enormous disproportion, coupled with the continuance of vast shipments of silver to India, naturally caused many economists to anticipate a serious and permanent depreciation of gold. It appears from the table that this did not take place in such a degree as expected—and for two reasons. First, the supply of the precious metals, particularly silver, on hand in Europe was so great that even the immense production of the gold mines in California and Australia could not immediately cause an overwhelming revulsion. General prices, of course, advanced; but that is not the point now in question. Chevalier estimates that the gold production from 1500 to 1847, inclusive, had been nearly $3,000,000,000, of which (according to other authorities) something less than $2,000,000,000 had come from Spanish America, which had furnished in the same period about $5,000,000,000 in silver. Of the latter, perhaps $1,000,000,000 had been exported to India; but the stock of both metals still remaining in Europe was large; and the introduction of silver-plated wares liberated much silver which had been kept in the form of solid ware. But this would not long have sufficed to retard the fall of gold but for another cause—namely, the enormous coinage of gold in the countries employing the French system. Before discussing this important element, it is well to point out that the gold production of California and Victoria suffered a diminution, through the exhaustion of the richest superficial placers, say about 1860, which was but partially compensated by the new discoveries in New Zealand, Idaho, Montana, etc. Moreover, after 1866 the shipments of silver to India notably declined; and finally, the production of silver from Nevada and other Territories advanced to colossal proportions. It was in the period preceding these changes that the French coinage system exercised its restraining influence against the depreciation of gold. By the French law of 1803, the franc was fixed at five grammes of standard silver, 9-10 fine, and it was provided that the kilogramme of standard gold, of the same fineness, should be coined into 155 twenty-franc pieces. In other words, the relative value of the metals was established by law as 1 : 15.5. By the payment of a small coinage-charge, any one could obtain at Paris coin of either metal in exchange for fine bars of the same. Now, by reference to Table III above, it will be seen that the ratio between gold and silver in the market (which had been up to the beginning of the nineteenth century always less than 15.5) ranged steadily, during the first half of the century, above that point. Hence, there was no inducement to coin gold. The gold coins themselves commanded a premium for melting. From 1825 to 1848, inclusive; the French coinage was only 268,000,000 francs in gold, against 2,380,000,000 francs in silver. The law of 1803 had been passed at an unlucky period, and its effect for nearly fifty years was to drive gold from circulation and flood Western Europe with a redundant silver currency. But it undoubtedly operated, during that period, to check the depreciation of silver by employing an excess of it as currency, and by diminishing the similar employment of gold, and thus increasing the available supply of that metal for other uses.

The reaction caused by the influx of American and Australian gold was immediate. So soon as fine gold was enough cheaper in the market than 3444$\frac{4}{9}$ francs per kilogramme to make it profitable to holders of it to take coin for it at that rate. The amount of gold presented for coinage in France was immense. From 1851 to 1867 there were coined in that country more than 5,806,000,000 francs gold against 383,000,000 francs silver; and the silver coinage rapidly disappeared. Of $800,000,000 silver shipped to India in the period just named, probably more than half was melted down from the coinage of the franc-using countries—France, Italy, Belgium and Switzerland. Thus the new supplies of gold found a new application, and the Eastern demand for silver found a partial supply: so that the value of gold was kept at 15.09 to 15.21, in spite of the excessive influx of it, which would otherwise have caused it to sink much lower. The practical abolition of the double standard by the United States in 1853, and the increased gold coinage of Great Britain and her colonies, were subordinate causes assisting this tendency. But the French system, serving for a while as a breakwater against the natural effects of great commercial facts, was itself swept away by the tide. The disappearance of a silver coinage is more inconvenient to the masses than the lack of gold. The lack of silver for currency brought about the famous Convention of December, 1865, at which France, Italy, Belgium and Switzerland united in the attempt to regulate again the relative values of the metals in coinage. But for the obstinacy of France, the cumbrous and fluctuating system of a double standard would have been given up. What was done was to diminish the value of the silver coinage, or, rather to establish a coinage of pieces from a half-franc to two francs, which being legally as coins worth more than they were worth actually, could not be remelted or exported with profit. It was a pity that even a measure of this kind was carried out in the most unfortunate way. By changing at that time the weight of the gold instead of the silver coinage, the franc-countries might have obtained a system in which the weights of coins would have borne a direct relation to the metric system; and, if the double standard had been definitely abolished, and gold adopted as the sole standard, a foundation would have been laid for that international system which still appears an unattainable blessing—a system, namely, by which the different nations, each coining its own money, might maintain a certain uniform fineness in gold coinage, and accept as legal tender all gold coins according to their weight in metric units. The gramme of standard gold would then be the international unit of money, with which all coins would gradually be brought into simple integral relations.

But the Convention of 1865 chose a different course, and it had hardly taken the step of debasing the silver coinage, to counteract the effects of the enhancement of silver, when a revolution took place, and a depreciation of silver was inaugurated, which has continued to the present time. The causes of this change, some of which have been already alluded to, deserve closer attention. The exports of silver to India, down to 1856, were to pay for products of the East, exported to Europe and America. During our civil war, the extraordinary production of cotton in India increased this balance of trade, and thus augmented the drain of silver in that direction. Moreover, between 1856 and 1866, large sums of silver went to India as loans, to be employed in the construction of an extensive railway system. These special causes ceased after 1866, and the payment of the interest on the Indian loans is now, so far as it goes, an element on the other side of the balance of exchange. The demand of silver in India is, however, by no means extinct; and one effect of the increased development of internal trade and industry in that region will be to maintain this demand. Prof. Soetbeer, in proof of the intimate relation between the rate of Indian exchange and the ratio of silver to gold in London, calculates the following five-year averages from the London prices, and the Calcutta quotations for 6-month drafts:

Average of Period.	*Drafts on London in Calcutta.*	*Price of the ounce standard silver in London.*	*Ratio of gold to silver.*
	Pence per rupee.	Pence.	
1856–60	25¼	61½	15.33
1861–65	25	61¼	15.40
1866–70	23½	60½	15.59
1873	23	59¼	15 91

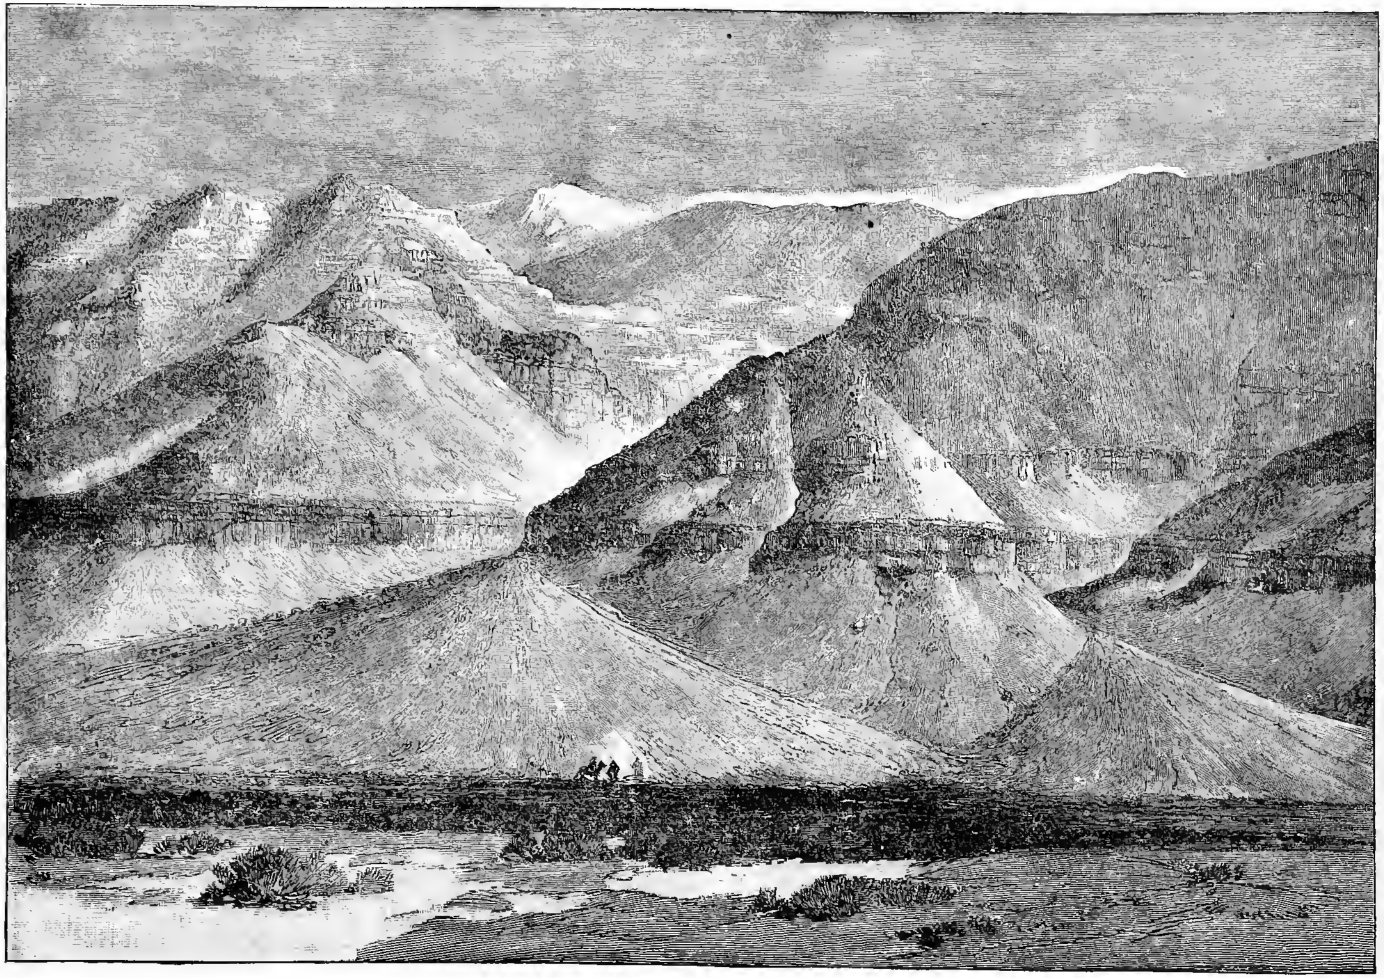
The second great cause of depreciation of silver was the colossal production from the United States. The product of this country, as I have shown, was in 1861 but $2,000,000. From 1862 to 1866, inclusive, it was $45,000,000, or an average of $9,000,000 per annum. In 1867, it was $13,500,000; in 1868, $12,000,000; in 1869, $13,000,000; in 1870, $16,000,000; in 1871, $22,000,000; in 1872, $25,750,000; in 1873, $36,500,000. The declared importations into Great Britain were:

1870, ...	£3,387,000
1871, ...	5,689,000
1872, ...	4,575,000
1873, ...	5,992,000

The great *bonanzas* discovered in the Comstock lode of Nevada have been the chief cause of the latest increase; but the extraordinary and rapid development of the silver-lead smelting industry in Nevada (Eureka) and Utah has also been an important factor. A third cause of the depreciation of silver was the abandonment by Germany, after the Franco-German war, of the silver standard, and the issue of a standard gold coinage for the Empire. Prof. Soetbeer estimates that in November, 1874, there was still in circulation in the different German States about $230,000,000 in silver coin, less than half of which would probably remain in circulation after recoinage—the remainder being thrown upon the market for exportation. The effect of the change is twofold—the liberation of silver from circulation as coin, and the increased demand for gold. The amount of Imperial gold coinage resolved upon in 1871 was 400,000,000 thalers (about $290,000,000), of which 362,000,000, had been coined up to November, 1874. It was evident, however, that at least 500,000,000 thalers would be required; and this would tend to continue the special demand for gold.

The countries of the franc-system, with double standard, have, however, again furnished a check to the prevailing tendency which has, doubtless, greatly modified the fall in silver. In these countries, the ratio being fixed at 15.50 by law, it has been, since 1866, profitable to have silver coined. In 1872, the coinage of silver in the Netherlands was 33,540,945 florins; in 1872 and 1873, all the states of the franc-system coined some 200,000,000 francs in silver. But this could not continue, and in 1874 a limit was provisionally set to the coinage of five-franc pieces. The depreciation of silver may be retarded, if the coinage of it as a legal tender currency, at a rate above its market value, is continued. But this policy, whatever its immediate conveniences, is contrary to the true principles and tendencies of political economy. The demonetization of silver, and the universal adoption of gold as a standard currency, with silver as a material of subsidiary-coinage, is that to which all nations must come. The ratio of 15.5 is too near the average market ratio for the last century, to be safely adopted. But the ratio of 15, as proposed by Mr. Elliott and other American writers on this subject, and partly adopted in our coinage, is reasonably certain to remain permanently below the market ratio, and hence to serve satisfactorily in coinage, while it possesses practical value as an integer, simply related to the decimal system.

A review of the whole history shows us that the natural tendency has been, since industry and commerce were organized, towards a depreciation of silver; that this tendency has been periodically counteracted by three great causes:



WESTERN SCENERY—ALLUVIAL CONES, BONNEVILLE BASIN—UTAH.

—FROM U. S. GEOLOGICAL SURVEY REPORT.

the successive discovery of new gold fields (Africa, Brazil, the Ural, California, Australia, New Zealand, Idaho, Montana, etc.); the exportation of silver to the East; and its elastic employment for coinage. It is highly improbable that new Californias will be opened, though the present production from quartz and hydraulic mines, in this country at least, is likely to be maintained and even increased; the demand for India will not be augmented, but by growing reciprocity of commerce, probably decreased, though slowly; and the use of silver in coinage will probably also remain stationary or decline. On the other hand, the production of silver will probably increase—though the enormous reinforcements from this or that great *bonanza* will be temporary in their effects. Looking at the subject on a larger scale, it is not this or that single mine, but the vast era of silver-bearing territory in this country and Mexico which may be expected to develop and maintain an increased production. What may be the metallic treasures of Asia, we scarcely know as yet; but their exploration will, at all events for many years to come, produce nothing that the vast population of that region will not immediately swallow up.

All general considerations, so far, seem to point to a permanent depreciation of silver. Not that the price of November, 1874—the lowest ever reached in history by the free action of commercial and industrial causes—will be maintained or further decreased; but that the ratio ruling a dozen years ago is not likely to be regained, and the low price of silver must be accepted by miners and metallurgists as a part of the economical problems submitted to them. When I say that the gross product of a silver mine to-day is worth in gold nine per cent. less than it would have been in 1859, you will see that this is a question intimately connected with profits and dividends. Indeed, the probable suspension of mining and metallurgical operations which cannot afford this loss will, perhaps, be one reaction tending to diminish the production, and thus check the depreciation of silver. In whatever way the general current flows, it is sure to be interrupted by such eddies, the results, indirectly, of its own motion.

—*Compiled from a paper by R. W. Raymond, Ph.D.—Transactions American Institute of Mining Engineers,* 1875.

COMMONPLACE FALLACIES CONCERNING MONEY.

FEW questions have been so frequently discussed by competent writers as that of money and currency; and, at the same time, there is no other subject on which opinions so diverge. As Mr. Bonamy Price, professor at the University of Oxford, states it, "It may almost be said that every man contradicts every other man about money, about what money is and what it is not, what it can and what it cannot do. In no other subject which occupies the thoughts of men does anything approaching the same disorder exist."[1] I hope, therefore, I shall not be accused of presumption if I endeavor to point out that many of the principles put forward by the deductive school of political economy, and accepted by the English public as being evident truths and clear axioms, are in reality demonstrable errors, and in total contradiction to facts and events of daily occurrence. I will examine some of these axioms as they have been formulated by writers of well-deserved authority, and who may be taken best to express the generally accepted ideas.

The point which I think first needs to be elucidated is the following:—Is there an advantage in a community's possessing more or less money, or, rather, more or less of what may be styled monetary metal? It is known that the upholders of "the mercantile system" believed the principal riches of a nation to consist in the amount of precious metal it possessed. Everything, they urge, must be therefore done to increase that amount; and, to that end, a favorable balance must be created by stimulating exportations, and also by impeding as much as possible the importation of merchandise, so as to force foreigners to pay the difference of the commercial balance in precious metal. These notions, however, were early contested in England. In the year 1682, Petty maintained that it was an advantage to export coin, when goods of a greater value were secured from foreign countries in exchange for it ("Quantulumcunque concerning Money"). Again, North, in 1691, says that a fortune in coin is no gain, as coin in itself is unproductive: therefore, no State should feel uneasy about its provisions of gold or silver. A rich country, he observes, will never lack either ("Discourse upon Trade," 11.17). Berkeley assumes that a greater error cannot exist than that of estimating the wealth of a State by the quantity of gold or silver in its possession ("Querist," 1735). If we turn to the father of the Physiocratic School, Quesney, he labors to prove that it is impossible exportation can ever permanently and absolutely exceed importation; for, he says, "*Every purchase is a sale, and every sale is a purchase*" ("Dialogues sur le Commerce"). Finally, Adam Smith, in his treatise, completely overthrew the mercantile doctrine, and molded into definite shape the ideas which have remained current from his day until the present time. But the case might even be put more strongly. J. B. Say considers the exportation of coin as still more advantageous than that of any other merchandise, for he alleges it is the value of coin which constitutes its utility, and the value of what coin remains in the country increases in proportion to the amount exported. I borrow from Mr. Bonamy Price a statement of the opinion prevailing at the present time on this subject. It is couched in the most definite terms, and may be summarized as briefly. Professor Price first lays down that coinage is indispensable amongst civilized nations. It serves as a means of exchange, and is the common measurement of values; but it is quite useless to accumulate more of it than is necessary for this end. Gold is merchandise, and is only to be obtained by the exchange of other merchandise of equal value in its stead. In this exchange, the person who receives the precious metal is no better off than the one who receives the commodities. It is therefore absurd to believe that a nation gains when what is called the "commercial balance" is in her favor; that is to say, when she has an excess of exportation, and foreign countries are obliged to pay her by a consignment of precious metals. Gold brings no advantage to the person possessing it, except at the moment when he parts with it, to purchase an object he can consume, or in some way enjoy.

Coin is a tool, a machine, a vehicle of interchange, like a ship or a wagon. It is a means, not an end; it transfers possessions and the right of property, just as a van transports bales. Who would think of accumulating wagons in his sheds solely for the satisfaction of feeling that he possessed them? Why, then, was so much joy exhibited on the arrival of bullion from California? It did not increase the wealth of England to the amount of one single pound sterling, for she paid for it all with her produce, value for value. Would agriculturists raise shouts of joy if it were announced to them that a whole cargo of plows had been imported? At a given moment a country requires a certain quantity of cash to accomplish exchanges, but all in excess of that quantity is useless, and is even burdensome; for gold, when remaining inactive, eats its own interest. It is a noticeable fact that the further a country has advanced economically, the less requirement it has for precious metals. No country has, in comparison to the importance of her business transactions, so little of it as England. Less civilized nations have, on the contrary, a large amount of gold and silver—firstly, because they treasure it up; and secondly, because a sale is never effected save for ready money. But can a country suffer through a lack of cash, diminishing its economic activity? By no means; it is not with cash as with other necessary instruments of production. If there were fewer plows some agricultural land would remain unplowed; harvests would diminish there, and the well-being of the country would be affected. Were there less cash there would be no diminution whatever in the production of commodities. Exchanges would be accomplished as before, either because credit would become more general, or because the gold remaining in the country would be enhanced in value, and would, therefore, serve to transfer the ownership of a greater quantity of goods. A fall in the value of any special merchandise—tea, for instance—increases the well-being of a community, for a larger amount of it is consumed. A fall in the value of cash, as a result of its superabundance, would be productive only of difficulties. The cheapness of precious

[1] "Practical Political Economy," p. 360.

metals would entail, as a necessary consequence, the being obliged to tender a heavier weight of them. Money would thus become very inconvenient to carry about, and bank notes and checks would be largely substituted in its place. When, after a bad harvest, gold is seen to emigrate abroad, people get alarmed; doing so quite unreasonably. This gold brings in exchange what supports our workmen and laborers. Far from seeing a calamity in this, we should rejoice at it as a benefit for the nation. It is supposed that a drain of gold would thus cause a scarceness and "depreciation" of the monetary metal, and that a fall in prices would ensue as a natural result. These are unjustified fears. The power and the value of gold are about equal in all civilized countries, and the fall in prices would soon bring back the gold, and in that way re-establish the former level in prices.

The language of our merchants, of our bankers, of our financial papers, is still tainted with mercantile error; they always speak, of "favorable and unfavorable balances," "favorable and unfavorable exchanges." One would almost say that Adam Smith had published in vain his book, "The Wealth of Nations." The exportation and importation of gold are watched by attentive and, frequently, by anxious eyes, as if it were the one riches, *par excellence.* If we export much iron or coal there are rejoicings. If we export much gold it is just the reverse: we find lamentations and fears expressed in every financial paper. Whence this difference of opinion? Is not gold just as much merchandise as iron or coal? Those who propagate these ridiculous ideas really deserve to be buried, as Midas was, beneath the gold for which they clamor so madly. There is no necessity for uneasiness concerning the circulation of gold; it will distribute itself in different countries, according to the needs and requirements of each. It is even true that the more a country imports gold, the poorer she becomes. For, says Mr. Price, "what becomes of it when brought in by an excess of exports? So long as they remain, let us say, in England, they are locked in the Bank of England's vaults; they are wealth annihilated for the time. Meanwhile, how has it fared with England in respect of the exports for which there is so much rejoicing. They consumed a vast amount of wealth in making; food and clothing for laborers were used up, and all is gone. What has England in return? Some metal locked up in cellars. As long as it remains in England she is the poorer for these exports. The wealth returns only when the buried gold goes abroad to buy, and when the imports will exceed the exports, and the country is made the richer. Imports alone enrich a country, not exports. To buy gold which cannot be used is as pure an impoverishment for the time as if the purchasing goods had been given away for nothing."[1] The above is a short statement of what Mr. Bonamy Price teaches us on the subject of currency, summarizing, as clearly as possible, the doctrine of the deductive school. Can a more complete contradiction be conceived than that existing between these doctrines of speculative political economy and the language of the writers of the money market articles in the daily and financial papers? In spite of the remonstrance of Mr. Bonamy Price, and of other economists, they follow with the greatest attention every movement of the precious metals. When they flow in excess toward foreign countries, cries of alarm are raised; when, on the other hand, they return, or come in first, they at once announce prosperous times It is sufficient to have read the columns of the *Economist*, the *Statist*, the *Bullionist*, or the financial report in the *Times*, or any other daily paper, during the last two months, to be struck by this strange contradiction.[2] Who is right, and who wrong? Economists are not wrong *in abstracto;* but one should also say that financial editors must be right, for they grasp economic life in its daily reality. Is it possible that merchants, bankers, and writers of the newspaper money-market articles should all be led astray by the sophism of "mercantilism," so as to understand nothing of the transactions occurring under their eyes? On the other hand, is it possible that the most eminent economists should be completely deceived on this subject? We can allow of neither hypothesis. The apparent contradiction arises from the fact that the problem has been regarded from different standpoints. It has been viewed in the "static" condition by economists, and in the "dynamic" aspects by capitalists and men of business, phenomena being looked upon at a given moment by the first as being at rest, in their development and as in movement by the second. Let us explain this: England, for instance, could easily effect all her exchanges with £80,000,000, or with £40,000,000 in gold, instead of the £120,000,000 she now employs; for, as J. B. Say remarks, the value of gold, as compared to that of merchandise, would increase as the quantity of the former diminished; or, in other words, the prices, calculated in money, would diminish as money became scarcer. If I have one shilling instead of two, it makes little difference to me if I can now purchase as much with my shilling as I could formerly with two. Double, triple, if you will, the amount of precious metal in a country, that country will be none the richer. The number of useful objects which constitute its real wealth will have remained the same, only two or three times as high a price in money will be put on each one. All these are evident facts, and hitherto the reasoning of the economists is perfectly sound; but as soon as we attempt to carry these abstract ideas into practice, they are completely contradicted by facts which are daily reported by the financial papers accused of "mercantilism." This is what we will next endeavor to show.

In the world of actual affairs all contracts, whether for a long or short date, the terms of loans made by banks, the rate of discount, in fact all business, are based on certain prices and on the availability of a certain amount of cash. If this amount of cash, or the prices which it determines either increases or diminishes, the basis of all business transactions becomes necessarily modified. This is the important fact that economists have neglected to examine in its consequences. What are these consequences? That is the question we must weigh with the greatest attention. Let us suppose, first, that gold increases in quantity; what happens? Here we are by no means reduced to speculative reasoning on a hypothesis. This phenomenon occurred and assumed colossal proportions under our own eyes subsequently to the year 1850. Compared with the year 1840, the production of gold increased tenfold after the discovery of the *placers* of California and Australia, and the production of gold and silver combined is fifteen times what it then was. The consequences of this unheard-of change, have been perfectly analyzed in the well-known work of Tooke and Newmarch, "History of Prices." When this extraordinary influx of precious metal reached Europe, Michel Chevalier raised a cry of alarm, which Cobden repeated, and which greatly impressed the different Governments. Prices, it was commonly said, would double, and this would lead to profound economic disturbance; gold should, therefore, be at once rejected, a silver standard being adopted. But Newmarch explained that this danger was not at all to be dreaded because the gold, in arriving, would stimulate fresh economic activity, and in thus making for itself greater employment, would prevent its own depreciation. What followed proved that Newmarch was right and Chevalier wrong. After some few years, prices rose a little, to the extent of about 15 per cent., according to Mr. Jevons. The rise, however, was of short duration, and a fall ensued, although the total produc-

[1] "Buying and Selling:" *Journal of the Society of Arts*, May 6, 1881.

[2] Here is an example of what can be read every day in all the financial papers of the world:—"In their last summary of the state of the New York money market, Messrs. Melville, Evans, & Co., mention 25 to 30 million dollars of gold as the probable import requirement of the State between August 1 last and January 1 next. This was the current estimate in New York a fortnight ago, and we think it not unlikely to prove an under estimate should the speculation fever break out to the degree anticipated. But five or six million sterling is a large enough sum to alarm us on this side in the present state of European bullion stores and gold requirements, for one million more withdrawn from the Bank of England would agitate our market, and cause rates to advance to at least 5 per cent.—no very serious rate for sound business, but a destructive one to much of the speculation now sustained here and on the Continent." —*Pall Mall Gazette*, Sep. 22, 1881.

Mr. Bonamy Price and all the orthodox economists tell us that the export of gold is not merely a matter of indifference, but is rather a benefit; and, on the other hand, the City says that the loss of only one million— a mere trifle, indeed— would agitate, and perhaps upset, the money market in all Europe. Can there be a more complete contradiction? Why should not political economy lose its credit, as a science, when its statements are in such open opposition to the most undeniable facts?

tion of gold and silver has maintained itself at about £38,-000,000. Thus the predictions of Michel Chevalier and of Cobden were not borne out by facts. The banker had made sounder deductions than the economists. From the beginning, the prodigious development of the gold-producing countries, California and Australia, brought fresh stimulus to the industry and commerce of the whole world. These new countries did not send us the produce of their labor for nothing. For every million of gold received in Europe an equal quantity of goods was returned to them. These goods had to be made and transported, and thus fresh outlets for labor were created, This new opening for trade in the gold countries and the increased production in Europe which was needful to supply the wants arising—these occasioned more exchanges and therefore led to a more extensive employment of the precious ores, which are the metallic means of exchange and the basis of all fiduciary circulation. Gold arriving in Europe is deposited in banks where it finds its prices fixed by the mints, and so those sending it get immediate remuneration. This accumulation of cash of course leads to a fall in the rate of interest. After 1850, discount fell 1½, and even to 1 per cent. A fall in the rate of interest stimulates the spirit of enterprise and the creation of new companies of all kinds, both at home and abroad. The surplus money must find employment for itself somewhere. Besides, when capital can be obtained at the moderate rate of 2 or 3 per cent., a great many undertakings may prosper which would never do so where the rate of interest is 4 or 5 per cent. I will here borrow a very just comparison made by Mr. Bonamy Price, when he says that cash is a conveyance, but I draw it from a totally opposite conclusion.

When vehicles are plentiful they can be hired cheap, and, as a natural consequence, everybody uses them, and there is an extraordinay circulation. You see this at Naples, where the hire of a decent carriage is fivepence, and even tne beggar rolls in a *corricolo*, at a penny. So, too, when the monetary mediums of conveyance are abundant, they also are lent cheap. Circulation is active, and business is "brisk," as people say. Certainly the capital lent and borrowed is not in reality "money." Capital truly consists of all the materials requisite and necessary to production. Still, cash is the means of obtaining these materials. It is with gold that they are paid for, and it may be said to be gold which is necessary for every exchange. It follows therefore that, when gold is plentiful, the real capital is easily brought into action, and then production is developed.

The first effect of an influx of gold certainly is a fall in the rate of discount. But the phenomenon does not stop there. This fall promotes a movement of economic expansion until the demands for capital exceed the disposable quantity, and then the rate of discount rises. This was observable during the period of prosperity, from 1853 to 1870. The average rate of interest was high, in spite of the abundance of gold, because the prodigious development of production for which this period is noticeable caused an endless demand for capital. It was during this period that railways were largely made in all parts of the habitable globe; canals were opened, isthmuses cut, mountains pierced, and works, factories, and banks innumerable started. Mr. Newmarch only gives expression to general opinion when he says that the gold of the *placers* was the chief cause of this wondrous development. The second result of an exceptional influx of the precious metals is to produce an average rise in prices. Gold, which gives facility to the creation of fresh business enterprises, occasions a greater demand for everything. In works and factories, in railways, in all sorts of concerns undertaken on all hands, workmen, and iron, and wood, and every kind of raw material are wanted in greater numbers and in larger quantities than previously. The increase of demand produces necessarily a rise in value. This rise takes place gradually, and the result of it is to produce that state of the market which we call "brisk." All who are engaged in producing profit by this. Workmen, being more sought after, are better paid; they consume more in the way of fuel, food, &c., and thus raise the price of the articles of common necessity, which naturally brings benefit to those who produce or manufacture them. Manufacturers, making more profit, buy more, and the prices of the articles they want rise in their turn; and in this way profit flows in upon a second category of manufacturers and tradesmen. The buyers of raw materials for the purpose of their conversion into manufactured goods almost invariably gain by a general rise in prices; for this raw material, flax, cotton, wool, iron, is worth more when resold than when it was purchased. The economic and commercial world thus forms one immense chain of causes and effects in which the value of each link is heightened by the activity imparted to labor, the true source of all riches. It may even happen that an "industrial" fall occurs in the price of many articles, great enough to counterbalance in the increase "monetary value;" because, thanks to the multiplication of fresh enterprises and the introduction of fresh machinery, these commodities are produced at a much cheaper rate. These are the many favorable results which follow on an influx of the precious metals.

But, it will be said, these advantages are also attributed by inflationists to an abundant issue of paper money made legal tender. Doubtless this may be so; but the factitious excitement caused by the inflation is dearly bought, as it rests on no firm basis, and is brought about by an abuse of legislative power. It occasions a depreciation of the currency, the degradation of exchanges, and the permanent disturbance of foreign trade; and, sooner or later, large sacrifices have to be made in order to revert to the metallic circulation. It is quite otherwise when the impulse given to business springs from a natural source—viz., an increase in the amount of precious metal, the real basis of exchanges, and, at the same time, the true equivalent of every value. In this case, there is neither depreciation of currency nor disastrous reaction. All that could in any way occur would be a general rise in prices resulting from the large amount of cash suddenly thrown into circulation; but, as we explained, even this will probably not take place, for owing to the number of business transactions rapidly and permanently increased by the economic development which the abundance of cash will have stimulated, gold wild find further employment. The demand for it will increase in about the same proportion as the supply. The precious metals will lose nothing of their powers of purchase, and prices will not rise. This is exactly what has occurred since the year 1850. The average annual production of the precious metals during the decade 1840–1850 was 362,000,000 francs. From 1850 to the present time, the average production has tripled, having risen to from 900,000,000 to 1,000,000,000 francs annually; and, in spite of this, if prices have risen for a time a trifle, they have fallen again to about what they were formerly. Thus the extraordinary influx of precious metal which commenced 30 years ago, has been most beneficial in increasing economic activity all over the world, and this great advantage has been unaccompanied by drawbacks or difficulties. So long as I thus limit myself to stating only undeniable facts, I hope I shall not be thought guilty of either "mercantilism" or of "inflationism." I merely give a summary of Newmarch's chapters, [1] and he, I imagine, is not likely to be accused of any such heresies.

Let me now examine the opposite phenomena — the scarcity of cash—and try to ascertain its effects. The exportation of gold is a purely indifferent matter, says Mr. Bonamy Price, for exchanges are just as well effected with little as with much money.[2] Let us rather say, writes J. B. Say, that the exportation of gold is an advantage, for in exchange for gold, which is dead capital, useful goods are obtained, and the gold remaining in the country is rendered more serviceable; since, to pay for the same number of articles a less weight is given and received, according as the quantity has diminished, its value being increased. If these

[1] It is useful to read with attention the chapters devoted by Mr. Newmarch, in Tooke's "History of Prices," to the study of the effect produced by the gold of California and Australia during the period 1848–1856.

[2] At the close of his book, "Practical Political Economy," Mr. B. Price publishes, as an appendix his correspondence with Mr. Henry Gibbs, ex-Governor of the Bank of England, on the question as to whether the Bank, in fixing the rate of discouut, should, as a general rule, be guided by the amount of its reserve in gold. Of course, Mr. B. Price is strongly against this line of conduct, which is contrary to his theory. Mr. H. Gibbs replies that if the learned Oxford Professor were a "practical man" and a banker, he would understand the question better. How should not political economy lose its authority when it thus places itself in opposition to the most evident daily business necessities?

propositions (which, not long since, all the economists of the deductive school were fully prepared to vouch for), be exact, we must conclude that the entire business of the world, the Bank of England, merchants, bill brokers, speculators, and all the writers of financial articles in the newspapers, must be suffering under the strangest hallucinations. All these authorities affirm that the crisis which has so long depressed the money market, and which becomes just now more acute, was in great part brought about by a monetary contraction, and recently by the exportation of gold to America, and argue that it became more or less serious as gold left us in larger or smaller quantities for the opposite shores of the Atlantic. It is, of course, economists who are mistaken, they having made a superficial analysis, basing it solely on abstract ideas. The study of the phenomenon must be recommenced by paying special attention to facts as they really exist. Here, again, we have only to recollect what has recently taken place beneath our very eyes. When gold is to be exported it is taken from the banks of issue, because in their hands a large stock is always to be found ready at the command of all holders of bank notes or of all well guaranteed commercial drafts. Banks, being compelled to have sufficient cash in hand to guarantee the fiduciary circulation, raise the rate of discount. That is exactly what is now going on (September, 1881). In a general way a rise of 1 or 2 per cent. is sufficient to bring back the precious metal by diminishing the price of all commodities, shares, debentures, and stocks in State funds, and by raising the hire of money; but sometimes (and it has been noticed that this happens about every nine or ten years) the outflow of gold induces a sharp crisis. Mr. Jevons connects these periodical crises with the spots on the sun. I have endeavored, in a work especially on this subject, "Le Marché Monétaire depuis cinquante ans," to prove that they are brought about by the agency of three circumstances. 1st, the very general use of "instruments of credit," which in turn causes the immense mass of fiduciary circulation, notes, checks, promissory bills, and unpaid accounts, to rest on a very small metallic basis; 2d, the existence in the market of a great many term engagements, the result of the multiplication of fresh enterprises, of increased purchases of goods, and of the general speculation fever which invariably accompanies a period of expansion and prosperity; 3d, and finally, the still more decisive cause is to be found in the exportation of cash, necessitated either by the bad harvest, as in 1847, by foreign investments, as in 1825 and again in 1856, or by exceptional purchases of certain goods, as happened after the cotton famine in 1864. Indeed, whatever may be the minor causes which work toward a crisis, it is always determined by the exportation of cash, which induces either the shrinkage or else the complete collapse of credit, which follows on a sudden and too high a rise in discount. These exportations of cash are generally occasioned by some disturbance in the balance of trade. Mr. Bonamy Price and other economists make gentle fun of the balance of trade, and speak of it as an "exploded fallacy." Nevertheless the *Economist* and other special newspapers continue to write about it and to follow its course with the greatest care and attention. Here, again, business men are right. It is evident that the balance of trade can no longer be estimated, as it was formerly, by a mere calculation of exported and imported merchandise. The amount of money invested abroad, and the interest gained upon it, has now assumed immense proportions, and this, of course, modifies the balance, without the tables of the Custom House showing any record of it. The richest countries, England and France, for instance, are creditors of other countries for many millions sterling. The interest of these hundreds of millions, represented in goods, occasions imports to be made without any return exports. It follows, therefore, that rich countries import regularly much more than they export, and this without occasioning any disturbance in the balance of trade. Here are the figures for England:

	1877	1878	1879	1880
		In millions sterling.		
Imports	349·41	368·77	362·99	411·22
Exports	252·34	245·48	248·78	268·41
Imports exceeding exports by	97·07	123·29	114·21	142.81

This excess of imports naturally includes, besides the interest of money lodged in investments abroad, the immense sums for freights of merchandise, and for wares of all kinds which English vessels transport to all parts of the world, and also the profits of trade on the national and foreign produce that English merchants sell everywhere. The following is a calculation made on this subject by Mr. G. Medley. (See his work, "The Reciprocity Craze.")

Profits on Ocean Carrying Trade	£45,000000
Insurance	3,500,000
Interest on Capital in Foreign Trade	5,000,000
Merchants' Profits	17,500,000
Income from Foreign Investments	55,000,000
Total	£126,000,000

But if the state of things thus established, with an excess of imports for the creditor country, be troubled by the necessity of completing fresh foreign investments, or by an exceptional purchase of corn being needed after a bad harvest, the result will be an unusual exportation of cash, followed by a crisis more or less severe. These sharp crises have sometimes most disastrous consequences. All shares fall in the market; bankruptcies may be counted by thousands; workshops are closed; workmen find themselves without employment, and want and suffering become very great. It cannot be maintained, therefore, that even in such a case as this, the exportation of the precious metals is a matter of indifference. All that can be meant is that its advantageous effects are but transient, commerce and industry quickly again presenting their habitual aspect. Prices rise, and two or three years' practice of economy suffices to repair what losses may have been sustained. A fresh period of prosperity, of expansion and speculation soon commences, which generally terminates in another crisis. The effects of a slow and steady reduction of the stock of money are of a different character. They come into operation almost insensibly, being unaccompanied by any violent disturbance. Indeed, the cause of the evil is usually ignored, or else disputed. Instead of a burning fever it is a decline with which the social body is afflicted. A crisis of this description first occurred in the period 1816–40, and it has been repeated from 1873 to last year. Each was brought about by identically similar circumstances. They may be thus specified—1st, insufficiency of the production of the precious metals; 2d, exceptional demand for gold. Let us examine the facts. 1st, from 1816 to 1822, England, abandoning paper money, established the gold standard, and took from the general circulation of the world £20,000,000 sterling. This was an immense sum for that period, for it corresponded to ten times the then annual production;[1] 2d, the average annual production which was from 1801 to 1810, 259,000,000 francs, fell from 1811 to 1820 to 159,000,000 fr., sank still further to 151,000,000 fr. from 1821 to 1830, and amounted only to 202,000,000 fr. in the period from 1831 to 1840. After 1873 the United States, Germany, and the Scandinavian States, by adopting the gold standard, absorbed from 300,000,000 fr. to 400,000,000 fr. of gold. The production of both the precious metals taken together has not decreased; but silver, being no longer received in any mints, save for the currency in India, the monetary stock has had to be fed by gold alone, the production of which has diminished by one-third. The annual influx into circulation of the precious metal has thus fallen one-half—viz., from £40,000,000 to £20,000,000. Added to this, during these last three and a half years, America has taken from us £50.000,000 of gold. These three circumstances combined have produced subsequently to 1873, as they did also after 1816, a monetary contraction. It is that phenomenon, exactly the reverse of the expansion after 1858, which has been neglected by economists, and it is this which we must now study. This has not yet been systematically done, though striking references to it are to be found in different works, notably in Alison's "England in 1815 and in 1845; or a Sufficient and a Contracted Money;" D. Lubé, "Argument against one Gold Standard;"[2] "Report of the Monetary Commission of the

[1] Albert Gallatin, whose authority is frequently cited on these questions, wrote in 1829: "Not only has England by that experiment, in the face of the universal experience of mankind, gratuitously subjected herself to actual inconvenience, for the sake of adhering to an abstract principle, but, in so doing, she has departed more widely from known principles, and from those which regulate a sound metallic currency."

[2] The following are a few passages from these writings.—"Is

Senate of the United States, 1876;" Dana Horton, "Silver and Gold;" R. Giffin, "The Recent Fall in Prices," *Journal of Statist. Soc.*, March, 1879.

In the case of a slow monetary contraction crisis, the precious metals are not suddenly taken away from the banks in large quantities, as is the case in sharp crises; credit is not shaken, and monetary stock diminishes almost insensibly by the industrial consumption of the precious metals, since the stock, not being fed as usual, does not keep up to the level of the growth of the economic development. Then commences an almost imperceptible fall in prices, spreading from one article to another. The unfortunate consequences of this circumstance, left unnoticed by Mr. Bonamy Price and by other economists, are as follows: During the fall in prices merchants and tradesmen frequently lose, for they are often obliged to sell cheaper than they bought. Enterprises no longer bring in profit; on the contrary, they have often to be abandoned at a loss. Merchants, their hearts failing, relinquish part of their business, new undertakings of any kind become rare. Workmen, less and less sought after, see their wages lessened. They, in turn, consume less, and thus the manufacturers who provide for their wants have to reduce their productions. Merchants and tradesmen, making small or no profits, do not live so well, and here again the manufacturers who work for the middle classes also suffer. There is a general decrease in economic activity. Capital, sunk into inactivity, lies in the banks, and the rate of interest falls, the demand for advances being few and small. Cash does not appear to be lacking, and, indeed, is not wanting, for, as J. B. Say said, the quantity, if it is diminished absolutely or comparatively, is "appreciated." Each unit is worth more and effects more exchanges. Reduce as much as you will the monetary stock, it will always remain sufficient, for, as prices fall, in proportion its value rises, and it will always buy and pay for the same amount of goods. When the fall in prices is at an end, the period of suffering resulting from it finishes, and the economic world gradually regains its normal condition. Only the transition is often tedious and accompanied by many cruel trials, as we have had occasion to see during the last few years.

The question now is whether when exchanges are effected with less cash, and consequently on a lower scale of prices, will the situation be what it formerly was, as the economists who reason on abstract principles pretend? I venture to say, not at all. The pressure of previously contracted debts will have increased exactly in the same ratio as prices will have fallen. In fact, to obtain the same amount of money, more goods or more labor will have to be given, as these will be worth less. The nation in general, that is to say, taxpayers, mortgagees, public companies who have issued debentures, landed proprietors bound to pay fixed yearly incomes, pensions of one sort or another, all will be burdened and the bond holders alone will benefit. Some people will say, What does it matter? Some gain what others lose.

This was a mischievous mistake. It matters greatly, for production is sacrificed in favor of the fund holding class, or, as John Stuart Mill puts it, active capital is sacrificed for idle capital.[1] As already most European communities are taxed to the extreme limit, the consequence of any indirect increase of the burden which these loans lay upon them would inevitably be the misery of the populations, if they continued to pay, or general bankruptcy in the event of their refusing to do so. It opens up a vision of the world of Stock Exchange towering over the crushed ruins of the working world. Finally it may also happen that the two sorts of crisis, that which may be called the "anæmic" crisis, that is to say, the one which is due to a slow decrease of monetary stock, and the sharp crisis, due to the sudden and considerable outflow of gold, graft themselves so to speak one on the other, as they are doing at the present time. The exportation of metal to New York is impoverishing further our store of precious metal, and so is doubly disastrous. It retards the impetus of business which seemed to be springing again into life, and at the same time it keeps down prices which are already merely remunerative. We thus see to what extent the abstract ideas of the deductive school are contradicted by a simple statement of facts. But these economists ask, Is it then not true that produce is exchanged for produce? If that be so, gold is as much a produce as anything else. The merchant exporting it has obtained in exchange goods of a higher value, or he would not have consented to the transaction. Therefore, if the merchant has gained, it is not possible that his country loses. All these axioms, which seem so clear and evident on paper, are nevertheless daily contradicted by experience. In reality, Ist, a great deal depends on the nature of the objects exchanged; and, 2ndly, it is not true that the metal of which money is composed is a merchandise like any other. Some very simple example will serve to prove these two observations. Hunters are out in a forest in the far west of America, and live on the game they shoot. The Indians they meet propose to give them in exchange for their guns furs of at least double their value; they accept the offer, for economists have persuaded them that produce must be always exchanged for produce, and that it is always a gain to obtain articles of a higher for those of a lower value. Their want of forethought, however, is speedily punished. They are very soon nearly dying of hunger. To get back their guns, they would now be willing to transfer not only their furs, but everything else they possess into the bargain. Again, a manufacturing town has sufficient cars and wagons

there one man of sense and reflection whose mind is not sometimes occupied, and whose imagination is not startled by the actual and prospective state of the country? The monetary standard of England was what it is now and has always been throughout the rest of Europe—silver. Monstrous and incredible delusion! We are now told that the question is settled forever. But with a gold standard, circulation cannot increase; so it opposes an effectual barrier to all improvement. By the gold standard the currency has been reduced below the point that would afford remunerative prices with the present taxes."—*Argument Against One Gold Standard*, D. Lube, M. A., Trinity College, Dublin. In 1832, Lube strongly advocated the silver standard. This is what Sir Archibald Alison says on the subject of monetary contraction:—"The distress among the mercantile classes for years after the dreadful crisis of 1825, of the agricultural interest during the lowering of prices from 1832 to 1835, and of the whole community from 1835 to 1842 was extreme. The investment of capital in agriculture was, during this distress, everywhere grievously abridged, and in many places totally annihilated. Ireland, during the whole period, has been in a state of smothered insurrection. The heart sickens at the evidence, numerous and incontrovertible, which the Parliamentary reports for the last ten years have accumulated of wide spread and often long-enduring suffering amongst the laboring poor of England." After having described the progress of this state of things Alison adds: "Some external cause must therefore have paralyzed and blighted the wealth of the country in the midst of such an increasing growth of the national resources. Since the Peace, the all-important question arises, what was it which had this effect? The answer is, it was the contraction of the currency which was mistakenly made to accompany the resumption of cash payments by the Bill of 1819 that has been the chief cause of all these effects." Alison gives a perfectly complete description of the unfortunate results of the monetary contraction, the real cause of which generally passes unobserved. "It is as difficult to get the great bulk of men to understand that it is the currency itself that is shifting in value when great changes of price are going on around it, as it is to make them comprehend that the earth is moving rapidly through the heavens."—*England in 1816 and 1845; or, A Sufficient and a Contracted Money*, 1846, page 51.

[1] All the leading economists agree in thinking that abundance of money is more favorable to the progress of mankind than scarcity. Here are some quotations on the subject: "In fine," says Michael Chevalier, "a fall in the value of money will profit those who live by present labor, it will injure those who live on the fruits of past labors be it their own or that of their fathers. In this respect it will act in the same direction with the greater part of those evolutions which are accomplished by virtue of the great law of civilization, to which ordinarily we assign the noble name of progress." *La Monnaie*, 2d edition, 1866, p. 760. J. R. MacCulloch, in his discussion on the effect of the great increase in the world's stock of gold after 1850, says in conclusion: "Though like a fall of rain after a long course of dry weather, it may be prejudicial to certain classes, it is beneficial to an incomparably greater number, including all who are actively engaged in industrial pursuits, and is, speaking generally, of great public or national advantage."—*Encyclopædia Britannica*, Art, "Precious Metals. W. Roscher, the learned professor of Leipzig, points out that the gold discoveries, by preventing a dearth of money, which without them would have probably occurred, saved the nation from a grievous malady. On the other hand, he explains, in the same sense as MacCulloch aud Chevalier, how a fall in the value of money may stimulate to a notable increase of national production—*Grundlagen der Nationatoekonomie*, § 141. All the more known German economists—Nasse, O. Arendt, Adolph Wagner, Lexis, Schaffle, and even Soetbeer—express the same opinion. *Vide* for example, Erwin Nasse, *Der Bimetallismus und die Wahrungsfrage*. Holtzendorff. Brentano, Jahrbucher II. 1.

to effect all necessary transports; foreigners buy from them a part of these at a very high price. The sellers profit by many thousands of pounds, and it seems a splendid business exchange of produce for produce, with clear gains on their side. But the vehicles having disappeared from the wharves and streets, there is no means of conveying goods from place to place. The manufacturers, no longer able to obtain raw materials, are obliged to stop working their machinery and to discharge the workpeople. A general crisis arises, there being a dead-lock as regards production, and misery continues to spread among the laboring classes until fresh wagons are made or got. The loss in this way incomparably exceeds the gains which were obtained from the sale of the vehicles. Exactly the same thing occurs when gold goes off in too great quantities. He who exports it in payment of goods purchased in exchange does a good stroke of business, but the community suffers for it. Pieces of money are, for practical purposes, conveyances by means of which products are exchanged. If there be an insufficient quantity of these, the circulation becomes impeded; commerce and industry have to face difficulties in buying and selling; a crisis ensues. It is, therefore, not correct that the precious metals are as much a merchandise as anything else, and that it is a matter of indifference whether they are exported or imported.

But, Mr. Bonamy Price will say, you will not deny the truth of the following proposition, which, with several others, Mr. Mill has very clearly explained: A country has always as much money as it needs; in fact, it is impossible that one country should export, and that another, with which it trades, should, at the same time, import cash for any lengthened period. Prices will fall in the country where gold is leaving, and will rise where it is accumulating. It would soon be to the advantage of the former country to buy where things are cheaper, and thus the excess of imports would quickly bring back the gold, and the balance would be again established. I beg, first, to remark that this reasoning is neither more nor less than an application of the theory of the "Balance of trade," so described by recent economists. On the other hand we find here again the same use of abstract ideas, leading to conclusions in which falsity is mixed with truth. Contemplating this purely superficial analysis, one is led to suppose that gold can pass from one country to another, in a similar manner to water passing from basin to basin seeking its level, and that neither advantage nor disadvantage is likely to accrue to either nation from the transfer. It is not so by any means. And, first of all, there is one very great exception to be taken as to the general axiom given us by Mr. Bonamy Price and Mill—an exception which plays a very important part in the general movement of the precious metals on our globe. I speak of India. From antiquity to the present time, an uninterrupted current has always carried silver to the far East. A rise in prices there, such as would have induced the Indians to buy more goods in Europe, and discouraged Europeans from buying from the Indians, has never taken place. And why? Because the silver on arriving in Asia is made into jewels and idols, and is, further, lost and hidden away by a population in India of 300,000,000, and of 400,000,000 in China, and so does not remain in circulation; thus, having no influence whatever on prices. The fact of the balance being always favorable to Asia is explained by the circumstance that Europe needs much commodities from thence, while the East takes very little of our produce. Between European nations the balance is generally pretty equal; any momentary inequality is quickly set to rights by the variations in the rate of exchanges, and very little precious metal actually passes from country to country. In this case current economical theories find their application; but let us consider the example of a balance where the tendency is persistently unfavorable, and where a constant exportation of precious metal becomes necessary. For the study of this phenomenon we have only to examine facts in connection with the trade between Europe and America. Here, as in the case of India, an unfavorable balance seems likely to become persistent. Since the United States re-established a metallic circulation, Europe is obliged to send them each year a growing quantity of gold. In 1879–1880 it amounted to 75,000,000 dollars, and in 1880–1881 to 91,000,000 dollars. The reasons tending to the production of this unfavourable balance for Europe are the same as in the case of India. We are absolutely forced to take certain produce from America; for instance, corn, meat, petroleum, and cotton. On the other hand, as industry becomes developed in the United States, thanks to the more general employment of machinery, and to the higher intelligence of their workmen, they are less in need of our products and manufactures. The difference, in this way, of the commercial balance that we owe to the United States, we are obliged to pay (silver being refused there) entirely in gold. Hence, these exports of cash, which occur generally in the largest quantities in the autumn, and greatly disturb the European money-market. It is certain that these exceptional exports will cease some day, sooner or later. With a yearly drain of £15,000,000 to £18,000,000 sterling, there would soon be no gold left in Europe. for it produces none; and already her stock is very much reduced. On the other hand, as the Americans do not hoard their gold, or make anklets or bangles of it, as the Indians do with silver, the gold they receive, and that which they produce, by swelling the circulation, will raise the prices there, while they will fall in Europe, as a natural result of the diminution of the monetary stock. But to what famine prices will European produce have to fall before being able to pass the protectionist barrier—the American Custom-House—in quantities sufficient to turn the scale in our favor? For this to occur, the European market must be depressed severely—an event deeply to be deplored, whatever economists may say about it. One circumstance, which may singularly retard the reflow of gold to Europe is, that as soon as it reaches the opposite shores of the Atlantic, it finds immediate employment in creating new railways, new farms, fresh works of all kinds, fresh centers of production in the Far-West; for in these far-off regions the pioneers who people them love "hard money." As the financial chroniclers say, the New York market is insatiable; gold coming from Europe evaporates there like water on heated sands. It scarcely is landed before it starts off westward. The United States are now enjoying the monetary advantages of that period of economic expansion which Europe experienced after 1850. European Banks are to them now what the California "placers" there were to us then.

Gold can, however, return to the country where it has accumulated to the one whence it flowed, in another manner. In the impoverished country the fall in prices does not affect goods only; it extends, in some degree, to investments. It is therefore advantageous to lend money there; and the country where gold is plentiful, and where, consequently, everything is very dear, will not fail to do this. These exceptional purchases produce a reverse balance: gold obeying the fall in the rate of exchange, flows back again, and the equilibrium tends to re-establish itself. The economist theorem, stated by Mill and Mr. Bonamy Price, is thus verified; but an important change has taken place, which economists completely ignore. The country which, thanks to its gold, will have been able to invest money in the country momentarily impoverished, will hereafter be entitled to receive from the latter, as a kind of tribute, interest for the capital invested. It is thus that England has enriched herself, and that she can annually import a surplus of about £100,000,000 sterling in commodities, a large proportion of which represents the dividends of stocks, shares, bonds, &c., due to her by foreign nations. In 1847, France, in order to cover the deficit of a bad harvest, was forced to send large quantities of gold to Russia, and a crisis ensued. The Emperor Nicholas sent 50,000,000 francs to France. The gold returned, but Russia continued the Creditor of France to this amount. Only, here again it must be noted that the flowing back of gold from America to Europe will not be easy, because many years must elapse before capital can be more advantageously placed in Europe than in the United States.

Let us sum up these remarks on the movements of the precious metals. The real balance of trade, when all the facts are taken into account, is a very important point. It is that which determines the fluctuations in the rate of exchange, which again leads, when it passes the *gold point*, to the export of this metal. Under the influence of the variations in the exchanges, the balance generally regains its equilibrium, and thus the exports of precious metals are very nearly balanced. But when, after bad harvests, by large imports without compensating exports, or on account of freights or interest due, a country loses some of its monetary stock, it does not regain it without suffering some damage. The country in receipt of this excess of gold parts with it only to pay for goods at a cheap rate, or to purchase stock, the price of which has fallen through the scarceness of the metal, or as a result of the monetary crisis. I will finally examine one remaining question:—To what extent is it true, as orthodox economists allege, that it is a matter of indifference whether a nation be abundantly or scantily provided with the precious metals? I will restate their propositions. Precious metals, they say, are not essential to any absolute requirement. It is the abundance of useful or agreeable objects that constitutes the wealth of a nation. The more plentiful cash is, the higher each article will be priced; but this will add nothing whatever to individual well being. The only result will be that money payments will be heavier, because, in order to obtain the same number of objects, a greater weight of gold and silver will have to be given in exchange. These propositions are perfectly true, if we consider one country only, or are speaking of the entire world; but it ceases to be so when we examine the relations of one nation with others. This is what we must now make clear. It is necessary, preliminarily, to explain the meaing attached to the words "abundance of cash." It refers to abundance in comparison with what is requisite for exchanges, and not to absolute abundance. Thus, it is certain that the more highly a country becomes economically developed, the less precious metal it makes use of in accomplishing the same amount of exchanges; firstly, because the monetary media, better employed, circulates more rapidly; and secondly, because cash payments are replaced by an extensive credit system. England, for instance, does more business than France, with half the quantity of cash. But yet, allowing for the necessity England is under always to maintain a certain quantity of the metallic means of exchange, it can be truthfully said that she is always abundantly furnished in that particular. The greater portion of the precious metals produced in the entire world passes through the London market, which reserves for itself only what it requires. All the nations of Western Europe are rich countries, cash is not wanting, means of circulation are plentiful and prices are consequently high. The nations of Eastern Europe are, on the contrary, countries where gold and silver are scarce, the circulation slow, and consequently prices there are very low.

This difference in the prices of commodities is of very little consequence for the inhabitants of one or other of these groups of communities in their relations between themselves; everything there is dear or cheap. But it makes itself felt in any question of trade or intercourse between the highprice group and the low. The first can buy of the second at will; but the second, in their turn, cannot buy of the first. If I sell a chicken in London for 3*s.*, I could procure three in Bucharest for the same money. A thousand pounds sterling in England would give me a triple power of purchase in Roumania or Bulgaria. An Englishman could, therefore, if it suited his convenience, buy up everything there is to be had in a poor country, he being ready to pay a price that no one there would give. It is for this reason that everything of the finest and most costly description is sent to London and to Paris from the producing countries. It is on this account also that so many Englishmen settle abroad. Their income gives them there a much higher power of purchase, and they can live in a much higher style than in their own land. On the other hand, an inhabitant of Kief or of Sophia, wishing to come to London or Paris, to enjoy the value in his country of, say, forty or fifty quarters of corn, would have to sell double that quantity there to enable him to pay for the same enjoyment in the cities of Western Europe. The workman who in New York earns a dollar for one day's work, could for that sum get five men to work for him where the wages are a mark a day, as in Silesia, and ten where the remuneration is 5*d.*, as in India. An Anglo-Indian civil service functionary there keeps an establishment with ten or fifteen servants, wages being very low. Poor countries—poor in cash, or where the scale of charges is at a medium—are therefore, in truth, under the economic domination of rich countries where prices are high.

From all that has been said, therefore, I think it may safely be concluded that all the theories concerning the currency put forward in classic works need to be reconsidered and revised. They are superficial. They contain as much mistake as truth; and this portion of error has done much harm in preventing certain nations—England, for instance, and, quite recently, Germany and the Scandinavian States—from adopting a more rational monetary system. The "mercantile" school was right in maintaining that an influx of precious metal stimulates commerce and industry, while its withdrawal throws both into difficulty and induces crisis. It was also not in the wrong when it affirmed that gold and silver are not a merchandise like any other. These metals serve as conveyances to all other products; consequently, when they are in insufficient quantities, circulation, which is the life of the economic world, stops or languishes. But from these true observations, confirmed by daily experience, and relied upon by all business men and money-market chroniclers, the "mercantilist" reasoners have deduced erroneous conclusions: for instance, that gold and silver are the only riches, and that, consequently, in order to accumulate the largest possible amount of them, high protective duties must be imposed, so as to put an obstacle in the way of foreign import, and bonuses be offered for the purpose of stimulating exports. Economists were right in stating the true riches of a nation to consist in an abundance of useful objects, not of precious metals; but they made a mistake, and a very grievous one, in drawing the inference that it was a matter of indifference —in fact, it was rather advantageous than otherwise, to export cash. It suffices to reflect for one moment on the disturbance occasioned from time to time in the economic and financial world by the draining of gold and the ensuing crises, in order to see how grave is their error. Nevertheless, the deductive school continues imperturbably to repeat its abstract axioms, although experience too frequently gives them flat contradiction. What is to be desired in respect of currency, is that the monetary stock should be maintained at the level of the wants of circulation, and consequently that it should increase in proportion to the development of the exchanges effected in the world, so as to offer to all contracts, whether for a short or a long term, as stable a basis as possible. In spite of history, to reduce civilized nations to make use of gold only, when Nature has placed two monetary metals at their disposal, and when it is evident that the yellow metal is produced in too small and too variable quantity, is to provoke a series of disastrous crises, shackling commerce, and completely strangling free trade.

The question I will now proceed to examine is this: What determines the value of money? As Mr. Dana Horton, United States delegate at the Paris Monetary Conferences of 1878 and 1881, has clearly shown, two extreme opinions exist on this subject—that of *free trade*, which is not applicable here; and that of the *fiat money* theory, which maintains that it is the will of the legislator which creates and regulates the value of money. These two theories are evidently erroneous. Let the law once establish—as it has done from all time—a coin as legal tender, and there can be no longer *free trade* in this matter. There exists an enormous difference between gold as a simple commodity, and gold as a legal measure of value, and, at the same time, legal means of payment for any debt or purchase. Mr. Thomas Baring has mentioned the fact that, in the crisis of 1847, one sovereign was not to be procured in London for £60,000 in silver: and that in Calcutta, during the crisis of 1864, a merchant possessing £20,000 in gold became bankrupt, because he could not exchange it for silver rupees, the only legal tender. Mr. Dana Horton has clearly set forth the absurdity of attempting to introduce free trade where it is really not a question of it:—

"Free trade in legal tender may have existed in the primitive days of unsophisticated barter, and certainly must flourish in Utopia; but when we ask how it can be materialized to-day, we find ourselves in confusion. Can payees demand, or can payors give in payment, whatever merchandise they prefer? In what merchandise do men express their taxes and appropriations, salaries and fees, fines, official appraises and sales? Is it a matter of indifference, or a matter of choice, with payor or payee, whether all these obligations are fulfilled with saw-logs, whale's blubber, raw hides, or loads of gravel? Do men take up a bill of exchange, with freestone, or pay for postage stamps with dynamite? Now, all these questions occur naturally, and must be answered affirmatively, if we admit that free trade in legal tender is present in the flesh. Evidently the thinker who materializes ideal free trade in money in the nineteenth century, in the interests of science, must likewise be prepared to be done by as he does, and when he asks for bread to receive a serpent, and when he asks for fish to receive a stone."—*Gold and Silver*, p. 172.

I think we may conclude, from what we have just quoted, that those who speak of *free trade* in money do not know what they are talking about. The word "legal" tender in itself ought, however, to warn them of their error. The theory of *fiat money*—which is, at the bottom, the theory of the inflationist and of the partisans of paper money—is not less absurd when pushed to the extreme. Mr. Dana Horton gives us a curious example borrowed from Iwan Possoschkof, a Russian reformer of the time of Peter the Great:—"The foreigners estimate their money according to the quantity of metal it contains, and not according to the power of the monarch who issues it. But we honor our monarch as God, and most zealously obey his will. We do not look at the weight of the money, but upon the inscription. It is not the copper that is valuable to us, it is the name of our Czar." In truth, in former times, when sovereigns and statesmen were for ever changing the current value of money, or the proportion of precious metal in each coin, their ideas must have been very similar to Possoschkof's. To cite only one example, the following are the terms in which Phillip Valois, king of France, proclaims his absolute power with regard to the coinage of his realm, in an ordinance dated January 16, 1347:—"Aucun ne peut faire doute qu'a nous appartienne seulement et pour le tout en notre Royaume, le fait, la provision et toute l'ordonnance de la monnaie et de faire monnayer telles monnaies et donner tel cours comme il nous plait." Lord Liverpool, whose ideas as to the nature of money were so clear and just, does not overlook the predominating influence of law in the matter. He says, in his famous treatise on the "Coins of the Realm":—"Coins ought always to pass in tale, according to the rate or value which the Sovereign puts upon them in his Mint Indentures." (Bank of England edit., p. 177).

It is as little correct to pretend that the law can do everything with regard to money, as to say that it can do nothing. The following are the arguments of those who maintain the latter opinion: Doubtless the law can decree that a pound sterling shall be equal to forty shillings, as it can also diminish by one half the amount of pure gold contained in a sovereign, but in such a case the value of the new sovereign would be only half that of the old—that is to say, it would pay for only half the quantity of goods, prices having doubled themselves. Thus the step taken by the legislator would prove of no avail; it must, indeed, always come to naught, when we consider existing economic conditions which enforce themselves. The value of everything depends on the law of demand and supply, and not on the will of either Sovereigns or Parliaments. This argument is irrefutable, but does not at all prove that the law can have no influence whatever on the value of monetary metals, and consequently on that of money. In reality the influence of the State is not contrary to economic laws, but in accordance with them; for it is the State which, by opening the mints, occasions the chief demand for the precious metals. The value of gold and silver arises from their being used, firstly, for making either useful objects or objects of luxury, jewelry, etc.; and, secondly, for making coin. The monetary exceeds in influence the industrial demand—in the first instance, because it is of greater importance; in the second, because it fixes the price of the precious metals. If mints were completely closed, the value of the proscribed metal would fall to at least one-half. Gold would be worth no more than platinum—that is to say £24 to £30 a kilo, and its price would be as variable as the price of this rare metal. Silver has lost one-fifth of its former value; and this fact is entirely due to the legislators of civilized countries having forbidden its being freely coined in the mints. If the United States were to suspend the Allison Bill, which imposes a monthly coinage of at least two million dollars, and if India were also to close her mint, to what price would silver then fall? To one-half—or, perhaps, even one-third—of what it was recently worth. If, on the other hand, free coinage were to be re-established in those countries where it formerly existed, silver would certainly regain its former value. Thus we see that the power of law with regard to money consists in fixing its value by creating, suspending, or annulling the demand for the precious metals of which money is composed.[1] The law in itself does not entirely create this value, though very nearly so. Were the demand from the mints to cease completely, industry alone would, it is true, suffice to retain for the precious metals a portion of their present value, but the influence of law is certainly very great, for were the monetary employment of either metal entirely to discontinue, that metal would be offered to industry in double and triple quantities, and the price of it would consequently be enormously depreciated. In the correspondence between Mr. Gibbs and Mr. T. H. Farrer,[2] the latter sums up current opinion in the following passage:—

"What is a pound? Not merely a thing to which law has attached any particular value, but a bit of gold stamped to show its weight and fineness. The value of gold depends in no way on the stamp. It depends, on the one hand, on the supply—*i. e.*, cost, or rather difficulty, of production; on the other hand, on the demand, *i. e.*, on the extent to which men desire to use it. Over the supply law has no power whatever; over the demand law has some power, just as it has over the demand for other commodities."

All these affirmations, which have a seeming foundation, are, in reality, contrary to facts. Law has an influence over the demand for gold quite different from that which it exercises over the demand for any other commodity, for the State buys gold in unlimited quantities and at a fixed price. This it certainly does for no other merchandise. Will the State accept iron, corn, or tea, upon these conditions? It exercises also an indirect but decided influence on the supply, that is to say, on the production, for it determines the price which can be paid at the mines. If the State cease to fix the price, or if it lower it, the production will, of necessity, diminish. "A gold sovereign," says Mr. T. H. Farrer, "is, within a trifling fraction, worth as much in exchange, when melted down, as when it has the Queen's head on it." This is true, but why? Because the law allows you to change your melted sovereign back again into a sovereign "legal" standard, and this at the expense of the Mint. "It is, therefore, the law which maintains the bullion value of the melted sovereign. Let the law only close the Mint, and your gold as bullion would lose a large proportion of its value. Here is a proof of this. In France, at the present time, five francs in silver have the same power in buying and paying as five francs in gold. Melt a silver five-franc piece, and it will then be worth only four. Why? Because silver, as bullion, may not be changed back into coin. If the French mint were once more opened to silver coinage, five francs in bullion may be worth as much as five francs in money, just as with a sovereign.

Mr. Bonamy Price, and those who, like him, affirm that money is as much merchandise as any other article, or a piece of machinery, a tool, a wagon, or a cart, do not observe that the free coinage at the Mint in itself establishes a radical difference between the monetary metals and any other commodity. If you make too much cast-iron, or too much cloth, you cannot sell it all, your stock accumulates too largely, and you are a loser, for it eats up the interest

[1] In favor of the opinion that the value of money comes not from the law, but from the intrinsic value of its metal, Michel Chevalier, Bonamy Price, and other economists, quote these words of Aristotle: "It was agreed to give and receive in exchange a substance which, useful in itself, was easy of handling for the uses of men, such as iron, for example, or silver, or some other substance, of which the size and weight was first determined; and, finally, in order to avoid the trouble of continual measuring, it was marked with a stamp in sign of its value." They omit the conclusion of the passage, which runs thus: "But of itself money is an empty thing; it has value only by law, and not by nature, for a change of agreement among those using it can depreciate it entirely, and render it entirely unfit to satisfy our needs." The consequence of what Germany had done in 1873, in accepting no more silver as legal tender, is an example of the truth of Aristotle's remark. Mr. Dana Horton, in his remarkable book, "Gold and Silver," p. 118, quotes another passage of Aristotle even more explicit:—"Money (νόσμα) is, as it were, a substitute for demand (χρεία) or the thing needed; and hence it has the same 'nomisma,' because it is not so by nature, but by law (νόμω), and because it is in our power to change it and render it useless."—*Nichomachean Ethics*, book 5, chap. 5.

[2] "The Double Standard," by H. Gibbs, Appendix, p. 18.

of the value it represents. This is not at all the case with monetary metal; you can never have too much of that; thanks to free coinage, it can always be converted into money, and then you immediately draw a revenue from it. Monetary metal is never a dead capital; with money you can purchase, and pay for, any and everything. You are lord of the market. With goods you must wait to sell before purchasing or paying. This is the difference between money and tools or plows. If you possess the latter in excess it is dead capital, while this can never be the case with monetary tools, for you can always send them into circulation, and employ them in procuring your productive capital, consols for instance.

Mr. Bonamy Price thinks that surplus monetary conveyances will lie idle in the banks, like surplus plows in a shed. This is a mistake. Every piece of money will be sent into circulation, let them be ever so numerous; for, if they accumulate in banks, the rate of interest will fall. The lowered rate of interest will urge men to fresh enterprises, from which will spring an increased demand for goods of all kinds, and, as a natural result, a rise of prices will ensue. Higher prices will necessitate the use of more money, and thus the surplus coinage will find employment. Coin is, therefore, to its owner a living capital, current everywhere, and capable of being employed immediately, or of being put out to profit according as its possessor desires. This is an exclusive privilege of money, and when business men, whom economists scoff at, give it pre-eminence over all other merchandise, they are wholly in the right. According to Mr. Bonamy Price, and all the economists of the deductive school, the value of gold and silver depends on what it has cost to produce these metals. "The gold," they say, "buys by means of its cost of production." This maxim is daily contradicted by facts, as we will endeavor to prove, but this discussion needs great attention, because it is not easy to explain the changes in the value of money, which would appear unchangable as long as the coins contained a fixed quantity of precious metal. For instance, an ounce of gold, standard fineness, which can always be exchanged at the Bank of England for £3 17*s.* 10½*d.*, would appear to retain always the same value. This is, however, not the case. Without taking into consideration the abstract theory of value, we can say, with economists, that the value of an object is represented by the quantity of other objects to be obtained in exchange for it. Thus it is admitted that the value of the precious metals has fallen to a quarter of what it was in the thirteenth century, because the same weight of gold or silver will now only purchase a quarter or a fifth of corn or other commodities. If bank notes and silver were simultaneously and universally suppressed in favor of gold, it is certain that the value of gold would enormously increase, although the amount of labor necessary to the production of an ounce of gold would in no ways have changed or diminished. Silver, after 1873, and notably in 1875 and 1876, lost suddenly a large proportion of its value. The price of this metal fell from 60 to 61 pence per ounce, to 50, and even for a time as low as 46, and now the average price is about 52 pence. Has the cost of producing silver suddenly fallen a fifth or fourth? No one will attempt to maintain such a statement. Mr. Otto Arendt has proved with most accurate figures ("Die vertragsmässige Doppelwährung") that the fall in the price of silver was occasioned by Germany, selling it, combined with the prohibitions against its free coinage in all civilized countries.

The price of articles depends principally—and this will not be denied—on the demand; and as the demand for silver from the Mints ceased all at once, how could this metal not fall considerably in the market? If the free coinage of this metal were re-established in France, the United States, and Germany, on the basis of a fixed ratio of 1 to 15½ between gold and silver, is it not evident that silver would immediately regain its former value? When Belgium and, later on, Germany adopted nickel in place of copper coin, the value of that metal tripled. Had the cost of its production increased? Not at all; but the demand increased, and as nickel cannot be produced at will, the tripled price maintains itself. Suppose that men again attempted to make money out of platinum, as was once done in Russia, that metal, instead of being worth from £12 to £14 a pound, would rise to four or five times that value. If, on the other hand, the coinage of gold were everywhere to be suppressed, it would certainly fall to half its present value. The value of gold depends so little on the cost of production, that we learn from those of competent authority, who have given the question their time and attention, that the *average* cost of each ounce obtained is the price of two. It will be asked: Why, then, is such a losing business carried on? It cannot be possible! The explanation is very simple. Certain mines make very large profits, and those who work at a loss hope, some day, to strike a rich vein, a "bonanza," and they work on, cheered by that hope, until they have expended all their resources. Sometimes they succeed, and their good fortune stimulates others to similar labors. At Monaco, an analogous state of things may be observed. It is quite certain that for the totality of players the gaming there is a losing operation, for the yearly profits made by the bank amount to a considerable sum. Therefore, each franc gained by the mass of players cost them more than a franc. But the gambling goes on, each individual believing he will one day be the favorite of fortune—and there are, indeed some who prove to be so. It is most essential with the precious metals to distinguish very carefully between *price* and *value.* The price of the precious metals is determined by the Mints. The "market price of gold" is an expression in constant use, especially in England. The market price of gold is no other than the Mint price. This price enforces itself, and for a self-evident reason, which is this. Mints are not only the principal consumers, but are, at the same time, insatiable, for they buy up all monetary metal at a price fixed by themselves. Why, in any part of the world should gold be sold under £3 17*s.* 10½*d.*, due deduction being made for transport expenses, as this price can always be obtained at the Bank of England? Gold will never be sold cheaper while the Mint in London maintains its price. It cannot either fetch a higher price as long as a sovereign remains in circulation, for industry has but to melt sovereigns for £3 17*s.* 10½*d.*, and it will secure an ounce standard, and will therefore pay no higher price in the market. Certain writers imagine that if silver were universally received as standard money, with a ratio as to gold of 1 to 15½, the dearer metal, that is to say, gold, would be gradually withdrawn, and would no longer remain in circulation. But then, what would become of this metal? Could it be treasured up indefinitely? Impossible; for it would consume its own interest. Could it be sold to industry at a higher price than that fixed by the legal ratio? More impossible still; for, goldsmiths and jewelers being able to draw, at will from the monetary stock, at the price fixed by the Mint, would refuse to pay higher. The producers and holders of gold would therefore be forced to resign themselves to accept the price imposed by the Mint, for they would be unable to dispose more advantageously of their metal elsewhere. Gold could only disappear if the production were to be reduced one-half or two-thirds. But then, of course, gold could be no longer the monetary metal of the world. Let us suppose that the cost of the production of gold diminishes suddenly very much, as it probably did when the *placers* of California and Australia were first worked after the year 1850. The price of gold would not fall on that account, for the bank would still continue to pay £3. 17*s.* 10½*d.*

The value of the monetary metals, that is to say their power of purchase of other objects, is a more complicated subject. It depends on the connection existing between the exchanges to be effected, on the one hand, and the total quantity of metallic money, or other mediums of exchanges substituted for this metal, on the other. For instance, bank notes, fulfilling precisely the same mission as gold or silver coin, compete with these metals and, at all events, render them less essential, and, consequently, diminish their utility and their value. This diminution of value, or of power of purchase, occasions a rise in prices. Suppress bank notes everywhere, and the value of metallic money will considerably increase, for each monetary unit will be more sought after, and its power of purchase will augment in proportion as prices fall, although the cost for the production of the precious metals will have remained identically the same. On the other hand, if more bank notes be issued, gold and silver will be depreciated in value. For instance, when the United States and Italy adopted paper money, and allowed their monetary stock to pass into other hands, a marked depreciation in the value of coinage was observable all over the world. On the contrary, since these countries, wishing to re-establish a metallic currency, are drawing to themselves a portion of the world's monetary stock, they have occasioned a considerble increase in the value of money, by a fall in prices. These changes in the value of gold and silver are entirely independent of the cost of production. The cost of production of the precious metals can only influence their value in the long run, and that insomuch as it has the power to limit or increase the amount produced. Let us suppose that the excavation of an ounce of gold from a mine costs double what it now does; the majority of mines, commencing, of course, with the poorest, would be abandoned. The monetary stock would diminish and prices would fall. The value of goods would increase. But this fall in the price of everything, including also labor, would probably diminish the cost of excavation and allow of the abandoned mines being reopened. If, on the other hand, precious metals could be obtained at a less cost, it would probably happen that a larger quantity would be extracted from the mines and a diminution in their value *might* ensue, which would manifest itself by a rise in prices. At all events, this influence, never other than feeble, which the increase or diminution of the cost of production can exercise over the value of gold and silver has been often counteracted and annulled by circumstances other than those we have previously mentioned. Firstly, money, gold and silver, cannot be regarded as corn, coal, or such commodities. One cannot, at will, secure any amount of gold. Mines must be found to be worked, and these mines are very rapidly exhausted. During the first fifty years of this century the value of gold rose considerably without occasioning any corresponding growth in the amount produced. The discovery of the *placers* of California and Australia increased extraordinarily the annual produce of the yellow metal. This abundance of gold, and the great diminution of the cost of production at the gold-fields, occasioned but a transitory fall in its value; indeed, the price of gold very quickly regained its previous level, as I have already endeavored to prove; and this was due to the fact of there being fresh demands for it,—a necessary consequence of the extraordinary activity of commerce and industry all over the world.

Another consideration which must not be overlooked is, that while ordinary commodities are more or less rapidly consumed, the precious metals are preserved and accumulate. Therefore a difference in the annual production, unless it were to continue during a prolonged period, would have a scarcely perceptible influence on their value, for this influence would become deadened on losing itself in the immense monetary stock, the result of the labor of centuries. History proves that the value of gold is not at all regulated by the abundance of production, as economists, following Lord Liverpool, generally affirm. The latter writes in his famous book, "The Coins of the Realm," chap. iii.:—"This variation (in the value of gold and silver) is occasioned by the greater or less quantity that may happen to be at different times in the market or in circulation." We will now show that this affirmation is contradicted by facts, and, if this be the case, as a reduction in the cost of production can only affect value by increasing the production, we think the error of the thesis of Mr. Bonamy Price, "*The gold buys by means of its cost of production,*" will then be clearly proved. The value of gold in past centuries can be estimated by comparing it with that of silver; for, until the year 1816, silver was everywhere the principal standard, and the common measure of value. It will be seen, by the figures given below and borrowed from Mr. Soetbeer, that the value of the precious metals is in no way determined by the cost of production, but solely by the prices fixed at the Mints of the preponderating countries.

Average annual production in millions of German marks (a mark is worth about a shilling).

	1561–80.	1581–1600.	1601–20.	1621–40.	1641–60.	1661–80.	1681–1700.
Gold	19	20	23	23	24	25	30
Silver	53	75	76	70	65	60	61
Relative value of gold to silver.	11·50	11·80	11.25	14·00	14·50	15·00	14·96

We see that from 1561 to 1600, the annual production of silver rose from 53 to 75 millions of marks; while that of gold remains almost stationary. The value of silver ought to have fallen. It did not, however, do so, for the relative value of gold only rose from 11.50 to 11.80. From 1600 to 1700 the production of silver diminished: it fell from 76 to 61 million marks: while that of gold rose from 20 to 30 million marks. The value of silver should therefore have increased, and that of gold comparatively have diminished. We see, however, instead of this, that the value of gold rises from 11.80 to 14.96. The cost for the production of gold must have fallen, as the produce was more abundant. Why, then, has its value so increased? Because the Mint indentures of different States fixed a higher and higher value on it. Are economic laws at fault here? Not at all; but they have been badly expounded by economists. It is the demand of those insatiable consumers, Mints, which has brought about the rise in the value of gold. During the 18th century, the production of silver enormously increased, thanks to the facility with which the rich mines of Mexico were able to be worked. According to the theory of the cost of production of Mr. Bonamy Price, the value of silver ought to have lessened. The contrary took place. Here, again, I borrow the figures of Mr. Soetbeer, which are generally admitted to be the most accurate we have—

Average annual production in millions of German marks.

	1701–20.	1720–40.	1741–60.	1761–81.	1781–1800.
Gold	35	53	68	57	49
Silver	46	77	95	117	158
Ratio between gold and silver.	15·27 and 15·15	15.09 and 15·07	14·93 and 14·50	14·81 and 14·64	14·76 and 15·42

Thus, from 1700 to 1800, the production of gold increased very little—from 35 to 49 millions of marks; while that of silver grew enormously—from 64 to 158 millions; and, at the same time, until the year 1780, the relative value of gold fell, and that of silver rose. A kilo of gold (about two lbs.), which was worth, in 1700, 15.27 kilos of silver, would only fetch $14.76 in 1780. If gold in 1880 attained the ratio of 1 to 15.42, it was on account of the French Minister, De Calonne, having established a ratio of 1 to 15½, which was higher than the value known as the commercial value, and determined, before this date, by the price at the English Mint.

Facts which occurred subsequently to the year 1850, give a still more formal contradiction to the theory which asserts that the value of the precious metals depends on the cost and amount of production. The average annual production of gold which was, from 1840 to 1850, about £2,800,000, rises suddenly after 1850 to £32,000,000, or to an average of about £28,000,000 for the period 1850–60. In the twenty-five years following 1850, more gold is produced than in the 358 years between 1493 and 1850. What a prodigious change in all the elements of production of this metal! If the theory of Mr. Bonamy Price be correct, its value ought to decrease enormously. But no. The ratio of gold to silver scarcely changes. From 1851 to 1875 it is quoted at 15.53. Thus we see that the diminution in the cost of production and the more than extraordinary growth of production produced no effect on the relative value of gold. These facts give a decisive negative to the theories of economists; but they are in strict accordance with true economic laws. Let us suppose an unlimited demand for any commodity at a fixed price. This price will of necessity be forced upon the market. The free coinage of a monetary metal, at a fixed price by the Mint, constitutes an unlimited demand for that metal; the price of the Mint will become consequently the established price, if the State be sufficiently powerful to absorb all that is produced. In the event of the production increasing very considerably all that could ensue would be a depreciation of the monetary units, and consequently a rise in prices. Stuart Mill stated and proved the following principle: "Alterations in the cost of production of the precious metals do not act upon the value of money except just in proportion as they increase or diminish its quantity, which cannot be said of any other commodity." [1]

It is now time to examine if a rise or fall in prices is always in proportion to the growth or diminution in the

[1] Principles of Political Economy, People's Edition, p. 306.

quantity of money. This is what German economists call the "*Quantitats Theorie.*" I borrow also from Stuart Mill the statement of this theory: "The value of money, the other things being the same, varies inversely as its quantity, every increase of quantity lowering the value, and every diminution raising it in a ratio exactly equivalent." The great Roman jurist, Paulus, already understood this law, when he said, speaking of money,[1] "*Usum dominiumque, non tam ex substantia præbet, quam ex quantitate.*" Mr. Cernuschi has given expression to the same idea, with his usual precision, in the Proposals which he submitted to the Monetary Congress of 1881:—"Money is a legal and mathematical value; legal, for the material from which it is made is fixed upon by legislators, and its enforced currency is also imposed by them; mathematical, for the value of money varies inversely as its mass; that is to say as the quantity existing." This theory is correct if we add to it, as Stuart Mill did, *cæteris paribus*, or "the other things remaining the same." If, referring to Hume's hypothesis, we imagine that, one morning, every one wakes up finding in his pocket twice as much cash as the day before, it is certain that every commodity would be worth twice as much, for each one could offer twice as much cash in order to obtain what he wanted. But the "quantity" monetary theory is contradicted by facts, *if other things do not remain the same.* Now, many circumstances may alter. For instance: Firstly, the circulation of money may become more rapid, and, consequently, each coin, operating more exchanges, the quantity of money may be reduced, without any proportionate fall in prices occurring. Secondly, a similar effect is produced if money is replaced by means of credit. Here, again, the quantity of money may diminish, or the number of exchanges increase, without being followed by a fall in prices. So it is well known that in England and America, nine-tenths of all the great transactions are settled by credit and banking. Thirdly and finally, an increase, even very great, in the quantity of money does not produce a rise in prices, if its effect be, as is generally the case, to stimulate the creation of fresh enterprises, and thus to increase the amount of merchandise to be exchanged and transactions to be settled. We see now in what way facts contradict the maxim generally accepted in England, and thus stated by Mr. Bonamy Price: "The market value of the sovereign is what it cost to produce." As Mill has proved, the cost of production of the precious metals does not act upon the value of money except in proportion as it increases or diminishes its quantity. In its turn, the quantity of money does not influence the value, save in a manner by no means mathematical, rather irregular, and frequently in total opposition to anything the "quantity theory" would have led one to contemplate. I now approach the question which is occasioning such lively discussion at the present time. Should money, legal tender, be made of only one metal, or can it be made of either gold or silver, a ratio of value between these two metals being fixed by law? Until quite recently the question had been very little studied in England, and opinions there were almost unanimously in favor of a single metal—*i. e.*, gold monometallism. Lord Liverpool's book, "The Coins of the Realm," was considered decisive authority, and, in all respects, it well deserved to be so. Both theoretical arguments and historical facts are there clearly and perfectly stated. I will endeavor to prove from the premises of Lord Liverpool, and of other authors whom he quotes in his work, that a bimetallic coinage is better calculated to fulfill the conditions necessary to a good legal tender than a monometallic. When Lord Liverpool, contrary to universal custom, reduced England to the exclusive adoption of gold as money, he was guided by two chief considerations. The first, borrowed from Petty, Locke, and Harris, was this: It is impossible to establish a fixed ratio between two sorts of merchandise, gold and silver; therefore, in accepting these two metals at a time as a legal tender, we run a double risk of variations in its value. The second, which Lord Liverpool gathered chiefly from the monetary history of England, is as follows: It is impossible to maintain two metals in circulation. The most sought after is exported abroad or melted by industry. This law is what is called the Gresham law,[1] which might also be named "the law of alternation." The following are Lord Liverpool's authorities:—Sir William Petty ("Political Anatomy of Ireland," chap. xi,) observes, "that money is understood to be the uniform measure of the value of all commodities," and then adds, "that the proportion of value between pure gold and fine silver alters, as the earth and industry of men produce more of one than the other, so there can be but one of the two metals of gold and silver to be a fit matter for money." Locke says "that two metals, that is, gold and silver, cannot be the measure both together in any country, because the measure of commerce must be perpetually the same, invariable, and keeping the same proportion of value in all its parts."

Mr. Harris says, "that one only of these metals, gold or silver, can be the money, or standard measure of commerce, in any country; for the standard measure must be invariable, and keep the same proportion of value in all its parts,"—("The Coins of the Realm," Bank of England edit. p. 129.) Lord Liverpool allows that gold, as well as silver, varies in value, and that "coins, on that account, are an imperfect measure, though they are made of one metal only." "But," says he, "if coins are made of two of these metals, a second imperfection is then introduced; for any two of these metals, in successive periods, vary in value with respect to each other." Thus, what causes Lord Liverpool, and the authorities he quotes—Petty, Locke, and Harris—to prefer a monometallic coinage, is the opinion that a legal tender of only one metal is more stable in value. Stability in the value of money is its most essential quality. Both Aristotle and Locke recognized this: "*The measure of commerce must be perpetually the same, and invariable.*"

This ideal of permanent value being unattainable, as Lord Liverpool himself admits, the next point to examine is which legal tender approaches nearest to it, bimetallic or monometallic? We may say, at the present time, that it is a scientific truth, demonstrated by both arguments and facts, that a legal tender formed of two precious metals, gold and silver, is more stable in value than one formed exclusively of either gold or silver. This truth was clearly set forth in 1809, by Adam Müller in his book, "Elemente der Staats

[1] The passage from Paulus, whence these words are quoted, so admirably sums up the whole monetary theory, that we think we cannot do better than reproduce it in its entirety:—"Origo emendi vendendique a permutationibus cœpit. Olim enim non erat nummus; neque aliud Merx, alid Pretium vocabatur; sed unusquisque, secundum necessitatem temporum ac rerum, utilibus inutilia permutabat; quando plerumque evenit ut quod alteri superest, alteri desit. Sed quia non semper nec facile concurrebat, ut, quum tu haberes quod ego desiderarem, invidem haberem quod tu accipere velles, electa materia est, cujus publica ac perpetua estimatio difficultatibus permutationum, æqualitate quantitatis subveniret: eaque materia forma publica percussa, usum dominiumque, non tam ex substantia præbet, quam ex quantitate. Nec ultra Merx utrumque; sed alterum, Pretium vocatur."—Dig. xviii.

[1] "Gresham law" had already been observed in Greece. Aristophanes speaks of it very wittily in his comedy, "The Frogs." During the extreme distress caused by the Peloponnesian war, Athens had, for the first time, issued a debased gold coinage; the consequence was that the good money immediately disappeared from circulation. Aristophanes ("Frogs," 665) says: "The State has very often appeared to us to be placed in the same position toward the good and noble citizens as it is in regard to the old currency and the new gold. For we make no use at all, either at home or abroad, of those which are not adulterated but the most beautiful of all money as it would seem, which are alone well coined and ring properly, but of this base copper, struck only yesterday, and recently, of a most villainous stamp. And such of the citizens as we know to be well born and prudent, and honorable gentlemen and educated in the palæstra and chorus and liberal knowledge, we insult; but the impudent and foreigners, and the base born, and the rascals, and the sons of rascals, and those most recently come, we employ." Sir Thomas Gresham was a rich merchant of the City of London, a mercer who negotiated Flemish loans for Henry VIII, and for Elizabeth. He interested himself greatly in monetary matters, and gave very sound advice to the Queen on this subject. He remarked that good and bad coin cannot circulate together, and that the good coin is always withdrawn from the circulation, where speculators in the precious metals leave only the bad. *Vide* "The Life and Times of Sir Thomas Gresham," by John William Burgon; and "Dictionary of Political Economy," p. 46, by Macleod. *Vide* "Aristophanes." Montesquieu states the facts observed by Gresham, but without knowing their cause: "L'or disparait quand l'argent est commun parceque chacun en a pour le cacher; il reparait quad l'argent est rare parcequ on est oblige de le retirer de ses retraites. C'est donc une regle: l'or est commun quand l'argent est rare, et l'or est rare quand l'argent est commun."—*Espirit des Lois*, liv, xxii, chap. 70.

Kunst." It was still more plainly demonstrated by Sismondi, in 1827, in his "Nouveau Principes x d'Economie Politique," t. ii, p. 60. These two authors make use of a comparison often reproduced since, that of the "compensated pendulum." "The way," says Sismondi, "to diminish the chances of fluctuation in the value of money is to employ gold and silver simultaneously, as common measure, and to establish a legal proportion between them. In the same way, in order to have a pendulum unvarying in length, the rods are made of different metals, so that the expansion of one, produced by heat, may be counteracted by that of another, and thus the equilibrium is maintained." The essential truth which governs the whole monetary question has been demonstrated by Mr. Jevons, aided by diagrams and comparisons, with a clearness which defies all dispute:—

"In the first place," remarks Mr. Jevons, "I have no doubt whatever that M. Wolowski is theoretically quite correct in what he says about the compensatory action of the double standard system. English writers seem completely to have misunderstood the question, asserting that the system exposes us to the extreme fluctuations of both metals." [Here Mr. Jevons inserts his diagram, showing that the fluctuations in value of both metals, taken together, do not proceed to so great an extent as those of either gold or silver. And then he goes on saying] "Nor is this the whole error of English writers; a little reflection must show that MM. Wolowski and Courcelle Seneuil are quite correct in urging that a *compensatory* or, I should prefer to call it, *equilibratory action*, goes on under the French currency law, and tends to maintain both gold and silver more steady in value, than they would otherwise be. Imagine two reservoirs of water, each subject to independent variations of supply and demand. In the absence of any connecting pipe, the level of the water in each reservoir will be subject to its own fluctuations only. But if we open a connection, the water in both will assume a certain mean level, and the effect of any excessive supply or demand will be distributed over the whole area of both reservoirs. The mass of the metals, gold and silver, circulating in Western Europe, in late years, is exactly represented by the Water in these reservoirs, and the connecting pipe is the French law of the 7th Germinal; An. XI., which enables one metal to take the place of the other as an unlimited legal tender."—*Money*, pp. 137-140.

Another example may serve to demonstrate the general principle that the price of two sorts of merchandise, which can replace each other, will be steadier than that of a merchandise without a substitute. For instance, in a country where the nourishment is both rye and wheat, the price of food, and even the price of each of these cereals, will be less subject to variation than in a country where the consumption is entirely of one or the other. The figures concerning the production of gold and silver prove that the comparison made by Mr. Jevons is perfectly exact. The table of figures reproduced here[1] shows that the production of either gold or silver, taken separately, is subject to very great and frequent fluctuations, while that of the two metals, taken together, gives a remarkably stable total. If there exist in the world, as is generally supposed, a stock of precious metal amounting to 2,000 millions sterling, half gold, half silver, it is evident that the variations in the annual productions would have less influence on the value of money, and consequently on prices, if the monetary stock were formed of 2,000 millions, gold and silver together, instead of 1,000 millions either gold or silver. For instance, in comparing the year 1849 with 1853, we find that the production of gold increased sixfold, while that of the two metals combined only tripled. All economists agree in admitting that if, in 1850, the gold standard had been in force in all civilized countries, the increase in the production of gold, from £5,420,000 in 1849, to £31,090,000 in 1853, it would have occasioned considerable disturbance everywhere, while, thanks to French bimetallism, the effect of this sudden increase was very much neutralized. As M. Michal Chevalier proved, by a very just comparison, the unlimited coinage of gold and silver in France acted as a "parachute."

In conclusion, Lord Liverpool was right in seeking, above all else, stability in the legal tender; only at the present time it has been scientifically proved that this is more easily attainable with a double than with a single standard. The second motive which induced Lord Liverpool to advise the adoption of a single standard had better foundation. It was, as we have previously stated, the Gresham law, or "law of alternation, which means that when gold and silver are simultaneously in use as money, the depreciated metal only remains in circulation. At the period from which Lord Liverpool deduces his historic examples, the different countries were constantly modifying and changing the ratio of value between gold and silver,[1] and the result of this was that a country where the two metals were allowed to be freely coined was liable to lose all she possessed of either which had, for the time being, the higher value at foreign Mints. Lord Liverpool proves, by referring to the monetary history of England, that the Gresham law has in fact been a reality. At the beginning of the reign of James I. gold was valued too low, and was consequently exported. This monarch then, by successive proclamations, raised the value of gold in his coins, so that the silver coins were, in their turn, exported. In 1663, under Charles II., when a new estimate was made of the relative value of gold and silver at the English mint, that of gold was underrated; but gold was received at a higher rate, so it remained in circulation. After the great recoinage in the reign of William III., gold was estimated at a higher value than on the Continent, so the new silver coins were immediately exported. In conformity with the advice of Newton, the value of the guinea was lowered sixpence. But it was not enough to recall silver.

[1] *Annual production of Gold and Silver from* 1849 *to* 1879, *according to English and American statistics.*

	Gold.	*Silver.*	*Total.*
	£	£	£
1849	5,420,000	7,800,000	13,220,000
1850	8,890,000	7,800,000	16,690,000
1851	13,520,000	8,000,000	21,520,000
1852	26,550,000	8,120,000	34,670,000
1853	31,090,000	8,120,000	39,210,000
1854	25,490,000	8,120,000	33,610,000
1855	27,015,000	8,120,000	35,135,000
1858	29,520,000	8,130,000	37,650,000
1857	26,655,000	8,130,000	34,785,000
1858	24,930,000	8,130,000	33,060,000
1859	24,970,000	8,150,000	33,120,000
1860	23,850,000	8,160,000	32,010,030
1861	22,760,000	8,540,000	31,300,000
1862	21,550,000	9,040,000	30,590,000
1863	21,390,000	9,840,000	31,230,000
1864	22,600,000	10,340,000	32,940,000
1865	24,040,000	10,390,000	34,430,000
1866	24,220,000	10,145,000	34,365,000
1867	22,805,000	10,845,000	33,650,000
1868	21,945,000	10,045,000	31,990,000
1869	21,245,000	9,500,000	30,745,000
1870	21,370,000	10,315,000	31,685,000
1871	21,400,000	12,210,000	33,610,000
1872	19,920,000	13,050,000	32,970,000
1873	19,240,000	17,850,000	37,090,000
1874	18,150,000	14,300,000	32,450,000
1875	19,500,000	16,100,000	35,600,000
1878	19,000,000	14,800,000	33,800,000
1877	19,400,000	16,200,000	35,600,000
1878	19,000,000	17,000,000	36,000,000
1879	18,000,000	16,000,000	34,000,000

[1] Here are some examples of variations in the ratio of value between gold and silver produced, not by trade, as is generally imagined, but by the indentures of the Mint. Spain, who in the sixteenth century, adopted a ratio of 1 to $13\frac{1}{2}$ raised it in 1730 to 16. The result was that silver, being estimated at a lower value than elsewhere, was exported, and was always at a premium of even six per cent. To remedy this, the ratio was lowered to $14\frac{41}{116}$, and then raised again to 16 in 1779. In the Netherlands, the ratio was $11\frac{1}{4}$ in 1589, $12\frac{1}{2}$ toward the year 1640, $14\frac{43}{100}$ in 1663, and $14\frac{83}{81}$ toward the close of the eighteenth century. In France the ratio, which was 1 to 11·88 in 1602, was raised in 1631 to 13·62, in 1679 to 14·91, and finally in 1785 Calonne fixed it at 15·50. Calonne himself explains that the ratio existing in France was more unfavorable to gold than that of $15\frac{1}{2}$, which was the market value, and so gold being exported, in order to call it back he proposes fixing it at $15\frac{1}{2}$. What he calls the commercial price is the price fixed by the English Mint. Formerly the Gresham law could act but slowly, because, save in England, coinage was not free. Depreciated metal could not therefore be brought into any country to be made into money, the more valuable metal being taken out in exchange. In 1679 Colbert decreed the free coinage of the two metals in France, the Mint giving, weight for weight, cash for gold or silver ingots. But this measure, which according to Leblanc, attracted unexampled quantities of gold and silver to the country, was retracted in 1869. Mr. Cernuschi has clearly demonstrated that two bimetallic systems, with a different ratio between gold and silver, cannot coexist. Silver would accumulate in the country where it is estimated the highest, and gold in the other. For instance the United States, having adopted a different ratio from that in force in France, first, 1786, that of 1 to 15, then, in 1834, 1 to 16, had, in the first place, nothing but silver, and afterward nothing but gold. *Vide* "Bimetallism in England and Abroad: Letter to Henry Hucks Gibbs," by H. Cernuschi, 1879, p. 8.

Gold remained in England as the cheaper metal, and silver was smuggled to the Continent by the Dutch as the dearer metal, as was shown in a speech in the House of Lords, on the 23d of January, 1718, by Lord Stanhope, who proposed to lower again the value of gold. After 1785, when Calonne raised in France the ratio between gold and silver to 15½, gold was exported to Paris and silver returned to London. To stop this, under the influence of Lord Liverpool, the free coinage of silver was prohibited in England, in 1798, till the Privy Council should have time to consider all the questions relating to the monetary circulation in the United Kingdom. This summary of English monetary events clearly shows the power of the Gresham law, and it also proves that, at this period, when it was impossible to think of determining, by international treaty, a fixed ratio of value between the two metals, the only means of avoiding the alternative withdrawals of gold and silver was, as Lord Liverpool maintained, to permit the free coinage of only one metal. This advantage being in all probability of greater practical importance than the maintaining a steady value in coinage, by making use of two metals, it follows that, at the time he wrote, Lord Liverpool was not wrong in recommending monometallism.

Nevertheless, he might have known that Newton had already indicated the means of maintaining the "equilibratory" action of the double standard, remedying at the same time the difficulty of alternation entailed by the Gresham law. These means are, that the Mints of all the preponderating nations fix the same ratio of value between gold and silver.

"If," says Newton, "gold in England, or silver in East India, could be brought down so low as to bear the same proportion to one another in both places, there would be here no greater demand for silver than for gold to be exported to India; and if gold were lowered only so as to have the same proportion to the silver money in England which it has to silver in the rest of Europe, there should be no temptation to export silver rather than gold to any part of Europe."—(*Reports made by Sir Isaac Newton, Master of the Mint, concerning the state of the gold and silver coins*, 1717: *Vide* "Monetary Documents, published by order of the Congress of the United States," by Dana Horton, p. 317.

As long as gold was worth 15:25 in England and only 15 on the Continent, as during the eighteenth century, the flow of gold must evidently be to England and that of silver to the Continent. This result was as inevitable as that of the electric battery, which attracts one metal toward the positive, and the other toward the negative pole. When, in 1785, France adopted the ratio of 1 to 15:50, England began losing her gold and winning back silver. But if England and France had both adopted the ratio of 15:50, these two countries would have formed but one, from a monetary point of view, and all reason for exporting or importing the one metal in preference to the other would have disappeared. The laws of universal bimetallism, as expounded by Newton, are no less mathematically evident than the law of gravitation and of universal attraction. If all the principal states were to adopt the same ratio, the Newton law would completely put an end to the Gresham law. These are truths which have so clearly demonstrated in the luminous writings, amongst others, of Mr. Cernuschi, that they may be considered as acquired by economic science, and he alone will attempt to deny their veracity who has never taken the pains really to study them.

From what precedes, I think, we may draw the following conclusions:—Considering that the quality Lord Liverpool especially wished to secure to money was steadiness in value; that this steadiness is much more easily attainable by the simultaneous employment of gold and silver; and that, at the present day, the inconveniences arising from the alternations of the Gresham law could be easily remedied by an international treaty, it follows that Lord Liverpool and his authorities, Petty, Locke, and Harris, would now declare themselves in favor of a bimetallic coinage, for precisely the same reason that they rejected it in their time. To elucidate this question as completely as possible, we will now examine the objections which have been raised against the solution we consider the best. The question of a bimetallic coinage must have been very little discussed in England, or such eminent economists as Mr. Bonamy Price and Mr. Robert Giffen would not put forth objections on this subject so strange that they quite amaze one. According to Mr. B. Price, if England were to join a monetary union with the principal civilized nations, for the purpose of establishing a legal and simultaneous circulation of both gold and silver with a ratio of 1 to 15½, the following deplorable results would ensue:—First, in any conceivable case, many silver-producing nations would be left out, and they would ruin the projected scheme. They would make silver coins for the Monetary Union States, forged, but all of full silver weight, introduce them easily into these countries, and deluge them with these coins, with immense profit to themselves."[1] We give here Mr. Bonamy Price's own words, otherwise it would be hard to believe that such an objection could have been brought forward. Bimetallism being established, what reason could there be in silver-producing countries, making money of full weight, and fraudulently introducing it into the circulation of the Monetary Union? Everywhere in the United States and in Europe, the Mints would accept silver in unlimited quantities and at its full value of 60⅞ pence. A false coinage would entail great expense, and its issue would not be unattended with danger, while all the States of the Monetary Union would be ready to receive silver at a price as high as fraud could obtain for it, and would even give the money in return almost gratuitously. It would be a very strange undertaking. It is now, when Mints are closed to silver, and when, at the same time, silver pieces are standard money, as is the case in France, that the danger Mr. Price warns us of really exists, for by forging these pieces 15 or 16 per cent, could be made; as silver can be bought at 52 pence, and sold as coin at 60⅞ pence. In England, the benefit made by forging shillings and half-crowns might be still greater. If the Americans do not make shillings, half-crowns, and crowns, now that silver costs 52 pence, what inducement would there be for them to commence, if its price were 60 or 61 pence, and when their own Mint would be ready to pay for it at that rate? The truth is then quite the reverse of what Mr. Bonamy Price states. The danger of false coinage which exists at the present time, on account of the depreciation of silver through its proscription, would entirely disappear if a free coinage were introduced.

According to Mr. Bonamy Price, the second unfortunate consequence of the free and simultaneous coinage of the two metals would be that "all goods would have two prices, one in gold, the other in silver, and this last would vary with all the fluctuations of the worth of the metal." The learned Oxford Professor has certainly traveled in France or Belgium, in Switzerland, Spain, or Holland. In all these countries bimetallism is in force. All debtors and buyers can pay in either gold or silver. Are there, then, two prices? Not at all. Let Mr. Price go to Paris and buy ten thousand francs' worth of goods, or invest a million in the public funds, or pay his bill at the hotel, no one will say to him, "It is so much; but if you pay in silver, the price is different; it is 15 per cent. more." Mr. Price would pay in bank notes, if for a large sum, and his small bills in gold or silver, as he prefers. No one has observed fluctuations in the white metal in France. India and England alone lose by the exchange of silver. In France, as in England, large payments are made in bank notes; these notes are guaranteed, for the greater part, by the stock of silver at the Banque de France. No one objects to receive it, in spite of silver being very much depreciated, which would not have happened if men were not so mad as to proscribe it, although it is endowed in the highest degree with monetary qualities.

The third grievance which Mr. Bonamy Price has discovered is quite as extraordinary as the two preceding ones. If England, says he, were to adopt bimetallism, debts would be paid in silver shillings instead of sovereigns, twenty shillings to a pound sterling; and the shillings would be worth much less, for one would be able to procure nearly twenty-four shillings for a gold sovereign. The eminent professor here supposes a state of things which, were it really to occur, would be a direct contradiction to all economic laws—viz., that silver, being worth 52 pence, at the present time, should remain at the same price, when the Mints of all the great countries would be ready and willing to purchase it at 60⅞ pence, the equivalent of the ratio of 1

[1] "Buying and Selling," *Journals of the Society of Arts*, May 6, 1881, p. 531.

to 15½ which is supposed to be adopted. Is it not inconsistent to pretend that silver would not rise in value if, instead of being proscribed everywhere, it were to be received at all the Mints? Mr. Henry Gibbs, whom Mr. Bonamy Price esteems so highly, and justly so, states, in his remarkable work, "The Double Standard," that the very day France readmits the free coinage of silver on its ancient footing of 200 francs the kilogramme, that metal will again rise to its former price in the London market—*i. e.*, to 60⅞ pence, the equivalent of the French price. Why should silver be sold at 52 pence, when in Paris nearly 61 could be obtained for it? As free coinage in France has sufficed during seventy years to maintain silver at a price of 60 or 61 pence, the little variations being occasioned solely by the fluctuations in the exchange, as demonstrated by Mr. Ernest Seyd, is it not absolutely certain that this price would be maintained far more easily if all the greater nations were to agree to it and adopt the ratio of 1 to 15½? But, says Mr. Bonamy Price, by adopting the ratio of 1 to 15½, instead of 1 to 18, which is the one now in existence, you give "an excessive, unnatural, unreal, and purely artificial value to silver." On the contrary, it is the present value of silver which is "unnatural and artificial," for it is the result of the legislative measures taken recently by Germany and France and all civilized nations. To re-establish a free coinage for silver, as before 1873, would be but to restore to this metal its normal value, which it had preserved from the end of the last century.

"The bimetallists," says Mr. Price, "do not deny that by the adoption of the 15½ ratio the creditor would be wronged, but they think they have found the remedy in limiting the coinage of silver, so as to make it pass for what they please." Two errors in a single sentence are a great deal. Bimetallists have never admitted that creditors would be wronged. Far from that, they believe that silver would regain its former value, and that creditors would be indifferent whether the debts owed them were paid in gold or silver, or, rather, they would receive payment in bank notes, representing indifferently the one metal or the other, as now in France. Still less do bimetallists, desire, in any way, to limit the coinage of silver, for, as Mr. Price himself writes, some lines before the passage just quoted, "bimetallism consists in authorizing any quantity of silver to be coined into shillings." Mr. Price imagines that, contrary to all economic laws, bimetallists, wishing to raise the value of silver, would limit the coinage, or, in other words, restrict the demand; while, far from that, they desire to raise the demand to the level of the supply, by decreeing a free coinage—that is to say, creating an unlimited demand. It is certain that if the learned Oxford professor had deigned seriously to study the pith of the question, and the consequence of the doctrine he combats, he would have refrained from raising objections which are groundless, or even contradictory. He speaks of bimetallism as a thing unheard of, unknown, unimaginable, which would bring incalculable evils upon England. Is he not aware that it has existed in France since the beginning of the century, and that that country has been in possession of an abundant and easy circulation, much less disturbed by crises than that of England? None of the difficulties predicted by Mr. Price have arisen there. Mr. Robert Giffen published in the *Fortnightly Review* (August 1st, 1879) the best article which has yet appeared in opposition to bimetallism. But, in our opinion, the concessions he makes there are very important, while his objections are contrary either to his own premises or to facts.

To mention one or two examples. Mr. Giffen admits that, in periods of transition, bimetallism increases the steadiness of value of gold and silver, by means of the equilibratory action, so well described by Mr. Jevons. But, he says, this influence soon ceases. Thus, "after 1850, French bimetallism was powerless to stop the fall in the value of gold, because there was no silver in exchange for it. In the same way, from 1820 to 1850, it could not stop the fall in silver, because France was then practically a silver-using country." Mr. Giffen's observation is, in the first place, contradicted by facts, for there are many gold pieces still in circulation bearing a date between the years 1803 and 1850, and after 1850 France was very far from losing all her stock of silver; for, of the 824,987 five-franc pieces found in the offices of account (19,511 in number), on the 14th of August, 1878, 572,916 had been coined before 1851."[1] So if the same percentage of 62 per cent. hold good for the entire French stock of five-franc pieces, it would appear that France holds to-day something like 300,000,000 of these pieces coined before the drain of silver commenced. But, as Mr. H. Gibbs proves, even supposing France to be completely deprived of gold, the compensatory action of her bimetallism would not be annulled:—

"If, for example, France were to restore to-morrow the full operation of her bimetallic law, there can be no doubt that, on the same day, the exchange being about par, the price of silver here would be at its old value. It would be wholly a question of exchange. So, let us suppose France, under the operation of a bimetallic law operative in France alone, to be absolutely denuded of gold; still for 15½ ounces of pure silver remitted to my correspondent at Paris, and delivered by him to the Mint, I should be able to draw on him for the equivalent, *i. e.*, for 107.1342 francs coined for and delivered to him by the Mint. My draft would sell on Change for £4 4s. 11⅜d in gold, if the exchange between the two countries were at par; and the exchange, I need not say, depends on the balance of trade between the two countries—on there being, or not, a demand for bills for remittance, or England being, or not, for the moment, a debtor to France."[2]

The truth of what Mr. H. Gibbs states is clearly borne out by facts. France prevented a fall in gold, not by giving up her silver, but by importing gold in exchange for merchandise she sold to other countries. France coined, between the years 1851 and 1875, 6,745,565,000 francs worth of gold. She, therefore, absorbed more than half the total amount produced by California and Australia, and she only lost, through excess of importations, 1,800,000,000 francs of silver. The compensatory action of bimetallism displays itself by throwing open a free field of employment to the metal, the production of which is increasing; and this effect would be the greater as more States adopted bimetallic law. "But," Mr. Giffen says, "this is not the truth. If all bimetallic countries had the same ratio, and the cheaper metal tended to become still cheaper, they would simply be as one country." Yes, but as a country of 300 or 400 millions of inhabitants, instead of one of 36 millions, like France. If the superabundant metal, whether gold or silver, were to increase tenfold, would its value not be better sustained by bimetallism being adopted in the leading States. Bimetallism, in force in France only, was able, during seventy years, to maintain a ratio of 1 to 15½: is it not certain, therefore, that a Monetary Union, comprising the principal States, would render this ratio infinitely steadier still? Mr. Giffen does not deny that the suspension of bimetallic law profoundly disturbs the rate of exchanges with silver countries; which latter, we must recollect, represent three-quarters of the British trade. But, he says, on this subject: "Even serious evils may have to be endured, because, relatively, they are unimportant, compared with the great objects proposed in a sound currency." But, then, what is "a sound currency?" Is it not the one which gives the most steadiness to the value of money and to the rate of exchange, and is it not a bimetallic standard which answers best those two desiderata? Mr. Giffen supposes that, in 1696, England freely chose gold in place of silver, against the law. Nothing could be less exact. England was deprived of the silver she wished to preserve by the Gresham law, and gold took its place as the overvalued money, against the wishes of the country in general. To assure oneself of this fact it suffices to read the Royal Proclamation, dated December 22, 1771.[3]

[1] "Exhib. A. 7th Session of the Monetary Conference of 1878."

[2] "The Double Standard," p. 32.

[3] "G. R.—Whereas . . . . the overvaluation of gold in the current coins of this realm hath been a great cause of carrying out and lessening the species of the silver coins thereof, which is highly prejudicial to the trade of the kingdom."

"The 22d of January, 1718, the Lords, in a grand committee, took into consideration the state of the nation, in relation to the gold and silver coins. The Lord Bingley, having represented the great prejudice that trade received from the scarcity of silver, said it was a matter of wonder a remedy had not seasonably been applied to so great an evil. Lord Stanhope answered that the scarcity of the silver species was owing to several causes: 1st. The increasing luxury in relation to silver plate. 2d. To the vast exports of bullion to the East Indies, 3dly. To the clandestine trade that had lately been carried on of exporting silver and importing gold to and from Holland, Germany, and other parts."—*Monetary Documents of the Conference of Paris*, 1878, by Dana Horton, pp. 316-321.

Mr. Giffen appears to imagine that if one State of the Monetary Union were to adopt paper-money, the whole bimetallic edifice would fall to the ground, as was the case, he says, with the Latin Union when Italy was obliged to reintroduce paper after 1866. All this is inexact. The other countries of the Union were not in the least inconvenienced by this Italian forced currency, and they only put a stop to the coinage of silver when Germany demonetized that metal. Let us suppose that one of the States of the great Bimetallic Union has recourse to an inconvertible paper currency, the result would be that its metallic coin would return to the other countries. This is, in fact, exactly what took place when the United States issued their greenbacks. Was England, at that time, embarrassed by American gold? "The only chance for bimetallists," says, again, Mr. Giffen, "is universal bimetallism. But what a wild dream! Who is to draw the treaty? What power of persuasion will bring all Governments to accept this Gospel?" I answer, the power of reason and the pressure of necessity, or, rather, I will let the most competent authority on this matter speak for me. "If our Government," writes Mr. Henry Gibbs, "could say, 'England is willing,' no one would doubt that France, with the Latin Union, Austria, Holland, Spain, and the United States would at once agree, and it is asserted that Germany would also. If so, the impossibility is at once overcome, that installment of universality being quite sufficient for the purpose."

—Emile de Lavelaye in the "Contemporary Review."

THE FUTURE OF GOLD.

AFTER the year 1850, when California and Australia were sending out into the world annually about thirty-five millions sterling in gold, Michael Chevalier and Cobden raised the cry of alarm: the world would be completely submerged by a deluge of gold. After 1867, the production of gold rapidly diminishing, an entirely opposite fear gradually gained ground amongst far-seeing business men. In 1869, in the review of the preceding year, the *Economist* wrote: "It may safely be affirmed that the present annual supply of £30,000,000 of gold is no more than sufficient to meet the requirements of the expanding commerce of the world. The real danger is that the present supply should fall off, and amongst the greatest and most salutary events that could now occur would be the discovery of rich gold deposits." In 1871, after the decision of Germany to proscribe silver, the uneasiness of the *Economist* increases, and it writes thus: "As the annual supply of gold is reckoned a little more than £20,000,000, and the annual demand for miscellaneous purposes is very large, it follows that if the German Government perseveres in its policy, the strain upon the existing stocks and currency will be most severe. Unless the annual production of gold should suddenly increase, the money markets of the world are likely to be perturbed by this bullion scarcity."

What the *Economist* foresaw has taken place. The scarcity of gold has induced so great a fall in prices that they are now lower than in 1850. Mr. Robert Giffen clearly showed this in an excellent study which has never been disputed, but which has, on the contrary, been confirmed by such men as Thorold Rogers, Patterson, Samuel Smith and Williamson, of Liverpool, John Hector, T. Smith, and many others. Who can doubt that the present crisis from which the entire world is suffering is due to the scarcity of gold? Up to the present time, exchanges have been effected in civilized countries by means of two metals, gold and silver; to-day, the coinage of silver having been suspended, except in India, the stock of money in the world is now only fed by gold, and at the same time the production of gold is yearly diminishing, and, what is worse, for the last three years America has taken for herself more than sixteen millions annually—that is to say, the whole total production, less four millions, which do not suffice to cover even industrial wants. Bagehot estimated that England absorbed yearly for industry and coinage from four to five millions sterling. On the contrary, in 1879 England exported a surplus of gold, amounting to £2,389,826 and in 1880 £4,249,449. The coinage in Europe has now sunk to almost nothing. In France the coinage of gold, which amounted in 1877 to 271,645,425 francs, and in 1878 to 189,139,520 francs, sank in 1879 to 24,610,540 francs. In England last year (1881) the amount of gold coined was quite insignificant, £35,000 only. Silver can no longer, as recently, help the circulation and effect exchanges, for it is no longer admitted at mints. The production of gold, which was thirty-five millions annually some years ago, does not now exceed nineteen or twenty millions. It is clearly evident that these circumstances united—viz. the proscription of silver, the decrease in the production of gold, and the draining of gold to America—have led to an appreciation of gold, a fall in prices, and to the present crisis, as the inevitable consequence of monetary contraction. This being the case it is of the highest importance that we should carefully examine if the production of gold is destined to increase or diminish, for the economic conditions of the whole civilized world are dependent on this. If more gold be not found, silver still being proscribed, prices will continue to fall. Prices falling, the burden on all those owing gold will increase, for they will be forced to sell more articles to obtain the same quantity of gold; farmers will have more and more difficulty in paying, for the produce of their farms will lose in value; manufacturers will be exposed to heavy losses, for while converting the raw material into manufactured goods, the general fall in prices will make itself felt, and the manufacturer will in all probability find himself working at a loss.

It would be rash to predict, with too great certainty anything definite with regard to the future of gold; nevertheless, taking as a basis ascertained historical facts, and geological researches with respect to the earth's crust, it is not impossible to arrive at certain conjectures which may be at least looked upon as probabilities. This is what an eminent professor at the University of Vienna, Dr. Suess, has attempted to do in a work entitled *Die Zukunft des Goldes* (*The Future of Gold.*) This book attained a very high reputation throughout Germany, and has been successful in convincing some of the most able economists that it is essential to restore to silver its attribute of money, of which it never should have been deprived. The conclusions Dr. Suess reaches are as follows: The production of gold will in the future diminish and the mines become exhausted the more rapidly as the present means of working them are more perfected and powerful. The discovery of new mines in hitherto unexplored regions may, for the time being, stop this exhaustion, but the expanse of new country where we may hope to meet with these mines is rapidly diminishing, and in the parts previously colonized, mines once very productive are being one after another abandoned. We will examine how Dr. Suess treats these different points.

Gold and silver are essentially the "precious metals" from the mere fact of their being rare. The scarcity of gold is certainly the chief cause of its value. But can it be explained why gold is so rare? According to Dr. Suess, it is because gold is one of the heaviest metals. Three metals are noted for their extreme density—iridium, platinum, and gold. Their weight compared to water taken as a unit is represented by the following figures: iridium 22·23, platinum 21·50, gold 19·253. With the exception of that strange and also rare metal, mercury, the density of which is 14·49, gold and platinum weigh more than any other metals; for, as an instance, lead reaches 11·35, silver 10·47, bismuth 9·82, copper 8·80, nickel 8.27, and iron only 7·84. Is there a connection of cause and effect between these two facts, that gold is a rare metal, and, at the same time, one of the heaviest that exist? One would be inclined to think that there is, if one admit that the earth was first in a gaseous and afterward in a liquid state. In this case the heaviest matters must have occupied the centre of the globe in a smelting condition. If it be true that our whole planetary system has been formed from matter which constituted in the beginning an immense nebula, it follows that the planets the nearest the centre must be the heaviest. These ideas were brought forward by the great German philosopher Kant about the middle of the last century, and have been from time to time referred to since. "The great weight of platinum and gold," says a German naturalist, Petzholdt, "is the reason for these metals being so scarce on the surface of the globe, for the greater quantity of them is contained in the still liquid kernel of the earth there shielded from men's greediness." Some observations that have been made help to support these ideas. The spectrum analysis reveals no gold in the sun; we may therefore conclude that it is quite in the center, hidden from view by other lighter bodies in a gaseous state forming the photosphere. The planets may be divided according to their weight into two groups. The planets in the interior of the circle of asteroids are comparatively heavy, those exterior are comparatively light. Mercury, the nearest to the sun, weighs almost seven times as much as water; Venus, the Earth, and Mars, five times as much; while Jupiter weighs barely as much as water; Saturn 0·73, and Uranus 0·84, therefore less than water. The density of Neptune, which has not quite been accurately determined, is at all events very trifling. So we see that in our planetary system the heaviest bodies are the nearest to the center, and this leads us to assume that the same distribution of matter will be found in each planet. As the rocks forming the surface of our globe weigh on an average 2½ times as much as water—limestone 2·6 to 2·8, granite and gneiss 2·54 to 2·7, and lava or basalt 2·7 to 3—and as, on the other hand, the specific gravity of the globe is five, we are necessarily led to conclude that the interior must be composed of heavy matter, far exceeding in weight the earth's average of 5. The existence of gold in the central strata of our globe appears, therefore, very probable. But if this be the case, how can we account for gold and platinum being found on the surface of the earth? It can be explained by the action of hot springs and volcanoes. These two heavy metals are always found amongst rocks of an igneous origin—here where volcanic rocks have pierced through and scattered earlier formations, and there where granite has broken up schists. Platinum, which has only been found in abundance in the washings of Nijni-Tagil in the Ural, comes from the serpentine, a rock coming from the depths. Gold is chiefly found in quartz veins. These veins appeared to have been formed in the following manner. As a natural consequence of the contraction of the earth's solid crust, and of the upheaval and disturbance of the previous formations, crevasses have formed themselves. They have become filled with quartz, sometimes auriferous, either by the action of hot springs or by sublimation. In these veins, usually poor, exceptionally rich zones are here and there to be found. German miners call them "edle Saulen" (noble columns), and American "bonanzas." It is the working of these bonanzas that renders veins profitable, which generally contain, apart, from them, so little gold that the miner literally works at a loss. If the work be continued it is in the hope of coming upon one of those rich zones, which sometimes far more than compensate for any former deficit. The extreme scarceness of gold that can be dug up is therefore a fact, and a fact easily accounted for when we consider its distribution and the geological origin of this metal. Let us now recall some historical facts which lead Dr. Suess to conclude that the production of gold will diminish in the future. The soil from which we obtain gold may be placed under three heads: auriferous rocks, auriferous veins, and auriferous alluvium.

I. The first group comprises rocks rich in magnesium and with gold scattered through them. A good example of this is the mines of Nijni-Tagil in the Ural, where platinum is also found. As a transition between this division and the next may be cited the auriferous minerals contained in some rocks of an igneous origin, as, for instance, the gold that is to be found in the granite of the west coast of South America and in certain parts of Brazil. Granite containing tin in the Erzgebirgen, in Bohemia, is a similar formation. This division of auriferous grounds, very interesting from a geological, is less from an economic point of view, for it contributes but very slightly to the product of gold.

II. The next group, the auriferous veins, comprises all the veins that have filled up, by means of hot springs or geysers, the fissures in ground upheaved and broken. These veins may be subdivided into three categories according to the different natures of the soil in which we find them. (A.) Veins of recent volcanic rocks, principally the propylite. Gold is here found mixed with silver, and it is only in this division that those exceptionally rich seams—the bonanzas—are met with. To this category belong the Comstock Lode, in Nevada, which is the most noteworthy example; the auriferous beds of Queensland, some in New Zealand and those of Schemnitz in the Carpathian range of Hungary. The gold is found sometimes in spangles and as "electrum," or silver and gold combined, or, again, mixed with copper or sulphur. (B.) Veins in more ancient volcanic rocks, especially diorite. The gold here is not, as in the preceding division, mixed with silver, but, on the other hand, there are no bonanzas. The best example of this category are the veins of Victoria. (C.) Veins in the schists, where they meet with granite, or even in granite itself, even distant from volcanic regions. It is supposed that in this case granite has been the eruptive force which has brought the gold with it. These veins are sometimes very extensive: as, for instance, the famous Mother Lode in California, which spreads itself over a vast region; but experience proves that they are seldom sufficiently productive to repay a miner's toil. Silver is never found here, and gold only in the same circumstances as in the preceding divisions. Examples of this class are to be found in California, in New Caledonia, in Tasmania, and in the Pennine Alps.

III. Auriferous alluvium. This alluvium is formed by the decomposition of different rocks containing gold, but it has been remarked that recent volcanic regions give much less than other classes of grounds. The veins richest in precious metals are, therefore, not those which produce deposits containing the most. Gold is in this instance generally found as spangles or quite tiny grains, and sometimes as nuggets, of the size of a hen's or even turkey's egg. An extraordinary point is that the gold found in this alluvium is purer than the metal found in the veins from which it comes, though, of course, this must have proceeded from them originally. Neither this phenomenon nor the formation of nuggets has yet been satisfactorily accounted for or explained. The "placers" of California, Australia, and Siberia are the most remarkable examples of auriferous alluvium. This latter can also be divided into two categories: (A.) that found on the surface of the earth, on river banks, where gold can be almost picked up, sifted from the soil and washed in the most primitive fashion; and (B.) that of an earlier date, covered over by more recently deposed soil, and which can only be reached by labors which frequently entail large expense. In California these ancient deposits named "deep leads," are sometimes covered with basalt or lava. They are then generally worked by hydraulic pressure. Water, inclosed in dykes at a higher level, is made to flow in the direction of the works by means of pipes; then branch pipes are put which carry it with great force on to the auriferous deposit, and reduce the whole bed to a state of liquid mud. This runs away in wooden troughs, so arranged that the particles of gold are stopped in their passage. The "deep leads" worked at Ballarat, in Australia, are most curious. They are covered by 400 feet of relatively recent soil, amongst which are four layers of lava proceeding from a neighboring volcano, now extinct. These "deep leads" are the banks and alluvium beds of ancient watercourses now hidden under successive layers of sediments. The wealth of these deposits is very unequal, and the amount they produce most uncertain. The capital point in these views concerning the production of gold is that by far the greater amount proceeds from these alluvium beds. In 1854, Whitney estimated that nine-tenths of the gold in the possession of men had this origin. Dr. Suess has made a calculation for the period from 1848 to 1875 with the following result:—

Value of gold in millions of francs derived from

		Million francs.
I. Veins:		
Modern volcanic	769	
Ancient volcanic	822	
Schist and granite . . .	240	
		1,831
II. Alluvium beds		14,973
Total		16,804

We learn from these figures that of the whole sum of gold produced between the years 1848 and 1875, the working of rocks has produced an average of 12.02, and that of alluvium beds 87.98. During the last few years, as the quantity of gold procured from the placers has rapidly diminished, the gold that the miners' work extracts from veins has taken a more important place. But, in spite of this, according to Dr. Suess, the future production of gold depends almost entirely on the riches of alluvium beds. The finding and extracting of gold from the earth goes on always in the same way. Some explorers arrive in an unknown region and find on the banks of a river some gold-dust or may be some nuggets. The good tidings are spread abroad at once, and adventurers from all sides arrive in crowds. The surface sand is very quickly washed and produces a large quantity of gold, but the more active the workers, the sooner is all the superficial gold taken. Individual labor is no longer of avail. Large capitals must be employed to establish necessary apparatus for the working of the "deep leads," or for sinking shafts in volcanic or granite rocks. The "deep leads" are in their turn worked out, and the working of the veins brings but scant profit, in a general way, if one have not the good fortune to fall on a bonanza, which is rare.

These mines are thus all abandoned, one by one, and fresh regions must be resorted to, to take their place. While the working of silver continues sometimes for centuries in the same region, that of gold cannot be counted upon; it is always of far shorter duration. It follows, therefore, that gold mines are constantly to be found, and, in fact, generally are situated at the extreme limits of civilization. This curious fact had already been remarked by Herodotus (III. 106). After having spoken of the quantity of gold-dust sent to Darius by the inhabitants of India as tribute, he adds that, for one reason or another, it generally happens that the rarest and most precious metals come from the remotest corner of the inhabited globe, and Humboldt has taken this passage of Herodotus as an epigraph to his studies on the variations in the production of gold. The discovery of fresh countries is often the cause of an influx of the precious metal, and this is in itself frequently an incentive to the colonization of countries hitherto uninhabited, as we have seen in California, Australia, and Siberia. The old countries have completely ceased producing gold, and it is only in regions as yet unexplored that we can hope to discover fresh veins. A rapid epitome of the history of gold-workings will serve to confirm this law of the continuous exhaustion of auriferous beds.

In ancient times gold was, comparatively speaking, abundant. It proceeded principally from the washings of the rivers of Asia. The sands of Pactolus, the golden fleece conquered by the Argonauts, the gold of Ophir, the fable of King Midas, all contribute to show the Eastern origin of the yellow metal. According to Pliny, Cyrus brought back 34,000 Roman pounds in gold, a sum corresponding to nearly two millions sterling. The treasures Alexander the Great took from Persia amounted to 351,000 talents, or eighty millions sterling. Gold came also from Arabia and, by the Nile, probably from the center of Africa. One may read too of the rivers of Spain and of the mountains of Dacia. In Abrudbania, in the center of Transylvania, galleries are to be found that date from the time of the Romans, in rocks that are still being worked at the present time, but producing only insignificant quantities of metal. Roman writers speak of the quantity of gold found in the Tagus and the Douro. Pliny mentions Asturias as the country producing the largest amount of gold. At Indanha Velha, in Portugal, a tablet has been found bearing the following inscription: "Claudius Rufus returns thanks to Jupiter for his having caused him to find 130 pounds of gold." *Ti. Claudius Rufus Jovi optimo maximo ob raperta auri pond. CXXX votum lubens solvit.*

During the middle ages these sources of riches dried up, and the attempts made by several English companies to resume the workings were ineffectual. Bohemia, Silesia, Moravia, the Tyrol have all produced gold, and fortunes have formerly been made there. Gneiss, above Gastein, the retreat of the glaciers has brought to light old workings and at the present day a little metal is still to be found there. On the Italian side of Monte Rosa, in Val Sesia, and in the Val Ansasca, at Pestanera, auriferous veins are worked, but the production is insignificant. The only workings in Europe at all worth mentioning are those of Schemnitz in Hungary. In fact, our continent may be fairly regarded as exhausted. After the discovery of America, the Antilles, principally Hispaniola and the western coast of the Gulf of Mexico yielded a great deal of gold. It is from Hispaniola that the gold offered to Alexander VI., and which he employed for the gilding of Santa Maria Maggiore, came, as the following inscription proves: "*Quod primo Catholici reges ex India receperant.*" Very soon these mines ceased to produce. Some curious facts relating to the production of gold during the sixteenth century are to be found in a Dutch book published in "Amsterdam," 1590: "Gold comes," it says "from different countries—from the mountains of Bohemia, from the rivers of Pannonia and Sweden. More than 20,000 pounds weight of gold came from Spain every year, but now these mines are exhausted. Gold arrived afterward from the east Spanish Indias, from San Domingo, at first, and then from other parts; but all that is now a matter of the past. Actually gold comes to us from Peru, some time ago for three millions yearly, and now for five, six, and eight millions. But as time goes on these mines will be exhausted and abandoned, as the others have been." This prediction of the old book, *Tresoir van de Maten ende Gewitchen*, which resumes all in Suess's theory, has come to pass, and now no more gold is yielded by these parts of the world.

Humboldt had great hopes for New Granada and Columbia, where precious metal was to be found on all sides, but, in spite of English capital which brought over the most perfected means of working the mines, the gold yielded annually does not amount to more than £500,000. Before the arrival of the *Conquistadores*, the Indians had gathered from the river sands large quantities of gold in Peru, Chili, and along the whole western coast of South America. Later these countries produced a considerable amount of silver, but very little gold; to-day the production is ten or twelve times less than when Humboldt visited them. From 1500 to 1875, the total production of gold in South America, with the sole exception of Brazil, has been £260,000,000 sterling. Nowhere can the typical history of the working of gold mines be so well followed as in Brazil. At the close of the sixteenth century, the inhabitants of the province of S. Paulo, apprised of the presence of gold by the nuggets with which the savages adorned themselves, commenced washings. In 1697 Bartholomeo Bueno found rich deposits of gold in the province of Minas Geraes. Adventurers quickly reached the spot and war broke out between the Paulists and the Portuguese of the coast. Finally, the governor succeeded in re-establishing peace and order, and the collecting of the precious metal was set on foot on a firm basis and developed with extraordinary rapidity. Towns were built, and amongst others Villa Rica. After the year 1720, the province of Matto Grasso begins to yield up her treasures. In the eighteenth century the placers of Brazil played a similar part to that of California in the nineteenth. Minas Geraes alone gave, in the middle of this century, about £1,200,000 a year and Brazil more than £2,000,000 sterling, but the alluvium beds were soon exhausted. The working of the veins was then commenced, but with no profit. Toward the year 1820 the total production of Brazil had fallen to £100,000. Since that date, English capital has paid for the working of many mines, and notably those of Jacotinga and of St. John d'Elrey, but in each case the money has been all or in great part lost. Only the last-named mine yielded recently (in the year 1876) a sum worthy of mention, £200,000, but almost without profit. The yieldings of the mine Don Pedro North Del Rey are regularly diminishing; here are the figures—1875, £34,992; 1877, £28,172; 1879, £4,956. It follows, then, that Brazil, which a hundred years back exceeded in riches all other auriferous countries became impoverished in fifty years, and may now be considered as exhausted. The total production of gold in Brazil from the end of the sixteenth century till now is estimated to be £140,000,000.

In ancient times, and in the middle ages, Africa was noted as the country of gold. Herodotus speaks of the gold gathered by the Carthaginians from beyond the columns of Hercules. The Arabian geographer El Edrisi (A. D. 1154) speaks of the gold produced by the Wangara country, from where the river Niger rises; and the Moor baptized by Leo X., Leo Africanus, who had scoured the interior of Africa, also speaks of the gold of Wangara and of Timbuctoo. It is thence that the Moors of Spain and of North Africa procured the precious metal. Recently the French from Senegal have occupied this gold country, and have in reality found "deep leads" and veins in diorite, as in Victoria, but the produce is too small to be remunerative. All the famous Gold Coast does not yield £80,000 a year. The golden sand, washed by the negroes, is sufficient to reward them for the labor they bestow during their leisure hours, but not to pay a proper interest to any European undertaking.

The Egyptians obtained large quantities of gold from the Upper Nile and from Ethiopia. An inscription under Thutmes III., 18th dynasty (B.C. 1600), speaks of gold coming from the land of Mayu. Another inscription, of the time of Ramses II., 19th dynasty, tells us that the king, seated on a golden throne, issued orders for the opening of gold mines in the land of Atika. A papyrus now at Turin contains a detailed account and map of these workings. Mummies are often found with necklets and jewels in massive gold. Gilding was in noways spared. Herodotus tells us of a king of the Ethiopians attacked, but not defeated, by Cambyses, who loaded his prisoners with golden chains, this metal being commoner than bronze. At Sofala also gold was very plentiful in the middle ages. The geographer Edrisi tells us that copper was worn as an ornament in preference to gold. At Daghouta still more gold was found than at Sofala. When, in the year 1867, the German traveler Mauch discovered near Sofala ancient alluvium workings, and even remains of the masonry of shafts and traces of ancient Israelitish worship, it was believed that we had discovered the biblical Ophir, and the more so as in ancient maps Sofala is written Sophir. However that may be, neither on this coast, nor in the Transvaal, nor in the Orange Free State, have any of the attempts at workings which have been made proved a great success. The riches in gold of the African continent is a thing of the past. The marvellous necklace of the Queen Aah-Topeh which is exhibited in the museum of Bulak, and which dates 3600 years back; the golden chains of the Abyssinian captives in the time of Cambyses; the treasures brought by the Queen of Sheba to the temple of Solomon 2860 years ago; the masses of gold hanging on to the throne of the King of Ghâna, of which Edrisi speaks, 700 years ago, and which weighed 300,000 mithkal (value £175,000)—all these memories or legends prove beyond a doubt that in ancient times the "dark continent" produced a great deal of gold. What it yields to-day is of very little importance, at most £240,000 a year. The total production since 1495 is estimated—we must say, upon very uncertain authorities—at £100,000,000 sterling. The whole of North Africa to the Sahara and the falls of the Nile is formed of a sedimentary soil which has never yielded precious metals, but in the center of the continent ancient rocks are to be met—granite, gneiss, syenite, hornblende—with quartz veins containing gold, and thus auriferous alluvium has been formed. Only it appears that antiquity and the middle ages have exhausted it all. According to remarks made by M. Jevons, the aborigines have always been the first to discover and take advantage of auriferous sands. It is certainly possible that in the center of Africa rich golden veins and even bonanzas may be found, failing rich "placers" which must not be counted on, for, did they exist, their produce would already have reached the coast. At all events, when we consider that the workings of rocks have not yielded one-fifth of the total produce in gold, we cannot expect that, in this instance, the continent of Africa will give the lie to the general law. What China and Japan produce is far from sufficing for their own consumption.

The three important centers of production at the present time are Siberia, the United States, and Australia; but the two latter are already beginning to fall off. Let us first examine Siberia. Here the auriferous alluvium spreads itself over an enormous space, from the Ural to the region of the Amour River. In Siberia the work is less active than in the Australian or Californian placers. It is carried on either by laborers who pay the privileged contractors, or by convicts. The severity of the climate and the frosts make any washings out of the question during the greater part of the year. Accordingly, progress is not so rapid, and exhaustion will not come so soon. The washings are found in the volcanic districts of the Asiatic Ural Mountains and in the syenite, the gneiss and the hornblende, at Jenisei, at Tychovo-Sadomsk on the Nigra, in the valley of Chomolcko, and on the banks of the Muza, in the government of Nertschink; finally, in Upper Amour, and quite recently in a very remote region on the banks of the Nyman and Olga rivers. Here, as in California, gold is nearly always found where granite comes in contact with the schists. In Siberia the washings are slowly falling off, as elsewhere. Those of Jenisei fell from 1000 puds in 1850 to 300 during the last few years. Only, as the alluvium is to be found more or less everywhere spread about over an immense territory, fresh workings take the place of those that are no longer productive, and the total yield tends rather to increase. In 1869 it amounted to £4,500,000 sterling. In 1876 it had risen to £4,650,000; in 1877 to £5,700,000; in 1878 to £5,850,000; and in 1879 to £5,550,000 sterling. The total contribution of Russia to the gold stock of the world is estimated at £120,000,000 sterling.

It is North America which has produced in the latest years the greatest amount of gold. The rapidity with which the production of this metal has developed itself there is really prodigious. This was due to two causes: first, the natural riches of the country; and secondly, the extraordinary energy displayed by the Americans in making the best of these riches. The precious metal is to be found in that long double chain of mountains which extends between the coasts of the Atlantic and the plains of the center. In this great range, which is called the Rocky Mountains, the upheaval of the earth's crust by eruptive rocks have brought near the surface both gold and silver. In British Columbia even, the washings of Cassiar, of Omenica, and of Cariboo, have produced annually about half a million sterling in gold. The States of Idaho, Montana, Oregon, and Washington yielded in the year 1870 about a million sterling. In Montana the annnal production has very soon considerably decreased. In 1866 it amounted to $18,000,000; to-day it is not more than $2,500,000. From 1864 to 1871 Idaho produced annually from five to seven million dollars; in 1880 the production had fallen to $510,546. In 1868 Oregon and Washington yielded $4,000,000; in 1879 they did not reach more than $1,275,000. Dakota slightly increased from $2,000,000 in 1877 to $2,420,000 in 1879. Colorado sustains an average annual production of about $3,000,000. California has passed through the three habitual periods of the gold production. After the year 1848 the washings of the river sands produced immense quantities of gold; now, only the Chinese find this sufficient to procure them sustenance. The superficial washings were soon exhausted, and excavation of the "deep leads" and veins were then proceeded with.

The whole highest ridge of the Sierra Nevada, running parallel with the Atlantic, is granite, but half-way down the slope of the chain, toward the west, strata of schist and limestone are found amongst the granite. At the point of contact there extends from north to south of the State a zone, about eight to nine miles in width, which contains all the auriferous veins of this country. This stratum, brought to light by erosion, forms in many places an almost perpendicular wall, overhanging the forests spread out at its feet. The "Mother Lode" commences in Mariposa, and passes the limit of the State at the north, where it is covered by the lava of the powerful and as yet unextinct volcanoes Pilot Peak and Lassen Peak. This lava has also covered ancient alluvium soil with basaltic streams, from 50 to 200 feet thick, which form the present "Table Mountains." This formation is also found more south in the Sierra Nevada, not far from the "Big Trees." The alluvium beds, covered by basalt, and resting on the strata of granite and of schist in the chain, contain gold, and it is from there that the lower, superficial, and now exhausted auriferous sands were washed away by the force of the mountain streams and torrents. These "deep leads," and the veins of the Mother Lode combined, have taken the place of the river "placers," and so the Californian production is still from fifteen to seventeen million dollars.

It was in Nevada that the famous Comstock Lode was discovered, which, quite recently, was supposed to be going to inundate the world with a complete overflow of gold. Parallel to the west of the Sierra Nevada runs a chain, the Virginia Range, which is composed of comparatively recent volcanic rocks. These rocks have submerged the lower part of the mountains, and principally Mount Davidson, which rises to a height of 7827 feet, and which is composed of older syenite. At the point where the more modern volcanic rock, known as propylite, terminates, at an altitude of from 5800 to 6000 feet, appear the veins of the Comstock Lode. A crack was formed between the more ancient mountain and the rock covering it. This rent extends for a distance of 22,000 feet. Its width varies a great deal: sometimes it reaches 200 feet, and sometimes it is very much narrowed by the two walls of propylite on the one side and syenite on the other. Broken pieces falling from these walls fill it up in places; the rest is occupied by the auriferous quartz, where the "rich chimneys," the bonanzas, are found.

The most powerful of these is the bonanza of Gold Hill, which descends to a depth of 700 feet. Several companies are engaged in the excavation of this marvelous vein. The most favored has been the *Virginia Consolidated*, which, out of twenty-five million dollars produced by the Comstock in 1875, yielded seventeen million. The richness of the vein was ascertained at a depth of 1600 feet. Shafts have been sunk to 2500 feet, and one has been commenced which it is hoped will descend to 4000 feet. A tunnel, the total length of which is to be 20,000 feet, has been bored in the side of the mountain to enable the vein to be worked from underneath, and the water to be carried off without using pumps; but this gigantic undertaking, which is being directed by the engineer, Sutro, has, to all appearances, been commenced too late. On the one hand, the vein, contrary to all expectations, is poorer as the workings attain a greater depth; and on the other hand, the heat at the bottom of the shaft is simply intolerable, viz. 46° Centigrade, and the hot springs that are found there have a still higher temperature, according to the close proximity to the center fire. The workmen, who work quite naked, are instantaneously in a bath of perspiration; they can scarcely breathe, and are obliged to rest every ten minutes. Under these circumstances the price of labor is of course extremely high, and unless a fresh bonanza be found, the mine will finally be abandoned. The rapid diminution in the amount of production, and the alarming fall in the value of the shares, do not allow one to count on a brilliant future. This prodigious vein has exceeded in riches all that had ever been found previously in as great a degree as the placers of California surpassed any ancient washings. In ten years it has produced two hundred million dollars, ninety millions of which were gold. The adventurer who in 1869 discovered the famous hoard of riches, Henry Comstock, after having sold his claim committed suicide. The "furia Americana" which has been displayed in the working of this mine has contributed to accelerate its exhaustion. The Comstock Lode, which in 1877 yielded $37,911,000 of which $17,771,000 were gold, fell off, in 1878, to $10,404,000 silver and $9,825,000 gold, total $20,230,000; in 1879, to $5,-190,000 silver and $3,639,000 gold, total $8,830,000; and, in 1880, to $2,634,000 silver and $2,678,000 gold, total $5,312,000. The production of the first quarter of 1881 shows a still greater decrease; the total is only $426,400, against $,7,549,-000 in 1877, and $1,615,800 in 1880. The aggregate value of the twenty-eight principal mines on the Comstock Lode, which was, in 1875, $271,059,200, was on the 1st of May, 1881, only $14,030,058. This rapid diminution has affected the total production of gold in the United States, which, according to official estimation, amounted to $47,266,107 in 1878, $38,900,000 in 1879, and $36,000,000 in 1880.[1]

The traveler who visits the American gold country sees everywhere works abandoned, buildings in ruins, and localities, which were but recently flourishing, with scarcely an inhabitant. Many of the mines established on the Mother Lode are no longer worked. Fortunately new ones are discovered, but they will be exhausted in their turn. The director of the Mint of the United States, Mr. Burchard, thinks that the number of mines worked exceeds a thousand, but many of them leave the workers at a loss. It is in the north of the Rocky Mountains that one still hopes to make happy discoveries. It is estimated that North America has contributed £14,000,000 sterling of the stock of gold of the world. The production of gold in Australia has followed pretty much the same course as in California. There, also, they have passed from the river sands to the deep alluvium, to arrive at last at the direct working of the veins; but from that moment the produce has gradually diminished. The chain of mountains which extends in Australia from north to south, parallel to the east coast, is formed of sedimentary strata, interspersed in many places with volcanic and eruptive rocks. Numerous veins, "quartz reefs," are visible, and contain gold. It is of their fragments that the auriferous alluviums are formed, which one meets with on all sides. These alluviums are easily worked, and yielded to the province of Victoria, as soon as they were discovered, a quantity of precious metal. After Campbell in 1850, and Hargreaves in 1851, had found the first nuggets, there was a rush to the gold fields. In 1852 the production had already risen to 1,974,975 ounces. In 1855 it attained to 2,497,723 ounces; in 1856 it reached its maximum with 2, 985,991 ounces, of a value of about £12,000,000 sterling. Since then, although gold has been found in New South Wales, Queensland, Tasmania and New Zealand, the supply has continually decreased. For Victoria the yield was, in 1876, 1,095,787 ounces, of which 605,859 came from the veins, and 357,901 from the alluviums, and, in 1879, only 758,947 ounces, of which 465,-637 from the veins, and 293,310 from the alluvium. The number of miners has already considerably diminished. In 1850 there were 147,358, of whom 33,673 were Chinese. In 1873 there were not more than 37,453, of whom 14,784 worked at the veins, and 22,769 at the alluviums.

In the province of New South Wales the mountains contain veins and the rivers auriferous sands. They were worked in all directions in a zone of at least 180 miles breadth; but the veins were not remunerative, and the alluviums were soon exhausted, so that the product regularly lessened. In 1871 it rose, according to Daintree, to 535,492 ounces.[1] For the later years I borrow the figures from the excellent report of the German Consul at Sidney, reproduced by M. Soetbeer.[2]

It says: "The gold received at Sidney, at the Mint of the Colony, from New South Wales, in 1876 rose to 126,780 ounces, of the value of £479,133. These figures diminish each year. In 1872, the year which yielded the most, the produce was £1,513,186. In 1878, as I have remarked in my report of last year, the production of gold continued to decrease. In 1877 the Mint only received 97,582 ounces, of the value of £366,329. In 1879 the gold receipts (as proceeding from the workings of New South Wales) have fallen to 75,492 ounces, of the value of £279,166. The yield of gold from all sources amounts to 109,347 of the value of £382,741. Three fourths of the ore are obtained from washings." The chain of Australian mountains on entering Queensland, widens, and with its lateral ridges attains a breadth of twenty-five miles. Here, also, volcanic rocks, diorite and even granite, have brought gold to the surface. In many of the rivers, auriferous sands and large nuggets have been discovered, and already the veins are heavily worked. The richest mine, the "Comstock" Lode, of that Colony, is that of Gympie, to the north of Brisbane, on the Mary river. At the end of 1868 this mine yielded nearly 84,000 ounces, and 70,852 ounces in 1869. Since then the produce has been maintained tolerably regularly. The works have already reached a depth of 600 feet. Queensland also has had its period of promising discoveries. Thus in 1874, the Palmers' gold fields, where 6000 men were collected, produced 175,000 ounces. The German Consul of Brisbane gave the following figures for this province: £1,429,929 in 1876, and £1,611,105 in 1879. He added, "As fresh discoveries continue to be daily made, and as this district contains hundreds of square miles where no white man has yet planted his foot, still further discoveries of rich gold fields may be hoped for." This hope, although not without foundation, is not yet realized, as from the most recent reports the exportation of ore from Queensland had fallen to about one million sterling in 1878. South Australia and Tasmania

[1] 1881, $34,700,000.

[1] Queensland 1873.

have also produced a little gold, the total value being about £40,000 in 1878.

New Zealand yielded about forty millions sterling of precious metal between 1857 and 1879. The northern island has not contributed more than five millions, found principally in the veins of the peninsula of Coromandel, which have not formed auriferous alluviums. In the southern island, on the contrary, which has produced seven times more (or thirty-five millions), the gold was found almost exclusively in auriferous sand and deep leads, which, strange to say, were discovered on the declivity of the mountains; here they also employed, as in California, hydraulic power for the working, and the process of exhaustion resembles that of the other gold countries. The growth is rapid, and the decline equally speedy; thus a gold field near Otago gives, in 1861, 187,695 ounces; in 1863, 580,233 ounces, and falls in 1869 to 149,364 ounces. The production of the two isles diminished, though slowly, of late years. The value of the gold exported was in 1874, £1,500,000; in 1875, £1,400,000; in 1876, £1,268,599; in 1877, £1,476,312; and in 1878, £1,244,192.

The following table, prepared from the very careful calculations of M. Soetbeer, shows the progressive decline of the total production of gold in Australia, which has fallen to the half of what it was twenty years ago:

Yearly average.

	Kilogrammes.	Value: German marks.
1856–60	86,700	241,893,000
1861–65	77,700	216,783,000
1866–70	70,400	196,416,000
1871–75	59,900	167,121,000
1876	59,100	164,889,000
1877	52,300	145,917,000
1878	45,300	126,387,000
1879	39,000	108,810,000

The exportations of metal to England have diminished still more rapidly and more abruptly. This seems to prove that Australia absorbs the metal, partly for her home circulation, and partly for her direct commerce with the Indies, China, and Japan. From 1871 to 1875 England received from Australia an average each year of £7,097,800 of gold; in 1878, £5,680,000; in 1879, only £3,180,600; and in 1880, £3,614,200. These are the actual facts, and they are not reassuring for the future. Certain mineralogists, as, for example, G. Ulrich of Dunedin in New Zealand, Director of the Mining Department of Sydney, do not share the gloomy forebodings of Dr. Suess. After all, they say, if the production of gold diminishes in Australia, it is not for lack of metal, but because the workmen prefer to buy the land for agricultural purposes, or for the rearing of cattle. So it is, but that is precisely what Dr. Suess affirms. When the gold-fields are exhausted, it is necessary to excavate the veins, and then the work generally ceases to be remunerative, though some continue to work for a time, encouraged by the exceptional success of some miners. Hope and the gambling fever stimulate them to work at a loss, but at length they become discouraged and stop. According to M. del Mar, on an average, each dollar drawn from the earth costs two. Australia still supports herself by the gold-fields and the deep leads; but when the miner shall be reduced to the "quartz reefs," the produce will certainly be reduced to one half. M. Ulrich himself, notwithstanding his sanguine views, admits that Victoria will fall to 600,000 ounces—that is, to half of what she has recently produced. It is estimated that Australia has supplied £260,000,000 sterling in gold to the world. The reader will, no doubt, have been fatigued with the uniformity of these details, but it is in *that* that the instruction consists. It is this identical repetition of the same facts which enables Dr. Suess to predict that the production of gold is fatally destined to decrease. He admits that one may perhaps still discover, in the less explored regions of the Rocky Mountains, of Central Africa, or in Australia, gold-fields as rich as those of California, or veins as marvelous as the Comstock Lode; but the more powerful our present process of working, the more rapid the exhaustion of the new mines. It has been so in the past, and it will not be otherwise in the future.

From all these facts Dr. Suess concludes that the desire to make everywhere gold the *only* coinage, to the exclusion of silver, is pure madness. Geology opposes it. There does not exist in the world gold enough for that purpose. The true money metal is silver. Locke was right in saying "Silver is the instrument and measure of commerce in all the civilized and trading parts of the world"; and Bagehot expressed the same opinion before the Silver Commission of 1876 (Question 1389): "Silver is the normal currency of the world." In proportion as the people become wealthy and industrious, they require more and more gold, so that the diminishing production of gold will be barely sufficient for the use of the arts and manufactures, and the yellow metal will disappear, little by little, from circulation. At all times gold has been a subsidiary money—a money of luxury. It was a consequence of natural laws. Economical necessities will oblige men to submit to them. That which has passed since the date of the publication of Dr. Suess' book (1877) has plainly confirmed his predictions. Already the scarcityof gold has created an appearance of disquietude. One cannot be surprised at it, when one thinks of the small quantity of gold which is at man's disposal. The total quantity of this metal produced since the discovery of America is calculated to be £1,400,000,000. A learned professor of the University of Rome, Messedaglia (*Storia e Statistica dei Metalli preziosi*), has calculated that this sum, equivalent to 535 cubic mètres, would be sufficient only to cover the pavement under the cupola of the Pantheon or of St. Paul's with a bed of gold of 37 centimètres, or one foot in depth, and the annual production would add to it barely one centimètre. Of this quantity what remains under the form of money and ornaments? Perhaps one milliard sterling. M. Soetbeer shows that there exists as money in civilized countries (less India and the extreme East) 13,400,000,000 German marks (£670,000.000) of gold, and 8,400,000,000 marks (£420,000,000) of silver. That which singularly aggravates the economical situation is that the world's currency, which was maintained yearly, till 1873 by gold and by silver united—that is to say, by a total value of £35,000,000 sterling—is now to be kept up by gold alone, of which the production does not attain more than £20,000,000 each year.

Trade consumes certainly from twelve to fourteen millions sterling; for official reports show that manufactures and arts require, in the United States, 10,000,000 dollars or two millions sterling, the same amount in France (54,000,000 francs in 1878), and even more in England; that is, six or seven millions for these three countries alone. India takes away every year between two and three millions, so what remains for the requirement of the coinage in all the civilized nations? We must not forget that, according to M. Soetbeer's calculations, there has been coined in the last twenty-five years, from 1851 to 1875, £800,000,000 sterling gold, and £440,000,000 silver. Deduct what you will for recoinage, there remains certainly, taken yearly by the mint, a sum immensely superior to the four or five millions gold that the arts leave for the monetary requirements. Even supposing that the absorption of gold by America will suddenly stop—and it amounted in 1879-1880 to $75,891,391, in 1880-1881 to $91,168,650, or for these two years nearly 34 millions sterling, that is the third of all the gold coin of England—it is beyond all doubt that if silver remains proscribed, there will not be gold enough for the monetary and industrial uses of Europe. Already at the very moment these lines are written, the gold scarcity begins to be seriously felt on the money market. The Stock Exchange is looking with anxiety to every withdrawal of metal from the Bank. What the late Mr. Bagehot used to call "Apprehension Point" is very near. Soon the sentiment of living under the perpetual fear of lacking the breathing air of commerce—*i. e.* of the means of exchange—will become intolerable, long before the exhaustion of the gold washings predicted by Dr. Suess will be realized. It becomes every day more evident that the dream of using gold alone as universal money is a mere impossibility. The two precious metals, gold and silver, are not even sufficient for the rapidly growing wants of trade and luxury throughout the world

Emile de Laveleye in The Nineteenth Century.

WHY GOLD AND SILVER ARE USED FOR MONEY.

GOLD and silver were adopted as standards of value long before the beginning of the historical era; and their fitness for money was evident, even to barbarians. They are hard and not subject to oxidation, and therefore they can be kept and handled with comparatively little loss. They have a brilliant lustre, suitable for articles of ornament; and the peculiarity of the lustre, color, and high specific gravity, renders them easily distinguishable from other substances, and makes imitations difficult. They are fusible and malleable, so that they can be made into any form, or stamped with any impression, and the hardness will protect the form or impression from wearing out. Both metals are found pure, so that savages would become accustomed to their use before learning to smelt the ores of iron, copper, and lead. Both metals are rare, and thus a small quantity has served to represent a large value of other articles; and wealth in the form of gold and silver could readily be concealed, or transported from one country to another. There are other hard, rare, and lustrous metals, but they cannot be refined, or their lustre is not peculiar, or the supply is not regular, or they have no recognized value in the arts; and thus gold and silver are to-day, as they were five thousand years ago, the best of all metals for the purposes of money.

The Quantity of the Precious Metals in Greece and Rome.—The quantity of precious metals was small when Athens began to throw the brilliancy of her intelligence and genius over the ancient world. About the year 600, B. C., nine bushels of wheat could be bought for an ounce of silver in Greece; or, in other words, a bushel of wheat cost fifteen cents of our money. The advance of civilization was accompanied by an increased production of gold and silver. There were mines of both metals in Egypt, Thrace, Armenia, Spain, and the dominions of Attica. Spain had the richest mines, and the placers in the Asturias produced $4,000,000 annually for a time, and a silver mine at Guadalcañal yielded three hundred pounds of metal daily. The spoils of Persia added greatly to the stock of the precious metals in Greece, and after the death of Alexander an ounce of silver would buy only three bushels of wheat, or only one-third as much as three centuries earlier. In Italy, previous to the first Punic war, gold and silver were still very scarce and high in price, but when "the senate and people of Rome" became masters of the world, wealth poured in upon them from all the borders of the Mediterranean, and the bushel of wheat which cost the twentieth of an ounce of silver 350 B. C., cost an ounce and a third in the middle of the first century. The annual revenue of the empire in the time of Augustus, was $200,000,000, and that emperor received $150,000,000 in legacies from his friends. Cicero received $800,000 in fees, a sum which has probably never been paid to any modern lawyer. C. C. Isidorus, besides large estates and four thousand slaves, had $15,000,000 coin at the time of his death, calculating the value of the money according to weight. Jacobs estimates the total stock of coin in the Roman empire in 40, A. D., at $1,750,000,000.

The Principal Epochs in the Modern Production of the Precious Metals.—As civilization declined the quantity of the precious metals decreased, and Alaric consented to spare Rome for $1,500,000, and forty years later the Eternal City had some difficulty in raising $1,200,000 to buy off Attila. The annual average wear of coin is estimated at about one part in 360; and when this continues for centuries with no new supply it makes a great reduction. According to the estimate of Jacobs there were in 1492 only $170,000,000 of the precious metals in Christendom. Previous to the conquest of Mexico the new world yielded only about a quarter of a million dollars annually to Spain, the government of which lost considerably by the discovery, until Cortes succeeded in overthrowing the government of the Montezumas. The Aztecs washed gold from the placers and smelted silver from the ores, and had a considerable stock of precious metals on hand when Cortes came. He, of course, took all he could get, and he and his associates soon commenced the working of the lodes known to his subjects. Among these were Tasco, Zultepec, Tlalpujahua, and Pachuca, all in the vicinity of the capital. The annual shipment to Spain from 1519 to 1545 was $3,150,000. In the latter year the mines of Potosi were discovered, and their yield was so great for that age that a wonderful impulse was given to mining industry throughout the new world. In 1548 Zacatecas began to produce its treasures; Sombrerete in 1555, and Guanajuato in 1558. In 1557 a miner named Pachuca, made a discovery that was more important to silver mining than even the opening of Potosi. He found that silver could be extracted from the common ores by mixing the pulverized mineral with water, salt, and copper pyrites, and it was a process that required very little water, no fuel, little machinery, no mechanical skill, and few buildings. It was a method of reduction peculiarly adapted to the treeless and waterless mountains, and to the ignorant mining population of Mexico and Peru. Previously all the silver had been obtained by smelting in a very expensive and wasteful manner, the furnaces being small and very numerous; so that it was impossible to prevent great loss, both by incompetency and dishonesty.

Some years elapsed before the amalgamation process was extensively adopted, but within ten years it had been introduced into all the mining districts of Spanish America; and the workmen became expert, and as the mine-owners found the separation of the metal on a large scale could be supervised by one or two men, and that thus waste and thieving could be prevented to a much greater extent than before, they made renewed exertions to extend their works. The production of Potosi was six times as great in 1585 as it had been twelve years before, owing partly to the general use of amalgamation, which was first introduced there in 1570, and was not generally accepted until some years later. The copper-pan or cazo amalgamation was discovered in 1590, at Potosi, by Alonzo Barba, but its use was confined to a few districts. It was during the last decennium of the 16th century that Potosi was in its most prosperous condition, producing $7,500,000 per annum. In 1630 the mines of Cerro Pasco were discovered. In the years 1726 and 1727 the Vizcaina and Jacal mines of Zacatecas yielded $4,500,000. The great bonanza of Real del Monte was opened in 1762, yielding $15,000,000 in twenty-two years. The great wealth of the Veta Madre was demonstrated in 1768, and Guanajuato rose almost to the leading position among the argentiferous districts. The production of silver in Mexico increased very rapidly from 1770 until the beginning of the revolution; and the increase was owing to various causes, including the reduction of the royal tax from 20 to 10 per cent. on the gross yield, the reduction in the price of quicksilver, the opening of commerce to Spain, merchant vessels from numerous ports instead of confining the trade to vessels from only two ports, the reduction of the price of blasting powder from 75 to 50 cents per pound, the abolition of the alcabala, an article needed at the mines, (an odious and oppressive tax on internal trade), and the purchase of bars by the provincial treasury. The fact that the country could produce $10,000,000 annually from 1760 to 1770, as it did, in spite of all these restrictions, furnishes conclusive proof of the wonderful wealth of the mines, and also of the industry of the people. A tax of 20 per cent. on the gross yield would paralyze every branch of British and American mining, and would entirely stop the production of the precious metals in many districts of California and Australia. Quicksilver, of which more than a pound was lost for every pound of silver extracted, cost 80 cents per pound in 1750, and was reduced in 1767 to 62 cents, and in 1777 to 41 cents. The purchase of bars by the provincial treasuries was of great benefit to the miners, who previously had to sell their bullion at a loss of 20, 30, or in remote districts even 40 per cent. There were few merchants, and those few expected to make great profits from their transactions. The mines of Hualgayo in Peru were found in 1771, and three years later the placers of the Ural, which were known in the time of Herodotus, were rediscovered. It was estimated in 1777 that two-fifths of the silver of Mexico was obtained by smelting, but this was probably an exaggeration, and when Humboldt was in the country only one-seventh was taken out by the means of fire. The mines of Catorce were opened in 1778, and proved to be very rich, the mine of Padre Flores yielding $1,600,000 the first year. The mines of Guarisamey, near Durango, became productive in 1788. For two centuries the pulp in the yard amalgamation process, made with pulverized ore, quicksilver, salt, pyrites, and water, was mixed by the treading of men, who, notwithstanding the cold, moisture, and mercury, were generally healthy. Singular as it may seem, it was not tilll 1783 that mules and horses were introduced to this work; and, although the change saved 75 per cent. of the expense on that branch of the working, still it would probably not have been adopted when it was, but for the greatly increased production of silver in Mexico, and the difficulty of getting Indian *repasadores* in some districts. The great bonanza of Ramos, that yielded $18,000,000 in nine years, was opened in 1798. The mines of Mexico continued to increase in productiveness until the revolution, which was a war of races, the Mexicans against the Spaniards, the latter being in a small minority, but possessing most of the wealth, mining and commercial knowledge and enterprise in the country. They were driven out, and with them went three-fourths of the men who had the money and brains to conduct large mining operations. The production fell from $22,000,000 to less than one-third that amount, but it soon began to increase again, and from 1850 to 1860 it was as large as from 1795 to 1805. When the independence of Mexico was recognized and peace was restored, it was expected that the production would soon rise far beyond its former figure. The most brilliant hopes were excited in England, and they were based on many plausible considerations, but they were destined to bitter disappointment. Many of the best mines were offered for sale for about the amount which they produced annually. They had been well opened; their value had been proved; they had been abandoned while in full production, with large bodies of rich ore in sight; some of them had not suffered much by standing idle; their production had been increased at the average rate of three per cent. annually for 40 years before the revolution, and the workmen familiar with all the processes of mining and reduction were still numerous. And if such production and increase occurred under the oppressive policy of the Spanish government, and under the ignorant management of the Spanish mine owners, what might not be expected under a liberal republic and English engineering? The mines would no longer be burdened with the payment of one-tenth of the gross yield, over and above all the costs of refining and coining. The ore would no longer be carried up to the surface from depths of 1,500 or 2,000 feet on the backs of Indians, nor would it be packed 6, 10, or 20 miles on mules to the reduction works, nor would the water be hoisted up in raw-hide buckets by horse whims, nor would mules and horses drive the arrastras and stamps. Steam would pump the water, hoist the ore, and drive the pulverizing machinery. Wagons would do the transportation. Skilful engineers would direct the cutting of adits, shafts, and working levels, and educated metallurgists would have charge of the amalgamation. The production should rise to $50,000,000 or $100,000,000 a year, and those companies which could get possession of the best mines should make princely fortunes for all their shareholders. Great care should be exercised in the purchase of the property; only those mines should be bought which had been visited by Humboldt in 1803, and were mentioned in his book, and were known to have continued productive up to the revolution. On these principles, it was supposed that failure would be impossible. But failure was possible, and it came. England during the silver fever spent $50,000,000, for which she got little return save dear experience. Independence did not prove a great blessing to Mexico. Peace never came, and without peace there could be no success, for silver mining above all other pursuits demands peace. Forced loans were levied by the government on the productive mines, and the silver bars while on the way to the coast were taken by highway robbers. The steam machinery could not be taken to the mines till roads had been made and wagons imported; the roads cost immense sums; when the engines were in place native engineers could not be found, and foreign engineers were murdered; English superintendents and Mexican miners could not get along together; the mines were found in a much worse condition than that in which they were at the time of sale represented to be; and in a few years the mines of Mexico were, with a few exceptions, unequivocally abandoned to the Mexicans. The most notable mining districts opened in the 19th century have been the placer district of San Francisco in Sonora, in 1803; the Melkowka placers in Siberia, in 1816; the silver district of Fresuillo, in 1824; the silver district of Chañarcillo, Chili, in 1832; the silver district of Guadalupe y Caloo, in 1834; the silver district of Guadalcañal, in Spain, about 1830; the placers of the Altai mountains, in Siberia, in 1830; the placers of the Sacramento basin, in 1849; the placers of Australia, in 1851; the placers of New Zealand, in 1857; the placers of British Columbia, in 1858; the placers of Colorado, in 1859; the silver district of Washoe, in 1859; the Nevada iron pan amalgamation, in 1860; the silver and gold of Idaho in 1861; the placers of Montana in 1862.

Stock of Precious Metals.—The stock of coin in Christendom in 1492, and at various epochs since, may be thus estimated:

Stock of gold and silver coin in Europe in 1492			$170,000,000
Production of 108 years, less loss by wear		$690,000,000	
Used in arts	$140,000,000		
Sent to Asia	70,000,000		
Deductions		210,000,000	
Net gain from 1492 to 1600			480,000,000
Stock at end of 1600			650,000,000
Production of the XVIIth century		1,687,000,000	
Sent to Asia	165,000,000		
Used in the arts	300,000,000		
Abrasion and loss	385,000.000		
Deductions for the XVIIth century		850,000,000	
Net gain of the XVIIth century			837,000,000
Stock at end of 1700			1,487,000,000
Production of the XVIIIth century		4,000,000,000	
Sent to Asia	400,000,000		
Used in the arts	800,000,000		
Wear and loss	600,000,000		
Total deductions for XVIIIth century		1 800 000,000	
Net gain of XVIIIth century			2,200,000,000
Stock at end of 1800			3.687,009,000
Production of 1st quarter XIXth century		750,000,000	
Wear and loss	175,000,000		
Used in the arts	200,000,000		
Sent to Asia	125,000,000		
Deductions for 1st quarter XIXth century		500,000,000	
Net gain of 1st quarter XIX century			250,000,000
Stock at end of 1825			3,937,000,000
Production 2d quarter XIX century		1,200,000,000	
Wear and loss	200,000,000		
Used in the arts	350,000,000		
Sent to Asia	175,000,000		
Deductions 2d quarter XIXth century		725,000,000	
Net gain 2d quarter XIXth century			475,000,000
Stock at end of 1850			4,412,000,000
Production from 1851 to 1866, inclusive		2,500,000,000	
Wear and loss	250,000,000		
Used in the arts	600,000,000		
Sent to Asia	800,000,000		
Total deductions for 16 years		1,750,000,000	
Net gain from 1851 to 1866			750,000,000
Stock at end of 1866			5,162,000,000

The following is Jacobs' estimate, as given in Vol. II, pp. 70, 131, 214 and 322:

Stock on hand in 1492			£34,000,000
Production 1493–1599 over loss and wear		£138,000,000	
Used in the arts	£28,000,000		
Sent to Asia	14,000,000		
Total deductions 1493–1599		42,000,000	
Net gain 1493–1599			96,000,000
Stock on hand at the end of 1599			130,000,000
Productions of XVIIth century		337,500,000	
Sent to Asia	32,250,000		
Used in the arts	60,250,000		
Wear and loss	77,000,000		
Total deduction for XVIIth century		170,500,000	
Net gain of XVIIth century			167,000,000
Stock on hand at the end of 1699			297,000,000
Production of 1700 to 1809		880,000,000	
Sent to Asia	352,000,000		
Used in the arts	352,000,000		
Wear and loss	93,000,000		
Total deductions 1700 to 1809		797,000,000	
Net gain from 1700 to 1809			83,000,000
Stock on hand at end of 1809			380,000,000
Production from 1810 to 1829		103,736,000	
Sent to Asia	40,000,000		
Used in the arts	112,252,220		
Wear and loss	18,095,220		
Total deductions from 1810 to 1829		170,343,440	
Decrease from 1810 to 1829			66,611,440
Stock on hand at end of 1829			313,388,560

It has been customary to make estimates of the amount of precious metals in Christendom at various times by deducting the quantity shipped to China and Hindostan, and the quantity used for plate; but there is a constant change from coin to plate and from plate to coin, and the wide line which once separated China and Hindostan from European trade has now disappeared, and those Asiatic countries are within the pale of civilized commerce, and are almost as near to London and New York as California and Victoria. Whitney, in his Metallic Wealth of the United States, says that in 1853 the Russian empire produced 64,000 pounds Troy of gold; Austria, 5,700; the remainder of Europe, 100; Southern Asia, 25,000; Africa, 4,000; South America, 34,000; and the United States, (exclusive of California,) 2,200. The gold production of Chili in 1845 (the statistics for later years not being obtainable at the time) was 2,850 pounds Troy; of Bolivia, 1,200; of Peru, 1,900; of New Grenada, 13,300; of Brazil, 5,100; and of Mexico, 9,900. The yield of silver in 1850 is thus stated: Russian Empire, 60,000 pounds Troy; Scandinavia, 20,400; Great Britain, 48,500; Harz Silver District, 31,500; Prussia, 21,200; Saxony, 63,600; other German states, 2,500; Austria, 87,000; Spain, 126; France, 5,000; Australia, 10,000; Chili, 238,500; Bolivia, 130,000; Peru, 303,150; New Grenada, 13,000; Brazil, 675; Mexico, 1,650,000; California, 17,400; total 2,817,425 pounds Troy.

The effects of Prosperous Mining.—The first effect of the production of the precious metals in rich mines is that it enriches the individual engaged in mining, or at least gives him an opportunity to enrich himself. A large proportion of mankind are so stupid, so imprudent, so wasteful, or so indifferent to the value of money, that they cannot make money when they have the best chances, or keep it after they get it. The wages of miners are higher than those of other laborers, and when the mines are very rich the proprietors become possessed of immense sums. In the mining districts nearly every man when he goes out walking over the hills keeps a lookout for "indications," in hope of finding some vein that may make him a millionaire. The second effect of the production of the precious metals is to enrich the nation which possesses the mines, or to give it an opportunity to enrich itself. Nearly all mining districts are poor, although they consume luxuries which can elsewhere be afforded only by the wealthiest. The finest silks and the most costly wines went to Virginia City during the great bonanza in 1862, and similar extravagance had been witnessed before at Potosi, Cerro Pasco, Guanajuato, and Zacatecas. The owner of a rich mine cannot dig out the pure, precious metal with a shovel unassisted; he must employ a great number of laborers, and his money runs all through the community and stimulates every branch of industry. The whole nation feels rich, and it purchases for one day's work the productions on which other nations have spent two day's. The gold and silver are sent abroad to purchase those things which can be made cheaper abroad where labor has not felt the stimulus. The third effect of the production of the precious metals in large quantities is that the prices of other articles generally are affected. We want gold and silver for coin and for use in the arts, and the smaller the supply relatively to the demand the higher the value. The experience of ancient as well as of modern times has proved this principle. After Alexander conquered Persia, and enriched Greece with the spoils of Asia, three times as much silver was required to pay for a day's work as before; and now it requires in average years six ounces of silver to purchase as much wheat in Europe as could be bought in 1490 for one ounce. The cause of the change is the great relative increase in the supply of silver while there is no relative increase in the supply of wheat. The result of the great yield of the silver mines of Peru and Mexico in the 16th century was that between 1550 and 1600 wheat trebled in price. The production of the 16th century was about $690,-000,000, whereas, the production of $4,000,000,000 in the 18th century added only 50 per cent. to the price which wheat bore in 1600, but more than 200 *per cent. of the price which it bore in* 1500. When we compare ancient with modern times we see that the rise in prices was very much greater relatively in Rome after she became mistress of the world than it has been in modern Europe since the mines of America, Australia and Russia have yielded their treasures. The difference is owing partly to the fact that a large portion of the laborers in the Roman Empire were slaves, and the number of those who used money and could possess plate was comparatively small, and civilization was confined within narrow limits. The decrease of prices was less in proportion to the production of the precious metals in the 17th than in the 16th, and less in the 18th than in the 17th century, because business has increased with much greater rapidity in late times than before. Commerce, manufactures, and intelligent agriculture have grown wonderfully. Many branches of trade conducted mainly by barter several centuries ago are now managed exclusively with money. The laborers are all free, and each needs a stock of coin with which to make purchases in case of necessity. The use of silver table ware and of gold ornaments is very extensive, and large quantities of both gold and silver are used in various kinds of manufacture. The introduction of steam in mills, boats and cars has doubled the productive capacity of mankind, and far more than doubled the demand for money. The speed and cheap communication between all countries has added vastly to the general wealth, and has increased the demand for the representatives of wealth. The remotest parts of the world are now brought to our doors, and China and Hindostan open their laps to receive our gold and silver and prevent it from falling in value by becoming too abundant in our hands. One of the best indications of the increase of trade and the spread of civilization is the relative value of the precious metals, and we see that a net increase of $500,000,000, or an addition of 250 per cent. to the stock in the 16th century, trebled prices in half a century, while a net increase of $5,300,000,000, or 900 per cent., since the year 1600, has not trebled prices in 250 years.

—Compiled from R. W. Raymond's Reports.

BIMETALLISM: SINGLE AND DOUBLE STANDARDS.

THE purpose of this work and the references to coinage in the preceding paper of this part compel an examination into the great question of bi-metallism, and the maintenance of single or double standards.

The following clear exposition of mono-metallism though printed for private circulation, is too good to be lost in such a way, and is condensed here.

That there is a wide-spread misapprehension on the part of the public as to what constitutes the true value of the precious metals, as well as to the nature and functions of metallic money, and even among economists and financiers who have given the subject special attention; no one can, for a moment doubt, who has had occasion to examine the various theories upon the subject. The high estimation in which the precious metals have been held, in all ages and in all countries, and the avidity with which they have been sought by all manner of men, is, perhaps, more universal in its extent and influence, and uniform in its history, than that of any other object which relates to the aspirations or industries of mankind. And the pursuit of them has, apparently, always possessed a fascination which no other object could inspire, and which no danger or privation could repress. We trace back this thirst for gold not only to the remotest antiquity, and to the very confines of authentic history; but passing beyond these limits, we find it interwoven with all the traditions and legendary myths of prehistoric times, and coeval with the very creation of Gods and men.* Whether we trace back civilization through Aryan or Se-

*Sir John Lubbock supposes, in his "pre-historic Times," that gold was the first metal discovered and utilized by man. This is highly probable, as other metals are usually found as ores, combined with other substances; whereas, stream and placer gold is always found in metallic form, and from its native lustre, must have at once attracted attention.

The Hesiodic and Homeric Theogonies are full of references and allusions to the precious metals. And according to the "Works and Days," the successive races of men are named after the metals.

mitic channels, or attempt to penetrate the antiquity of the several families of the human race, as they successively come within the sphere of its progress and expansion; we everywhere find accumulated evidence of the fact that it was among the first objects to attract the attention of man and stimulate his industry. The human mind is sometimes almost appalled in contemplating the magnificence and opulence of the royal and commercial cities of those remote periods, as depicted by sacred and profane history, and the fabulous amounts of the precious metals accumulated in them, or expended in their construction and embellishment. We read the story in the hieroglyphics of the pyramids—in the ruined temples of the magnificent cities of the Thebaid—in the cuneiform inscriptions upon the walls and tablets found among the splendid ruins of Assyria—in the more classic ground of the Troad and the Peloponnesus—among the buried sepulchres of the Homeric heroes, of Ilium and Mycenæ—and even in those mysterious abodes, the tumuli of prehistoric man. Before the birth of commercial art, before the dawn of proprietary rights among men, the splendor of these metals had attracted the admiration and incited the acquisitive passions of mankind. In all ages historians have written and poets sung of their matchless properties and transcendent beauties, and the imagination and fancy have borrowed from them their happiest similes of all that is excellent in nature or admirable in art. And to tell us that these metals, for whose acquisition man, in all ages, has devoted the highest energies of his nature, and not unfrequently bartered his soul, possess no value except that bestowed upon them in subsequent ages, *as money*, is a travesty on the facts of history, which defies all dispassionate criticism.

It is well known that from the remotest antiquity down to the building of the Temple, and for several hundred years subsequent thereto, the quantity of the precious metals in existence far exceeded that, of which, modern times furnish us any account prior to recent discoveries. In all these hundreds, we may say thousands of years, before the precious metals—especially gold—were employed as *current money;* they were even more highly prized than now; if we measure their values by that of other commodities, or the wages of labor, as they existed in those days. Though they were then especially produced by slave labor, and belonged to the royal treasuries, and consequently, "their cost of production" was but a nominal element of value. In the ruder stages of society men dealt in exchange mainly by the simple barter of the products of their labor. As this became more subdivided, and its products more diversified, their exchangeable values became more incommensurable, and hence, the invention or origin of money, as a medium of exchange. At first, this usually consisted of some product of labor, possessed of general utility—then came the useful metals and their alloys—next came silver, and finally came gold; but not until some centuries subsequent to the invention of *coined money*. It is important to observe in this connection, that while the quantity of gold appears to have been greatly in excess of that of silver, it was then, as now, much the more valuable metal. And though we do not find that it was ever employed *as a currency*, until after the invention of coined money, it was doubtless employed in exchange and sold by weight—just as silver is to-day in England—long before it was made legal tender, or became current as money of account. We are told that Abraham returned from Egypt "rich in cattle, gold and silver," and somewhere about 1890 years B. C., we find him purchasing a burial ground from Ephron, for which he "*weighed* out to him four hundred shekels of silver, *current money*, with the merchant." This is the earliest mention we have of a precious metal as "*current money*." The shekel was both a coin and weight, and though the shekel of gold is frequently

The legend of the "Golden Fleece," in which the exploits of Gods, Demi-gods, and men, are so hopelessly mixed up, is supposed to be typical of the great wealth of Kolchis, and was a sort of prospecting party in quest of the golden sands of its famous rivers.

Zeus, the father of the gods, we are told, was "rocked in a golden cradle," and penetrated the "brazen prison" of the coy Danæ in a shower of golden dust—not an unsuccessful method, by the way, in more modern times, of propitiating the favors of that "fascinating mischief," which he inflicted upon mankind as a "punishment to mortals" for being outwitted in a little trade by Prometheus, their progenitor.

referred to in the Old Testament, and that metal seems to have been excessively abundant; we no where find it spoken of as *current money*. Indeed, we no where find that it was so employed prior to the invention of coined money, as already stated. And the Jews are said not to have adopted coined money until so late as the days of the Maccabees. The use of gold as money seems to have been first adopted by the Lydians, but to a very limited extent, and not until some 1200 years subsequent to the employment of silver for that purpose. And it was several hundred years subsequent to this, before it was so employed by the Greeks or Romans.

At the time of the building of the Temple, which was about 1000 years B. C., and still several centuries before we find any mention of gold as money; the metals had become excessively abundant, and, although silver was the current money of the day, and gold only a commodity, the former was but little better than a nuisance, and we are told that it was "in Jerusalem as stones * * for abundance," and that it was *nothing accounted* in the days of Solomon." It is true that some commentators undertake to explain this, by saying that it was so regarded for the purpose of art, but give us no authority for such an interpretation; whereas, Josephus tells us emphatically, that "there was nothing then to be *sold* or *bought* for silver," and elsewhere gives us a minute account of the enormous amount of that metal that was employed in the construction and decoration of the Temple. Economists tell us that the value of commodities arise from the "cost of production;" assuming labor as the true and ultimate measure of value. But practical miners and metallurgists know very well that the "cost" of producing silver is greater than that of gold; and that this great disparity of value between the metals existed for centuries before they were employed as money, or before it was attempted to "regulate" that value by "law." If there is any one thing well understood among all well informed economists—it is the nature and functions of money as expounded by Aristotle; and which has been made the basis of every definition of money by every subsequent writer who has represented it as an *intrinsic equivalent* possessing *inherent* value, as well as measure and sign of value.*

STANDARD MEASURE OF VALUE.

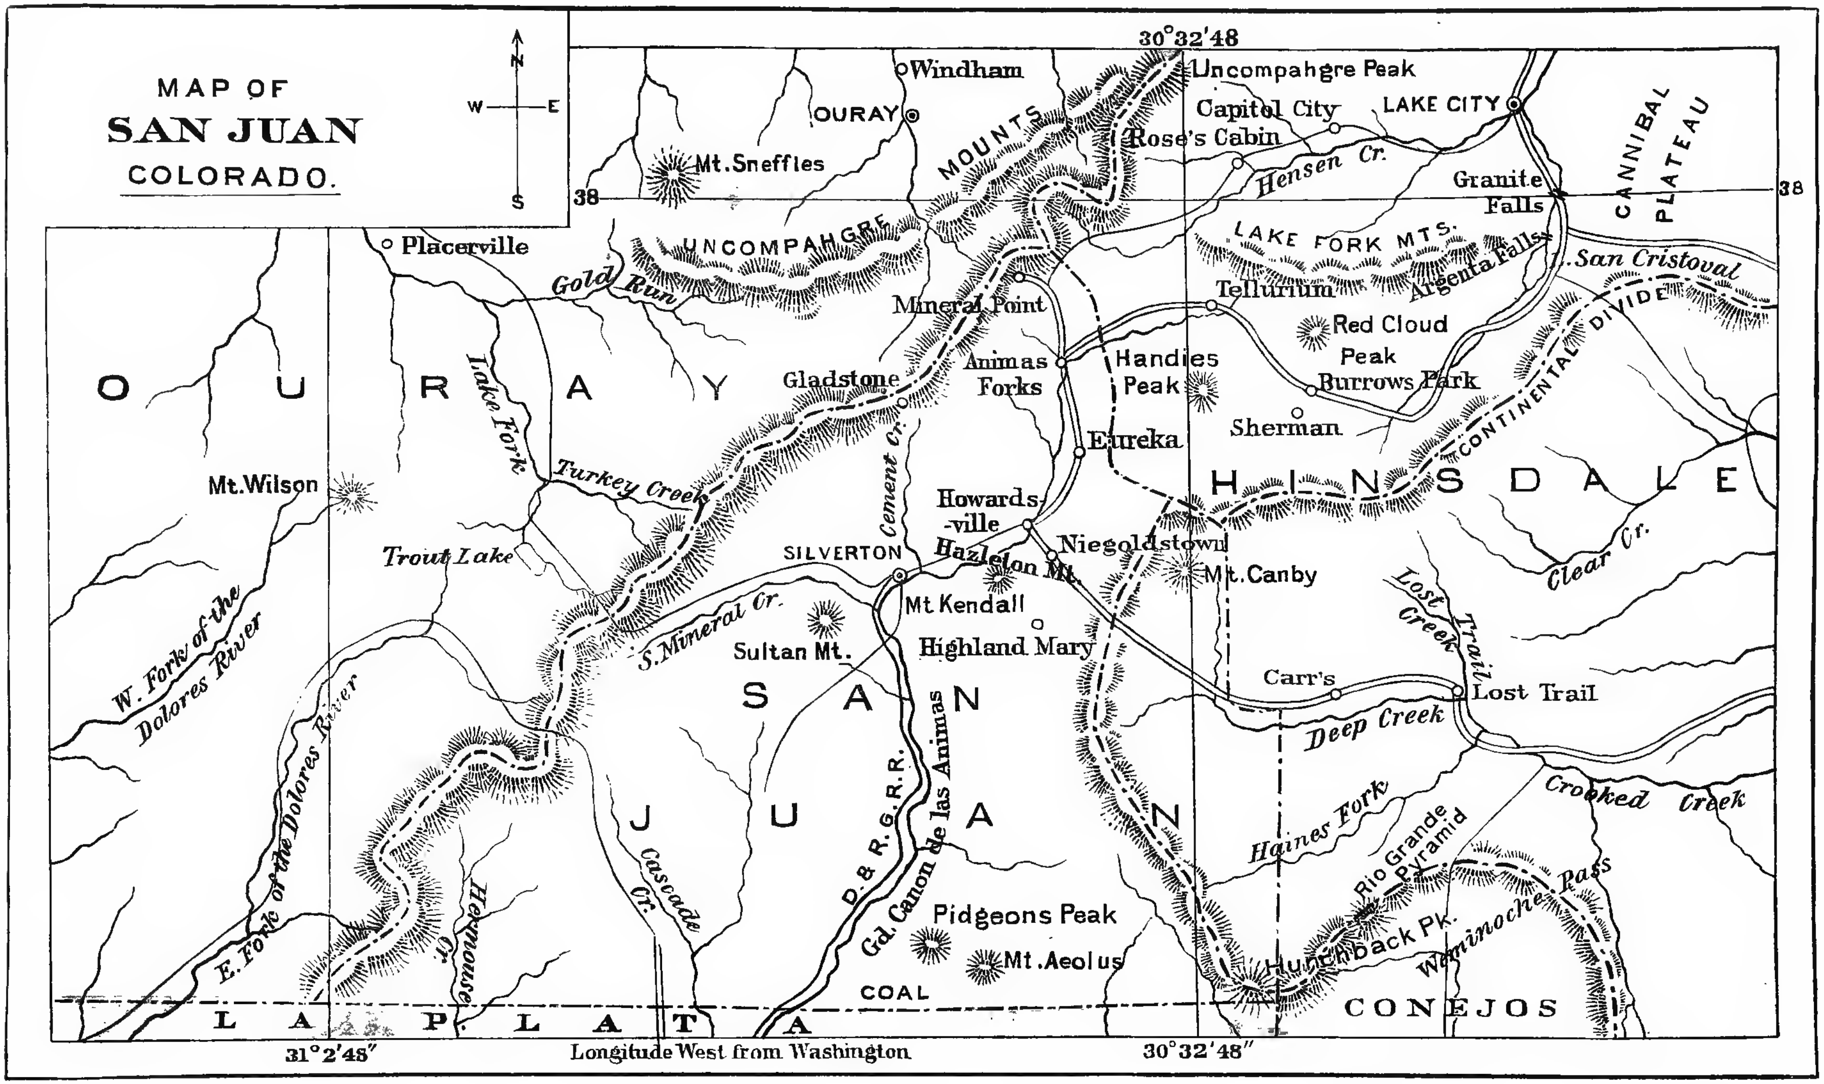
THE term "value," when applied to money *as a standard*, can only be taken in its mathematical sense, as meaning "quantity." When a standard of value has been once established, you may express the "relation" of value between other moneys, or between money and commodities, in terms of coin, made in accordance with such a standard; but you can convey no idea of the value of standard money *in terms of itself*, and can only do so by reference to some unit of physical magnitude or

* Among all modern writers, none are comparable to Locke in defining the nature and functions of money, or seem to have so clearly apprehended its true relations to human industry or stated them with such terse and philosophical precision.

"Men, in their bargains, contract not for *denominations or sounds*, but for intrinsic value, which is the *quantity* of silver by public authority, *warranted to be in pieces* of such denominations. And it is by having a greater *quantity* of silver that men thrive and grow richer, and not by having a greater *number of denominations* which, when they come to need their money, will prove but empty sounds." * * * * * * *

"Money is the measure of commerce and the rate of everything; it is the thing *bargained for*, as well as the *measure of the bargain*, being *equivalent* to the thing sold; it is not only the *measure* of value of the commodity it is applied to, but is given in exchange for it as of *equal value*." * * * * *

"The intrinsic value of silver, *considered as money*, is that estimate which common consent has placed upon it, whereby it is made *equivalent* to all other things, and consequently is the universal barter or exchange which men give and receive for other things which they would purchase or part with *for a valuable consideration*."—*Locke*. Montesquieu, Count de Verri, McCulloch, Chevalier, and others have embodied this essential idea of *intrinsic equivalent*, in their definitions of money; but in all of them we recognize the original idea of Aristotle, as something "really valuable itself."



—Drawn and Engraved for the Mines, Miners and Mining Interests of the United States.

"quantity." To say that a Sovereign shall be of the value of twenty shillings, or that an Eagle shall be of the value of ten dollars; gives us no idea of what either a Sovereign, a shilling, an Eagle, or a dollar is; but when we learn that a Sovereign contains 113.001 grains of pure gold, and an Eagle contains 232$\frac{2}{10}$ grains; we, for the first time, form a definite idea of the value or "quantity" which they express. Justinian evidently understood this, and what he meant by "perpetual value" of the "material," was its inherent or intrinsic value; and what he meant by the "power" of money, which he says depends upon its "quantity," was its *purchasing power;* and which, as before said, is entirely correct. For if it were enacted that hereafter a Sovereign should be worth forty shillings, or an Eagle should be worth twenty dollars; it would not, in the slightest degree, change the "value" or purchasing power of the Sovereign or the Eagle; *but would simply reduce the weight* or "*quantity,*" and consequently the "*value*" of the shilling and the dollar. This is shown by the fact that when we want to *over value* a coin, as in the case of subsidiary money, we simply reduce the *weight* or "*quantity*" of fine metal in it. It is surprising that the bimetallists do not detect the palpable inconsistency of their own arguments or interpretations. They endeavor to prove that money "*has value only by law,*" and not "*by Nature,*" and that the "value" of money consists in its "quantity," and that the "quantity is exactly that which *Nature produces.*" And it must follow, therefore, that "law" has nothing to do with the creation of "value," in the material of which money is made. But if the "value" or "power" of money "resides" only in the "quantity," and that "quantity is exactly that which *Nature* produces;" then it must be the "substance" only which the "law" creates; and as that substance is known to be gold, we have, at last, got a solution of the alchemist's problem, and the scare about the "insufficiency" of that metal is wholly sensational and unnecessary.

It seems almost puerile to comment seriously upon such statements as these; but it is just such material as this, furnished by "high authority," that has involved this whole question in such hopeless confusion, and by which these bimetallic enthusiasts attempt to establish the necessity of adopting the policy recommended by them. To any well informed person it will be scarcely necessary to state that not only did the precious metals have a high and well established value for centuries before they were employed as money; but when subsequently, they were so employed; their values, as such, were necessarily made to conform approximately to their previously established exchangeable values, for the very obvious economic reason, that any material *over valuation*, or *under valuation*, would either lead to an undue inflation of prices, or to expel them from circulation by over importation. And as the volume of money is but a very small percentage of the volume of commodities, whose exchange and distribution are affected by it—you would thereby either defeat the essential purpose of its creation, or produce disastrous results to the industries of the country. It would be a violent presumption, but no argument, to reason in reference to the value of any product or commodity, by assuming what the effect upon that value would be by suddenly throwing upon the markets of the world the entire stock of that commodity, which had been produced or accumulated for hundreds of years. This would simply be abrogating or suspending the operation of the laws of supply and demand; and would prove nothing. No product of industry would possess value by this process of illustration or reasoning.

It being abundantly evident then, from all the attested facts of history, as well as from the established principles of economic law, which imparts to and governs the value of the products of industry, that the precious metals possess an inherent value founded upon their utility, and have maintained this value in all ages and countries, with a greater uniformity than any other product in the pursuit of which men engage; we have next to examine to what extent that value is affected by their employment as money, or controlled by laws adopted for its regulation.

The Value of the Precious Metals but Slightly Affected by their Employment as Money.—From the quotations already made, it will be preceived that the phenomenal decline in the value of silver, which occurred in 1876, and from which it has but partially recovered, is specifically charged to the demonetization of that metal by Germany in 1873, and its *so-called* demonetization in this country by the act of February 12th, in the same year. It may be stated here, that so far as the recent disturbance in the relations of value of gold to silver is concerned; all the factors which enter into that problem have arisen since the discoveries of gold in this country and Australia. And to extend the investigation beyond this period, is only to ascertain the analogies afforded, in illustrating the principles of economic law, from which this disturbance has resulted. To show how entirely disproportioned this result has been to its alleged cause; we may state the following statistical facts as instructive upon this point, and which, at the same time, will have a bearing upon what follows further on. According to the elaborate report of the Goschen Committee of the British Parliament, it appears that for the twenty-one years ending December 31, 1871, the coinage of silver by the States now constituting the German Empire, had averaged about $20,600,000 per annum, and that the total amount remaining in circulation at that date was variously estimated to be from $225,000,000 to $295,000,000. For the purpose of argument, we will assume the maximum estimate. Of this amount $103,200,000 had been provisionally reserved for subsidiary coinage, of which $58,500,000 had been already coined to June 7th, 1876. The total amount called in to that date, was about $105,600,000, of which $29,200,000 had been sold within the three years since demonetization, leaving apparently, $17,-900,000 on hand; and $171,560,000 still in circulation and performing all the functions of legal tender money. Of the $207,300,000 on hand or in circulation, $44,640,000 still remained subject to the reservation for subsidiary curreney—leaving $162,660,000 as the extreme amount which might be called in and sold. Which, however, the committee state in their summary, might be as low as $40,000,000, with a "possibility" of exceeding $100,000,000. To determine to what extent this demonetization of silver has contributed to its decline in value; or whether, as an alleged cause of that decline it is at all adequate to the results produced, we may summarize the material facts as follows: Prior to the discovery of silver in the State of Nevada, the production of the world had been unusually uniform for a number of years, and at the time of that discovery was about $40,000,000 per annum. From 1860 to 1875, both inclusive, the aggregate production was about $905,000,000, being an average of something over $65,000,000 per annum; and which, for the sixteen years gives us a gross *exccss* of production of $240,000,000 or $15,000,000 per annum, as compared with the production prior to this discovery. We have already seen that about $30,000,000 had been sold by Germany from 1873 to 1876; or an average of $10,000,000 per annum. And that she had ceased to purchase silver for coinage to the extent of $20,600,000, which, had been her previous average consumption. The estimates of the production of the precious metals at remote periods are but little better than the wildest romance; and indeed, in our day, are extremely unsatisfactory. But for the purpose of illustration, we will here state the relative produce of the two metals at different periods as given by the most usually quoted authorities. For the periods stated, both years are inclusive.[1]

[1] We may state herc generally, that all statements we make concerning the production of the precious metals since 1850, are from tables compiled by us within the past thirty years, and which we have carefully compared with other *original* authorities, so far as they relate to foreign countries. From 1492 to 1800, we have substantially adopted Prof. Soetbeer's estimates, as he is now the most frequently quoted authority; although they appear to us very inaccurate, and we have been unable to discover upon what ground he has altered so materially, the estimates of Humboldt and others, whom we have been so long accustomed to regard as authorities best informed upon the subject. From 1800 to 1849, we have also followed compilations of our own from the best *original* sources accessible. As for this period, Prof. Soetbeer's estimates are so palpably erroneous that we were compelled to reject them. It may be observed that while there are many apparently irreconcilable discrepancies between the usually quoted authorities as to the production of the precious metals; when compared by single years, or short periods: therc appears to be a sort of compensating principle of error running through them, which, when applied to periods of fifteen or twenty years, eliminate these discrepancies, and the grand totals for such periods, as given by leading authorities, are, for all practical purposes, sufficiently accurate.

	Gold.	Silver.	Ratio.
Prior to 1492	$5,260,000,000	$3,430,000,000	69@40 per cent.
From 1493 to 1799, 307 y'rs .	2,360,000,000	5,030,000,900	32@68 "
" 1800 to 1849, 50 " .	750,000,000	1,350,000,000	36@64+ "
Total two last periods, 357 y's	$3,110,000,000	$6,380,000,000	33@67 +
From 1850 to 1875, 26 years,	$3,125,000,000	1,310,000,000	70½@29½

It will be perceived that for the twenty-six years ending with 1875—or the year before the great decline in silver occurred—more gold had been produced than in the previous three hundred and fifty-seven years ; and that the ratio of production had been more than reversed, as compared with the period prior to 1492. For the fifty years ending 1849, the average had been—

Gold — $15,000,000 per annum=36 per cent. } Average price of Silver,
Silver— 27,000,000 " 64 " } 60¼*d*.=15.53@1

For the twenty-six years ending 1875, the averages were, respectively—

Gold — $120,000,000 per annum=70½ per cent. } Average price of silver,
Silver— 50,384,000 " =29½ " } 60¾*d*.=15.53@1

It will be observed that in the latter period the *ratio of production* was more than reversed, as compared with the preceding period—and the average *excess production* of gold *per annum* was *seven hundred per cent.* Under ordinary conditions this great disturbance in the relative production, should have caused a marked decline in gold, as compared with silver. Whereas, by a remarkable coincidence, the *mean* of the *yearly averages* for the two periods *was precisely the same.* [For extreme fluctuations of each decade, see note, further on.] We shall presently attempt to explain the causes of this abnormal condition of things. In the meantime, it will be in the line of this explanation to briefly notice the circumstances existing in this country at the time of the so-called demonetization of silver by the Act of February 12th, 1873 ; to which the late Silver Commission attributed such disastrous results to our commercial and industrial interest, and such dire consequences to the entire human family. The reasons which led to the demonetization of silver in this country, we will state more in detail a few paragraphs beyond. For the present it will suffice to state that this demonetization *practically* took place in 1853, when the fractional silver coins were reduced at the rate of 28½ grains standard weight to the dollar, or nearly seven per cent.. From that date to 1872 inclusive, a period of twenty years preceding the alleged demonetization of 1873, something over $4,500,000 only of these dollars were coined—being an average of $225,000 per annum, or about half a cent per capita on the mean population for that period. But being undervalued, however, about 3½ per cent., they never went into circulation, but were exported; and never constituted any effective portion of the currency of the country. But for some twelve years prior to this alleged demonetization, it is well known that specie payments in the United States were suspended, and no kind of metallic money was in effective circulation—except on the Pacific coast—or had any monetary relations whatever to the current business of the country, during that period. But as the demand for, or consumption of silver is one of the effective factors in this question of its market price or value, as it relates to that of its demonetization—it may be stated, that, for the four years, from 1873 to 1876, both inclusive, the trade dollar and subsidiary silver coinage, amounted to over $65,000,000, or more than the entire silver coinage of the country for the previous twenty-five years; and therefore, the coinage of that metal in this country was much more effective in sustaining its market price, than it had ever been at any previous period.

Now, taking this condition of things in connection with that existing in Germany, what do we observe? We find the average price of silver in the London market for the year 1873, in which demonetization took place, to have been 59¼*d*. per standard ounce, corresponding to a ratio of 15·91 to 1 of gold, which is equivalent to a discount of 2$\frac{64}{100}$ per cent. on the ratio of 15½ to 1, and something less than ½ per cent. premium on our ratio of 15.988 to 1.* This average, by coincidence, corresponds exactly with that of the year 1845, some five years prior to the commencement of the extraordinary production of gold already referred to. No marked or sudden decline of silver occurred during the three years following this demonetization. But in the first six months of 1876 it declined from 56½*d*. in January, to 46¾*d*. in July, equivalent to 16½ per cent. Assuming the stock of silver in coin and plate among Occidental nations at that date, to have been $3,800,000,000 ; this depreciation would be equal to $627,000,000, or the entire product of the world for the previous ten years, *and nearly four times the whole amount that Germany was supposed to have for sale.* It is scarcely necessary to observe that we utterly fail to discover in this condition of things, any cause, at all adequate to such startling results. When, therefore, Mr. Seyd tells us, that because Germany had, in three years, sold 30,000,000 of silver, and some 160,000,000 more which she might sell at some future time; that this great and unprecedented decline was due to the demonetization, *"and that only;"* and when the distinguished gentlemen who constituted the late Silver Commission, repeat to us, that this demonetization, in connection with the fact that the United States had ceased to distribute among the people the enormous amount of a half a cent per capita of an old theoretical coin, which had never been in effective circulation; though coining silver to a greater extent than ever before: that not only was this depreciation due to these facts, but that it was also the cause of the wide-spreading commercial depression and industrial distress which had swept over two continents; paralyzing the energies of industry and trade in its course, and well-nigh bankrupting the Caucasian race, we are fairly appalled at the stupendous absurdity of the whole thing, and can but look upon it as—

"Resembling ocean into tempest wrought,
To waft a feather, or to drown a fly."

This great depreciation in the value of silver was undoubtedly due, to some extent, to the scare gotten up in relation to its probable excessive production in this country; which in that year reached a maximum not before attained. This is measurably confirmed by the fact, that from the low price of 46¾*d*. in July, it rose again in December of the same year, to 57*d*. or nearly 17½ per cent.—being equivalent to an appreciation of stock, of 660,000,000. The average for the year, however, was as low as 52¾*d*. Since that time, the fluctuations have not been violent, but the price has gradually gravitated downward, notwithstanding the unprecedented export to the East, in 1877, and the restoration of the double standard in this country in 1878. It reached its lowest annual average of 51¼*d*. in 1879—equivalent to a ratio of 18.40 to 1, or about 18 per cent. discount on the ratio of 15½ to 1. From this point of depression it has slightly recovered, and has now, for some time past, fluctuated between 52 and 53*d*.

Now, that Germany is no longer a seller, and the United States, for the past four years having become a much larger consumer than that country had ever been ; and therefore, more than an offset to her abandonment of the double standard : and as the present production of the two metals approximate each other more nearly than at any former period, this steadiness of price would seem clearly to indi-

* To ascertain *ratio* from any given price of silver per English standard ounce—

As one oz. of fine gold, at the Mint rate of 77½ per standard ounce, is worth 1019.4546 pence; and as one oz. of fine silver is equal to 1.081 ozs. of standard silver; the formula usually employed is—

$$\frac{1019.4546}{1081 \text{ x Price.}} = \text{Ratio.}$$

But as both the dividend and the divisor are fractional—a somewhat more accurate formula is this: The penny or $\frac{1}{240}$ part of a sovereign contains 0.47084 grains of fine gold without a fraction, and the oz. of English standard silver contains 444 grains of fine silver without a fraction; hence—

$$\frac{444}{0.47084 \text{ x Price.}} = \text{Ratio.}$$

To ascertain *price* per oz. of standard silver from any given ratio, we have the formula—

$$\frac{1019.4546}{\text{Ratio} \div 925.} = \text{Price.}$$

cate that there must be some more potent reason for the continued depression of silver than German demonetization affords. We are satisfied that it arises from a more deep-seated cause; and that *it is the effective result of economic laws* which have acquired vitality and been brought into active operation by recent radical changes in the commercial methods of the world, and by which the relative exchangeable values of the two metals *are being adjusted in accordance with their relative utility*, under existing commercial and industrial conditions. This, undoubtedly, is the true key to the solution of this perplexing problem. And this great decline in the value of silver is almost entirely due to the fact that its *utility*, upon which its exchangeable value is founded, has been impaired, if not superseded by the great abundance of gold, which has become more nearly adequate to the entire demands of commerce than at any former period, and performs all the functions of money more economically, and in that respect, as well as in others, more effectively: and is therefore, the preferred metal. This is a plain proposition, entirely susceptible of proof by indisputable statistical facts, concerning the production and movement of the precious metals, and requires no far-fetched theories of conspiracy, or imputations of insidious motive in the policy which any nation has adopted, or may think proper to pursue. Self-interest dominates the policy of nations as well as the acts of individuals, and it is a weakness in which none will indulge except visionary enthusiasts, to suppose that either will be controlled by the dictates of a more elevated principle. For the purpose of elucidating this theory, it will be necessary to state the essential facts concerning the production and movement of the metals, and the changes in business methods which they indicate. Having already stated this production down to 1850, we will only here repeat that of the last period for the purpose of illustration and comparison with those which follow. For the periods stated, both years are inclusive.

Productions of Precious Metals during the Undermentioned Periods.

	Gold.	*Silver.*	*Ratio.*
1800 to 1849, 60 years . .	$750,000,000	$1,350,000,000	36 @64
1850 to 1864, 15 years . . .	$1,925,000,000	$ 625,000,000	75½@24½
1865 to 1879, 15 years . .	1,615,000,000	1,015,000,000	61½@38½
Totals for 30 years . .	$3,540,000,000	$1,640,000,000	68½@31½
1850 to 1866, 17 years . .	$2,160,000,000	$730,000,000	
1867 to 1879, 13 years . .	1,380,000,000	910,000,000	

Annual averages of production by quintuple periods:

	Gold.	*Silver.*	*Total.*
1850 to 1854	$128,000,000	$40,000,000	$168,000,000

Excess of annual averages . . .	$ 103,000,000	$27,666,666	$130,666,666
Percentage increase of averages	700 per cent.	$102\frac{4}{10}$ per cent	311 per cent.
Estimated annual increase of population of Occidental countries	1½ per cent.	1½ per cent.	1½ per cent.

Exports of Silver to the East from Great Britain and Mediterranean ports.*

1850 to 1866, 17 years	$1,015,000,000	Average per annum	$59,800,000
Production for same period	730,000,900	" "	43,000,000
Excess of *exports* . .	$285,000,000	" "	$16,800,000

For the most active movement during this period, we have:

From 1853 to 1866, 14 years .	$963,000,000	Average per annum	$68,700,000
Production for same period	610,000,000	" "	43,500,000
Excess of *exports* . . .	$353,000,000	" "	$25,200,000
From 1867 to 1879, 13 years .	$560,000,000	" "	43,000,000
Product for same period	910,000,000	" "	70,000,000
Excess of *product* .	$350,000,000		$27,000,000

The exports of silver *into India*, approximate very nearly the *exports from Europe*, though a considerable portion of these imports comes from China and other points of the East to which they were originally consigned.

The gross and net imports into this country, for the 15 years from 1835 to 1849, both inclusive, were as follows:

		Per annum.	*Net.*	*Per annum.*
Gross	$180,141,085	$12,010,000	$122,264,595	$8,150,000
Produced . .	390,000,000	26,000,000	390,000,000	26,000,000
Excess . .	$209,888,315	$13,990,000	$167,735,405	$17,850,000

Sale of India Council Bills, prior and subsquent to the opening of the Suez Canal, in 1869:

From 1850 to 1869, 20 years .	$369,000,000	Average per annum	$18,450,000
" 1870-71@1879-80, 10 y's.	605,000,000	" "	60,500,000
Difference	$236,000,000	" "	$42,050,000

Gold Coinage.—The coinage of gold by Great Britain, France, Russia, the United States and Australia, for the 26 years ending with 1875, and just preceding the great decline in silver, was about $3,100,000,000. But the coinage of the last three named countries was so largely exported, and has undoubtedly entered so largely, by recoinage, into that of the two first named countries, that we take no account of it, nor of that which may have been coined by other Occidental nations, though, doubtless, it was very considerable. The total produce of gold for this period was about $3,143,000,000, being but slightly in excess of the coinage of the five countries mentioned. We, therefore, confine ourselves to the coinage of Great Britain and France, as probably representing the *effective supply* of gold, which took the place of silver drawn from Europe during this period:

1850 to 1866—coinage of gold	$1,575,000,000	From 1850 to 1875	$2,007,150,000
Exports of silver to the East	990,000,000	" "	1,296,000,000
Excess in supply of gold .	$585,000,000	" "	$711,150,000
Total production of gold . .	2,160,000,000	" "	3,143,000,000
" " " silver .	730,000,000	" "	1,300,000,000

Silver Stocked by Western Nations.

Average *annual exports* of silver to the East for 17 years ending 1866		$59,800,000
Average *annual produce* of silver in the world for same period—say		43,000,000
Loss of stock per annum		$16,800,000
Amount exported annually for 9 years ending 1875	$34,000,000	
Amount produced annually for same period—say .	61,000,000	
Gain in stock	$27,000,000	$27,000,000
Difference per annum in amount of silver *stocked*		$43,800,000

The foregoing figures show some phenomenal results in the production and movements of the precious metals. It will be observed that the produce of gold for the thirty years ending 1879 has been equal to that of the 400 *years preceding* 1850. It reached its annual maximum of $170,000,000, in 1852 * the greatest quintuple maximum of $755,000,000 in 1852-56, and the greatest decennial maximum of $1,405,000,000 in 1852-61. We further observe that after adding to the stock of precious metals over $4,500,000,000 in *twenty-five years*, an amount exceeding by $1,000,000,000, the product of *any previous period of* 100 *years*; the aggregate annual production of both metals during the last five years of this period of thirty years, exceeded, and is now exceeding, that which occurred during the period of *the maximum gold production*. It will also be perceived that simultaneously with this extraordinary production of gold, there also commenced the most remarkable export of silver to the East which has been witnessed in modern times. There appears to be no logical commercial connection between the two facts, and though their simultaneous occurrence is to be regarded simply as a coincidence, we shall presently see that it satisfactorily accounts for certain phenomena that would otherwise be very perplexing.

This unprecedented export of silver to the East continued

* These statements of the exports of silver are taken from the report of the Goschen Committee. The year 1850, from the table of Messrs. Pixley & Abell, page 20; and from 1851 to 1875, both inclusive, M. de Quetteville, p. 185, column 12. From 1876 to 1879, from the bullion circular of Messrs. Pixley & Abell, which, however, only state the export for these years from Great Britain. The exports of silver from the United States to the East are not included, but would not probably change materially the *proportion* existing between the exports of the two periods.

*The *"Journal des Economistes,"* and others, state this product at $182,500,000; but it includes the product of Australia for the *fractional* year 1851, which we have included in that year.

with unabated activity until 1866. The most active movement was for the 14 years from 1853 to 1866, during which the exports were over $960,000,000, which exceeded, by some $350,000,000, *the entire produce of the world for the same period.* In the meantime, the discovery of extensive silver mines in this country occurred; the produce of which, at the close of the period under consideration, reached $40,000,000 per annum, thus doubling the production of the world prior to its discovery. For the subsequent 13 years, comprised in the period from 1867 to 1879, both inclusive; these exports to the East fell to $560,000,000, while the world's produce for that period amounted to $910,000,000,—and which, without regard to the German supply, added $350,000,000, or $27,000,000 per annum, to the stock of Western nations, instead of a *deficit* of $353,000,000, as compared with the preceding period. *This increase in silver, coming upon the enormous accumulation of gold* which had been taking place while the former metal was being absorbed by the East, amounting to $585,000,000; gave an access of supply of nearly $1,000,000,000 to the current production of the two metals, then aggregating over $170,000,000 per annum; could not fail to produce abnormal relations in the value of the metals. If, now, in connection with this excessive stocking of the precious metals by Western nations, we consider the important and radical changes in the commercial methods of those nations as they related to Oriental exchanges, and which, by another coincidence, occurred at a period immediately following the cessation of the extraordinary exports of silver in 1866; we shall clearly understand why it was, that from 1850 to 1866, notwithstanding the enormous and excessive production of gold, as compared with that of silver, there was no corresponding disturbance of their relative values; and why it was, that the effective economic law, which controls their relations of value, did not assert itself, or develop its action until 1876.

Consumption of Silver as Affected by Important Changes in Methods of Oriental Exchange.—It must be borne in mind that, prior to 1866, when the exports of silver so suddenly declined, the commerce of the Western world with the great silver absorbing nations of the Orient, was carried on by sailing vessels around the Cape of Good Hope and Cape Horn. The commercial and financial centres of the Western world were thus in comparative ignorance of the condition of the Eastern markets, and the receipt of advices was usually months after date. The business with those remote quarters was carried on almost wholly by *direct exchange and remittances,* and it required from six to nine months to complete a commercial transaction and receive final returns. But within three years following this cessation of excessive exports of silver, which occurred in 1866, a complete revolution in the methods of business took place. In that year, the Atlantic cable connected Europe with the United States, and was rapidly followed by the completion of the transcontinental railway and the establishment of the China Steamship Company's line of steamers, as a branch of the Pacific Mail. Almost simultaneously with this, came the opening of the Suez Canal, in November, 1869, and the establishment of telegraphic communication with all parts of the East, via Cape de Galle. Thus, within a few years bringing the entire Western world *in daily* communication with the Orient. By these means business men in Europe and this country were kept daily advised of the exact condition of the exchange market of the East, as it related to inter-colonial as well as foreign exchange; and were thus enabled to utilize all the advantages of *cross and arbitrated exchanges,* in valuations on eastern markets, and the adjustment of balances. The advantages afforded by this new order of things is precisely the same with reference to foreign exchange—that clearance houses secure in local business. They obviate the necessity of the movement of bullion, just as the latter does the movement of coin; and it is only the final net balance that is to be covered, and not each separate intermediate balance, as must be the case where direct exchange only is employed.*

Concurrently with these radical changes in the channels of commerce, we notice some marked changes in the course of eastern exchange. For twenty years prior to the opening of the Suez Canal, the sale of India Council Bills, against the government revenues of India, had amounted to something less than $370,000,000, or an average of $18,000,000 per annum; whereas, for the ten years subsequent to that date, these sales amounted to over $600,000,000, or an annual average of $60,000,000; making a difference of some $42,000,000 per annum between the two periods. These sales obviated the movement of just so much silver, and in the latter period exceeded in amount, *the entire produce of silver in the world* for ten years prior to that event.

In pursuing this line of analysis, we further find that, for the twenty-six years ending with the year 1875, just before the great fall in the price of silver; the produce of that metal in the entire world had been $1,300,000,000, and the exports of the East for the same period amounted to $1,296,000,000 from Europe alone, thus practically absorbing the *entire amount of that produce.* For this same period of twenty-six years, the produce of gold had been over $3,140,000,000; and to say nothing of other mints, those of Great Britain and France alone, had coined and put in circulation in Europe over $2,007,000,000 of gold coin, in lieu of the $1,296,000,000 of silver coin and bullion withdrawn; an excess of over $710,000,000. In addition to this great accumulation of gold, and its current annual production, still some 530 per cent. in excess of the fifty years prior to 1849—comes an enormous addition to the stock of silver also, already noted. We here find an entirely rational solution of two problems. First, why it was that, notwithstanding the excessive production of gold from 1850 to 1866, there was but barely a perceptible appreciation of silver, as measured by gold. And secondly, why it was, that in 1876, and subsequently thereto, silver declined in value in a much greater ratio than the relative production of the two metals would require, as compared with their former relations of production and value.

The True Cause of the Depreciation of Silver.—This brings us directly to the consideration of the question of the relative "utility" of the two metals as the true underlying cause of this great disturbance of relative values. As already stated, from 1850 to 1875, both inclusive, the East drew from Europe alone, an amount of silver equivalent to the *entire produce of the world* for that period. And from 1853 to '66 it not only absorbed the entire produce of the world, but drew from Europe $350,000,000 of its old stock, but as fast as a vacuum was thus formed by this enormous withdrawal of silver, it was at once filled by the influx of gold from this country and Australia. And when it abated in 1866, its place had not only been entirely filled by gold, but the mints of England and France alone had supplied Europe with $585,000,000 of gold coin, *in excess of all the silver withdrawn.* This was largely more than was necessary to keep pace with any increase of population or expansion of commerce which had occurred, and had served to familiarize the business world with the superior advantages of gold as a medium of exchange for all large transactions. It, moreover, affords an ample explanation of the apparent suspension of the economic law, which regulates and adjusts the relative exchangeable values of commodities to their respective volumes and uses. The area of modern commerce is so extensive, and the diversities of human industry so great and complex, that the evidence of the effective operation of economic law is very slow in manifesting itself, in unmistakable industrial and commercial phenomena. It has been said that it was nearly 150 years after the discovery of America, before the full effect of the great increase

* A single example of the many important changes in the mechanism and course of exchange arising from these increased facilities, will suffice to indicate the saving in time and movement in bullion effected thereby. Instead of requiring from six or nine months as formerly, to make a remittance to China, for example, *via* Cape of Good Hope from London, and receive returns; a London banker can now telegraph his correspondent in San Francisco to remit fine silver or Mexican dollars for his account, to Hong Kong or Shanghai, as the local rates there may suggest, and to draw on London. Within twenty odd days the shipment reaches its destination. In the meantime the San Francisco banker can remit his sterling to New York or London direct, as prevailing rates may make most advantageous; and thus, from two to three times the amount of exchange will be effected *within thirty days on one movement of bullion,* that under the old methods required, as stated, from six to nine months. In the meantime, the London banker, being daily advised of local rates at all points in the Orient, can utilize all the advantages which arbitrated rates between those points afford.

in the precious metals, which followed that event, was attained. When, therefore, in 1866, and subsequent thereto, silver also began to accumulate rapidly—and coming upon markets abundantly supplied with gold for all legitimate commercial purposes, and its stock still increasing—it necessarily took some little time for the marked change in the supply of the metals which had occurred, as well as the important changes noticed in the commercial methods of distributing them; to manifest themselves by a corresponding change in their relative values. But it having now occurred, we think the facts stated clearly indicate that it is the legitimate result of effectual economic laws, whose operations for a time, acting with inverse momenta, counterbalanced each other; now reasserting themselves, and readjusting the relative values of the metals in accordance with the ratios of production and their relative utility under important changes of industrial and commercial conditions And that German demonetization has been altogether *a secondary factor* in producing this result. As already stated, utility is that inherent property possessed by commodities which enables them to fulfil some specific requirement or purpose of human economy. And while it is the source and basis of exchangeable value, it is in no wise affected thereby. Its only test is its *effectiveness* as an instrumentality, compared with other substances possessing similar functions. The utility of metallic money, therefore, must be measured by the security it affords as a "storage of value," and the effectiveness with which it performs the operations of commercial exchange and distributes the products of industry. These functions become necessarily impaired, as its volume becomes unnecessarily, or disproportionately increased, *as compared with the services to be performed by it*, or with the expansion of commerce and increase of material wealth. It not unfrequently occurs, that by new discoveries or improvements in commercial and mechanical arts, the utility of a substance is materially impaired by limiting its sphere of usefulness—and may be altogether superseded, and disappear from among the products of human industry.

If now we compare the enormous supply of gold for the last thirty years with the material progress of the Western world, we shall see that it has been greatly in excess of what that progress required, and out of all proportion to the relations previously existing between the metallic money in circulation among commercial nations, and the volume of their commercial transactions. And this excessive supply is abundantly shown by the enormous circulation of idle capital in all the financial centres of the Western world—and the unprecedented rates of interest, as shown by the marked advance in all interest-bearing securities, and the low rates obtainable for new loans—as well as by the speculative *mania* manifesting itself everywhere, and paving the way for over-production and commercial and industrial revulsion, at no distant day. While it may be true that recent political events and certain exceptional commercial exigencies have temporarily produced an abnormal movement and distribution of the gold of commerce; in view of the undisputed statistical facts produced, it is but reasonable to demand, at the hands of the advocates of bi-metallism, something a little more specific as to the insufficiency of the supply of gold, than the mere gratuitous statements of prominent financiers—however exalted their positions may be—unsupported by any statistical facts, either as they relate to the production of that metal, or to the increased volume of commercial transactions relatively thereto. With this stock of gold already largely in excess of the requirements of *legitimate* industries and commerce, and its annual supply, far in excess of any necessary increase of metallic money to keep pace with them, for years to come; to have some $350,000,000 of silver added to this stock within the last thirteen years, and its annual produce of $80,000,000, and prospective increase to be hereafter added thereto—is certainly sufficient to produce a great disturbance in the relative values of the two metals: and there cannot be a doubt that *the utility of silver for the purposes of money*, has been greatly impaired by the *great abundance of gold* and the marked advantages it possesses for all such purposes. The development and progress of human industry have long since established the fact that its *effective results* are largely in excess of the *increase of instrumentalities employed*—and it is a well recognized law of financial economy, founded upon this observation of fact, *that the increment of money which is necessary to keep pace with the increase of population and expansion of commerce, is but a very small per centage of such increase and expansion.* And the great increase in the facilities of communication and rapidity with which exchanges are effected, are daily reducing the ratio of that relative increase.

The Increase of Money Needed.—The factors which enter into this question of the quantity of money required for the *legitimate* purposes of commerce, *and the ratio of its increase*, are so numerous, that it becomes a very complex one, and it is practically impossible to establish any uniform rule upon the subject. First, we have the abnormal increase in the volume of money which expensive wars have, at some time within the past century, entailed upon all commercial nations, and which has arisen to a greater or less extent from the suspension or interruption of commercial intercourse, as well as from the necessity of increased disbursements. Then we have periods of high speculation, giving great activity to large volumes of money without adding, in any way, to the material wealth of the country, representing its progress, or distributing its products. But independently of these, we have the more legitimate variations in the quantity of money, and increase required; arising from differences in the nature and character of the commercial pursuits and industries of different nations, and their respective facilities of communication and exchange. The mere increase of population seems to be the least important factor which enters into the question; though it may furnish a convenient basis for computing the quantity, or indicating the ratio of increase.

Every man of family, and those who have had occasion to maintain large bodies of men, know that the increase in the expense of such maintenance, is not at all proportionate to the increase of numbers so maintained. It is also a well established fact that the percentum increase of material wealth and expansion of commerce, among leading commercial nations, is largely in excess of the increase of population, and is a much more important factor in the question of the increased supply of money which is necessary to keep pace with them. This again, however, is more or less modified by the nature of the industries pursued by each. Commercial nations seem to require much more money, *per capita* of population, than those engaged principally in agricultural and pastoral pursuits. And those which combine with commerce, manufacturing industries, involving minute subdivisions of labor and multiplied transactions; require still more. There are numerous other conditions which modify, to a greater or less extent, the final result. This will at once become apparent, upon a glance at the population and volume of money of Western nations, as shown by the most recent estimates:—The United States, Great Britain, Germany, France, Italy, Belgium, Netherlands, Denmark, and Spain, aggregating 224,500,000 population, average, *per capita*, $9.44 in paper money, and $15.69 in specie, making a total of $25.15. Among the highest are France and the Netherlands, being $53.10, and $39, respectively. And the lowest are Italy and Spain, being $13, and $13.77 respectively. Russia, Austria, Portugal, Sweden, Norway, Switzerland, and Greece—population 141,800,000. Paper, $7.93; specie, $3.15; total, $11.08. Canada, Mexico, Colombia, Peru, Central America, and Venezuela—population 24,600,000. Paper, $2.03; specie, $3.50; total, $5.53. Making a grand total of 391,000,000 population, with an average of $8.44 paper, and $10.88 specie, or $19.32 *per capita*. For Brazil and Chili we are unable to obtain, at the moment, any authentic data. The United States have in paper, $14, and in specie, $12, or a total of $26 *per capita*. Great Britain, $5.85 and $18.57, respectively, or $24.42 *per capita*.[1]

In 1860 the population of the United States was 31,400,000, with a circulation of $6.70 in paper, and $8.30 in specie, making $15. We now have a population of over 50,000,000; and have therefore, had, within the past twenty years, an increase of 60 per cent. in population, with only an increase

[1] With some modifications in the statement of population, based upon more recent estimates, we have taken the above figures from the report of the Director of the mint for 1880, which was obtained by extensive correspondence through the State Department, with our diplomatic and consular representatives in the several countries.

of 44 per cent. in metallic money—if so much.[1] And notwithstanding the great revival of business, and the gigantic speculative mania attending it; money is, relatively, far more abundant, and rates of interest much lower than they were in 1860. Money, undoubtedly, has an immense reserve power of measuring values, and its capacity is but partially developed by the greater or less activity of trade, and the momentum of its circulation, limited only by the facilities of exchange. The improved methods in this direction, which have taken place within the past twenty years, have greatly increased this power, and account for the fact, not unfrequently observed, of a largely increased business being effected with a diminished supply of money. In the vast extent of sparsely populated territory and limited credit system, this country is, undoubtedly, much below Great Britain and Continental Europe in those conditions which tend to reduce the volume of money required, as well as the ratio of its necessary increase. It will be, therefore, entirely safe to assume that it is above the average of the entire Western world in its monetary necessities. And if we admit the estimates of M. Chevalier, who has investigated the subject quite exhaustively, and which are undoubtedly high, we shall reach a conclusion that the alleged insufficiency of gold is wholly without foundation. He estimates that the increase of population is one-and-a-half per cent. per annum, and concedes, for safety, that money should increase *pari passu* with it. This gives us for the last thirty years an increase in population of 45 per cent. to provide for. We have already seen that for that period the average annual increase of gold has been 700 per cent. *in excess* of what it had been for the previous fifty years, and the increase of both metals had been 311 per cent. And that the increase of gold alone has been 181 per cent. in excess of that of *both metals* for the period prior to 1850. Now, if we assume that *one-half* of all the gold produced is consumed in the arts, it will still leave us 90 *per cent. increase* of that metal over that of *both gold and silver* for the previous period, which would be 100 *per cent. in excess of the amount required by the increase of population at this full estimate of M. Chevalier,* to say nothing whatever of the amount of silver produced and stocked for the same period.[2]

But we believe it has been much greater; for after repeated investigations, we have been unable to find any *authentic data* which at all justifies such an estimate as to the quantity of gold consumed in the arts, including losses and abrasion. The amount of the precious metals employed in the arts is regulated by the demands of trade, rather than by the vicissitudes affecting their production. And no impetus was given to this trade, following the discovery of gold in this State and Australia; at all commensurate with its enormous production. We find an apparent confirmation of this in the coinage of the metals. We have already seen, that, for the twenty-five years from 1850 to '74, an imperfect statement of the gold coinage of five mints, only, was nearly equal to the entire produce of the world. From 1875 to 1879, we have a more complete return, though that for the last year of this period is still incomplete. The produce of the world for this period was $495,000,000, whereas, the reported coin of nineteen States was $887,875,000; showing an excess over production, of $392,825,000, or *eighty per cent.* This, of course, is due to re-coinage. But if we only take the most prominent *producing* States, we have, for this period, a gold coinage by the United States, Russia and Australia of $412,000,000. This is over eighty-three per cent. of the entire produce. But Australia apparently only coined about one-half of her production. The re-coinage of foreign coins by the United States was about the same as her export of uncoined domestic gold. It will, therefore, be entirely safe to assume that at least $45,000,000, or *ninety per cent. of the produce of this period was converted into coin.* For the same period the produce of silver was $405,000,000, and the coinage of the same Mints $640,000,000; or an excess of sixty per cent. In view of all these facts, we cannot escape the conclusion, already stated, that, notwithstanding the statement of so many eminent authorities to the contrary; *the supply of gold alone* has been adequate to all the legitimate requirements of commerce, and its present and probable future produce, for a long time to come, abundantly sufficient to provide for any required increase. And that, therefore, the utility of silver for the purpose of money has been greatly impaired, if not superseded; and, as its exchangeable value is founded upon that utility, *its impaired usefulness is the true cause of its depreciation in the markets of the world.* There has been a marked tendency for the past two hundred years for silver to gravitate downward, as com-

[1] The above statement is based upon an estimate of about $260,000,000 of metallic money in circulation in 1860. This amount has been variously estimated from two to three hundred millions. We are rather disposed to accept the latter figures. The production of gold in this country from 1850 to 1859, inclusive, was $630,000,000. The coinage of gold for the same period was $345,000,000, and of silver, $45,000,000, making $390,000,000. In the exports of specie, which from 1850 to 1854, amounted to 119,165,000, coin is not separated from bullion. From 1855 to 1859, they consisted of $150,429,000, bullion, and $107,725,000, coin. The presumption is that much the larger portion of the 119,165,000 was bullion, as there are $285,000,000 of the $630,000,000 produced to be accounted for; and after deducting the 107,725,000 specified as coin, we have only $269,594,000 as the total export in all forms. The coinage apparently left in the country was 283,000,000, exclusive of any stock that may have been on hand in 1850. And as returning travelers and emigrants are supposed to bring more coin into the country than is taken out by that means, the specie in the country in 1860 was probably nearer $3,000,000 than the amount assumed, and which would reduce the percentage of increase, as stated.

[2] Senator Jones, in his speech of April, 1876, asserts that the increase of money should maintain a slightly increasing ratio to that of population, which is the converse of the proposition we have asserted and attempted to illustrate. In support of this theory he furnishes a number of statistical statements of population and stocks of specie at stated periods. These statements, when analyzed, *and taken in connection with the production of the world for the corresponding periods,* which he does not give, produce such discordant results, that it is impossible to deduce from them any general law or rule governing the question. For instance, he gives Jacob as authority for the statement that the stock of specie in the Western world in 1700 was $1,445,000,000. And in 1839, it was, according to Storch, $1,420,000,000. This shows an actual loss of $25,000,000 in 140 years, during which *population must have more than doubled,* and the supply of the precious metal to the Western world had been $3,510,000,000, after exporting $2,510,000,000 to the East, and *which is wholly unaccounted for.* We here give the *production* of the precious metals for the several periods stated, and his statement of the specie stocked during the same:

The Western World.

	Supply.		Specie stocked.
1493 to 1700	. . . $2,935,000,000		$1,280,000,000 = 43 per cent.
1701 to 1803	. . 2,485,000,000		355,000,000 = 14 "
1804 to 1839	. . 1,025,000,000		. . . . . . = ...
1840 to 1852	. . 1,000,000,000		700,000,000 = 70 "
1854 to 1872	. . . 2,055,000,000		1,100,000,000 = 53 "
Total supply	. . $9,490,000,000	Total stocked	$3,435,000,000 = 36 per cent.
To be accounted for	. . . .		. . 6,055,000,000 = 64 "

The Eastern World.

	Supply.		Specie stocked.
1493 to 1803	. . . $2,510,000,000		$700,000,000 = 27 per cent.
1804 to 1839	. 575,000,000		100,000,000 = 17 "
1840 to 1853	. . . 200,000,000		100,000,000 = 50 "
1854 to 1872	. . . 1,210,000,000		1,200,000,000 = 99 "
Total supply	. . $4,495,000,000	Total stocked	$2,100,000,000 = 47 per cent.
To be accounted for	. . . .		. 2,395,000,000 = 53 "

For the last period we have taken *the actual* exports of silver to the East, which exceeded the entire produce of the world—some $285,000,000. For the preceding periods we have taken these exports at one-half the produce.

The inconsistencies, however, as to the amount of money required do not end here. He tells us that "it has been calculated that specie measures *ten thousand times* its own value every year," and that it "will last, as against abrasion, loss by accident, etc., about *one thousand years.*"

Elsewhere, however, in stating the stock of specie in Asia in 1872, to be $2,100,000,000, he tells us that "merely to keep this stock reserved from the effects of abrasion and loss, Asia requires some $30,000,000 of silver every year." This would allow only the longevity of coin. In another place he makes it a little less than sixty-seven years. The measuring power of money, as stated, seems equally wide of the mark. If we take the population of the Western world at 400,000,000, and the amount of money at $20 per capita, we shall have $200,000 per annum, or nearly $600 per day, Sundays included, as the business transactions represented by every *man, woman and child in it.* And at this rate, we have no doubt, that a vast majority of people would be glad to compromise and take the equivalent of one year's operations for the balance of their natural lives. We scarcely think that such a data is sufficiently reliable to form the basis of any theory as to the monetary necessities of the commercial world, or to justify any important change of national policy concerning it.

pared with gold. Bnt prior to the discovery of the latter in this country and Australia; its supply was so limited, that, after satisfying the demand for the arts, the balance, when distributed among commercial nations, was so inadequate to the demands of commerce, that this growing preference for it could exercise no practical influence upon the relative values of the two metals, as it could never be said to have been in *effective* circulation as money. It is within the recollection of most of us, when a gold coin was regarded rather as a curiosity, and only to be worn as a *vade mecum*. But the phenomenal production of this metal which followed these discoveries, has not only familiarized the business world with it, but has demonstrated its many advantages over silver, as a medium of exchange. And notwithstanding all the absurd sentimentality in which the silver advocates indulged over the restoration of the dollar of our fathers, as some one has justly observed, it is now "always taken with a grudge, and given with a chuckle."

Depreciation of Silver but Slightly Affected by its Demonetization.—In view of the foregoing facts and considerations, it is scarcely necessary to say that Mr. Ernest Seyd's emphatic declaration, that the decline in the value of silver is due to German demonetization, and "*that only;*" is not only unsupported by fact, but is wholly illogical, as a deduction from principles of economic law. No one knows better than that gentleman, that England, from her extensive commercial relations with the silver producing, as well as silver consuming countries of the world, has, for many years, and until the discovery in this country; controlled nearly its entire produce of silver, and that all other nations have directly or indirectly drawn their supplies from her. Yet, when she demonetized silver in 1816, it at once *advanced in price*, and for five years following that event, averaged some $1\frac{3}{4}$ per cent. more than it had done for the five years preceding it. And for the 10 years subsequent to 1820, when the Bank of England had commenced accumulating gold, preparatory to the resumption of specie payments, it never declined beyond that percentage, below the average price, from 1811 to '15 inclusive. Just why, then, as he tells us, that "so long as Germany maintained silver, the equilibrium was maintained," and when she abandoned it "that equilibrum was lost;" we utterly fail to discover, when we consider the relative commercial importance of the two countries, and the diametrically opposite results which followed their respective changes of policy. It is only another illustration of the influence which hobbyism, or preconceived theories, will often exercise over the most intelligent minds, and the illogical positions in which it will betray them. Since the discovery of America, there has been no corresponding period in which the value of silver has continued so steady and uniform, as that of the fifty years following the demonetization by England in 1816.[1]

[1] The following extreme fluctuations of each decade since 1760, clearly proves this fact:

1761—67 $\frac{5}{8}$ *d* ℔ oz.=13 94 to 1· 1764—63 $\frac{3}{4}$ *d* ℔ oz.=14.91 to 1·	6 $\frac{96}{100}$ %	fall.
1774—62 $\frac{5}{8}$ *d* ℔ oz.=15.05 to 1· 1777—67 $\frac{3}{16}$ *d* ℔ oz.=14.04 to 1·	6 $\frac{71}{100}$ %	rise.
1781—70 $\frac{3}{4}$ *d* ℔ oz.=13.33 to 1· 1785—61 $\frac{3}{8}$ *d* ℔ oz.=15.21 to 1·	14 $\frac{1}{10}$ *d* %	rise.
1797—61 $\frac{1}{16}$ *d* ℔ oz.=15.45 to 1· 1799—65 *d* ℔ oz.=14.29 to 1·	7 $\frac{1}{2}$ *d* %	rise.
1806—66 *d* ℔ oz.=14.25 to 1· 1809—58 *d* ℔ oz =16.25 to 1·	14 %	fall.
1810—58 $\frac{3}{8}$ *d* ℔ oz.=16.15 to 1· 1816—69 $\frac{1}{8}$ *d* ℔ oz.=13.64 to 1·	15 $\frac{54}{100}$ %	rise.
1821—69 *d* ℔ oz.=15.98 to 1· 1824—60 $\frac{5}{16}$ *d* ℔ oz.=15.64 to 1·	2 $\frac{12}{100}$ %	rise.
1833—59 $\frac{3}{16}$ *d* ℔ oz.=15.93 to 1· 1839—60 $\frac{3}{8}$ *d* ℔ oz.=15.61 to 1·	2 $\frac{01}{100}$ %	rise.
1840—60 $\frac{3}{8}$ *d* ℔ oz.=15.61 to 1· 1843—59 $\frac{3}{16}$ *d* ℔ oz.=15.93 to 1·	2 $\frac{05}{100}$ %	fall.
1850—60 $\frac{1}{16}$ *d* ℔ oz.=15.70 to 1· 1859=62 $\frac{1}{16}$ *d* ℔ oz.=15.19 to 1·	3 $\frac{1}{4}$ %	rise.
1860—60 $\frac{11}{16}$ *d* ℔ oz.=15.28 to 1· 1869=60 $\frac{7}{16}$ *d* ℔ oz.=15.60 to 1·	2 $\frac{9}{100}$ %	fall.
1870—60 $\frac{9}{16}$ *d* ℔ oz.=15.57 to 1 . 1879—51 $\frac{1}{4}$ *d* ℔ oz.=18.40 to 1 .	18 $\frac{17}{100}$ %	fall.

We think now it should be abundantly evident that the precious metals have, and always have had, an inherent value wholly independent of that derived from the "legal fact" that they are "legal tender," notwithstanding Mr. Cernuschi's assertion to the contrary. And that also, the "quantity produced," is a very important factor among the causes which produce "variation" in the relations of value they bear each other. And that any proposition for the rehabilitation of silver, founded upon the theory that such is not the case; but that it is entirely within the control of legislative enactments, must end in disastrous failure.

As unamenable, as the advocates of such a proposition evidently are, to any statement of facts, or enunciation of economic principles tending to the demonstration of such a result; it may not be altogether uninteresting to state some of those historical analogies arising from the various experiments which other nations have made from time to time under much more favorable conditions, to accomplish the same thing in a modified form. The uniform result of all these experiments must go far to demonstrate to every dispassionate mind, the truth of what has been already stated—that there are, in this bi-metallic problem, elements of inherent antagonism arising from the operations of the economic and physical laws involved; which must forever prevent its furnishing either an *effective* medium of exchange, or *an equitable standard* of value.[1]

Why Double Standards have always failed, and must continue to do so.—Prior to the discovery of America, the production of gold had been about 60 per cent. as to 40 per cent. of silver; whereas, from 1492 to 1850, the ratio had been only 32 per cent. as to 68 of silver. We accordingly see that during the former period silver was, relatively, higher to gold than in the latter. The apparent suspension of the laws which regulates these relations of value, from 1850 until about 1875–6, has already been explained. But having again become effective, though still apparently not mathematical in the results produced; it is a question, as already suggested, whether the phenomenal relations of production and the revolution in commercial methods have not essentially altered their practical utility; and consequently their relative exchangeable values which are founded upon it? If this be true, it necessarily follows that all attempts to establish definite monetary relations between the two metals which do not exist between, or are inconsistent with their relative utilities for such purposes, must from a well-known principle of commercial exchange and the operation of physical law, result in failure. It is a maxim among cambists, that in the operations of exchange, remittances, by which bills or balances are to be covered, should always be such—the security being equal, as have the highest value, relatively to the par of exchange, at the point where the bill is to be paid; as compared with its cost at the point where the bill is drawn. Under this law the *undervalued* metal, or *better* currency, will invariably be expelled

[1] "As the values of gold and silver *perpetually vary*, not only relatively to other things, but also to each other, it is impossible arbitrarily to fix them by Mint regulations. * * The absurdity of employing two metals as legal tender, or a standard of value, was unanswerably demonstrated by Locke and Harris, and have been noticed by every subsequent writer."—*McCulloch.*

"Two metals, such as gold and silver, cannot serve at the same time, in the same country, for the medium of exchange, because this medium ought to be always the same and *retain the same proportionate value.* To adopt, as a measure of the exchangeable value of commodities, substances *which have no fixed or unvariable relation to each other*, is as if we were to choose for a measure of length an object which was subject to the process of distending and contracting itself. In each country there should be but one metal to serve for money of account, the payment of contracts, and the *measure of value.*"—*Locke.*

"What, then, shall be said of measures that are not only discordant and unprecise, but fluctuating also? What would be said of a bushel that alternately contracted and expanded, and contracted more than it expanded; of a rule of elastic rubber, or a pair of scales with a shifting fulcrum? And what shall be said of a fluctuating measure of value."—*Senator Jones.*

Echo answers what? As this is precisely to what the Senator has been devoting the highest energies of his intellect to accomplish, it would perhaps be edifying to the "fledglings of political economy. the charlatans of monetary conventions, and the numerous other dupes of Lombard street," if he would answer his own conundrums.

from circulation, and leave only the inferior one, for local or domestic purposes.[1]

This is not only theoretically and technically true, but the history of every experiment of the kind which has heretofore been made, furnishes overwhelming evidence, not only of its practical illustration, but of the endless vexation and annoyance in business transactions. But even if the vicissitudes of mining industries and the laws of commercial exchange did not defeat every attempt of this kind; the physical law of abrasion would be abundantly sufficient to produce the same result. This arises from the great disparity between the wearing surfaces of gold and silver coins *as compared with their relative units of valuation and velocities of circulation.* It is well known that coins of small denominations change hands much more frequently than larger ones—but even if this circulation was uniform, there would still be an immense difference in the relative abrasion. To show the extent of this disparity of wearing surfaces, we will here state the proportions of the relative areas in square inches, of the gold and silver coins of the United States, as compared with their units of valuation:[2]

	To $1 Gold in Double Eagle.	*To same in Eagle.*	*To same in ½ Eagle.*	*To same in ¼ Eagle.*	*To same in Gold Dollar.*
Silver Dollars . . .	24.08	19.77	15.31	11.50	6.70
2 Half Dollars . . .	30.87	25.35	19.63	14.74	8.59
4 Quarter Dollars . .	38.52	31.63	24.49	18.40	10.72
10 Dimes	52.33	42.97	33.27	25.00	14.56

So far as this question relates to the laws and usages of commercial exchange, as already stated, these disparities of wearing surfaces and the unequal abrasion arising therefrom, are practically confined to the silver dollar and the double Eagle and Eagle; and between them, it will be seen, the difference is from twenty to twenty-four times greater to the unit of silver than to that of gold; and the relative abrasion is doubtless still greater, and is amply sufficient to destroy, in a very short time, their *relative standard weights*, and, consequently, their *relative exchangeable values as bullion* for the purposes of export or use in the arts. Indeed, this physical law has heretofore been much more effective in producing the results indicated, than the economic law which relates chiefly to the question of supply and demand. Let us now, for a moment, see what has been the practical effect of these laws, as exemplified by the experience of the leading commercial nations who have heretofore attempted to maintain double standards. The first experiment of this kind affording any practical illustration of the action of these laws, was that made by England in 1663. Prior to that time silver had been, practically, the only legal tender, and, indeed, the commerce of the world at that period was almost entirely carried on by means of that metal. In that year, however, the guinea was for the first time coined, and we find the "irrepressible conflict" at once inaugurated. By the Act 2, Chas. I, in 1626, twenty shillings of gold had been made to contain 128,780 grains of pure metal, and the seignorage on silver was reduced from 2*s.* 6*d.* to 2*s.* on the pound troy of standard silver. This was equivalent to a ratio of 13,346 to 1 by Mint indentures, and to 13,431 in the market rate of silver. By the Act 18, Chas. II, in 1666, the weight of the guinea was fixed at 118,651 grains of pure gold; being a reduction of 10,129 grains, or nearly eight per cent. By the same Act the seignorage on silver was entirely removed, thus practically raising its market value some $3\frac{1}{3}$ per cent., and making the ratio to gold as 14,485 to 1; being a rise of 8.45 per cent. on the former ratio of fine metal in the coins, or $7\frac{7}{8}$ per cent. on that of the market price of silver. By this alteration of proportions of fine metal contained in the coins, gold was undoubtedly over-valued. In the meantime, the silver currency was in a most wretched condition, and prior to the great re-coinage under William III, the guinea had become current at from 28 to 30 shillings—equal to a discount in silver of from *forty to fifty per cent.* And even after the re-coinage, though only rated at 20*s.* by Mint indentures, it continued to circulate by common consent and usage, at 21*s.* 6*d.*, or some $7\frac{1}{2}$ per cent. premium on its nominal value. The consequence was, that the new silver coins disappeared as soon as put in circulation, and gold, as the over-valued metal, became practically the only legal tender. Subsequently, upon the recommendation of Sir Isaac Newton, the value of the guinea was fixed at 21*s.* by proclamation in 1717, and its weight of fine metal was reduced $\frac{1}{21}$ part, or 5,650 grains, which made its ratio to silver as 1 to 15,209, at which it remained until 1816, when the latter metal was demonetized, except as a subsidiary currency with limited legal tender capacity.

During this long period of 100 years, from 1717 to 1816, we are told that "*no silver coins of legal weight* were found in circulation," and nothing but the minor coins in a most degraded condition were current; and had been as far back as 1774 limited as legal tender *by tale* to payments of £25, and for larger sums only *by weight.* And to show how utterly non-effective was this metal, either as a currency or as a standard measure of value; we have the authority of Lord Liverpool for the statement that, for 83 years of this period, less than $35,000 per annum of silver was coined, and that for forty years prior to the suspension of specie payments by the Bank of England in 1797, less than $8,000 a year had been coined. And at that date, the half crowns in circulation were degraded, by abrasion, about *nine per cent.* below legal weight—the shillings *twenty-four per cent.*, and the sixpenny pieces *thirty-eight per cent.* Thus, we perceive, that for 150 years prior to 1816, and, indeed, we may say for the entire period over which this experiment extended; *the two metals* were never in *concurrent and effective circulation*, nor did they ever furnish anything approaching an effective or equitable standard of value, and were only productive of endless vexation and annoyance, unexampled in the financial history of that country. When now, we remember that the fruits of this experiment were just what her ablest economists had pointed out, as the inevitable results of such a violation of economic principles; and it was such eminent statesmen and practical financiers as Liverpool, Huskisson, Harris and others, who, with these disastrous results before them, recommended the adoption of a policy more consistent with the principles of economic and financial science, and which would obviate the inherent and self-asserting antagonisms of a double standard: we can well afford to be amused at the diatribes against England and her statesmen, of the financial charlatans whom this discussion has brought to the surface, and who, by some inscrutable and perverse ordination in the fitness of things; find themselves in positions sufficiently elevated to attract, if not to monopolize public attention with their driveling inanities.

Now let us look to France, whose example is so often referred to by double standard advocates. Here the condition of things was the converse of that which existed in England. But the operation and effective results of the underlying economic law were precisely the same. Prior to 1785, the louis d'or, or twenty-franc gold piece, was undervalued about one livre and ten sols, or $6\frac{1}{4}$ per cent. And the result was, according to the authority of the eminent economist, M. Jean Baptiste Say, *that all gold was expelled from circulation*, and silver only remained. To remedy this, the weight of the louis d'or was reduced $\frac{1}{16}$, which temporarily assimilated the legal and market ratios of value between the two metals. But before any effective restoration of circulation could take place, the revolution which was to convulse the world, was inaugurated, and specie was superseded by that valuable *fiat* currency, so memorable in her financial history, under the names of *assignats and mandats.* And before this nuisance could be fully abated, we find France again tinkering her metallic money by the celebrated law of 7 Germinal, year 11 (28 March, 1803). This law is memorable, as affirming that *inspired ratio* of $15\frac{1}{2}$ to one, which seems to possess such a mysterious potency, and to be founded upon principles of such eternal justice—that is but little short of sacrilege to intimate the propriety of its

[1] This is frequently called the "Gresham law," from the fact that Sir Thomas Gresham was supposed to have first called attention to it. But the principle is doubtless as old as commercial art, and has always been in effective operation. We might as well designate the law of gravitation and attraction as the "Newton law." But apples have been falling to the earth ever since "the fruit of that forbidden tree * * * brought death into the world"; and the law is coeval with the creation of matter itself.

[2] The above ratios of wearing surfaces to units of valuation of the several coins, are computed from their areas, as determined in square inches, by careful measurement of their discs and rims, kindly made for me by Prof. Geo. Davidson, of the U. S. Coast and Geodetic Survey, and whose name is an ample guarantee of their accuracy.

abrogation; although we cannot find that it ever corresponded with the relative exchangeable values of the metals in the markets of the world, except occasionally by accident. Up to this time there had evidently been nothing like an effective double standard. Soon after the restoration of peace, however, financial matters began to assume something of their former normal relations; but after such gigantic revulsion as that which had swept over Europe for twenty-five years, it was necessarily slow. No sooner, however, do we find preparations for the resumption of specie payments being made, than this irrepressible conflict of the standard reappears.

In 1816, some five years before the Bank of England resumed specie payments, silver had been demonetized, as we have seen. For five years prior to that date, the average ratio of the two metals, as determined by their market prices, had been 15.49 to 1—equivalent to $60\frac{7}{8}$*d.* per English standard ounce, and which is the nearest approximation we ever find for any similar period, to the French standard ratio of $15\frac{1}{2}$. For five years immediately following demonetization, contrary to all the theories we now hear from bi-metallists, silver advanced to $61\frac{15}{16}$*d.* per ounce, corresponding to a ratio of 15.23 to 1, and equal to a premium of $1\frac{3}{4}$ per cent. on that of $15\frac{1}{2}$ to 1. In 1819, the Bank of England commenced preparing for resumption, which became effective in 1821. Gold being now her only standard, the demand thus created for that metal, favcred, at a later period, by the political disquietude felt in France, and which culminated in the revolution of 1830; caused it to advance in price. And we find, for the decade ending 1829, a mean average of $59\frac{11}{16}$*d.* per ounce for silver, equivalent to a ratio of 15.88 to 1, or to a discount on silver of $1\frac{9}{10}$ per cent. at the ratio of $15\frac{1}{2}$, as against a premium of $1\frac{3}{4}$ per cent. for the five years ending with 1820. For the decade ending 1839, silver slightly recovered, averaging $59\frac{13}{16}$*d.* per ounce, equivalent to 15.74 to 1, and being $1\frac{3}{10}$ per cent. discount on the French ratio. As small as these divergencies were from that ratio, they were quite sufficient *to expel all the gold from France.* The official statements, show, that for the twenty-four years ending with 1839, and following demonetization by England, France exported through the customs alone, *an excess* over her imports, of $105,000,000—to say nothing of what must have been taken out of the country by private means, or was consumed in the arts. And her coinage of gold for this whole period averaged less than *two millions and a half per annum,* which is altogether too insignificant, in view of the hoarding tendencies of the working classes of that country, to afford anything like an adequate and effective currency. We do not find, therefore, that for any considerable portion of this whole period of fifty-five years following 1785, up to which silver had been the currency, that she possessed anything like an *effective* double standard. Now let us come to our own experience. By the Act of April 2d, 1792, our standard was first established, and the ratio of the metals was fixed at 1 to 15. Under London market rates, this corresponded approximately, to $62\frac{7}{8}$*d.* per English standard ounce. The average ratio in that market, however, for that year, was 14.43 to 1, equivalent to $65\frac{13}{16}$*d.* In fixing the ratio at 15 to 1, it was consequently, *undervalued* some $4\frac{3}{8}$ per cent. The next year, however, it fell to 15.01 to 1, or very nearly the exact standard ratio which had been adopted by this country. For the following fifteen or twenty years, from political and financial disturbances in Europe, it was subject to many fluctuations, more or less marked, but its general tendency was downward; and for the forty-two years, from 1792 to 1834, the average was 15.37 to 1 of $61\frac{5}{16}$*d.* per English standard ounce by this ratio, therefore silver was *overvalued* some $2\frac{1}{2}$ per cent. as compared with the average market rates, and $3\frac{1}{3}$ per cent. as compared with the French ratio of $15\frac{1}{2}$ to 1, which was $\frac{82}{100}$ per cent. below the average market value. This overvaluation of silver should, by the operation of ordinary economic laws, have retained it in circulation, and have expelled the gold; and doubtless did expel what little we had, as gold coin was still a curiosity in this country at a much later date. The real conflict was therefore, between the new silver dollar and the old abraded Spanish and Spanish-American silver, which constituted the major portion of our circulation; and which had been made legal tender at the same ratio but which, from its degraded condition, was the overvalued metal, and effectually expelled all full weighted coins as soon as put in circulation.

About 1828, however, gold began to be produced in appreciable quantities in several of the Southern States, and to assume more importance in the currency of the country. And in 1834, Congress reduced the weight of fine gold contained in the eagle, some $15\frac{1}{2}$ grains, or about $6\frac{1}{4}$ per cent.; thus establishing a new ratio of 16 to 1. By the general Mint Act of 1837, both gold and silver were required to contain $\frac{9}{10}$ of fine metal. Previously, the silver dollar had consisted of 4.16 grains, 892.4 fine, making 371.25 grains of pure silver; and the eagle contained 258 grains, 899.225 fine, making 232 grains of pure gold. The gross weight of the silver dollar was reduced to $412\frac{1}{2}$ grains, which, at 900 fine, gave $371\frac{1}{4}$ grains of pure silver, being the same as before; but the weight of the eagle, not being changed, the increase of fineness raised the amount of fine gold $\frac{2}{10}$ of a grain, which made a new ratio of 1 to 15.988. This ratio is practically equivalent to 59*d.* per English standard oz. (58.979.) But the average price in the London market for that year, was $59\frac{9}{16}$*d.*, (15.83 to 1), and for the following sixteen years, and until the parts of the dollar were reduced to subsidiary currency by the Act of 1853; the mean of the annual averages was $59\frac{15}{16}$*d.*, equal to a ratio of 15.73 to 1, which would be equivalent to an *undervaluation* of the silver coin of $1\frac{6}{10}$ per cent. As small as it was, it was quite sufficient to expel every dollar from circulation, and for several years prior to 1853, the Secretary of the Treasury had regularly called the attention of Congress to the urgent necessity of some legislation to supply the demand for small change for retail transactions. Although the silver dollar was, and had been, *wholly non-effective as a circulating medium,* it was the stipulated consideration in most existing contracts and obligations; and Congress supplied this want by demonetizing the parts of the dollar only, by reducing them some seven per cent. in weight, and limiting them to the payment of sums not exceeding $5. In the meantime, gold becoming abundant, the coinage of the *silver dollar became wholly non-effective.* Here, then, we have the practical results of the three most noted examples which the history of commercial nations furnishes, of attempts to establish and maintain a double standard; and in every case we see only disastrous failure. And its advocates may well be called upon to point to *a single example in the whole range of commercial history, of any nation, ever maintaining successfully an effective circulation of both metals.* We invariably find, in every instance, the *overvalued* metal only in effective circulation, in conjunction with the minor coins of the *undervalued* metal *in a most degraded condition;* and in no wise furnishing anything approaching a uniform and equitable standard of value, or an effective currency. Yet, in face of the fact that history furnishes no example of an effective double standard, where there was a difference of *even two per cent.* between the exchangeable market values of the two metals; and in violation or disregard of every principle of economic and commercial law: we find these distinguished gentleman in Paris seriously discussing the proposition to overvalue one metal *some eighteen per cent.,* and claiming that with a "*free and unlimited coinage,*" they can be made to circulate effectively, at such radically disproportioned values. The only conceivable result of such an experiment would be, as already intimated, *the rapid concentration of all the overvalued silver among the nations having credit balances,* and of which we have a striking illustration in the example of France, which has accumulated, since 1871, an amount of silver equivalent to nearly the *entire amount stocked by the Western world since* 1867, when exports to the East so perceptibly decreased.[1]

The advocates of bi-metallism, would perhaps, consider it as an attempt to evade what they regard as the most important example of all the experiments which have been made to maintain a double standard; if we failed to notice that of France in 1853. As already stated, silver had been the

[1] In 1870, the reserves of the Bank of France were $13,700,000 in silver, $85,740,000 in gold: a ratio of $13.8 to 82.2. In 1880, they were $245,789,000 in silver, to $116,140,000 in gold: a ratio of 68.3 to 31.7. In 1876, however, she held as much as $306,080,000 gold: a loss of $189,940,000 of gold in five years, with a gain of $236,089,000 of silver in ten years.

effective currency of that country up to that time, and was its standard measure of value, as declared by the law of March 28th, 1803. But in consequence of the enormous withdrawal of silver for Eastern account, which had then actively set in; she undertook to supply its place by the substitution of gold. This experiment has attracted much attention, and has been widely commented upon by subsequent writers on financial and economic questions. The distinguished economist, M. Wolowski, especially draws attention to it, as a practical illustration of the "compensatory" theory of a double standard which he espouses. It is claimed by him that a bi-metallic standard possesses *an inherit principle of self-adjustment.* A sort of automatic back-action, by which it maintains a perfect equipoise in the value of the two metals. That, as one metal has a tendency to fall below its legal relation of value to the other; by coining more largely the "cheaper" metal, the increased demand for it thus created, affects correspondingly, their relative market values, restores the equilibrium, and keeps the standard measure uniform. As an economic *postulatum*, this theory is not without its attractions; but when we come to analyze its *practical utility*, we not only find it subject to insuperable objections, but that M. Wolowski is very unfortunate in the illustration by which he seeks to demonstrate its utility and practical effect. The uncertainty, expense, and annoyance of constantly alternating from one metal to the other, would be a sufficient obstacle to its adoption; but the factors to be utilized are, unfortunately, not within the control of those who may desire to adopt it. A nation, may make laws for the regulation of its currency, but this question is subject to the laws of commerce and not to Mint regulations. A nation whose commercial balances are *all* favorable, might maintain a double standard when the divergencies from the legal ratio of the metals did not exceed, or only slightly so, the cost of transportation, loss of interest and commissions, or brokerage. But the net balance in favor of any commercial nation is usually the difference, only, between its favorable and unfavorable, or, adverse balances. And as, under a well-known law of commercial exchange, already referred to, balances or bills are always paid in that metal which has the *highest* value *at the point where payable*, relatively to the *cost* of the remittance at the point where drawn; the "cheaper" metal cannot be obtained, when wanted, in sufficient quantities, as suggested by M. Wolowski, without going into foreign markets and buying it; and the expense of doing so, fully offsets the supposed profit, if, it does not exceed it. And this is precisely what France had to do in this particular instance, and with precisely this result.

As already stated, this change of policy was a matter of necessity, rather than choice; growing out of the extraordinary withdrawal of silver for the East. The drain upon her reserves was so great that it became, almost, if not quite impossible to maintain them in silver. For the eight years ending 1860, she exported $296,000,000 of her coined silver, or $35,750,000 per annum, and $170,000,000 in bullion, or $21,250,000 per annum—making together $476,000,000, or an average of $57,000,000 per annum, *being* 40 *per cent. more than the entire produce of the world for the same period.* Now, the average price of silver in the London market for 1853, when this extraordinary export of silver, and coinage of gold, commenced, was 61½*d.*, corresponding with a ratio of 15·33 to 1, and equivalent to a discount of about one per cent. on gold, on the basis of 15½. The Bank of France went into the London market and made immense contracts for the purchase of gold to replace her silver. According to M. Chevalier, she paid as high as 15 per mille premium (1½ per cent.) for much of this, and for the two and a half years ending December 31st, 1857, she paid $2,707,700 premium on $262,000,000 of gold purchased. This was equivalent to an average of 1·03 per cent., to which, if we add the ⅕ per cent. as the cost of coinage, *we make the cost of the new coin* ¼ *per cent. greater than it was in the legal ratio of* 15½ *to* 1. And instead of this extraordinary coinage of $767,000,000 of gold for this period, *restoring the equilibrium*, according to the "compensatory" theory of M. Wolowski, it continued to decline, and reached its lowest price in 1859, just when this coinage reached its maximum of $135,000,000, in a single year, In the meantime, we find that in 1852, just before these extraordinary movements of the precious metals were inaugurated, the reserves of the Bank of France consisted of 86 per cent. of silver to 14 per cent. of gold, whereas in 1866, when the excessive report of silver ceased, they were 19 per cent. of silver to 81 of gold, and for this whole period the coinage of 5 franc pieces had averaged less than $1,000,000 per annum. In 1871 these reserves were only 13 per cent. of silver against 87 per cent. of gold, thus a little more than reversing the condition of things as it existed in 1852, and showing clearly, that *gold was the effective currency during this period, silver being comparatively nominal, and performing but little more than the functions of a subsidiary currency.* Thus, we see that the only theory advanced by the advocates of bimetallism, possessing the slightest plausibility, *and not absolutely absurd upon its face*, signally fails to accomplish what is claimed for it; and when tested by the practical operations of economic law and commercial usage, is proven to be wholly non-effective, except under conditions which would destroy the advantages upon which the theory of its supposed benefits is founded.

Monetary Functions of Coin only local, and affect but slightly the Exchangeable Value of the Precious Metals.—We think, now, it has been shown that no such thing as an *effective* double standard has ever existed in any country or in any age, and for the sufficient reason that it carries with it *an inherent element of self-destruction arising from antagonisms of economic and physical laws, which, from their nature, are beyond the control of legislative enactments or conventional agreements.* But while it is true that all these various attempts to make the metals circulate together as legal tender money, have signally failed; it is important to observe that they have scarcely exercised *any appreciable influence* upon their relative exchangeable values in the markets of the world, *or impaired their utility for the purpose of effecting commercial exchanges.* This is especially noticeable in the example afforded by the experience of England. We have already seen that when she demonetized silver, it made a material advance in market value, instead of declining. Of course, it would be absurd to claim that this advance was due to such a fact; it was doubtless due to other causes, and only goes to show that *the inherent value of the precious metals is founded upon a utility so universal throughout the world*, that the policy of *no one country*, however important in the family of nations, can materially affect it. It is well known that in times of great monetary stringency, especially when arising from financial or commercial revulsion; all inconvertible commodities suffer great depreciation or depression in prices, and are often wholly unavailable as a means of relief. Now, while silver has had no monetary function in England for some sixty-five years, except as a subsidiary currency, to the extent of £2; yet, she has continued to control, through her exchanges, the silver produce of the world, and to supply the wants of all other countries. An examination of the various financial panics, or periods of unusual monetary pressure, which have convulsed the London money market within the last fifty years, discloses the significant fact that *in no instance did silver bullion decline in value*, but in nearly every one *a marked advance* occurred, and reached its highest point when the alarm was most intense. Thus showing, that its utility for the purposes of exchange or the storage of value, *was in nowise impaired by the fact that it was not a legal tender.* And we cannot escape the conclusion, therefore, thus made apparent, that the importance of clothing both metals with specific monetary functions, has been immensely exaggerated by the advocates of bi-metallism, and that it is really a question of *only local or domestic financial policy.*

The *coined money* of all nations is treated *only as bullion in foreign markets*, and its *local monetary valuation* in nowise affects *its exchangeable* value in those markets, or its utility in the operations of foreign exchange. The whole trouble arises from the reluctance of commercial nations to realize and charge off the loss on their stocks of silver, which has resulted from its impaired utility and consequent depreciation of exchangeable value; in the vain hope that by some device or expedient, that exchangeable value can be maintained at a ratio to gold *wholly inconsistent with the respective volumes* of the two metals, *and their relative utility* for the purposes of commerce. We think now that we have presented facts amply sufficient to sustain the theory that, contrary to the general popular impression, the depreciation of silver has been but slightly affected by German demonetization, *and is really due to a loss of utility, arising from the excessive accumulation of gold.* We have, also, stated all the essential facts relating to the production and movement of the precious metals, and the economic effect of the laws of commerce and industry which control them; to demonstrate, clearly, that no such thing as *an effective* double standard has ever existed, and from the nature of the antagonisms involved, never can exist; and that it is wholly beyond the control of statutory regulation.

—*Compiled from Louis A. Garnett's "The Paris Monetary Conference and Bi-Metallism."*

MR. MULHALL'S ESTIMATES.

MR. MICHAEL G. MULHALL, F.S.S., who has won considerable praise for his careful calculations furnishes some tables upon this matter that throw a few side lights upon the subject. Upon gold and silver he says: These two metals, which have materially aided the cause of progress, have suffered such mutations of fortune in the nineteenth century, that it may be worth while to study their antecedents. Michael Chevalier is of opinion that at the period of the discovery of America the total amount of gold in Europe was only £12,000,000, and of silver £28,000,000. At that time an ounce of gold was worth ten of silver, but as soon as the conquest of Mexico and Peru by the Spaniards poured a flood of silver into Europe this metal lost one-third of its value. In the seventeenth and eighteenth centuries gold stood for fifteen times the value of silver. A new epoch occurred with the discovery of gold in California and Australia, but silver never recovered its position as a precious metal. The following table shows the progress of both metals since the time of Columbus:—

Date.	*Gold.*	*Silver.*	*Total.*
1492	£20,000,000	£40,000,000	60,000,000
1700	227,000,000	520,000,000	747,000,000
1800	440,000,000	1,026,000,000	1,466,000,000
1848	560,000,000	1,322,000,000	1,882,000,000
1880	1,220,000,000	1,612,000,000	2,832,000,000

During 300 years of the Spanish dominion in America the mines of Mexico, Peru, and Brazil yielded a little over £1,200,000,000, of which three-fourths were silver. Since Marshall's discovery of gold in California (1848) there has been an increase of £950,000,000 in precious metals, as follows:—

	Gold.	*Silver.*	*Total.*
United States	£282,000,000	£74,000,000	£356,000,000
Australia	252,000,000	. . .	252,000,000
Spanish America	20,000,000	160,000,000	180,000,000
Russia	93,000,000	3,000,000	96,000,000
Other countries	11,000,000	55,000,000	66,000,000
	£658,000,000	£292,000,000	£950,000,000

By a strange coincidence the annual yield of California and Australia has averaged the same amount, namely £9,000,000, and in each case the highest year reached £15,000,000, the number of diggers being also about equal, and their gains averaging from £100 to £150 per man per annum. The biggest nugget was found in Australia, namely the "Welcome" nugget, found at Ballarat, June 11th, 1858, weighing 2020 ounces, worth £8376 sterling. Siberia produces at least £3,000,000 per annum, possibly double that amount, as the Russian Government is little anxious to publish the actual yield. Spanish America, during the last thirty years, has averaged from £5,000,000 to £6,000,000 sterling of silver, but the Nevada mines, in the United States, have recently eclipsed Mexico and Peru. Since the discovery of the Nevada fields, in 1862, the production of silver has rapidly increased, while the gold-fields of the world are rapidly declining in equal ratio. The official returns since 1848 may be summed up thus:—

	Gold. *Annual Production.*	Silver. *Annual Production.*	*Total*
1848 to 1851	£14,000,000	£9,000,000	£23,000,000
1852 to 1861	27,000,000	8,000,000	35,000,000
1862 to 1871	21,000,000	10,000,000	31,000,000
1872 to 1878	16,000,000	12,000,000	28,000,000

Although the stock of gold in the world is more than double what existed in 1848, and silver shows an increase of only 25 per cent., the purchasing power of these metals has declined in different ratio. Thus gold seems to have lost but 20, and silver fully 33 per cent. It appears, meantime, from the mint returns of the various countries, that, owing to the increasing demands of trade, the amount of coin issued since 1848 has been three times as much as then existed in the world (based on the estimates of the best authorities of thirty years ago):—

	Gold Coin.	*Silver Coin.*	*Total.*
Stock in 1848	£120,000,000	£240,000,000	£360,000,000
English mint	148,000,000	12,000,000	160,000,000
Indian "	1,500,000	155,000,000	156,500,000
Australian "	38,000,000	. . .	38,000,000
United States "	186,000,000	17,000,000	203,000,000
French "	270,000,000	42,000,000	312,000,000
German "	70,005,000	45,000,000	115,000,000
Austrian "	12,000,000	27,000,000	39,000,000
Russian "	84,000,000	15,000,000	99,000,000
Belgian "	15,000 000	18,000,000	33,000,000
Italian "	10,000,000	18,000,000	28,000,000
Holland, Sweden, etc.	5,500,000	31,000,000	36,000,000
Total	£959,500,000	£620,000,000	£1,579,500,000

Thus the quantities coined since 1848 sum up £1,220,000,000, which is £270,000,000 more than the world has produced of precious metals in these thirty years. In fact we had to fall back on the uncoined bullion existing in 1848, to the extent of £180,000,000 gold and £90,000,000 silver, viz.—

	Gold.	*Silver.*	*Total.*
Coined since 1848	£840,000,000	£380,000,000	£1,220,000,000
Yield of mines	660,000,000	290,000,000	950,000,000
Deficit	£180,000,000	£90,000,000	£270,000,000

How much coin has been melted down[1] or reminted it is impossible to judge, but we know that India has absorbed since 1840 no less than £10,000,000 of gold and £238,000,000 of silver, together forming a greater value than the gold taken either from California or Australia. It is generally supposed that India is to blame for the fall of silver from 63 to 50 pence per ounce; if this be so, how comes it to pass that in 1877–78, when India absorbed £22,000,000 of silver, the price of this metal was lowest? The sale of German silver tended so much to its depreciation that Prince Bismarck, after selling £32,000,000 at a loss of 15 per cent., judged proper to stop the sale in June 1879. Meantime, the United States continue to mint £4,000,000 of silver yearly, but most of it finds its way to China. The total coinage now in use in the world is approximately as follows:—

	Gold.	*Silver.*	*Total.*
Europe	£725,000,000	£375,000,000	£1,100,000,000
America, Asia, etc.	230,000,000	200,000,000	430,000,000
	£955,000,000	£575,000,000	£1,530,000,000

About one-sixth of the bullion of the world is locked up in banks, and the actual circulation compares, as follows, with population:—

	Total Specie.	*In Bank.*	*Circulation.*	*Per Inhab.*
United Kingdom	£120,000,000	£32,000,000	£88,000,000	55 shillings
France	310,000,000	90,000,000	220,000,000	120 "
Germany	123,000,000	27,000,000	96,000,000	45 "
Austria	50,000,000	16,000,000	34,000,000	18 "
Italy	48,000,000	3,000,000	45,000,000	33 "
Belgium	37,000,000	4,000,000	33,000,050	140 "
Spain and Portugal	63,000,000	8,000,000	55,000,000	55 "
Russia	110,000,000	26,000 000	84,000,000	22 "
Holland, Greece, etc.	239,000,000	17,000,000	222,000,000	. "
Europe	£1,100,000,000	£223,000,000	£877,000,000	54 "
United States	70,000,000	41,000,000	29,000,000	14 "
Australia, Asia, etc.	360,000,000	20,000,000	340,000,000	"
	£1,530,000,000	£289,000,000	£1,241,000,000	20

The official returns of bullion imports and exports show that in the last ten years Europe has imported a surplus of £327,000,000, viz.—

From United States	£108,000,000
" Australia	81,000,000
" South America, etc.	138,000,000
	£327,000,000

[1] The annual wear-and-tear of gold, between jewellers and shipwreck, is usually estimated at £6,000,000. From 1840 to 1850 the Paris jewellers consumed per annum 5¼ tons of gold, worth £720,000, and 99 tons of silver, worth £500,000 sterling.

In the following Table are shown the countries which have absorbed the above amount, Russia being the only country in Europe which exports precious metals:—

	Imports.	*Exports.*	*Surplus. Imports.*	*Surplus Exports.*
Russia	£20,000,000	£40,000,000	. .	£20,000,000
France	272,000,000	136,000,000	£136,000,000	.
Great Britain	314,000,000	268,000,000	46,000,000	. .
Austria	33,000,000	33,000,000	. .	.
Italy	4,000,000	3,000,000	1,000,000	
Spain	26,000,000	2,000,000	24,000,000	.
Scandinavia	8,000,000	5,000,000	3,000,000	. .
Low Countries and Germany	239,000,000	102,000,000	137,000,000	. .
	£916,000,000	£589,000,000	£347,000,000	£20,000,000

While the above Table shows the shipments of bullion between the various countries, there is no way of ascertaining, even approximately, how far the passenger traffic tends to restore equilibrium, or how much the precious metals may accumulate in Europe in a given period.

Banks and Paper Money.—The Chinese invented bank-notes in the ninth century, and called them "flying money," but the currency became so inflated, that two centuries later a £20 note would only purchase a pound of rice. When Sir John Mandeville visited China, in the fourteenth century, the Emperor issued leather money ("which His Majesty spends outrageously"), and some years later the currency was transferred to a joint-stock bank of Chinese merchants, who ultimately failed, and paid only two shillings in the pound. In Europe the first bank was founded by two Jews at Venice, in the thirteenth century, but no regular bank of emission seems to have been established till that of Mr. Palmstruck, in Sweden, a few years before Patterson founded the Bank of England. At the beginning of the nineteenth century paper money was in bad repute, because people remembered in Paris when a pair of boots cost £350 in the currency of the French Republic. Confidence was again shaken in 1836, when the "wild-cat" banks of the United States caused such widespread disaster. At present paper money is of general use throughout the world, summing up a total of almost £900,000,000, which is about equal to the total stock of existing gold coin. It consists of two kinds, convertible for gold and inconvertible, the latter increasing so fast that it doubles in ten years. The actual issues are—

Convertible for gold	£385,000,000
Inconvertible	505,000,000
	£890,000,000

The following Table shows the convertible paper money, and its ratio to population:—

	Amount of issue.	*Ratio to population.*
United States	£132,000,000	60 shillings
France	90,000,000	50 "
United Kingdom	47,000,090	28 "
Germany	42,000,000	19 "
Low Countries	29,000,000	60 "
Scandinavia	9,000,000	20 "
Spain and Portugal	8,000,000	8 "
Switzerland	3,000,000	25 "
British Colonies	25,000,000	3 "
Total	£385,000,000	20 "

As regards the inconvertible currency, it varies so much that its value for gold can only be given approximately. The following Table, moreover shows how the issue has increased since 1868:—

	Amount in 1868.	*Amount in 1880.*	*Value in gold.*
Russia	£108,000,000	£211,000,000	60 per cent.
Turkey	. . .	100,000,000	50 "
Austria-Hungary	40,000,000	64,000,000	99 "
Italy	36,000,000	36,000,000	89 "
Brazil	15,000,000	28,000,000	80 "
Japan	. . .	28,000,000	87 "
Cuba	5,000,000	13,000,000	45 "
Peru	5,000,000	10,000,000	50 "
Chili	3,000,000	6,000,000	80 "
River Plata	7,000,000	9,000,000	72 "
	£219,000,000	£605,000,000	

Russian paper money dates from the time of Catherine II., and its progress has been as follows:—

	Issue.	*Value in gold.*
1788	£6,000,000	97 per cent.
1817	134,000,000	25 "
1864	101,000,000	95 "
1875	128,000,000	75 "
1880	211,000,000	60 "

In 1843 the Empire declared bankruptcy by calling in the paper money, and giving thirty new roubles for one hundred old ones. The recent war with Turkey has increased the issue by 60 per cent. yet the depreciation has only been 20 per cent. showing the elastic nature of paper money and its temptation to reckless financiering. The specie reserve of the Imperial Bank is £26,000,000 sterling.

The United States have the next largest issue after Russia, one-half emitted by Government, the other half by the banks. Paper money was first used by Gen. Washington to pay his troops, but the present issue dates from the Civil War of 1862, as follows:—

	Currency.	*Value in gold,min.*
1862	30,000,000	97 per cent.
1864-1865	166,000,000	35 "
1868	137,000,000	75 "
1880	132,000,000	100 "

Since the resumption of specie payments in December 1878, the country has entered on a new era of prosperity. Turkey comes next in amount of paper money, but everything regarding Ottoman finances is involved in obscurity. In France the monopoly of emission is held by the Bank of France, with limit, £128,000,000. Since the foundation of the bank by Buonaparte, in 1803, it has twice been compelled to suspend specie payments, but its notes only declined 5 per cent. for a brief interval. The issue has doubled in fifteen years, although the growth of trade has been only 20 per cent.

	1860-1870.	1875-1879.
Average iesne	£44,000,000	£101,000,000
Trade	306,0000,000	368,000,000
Issue to trade	15 per cent.	27 per cent.

At present the issue and specie reserves are almost equal—about £90,000,000. Austrian currency consists partly of Government notes, partly of the issue of the Imperial Bank. The first emission was in 1762, since which time the growth of paper money has been thus:—

	Issue.	*Value in gold.*
1762	£1,200,000	100 per cent.
1811	106,000,000	20 "
1814	25,000,000	40 "
1841	45,000 000	30 "
1879	64,000,000	98 "

The Empire twice declared bankruptcy, first in 1811, when new notes were exchanged for the old ones at the rate of one florin for five, again in 1814, giving two florins for five, so that the holder of £100 in 1810 was holder of £8 in 1814. The Imperial Bank re-modelled the currency in 1841, putting it on a better footing, since which time (except during the war with Prussia) it has steadily improved, and is now almost at par. Specie reserve £15,000,000. The United Kingdom shows a total issue of £47,000,000, made up as follows:—

Bank of England	£29,000,000
Other banks	18,000,000
	£47,000,000

In forty years the issue has only risen 35 per cent. while the increase of trade has been 400 per cent. Germany has an ordinary issue of £42,000,000, but the Reichsbank has power to emit £9,500,000 more than at present. The currency stands thus:—

Reichsbank	£30,500,000
Small banks	5,500,000
Government notes	6,000,000
	£42,000,000

The specie reserve of the Reichsbank is 70 per cent. or upwards of its issue. Italy dates her inconvertible currency from April 1866, when war was declared against Austria. The war lasted twenty days, and cost £10,000,000 of paper money, emitted by the National Bank. According to law this bank may emit up to £40,000,000, and other banks an aggregate of £20,000,000; but it is believed the total circulation does not exceed £36,000,000. Specie reserve £3,000,-000. Brazil has £25,000,000 of Government notes, besides £3,250,000 emitted by banks. Since 1872 specie payments are suspended. Peru, Chili, Buenos Ayres, and Montevideo have also £25,000,000 of inconvertible notes, making a total of £53,250,000 for South America. Japan owes the recent inflation of her currency to the Satsuma rebellion, the notes being now 13 per cent. below par, and the specie reserve uncertain. The Low Countries have £29,000,000 convertible notes, the Netherlands Bank having a minimum specie reserve of 40 per cent. and the National Bank of Belgium 33 per ceut. Scandinavia emits £9,000,000 in the following manner:—

Danish Riks-bank	£4,000,000
Swedish Riks-bank	1,700,000
Enskilda joint-stock banks	3,300,000
	£9,000,000

The Danish Riks-bank has the sole right of emission in Denmark, keeping a minimum specie reserve of 40 per cent. The Bank of Sweden, founded by Mr. Palmstruck in 1656, suspended payments in the last century, compounding for 70 per cent. and again in 1834 it compounded for 40 per cent. of its liabilities. Swiss currency comprises the issue of thirty-five banks, the specie reserve ranging from 45 to 50 per cent. The British colonies emit £25,000,000, as follows:—

India	£12,300,000
Canada	7,720,000
Australia	4,340,000
South Africa	510,000
	£24,870,000

Great Britain and her colonies stand for one-third of the banking-power of the world, as shown in the following Table, which expresses, moreover, the ratio for population and for the estimated capital value of each country:—

	Banking power.	*Per inhabitant.*	*Ratio to capital.*
Great Britain	£780,000,000	£33	9 per cent.
United States	620,000,000	12	8 "
France	340,000,000	9	5 "
Germany	280,000,000	7	7 "
Austria	170,000,000	6	7 "
Russia	145,000,000	2	5 "
Italy	62,000,000	2	3½ "
Low Countries	65,000,000	6	2½ "
Scandinavia	40,000,000	4	4 "
Australia	60,000,000	22	. "
India	40,000,000	.	. "
South America	50,000,000	2	. "
Canada	28,000,000	7	. "
Spain and Portugal	30,000,000	1½	2 "
	£2,600,000,000	£8	

Bank rate of interest rules cheaper in England than in other countries, which as Mr. Mundella observes, is one of the secrets of England's greatness. The following Table shows approximately the value of money in England, France and Germany, during a term of thirty-three years ending with 1878:—

	England.	*France.*	*Germany.*
1846-1853	3½ per cent.	4 per cent.	4¼ per cent.
1854-1869	4½ "	4⅛ "	4½ "
1870-1873	3¾ "	4¼ "	4½ "
Average	3$\frac{9}{16}$	4$\frac{1}{7}$	4$\frac{3}{7}$

Savings banks (although first instituted at Brunswick in 1765) may be said to belong to the nineteenth century. So rapidly have they increased in the last twenty years, that Europe now counts more than 14,000 of these banks, with nearly 14,000,000 depositors, viz.—

	Savings banks.	*Depositors.*	*Amount.*	*Ratio for population.*
United Kingdom	5,068	1,668,000	£74,640,000	44 shillings
Germany	1,687	4,033,000	76,580,000	36 "
Austria-Hungary	557	1,639,000	79,150,000	44 "
France	2,221	2,853,000	40,430,000	22 "
Italy	3,627	1,115,000	28,094,000	20 "
Scandinavia	847	1,099,000	21,305,000	50 "
Switzerland	312	542,000	11,581,000	84 "
Belgium and Holland	250	273,000	6 550,000	15 "
Russia	120	260,000	3,100,000	1 "
	14,689	13,482,000	£341,430,000	25

In Australia, if the deposits in banks be regarded as savings, we find 64,000 depositors, with £52,617,000,—a sum equal to £20 per head for the population of those colonies. The total deposits in banks of all descriptions in the United States amount to £384,000,000, or about £9 per inhabitant.

Summing up all the various banks of the world including branches and savings banks, we find as follows:—

Great Britain	8,701 banks
European Continent	15,847 "
United States	6,456 "
British Colonies	815 "
Other Countries	298 "
	32,117 "

The banking business of Great Britain has multiplied threefold since 1850.

Finances and Wealth.—Sixty years ago after peace had been restored in Europe, the expenditure of all nations summed up £239,000,000: at present it reaches £778,000, having more than trebled in the interval.

	1820. *National expenditure.*	*Shillings per inhab.*	1879. *National expenditure.*	*Shillings per inhab.*
Great Britain	£54,000,000	51	£83,000,000	49
France	27,000,000	19	111,000,000	60
Germany	8,000,000	8	85,000,000	40
Russia	23,000,000	11	73,000,000	18
Austria	15,000,000	11	68,000,000	37
Italy	8,000,000	8	69,000,000	41
Low Countries	6,000,000	16	20,000.000	42
Turkey and Egypt	4,000,000	7	29,000,000	14
Spain and Portugal	9,500,000	13	34,000,000	34
Scandinavia	2,500,000	12	8,500,000	21
Switzerland and Greece	1,000,000	7	3,500,000	16
Europe	£167,000,000	16	£572,000,000	34
United States	6,000,000	14	48,000,000	22
South America	2,000,000	3	33,000,000	25
India	20,000,000	2	60,000,000	4
China and Japan	54,500,000	3	49,000,000	3
British Colonies	500,000	10	26,000,000	66
Total	£239,000,000	6	£778,000,000	16

Europe has quadrupled her taxation, the ratio per inhabitant having doubled or trebled in all countries except Great Britain, which shows a reduction of 4 per cent. The enormous increase of taxation in Europe and America arises from the accumulation of public debt and from war expenditure. If the interest on all existing debts in Europe were duly paid, it would absorb one-third of the total revenue. Compared with 1820, we find the burthen of public debt as follows:—

	1820. *Interest per inhabitant.*	1880. *Interest per inhabitant.*
Great Britain	25 shillings	14 shillings
European Continent	3 "	11 "

Thus the relative weight of our debt is reduced nearly one-half, while that of the Continent has quadrupled. The growth of debt from 1820 to 1848 was slow, the total amount in the latter year not exceeding £1,720,000,000, equal to an increase of £9,000,000 per annum. Since 1848 the average increase has been £130,000,000 a year, the principal causes of outlay being shown in the subjoined Table:—

National debts in 1848	£1,720,000,000
Crimean War	192,000,000
Italian War	105,000,000
United States War	490,000,000
Brazil and Paraguay, etc., War	85,000,000
Austro-German War	90,000,000
Franco-German War	370,000,000
Russo-Turkish War	210,000,000
Armaments	1,607,000,000
Railways, Docks, Telegraphs	575,000,000
	£5,444,000,000

The only countries that have reduced their public debt since 1820 are Great Britain and the Low Countries, as appears from the following statement:—

	Imports.	*Exports.*	*Total.*
1815	£8,136,000	2,566,000	£10,702,000
1830	5,679,000	4,087,000	9,766,000
1863	57,200,000	60,900,000	118,100,000
1877	67,900,000	82,975,000	150,875,000

Exports are usually £10,000,000 a year over imports, and all the chief products are increasing in the following manner:—

	1868.	1878.	Increase.
Opium	£12,330,000	£12,374,000	
Rice and Grain	3,780,000	9,790,000	150 per cent.
Coffee	3,310,000	6,050,000	80 "
Tea	730,000	3,062,000	320 "
Hides	988,000	3,757,000	275 "
Jute	1,601,000	3,518,000	120 "
Sundries	20,461,000	37,365,090	66 "
	£43,200,000	£75,916,000	76 "
Cotton	20,100,000	9,384,000	decr. 53 "
Total	£63,300,000	£85,300,000	incr. 35 "

Trade has, moreover, been facilitated by the introduction of paper money in 1861, the emission rising to £5,000,000 in 1864, and at present exceeding £12,000,000. The coin mostly in use is silver, the Government having coined £40,-000,000 of this metal in the last ten years, say £4,000,000 per annum. Previous to 1870 India used to absorb £20,-000,000 of bullion, chiefly silver, every year, but since that date the influx of precious metals has fallen:—

	Amount.	Per annum.
1864–1870	£138,000,000	£19,700,000
1871–1876	53,000,000	8,770,000
1877–1878	22,200,000	11,100,000

This is by some ascribed to poverty, partly resulting from famine, partly from the taxation having been increased 18 per cent. in the last ten years.

The rise of public debt has been as follows:—

	Amount.	Per inhabitant.
1814	£18,000,000	5s.
1857	60,000,000	10s.
1862	100,000,000	15s.
1879	139,000,000	14s.

The service of the debt costs £5,500,000 per annum, or 9 per cent. of the revenue; the latter averages 6s. per inhabitant.

The number of Europeans is very small, the returns of population for 1877 showing as follows:—

Hindoos	140,000,000
Mahometans	41,000,000
Buddhists, etc.	10,000,000
British troops	66,000
civilians	64,000
	191,129,000

The British are therefore less than 1 in 1000 of the population. The annual mortality among British troops in India was 69 per 1000 (say 7 per cent.) previous to 1850; the improvements introduced by order of Parliament have reduced the rate since 1870 to 20 per 1000, which saves 3500 soldiers' lives yearly. In 1877 the rate was only 13 per 1000. The annual expenditure for the garrison of white troops is £15,-000,000, or £250 per soldier. In India there are at present 644 newspapers, of which 600 are published in the various vernacular languages—chiefly in Bengali, Urdu, Marathi, Gujarati, Tamil, and Telugu. There are 40 journals published in English. The universities of Calcutta, Madras, and Bombay educate 6000 youths, and there are also State schools in the various provinces. India has 17,900 miles of telegraph constructed at a cost of £3,000,000 sterling.

Sir Hector Hay, in his examination before the House of Commons, estimated the production of precious metals from 1852 to 1875 as follows:—

Gold	£572,195,000
Silver	241,890,000
	£814,085,000

According to Humboldt's estimates in 1803, and others carried down to 1848, the yield of Spanish America from 1521 down to the discovery of gold in California was as follows, in millions sterling:—

	Before 1803.	From 1803 to 1848.	Total.
Mexico	£406	£164	£570
Peru and Chili	482	168	650
Brazil	171	19	190
Venezuela, etc.	82	46	128
	£1141	£397	£1538

The above total was distributed thus:—

	Before 1803.	From 1803 to 1848.	Total.
Gold	£301	£142	£443
Silver	840	255	1095
Millions sterling	£1141	£397	£1538

The annual production of precious metals at different epochs in the present century is shown as follows:—

	Gold.	Silver.	Ratio of gold to silver.
1801	19 tons.	856 tons.	1 to 45
1846	42 "	727 "	1 to 17
1850	134 "	778 "	1 to 7
1852	242 "	1027 "	1 to 4
1879	90 "	1060 "	1 to 12

The actual production of precious metals is estimated thus:—

	Gold.	Silver.	Total.
United States	£5,000,000	£6,000.000	£11,000,000
Australia	3,000,000	....	3,000,000
Siberia, etc.	4,000,000	....	4.000,000
Spanish America	....	3,000,000	3,000,000
	£12,000,000	£9.000.000	£21,000,000

The first bank is now said to have been at Barcelona. The Bank of England was founded by a Scotch clergyman, Rev. William Patterson, in 1694; the founder died in extreme misery.

Sweden was the first country to establish a regular bank of emission, and is still, according to an eminent English economist, the only country in Europe that can present a complete annual balance-sheet. In 1656 Mr. John Palmstruck obtained the right of emission for his bank, now known as the Riks-bank. It was forced to suspend payments in 1745, but resumed in 1776, on paying 14s. in the £ for its notes. It again stopped payment in 1818, and again resumed in 1834, this time compounding for 7s. 6d. in the £, say 37 per cent. Since then it has always paid gold for its notes on demand. In 1852 its metallic reserve was £2,-750,000, but in October 1877 it had fallen to £640,000. Its dividends for twelve years have averaged 7 per cent. In 1830 the first of the Enskilda or joint-stock banks of issue was authorised, and in a few years their number multiplied. At present there are twenty-eight banks of issue (independent of the Riks-bank, which have 153 branches all over Sweden, the country people preferring the notes to gold. The notes range from 5 shillings to £30, and the metallic reserve varies from 35 to 50 per cent. of the emission. Each bank of issue must have at least thirty-three shareholders, all Swedes; minimum capital £55,000 all paid up, each subscriber being liable for all the bank's obligations. These banks have been so well managed that their profits every year range from 4 to 20 per cent. There are also fifteen joint-stock banks of limited liability, without right of emission, and 324 savings banks.

FIGURES AND FACTS IN CONSUMPTION AND DISTRIBUTION OF PRECIOUS METALS.

THE excellent little compilation issued annually by Messrs. Fisk & Hatch contains the following, which are valuable for their form, though taken from tables printed elsewhere.

PRESENT MONETARY STANDARDS OF THE NATIONS OF THE WORLD.

I—Gold Standard Countries.

** No statistics obtainable. ‖ Bank reserve only. † Amounts are those given in the U. S. Mint Report, 1881. ‡ Bank circulation only. The total circulation is given in the U. S. Mint Report for 1880 at $778,514,300.

The introduction into Germany of the single gold standard instead of the silver standard, which prevailed up to 1871, in most of the German States, was decreed by the laws of the 4th of Dec. 1871, and 9th July, 1873. The gold mark is the $\frac{1}{1395}$ part of a pound of gold (of 500 grammes= 7.716.25 grains troy) nine-tenths fine, and it is coined into gold pieces of 20, 10, and 5 marks. Silver, nickel and copper coins are used as subsidiary coins.

The total amount of silver coin must not, under the present laws, exceed ten marks per head of population. Silver money is a tender only to the extent of 20 marks ($\$4^{76}$); but these coins are received in payment without limit of amount at the German Imperial and State Treasuries, and can at will, be changed for gold at a certain number of offices appointed for this purpose.

As it was impossible to withdraw from circulation all at once the former coins of the different States, and also to make the new Imperial money circulate in them suddenly, the laws in question established temporarily a régime like that of the double standard; and under it the former coins of the States were recognized as legal tender for payment, at the rate of one thaler for three gold marks, a rate which is based on the proportion of 1 to $15\frac{1}{2}$ as the value of the two metals. Up to the end of 1880, the amount of silver withdrawn from circulation on account of the Empire, was 1,080,486,138 marks.

Of this sum there have been—

1. Delivered to the mints for coinage of new Imperial silver money.

	Marks.
(a) On account of the Empire	382,501,331
(b) On payment of its value (2,034 pounds of fine silver.)	183,510
	382,684,841

2. Melted into ingots of silver 697,797,069 marks, which have produced 7,474,644 pounds of fine silver.

Of this quantity there have been—

	Pounds of Fine Silver.
(a) Sold on account of the Empire	7,102,862
(b) Used in coinage of new silver money	32,429
	7,135,291
Leaving a residue in possession of Government of	389,353

The sale of these 7,104,896 pounds of silver (*i. e.*, the above 7,102,862 plus the 2,034 pounds given to the mints on payment of their value) has realized as follows—

Year.	*Pounds of Fine Silver Sold.*	*Total in Marks.*	*Per Pound of Fine Silver in Marks.*	*Per English Ounce of Standard Silver in Pence.*
1873	105,923,372	9,296,686.77	87.77	$59\frac{5}{16}$
1874	703,685,175	61,135,676.29	86.88	$58\frac{3}{4}$
1875	214,898,594	18,208,449.08	84.69	$57\frac{1}{4}$
1876	1,211,759,204	93,936,482.37	77.52	$52\frac{3}{8}$
1877	2,868,095,533	230,424,238.51	80 34	$54\frac{5}{16}$

1879 (till May.)	377,744,712	27,934,417.89	73.95	50
Total . .	7,104,895,993	*567,139,992.99	79.82	$53\frac{15}{16}$

* Value in United States money, $\$134,978,318.^{33}$, taking the Mark at 23.8 cents. The cost of the Monetary Reform to Germany may be thus stated.

	Marks.
7,104,896 pounds of fine silver received into the Treasury,	663,621,109
Proceeds of sales of same as per previous table	567,139,993
Loss	96,481,116
To this must be added the other costs of the reform (mintage, loss on copper, &c.)	29,316,438
Total	125,797,554
On the other side must be credited the profits resulting from the monetary reform (viz: mintage, &c.) . .	81,758,134
Net cost of the reform to the Empire . . . . [*i. e.*, $10,488.522.]	44,069,420

The estimated amount of silver yet to be withdrawn, including the bullion balance in the vaults of the Imperial Bank, is from 410 to 500 millions of marks. If sales were resumed the Government would only have to get rid of that part of the 410 (or 500) millions of silver, which it could not employ to increase the subsidiary silver money. The Government therefore estimates the amount which would finally be left for sale, at from 337 to 427 millions of marks (*i. e.* 3,740,000 to 4,740,000 pounds of fine silver).

[NOTE.—The authority for the above account of the German Monetary Reform is a paper entitled a "Statement of the Monetary Situation in Germany," submitted by the German Imperial Government at the International Monetary Convention held in Paris in 1881.]

Amount of Silver Withdrawn, Sold and Reminted by Danish Government.

Withdrawn	$11,397,500
Sold	6,882,150
Reminted	4,515,350

The Demonetization of silver was accomplished October 1, 1876.

* So in B. C. Tupp's Report of the Proceedings of the Paris Conference, probably a misprint for DelMar.

Production of Gold and Silver for the years named, as given by Mr. Burchard, Director of the U. S. Mint, (1881).

Years.	By Weight in Kilograms.		By Value in Dollars.	
	Gold.	Silver.	Gold.	Silver.
1877	171,453	2,174,610	113,947,173	81,040,665
1878	179,175	2,282,573	119,092,786	94,882,177
1879	161,579	2,143,018	107,385,421	89,080,680
1880	160,984	2,105,966	106,989,846	87,643,072

Note Explanatory of the Foregoing Tables.—Last year we gave in these notes the estimates of Gold and Silver Production, published in the Report of United States Monetary Commission (1877). This year, for purpose of comparison, we present the estimates submitted to the International Monetary Conference held at Paris in 1881. They will be found to differ somewhat one from the other, as well as from the estimates made by Mr. DelMar, and this leads us to remark, that, at the best, the figures of gold and silver production must be looked upon as careful estimates, made from the best obtainable data, in the manner more fully set forth in Note D, rather than exact statements of facts.

II.—Production of Gold and Silver in the United Statee, according to the Mint Reports of 1874 and 1881.

Year.	Gold.	Silver.	Year.	Gold.	Silver.
1848	$10,000,000	$50,000	1865	$53,225,000	$11,250,000

1864	46,100,000	11,000,000	1881	36,500,000	42,100,000
Total, 1848–1881			. . .	1,557,141,532	501,072,260

Total Gold and Silver, $2,058,213,792.

*1874–1881 Fiscal Years ending June 30.

NOTE.—The figures presented under this head last year, were taken from the Report of the United States Monetary Commission (1877) as compiled by Mr. Alexander DelMar.

For the purpose of comparison, we now present the figures given in the Mint Reports. We do not attempt to explain the evident discrepancy between the two statements. The present director, Mr. Burchard, in his "Special Report to Congress on the Production of the Precious Metals in the United States," (1880), says of the estimates from 1848 to 1873, inclusive, which were prepared by R. W. Raymond, U. S. Commissioner of Mining Statistics, "I am unable at present to review the data from which this table was prepared, or to vouch for its accuracy."

1855	148,000	1878	10,853,400
1856	40,971,875	1879	
1857	55,366,235		
1858	61,094,740		

II. Amount in use as Coin in Thirty-one of the Principal Countries of the world as estimated by the Director of the Mint, in his last Annual Report, at—

Silver—Full value.	$2,115,189,997
Subsidiary	423,787,978
Total Silver	$2,538,957,975
Gold	3,221,223,971
Grand Total	$5,760,181,946

These figures do not include the circulation of China, which must be large, but of which it is impossible to make a reliable estimate.

III. Amount Annually used in the Arts as Estimated by the Director of the Mint (1881) at—

Silver	$35,000,000
Gold	$75,000,000

On the Stock of Gold and Silver now in the World.

Estimates of the production of the precious metals since the discovery of America, and of the stock in existence before that event (compiled from various sources), by R. B. Chapman (1881), and submitted to the Paris Conference.

	Gold.		*Silver.*	
	Kilograms.	*Lbs. Troy.*	*Kilograms.*	*Lbs Troy.*
In existence in 1492*	87,870	235,420	3,222,395	8,633,833

Values in sterling money in 1878: Gold	£1,519,482,000
Silver at 50*d.* an oz. troy .	1,298,665,000
At 60*d.* ditto . .	1,558,398,000

*Tooke and Newmarch, Vol. VI., pp. 141, 142, 150, 231.

†Soetbeer, Production of the Precious Metals (1879).

‡Sir Hector Hay, Statistical Society's Journal, 1879, p. 436.

Note.—All the authorities who have shared in the compilation of these statistics concur in the warning that the figures, especially before 1848, must be taken with reserve. They are in fact, at the best, only guesses carefully made by competent observers, after examining all kinds of data.

Even as such they are open to the following criticisms and remarks:

I. The estimate of the metal already won in 1492, avowedly, only includes the stock in Europe, Russia in Asia, and Mediterranean Africa. It does not include the stores already won from the earth in America, Asia and the rest of Africa. Even the European stock seems probably much under-estimated; and it is likely that the Asian store was already large.

II. The estimate of the produce of Extra-Russian Asia between 1493 and 1847 is by a Russian authority, M. Otreschkoff. It does not apparently include India or Japan; yet there are indications that the production of gold in India may, in the past, have been considerable.

III. The statistics since 1847 apparently include little or nothing for Extra-Russian Asia; and the greater part of Africa is thoroughly excluded. But Jacob speaks of considerable produce in Africa, and values the produce of Asia in gold at £1,235,000 a-year, and in silver at £165,000 (Jacob, *On the Precious Metals* [1831] chapter xxvii). Otreschkoff estimated the gold production of China at £600,000 a-year, and of Sumatra, Java, Borneo and the Archipelago at £2,-400,000, and the silver production of China at £188,000 a-year (Tooke and Newmarch, vol. vi., p. 762). Chevalier estimated the yearly produce, before 1865, of Extra-Russian Asia and the Asiatic Archipelago and Africa at no less than 80,000 kilos. of gold (nearly £11,000,000), and 500,000 kilos. of silver (about £4,300,000) (*Money*, edition 1866, p. 557).

IV. On the other hand, the figures in this Table since 1492 allow for no waste and no losses, as for example, by shipwrecks, fires, forgotten hoards, and the like. Perhaps, these several omissions may be set against each other, and the weight of the precious metals now in existence estimated as follows:

	Kilograms.	*Lbs. troy.*
Gold	11,200,000	30,000,000
Silver	179,200,000	480,000,000

But these estimates probably err in the direction of being too low. Adopting these figures as correct for the end of 1878, and adding to them the amounts estimated to have been produced in 1879 and 1880, according to Mr. Burchard, in the Mint Report, 1881, and assuming that the production for 1881 approximated that of 1880, we arrive at the following figures as the amount of the precious metals in existence at the end of 1881:

	Gold.	*Silver.*
Amount in existence in 1878, ozs. troy	860,000,000	5,760,000,000
Amount produced in 1879 " . . .	5,194,764	68,898,028
1880 "	5,175,635	67,706,806
1881 "	5,175,635	67,706,806
Total in existence at the end of 1881	375,547,034	5,964,311,640
Equivalent in gold dollars: Gold		$7,763,223,772
Silver, at 51$\frac{11}{16}$d. an oz. troy (the average value for the year 1881)		6,757,843,025
Total Gold and Silver		$14,521,066,797

The weight of *gold* in existence—the above estimate being correct—is to the weight of *silver* as:—1 : 15.88.

The average ratio of the market value of gold to silver for the year 1881 was as 1 : 18.24.

On the Relative Value of Gold to Silver.—

TABLE 1.—As stated by Lord Liverpool in his letter to the King of England.

In Persia, according to Herodotus	1 : 11⅔
In Greece, at same period	1 : 13
In Greece, in the time of Plato	1 : 12
In Greece, it is stated by Xenophon at	1 : 10
After the plunder of gold from the temple of Apollo, according to Menander, it was	1 : 10
In the reign of Alexander the Great, it was	1 : 10
In Rome, according to Pliny the elder	1 : 14$\frac{12}{25}$
In Rome, after the tribute from the Italians	1 : 10
The plunder of gold from the Gauls by Julius Cæsar, reduced the proportions to	1 : 7½
In the reign of Claudius, Tacitus states it at	1 : 12½
Until the reign of Alexander Severus, it continued	1 : 12½
In the reign of Constantine the Great	1 : 10½
The disorders in the Roman Empire under Arcadius and Honorius, raised it to	1 : 14⅔
From which it appears that gold, unless when depressed by sudden and unusual occurrences or enhanced by a dread of public insecurity, may be stated to have been for upwards of nine hundred years, in the proportion of . .	1 : 10 or 12

TABLE 2.—According to Dr. O. J. Broch, International Monetary Conference, 1878.

In the middle ages the relation in the price of Gold and that of Silver was from 10½ to 12.

According to the various monetary laws, this relation should have been:

In the year 1526, in England	1 : 11.30
" " 1542, "	1 : 11.10
" " 1551, in Germany	1 : 11.17
" " 1559, "	1 : 11.45
" " 1561, in France	1 : 11.70
" " 1575, "	1 : 11.68

It was only after the discovery of the rich mines of Silver at Potosi in 1545, and still more after the invention of the method of cold amalgamation in 1557, that Silver began to fall as compared with Gold.

According to monetary laws, the relation was:—

In the year 1604, in Great Britain	1 : 12.16
" " 1612, "	1 : 13.20
" " 1619, "	1 : 13.35
" " 1640, in France	1 : 13.51
" " 1667, in Germany	1 : 14.15
" " 1669, "	1 : 15.11
" " 1670, in Great Britain	1 : 14.60
" " 1679, in France	1 : 15.00
" " 1685, "	1 : 15.10

According to the Exchanges quoted at Hamburg, with reference to Dutch Ducats, the following relation is calculated:—

1687-1700, average . . .	1 : 14.97	1741-1799, average . . .	1 : 14.74
1701-1720, " . .	1 : 15.21	1799-1800, " . . .	1 : 15.42
1721-1740, " . . .	1 : 15.08		

In the XIXth century the relation of the price of gold and that of silver, has been in the London market:—

1801-1811, average .	1 : 15.60	1831-1840, average . .	1 : 15.07
1811-1820, " . . .	1 : 15.61	1841-1850, " . .	1 : 15.83
1821-1830, " .	1 : 15.80		

After the discovery, in 1848, of rich gold beds in California, and later in Australia, the relation in the London market was:—

1850, average	1 : 15.70	1859, average	1 : 15.21
1851, "	1 : 15.46	1860, "	1 : 15.27
1852, "	1 : 15.59	1861, "	1 : 15.50
1853, " . .	1 : 15.33	1862, " . . .	1 : 15.35
1854, "	1 : 15.33	1863, " . .	1 : 15.38
1855, " .	1 : 15.30	1864, "	1 : 15.35
1856, " . . .	1 : 15.33	1865, " . .	1 : 15.46
1857, "	1 : 15.29	1866, " . . .	1 : 15.41
1858, "	1 : 15.36		

After the discovery of rich silver mines in California, in Nevada, Arizona, and Colorado, the price of silver began to fall, and the fall was accelerated by the introduction of the Gold Standard in the place of the Silver Standard in Germany in 1872, and in the Scandinavian countries in 1873.

The relation of Gold to Silver in the London Market was:—

In the year 1867, average	1 : 15.67	In the year 1873, average	1 : 15.92
" 1868, "	1 : 15.60	" 1874, "	1 : 16.17
" 1869, "	1 : 15.60	" 1875, "	1 : 16.58
" 1870, "	1 : 15.58	" 1876, "	1 : 17.48
" 1871, "	1 : 15.58	" 1877, "	1 : 17.01
" 1872, "	1 : 15.63		

The lowest price of Silver in relation to Gold was reached in July, 1876; the price of Silver, $\frac{37}{40}$ fine, had then fallen in London to 46¾d. per ounce, a price which corresponds with the relation of 20.17 between the price of Gold and that of Silver of the same fineness.

Relation of the price of Gold to that of Silver according to the Monthly Average Price of Silver in the London Market, submitted to the Paris Conference (1881) by Dr. O. J. Broch.

Years.	Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Annual Average.

* Germany, Denmark, Sweden and the United States demonetize silver.

† The Latin Union agree to limit their silver coinage exclusively to subsidiary coins.

‡ Holland determines to coin silver only on Government account.

‖ Spain stops silver coinage except on Government account

** The United States remonetize silver, again adopting the double standard.

¶ The Latin Union renewed for another term of years.

§ Germany contemplating the remonetization of silver. Japan adopts silver as a standard.

a Paris Monetary Conference adjourns, (without definite action), to April, 1882.

According to Dr. Soëtbeer of Göttingen, (1879 and 1880).

* From the Report of the United States Monetary Commission, 1877.

† Eagles, half-eagles and quarter- eagles.

The weights above given are for the amount of *pure metal* in the coin. All the full value coins are (since 1837) .900 fine, *i. e.*, there is .100 of alloy to .900 of pure metal. The 371.25 of pure silver given in above table is the equivalent of the 412½ grain dollar of coined silver.

§ Half dollars, quarters, dimes and half dimes.

HOW MONEY IS MADE.

ALTHOUGH the United States Mint is a never-failing attraction to visitors, it is probable that but a few obtain more than a very superficial glimpse of the manifold chemical and delicate mechanical manipulations through which the precious metals must pass before evoluting into the noble double eagle or the bright new silver dollar; and it is perhaps with a slight feeling of disappointment that the visitor, after completing the circuit of the operating rooms which are open to public inspection, is ushered into the cabinet of coins, and politely invited by the guide to make himself perfectly at home, stay as long as he likes, and "look at the coins of all nations and specimens of gold from all parts of the world." It is with a view of partially satisfying the curiosity which may have been whetted by such a visit that this descriptive article is written, and it is proposed to give the reader a little glimpse behind the scenes, and to initiate him into some of the delicate means by which the noble metals are prepared to receive the impress of the American Eagle. The early history of the precious metals forms an exceedingly interesting subject of research, but an attempt to explore this tempting by-path of knowledge would be impossible within the brief space of one article. The precious metals are never found in the pure state, and they are deposited at the mint alloyed with other metals and in a great variety of forms, such as native grains, dust, amalgam, bars or pigs, old jewelry, etc. The mixed metals are known under the generic name of "bullion." The bullion is first weighed in the "deposit weigh-room," where several balances are kept for the purpose; the largest of these will weigh as much as ten thousand ounces in one draught, and the scale will readily turn, even when loaded to its full capacity, with a weight of one-hundredth part of one ounce. The metal is then placed in a box provided with a cover and lock and taken to the "deposit melting room." Here it is put in a crucible which has been previously heated in the melting furnace, and covered with a thin coating of borax, which forms a sort of fluid glass, acting as a hermetic cover to protect the metal, when it is molten from the oxidizing influence of the air. A stalwart workman, wearing a pair of large canvas mitts (somewhat resembling boxing-gloves) stands guard, and grasping, with a pair of iron tongs, a rod or stick made of plumbago, he stirs the now fluid mass back and forth, up and down, round and round, for the purpose of rendering it thoroughly homogeneous; the metal is then cast into an iron mould called a "shoe." It is plunged into water to cool, as well as to dissolve off any particles of the borax glass which may have adhered to its surface. It is now returned to the weigh-room and reweighed. A slight loss in weight usually occurs owing to a practical refining out of the base metals, and the new weight is the amount with which the depositor is credited. Let us suppose that a depositor brings a miscellaneous assortment of old gold; watch-cases, jewelry, dentist's plates, etc., representing every grade of fineness or proportion of pure gold, desiring to obtain its equivalent in coin. We will follow in imagination the usual course pursued. After the metal has been returned from the melting-room (where it was cast into the shoe mould) and the bar reweighed, a small chip is cut off from one end of the bar and taken to the assay laboratory.

The Analysis.—The sample is laminated or rolled into a thin ribbon and stamped with the number of the deposit which it represents, it is then assayed to determine the proportion of gold, silver, and base metal, and so accurate are the processes of assay, that the exact value of a deposit, frequently aggregating many thousands of dollars in value, is determined to the fraction of a cent by calculations based on the assayer's report. The largest weight which the assayer uses in making an analysis of gold bullion is the French half-gramme (or about seven and three-quarter grains Troy). The balances used in this work are marvels of mechanical construction; they are so sensitive that a weight of one-twentieth of a milligramme (less than one-thousandth of a single grain) will cause the indicator needle to deflect a very appreciable distance from the zero point on the graduated scale marking the equilibrium. These little balances are inclosed in glass cases, provided with sliding windows to exclude any draught of air. The beam is usually made of aluminum, one of the lightest metals, and the knife edges rest on jewels. The weights are made of gold, silver and aluminum, and are graduated from the half gramme, which is arbitrarily denominated "1,000," down to the ten thousandth degree. The assayer first determines approximately the relative proportions of the metals existing in the alloy, and from this bases his more careful determinations; he weighs out on the balance exactly one-half gramme, or 1000 parts of the alloy; he wraps this in an envelope of pure lead and rolls it into the form of a "bullet." The bullet is then placed in a small "cupel" or cup, made of calcined bone-dust, which has been brought to a white heat in the muffle or oven of the assay furnace. The mass melts immediately, and the lead oxidizes rapidly by absorbing oxygen from the heated air which passes continually over its surface, and on account of the extreme fluidity of the oxide it sinks into the pores of the cupel, which absorbs it as readily as a sponge absorbs water; the lead also carries with it all the base metals which may be originally combined in the alloy, but the precious metals not being oxidizible, simply melt, and are not so fluid as to be capable of sinking into the cupel. A preparation thus takes place, and at the moment when all the base metal is removed a beautiful "flash" is observed to take place on the surface of the metal; the "button" of purified gold and silver resulting from this operation is then removed from the cupel, returned to the balance, and weighed; the loss indicates the proportion of base metal. Another weighing of the sample is then made, to which is added pure silver in the form of fine granules, in the proportion of about two parts of silver to one of gold, the alloy is enclosed in a sheet of lead and cupelled as before; the silvery button remaining is laminated, coiled into a roll called a "cornet," and boiled in nitric acid. The acid dissolves the silver, leaving a little roll of pure gold. This gold cornet is then annealed in the furnace to give it toughness, and is finally weighed; this weight represents the proportion of pure gold. The proportion of silver is ascertained by subtracting the weight of the pure gold plus the weight of the base metal from the original weight of the assay sample. Silver was formerly assayed in the same way, but it was long known that the result was not quite accurate, owing to a partial volatilization of the metal when exposed to the high temperature of the fire. Experiments were some years since instituted by the French government to overcome this difficulty, which resulted in the beautiful "humid process" devised by a celebrated chemist, Gay Lussac. This is one of the most accurate methods known to chemical science, and so complete was Gay Lussac's original description that but little room has been left for any improvements, and many thousands of dollars' worth of silver bullion are rapidly and accurately determined every day in the mint in this way. The rationale of Gay Lussac's method is very simple, viz.: a given amount of chlorine gas will precipitate a definite proportion of pure silver from its solution in nitric acid. The assayer prepares two solutions of common salt-water (chloride of sodium); one is known as the "normal solution," and the other as the "decimal solution." One begins and the other finishes the assay. The sample of silver to be assayed is weighed out, as in the case of gold, the assayer taking care to place a sufficient weight of the alloy in the scale-pan to contain at least one gramme (a little over fifteen grains) of pure silver; the weighed sample is then placed in a glass bottle, and a charge of nitric acid is added to it; the acid is caused to boil, and in a short time the silver alloy is completely dissolved. A charge of the normal salt solution is then allowed to flow into the bottle from a glass "pipette," which is made of such a capacity that it shall contain just enough salt-water to precipitate one gramme of pure silver; the chlorine in the salt-water combining instantly with the silver, precipitates it in the form of a white cloud; the bottle is agitated rapidly for a few moments, when the precipitate settles to the bottom, leaving a clear solution above; the assayer next allows a charge of the "decimal solution," which is one-tenth the strength of the normal solution, to flow into the bottle from a glass tube with graduated divisions, each division marking one hundredth the capacity of the large pipette. If any silver remains in the solution a cloud will be observed on the surface. Now, as this decimal charge is one-tenth the strength and one-hundredth the volume of the large pipette, it will, of course, precipitate just one-thousandth as much silver, or one milligramme. The bottle is again agitated to settle the precipitate, and successive charges of the "decimal solution" are added until all the silver is precipitated, and then a simple rule of three sum gives the exact proportion of pure silver contained in the original weight of the alloy. The assayer guards against all probable sources of error by an elaborate system of checks, and each set of assays is accompanied in all its mutations by one or more "proofs" or synthetic assays, made either from pure metal or from alloys of known composition. After the exact proportions of gold, silver, and base metal constituting the alloy are reported by the assayer to the superintendent the value of the deposit is calculated and the depositor is paid the full equivalent, less the charges for refining, the amount of charges depending, of course, upon the nature of the bullion.

The Refining Process.—The metal now passes into the hands of the "melter and refiner." We will suppose that the representative deposit that we have already alluded to contains a small percentage of base metals, such as tin and lead, which tend to make the alloy brittle or "short," rendering it unfit for coin. The first operation to which it is subjected is intended to eliminate these impurities, and is called "toughening." The metal is melted in a crucible and an oxidizing flux (saltpetre) is added to it while fluid, the saltpetre or niter decomposes and liberates oxygen gas; the oxygen seizes the base metals forming oxides; these rise to the surface and are dissolved in the flux; the flux, when sufficiently thick, is skimmed off, and the purified metal, consisting only of gold and silver, is cast into a bar or poured into ice water to form granulations. The next operation is designed to remove the silver; this is effected by boiling in nitric acid, when the silver dissolves, leaving the gold in a finely divided state. The "plant" used for this purpose consists of a number of large porcelain jars capable of holding about fifty gallons of nitric acid each. These are arranged in a double row and heated by steam pipes; they are inclosed in a chamber provided with sliding doors to prevent the escape of the noxious fumes, which are carried into a tall chimney from which they issue in a yellowish cloud. The dissolved silver is drawn off by means of a large siphon made of native California gold (valued at three thousand dollars) and transferred to a vat made of wood, resembling those used in breweries. The vat contains several hundred gallons of salt water, and the silver is precipitated by the chlorine, a workman facilitating the operation by agitating the liquid with a large paddle provided with a long handle.

The precipitated silver is drawn off into large filters placed on trucks and thoroughly washed by running water until the test of litmus paper shows that all trace of acid has been removed. The chloride of silver now resembles pure white cottage cheese. It is transferred to another vat lined with lead. Zinc (which has been previously granulated by pouring while melted into cold water) is added to the silver, together with a little sulphuric acid; the chlorine deserts the silver for the baser metal, forming a soluble salt of zinc. The solution is allowed to flow off, and the precipitated silver is pressed into round cakes called cheeses, dried in an oven and melted in the furnace; it is finally cast into a bar, and is found to be uncontaminated with its former base associates. The gold which remained in the porcelain jars is in the form of fine powder, and resembles sifted gravel as nearly as may be. It is also pressed into cheeses, dried, and melted under a covering of borax or charcoal, and is cast into a bar of nearly pure gold. All that now remains for the melter and refiner to do is to weigh out the requisite amount of copper to form the coin standard, which is nine parts of gold or silver (as the case may be) and one part base metal. In other words, our coin standard is nine-tenths fine. The alloy is melted in large crucibles made of plumbago and constantly stirred to render the mass homogeneous. The standard metal is cast into flat bars called ingots, twelve inches long, one-quarter of an inch thick, and from three-quarters to one and a half inches wide; the ingots are filed to remove the ragged edges, and the rough tops are cut off with large steam shears. Two samples from each melt are assayed, and if the alloy is found to be of the proper fineness and of uniform composition, they are delivered to the coiner.

The Mechanical Process.—The coiner transfers the ingots to the rolling mill, and when they have been sufficiently laminated by successive rolling and annealing, the strips are passed through a machine called the "draw bench," for the purpose of reducing them to the exact thickness required for the coin; this operation is similar in principle to the wire drawing, and consists simply in squeezing the flat strips of metal between two stationary steel cylinders set to the desired gauge. The strips are now passed to the cutting press, which consists essentially of a round punch, the size of the "planchet," or blank required for the coin, working up and down very rapidly into a hole on the steel bed plate. The strips are passed by hand through the press, and the blanks fall into a box below. The unused portion of the strips, or "clippings," is returned to the melter and refiner and remelted. The planchets are next taken to the "adjusting room," where may be seen a number of ladies seated at a long table, each one provided with a little balance and a file. Every lady is supplied with a pile of planchets, and she proceeds very deftly to weigh each one against a properly adjusted counter-weight. The planchets that are too light are thrown into a separate pile and returned to the melter and refiner, to be remelted with the clippings, while those that are too heavy are adjusted by filing on the edge. Within a very few years a novel automatic adjusting machine, designed by Mr. Ludwig Seyss, of Vienna, has been introduced for the purpose of facilitating the work and diminishing the necessity of hand labor. It is an exceedingly beautiful and ingenious piece of mechanism, but is too complicated to admit of an intelligible description without the aid of sectional drawings. A description of this instrument will be found in the Journal of the Franklin Institute. It not only weighs the blanks automatically, but separates them into three kinds; those that are too heavy falling into one box, the light ones into another, and those of the right weight into a third. The machine never makes a mistake, and will weigh and assort as many pieces in an hour as five expert ladies can do by hand, but when we consider that there are ten balances in the machine engaged in weighing at the same time, and only five used by the ladies, they must be awarded the palm for expedition. The machine also requires the constant attention of one person to supply the blanks or planchets, and when the additional cost of steam-power and wear and tear of the parts are added to the original expense of the apparatus, its merit from an economical point of view is not so great as would at first sight appear. The next operation to which the blank pieces are subjected is to impart the raised edge, technically called "milling." The machine used for this purpose is an American invention, and is admirable for its simplicity as well as for the rapidity with which it accomplishes the work. The blanks are fed by an attendant into a tube, and they are drawn horizontally, in single file, through a gradually narrowing channel formed by a groove in the periphery of a rapidly revolving disk on one side, and a stationary segment of corresponding curve on the other, keyed a little closer to the wheel at one end. The blanks are in this way compressed on the rim, acquiring the "milled edge." This machine is capable of milling as many as 1,200 pieces per minute. The blanks are now taken to the pickling vats, where they are immersed for a couple of minutes in weak sulphuric acid for the purpose of removing the black oxide of copper; they are then washed in pure water and placed in a rotating cage filled with sawdust. This rapidly dries the blanks, and when removed to the coining room they have acquired a fine, bright surface.

The Coining.—The early methods of coining were exceedingly crude and imperfect. The metal was hammered into a thin plate; pieces of irregular size were cut out and beaten into a bullet shape; this bullet was placed on a sort of anvil having the reverse die cut upon its face. The obverse die was held in the hand like a punch, and by the aid of a heavy hammer the bullet was flattened out and coined at the same time. There are many interesting specimens of this antique coinage to be seen in the mint cabinet. The oldest pieces are to be found in the case devoted to coins of the Greek Republic, dating back to seven centuries before the Christian era. It was not until the middle of the sixteenth century that the forge and hammer were succeeded by more scientific methods. In the British mint the coins are struck in the presses worked by a screw; but we have adopted the admirable invention of a Frenchman, named Thenolliér, which has been further improved upon by the skill of a former coiner, the late Mr. Franklin Peale. This machine operates on the mechanical principle of the "toggle joint" (of which the elbow-joint is a familliar example). It is controlled by a lady who feeds it with the blanks, which she places in a vertical tube. A pair of "feeders" catch the bottom piece and carry it forward, where it rests in the "collar" between the upper and lower dies; the lever is now descending with the upper die while the lower die remains fixed; the pressure increases with perfect uniformity up to the maximum, which is equivalent to about ten tons for the dime, 80 tons for the double eagle, and 120 tons for the silver dollar. The pressure gradually decreases again by reason of the relaxation of the upper joint, the lower die pushes the piece out of the collar into which it has expanded, and from which it acquires the "reeded edge." Meanwhile, the feeders have provided another blank, and as they bring it forward they push the coined piece into a channel, through which it slides into a box beneath the machine. The coins are then inspected by the foreman, and any cracked or defective pieces set aside. The larger denominations of coin are counted by hand, and the smaller pieces, as well as the "bronze" and "nickels," are numbered by means of a simple and ingenious arrangement called the counting board. After the coins have thus been counted and weighed, they are tied up in linen bags and delivered to the treasurer in drafts of $5,000 each. The accuracy of the adjustment of the weight is so nice that there is rarely a deviation from the true standard weight of as much as one hundredth of an ounce in any delivery of either gold or silver coin. As a final precaution, the assayer is required by law to select at random one coin from every lot of twenty thousand dollars; these are sealed in envelopes, numbered, and placed in a strong box provided with two locks; the key of one is kept by the treasurer and the other by the assayer. These sample pieces are called the "pyx." They remain sealed until the commissioners appointed by the President assemble at the annual "assay" in February of each year to test their purity and weight; and it has rarely, if ever, happened that any piece has been found to exceed the small limit of "tolerance" allowed by law.

The manufacture of the dies for coin requires a high order of artistic and mechanical labor, involving "the talent of the designer and the skill of the engraver and sculptor." A detailed description of the processes involved would necessarily extend this article beyond the limits assigned to it. A brief outline must, therefore, suffice. The artist first makes a free sketch on paper, he then models his design in wax upon a glass plate, and it is probably five times the size intended for the coin; from this he takes a cast in plaster, which serves, when coated with plumbago, as a matrix from which an electrotype in copper is obtained. The electrotype relievo, after being finished by hand, is used as the model from which the steel die is cut by means of a reducing pantographic cutting machine, somewhat similar to those used for reproducing designs for steel rolls used in making printed fabrics. A traveling pointer attached to the long arm of a lever is caused to move back and forth over all portions of the raised model, and a steel drill attached to the short arm is thus caused to cut an intaglio design in a block of steel corresponding in all its details to the model, but reduced to the proper diameter for the coin; the stars and lettering are now added, and the whole is finally touched up by the hand. The intaglio is not used for coining, but from it a relievo called the "hub" is made. A block of steel having been softenened by annealing, is placed in a screw press carrying the "hub," and by a succession of blows, followed by frequent annealings, the die from which the coin is to be made is produced. It is possible (owing to the great value of the raw material) to bring the processes involved in our gold and silver coinage to the perfection which would not perhaps be found profitable in any ordinary industry, and this fact, together with the national pride which is felt in the matter, should offer encouragement to the invention of all practicable methods of producing perfect work and preventing losses.

—*A. E. Outerbridge, Jr., in the Scientific American.*

PROCEEDINGS OF THE ASSAY COMMISSION OF 1882.

WEDNESDAY, *February* 8, 1882.

THE Commissioners appointed by and under the provisions of section 3547 of the Revised Statutes of the United States, met in conformity therewith for the purpose of making the annual trial of the coins reserved at the mints at Philadelphia, San Francisco, Carson, and New Orleans, during the year 1881. The director of the mint having announced that a quorum was present, Hon. William Butler, judge of the district court for the eastern district of Pennsylvania, took the chair, and the director's clerk was designated as secretary. The letter of the President appointing the following special commissioners was then read:

Hon. William B. Allison, U. S. Senate; Hon. William S. Rosecrans, House of Representatives; Prof. John Towler, Hobart College, Geneva, N. Y.; Hon. Paul A. Chadbourne, Mass.; Prof. Chas. E. Munroe, Naval Academy, Annapolis, Md.; Prof. J. E. Hilgard, U. S. Coast and Geodetic Survey; Dr. Wm. Pepper, University of Pennsylvania, Philadelphia, Pa.; Dr. Le Baron Russell, Boston, Mass.; Dr. W. P. Lawver, Assayer, Mint Bureau; Anthony J. Drexel, Esq., Philadelphia, Pa.; Thomas Donaldson, Esq., Philadelphia, Pa.; Hon. Horatio G. Fisher, chairman of the House Committee on Coinage, &c.; Hon. J. B. Belford, chairman of the House Committee on Expenditures in the Treasury Department; George W. Childs, Esq., Philadelphia. Senator Allison, Professor Towler, Doctor Russell, and Mr. Drexel declined the appointment. The *ex-officio* members of the Commission were Hon. Wm. Butler, judge of the district court of the United States for the eastern district of Pennsylvania; Hon. John Jay Knox, Comptroller of the Currency, and Herbert G. Torrey, Assayer of the U. S. Assay Office at New York. The Director of the Mint and all the members of the Commission who accepted the appointment answered to the roll-call except Hon. J. B. Belford.

On motion of Mr. Donaldson, the reading of the section of law under which the Commission is constituted, the several sections bearing upon the duties of the Commissioners, the rules for the organization and government of the Board, and the minutes of the last preceding assay was dispensed with.

On motion of Professor Hilgard, the chairman appointed and announced the following committee:

On Counting—Messrs. Donaldson, Fisher, and Pepper.

The chairman then announced the following committees:

On Weighing — Messrs. Hilgard, Fisher, Donaldson, Knox, and Childs.

On Assaying—Messrs. Rosecrans, Torrey, Chadbourne, Pepper, Munroe, and Lawver.

On motion of Professor Hilgard, it was ordered that upon the reserved coins being produced, selections should be made by the committees on weighing and assaying of a sufficient number of pieces for their purposes, and the number and dates of the deliveries from which pieces were taken should be minuted, and the selected coins be kept distinct from each other until the examination be completed. The Commission then took a recess subject to the call of the chairman.

THURSDAY, *February* 9, 1882.

The Commission convened at 3 P.M., at the call of the chairman, and came to order. Present: Messrs. Butler, Torrey, Rosecrans, Chadbourne, Munroe, Hilgard, Lawver, Donaldson, and the Director of the Mint. The committee on Counting submitted the following report, viz.:

The Committee on Counting reports that all the packages of reserved coins were opened and counted by it, or in its presence, and that the count verified the respective amounts exhibited by the abstract sheets from the books of the mints. A sufficient number of each denomination of coin of the coinage of the several mints was taken from the reserved coins by the Committees on Weighing and Assaying. The remaining coins from all the mints were at once delivered to the Superintendent of the Philadelphia Mint. The coins selected and weighed by the Committee on Weighing have also been delivered to said Superintendent, as well as the bullion made from the coins selected, assayed, or melted by the Committee on Assaying. All the packages of reserved coins from the several mints delivered to the Assay Commission of 1882, have, after use in the manner provided by law, been returned to and placed in the charge of the Superintendent of the Philadelphia Mint.

THOMAS DONALDSON.
H. G. FISHER.

On motion of Professor Hilgard, the report was adopted.

The Committee on Weighing submitted the following report, viz: The Committee on Weighing beg leave to report that they have concluded the examination intrusted to them in accordance with the order of proceedings adopted by the Commission. Single coins taken at random from the reserved coins of various deliveries throughout the year, kept separate and distinguished as to their origin and date, were accurately weighed; the gold coins to $\frac{1}{100}$ grain, the silver to $\frac{1}{10}$ grain. The aggregate weight of gold coins, similarly selected, but not kept separate, to the amount of $1,000, was also ascertained, as well as that of $100 standard silver dollars of each mint. In addition, the standard weights used for the verification of those in constant use in the Mint have been verified by comparison with the verified copy of the troy pound designated by law, (which itself should not be used oftener than once in ten years,) and have been found entirely satisfactory.

The following are the results of the selected coins:

Philadelphia gold mass weights.

134 eagles	Standard weight	72.025 oz.
	Actual weight	72.023 oz.
153 half eagles	Standard weight	41.119 oz.
	Actual weight	41.114 oz.

Philadelphia—Single pieces.

From the foregoing weighing it appears that all the coins weighed are within the limits of exactness required by law, and that, in fact, very few vary from the standard by one-half the tolerance. The results are therefore entirely satisfactory.

J. E. HILGARD.
THOMAS DONALDSON.
H. G. FISHER.
JNO. JAY KNOX.
GEO. W. CHILDS.

On motion of Professor Munroe, the report was adopted.

The Committee on assaying submitted the following report, viz: That in conformity with the law and regulations governing this Commission they have taken the gold and silver coins reserved from the several mints, to wit, Philadelphia, San Francisco, Carson City and New Orleans, the same being samples representing each delivery made during the year 1881, in the several mints named, from the coiners to the superintendents, and have assayed the same in mass, and also the individual coins, with the following results:

Gold—Philadelphia.

* Made from condemned coin of 1880.

From the foregoing, it will be seen that the greatest excess in the assay value of the gold coinage above the standard at the different mints, as stated in the following table, while the limit of tolerance is one-thousandth, is—

At Philadelphia, .2 of one-thousandth.
At San Francisco, .0 of one-thousandth.
At New Orleans, .1 of one-thousandth.
At Carson, .3 of one-thousandth.

The greatest deficiency below the standard, the limit of tolerance being one-thousandth, is—

At Philadelphia, .2 of one-thousandth.
At San Francisco, .4 of one-thousandth.
At New Orleans, .2 of one-thousandth.
At Carson, .3 of one-thousandth.

For silver, the maximum assays above the standard, the limit of allowance being 3 one-thousandth, is—

At Philadelphia, 1.1 one-thousandth.
At San Francisco, 0.9 one-thousandth.
At New Orleans, 0.9 one-thousandth.
At Carson, 1.5 one-thousandth.

The greatest deficiency below the standard, the tolerance being the same, 3 one-thousandth—

At Philadelphia, 0.8 one-thousandth.
At San Francisco, 1.7 one-thousandth.
At New Orleans, 1.6 one-thousandth.
At Carson, 1.5 one-thousandth.

Hence, the greatest deviation from the standard in the coinage examined is far within the limits allowed by law, and exhibits a remarkable degree of uniformity in mixture, while there appears a very great perfection of workmanship.

An analysis of the copper alloy present shows that it is substantially in accordance with the law and regulations.

W. S. ROSECRANS.
CHAS. E. MUNROE.
W. P. LAWVER.
H. G. TORREY.

On motion of Mr. Chadbourne, the report was adopted.

On motion of Mr. Donaldson, the following resolution was adopted:

"*Resolved*, That the Assay Commission having examined and tested the reserved coins of the several mints for the year 1881, and it appearing that these coins are within the tolerance prescribed by law, the trial is considered and reported as satisfactory."

On motion of General W. S. Rosecrans, the following resolutions were adopted:

"*Resolved*, That the thanks of the Commission be and are hereby tendered to Hon. A. Loudon Snowden, Superintendent of the Philadelphia Mint, for his kindness and attention to them during their meetings.

"*Resolved*, That the thanks of the Commission are also tendered to the officers and other employees of the mint who assisted in the annual assay of 1882."

On motion, the Board adjourned to meet at 10 A. M., Friday.

FRIDAY, *February* 10.

The Board convened at the hour appointed.

Present: Messrs. Butler, Knox, Rosecrans, Munroe, Hilgard, Lawver, Donaldson, Fisher, Torrey, Childs, and the Director of the Mint, Hon. Horatio C. Burchard. On motion of Dr. Lawver, seconded by Professor Munroe, the following resolution was adopted:

"*Resolved*, That the Assay Commission of 1882, in recognition of the long services of William E. DuBois, assayer of the United States Mint at Philadelphia, who entered the Mint in September, 1833, died July 14, 1881, after a service of forty-seven years, and of Charles B. Hare, foreman of the Assay Office of the said Mint, who entered that institution in 1830, died May 29, 1881, after a continuous service of fifty-one years—enter this minute upon the records of the Assay Commission of 1882, in appreciation of the faithfulness of these efficient officers."

On motion, the Commission adjourned *sine die.*

LAWS RELATING TO THE RESERVATION OF COINS FOR THE ANNUAL ASSAY.—*Revised Statutes, June* 22, 1874. Title XXXVII.—Coinage, Weight, and Measures.

Standard Weight of Gold Coins.—Sec. 3511.—The gold coins of the United States shall be a one-dollar piece, which, at the standard weight of twenty-five and eight-tenths grains, shall be the unit of value; a quarter-eagle, or two-and-a-half-dollar piece; a three-dollar piece; a half-eagle, or five-dollar piece; an eagle or ten-dollar; and a double eagle, or twenty dollar piece. And the standard weight of the gold dollar shall be twenty-five and eight-tenths grains; of the quarter-eagle, or two-and-a-half-dollar piece, sixty-four and a half grains; of the three-dollar piece, seventy-seven and four-tenths grains; of the half-eagle, or five-dollar piece, one-hundred and twenty-nine grains; of the eagle, or ten-dollar piece, two hundred and fifty-eight grains; of the double eagle, or twenty dollar piece, five hundred and sixteen grains.

Standard Weight of Silver Coins.—Sec. 3513.—The silver coins of the United States shall be a trade dollar, a half-dollar, or fifty-cent piece, a quarter dollar, or twenty-five cent piece, a dime or ten-cent piece; and the weight of the trade-dollar shall be four-hundred and twenty grains troy; the weight of the half-dollar shall be twelve grams (grammes) and one-half of a gram, (gramme;) the quarter-dollar and the dime shall be, respectively, one-half and one-fifth of the weight of said half-dollar.

AN ACT to authorize the coinage of the standard silver dollar, and to restore its legal-tender character.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there shall be coined at the several mints of the United States, silver dollars of the weight of four hundred and twelve and a half grains troy of standard silver, as provided in the act of January eighteenth, eighteen hundred and thirty-seven, on which shall be the devices and superscriptions provided by said act. * * *

Standard of Fineness.—Sec. 3514.—The standard for both gold and silver coins of the United States shall be such that of one thousand parts by weight nine hundred shall be of pure metal and one hundred of alloy. The alloy of the silver coins shall be of copper. The alloy of the gold coins shall be of copper, or of copper and silver; but the silver shall in no case exceed one-tenth of the whole alloy.

Allowed Deviations from Standard Fineness and Weight.—SEC. 3533.—No ingots shall be used for coinage which differ from the legal standard more than the following proportions, namely: In gold ingots, one-thousandth; in silver ingots, three-thousandths.

SEC. 3535.—In adjusting the weights of the gold coins the following deviations shall not be exceeded in any single piece: In the double-eagle and the eagle, one half of a grain; in the half-eagle, the three-dollar piece, the quarter-eagle, and the one dollar piece, one fourth of a grain. And in weighing a number of pieces together, when delivered by the coiner to the superintendent, and by the superintendent to the depositor, the deviation from the standard weight shall not exceed one-hundredth of an ounce in five thousand dollars in double-eagles, eagles, half-eagles, or quarter-eagles, in one-thousand three-dollar pieces, and in one-thousand one-dollar pieces.

Sec. 3536.—In adjusting the weight of the silver coins the following deviations shall not be exceeded in any single piece: In the dollar, the half and quarter-dollar, and in the dime, one and one-half grains; and in weighing a large number of pieces together, when delivered by the coiner to the superintendent, and by the superintendent to the depositor, the deviations from the standard weight shall not exceed two hundredths of an ounce in one thousand dollars, half-dollars or quarter-dollars, and one-hundredth of an ounce in one-thousand dimes.

Coins to be Reserved for the Annual Assay.—Sec. 3539.—At every delivery of coins made by the coiner to a superintendent, it shall be the duty of such superintendent, in the presence of the assayer, to take indiscriminately a certain number of pieces of each variety for the annual trial of coins, the number for gold coins being not less than one piece for each one thousand pieces or any fractional part of one thousand pieces delivered; and for silver coins one piece for each two thousand pieces or any fractional part of two thousand pieces delivered. The pieces so taken shall be carefully sealed up in an envelope, properly labeled, stating the date of the delivery, the number and denomination of the pieces inclosed, and the amount of the delivery from which they were taken. These sealed parcels containing the reserved pieces shall be deposited in a pyx, designated for the purpose at each mint, which shall be kept under the joint care of the superintendent and assayer, and be so secure that neither can have access to its contents without the presence of the other, and the reserved pieces in their sealed envelopes from the coinage of each mint shall be transmitted quarterly to the mint at Philadelphia. A record shall also be kept at the same time of the number and denomination of the pieces so taken for the annual trial of coins, and of the number and denomination of the pieces represented by them and so delivered, a copy of which record shall be transmitted quarterly to the Director of the Mint. Other pieces may, at any time, be taken for such tests as the Director of the Mint shall prescribe.

Constitution of Commission.—Sec. 3547.—To secure a due conformity in the gold and silver coins to their respective standards of fineness and weight, the judge of the district court for the eastern district of Pennsylvania, the Comptroller of the Currency, the

Assayer of the Assay Office at New York, and such other persons as the President shall, from time to time, designate, shall meet as Assay Commissioners at the Mint in Philadelphia, to examine and test in the presence of the Director of the Mint, the fineness and weight of the coins reserved by the several mints for this purpose, on the second Wednesday in February, annually, and may continue their meeting by adjournment, if necessary. If a majority of the Commissioners fail to attend at any time appointed for their meeting, the Director of the Mint shall call a meeting of the Commissioners, at such other time as he may deem convenient. If it appears by such examination and test that these coins do not differ from the standard fineness and weight by a greater quantity than is allowed by law, the trial shall be considered and reported as satisfactory. If, however, any greater deviation from the legal standard or weight appears, this fact shall be certified to the President; and, if, on a view of the circumstances of the case, he shall so decide, the officers implicated in the error shall be thenceforward disqualified from holding their respective offices.

Standard Weights of the Mint—Sec. 3548.—For the purpose of securing a due conformity in weight of the coins of the United States to the provisions of the title, the brass troy-pound weight procured by the minister of the United States at London, in the year eighteen hundred and twenty seven, for the use of the mint, and now in the custody of the Mint in Philadelphia, shall be the standard troy-pound of the Mint of the United States, conformably to which the coinage thereof shall be regulated.

Sec. 3548.—It shall be the duty of the Director of the Mint to procure for each Mint and Assay office, to be kept safely thereat, a series of standard weights corresponding to the standard troy-pound of the Mint of the United States, consisting of a one-pound weight and the requisite subdivisions and multiples thereof, from the hundredth part of a grain to twenty-five pounds; and the troy-weights ordinarily employed in the transactions of such mints and assay offices shall be regulated according to the above standards at least once in every year, under the inspection of the Superintendent and Assayer; and the accuracy of those used at the Mint at Philadelphia shall be tested annually, in the presence of the Assay Commissioners, at the time of the annual examination and test of coins.

Rules of the Board of Assay Commissioners.—*Adopted by the Board in* 1880.—I. At the hour appointed for meeting by the Director of the Mint, if a quorum appears to be present he shall so announce, and the judge of the district court of the United States for the eastern district of Pennsylvania, or in case of his absence, such member as the commissioners present may designate shall take the chair, and the Director's clerk, unless otherwise ordered by the board, shall act as secretary.

II. The letter of the President, or the Director of the Mint, naming the commissioners who have been specially designated by the President of the United States, will be read, and the roll of the members, *ex-officio*, and of the others accepting the appointment, will be called.

III. A quorum being present, the secretary will read section 3547 of the Revised Statutes of June 22, 1874, under which the commission is constituted; the several sections bearing upon the duties of the commissioners; the rules for the organization and government of the board; and the minutes of the last preceding assay.

IV. The "reserved coins" having been produced by the officers in charge of them, the several packages in which they are contained will be opened in the presence of the commissioners, or of a committee for that purpose appointed, who shall report to the commission for confirmation, and the coin distributed by them in parcels with reference to their places of coinage and their metallic character as follows:

1. Gold coins from the mint at Philadelphia.
2. Silver coins from the same.
3. Gold coins from the mint at San Francisco.
4. Silver coins from the same.
5. Gold coins from the mint at Carson.
6. Silver coins from the same.
7. Gold coins from the mint at New Orleans.
8. Silver coins from the same.

But when it shall be made known to the board that at either of the mints there has taken place, during the year, a change in any of the officers that are responsible for the coinage, the coins made during the terms of the respective incumbents will be distributed in separate parcels.

V. The coins contained in each parcel having been examined and counted, the number will be compared with the number reported as "reserved," and having been verified, the secretary will note the results on the minutes of the commission.

VI. The chairman will then arrange the members of the board in *two committees;* one to take charge of the *weighing*, the other of the *assaying;* with power to associate members interchangeably, and to require the manipulatory aid of the officers of the mint.

VII. Of the Weighing.—*a.* The committee on weighing shall take from each parcel of the coins, as distributed, two or more piles —each of ten or more pieces, and embracing two or more denominations, and five or more single pieces of two or more different denominations.

b. They shall arrange the piles, and the single pieces thus taken out, with the mint marks downwards, in such order that the particular place of mintage shall be known only to the members of the committee.

c. The piles, and the single pieces shall then be severally weighed under the scrutiny of the committee, and their respective weights ascertained; the piles to one-thousandth of an ounce, the single pieces to the eighth of a grain; and the results shall be noted, with a special reference as to any that may be found without the legal limits of weight.

d. The committee shall then examine the weights ordinarily employed in the mint, and shall attest their accordance with the standards prescribed by law.

VIII. Of the Assaying.—*e.* The committee on assaying shall receive the residues of the several parcels of reserved coins; and adding to them—if it shall be necessary, but not otherwise—from the piles in the possession of the committee on weighing, shall first cause a portion of each parcel to be melted into an ingot of convenient size; and from each of the ingots so made they shall take test-samples for assay.

f. They shall then select a convenient number, not less than three, of single pieces of diverse denominations from each parcel; from which they shall take test-samples for assay.

g. They shall then arrange all the test-samples in such order as shall be known only to the members of the committee; and in that order such samples shall be assayed, the silver first, and the gold afterwards.

h. Should the operations of the assay be not consummated before the adjournment of the board for the day, the parcels of reserved coins, ingots, and test-samples will remain in a chest or vault, under the joint and separate charge of the chairman and the Director of the Mint.

IX. The weighings and assayings having been completed under the scrutiny of the committees, respectively, the committees will report fully and specially, as to the coins of each mint.

X. And thereupon the commissioners will proceed to declare their judgments by an open vote; and full record thereof, and of all their doings, having been engrossed by the secretary, it will be signed by all the members, and delivered to the Director of the Mint. After which the board will be adjourned *sine die.*

The foregoing rules are subject to such modifications or alterations as a majority of the board may at any time during each annual assay, deem expedient and proper.

PART VI.

STOCK EXCHANGES—THE LAW OF STOCK BROKERAGE—REVIEWS OF THE STOCK AND METAL MARKETS—PRICES FOR EIGHTEEN MONTHS—THE FUTURE.

OF all the facts of the MINES, MINERS AND MINING INTERESTS OF THE UNITED STATES, Part VI., will be the one to which, possibly, the majority of our readers will turn. The fascinations, the misfortunes, the fortunes, the rise and fall of the Stock Market, the state of Trade, are absorbing studies to the majority of business men. These are vital interests, and in such way have we considered them. The part opens with some points of law that are necessary to a full understanding of the situation. Then follow careful, elaborate, thoroughly able reviews of the Mining Stock Market of the United States, with such data concerning the various stock exchanges as will serve as collateral information to aid in forming a correct judgment upon the points covered in this part. The matter of the reviews was furnished for all markets except Philadelphia, by Mr. L. E. Thorne, of New York. That for Philadelphia, by Mr. J. V. Sears. Other matter is added by the compiler. The reviews of the metal markets were also written by Mr. Thorne.

LAW OF MINING STOCK BROKERS AND MINING STOCK EXCHANGES.

MR. J. R. Dos Passos has recently published a volume entitled, "Law of Stock Brokers and Stock Exchanges," which has received most favorable recognition. From its pages we take the following as of interest to the rights of purchasers of mining stocks. Touching the origin of stock brokers and stock exchanges Mr. Dos Passos says: There is a great diversity of opinion respecting the origin of the word "broker," some of the authorities maintaining that it was originally applied to those who broke up goods into small pieces—retail dealers; while others contend that the term is derived from the Saxon word *broc*, misfortune, and that the name "broker" comes from one who is a broken trader by misfortune, which is often a true reason for a man's breaking, and that none but that class of persons were formerly admitted to that employment in London.[1] But the statutes passed in the reigns of Edward the First and James the First, hereafter referred to, would seem to indicate that the latter view can hardly be correct. In England, the term "broker" occurs in an Act of Parliament as early as the year 1285.[1] It recites, in substance, that whereas divers persons do resort unto the city (London) from parts beyond the sea, fugitives from their own lands, and of these some become "brokers," hostlers and innkeepers, etc., and they do wear fine clothing, and do eat costly meat and food, etc.; it therefore enacts that "there shall be no broker in the city except those who are admitted and sworn before the warden, mayor, or aldermen." It is evident from a perusal of this statute, that the occupation of brokers in those days was subverted by persons who used the name as a cover to transact a species of disreputable pawnbroker's business, and hence the severe penalties of the second section of the act, which provided that "if any other innkeeper or broker be found within the city, or any other of whom there is evil suspicion, he shall be arrested by the warden or mayor, or the sheriffs, or the alderman of the ward, and punished, viz.: innkeepers and brokers shall be incapable of their freedom and adjudged to prison, and the others shall be punished by imprisonment or otherwise."[2]

The next statute, passed in the reign of James the First, more than three hundred years after that just recited,[3] regu-

[1] Jacob's Law Dict., tit. "Brokers." "The etymology of the term Broker has been variously given. By some it has been derived from the Saxon *broc*, misfortune, as denoting a broken trader; the occupation being formerly confined, it is said, to unfortunate persons of that description (Tomlins). According to others, it was formed from the French *broieur*, a grinder or breaker into small pieces; a Broker being one who *beats* or draws a bargain into particulars (Termes de la Ley, Cowell). The law Latin from *obrocator*, however, seems to point distinctly to the Saxon *abrœcan* (to break), as the true root, which in the old word *abbrochment* (q. v.) or *abroachment*, had the sense of *breaking up goods*, or selling at retail. A Broker, therefore, would seem to have originally been a *retailer*, and hence we find the old word *auctionarius* (q. v.) used in both these senses" (Burrill's Law Dict., tit. "Broker"). Wharton gives, as the derivation of the word, the French *broceur*, and the Latin *tritor*, a person who breaks into small pieces (Whar., Law Dict., tit. "Broker"). Webster gives as its derivation, the old English *brocour*, Norman French *broggour*, French *brocanteur*. Under the word "broke," to deal in second-hand goods, to be a Broker, Webster says it is probably derived from the word *brock*. Worcester derives it from the Anglo-Saxon *brucan*, to discharge an office; *brocian*, to oppress; and the French *broyer*, to grind. See "Broke" and "Broker." The word "Broker" seems first to occur in literature in Piers Ploughman, "Among burgeises have I be Dwellyng at London. And gart Backbiting be a brocour. To blame men's ware." It clearly means here a *fault-finder*, as in Provencal *brac* is refuse. The broker was originally one who inspected goods and rejected what was below the standard (Wedge-wood).

[1] 13 Ed. I., Stat. Civ. London, 1285.

[2] See also 2 Crabb's Dig. of Stat., tit. "Broker," 261. There were a class of persons known to the Romans, who were deemed public officers, and who united the functions of bankers, exchangers, Brokers, commissioners, and notaries all in one, under the description of *proxenetæ*. (Whar., Law Dict., tit. "Brokers;" Story on Ag. § 20 Dig. Lib. 50, tit. 14, ch. 2.) Spelman, cited in Gibbons vs. Rule, 12 Moo. 539, 543. There is very high authority, however, for asserting that the term *proxenetæ* does not occur in any Latin author before the first century after Christ. See Freund's Latin Dictionary, revised by Lewis and Short where *proxenetæ* is thus given: "negotiator, factor, broker, agent, Sen. Ep. 119; Mart. 10. 3. 4; Dig. 50. 14. 2."

[3] 1 Jac. I. c. 21, 1604.

lates the calling of Brokers with greater detail than the first act, and clearly shows, by the use of the words "merchandise and wares," that down to this period the Broker in money, stock and funds had no recognized legal existence. The preamble to the statute also indicates that the regular calling was and had been a favored one: "Forasmuch as of long and ancient time by divers hundreds years there have been used within the City of London and Liberties thereof, certain Freemen of the city to be selected out of the Companies and Mysteries whereof they are free and Members, and the same persons to be presented at least by six approved and known honest persons of the same Mystery to the Lord Mayor of London for the time being, and to the Aldermen his Brethren, and to be recommended by such Presentors to be persons for their known approved Honesty, Integrity, and Faithfulness, Persons meet for to be Broker Brokers." It was not until the latter part of the seventeenth century, when the East India Company came prominently before the public,[1] that trading or speculating in stock became an established business in England; and the term "Broker," which had then a well-understood meaning, was promptly transferred to those persons who were employed to buy and sell stock or shares, and who thenceforth became known as "Stock-brokers." In 1692, William the Third having adopted, for the first time in England, the system of raising funds[2] for governmental purposes by creating a national debt, speculations in the "funds" and the shares of the East India Company at once became general;[3] and in 1697 the Brokers and Stock-jobbers, to borrow from the language of the statute passed in that year, had been guilty of such "unjust practices and designs" in selling and discounting tallies, bank stock, bank bills, shares and interest in joint stock, that it became necessary to pass a stringent act, by which no persons except regular sworn appointees were appointed to act as Brokers; and the latter were compelled to keep a register in which all contracts were to be entered within three days after they were made, and their compensation was fixed at ten shillings per centum.[4] And Best, C. J., in commenting upon this statute, says: "The statute 8 and 9 William III., ch. 20, by which the first government loan was raised, speaks of a new description of 'Brokers'—persons employed in buying and selling tallies, the government securities of those days: these have since been called *Stock-brokers.*"[5] Several other similar statutes were passed in the subsequent reigns of Anne and George.[6]

An early legal writer gives the following account of Stock-brokers, which is interesting in this connection: "Stock-brokers are persons who confine their transactions to the buying and selling of property in the public funds and other securities for money, and they are employed by the proprietors or holders of the said securities. Of late years, owing to the prodigious increase of the funded debt of the nation, commonly called the stock, they are become a very numerous and considerable body, and have built by subscription, a room near the Bank, wherein they meet to transact business with their principals, and with each other; and to prepare and settle their proceedings before they go to the transfer-offices at the Bank, the South Sea, and India houses, thereby preventing a great deal of confusion at the public offices, where the concourse of people is so great, during the hours of transferring stock, that if the business was not prepared beforehand, it would be impossible to transact it within the given time."[7] The whole business of stock-jobbing being contrary to law, except as the persons acting as Brokers were licensed, under the act of 6 Anne, ch. 16; and as many other persons, irrespective of the requirements of the statute, acted as Stock-brokers without having received a license as such, a *silver medal* was given to each licensed Broker, having the king's arms on one side, and the arms of the city of London on the reverse, with the Broker's name, which he was ordered to produce upon every occasion when he should be required to show his qualification; and, to give further publicity to the names of the regular Brokers, a list of the licensed Brokers was annually printed by the order of the Lord Mayor and the Court of Aldermen, which was hung up in the walks of the Royal Exchange and in Guildhall, and at most of the reputable coffee-houses near the Exchange. This was before the Brokers left the Royal Exchange and located their business in Change Alley.[1] By an act passed in 1870,[2] called the "London Broker's Relief Act," the restrictions and guards which were formerly placed upon Stock-brokers were removed, and the jurisdiction of the Court of Aldermen over Brokers ceased. The effect of this act is practically to enable any person to exercise the calling of Broker in London, outside of the Stock Exchange; and this result seems to be justly deplored in the Report of the Royal Stock Exchange Commission presented to Parliament in 1878.

The advantage of employing brokers as intermediaries, in the purchase and sale of property, seems to have been early recognized among the merchants; and a very old writer on the law merchant says, "It is an old proverb, and very true, that between what will you buy? and what will you sell? there is twenty in the hundred differing in the price, which is the cause that all the nations do more effect to sell their commodities with reputation by means of brokers than we do; for that which seems to be gotten thereby is more than double lost another way. Besides, that by that course many differences are prevented which arise between man and man in their bargains or verbal contracts; for the testimony of a sworn broker and his book together is sufficient to end the same."[3]

The Venetians, says Malynes, had an office called Messacaria (Messageria?), consisting only of brokers who dealt between man and man; "and in Spain they are of such estimation that they ride on horseback, upon their foot-cloths; and, having the invoices of merchants' goods, they will deal for great matters at a time, against the lading of the fleet from Nova Espagna, and the islands of the West Indies, to be paid partly ready money and partly at the return of the said fleet; and these afterwards let you understand their merchant."[4] The origin of stock-certificates—dealings in which, at the present date, constitute the main business of Stock-brokers—cannot in England be satisfactorily traced beyond the middle of the seventeenth century. Such species of property was altogether unknown to the law in ancient times, nor, indeed, was it in usage and practice until a short period antecedent to the passage of the Bubble Act in the reign of George the First.[5]

Although it is fully established that mercantile or commercial corporations existed among the Romans,[6] and

[1] This company was incorporated by Queen Elizabeth in 1600.

[2] The system of obtaining money for government purposes by loans is said to have originated in the fifteenth century in Venice. It was next adopted in Holland, and was introduced into England shortly after the Revolution of 1688 (Tit. "Funds," Cyclopædia of Com. [Waterston]).

[5] Garrard vs. Hardey, 5 Man & G. 471, 483.

[6] Ang. & Ames on Corps. (10th ed.) ch. 18, § 26: "A *Collegium Mercatorum* existed at Rome 493 B.C.; but the modern bourse, from the Latin *bursa*, a purse, originated about the fifteenth century. Bourges and Amsterdam contend for the honor of having erected the first bourse. The Paris Bourse was erected in 1808" (Johnson's New Univ. Cyclop., tit. "Bourse"). "A Rome, malgre que le commerce n'y fut pas en grande consideration, nous trouvons ce meme usage publiquement pratique. Tite Live nous apprend, en effet, qu'en l'an 259 de sa foundation, sous le consulat d'Appius Claudius et de Publius Servillius, on construisit un vaste edifice, dont les vestiges portent encore le nom de *Loggia*, et qui, sous la denomination de Collegium Mercatorum, avait une destination analogue a celle de nôs bourses actuelles" (Droit Commercial, "Bourses de Commerce," par Bedarride). But, according to Livy (ii 27), the *Collegium Mercatorum* does not belong to this period. Livy says that when the consuls were disputing which of them should have the honor of dedicating a temple to Mercury, the question was referred to the people; and the Senate decreed that whichsoever of the consuls should be chosen should also form a "Collegium Mercatorum," or association of corn-dealers, to help him and the priest in religious

though much light has been thrown upon the character and mode of conducting these bodies,[1] there is an utter dearth of information respecting the form and manner by which ownership in the corporate property was attested and established. The Roman law required three persons to organize a corporation:[2] and as each body had at least that number of members, if not more, it would seem but natural that a certificate or some other substantial muniment of title, should have been issued by the corporation to its respective members, in which the proportion of interest of each in the capital or corporate property of the Association appeared. But whether a certificate was, in fact, issued, and, if so, was regarded as property capable of sale or other negotiation, and of vesting in the representatives of the owner, on his decease, or whether the corporations were all of the nature of guilds conferring upon the members mere *personal* rights —all of these questions seem now to be incapable of solution; and the Roman law, which sheds such floods of light upon commercial subjects, apparently leaves the above matters in total darkness.

In England, stock-certificates were not introduced into the courts of law for many years after they had become established in the mercantile community; for Lord Mansfield, in 1770,[3] in a case wherein it was contended that such certificates were *money*, in deciding against that view, said: "This is a *new* species of property *arisen within the compass of a few years*. It is not money.[4] The Bubble Act[5] having been repealed,[6] it was held[7] that the formation of a company, the stock in which should be transferable, was not an offense at common-law. And this doctrine was subsequently affirmed.[8] A Stock Exchange or Bourse, in the sense in which it is considered in this article, is also a creation of modern times. An Exchange was erected in Cornhill, London, in 1571, but it was used exclusively by dealers and Brokers in merchandise. This structure was destroyed in the great fire of 1666;[9] but it was not until several years after, when it was rebuilt, that the Brokers in funds and stock were assigned a portion of the building for the transaction of business.

In 1698, the Stock-jobbers, annoyed by the objections made to their remaining in the Royal Exchange, and finding their numbers seriously increased removed to Change Alley, a large and unoccupied space, where extensive operations might be carried on.[10] In the United States there seems to be no trace of a Stock Exchange until about the beginning of the present century, at which time there existed in Philadelphia a Board of Stock-brokers, possessing a formal organization and regular constitution, which the Brokers in New York, in 1817, used as a model in framing the rules of their own Exchange.[11] Although there is in the archives of New York Stock Exchange a document bearing date May 17, 1792, signed by a number of Brokers, in which it is, *inter alia*, stated that "We, the subscribers, Brokers for the purchase and sale of public stock, agree to do business at not less than one-fourth of one per cent.," no organization appears to have been formed in the City of New York until the year 1817, when a constitution was adopted, which is no longer in existence, it having been destroyed in the great fire of 1853.[1] It appears that in the beginning, the dealings of the Stock-brokers in this country were confined to speculations in Continental money; but when, in 1812, the United States government issued Treasury notes and negotiated loans to the amount of many millions of dollars, the dealings embraced all these securities, besides operations in the stocks of banks, which were being rapidly formed in all parts of the country. From the year 1820, when the real history of the New York Stock Exchange may be said to have commenced, it has gone on steadily increasing in its members, power and influence, until to-day it can be safely affirmed to be the most powerful organization of the kind in the world; and by forming a mart where all kinds of securities can be promptly converted into cash, it has largely contributed to the development and wealth of the country by encouraging and sustaining our great railroad systems, which have brought all parts of the Republic into a closer relation to each other, and firmly strengthened the union and prosperity of the States.

Legal Relation of Stock-broker to his Client.—In the United States, the business of buying and selling stocks and other securities is generally transacted by Brokers for a commission agreed upon or regulated by the usages of the place; and although any person may enter into such an occupation, no license to perform it being necessary,[2] such

and mercantile matters related to the temple. But the plan fell through, and it does not appear that the "Collegium" was ever formed; nor that it would have had, if formed, anything but a religious significance. Accordingly, the above citations seem to be unfounded.

[11] Medbery's Men and Mysteries of Wall Street, 286.

[1] "The earliest annals of the New York Stock Exchange are meagre, the fire of 1835 having destroyed the record of the constitution adopted in 1817, the date of its first regular organization. A tablet in the wall of the present room recites that the Exchange was founded in 1792, but the evidence of that exists only in a document still preserved among its archives" (Johnson's New Univ. Cyclop., tit. "Stock Exchange," by Strong Wadsworth).

The following account is from Medbery's Men and Mysteries of Wall Street, 286: . . . . when Washington was President, and Continental money was worth a trifle more as currency than as waste paper, some twenty New York dealers in public stock met together in a Broker's office, and signed their names, in the bold, strong hand of their generation, to an agreement of the nature of a protective league. The date of this curious paper is May 17, 1792. The volume of business of all these primitive New York Brokers could not have been much above that of even the poorest first-class Wall Street house in our time. The Revolutionary 'shinplasters,' as the irreverent already styled them, were spread over the land in such plenty that there were a hundred dollars to each inhabitant. Something was to be made, therefore, from the fluctuations to which they were liable. Indeed, one of the greatest Broker firms of subsequent years derived its capital from the lucky speculations of its senior member in this currency. "The war of 1812 gave the first genuine impulse to speculation. The government issued sixteen millions in Treasury notes, and put loans amounting to one hundred and nine millions on the market. There were endless fluctuations, and the easy-going capitalists of the time managed to gain or lose handsome fortunes. Bank stock was also a favorite investment. An illustration of one of the sources of money-making to Brokers at this period is found in the fact that United States 6's of 1814 were at 50 in specie and 70 in New York bank currency.

"In 1816 one could count up two hundred and eight banks with a capital of $82,000,000." . . . "One day in 1817, the New York stock-dealers met in the room of an associate, and voted to send a delegate over on the stage line to investigate the system adopted in the rival city. The visit was successful; and the draft of a constitution and by-laws, framed from that of the Philadelphia Board, received the final approbation of a sufficient number of the Brokers to enable the New York Stock Exchange to become a definite fact. Three years after, on the 21st of February, 1820, this preliminary code of a thorough revision, and the organization was strengthened by the accession of some of the heaviest capitalists in the city. Indeed, with 1820, the real history of the Exchange may properly be said to commence."

[2] By the statutes of Pa., the occupation of Stock-broker is regulated by statute (Brightly's Purd. Dig. 42), the substance of which is here given:

1. Stock-brokers to be licensed, etc.
5. License to be renewed annually, etc., to enure for the benefit of assignees or legal representatives. Proceedings in such cases: Brokers not to use more than one place of Business. The same person may be licensed as Stock, Exchange, and Bill Broker.
6. Penalty for acting without license.
9. Tax on Broker's license. Three per cent. on commissions, etc
10. To be appraised.
11. How classified.
12. To make annual returns on oath.
13. Statement of name of Broker or firm, location of business, and amount of capital engaged to be reported to the Attorney-general.
14. Penalty for neglect.
15. Power of Auditor-general in relation to penalties.
16. Tax to be additional to license.

business is now generally restricted to those Brokers who are members of the Stock Exchanges, there being one of these bodies in several of the principal cities of the Union.[1]

Considerable discussion has arisen in the cases, especially those in the State of New York, as to the precise relation which exists, where a Broker with his own money purchases or sells stocks, etc., for his Client, for the purpose of speculation. Does the Stock-broker in such a transaction, in the absence of an express agreement defining the relation, unite in himself the characters of "Broker," "pledgee" and "trustee?" The importance of this question is obvious, because, if it be answered affirmatively, it would seem to follow that all of the incidents and consequences of those characters would attach to the Broker, in his dealings with his Client; but, on the other hand, if the question be answered negatively, the simple relation of debtor and creditor, arising out of a breach of contract, would exist. The embarrassment of the question arises from the fact that, in the case of an ordinary purchase of stocks for speculation, on a margin, the Stock-broker, without literally filling the technical definitions of "Broker," "pledgee," or "trustee," comes within the purview of all those terms. He is a Broker because he has no interest in the transaction, except to the extent of his commissions; he is a pledgee, in that he holds the stock, etc., as security for the repayment of the money he advances in its purchases; so he is a trustee, for the law charges him with the utmost honesty and good faith in his transactions; and whatever benefit arises therefrom enures to the *cestui que* trust. The circumstances attendant upon an ordinary transaction between a Broker and his Client in a stock speculation are carefully described by Hunt, Ch. J., in a leading case in the State of New York:[2]

"The customer employs the Broker . . . to buy certain stocks for his account, and to pay for them, and to hold them subject to his order as to the time of sale. The customer advances ten per cent. of their market value. and agrees to keep good such proportionate advance, according to the fluctuations of the market. . . .

"The Broker undertakes and agrees:

"1. At once to buy for the customer the stocks indicated.

"2. To advance all the money required for the purchase, beyond the ten per cent. furnished by the customer.

"3. To carry or hold such stocks for the benefit of the customer, so long as the margin of ten per cent. is kept good, or until notice is given, by either party, that the transaction must be closed. An appreciation in the value of the stocks is the gain of the customer, and not of the Broker.

"4. At all times to have in his home, or under his control. ready for delivery the shares purchased, or an equal amount of other shares of the same stock.

"5. To deliver such shares to the customer, when required by him, upon the receipt of the advances and commissions accruing to the Broker; or,

"6. To sell such shares, upon the order of the customer, upon payment of the like sums to him, and account to the customer for the proceeds of such sale.

"Under this contract the customer undertakes:

"1. To pay a margin of ten per cent. on the current market value of the shares.

"2. To keep good such margin according to the fluctuations of the market.

"3. To take the shares so purchased on his order whenever required by the Broker, and to pay the differences between the percentage advanced by him and the amount paid therefor by the Broker."[3]

It may be well to set forth the history of an ordinary transaction between a Client and a Broker; even with a little more detail than that contained in the foregoing contract. The ordinary margin paid on opening an account with a Broker—that is, in ordering him to buy or sell securities—is ten per cent.[4] The margin may be less than this or frequently none is advanced, according to the confidence which the Broker has in the ability of his Client to respond to ultimate loss. But, whether the Broker advances all or only the principal

[1] Philadelphia, San Francisco, and Boston.

[2] Markham vs. Jaudon, 41 N. Y. 235.

[3] See also Brass vs. Worth, 40 Barb. 648.

[4] Markham vs. Jaudon, 41 N. Y. 235.

portion of the sum invested in the securities, the relation of the parties is unchanged. The fact exists that the Broker looks to the principal for an indemnity upon the entire transaction. The Client having given the Broker an order to buy or sell, either in writing or verbally, the next step in the transaction is, that the Broker goes into the Stock Exchange and executes the business, making a verbal contract therefor with another Broker. Frequently the Broker, upon receiving an order, deputes another, or subordinate, Broker to do the business. This is contrary to the general principle of law, that an agent cannot delegate his business to another—"*delegata potestas non potest delegari*;"[1] but it is justified by the general usage of Wall Street, of which the Client has express or implied knowledge. The exact transaction in the Stock Exchange is as follows: The selling Broker offers for sale his securities, and if there is a Broker present who wishes to purchase, the contract is completed, upon his assenting to the terms mentioned.

Where the number of shares is not named by the selling Broker, it shall be considered to be for one hundred shares of stock, of the par value of one hundred dollars, or ten thousand dollars of bonds.[2]

Some rules of the Stock Exchange are here given, which further illustrate the transaction in the Stock Exchange:

"All offers made and accepted shall be binding."

"Offers to buy or sell shall be entitled to the floor in the following order:

"1. Bids 'seller three days,' and offers to sell 'buyer three days,' shall take precedence of cash and regular.

"2. 'Cash' and 'regular' bids and offers may be made simultaneously, as being essentially different propositions.

"3. Offers to buy and sell on longer options than three days may be made at the same time with offers to buy or sell 'buyer or seller three.'

"4. In offers to buy on seller's option, or to sell on buyer's option, the longest option shall have the precedence.[3]

"In offers to buy on buyer's option, or sell on seller's option, the shortest option shall have the precedence."

"No party to a contract shall be compelled to accept a principal other than the member offering to contract, unless the name proposed to be substituted shall be satisfactory, or shall be declared at the time of making the offer."[4]

"Whenever there is a disputed claim for the purchase or sale of a security, made during the sessions of the Exchange, the presiding officer shall decide the same, or he may appeal to the board for their decision. If an appeal be made from the decision of the presiding officer, and seconded by two members, the question shall be put to a vote."[5]

"In any disagreement between members, growing out of the purchase and sale of a security or securities, as soon as the same is ascertained, if not settled by mutual agreement, the money difference shall be established forthwith by purchase or sale by an officer of the Stock Exchange, wherever the Exchange may be at the time convened."[6]

"All purchases and sales shall be settled for on the next business day, unless expressed to the contrary."[7]

Sales for "cash" are settled for immediately after the purchase, upon the delivery of the same.[8]

In all deliveries of stocks, bonds, etc., the party delivering shall have the right to require purchase-money to be paid at the time and place of delivery.[9]

By Article XXX. of the By-laws of the New York Stock Exchange, transactions may be made in government securities for the "account" for two "settling days"—viz., the 15th and last days of each month. Provision is also made for securing and carrying out such contracts, but, as a matter-of-fact, this system of dealing is rarely if ever used.

But to continue: the Brokers, in making transactions with one another, do not know for whom they are made, the names

[9] Id.

of the principals being jealously concealed. One Broker looks to the other contracting Broker to carry out the transaction, and in practice there is no attempt made to enforce any liability against the principal should he become known. Here another question arises, whether there is any liability on the part of the unknown principal for the default of his Broker? Is there any privity between him and the other contracting Broker? We shall not attempt to answer these questions in this place, but they are suggested as they arise in the history of the transaction.[1] There is no written contract, as a general rule, between the Brokers, each one merely dotting down the transaction made, and reporting it to his office, at which place, later in the day, the business is confirmed by comparisons made by each side. The Statute of Frauds here looms up to destroy such contracts; but the rules of the board make them inviolable between the members in the tribunal known as the "Arbitration Committee."

On the following day, if the transaction is made "regular," the stocks are duly delivered at the office of the purchasing broker by the selling broker, who receives payment for them. If the sale be made on time, the transaction is completed when the time expires. The stock, when received, remains in the office of the purchasing broker to await the further orders of the client. Sometimes the stock is held by the broker with merely a general power of attorney in blank attached to or endorsed on it.

"In the delivery of stock, of which but one transfer in a day is allowed, the receiver shall have the option of receiving said stock by certificate and power irrevocable in the name of, witnessed or guaranteed by, a member of the exchange, or a firm represented at the exchange, resident or doing business in New York, or by transfer thereof."[2]

"In all transactions exceeding one hundred shares, where the delivery is by certificate and power, the purchaser shall have the right to require the delivery in certificates of not more than one hundred shares each."[3]

"Powers of attorney, or substitution, signed by trustees, guardians, infants, executors, administrators, or attorneys, shall not be a good delivery."[4]

Sometimes the stock is transferred on the books of the company in the name of the Broker, rarely in the name of the principal. This stock is considered as the client's, subject only to the lien of the Broker for advances and commissions. The Broker collects the dividends, and pays assessments upon it, if any be levied, and the same remains in his hands through the whole transaction until it is sold, the client never having possession of, and rarely ever seeing, the stock. Upon the purchase of the stock, the Broker sends a notice to his client, giving the price and the name of the Broker from whom he has purchased.[5] What effect this would have upon a contest between the unknown principal and the other or selling, Broker is still another question. Frequently a Broker is himself a speculator, and, in executing an order for his principal, unites a purchase or sale on his own account. Finally, the Broker in many instances may have two clients, who, at the same time, give him counter-orders, the one to buy and the other to sell, which the Broker frequently executes at the market price, but without any real sale or purchase, merely making cross entries in his books. In the absence of any fraud or any damage to the clients, can such transactions stand? During the time the stock or securities remain in possession of the Broker, he uses them to raise money with which to carry on his business, and no attempt is made to keep the stocks separate, or to keep the identical certificates on hand, the client usually being satisfied if the Broker is able to deliver the number of shares purchased, without any regard to particular certificates. According to the strict legal definition it is manifest that a Stock-broker, in transactions such as

[3] Art. IX. § 2, id.
[4] Art. IX. § 3, id.
[5] And it was decided in Hoffman vs. Livingston, 46 N. Y. Superior Ct. (14 J. & S.) 552, that a failure of the Broker to give this notice was such negligence as to preclude him from recovering his commissions.

those described above, is not embraced within the term "Broker."

"Brokers" have been defined by a standard legal lexicographer to be "those who are engaged for others in the negotiation of contracts relative to property with *the custody of which they have no concern*;"[1] and "Stock-brokers" as those employed to buy and sell shares of stocks in incorporated companies and the indebtedness of governments."[2]

The distinction between a Stock-broker and an ordinary Broker are tersely summarized by Woodruff, J., in his dissenting opinion in the well-known case of Markham vs. Jaudon,[3] in this language: "In the first place, the Stock-dealer who is employed, though called a Stock-broker, does not act as Broker in this transaction. It is no part of the office or duty of a Broker to pay the price. It is no part of the office or right of a Broker to receive the property, still less to take the title in his own name.[4] "In this transaction he acts in a peculiar business, in his own name and on his own responsibility, protected against loss by the indemnity furnished, or by the agreement to be furnished to him. The idea of mere agency ordinarily suggested by the name Broker does not, therefore, arise out of the fact that the dealers in stocks for account of others, as to profit and loss, are called Stock-brokers, In the next place, the transaction, according to the intent and purpose of the employment of the Broker, does not contemplate that the customer will ever receive the stock, or own it. It may be that if the Broker desires to close his connection with the transaction, the customer, if he pays the cost, interest, and all commissions which the Broker has earned, or is entitled to earn, will receive the stock, whether he may so insist or not is a collateral question; and, if he be so entitled, it will nevertheless be true that this is not in pursuance of the arrangement, but a departure from it; for the intent is, that the stock shall be carried by the Broker until directed to be sold, the customer never having the title to the stock at all. And, finally, in my opinion, the transaction is an executory agreement for a pure speculation in the rise and fall of stock, which the Broker, on condition of perfect indemnity against loss, agrees to carry through in his own name and on his own means or credit, accounting to his customer for the profits, if any, and holding him responsible for the loss."[5]

Notwithstanding these technical differences, the decided inclination of the courts has been to visit a Stock-broker

[1] 1 Bouv. L. Dict., title "Broker." Ewall's Evans on agency, 4 et seq.
[2] Ibid. See also Clark vs. Powell, 1 Nev. & M. 494, arguments of counsel pro and con. Ab. L. Dict., title "Broker." As to liability of Broker to pay taxes, etc., see § 3407, Rev. Stat. U. S. (2d ed. 1878), which provides as follows:

"§ 3407. Every incorporated or other bank, and every person, firm, or company having a place of business where credits are opened by the deposit or collection of money or currency subject to be paid or remitted upon draft, check, or order; or where money is advanced or loaned on stocks, bonds, bullion, bills of exchange, or promissory notes; or where stocks, bonds, bullion, bills of exchange, or promissory notes are received for discount or for sale, shall be regarded as a bank or as a banker."

By the subsequent § 3408, a tax of one twenty-fourth of one per cent. is imposed each month upon the average amount of deposits; and a like amount on the capital employed.

[4] A Broker has not the custody of the goods of his principal; he is merely empowered to effect the contract of sale or purchase on his behalf. Chitty on Cont. (11th Am. ed,) 274; Paley on Ag. 13; Story on Ag. (8th ed.) § 28 et seq.
[5] In the case of Wood vs. Hayes, 81 Mass. 375, it was held that where a Stock-broker advances his own money in the purchase of stocks for another, and holds the shares in his own name, the transaction stands on the footing of contract, which is strictly conditional to deliver so many shares on payment of so much money. "A Broker is an agent simply. He transacts business not for himself, but for another. He is a middle-man, a negotiator between other persons for a compensation. A stock-broker deals in stocks of moneyed corporations and other securities for his principal. It is a calling of great responsibilities, in which punctuality, honesty, and knowledge are required." Per Van Vorst, J., White vs. Brownell, 3 Ab. (N. Y.) Pr. (n. s.)326.

with all of the responsibilities of a Broker and pledges, and, as we shall hereafter see, to confer upon him all of the advantages of those relations. It is conceded by Mr. Justice Woodruff, and all of the advocates of his view of the law, that where the Stock-broker makes purchases of stock, etc., for his principal *for investment*, with money furnished by the latter, the relation of pledgor and pledgee exists.[1] It is also conceded that when stock, etc., is purchased on a margin for the Client, it instantly becomes the property of the latter,[2] together with all of its future dividends and earnings;[3] and that the Client is entitled to the possession of such stocks, etc., upon paying the money represented in their purchase, with the commissions of the Broker.[4]

So it has been decided that a pledgee of stock is not liable for a loss occasioned by his neglect to sell the stock, it having depreciated in his hands till it became worthless, when, by the contract between the parties, the right to sell the stock had been conferred upon the pledgee or a third person; and the pledgee has never refused to transfer the stock for the purpose of a sale, and the pledgor has never requested that a sale should be made.[5] It has also been held that a Stock-broker is not liable where spurious securities are purchased by him for a Client in the regular course of business. And if he sell stocks or securities for his principal, which turn out to be spurious, and the Broker, in consequence, repays the purchase-money to the buyer, he can recover the same from the principal.[6]

So if the pledge be stolen from the Broker, he is not liable unless the theft arose from, or was connected with, a want of ordinary care on his part.[7] Again, if assessments or "calls" are made upon stocks which a Broker holds for a Client, the liability to pay them, if any, is that of the principal, and not the Broker.[8] In fine, all of the benefits, liabilities, and disadvantages of ownership are attached to the principal, while the Broker has no interest in the transaction except to the extent of his commissions. In view, therefore, of these considerations, the better doctrine would seem to be to hold the Broker to the responsibilities of that relation; in fact, it appears difficult to conceive of any other relation which could so fully harmonize with the circumstances as that of Broker and pledgee. And this now seems to be the established law.[9] The leading case of Markham vs. Jaudon was expressly overruled on the question of the measure of damages in an action for the conversion of stocks by a Broker.[10] It should also be noticed that there were two elaborate dissenting opinions by Woodruff and Grover, JJ., on the question of the relation which existed between the Broker and the Client, the two judges just mentioned holding that the Brokers were not pledgees, but that they held the stock under a contract which enabled them to sell upon the failure of the Client to furnish margins. When this question came again before the court of last resort in New York,[1] Commissioners Earl and Reynolds both wrote opinions affirming the judgment on the specific ground that the Brokers were pledgees. But in the case of Baker vs. Drake[2] (which was not adverted to in the preceding case), overruling Markham vs. Jaudon upon the question of the measure of damage, Mr. Justice Rapallo, in alluding to the latter case, said: "It seems to me, after as full an examination of the subject as circumstances have permitted, that the dissenting opinions (per Woodruff and Grover, JJ., alluded to above) embody the sounder reasons." Yet, when Baker vs. Drake came before the Court of Appeals again in September, 1876,[3] the court expressly reiterated and reaffirmed three propositions laid down in the case of Markham vs. Jaudon, the principal one being that "the relation of Broker and Client, under the ordinary contract for a speculative purchase of stock, is that of pledgee and pledgor." From this view Rapallo and Allen, JJ., dissented.

The doctrine of Markham vs. Jaudon was again distinctly reaffirmed in the last-mentioned respect in Gruman vs. Smith.[4] The theory that the relation which exists between a Stock-broker and his Client in an ordinary speculative transaction is not that of pledgor and plegee, is mainly based upon the argument *ab inconvenienti*. It is said that as stocks are a fluctuating species of property, whose value is liable to be wiped out in a moment, the burden should not be put upon a Broker to give his Client notice of a decline or rise, as the case may be, and to make a demand for further margins. But this argument is just as forcible when applied to the undisputed case of a pure pledge, where it is conceded that there must be notice to the pledgor before a sale can be made, as where the owner of stocks pledges them to secure borrowed money. In this instance, although the stocks are liable to a decline and leave the lender without security, it is clear that, in the absence of express agreement, they could not be sold without legal notice.[5] So it has been held that where, instead of money, the Client deposits stock, etc., as margin, the relation of pledgor and pledgee exists.[6]

The Broker may always, in the outset, protect himself against the fluctuations of an advance or decline in the market by exacting sufficient margins to meet the contingencies of speculation; and if he neglect to do this, he should not expect the law to aid him. But, finally, the Broker may always fully insure himself by making a special contract with his Client,[7] which will enable him to dispose of securities in any manner and at any time that may be agreed upon without notice, and such contracts the law will uphold and carry out.[8] Upon the whole, while it must be conceded that there are incongruous features in the relation, there seems to be no hardship in holding that a Stock-broker is a pledgee; for, although it is true that he may advance all or the greater part of the money embraced in the speculation, if he acts honestly, faithfully and prudently, the entire risk is upon the Client, and may be enforced against him as a personal liability, irrespective of the value of the securities, which are the subject of the transaction. To introduce a different rule would give opportunities for sharp practices and frauds, which the law should not invite; and if it be true, as Mr. Justice Woodruff[9] puts it, that "the transaction is an executory agreement for a pure speculation in the rise and fall of stock, which the Broker, on condition of perfect indemnity against loss, agrees to carry through in his own name and on his own means," accounting to the Client for the profits, it is very questionable whether all the transactions of Wall Street could not be set aside as mere

wagers. But, as we have seen, the cases most emphatically condemn this view, except those in Pennsylvania, in one of which—viz., North vs. Phillips[1]—the Supreme Court of Pennsylvania held that the peculiar facts there developed showed that the dealings between the Client and the Brokers were in "differences" and "margins" and the purchase and sale of the stock were a mere pretense; but it is plain, from reading the opinion of the learned judge in that case, that not only was no effect given to the verdict of the jury, which found that the purchases of stocks had been made *bona fide*, but the different elements which made up the transaction between the Brokers and their Client were completely overlooked—viz., that stock was actually purchased for the Client; that it was held subject to his orders; that he would have been entitled to the dividends thereon; that he could have insisted upon the instantaneous delivery of the stock to him upon tendering the purchase-money remaining due; that, if the Brokers had failed, the stock would not have passed to their assignees; and that, in fine, the Brokers were only interested in the transaction to the extent of their commissions. With great respect, therefore, we think that this case is not entitled to rank as an authority upon the question involved, especially as it appears to be directly opposed to the previous cases of Esser vs. Linderman[1] and Wynkoop vs. Seal,[2] where similar transactions were upheld.[3]

Definitions of Terms used.—There are a number of technical or well-known terms used in Wall Street which should be defined here. When a person is said to be "long" of stocks, it is meant that he has purchased stock through his Brokers or otherwise, in the expectation of a rise or advance in the market; he is then called a "bull."

To be "short" of stocks is where one sells stocks which he does not own or possess, and borrows the number of shares which he has sold from some third person to deliver to his vendee, expecting to be able to buy the stocks at a lower figure, and then return them to the person from whom he has borrowed them; he is called a "bear."[4]

To "carry" stocks means where a Broker or other person advances the money, or a principal part thereof, with which to purchase stocks, and holds the same subject to the orders of his Client.[5]

A "corner" in stocks is where the owners or holders (i. e. bulls) refuse to loan stocks to the "bears," with which to carry out their short contracts, in which event the "bears," being unable to deliver, are compelled to go into the market or Exchange and buy the stocks at any price at which they can obtain them.[6]

"Wash sales" are not real sales, but are made by persons interested to each other, for the purpose of giving a fictitious value to the stock.[7]

A "shave" is a consideration for carrying stock for a certain time.[8]

A "call" is a contract by which the party signing or making the same agrees, in consideration of a certain sum, to deliver, at the option of a party therein named, or his order or bearer, securities therein mentioned, at a certain day for a certain price.[9]

[9] The following is a copy of the call commonly used:

"NEW YORK, 1882.

"For value received, the bearer may call on me for shares of the common stock of the Railroad Company at per cent., any time in days from date. The bearer is entitled to all dividends or extra dividends declared during the time.

"Expires 1881, at 1¾ P. M.

"Signed, ."

By the usage of Brokers, it is negotiable, and it has been declared valid by certain courts.

A "put" is also an option contract, except the party holding the same has the option of delivering securities to the maker.[1]

A "straddle," or "spread-eagle," combines the advantages of a "put" and a "call," being a contract by which the holder has the right or option either to deliver or have delivered to him certain stocks at prices designated in the writing.[2]

Commission.—In respect to the commission or compensation which a Stock-broker is entitled to receive for transacting the business of the Client, the amount thereof rests either upon an express or an implied agreement. Of course, whenever there is an express agreement by which the amount of the commission is definitely fixed, all greater or other rates are excluded.[3] But frequently, in employing a Stock-broker, nothing is said as to the amount of his commissions, in which case they must be ascertained by other means. There is a uniform rate fixed by the New York Stock Exchange which is generally observed by the Brokers in dealings with their Clients.[4] And the law seems to be that where a broker is employed, and no special compensation is agreed upon, the rate of brokerage customarily charged for the same services is the proper measure of damages. The parties are then presumed to have contracted in reference to the usage.[5] The law is that where there is a general usage in any particular trade or branch of business, parties having knowledge of the usage are presumed to contract in reference to it; and, if the usage does not conflict with the terms of the contract, it will be deemed to enter into and constitute a part of it. Knowledge of the usage may be established by presumptive as well as by direct evidence. It may be presumed from surrounding facts, as the

[1] It is as follows:

"NEW YORK, 1882.

"For value received, the bearer may deliver me shares of the common stock of the Railroad Company at per cent., at any time in days from date. The undersigned is entitled to all dividends or extra dividends declared during the time.

"Expires at 1¾ P. M.

"Signed, ."

[2] Harris vs. Tumbridge, Ab. New Cas. 209; aff'd 83 N. Y. 92, where the court, in speaking of a "straddle," said "The word, if not elegant, is at least expressive. It means the double privilege of a 'put' and a 'call,' and secures to the holder the right to demand of the seller at a certain price, within a certain time, a certain number of shares of specified stock, or to require him to take at the same price, within the same time, the same shares of stock."

The following is the form of a "straddle:"

NEW YORK, 1882.

"For value received, the bearer may call on the undersigned for shares of the common stock of the Railroad Company at per cent., any time in days from date. Or the bearer may, at this option, deliver the same to the undersigned at per cent., any time within the period named. All dividends or extra dividends declared during the time are to go with the stock in either case; and this instrument is to be surrendered upon the stock being either called or delivered.

"Expires at 1¾ P. M.

"Signed, ."

[3] Wharton on Ag. § 323; Bower vs. Jones, 8 Bing. 65; Ware vs. Hayward Rubber Co., 85 Mass. 84.

[4] Art. XVIII. Const. §§ 1, 2, and 3. By these rules a commission of one eighth of one per cent. is chargeable on all transactions in securities made for all parties not members of the Exchange, other than gold, government bonds, and exchange. The minimum rate to members of the Exchange is one thirty-second of one per cent., except in certain cases, when it may be one fiftieth of one per cent. The rates are based upon the par value of the securities.

On mining stocks selling in the market at not over $5 per share the commission shall be $3.12½; on shares selling at not over $10 and above $5 per share, $6.25; on shares selling above $10 per share, $12.50 per 100 shares. The minimum commission to members of the Exchange shall be $1 per $100 on all shares selling at $10 and below. But in all other cases the rate shall be the same as directed in this article to Railroad stocks.

[5] Morgan vs. Mason, 4 E. D. Smith (N. Y.), 636; Miller vs. Ins. Co. of North America, 1 Ab. New Cas. id. 470, and note, which contains a collection of cases on the extent to which usage is admissible to establish a rate of compensation; see also Erben vs. Lorillard, 2 Keyes (N. Y.), 567; Adams vs. Capron, 21 Md. 186; Deshler vs. Beers, 32 Ill. 368.

uniformity, long continuance, and notoriety of the same. And it is held[1] that an agreement between Brokers to share commissions earned by one on information given by the other is legal.

But it seems that a Broker or Agent is not always entitled to a commission, although he may have performed the work or transacted the business for which he was employed. Mr. Parsons lays down a proposition[2] which seems to be very generally accepted by the courts, that "neither a factor nor a Broker can have any valid claim for his commissions or other compensation if he has not discharged all the duties of the employment which he has undertaken with proper care and skill and entire fidelity." This necessarily embraces all acts of bad faith on the part of the Broker; and it even applies where a Broker, without fraudulent intent, receives commission from a conflicting interest.[3] In the State of New York, however, it has been held that where a trustee wrongfully invested trust funds in securities not authorized by law, such act did not deprive him of his right to commissions; and Mr. Justice Woodruff doubted whether even misconduct or gross negligence would operate to debar trustees of their authorized compensation, where no imputation of fraud rests upon them.[4] A Broker is never entitled to commissions for unsuccessful efforts, even though, after his failure and the termination of his agency, his labor proves of use and benefit to his principal. He does not, however, lose his commissions where his efforts are rendered a failure by the fault of his principal, or where the purchaser declines to complete because of a defect which is the fault of the principal.[5] What constitutes a faithful performance of the Broker's duty depends greatly upon the nature of the business committed to his hands. It has been held, for instance, that he is obliged to keep and render a correct account of the business transacted.[6] And, although he may not absolutely forfeit his commission by a failure to do this, it may be construed as a failure of duty on his part, or as a suppression of evidence.[7] The case of Hoffman vs. Livingston[8] peculiarly illustrates the question of a right of a Stock-broker to recover his commissions. The plaintiff there sued to recover his commissions or transactions in stocks made for account of defendant. The transactions were conducted by the plaintiff under an arrangement by which the latter speculated for the defendant under a discretionary order, buying and selling whenever he deemed it advisable. Under this arrangement plaintiff made numerous transactions, resulting in a loss to the defendant of a large sum, more than one-half of which was for commissions. Notice of each transaction was not given to the defendant in accordance with the custom of Brokers. The action was contested on the ground that the circumstances showed that the operations were made with a view of merely yielding commissions for the benefit of the Broker, and it was held that the failure of the latter to give notice to his Client of each transaction was a neglect of duty which was a sufficient bar to the recovery of commissions. The rule of law is that if the Broker's services are wholly abortive, or executed in such a manner that no benefit results from them, he is not entitled to recover either his commissions or even a compensation for his trouble. That the question is one of due diligence and ordinary skill, and the want of this may be the result of an inattention or incapacity. It is not necessary in such case for defendant to show actual fraud. It has also been held that a Broker employed to purchase government bonds for a Client cannot act in the same transaction as agent for the seller, and receive commissions from both sides, although this may be done where the Client expressly assents to the same.[1]
